# EDITOR'S <br> EILE.COPY <br> DIRECT SOLAR RADIATION ON VARIOUS SLOPES FROM O TO 60 DEGREES NORTH LATITUDE 

JOHN BUFFO,
LEO J. FRITSCHEN,
AND JAMES L. MURPHY

Pacific Northwest Forest and Range Experiment Station Forest Service U.S. Department of Agriculture Portland, Oregon

## ABSTRACT

Direct beam solar radiation is presented in graphical and tabular form for hourly, daily, and yearly values for seven slopes on each of 16 aspects from the Equator to 60 degrees north in 10-degree increments. Theoretical equations necessamy for the calculations are given. Solar altitude and azimuth during the day and year are also presented for the same latitudes.

Keywords: Solar radiation, slopes, aspects.

John Buffo is Research Assistant and Leo Fritschen is Professor, College of Forest Resources, University of Washington, Seattle. James Murphy was formerly project leader of the Cooperative Forest Fire Science project, Pacific Northwest Forest and Range Experiment Station, Seattle, Washington. He is now Assistant to the Deputy Chief for Research, U. S. Forest Service, Washington, D. C.

## INTRODUCTION

Solar energy is by far the most important climatic factor. There are many situations in which accessible information concerning solar intensity might be used. For example, it is a significant parameter in ecological problems dealing with silviculture, entomology, pathology, and fire control.

Optimum use of solar energy requires knowledge of the exact location of the sun and the magnitude of insolation at any time of the day and year. Tables and graphs have been prepared which give the sun's location (that is, altitude and azimuth) as a function of latitude, time of day, and year (Smithsonian Institution 1958, Hutchinson and Cotter 1955). More recently, computer programs have been written which give not only the sun's location but also direct solar radiation on a horizontal surface (Robertson and Russelo 1968, Furnival et al. 1969). However, direct solar radiation on a horizontal surface may not be as useful as radiation on sloping surfaces or vertical walls. Such tables have been prepared by Frank and Lee (1966) and Fons et al. (1960). These tables present either daily solar radiation values or coefficients which have to be multiplied by direct solar radiation on a horizontal surface for specific aspects, slopes, and latitudes. Such tables are of limited use because of the range of latitudes and slopes presented and because additional calculations are required. Therefore, computer programs were modified and written to calculate direct solar radiation on selected slopes and aspects in $10-$ degree increments from the Equator to 60 degrees north. These results are presented in tabular form and as graphical plots of hourly and daily values.

## THEORY

Theoretical derivation of the necessary equations has been given by Byram and Jemison (1943), Fons et al. (1960), and Frank and Lee (1966), among others. These equations are presented here for completeness. A sample surface is located in the Northern Hemisphere as shown in figure 1. The sun is directly overhead at point $p$ on meridian $\tau_{q}$ with a declination $\delta$. The sample surface is located at latitude $\phi$, point $r$, on meridian $m q$ which has an hour angle $h$ from the meridian $l_{q}$. The surface $c f g i$ has a slope $\alpha$ from the horizontal $j o$, a deviation of $\theta$ from the vertical $c d$, and an aspect $\beta$ from the north no.

The sun's rays are striking the surface at $r$ with an altitude angle Sok, called $A$, from the horizontal. The altitude $A$ is given by:

$$
\sin A=\sin \phi \sin \delta+\cos \phi \cos \delta \cos h ;
$$

and the azimuth $A Z$ from the north, where $A Z=Z+90$ degrees, is given by:

```
sin}AZ=-\operatorname{cos}\delta\operatorname{sin}h/\operatorname{cos}A
```

The solar intensity $I$ on the surface efgi is:

$$
I=I_{o} p^{1 / \sin A} \sin \theta
$$

where

$$
\sin \theta=\sin A \cos \alpha-\cos A \sin \alpha \sin (Z-\beta) .
$$

$I_{0}$ is the radiation at the top of the atmosphere on a surface normal to the sun's rays and $p$ is the atmospheric transmission coefficient.

A computer program, written by Furnival et al. (1969), calculated direct solar radiation at the top of the atmosphere on a surface parallel to the earth's surface. This program was modified to calculate direct solar radiation at the earth's surface on any slope and aspect, at latitudes from 0 to 60 degrees north, with any atmospheric transmission coefficient.

## RESULTS AND DISCUSSION

Hourly solar radiation was computed for: slopes in 15-degree increments ranging from level to a vertical wall; 16 aspects, in 22-1/2-degree increments; 20 selected days of the year; latitudes, in 10-degree increments, from 0 to 60 degrees north; and atmospheric transmission coefficient of 0.9 . The possible combinations are detailed in table 1. Other options may have been desirable but were too costly. At latitudes greater than 60 degrees, where the sun does not set on certain days, the computations become more difficult and so were omitted.

The atmospheric coefficient of 0.9 was selected because it was representative of conditions on the top of a mountain, about $1,500 \mathrm{~m}$., on a clear day. Other values would be useful for some areas where atmospheric pollution is severe. List (Smithsonian Institution 1958) presents seasonal totals of direct solar radiation with different atmospheric coefficients at many latitudes. These values may be useful for comparison.

