**Richard W. Haynes** is a research forester, Forestry Sciences Laboratory, P.O. Box 3890, Portland, OR 97208-3890.

## **Abstract**

**Haynes, Richard W. 2003.** Assessing the viability and adaptability of forest-dependent communities in the United States. Gen. Tech. Rep. PNW-GTR-567. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 33 p.

The work responds to the need to assess progress toward sustainable forest management as established by the Montréal Process of Criteria and Indicators. The focus is on a single indicator (commonly referred to as Indicator 46), which addresses the “viability and adaptability to changing economic conditions, of forest-dependent communities, including indigenous communities.” From county-level data, a composite measure was developed that combined population density, lifestyle diversity, and economic resiliency. There are 837 counties assigned a low rating representing 36 percent of the area of the United States but that contain less than 3 percent of the U.S. population. The rest of the population is roughly divided among the 2,064 counties assigned medium ratings and the 209 counties assigned high ratings. Of the forest-dependent communities, there are 742 counties with a high proportion of forest land, but only 14 percent are classified as having low viability and adaptability.

**Keywords:** Community resiliency, criteria and indicators, forest dependency, Montréal Process, socioeconomic well-being, sustainable forest management.

## **Introduction**

A fundamental societal concern increasingly debated in the past two decades has been the need for human actions that lead to sustainable development that meets the needs of the present without comprising the ability of future generations to meet their needs (WCED 1987). This debate has broadened to include notions of sustainability as a normative concept reflecting the persistence over an indefinite future of certain necessary and desirable characteristics of both ecological and human parts of an ecosystem (modified from Hodge 1997). Within the forestry community, these concerns manifested themselves in the development of frameworks for assessing the progress toward sustainable forest management.

The United States is a signatory participant of the Montréal Process for assessing progress toward sustainable forest management. The Montréal Process is largely used by countries with temperate forest resources and involves seven criteria and 67 indicators.<sup>1</sup> Two of the criteria (numbers six and seven and containing 39 of the 67 indicators) address various human concerns including components of social well-being. These two criteria address the need for forest management to meet societal needs and maintain and enhance long-term multiple socioeconomic benefits. This is a broader context than the frequently cited goal of managing forests to sustain a flow of timber and other benefits to promote the stability of forest industries and communities.

The focus on communities is the subject of this paper. Specifically, the purpose of this paper is to describe an approach to assess community viability and adaptability in the context of the Montréal Process of Criteria and Indicators for sustainable forest management (Montréal Process Working Group 1998). This is Indicator 46 of Criterion 6, which deals with the viability and adaptability to changing economic conditions of forest-dependent communities, including indigenous communities. The term community refers to both the physical place and to the group of people who live in and identify with that place.

## **Indicator Interpretation**

Criterion 6 and its 19 associated indicators (including Indicator 46) reflect one of the enduring goals of land management: the concern that forest management sustains a flow of timber and other benefits to promote the well-being of forest industries and communities. This criterion takes a broad view of how sustainable forest management influences social well-being that includes the expected concerns about determinants of economic well-being (often measured by jobs) as well as concerns about community well-being. The criterion reflects a notable evolution in thinking on the part of decision-makers, researchers, resource managers, and the public about the relation between communities and forests, as well as what constitutes sustainable forest management.

---

<sup>1</sup> See [www.mpcf.org](http://www.mpcf.org) for a description of the Criteria and Indicators for the Conservation and Sustainable Management of Temperate and Boreal Forests. The seven criteria are Conservation of Biological Diversity; Maintenance of Productive Capacity of Forest Ecosystems; Maintenance of Forest Ecosystem Health and Vitality; Conservation and Maintenance of Soil and Water Resources; Maintenance of Forest Contribution to Global Carbon Cycles; Maintenance and Enhancement of Long-Term Multiple Socio-Economic Benefits to Meet the Needs of Societies; and Legal, Institutional, and Economic Framework for Forest Conservation and Sustainable Forest Management.

The discussions<sup>2</sup> of this indicator suggested that there are two types of variables for this indicator: (a) measures of economic dependency on forests and (b) social well-being of communities. Social well-being would be a measure of both the capacity of communities to respond to changes and the socioeconomic status of people. In the reviews of the U.S. efforts to develop a national report on sustainable forests,<sup>3</sup> there were suggestions that measures of dependency should be considered as part of Indicator 44 (employment in the forest sector), but for clarity, both economic and social aspects of well-being are considered in the development of this indicator.

The Montréal Process provides little guidance for defining communities although the information that is available largely addresses communities of place. The various technical notes on the subject refer to communities generically as forest-dependent communities and indigenous communities. They stress the need to assess using quantitative and qualitative information of the trends on the status of a community's flexibility and capacity to adapt to changing economic conditions. Little guidance is available for which scales need to be considered other than general direction to deal with national, regional, and local concerns. No guidance is provided for how to scale community information upward to broader spatial scales.

I acknowledge that there are severe data limitations for assessing community viability and adaptability at the national scale as required in the Montréal Process. Foremost, there is a lack of systematic community-level databases except in some unique cases (such as the Pacific Northwest) where they have been assembled as part of ecoregion assessments. Even where the data have been assembled, there are severe limitations for measuring certain elements of community viability and adaptability.

#### **The Evolution of Viability and Adaptability<sup>4</sup>**

The past two decades have seen an evolution of many terms used to depict communities that have distinct connections to forest resources: community stability, forest dependence, forest based, community capacity, community resiliency, and now with the Montréal Process, community viability and adaptability. Viability and adaptability are not explicitly defined in the Montréal Process but have the connotation of some of the more recent terms such as resiliency.

