## INTRODUCTION

### Objective

The Uinta-Wasatch-Cache National Forests Road System is essential in providing access to and through National Forest System lands. It provides access for the public and administration of land management objectives. Land allocations and management objectives, regulatory requirements and funding have changed in the last decade creating a need to reassess the management of the road system. This assessment of the road system is intended to provide land management officers with the framework needed to support land management objectives, desired future conditions, and management of a minimum road system that is safe and responsive to public needs and desires; is affordable and efficient; has minimal adverse effects on ecological processes and ecosystem health, diversity, and productivity of land; and is balance with available funding for needed management actions (*Forest Service Manuals (FSM ) 7712.10*). Information and guidance will also be provided to allow future site-specific travel management decisions to be made that meet the integrated transportation system goals.

### Process

The transportation analysis incorporates a six-step process that provides framework for periodic reevaluation of the road system and management strategies at the appropriate scale. Although the analysis consists of specific steps, the process may require feedback and iteration over time as the analysis matures and is evaluated at various scales. The following steps will guide this analysis:

- Setting Up the Analysis
- Describing the Situation
- Identifying the Issues
- Assessing Benefits, Problems and Risks
- Describing Management Opportunities and Setting Priorities
- Reporting

### Product

This roads analysis is a process, not a decision making document and does not allocate land for specific purposes. The purpose of this analysis is to inform managers and interested parties of the strategic intent of the road system for forest planning and demonstrate compatibility of the existing road system with ecological, social, and economic objectives. It also provides interdisciplinary teams and line officers context for sub-Forest scale analysis; identifies needed and likely not needed road segments; sets priorities for more detailed analysis and program planning; and identifies issues requiring further evaluation for both existing roads and roads planned for the future.

## SETTING UP THE ANALYSIS

### Analysis Area/Scale

The analysis area is the Uinta-Wasatch-Cache National Forests (UWC). The analysis focuses on classified arterial, collector and local roads (Maintenance Level 1, 2, 3, 4 and 5) currently shown on the Transportation Atlas and the Forest Service INFRA database.

### Interdisciplinary Team

An interdisciplinary team (IDT) approach was used for this analysis. The team consisted of the following core members:

|                  |  |
|------------------|--|
| Oscar Mena       | Civil Engineer / Interdisciplinary Team Leader |
| Pete Gomben      | NFMA Compliance                                |
| Ruth Ann Trudell | GIS Analyst                                    |
| Charlie Condrat  | Hydrologist                                    |
| Paul Chase       | Fishery Biologist                              |
| Kevin Labrum     | Wildlife Biologist                             |
| Dave Hatch       | Landscape Architect                            |
| Tom Flanigan     | Archeologist                                   |
| Matt Zumstein    | Salt Lake Ranger District                      |
| Dean Larsen      | Pleasant Grove Ranger District                 |
| Jim Percy        | Heber-Kamas Ranger District                    |
| Roger Kesterson  | Evanston-Mountain View Ranger District         |
| Juan Barrientez  | Ogden Ranger District                          |
| Ron Vance        | Logan Ranger District                          |
| Duane Resare     | Spanish Fork Ranger District                   |

### Plan for the Analysis

The IDT was directed to describe the existing condition; identify issues; assess benefits, problems, and risks; describe management opportunities and set priorities; and prepare a report of the findings.

The team followed law, policy and direction found in the *Revised Forest Plan for the Wasatch-Cache National Forest*, the *2003 Land Management Plan for the Uinta National Forest*, and the *final environmental impact statements for both plans*; *Administration of the Forest Development Transportation System*; *Final Rule and Forest System Transportation System*; *Final Administrative Policy* as published in the Federal Register on January 12, 2001; *36 CFR Part 212*; *Forest Service Manual (FSM) 7700*; *Forest Service Handbook (FSH) 7709*; and *Roads Analysis: Informing Decisions About Managing the National Forest Transportation System*.

Due to limited timeframes associated with this analysis, the team was directed to fully utilize existing information and data. Key sources of information and data included:

- The Forest's transportation management system database (INFRA)

- The Forest's Geographic Information System (GIS) layer
- *Roads Analysis Reports* for Uinta and Wasatch-Cache National Forests
- Road condition surveys
- *Forest Plans* for the Uinta (UFP) and Wasatch-Cache (WCFP) National Forests
- Interagency Recreation Travel Map
- Professional knowledge and experience of Forest personnel

This information and data was utilized to describe the existing condition and develop issues. For the Forest the issues were identified as:

- Watershed health, riparian function, and aquatic species
- Terrestrial wildlife
- Access
- Road maintenance costs

The IDT adapted portions of roads analyses completed by the Uinta and Wasatch-Cache National Forests, which utilize models to evaluate cost versus benefit. For each issue factors are developed, which include a description of indicator and associated measurement parameter(s). Issues with multiple factors will be evaluated and given an overall rating based on criteria.