The hourly computations for the selected days are displayed in four ways as: (1) isograms of radiation drawn on graphs of time versus slope for specific days, aspects, and latitudes, (2) daily totals in tabular form for specific days, aspects, and latitudes, (3) isograms of daily totals versus days for specific latitudes, and (4) annual totals in tabular form for specific slopes; aspects, and latitudes. The details of display are discussed in the following section.

The computed values apply only to surfaces on level terrain where sunrise and sunset are not restricted by topographic features. Many applications of the radiation values are in city or mountainous areas which have limited day length. Other computer programs can be utilized for these special applications. 1/ Knowledge of the solar altitude and azimuth as a function of the time of day and day of year is required to compute solar radiation for these areas. List (Smithsonian Institution 1958) presents, in convenient graphical form, solar azimuths and elevations for the same days and latitudes as listed in table 1. For completeness, the graphs are duplicated here (figs. 51-57). ${ }^{2}$

[^0]
## EXPLANATION OF FIGURES AND TABLES

Isograms of direct solar radiation (hourly values drawn for every 10 and labeled for every $20 \mathrm{cal} . \mathrm{cm}^{-2}$ ) were drawn on graphs of time (hours) versus slope (degrees) for each of the nine aspects and each of the 8 days at the seven latitudes. For convenience, all of the graphs for a specific day and latitude have been reduced and displayed together (figs. 2-36). Some subfigures are labeled double because the east and west aspects are mirror images with respect to solar radiation. The degree of slope is denoted across the bottom of each graph. The reader should note that:
(1) the left axis radiation values (zero slope) for each graph for a given day are the same for the same hours of each day,
(2) the south-facing walls (right axis of subfigure south) are in sunlight when the north-facing walls (right axis of subfigure north) are not,
(3) the east-facing slopes are in sunlight while the comparable west-facing slopes are not,
(4) the hours of daylight decrease from summer (fig. 21) to winter (fig. 17), and
(5) the degree of slope receiving the most radiation increases from summer to winter as the sun's altitude decreases.

The second method of presentation of the radiation data is in tabular form. The hourly values were accumulated to form daily totals. These are presented in tables 2-8 as a function of degree of slope and aspect for each of the 20 days and for each latitude. (See table 1 for days of equal value.)

The daily totals of solar radiation for selected north-, east-, and south-facing slopes were plotted versus day of the year (figs. 37-50). There are two graphs for each latitude, one containing the isograms for level, north $30-$, north $60-$, north $90-$, and east 30 -degree slopes, and the other containing isograms for east $60-$, east $90-$, south $30-$, south $60-$, and south 90 -degree slopes. These graphs can be used for quick comparison of various slopes and aspects; it should be noted that the values for the east and west slopes are equal. The latter half of the year can be assumed to be symmetrical to the first half.

Annual values of solar radiation for each slope and aspect are given in tables 9-15. Small errors exist in these totals because it was assumed that the period from December 22 to June 22 was identical to the period from June 22 to December 22. This error is small compared with variations in atmospheric transmission coefficients and in determining the slope and aspect of a particular surface.

Solar altitude and azimuth for the seven latitudes are given in figures 51-57 The user should refer to table 1 for the approximate date of the various declinations. For example, the declination of -5 degrees occurs on March 8 and October 6. Figure 51 shows the solar azimuth at 10:00 a.m. on either of the above dates to be 100 degrees and the elevation to be 60 degrees above the horizon. Intermediate latitudes can be linearly interpolated.

## LIST OF FIGURES

Page
Figure 1.--Ilustration of the angles necessary for the theoretical calculations of solar radiation on a particular surface in the Northern Hemisphere ..... 31
Figure 2.--Isograms of hourly values of direct solar radiation for various slopes at 0 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 32
Figure 3.--Isograms of hourly values of direct solar radiation for various slopes at 0 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis). ..... 33
Figure 4.--Isograms of hourly values of direct solar radiation for various slopes at 0 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 34
Figure 5. --Isograms of hourly values of direct solar radiation for various slopes at 0 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis). ..... 35
Figure 6. --Isograms of hourly values of direct solar radiation for various slopes at 0 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 36
Figure 7. --Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 37
Figure 8. --Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 38
Figure 9. --Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 39
Figure 10. --Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 40
Figure 11. --Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 41Figure 12.--Isograms of hourly values of direct solar radiation for various slopes at20 degrees north latitude on December 22. For westerly exposures, the time is readfrom top to bottom (left time axis); for easterly exposures, the time is read frombottom to top (right time axis)42
Figure 13. --Isograms of hourly values of direct solar radiation for various slopes at 20 degrees north latitude on February 23 and October 20 . For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis)43

Figure 14.--Isograms of hourly values of direct solar radiation for various slopes at
20 degrees north latitude on March 21 and September 23. For westerly exposures,
the time is read from top to bottom (left time axis); for easterly exposures, the time
is read from bottom to top (right time axis) ..... 44