This evolution of terms reveals the evolving emphasis on the complex, dynamic, and interrelated aspects of rural communities and the natural resources that surround them. The earliest terms dealt with the limits between improved forest management and stable communities achieved through stable employment. By the late 1980s, the notion of community stability as reflective of sustained-yield timber management was being called into question (Lee 1990, Schallau 1989). Although the use of the term stability continued to endure in policy debates, concern was raised about the lack of a clear definition of stability and how it might be measured (see Richardson 1996). Seeking alternative terms, some researchers began looking beyond employment indicators to other aspects of

<sup>2</sup> See [www.mpci.org/meetings/tac/mexico/tn1-6\\_e.html](http://www.mpci.org/meetings/tac/mexico/tn1-6_e.html) for a discussion of the rationale and approaches to measurement for Indicator 46.

<sup>3</sup> Roundtable workshops were held in Portland, Oregon, and Washington, D.C., in spring 2002. Reports are on file with: David Darr (ddarr@fs.fed.us).

<sup>4</sup> This section is condensed from Donoghue and Haynes (2002).

community life in order to assess community well-being (Doak and Kusel 1996, Kusel and Fortmann 1991). In addition to economic measures, indicators for poverty, education, crime, and other sociodemographic measures have been used to assess conditions within communities.

There are two definitions key to developing a measure for Indicator 46. First, communities are defined in terms of a sense of place, organization, or structure. Second, economies are defined by transactions among people that allocate scarce resources among alternative uses. The spatial configurations of both differ, with economies generally being spatially the larger of the two.

Concurrent with discussions about stability and well-being were discussions about the term forest dependence, including several appeals to redefine that term (Richardson and Christensen 1997). Forest and timber dependence were initially defined in terms of commodity production. Various research studies suggest that communities are more complex than traditional measurements of timber dependency would imply (see Haynes and others 1996). Most communities have mixed economies, and their vitality is often linked to other factors besides commodity production. Many of the communities thought of as timber dependent have been confronted with economically significant challenges, such as mill closures, and have displayed resilient behavior as they have dealt with change. Arguments for redefining the term forest dependence emphasized that the economic ties that some communities have to forests are not wood product based, but reside in recreation and other amenities (Kusel 1996). Another concern was that the term forest dependence did not reflect the local living traditions and sense of place held by many communities (Kusel 1996). This broader connotation of the term forest dependence is often what is implied by the term forest based.

The terms community capacity and community resiliency connote the ability of a community to take advantage of opportunities and deal with change (Doak and Kusel 1996, Harris and others 2000). The terms resiliency and, arguably to a lesser extent, capacity differ in meaning from terms such as forest dependence because they represent a projected condition or ability of a community over some period. Levels of resiliency are dynamic, just like external factors that might induce change within a community. The Forest Service is shifting its focus from dependency to concepts like resiliency (see Horne and Haynes 1999, McCool and others 1997). Based on Harris and others (2000), factors useful in assessing community resiliency or adaptability include:

- Population size—Resiliency ratings vary directly with population size:
  - Small (and often lower resiliency), less than 1,500 people.
  - Large (often associated with higher resiliency), greater than 5,000 people.
- Economic diversity—Resiliency ratings vary directly with population size.
- Civic infrastructure—Higher resiliency is associated with strong civic leadership, positive attitudes toward changes, strong social cohesion.
- Amenities—Combines both civic amenities as well as natural amenities.
- Location—Locations on major trade routes; near service centers; shopping, service, or resort destinations are associated with higher resiliency. Spatial isolation is often a characteristic of lower resiliency.

## **Developing a Measure of Community Viability and Adaptability**

The history behind the evolution of terms combined with the results of recent and current work suggest that connectivity to broad regional economies, community cohesiveness and place attachment, and civic leadership are greater factors in determining community viability and adaptability than factors related to employment.

There are three considerations necessary for the development of a measure of community viability and adaptability. First, there are various factors listed in the previous section used to depict communities and their ability to deal with changes such as changes in the management of the surrounding forests. Second, there is a need to be specific about the geographic scale at which to construct the measure. Third, there is also the issue about how to judge the “goodness” of any measure that is developed. Recent work on ecological indicators (see National Research Council 2000) suggests the following criteria for such judgments: the extent the measure is based on a well-understood conceptual model, its reliability, its ability to detect differences at appropriate spatial scales, and its robustness in the sense of being able to yield reliable measures given the variability in the data.

The first step is to select what factors to use and how to develop measurements of those factors. From the previous review, the following factors were selected for assessing the degree of community viability and adaptability: population size, economic diversity, and amenities lifestyle. The proportion of forest land in the surrounding area was used to measure forest dependency.

The second step involves at what spatial scale this work needs to be conducted. The notion of a social hierarchy combines both political and individual person organization units. For example, one representation is from broad common markets to nations, to states, to counties, to communities and neighborhoods, to families and persons (see for example, Quigley and others 1996). In the context of the Montréal Process, Indicator 46 needs to assess conditions at the national level based on an understanding developed from the next lower spatial scale. In the United States, that scale would most likely be states; however, it is difficult to generalize community conditions at that level.<sup>5</sup> A compromise to gain both greater spatial resolution and to overcome the lack of community data sets is to use county data. These data sets have been used to monitor well-being and to reveal geographic variation, but most social scientists do not like to use these data sets as proxies for communities, primarily because of the lack of data richness for various components of social well-being such as community leadership and infrastructure, quality of life, welfare, and social and economic health of a community.