Each road segment is then evaluated and assigned an overall cost and benefit rating of low, moderate or high. Based on those results specific recommendations and priorities are made regarding the road segment. These results and analysis of issues for the transportation system provide the framework to develop recommendations for road and Forest management.

This analysis is intended to provide direction and consistency in the evaluation of the road system at the Forest-scale and road segments at the project level independent of project team assigned to analysis. Prior to making specific road management decisions teams assigned to watershed or project scale analysis will have to validate data and opportunities as well as consider additional localized issues. At that time, overall ratings for each road segment are placed within a matrix that evaluates cost on one axis and benefit on the other. Each box in the matrix has been assigned a primary management opportunities (PMO), which include retain, decommission, or further evaluation needed. Secondary management opportunities (SMO) have been listed to consider for a sub-Forest scale analysis.

The team was directed to prepare a stand-alone report of their findings that specifically includes the following items:

- Inventory and map of all classified roads, and display how they are rated based on risk and benefits, management opportunities and priorities.
- Provide guidelines for addressing road management issues and priorities related to construction, reconstruction, maintenance and decommissioning.
- Identify significant social and environmental issues, concerns, and opportunities to be addressed in project level decisions.
- Information needs assessment for future analysis at watershed or project scale including user created roads that may exist.
- A list and map of roads likely needed and likely not needed for future use to provide a continued share understanding between Region 4 and Washington Office.

## DESCRIPTION OF THE EXISTING CONDITION

### Uinta-Wasatch-Cache National Forests

The Uinta-Wasatch-Cache National Forests encompasses about 2.5 million acres covering an area that includes northern and north-central Utah, and southwestern Wyoming. The Forest occupies the geographical transition zone between the Great Basin on the west and the Rocky Mountains on the east. The Wasatch Mountains, Uinta Mountains, Tavaputs Plateau, Bear River Range, Cedar Mountains, Stansbury Mountains, Wellsville Mountains and Sheeprock Mountains are major geographic features on the Forest.

Much of the Forest lies along the west side of the Wasatch Front; a zone of urban development that extends nearly 150 miles from north to south, occupied by 2.2 million people, representing roughly 80 percent of Utah's total population. Several major municipalities border the Forest, including the Salt Lake metropolitan area. The Forest lies within portions of fourteen counties, ten of which are predominantly rural and four of which are mostly urban. The Forest is near the Confederated Tribes of the Goshute Indians, the Skull Valley Band of Goshute Indians, the Uintah and Ouray Ute Indian Tribes, the Shoshone Bannock Tribe, the Northwest Band of Shoshone, and the Eastern Shoshone.

Urban growth and the issues associated with meeting expectations of a diversifying public will continue to challenge the ability of natural resource managers in balancing use with ecosystem capability.

Soils across the Forest are diverse and complex. There are two geologic provinces, the Colorado Plateau and the Basin and Range Province. The soils are composed of many landtypes, or soil associations; which are Fault-Block Mountain, Glacial Canyon, Moraine, Scoured or Sculptured Upland, Mountain Foothill, Stream Canyon, Structurally Controlled Limestone, Sandstone, Shale, Metamorphic, Tectonic Mountain, Plateauland, Landslide, and Lacustrine. Roads and trails have impacted soils in some areas. They compact soils and tend to collect and focus runoff which results in some localized accelerated erosion. Where feasible, roads are now being designed or relocated to prevent or minimize adverse impacts on the soil resource.

Approximately 309,00 acres, or 25 percent, of the Forest has been placed in the National Wilderness System. Approximately 1.28 million acres, or 51 percent, of the Forest is designated as inventoried roadless area. These areas provide opportunities to manage dispersed recreation opportunities, sources of public drinking water, and undisturbed landscapes that provide privacy and seclusion. In addition, these areas serve as safeguards against the spread of invasive plant species and often provide important habitat for rare plant and animal species. They support a diversity of native plant species and provide opportunities for monitoring and research.

### Management Direction

The allocation of land to management prescriptions and application of recreational opportunity spectrum (ROS) classifications through forest planning can affect the need for roads and helps develop forest-wide goals and objectives for transportation management. These in turn help define the level of development of the roads. Direction which ensures that transportation facility development is both environmentally sensitive and responsive to access needs is defined by standards and guidelines.

The g.Goals, objectives, standards, and guidelines as outlined in the Uinta and Wasatch-Cache National Forests Plans which were revised in 2003. The UFP and WCFP provides direction for natural resource

management and use on their respective planning areas. Road management under both plans includes direction for providing safe and efficient transportation facilities, and minimizing resource related impacts from the development and management of these facilities.

The Forest Plans emphasize watershed protection and maintenance. The standards and guidelines include direction related to best management practices for soil and water resources, terrestrial and aquatic habitat protection, and general levels and types of uses as described in application of the Recreational Opportunity Spectrum. In some areas, motorized use opportunities are favored and in other non-motorized use opportunities are emphasized.