Figure 15. --Isograms of hourly values of direct solar radiation for various slopes at
20 degrees north latitude on April 16 and August 28. For westerly exposures, the time
is read from top to bottom (left time axis); for easterly exposures, the time is read
from bottom to top (right time axis) ..... 45
Figure 16. --Isograms of hourly values of direct solar radiation for various slopes at 20 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis)46
Figure 17. --Isograms of hourly values of direct solar radiation for various slopes at 30 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis)
Figure 18. --Isograms of hourly values of direct solar radiation for various slopes at 30 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).48

Figure 19. --Isograms of hourly values of direct solar radiation for various slopes at
30 degrees north latitude on March 21 and September 23. For westerly exposures, the
time is read from top to bottom (left time axis); for easterly exposures, the time is
read from bottom to top (right time axis) ..... 49

Figure 20. --Isograms of hourly values of direct solar radiation for various slopes at
30 degrees north latitude on April 16 and August 28 . For westerly exposures, the
time is read from top to bottom (left time axis); for easterly exposures, the time is
read from bottom to top (right time axis) ..... 50

Figure 21. --Isograms of hourly values of direct solar radiation for various slopes at
30 degrees north latitude on June 22. For westerly exposures, the time is read from
top to bottom (left time axis); for easterly exposures, the time is read from bottom to
top (right time axis) ..... 51

Figure 22. --Isograms of hourly values of direct solar radiation for various slopes at
40 degrees north latitude on December 22. For westerly exposures, the time is read
from top to bottom (left time axis); for easterly exposures, the time is read from
bottom to top (right time axis). ..... 52
Figure 23. --Isograms of hourly values of direct solar radiation for various slopes at 40 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis)53
Figure 24. --Isograms of hourly values of direct solar radiation for various slopes at 40 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis)
Figure 25. --Isograms of hourly values of direct solar radiation for various slopes at 40 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis). ..... 55
Figure 26. --Isograms of hourly values of direct solar radiation for various slopes at 40 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 56
Figure 27. --Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 57
Figure 28. --Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 58
Figure 29. --Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 59
Figure 30.--Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 60
Figure 31. --Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 61
Figure 32. --Isograms of hourly values of direct solar radiation for various slopes at 60 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 62
Figure 33. --Isograms of hourly values of direct solar radiation for various slopes at 60 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis; for easterly exposures, the time is read from bottom to top (right time axis) ..... 63
Figure 34.--Isograms of hourly values of direct solar radiation for various slopes at 60 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis) ..... 64
Figure 35. --Isograms of hourly values of direct solar radiation for various slopes at60 degrees north latitude on April 16 and August 28. For westerly exposures, thetime is read from top to bottom (left time axis); for easterly exposures, the time isread from bottom to top (right time axis)65
Figure 36. --Isograms of hourly values of direct solar radiation for various slopes at60 degrees north latitude on June 22. For westerly exposures, the time is read fromtop to bottom (left time axis); for easterly exposures, the time is read from bottomto top (right time axis)66

Figure 37.--Isograms of daily values of direct solar radiation on level, north $30-$, north $60-$,
north $90-$, and east 30 -degree slopes at 0 degrees north latitude ..... 67

Figure 1.-Illustration of the angles necessary for the theoretical calculations of solar radiation on a particular surface in the Northern Hemisphere.

Figure 2.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{0}$ degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 3.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{0}$ degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 4.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{0}$ degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 5.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{0}$ degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 6.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{0}$ degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 7.-Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 8.-Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 9.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{1 0}$ degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 10.-Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 11.-Isograms of hourly values of direct solar radiation for various slopes at 10 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 12.-Isograms of hourly values of direct solar radiation for various slopes at 20 degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 13.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{2 0}$ degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 14.-Isograms of hourly values of direct solar radiation for various slopes at 20 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 15.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{2 0}$ degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 16.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{2 0}$ degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 17.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{3 0}$ degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 18.-Isograms of hourly values of direct solar radiation for various slopes at 30 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 19.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{3 0}$ degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 20.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{3 0}$ degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 21.-Isograms of hourly values of direct solar radiation for various slopes at 30 degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 22.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{4 0}$ degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 23.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{4 0}$ degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 24.-Isograms of hourly values of direct solar radiation for various slopes at 40 degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 25.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{4 0}$ degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 26.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{4 0}$ degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 27.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{5 0}$ degrees north latitude on December 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 28.-Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on February 23 and October 20. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 29.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{5 0}$ degrees north latitude on March 21 and September 23. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 30.-Isograms of hourly values of direct solar radiation for various slopes at 50 degrees north latitude on April 16 and August 28. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).

Figure 31.-Isograms of hourly values of direct solar radiation for various slopes at $\mathbf{5 0}$ degrees north latitude on June 22. For westerly exposures, the time is read from top to bottom (left time axis); for easterly exposures, the time is read from bottom to top (right time axis).