Using county data, we can use the general approach developed by Horne and Haynes (1999), which used county data to develop measures of socioeconomic resiliency (defined as the ability of human institutions [both communities and economies] to adapt to change) for the interior Columbia basin. The advantage of this approach was that it was measurable in the context of the definition of social well-being by using existing information. Horne and Haynes (1999) developed a composite measure of three factors: economic resiliency (as a measure of economic diversity in employment), population density (a proxy for civic infrastructure), and lifestyle diversity (a proxy for social and cultural

---

<sup>5</sup> For example, the state of Oregon (a relatively small state) has some 400 communities. Donoghue and Haynes (2002) found that about 10 percent of Oregon's communities with about 2 percent of Oregonians had low viability and adaptability.

diversity). Using this approach, we find that counties that have high socioeconomic resiliency demonstrate quick adaptation as indicated by rebounding measures of socioeconomic well-being, whereas counties with low resiliency have more lingering negative impacts. The terms high or low should not be thought of as good or bad but rather as a reflection of the ability of a county to respond to changes in social or economic factors.

Here, a similar approach was developed for the 3,110 counties (and some city-county and borough combinations) in the United States. A composite measure was developed for each county that considered civic infrastructure, economic diversity (in terms of employment), and lifestyle diversity. Forest dependency was interpreted as being related to the extent that each county was forested (measured by proportion of forest land in each county).

Proxy measures were developed for each component of the composite measure. Each proxy was assigned a rating of 1 for low, 2 for medium, and 3 for high. The definitions differ for each measure. Population density represents civic infrastructure. Here, counties with fewer than six people per square mile were assigned a rating of 0. These have been called frontier counties following the definition from the 1890 census. Counties with 6 to 27 people per square mile represent rural areas. Counties with 28 to 250 people per square mile are called intermix counties, and those with over 250 people per square mile are called interface counties<sup>6</sup> and essentially represent urbanlike characteristics. Economic diversity (based on a Shannon-Weaver diversity index) is computed from employment in major sectors including agriculture. Ratings are assigned that reflect how the diversity of a county compares relative to the average of U.S. counties. A high rating reflects counties that are in the top 16 percent (one standard deviation) of counties, and a low rating reflects those counties in the bottom 16 percent of counties. A proxy for lifestyle diversity is composed (in equal parts) of proportion of the county population that is minority (as a proxy for ethnic, income, and lifestyle diversity) and the availability of national forest lands (as a proxy for access to opportunities for outdoor recreation activities). Minority status is based on variation around the country average (15.6 percent). Counties with minority populations greater than 23.94 percent were rated high, whereas those with minority populations less than 7.3 percent were rated low. The ratings for national forest are based on actual acres in each county. Counties with fewer than 35,000 acres are assigned a rating of 1, whereas those counties with over 157,000 acres are assigned a rating of 3.

These indicators were used to develop a composite measure that combined population density, lifestyle diversity, and economic resiliency. Those counties with a composite score of 4 or less were assigned as having low adaptability and viability. Those counties with a composite score of 4.5 to 6.5 were assigned as having medium adaptability and viability. Those counties with a composite score of 7 or greater were assigned as having high adaptability and viability. A summary of the results is shown in table 1. There are 837 counties assigned a low rating representing 36 percent of the area of the United States but just less than 3 percent of the U.S. population. The rest of the population is roughly evenly divided among the 2,064 counties assigned medium ratings and the 209 counties assigned high ratings.

---

<sup>6</sup>The definitions for intermix and interface are consistent with research being undertaken as part of the fire plan.

**Table 1—Summary of county data and ratings**

Ranking	Population density	Minority status	Native American	Economic diversity	Forested acres	National forest acres	Composite score
<i>Number of counties</i>							
Low <sup>a</sup>	1,133	1,409	2,497	299	1,511	2,594	837
Medium	1,603	948	434	2,403	857	259	2,064
High	374	753	179	408	742	257	209
<i>Percent (by area)</i>							
Low	62.6	32.9	49.7	9.0	47.1	67.4	36.3
Medium	31.3	32.6	26.5	70.3	35.4	9.0	56.3
High	6.1	34.5	23.9	20.7	17.5	23.6	7.4
<i>Percent (by population)</i>							
Low	5.0	17.0	85.8	2.2	53.9	81.1	3.0
Medium	31.2	37.2	12.6	49.7	35.3	5.6	49.5
High	63.8	45.8	1.6	48.1	10.8	13.2	47.5

<sup>a</sup> Includes 384 counties assigned a rating of 0 because they are frontier counties.

## Discussion

Indicator 46 emphasizes the viability and adaptability of forest-dependent communities. Traditionally, this has been measured (in the United States) by the extent of employment in forest industries, but this tends to overstate the importance of manufacturing (relative to trade and services associated with activities such as recreation) and understates personal connections to the forest for subsistence and nontraditional economic activities. Here, I use the extent of forest land in each county as a proxy for the dependence of local residents on forest resources. Three maps show the results (figs. 1 through 3). The colors denote the extent of forest land in each county. Those with less than the U.S. average (32.5 percent) are shown in yellow, those with more than the U.S. average are shown in green (32.5 to 66.2 percent forest land), and those with greater than 66.3 percent forest land are shown in blue. For the purpose of this indicator, it is the counties shown in blue that represent forest-dependent communities. Figure 1 shows the counties assigned a rating of low viability and adaptability. These counties contain 8.3 million Americans but comprise 36 percent of the area of the United States. Figures 2 and 3 show the counties assigned a rating of medium or high viability and adaptability, respectively. Of the 742 counties with a high level of forest dependence (shown in blue), 102 are assigned a rating of low viability and adaptability.

Because the discussions of the indicator indicate a concern about those communities with less viability and adaptability, the detailed information for the 837 counties (and boroughs) assigned a low composite rating (shown in fig. 1) are listed in the appendix. The results for those counties with a low rating are summarized for both population and area in table 2 by four broad regions. The regional data illustrate how most of the people affected are in the two Eastern regions, whereas most of the area is in the West.

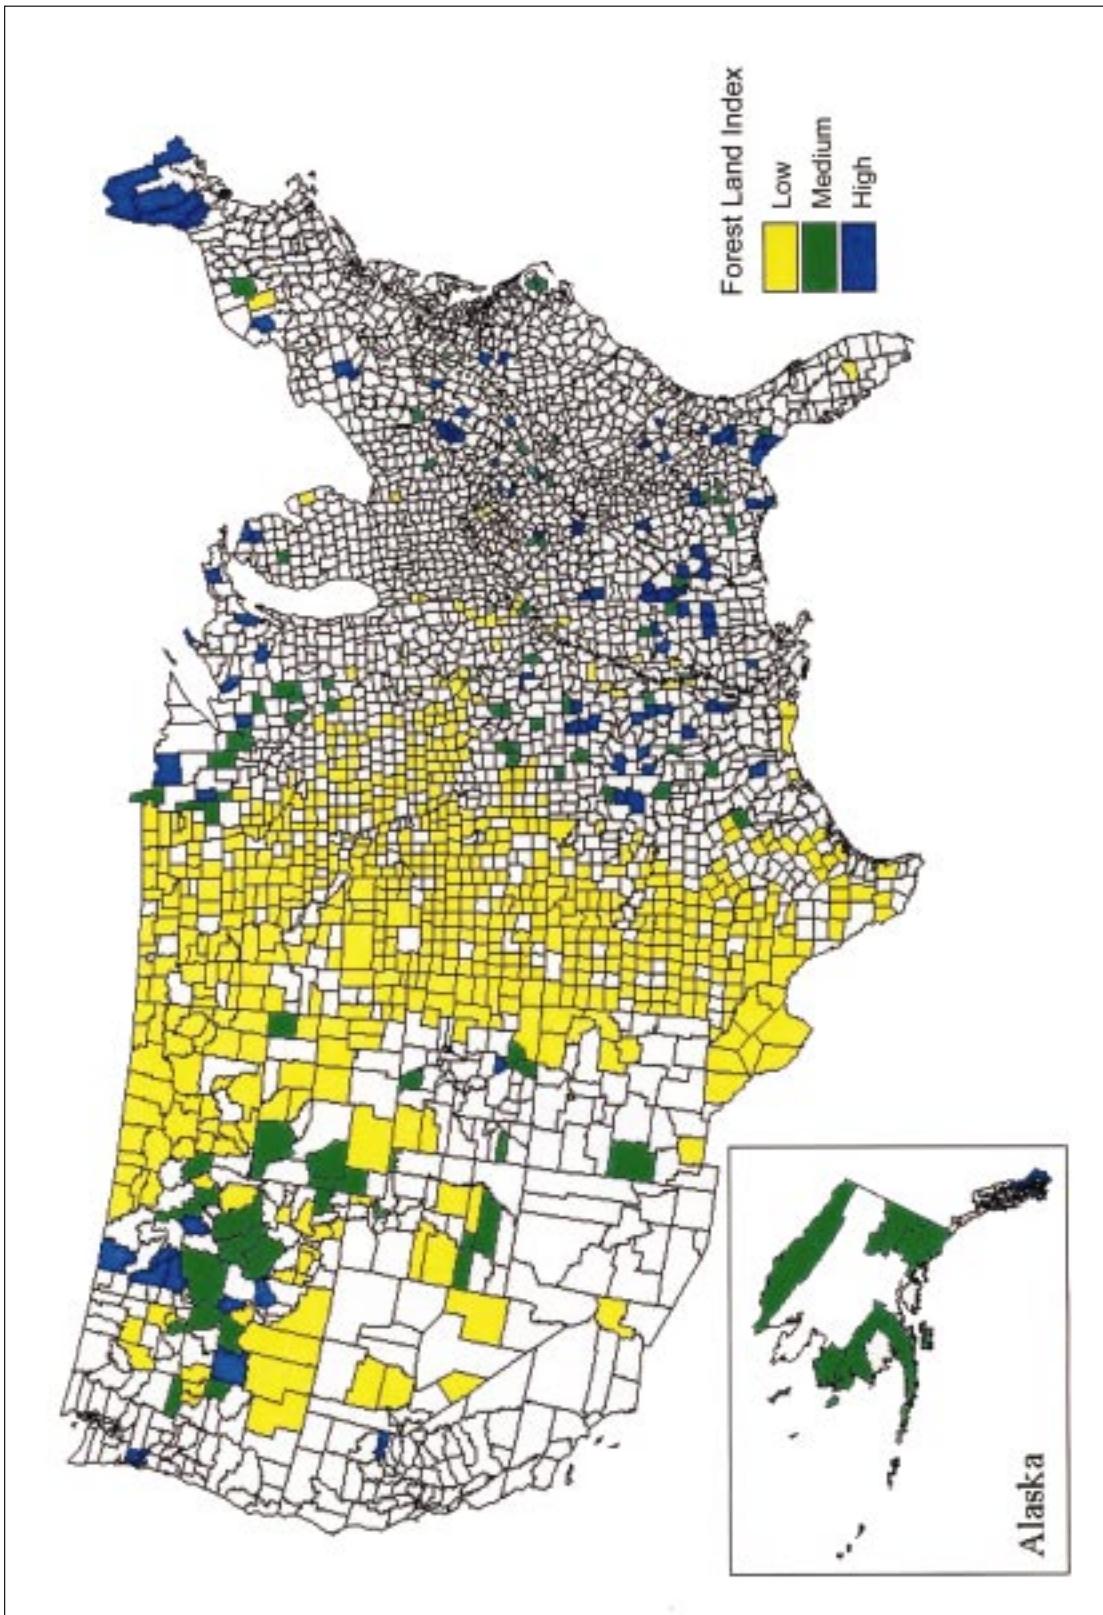

Figure 1—Counties with low viability and adaptability to changing economic conditions.

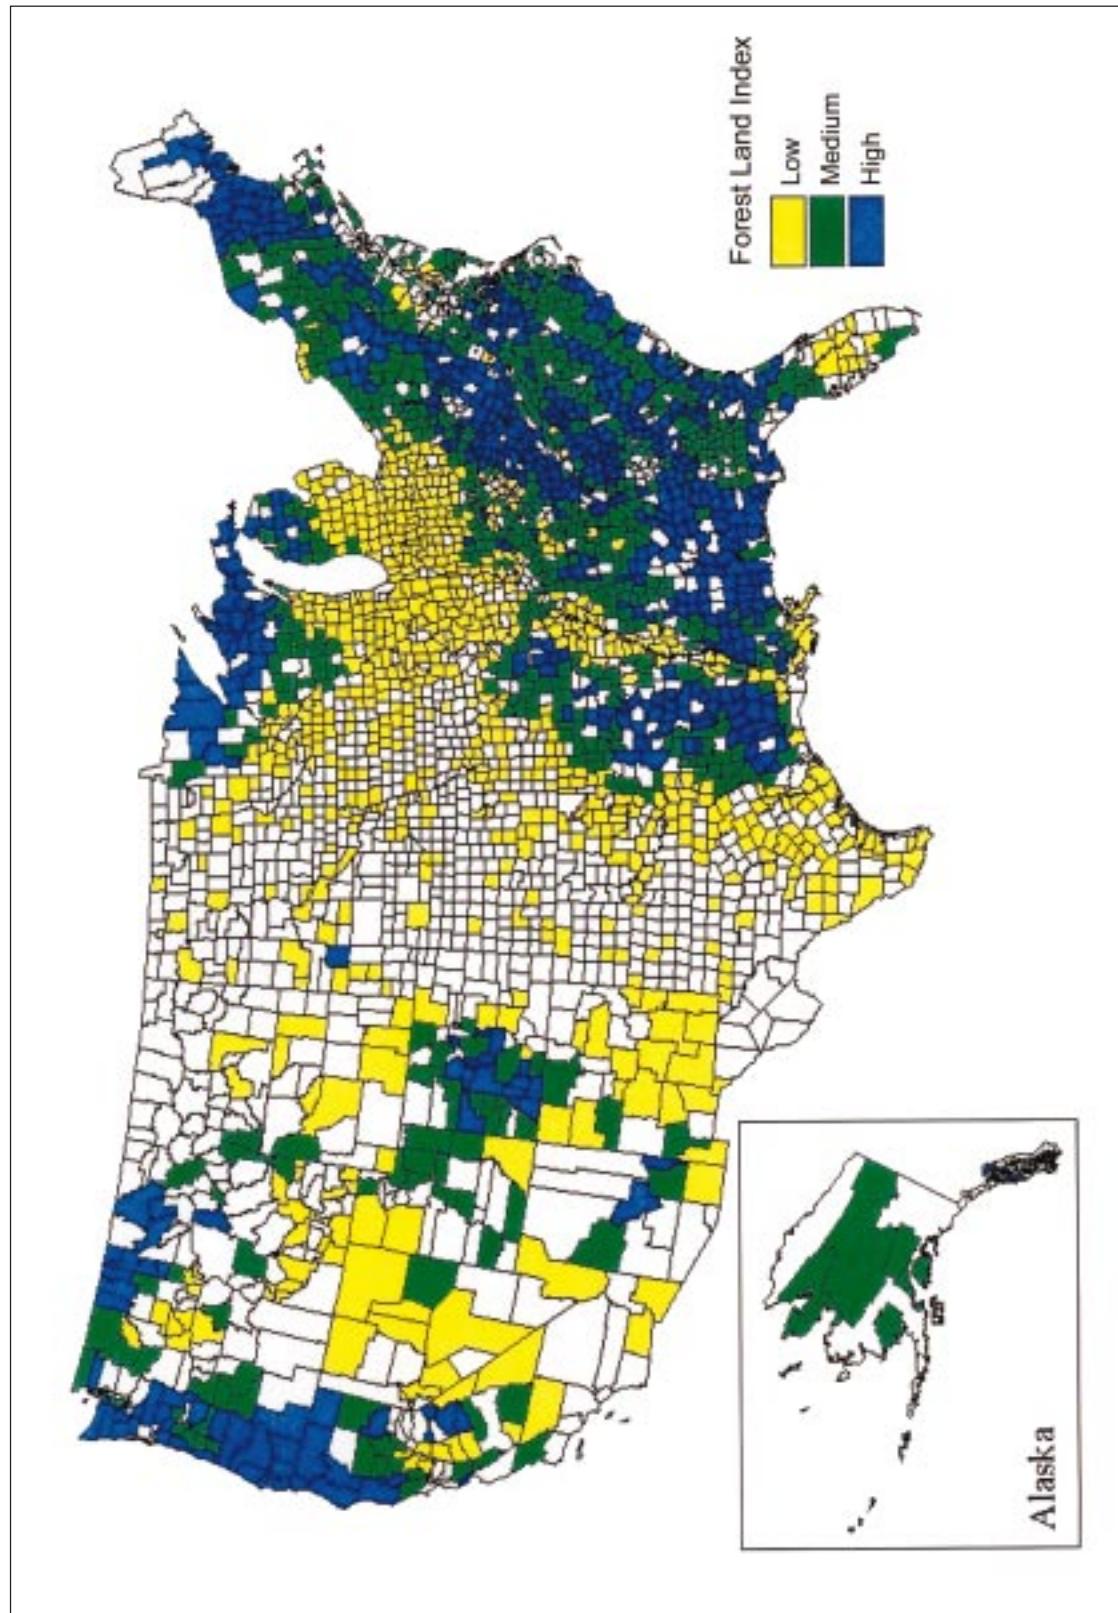

Figure 2—Counties with medium viability and adaptability to changing economic conditions.

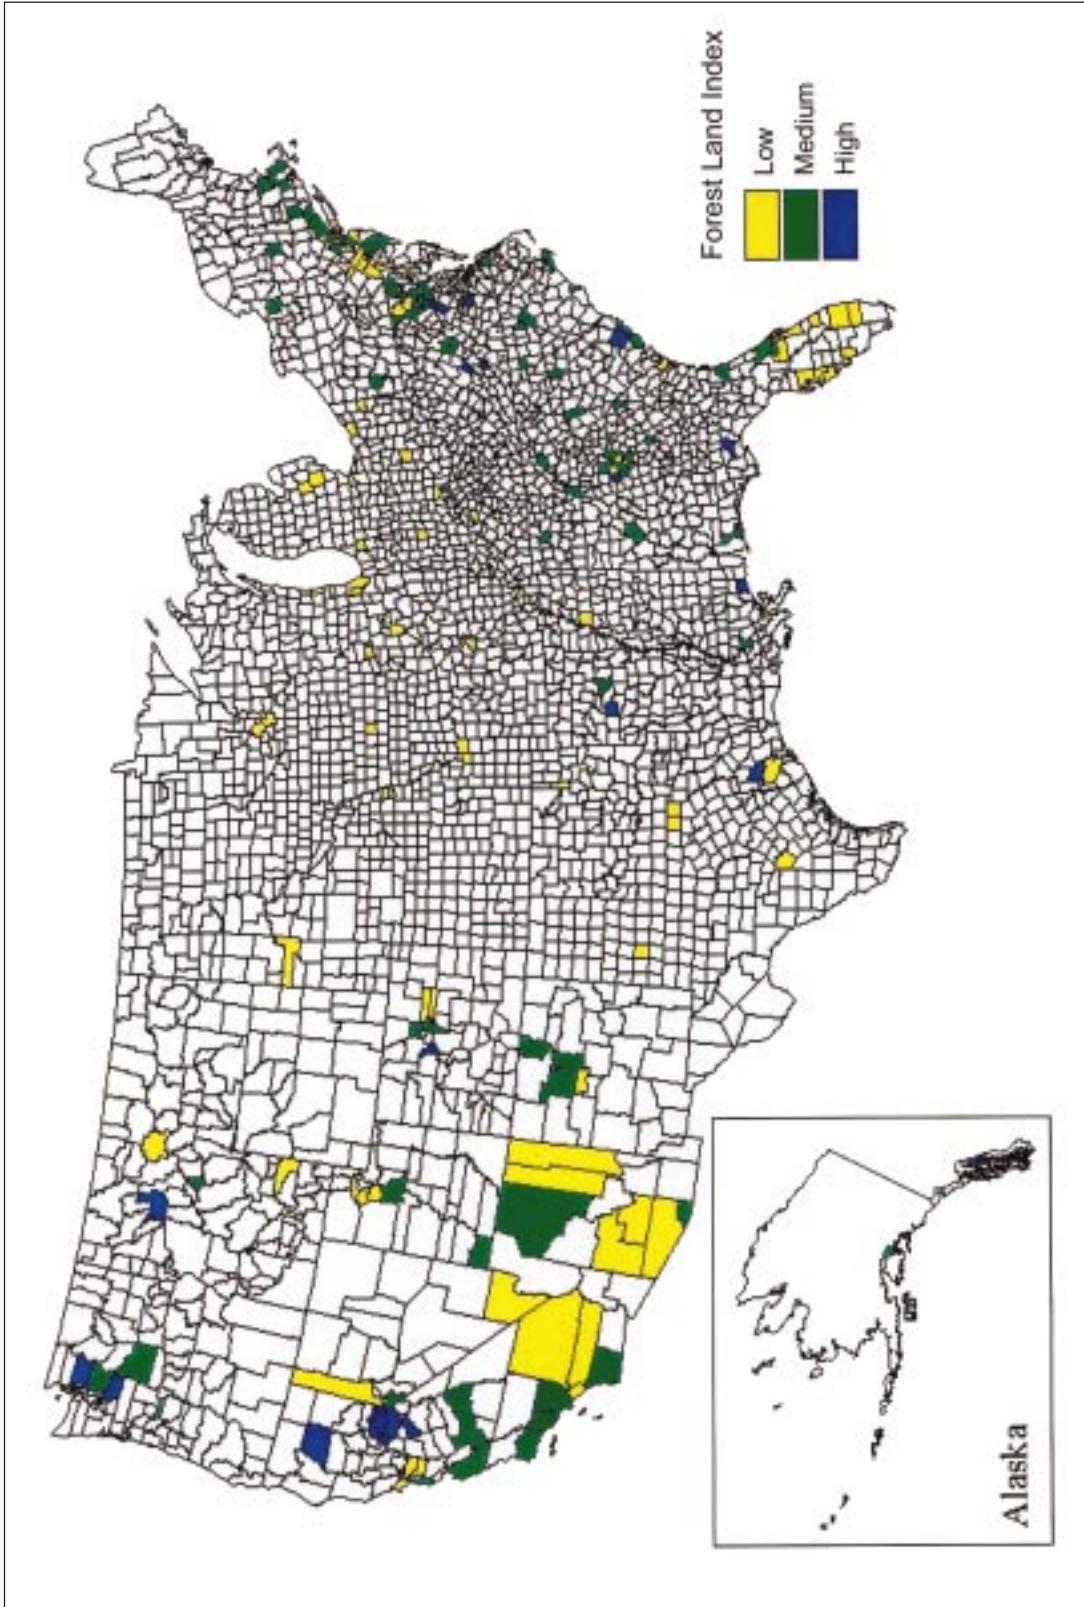

Figure 3—Counties with high viability and adaptability to changing economic conditions.

**Table 2—Population and area of the United States by region, with low variability and adaptability by region**

Region	Population			Area		
	Extent of forest land			Extent of forest land		
	Low	Medium	High	Low	Medium	High
--- Thousand/people ---						
North	2,702	492	513	164,223	14,328	22,844
South	1,843	367	682	120,405	9,272	21,347
Rocky Mountains	1,088	154	62	196,329	46,506	10,023
Pacific Coast	189	205	49	25,651	178,429	12,752
Total United States	5,823	1,219	1,306	506,608	248,535	66,966

Note: Individual columns may not add to the total owing to rounding.

Although much of the emphasis has been on the counties with low composite rankings, most (640 counties) of the heavily forested counties have actually medium or high rankings. Many of these are counties with extensive urban populations such as those in Atlanta, Seattle, or Portland, whereas others contain significant recreation areas such as Shenandoah and Olympic National Parks or the Upper Peninsula in Michigan. These results suggest that forests often contribute to positive notions of the amenities associated with residential and recreation areas.

There is a question of how well this indicator rates viability and adaptability. In the last section, several criteria were presented for such judgments. The first pertains to the extent to which the measure is based on a well-understood conceptual model. Throughout this paper, I have argued that the evolution of the concern about the viability and adaptability of a community reflects the broader changes in our understanding of community well-being and its relation to the surrounding forest or natural resources. Although there is often ambiguity about the definition of social well-being, there is acceptance of its utility (see McCool and others 1997). The second criterion addresses the reliability of the indicator. One demonstration of this has been the previous use of similar indicators in both community (Harris and others 2000) and bioregional assessments (see Horne and Haynes 1999, McCool and others 1997), and in state-level attempts to address sustainable forest management (see Donoghue and Haynes 2002). In all cases, useful measures were developed and helped expand our understanding of how communities differ in their propensity to deal with external changes. The third criterion pertains to the ability of an indicator to detect differences at appropriate spatial scales. The above examples also demonstrate these abilities in the various measures that were developed. The fourth criterion is robustness of the indicator to provide reliable measures given the variability in the data. The various maps do illustrate the ability to deal with spatial differences, but additional work will be needed to demonstrate the extent of temporal variation inherent in social and economic data. In summary, as a first approximation, the measure developed here for Indicator 46 meets most of the criteria for "goodness."

## Interpreting the Results

These results (like those of Horne and Haynes 1999) suggest that most Americans live in areas with moderate to high viability and adaptability, but there are extensive areas characterized by low viability and adaptability for economic and social changes. Figure 4 illustrates this dilemma. It also suggests that extent of forest land is more or less evenly distributed across areas of both low and high adaptability. Finally, it should not be concluded that these areas of low adaptability are in some type of distress. They simply have low adaptability or resiliency to social and economic changes.

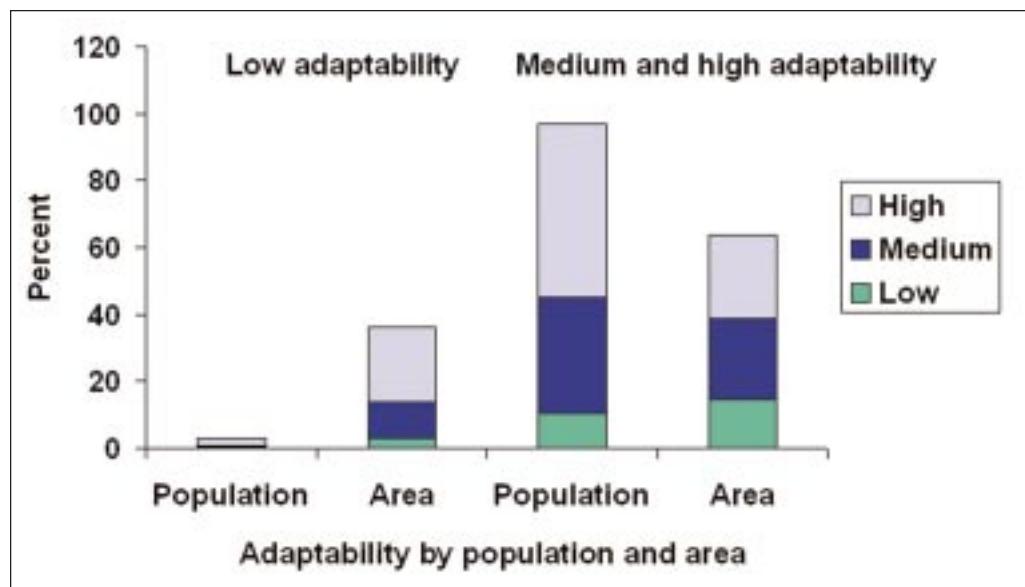

Figure 4—Population and area by degree of adaptability and extent of forest land.

It is interesting to note those counties that are both heavily forested and that have medium or high viability and adaptability. Of the 209 counties with high viability and adaptability, only 22 are heavily forested. Most of these are in urban areas such as Seattle. Of the 2,064 counties with medium viability and adaptability, 30 percent are heavily forested. Several are near urban areas, but others contain significant residential developments including counties thought of as recreation counties (see Johnson and Beale 1995) affirming the rich connections between forests and human populations beyond just timber for wood products. Of the 285 counties identified by Johnson and Beale (1995), 44 percent are heavily forested.

The intent of the original indicator was to identify forest-dependent communities. As was argued in an earlier section, this is both difficult to do and is probably inappropriate at the broad scale of national indicators. However, we do have community data for eastern Oregon where we can examine the relation between the counties rated as having low adaptability and the communities in those counties. In eastern Oregon, there are 10 counties rated as having low adaptability. These 10 counties contain 46 communities ranging in size from a population of 3 to nearly 10,000. Of the 46 communities, 26 were rated by Reyna (1998) as being small, isolated from major population centers, and lacking in economic diversity. The results suggest that the approach taken to develop a measure of Indicator 46 does provide a useful first approximation of areas where community assistance may be needed to offset the effects of changes in broad-scale land management.

Another inference concerns the intent of Indicator 46 to address those areas with indigenous communities. Each county was assigned a scale for its extent of American Indian or Alaska Native population. Counties with an American Indian and Alaska Native population less than 1 percent were assigned a rating of 0. Those counties with a population proportion between 1 and 5.77 percent were assigned a rating of 1 (the U.S. average is

1.9 percent). Those with a population greater than 5.78 percent were assigned a rating of 2. Generally, indigenous communities are difficult to identify other than as communities associated with American Indian reservations. For example, in eastern Oregon, Reyna (1998) identified seven communities as being associated with American Indian reservations. Only 1 of these communities is in 1 of the 10 counties identified as having low adaptability. Seven of the ten counties are identified as having average (1.9 percent of population) or higher populations of American Indians, but none has more than 5.77 percent of its population as being American Indian. There are 65 counties and boroughs that do have significant American Indian or Alaska Native populations. The largest numbers are concentrated in six states: Alaska, Kansas, Montana, North Dakota, South Dakota, and Oklahoma.

Finally, I caution against drawing inferences about economic conditions from the assignment of low viability and adaptability. In other studies (Horne and Haynes 1999), little relation is found between reduced economic opportunities and extent of forest land.

## Closing

Indicator 46 attempts to address the links among land management, the flow of goods and services, and social well-being of human communities. In that sense it reflects the current scientific thinking about the relation between the biophysical and socioeconomic components of ecosystems. It is difficult, however, to reconcile its intent with the almost mystical reference to communities without specific definition or clarity in terms of spatial hierarchy among communities and higher levels of administrative governments.

There are three possible research directions that can be taken to improve our treatment of this indicator. First, there is the need for refinement of the specific proxies used in the composite measure. There is the opportunity to develop other midscale measures that might better represent social and economic conditions. Included in this should be an examination of the relations between the variables used in developing the composite measure. Second, there is the need to use existing (or to develop new) community databases to better understand the relation between midscale measures of social and economic conditions and actual community-level measures. Third, there is the opportunity to improve our ability to estimate nontimber outputs (both goods and services) and to value them. These are key to better describing the benefits of forest management.

Thinking more broadly, there are significant science challenges in developing an indicator for community condition. First, there is the intellectual challenge of developing a measure for viability and adaptability. Multiple terms like adaptability, viability, and resiliency add confusion, but the essential point is the need to capture the essence of the dynamics of communities and changes in their functioning. Second, the development of indicators is a pressing managerial problem. Indicator 46 addresses the need to identify which communities may need assistance in adjusting to changes in land management approaches, outputs, or other changes. This poses two challenges: the need to better understand the relation between forest management and communities and the need to develop adequate proxies for broad-scale measurement of certain attributes of community adaptability. Finally, we need to develop a coincidental understanding of how to engage community development interests in a discussion of viability and adaptability as they are often the agents of change.

56045	WY, Weston County	0	1	1	3	2	4.0	1	

<sup>a</sup> Population density (person per square mile): 0 = 0–5, 1 = 6–28, 2 = 29–250, 3 = >250.

<sup>b</sup> Minority (percent): 1 = 0–7.33, 2 = 7.34–23.93, 3 = >23.94.

<sup>c</sup> Native American: 0 = 0–1, 1 = 1.1–5.77, 2 = >5.78.

<sup>d</sup> Region: 1 = North, 2 = South, 3 = Rocky Mountains, 4 = Pacific coast.

<sup>e</sup> Employment: (Shannon Weaver Index): 1 = 0–0.76684, 2 = 0.76685–0.87421, 3 = >0.87422–1.

<sup>f</sup> Composite: (population+[minority+NF area]/2)+employment).

<sup>g</sup> Forest land (percent): 0 = 0–5.0, 1 = 5.1–32.5, 2 = 32.6–66.2, 3 = ≥66.3.

<sup>h</sup> National forest: 1 = 0–35,000, 2 = 36,000–157,000, 3 = >157,000 acres.

The **Forest Service** of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 14<sup>th</sup> and Independence Avenue SW, Washington, DC 20250-9410 or call (202) 720-5964 (voice and TDD). USDA is an equal opportunity provider and employer.