Specific activities that affect transportation system management include wilderness recommendations, roadless area management, timber management, mineral exploration and development, wildlife and fisheries habitat management, watershed management and protection, and dispersed and developed recreation. These activities affect the miles of road constructed, reconstructed, or closed and the management objectives for each road. They also affect road improvement needs, realignment, and maintenance. Travel management restrictions and limitations (e.g., permissible presence or absence of off-road/off-trail use of all-terrain vehicles) affect road management objectives; which may affect road reconstruction, realignment, and maintenance needs. Conservation or mitigation measures associated with other resource needs (e.g., Best Management Practices for soil and water, and biological conservation measures for Threatened, Endangered, and Regional Forester Sensitive species or species of conservation concern) also affect the amount and location of roads and associated road management objectives.

## **The Road System**

### **Historic Overview**

In March 2008 the Uinta and Wasatch-Cache National Forests were administratively combined into the Uinta-Wasatch-Cache National Forests. These planning areas continue to be managed through the direction provided in their respective forest plans.

#### ***Wasatch-Cache Planning Area***

The Mormons entry into Utah in 1846 signaled the beginning of road building on what is now the Uinta-Wasatch-Cache NF. Mormon pioneers created roads to access forest resources, such as timber and water power/control, in the canyons outside Salt Lake City, Ogden, and Logan. In addition, intensive mining interests promoted road and railroad building in the tri-canyon area of Salt Lake City. These early roads most likely were fairly primitive and allowed wagon access for hauling resources such as timber and mineral ore, down the canyon or for repairing water diversions, ditches, pipes, and later water power plants and dams. Early canyon roads were washed out every year by spring floods and were rebuilt for the summer season.

The North Slope of the Uinta Mountain range witnessed road building to a limited degree beginning in the 1860s. Many small “tie hack” camps appeared throughout the Uintas for timber harvesting to create railroad ties in support of the transcontinental railroad construction during the 1860s. Trails usually accessed the smaller, seasonal camps, however, larger roads were built to support the commissaries or “store towns”. For example, the 1920 Wasatch National Forest map shows roads leading to the Black’s Fork Commissary (main Black’s Fork Road) and the Standard Timber Commissary (Mill Creek Road).

The city of Kamas was settled in the 1860s and immediately people started using the forest resources of the mountains to the east. By the 1870s, a rough road was constructed to the mouth of Shingle Creek and continued up the Provo River by 1891. Due to the growing number of sawmills in the area (Paulsin Basin), roads were created up to Soapstone Basin and to Spring Canyon in the 1890s.

Although roads were always used for recreation on the Uinta-Wasatch-Cache NF, recreational use increased significantly with the invention and widespread use of the automobile in the 1920s. Asphalt entered into road building during the 1920s and was widespread post-World War II. The road up Beaver Creek on the Kamas District was improved in the 1920s and a rough car road was built as far as Mirror Lake also in the 1920s. Logan Canyon road saw major improvements throughout the 1920s, particularly since many people escaped the heat of Cache Valley by heading to the nearby mountains for the cooler air. By 1920, the Forest Service built many roads to access the forest for administrative purposes. The 1920 Wasatch Forest map indicates roads were present up the West Fork Bear River, West Fork Black's Fork, East Fork Black's Fork and Gilbert Creek that access "scaler's cabins" or guard stations on the Evanston and Mountain View districts of the forest.

A major road and trail building initiative was started in the 1930s using Civilian Conservation Corps (CCC) enrollees stationed at camps throughout the Cache, Salt Lake and Kamas Valleys. Although scholars know that road, trail, and recreational structure building was one of the major emphases of the CCC era on almost all National Forests in the United States, there is a woeful lack of explicit documentation concerning exactly where and what road, trail, campground was built by CCC labor on the WCNF. CCCs generally built 14-foot wide roads to access their work areas even if the road didn't need to be that large after their work was completed. The CCC's built roads that wide to avoid intensive maintenance during the heavy use of the project. In addition, it was cheaper to build a higher grade road initially than to constantly repair the road or their trucks during construction.

Mirror Lake Highway, Logan Canyon, Ogden Canyon, and Brighton Loop roads are all mentioned as worked on by the CCCs in the 1930s. From 1933 to 1934, Camps F-2 and F-1 on the Logan District spent the majority of their time working on roads and trail construction. Camp F-1 built the road from Cowley Canyon and Herd Hollow into Blacksmith Fork while Camp F-2 constructed the Left Hand Blacksmith Fork Road.

Starting in the mid-1950s, the Wasatch-Cache NF began to build or improve roads to a significant degree to open up timber stands that local operations would otherwise be unable to big on due to the high cost of access. One such improvement was the road into Upper Setting on the Kamas District. The road into Paulsin Basin through Wide Hollow (Kamas District) was also improved during this time. In addition to timber harvest, many roads on the Forest were constructed for commodity needs such as timber production, mining, grazing and range management and special use access. Although access is still needed for these uses, access for recreational purposes is the largest single use of National Forest System roads.

Traditional forms of recreation travel, such as driving for pleasure, hiking and horseback riding are showing steady increases. There has been a steady increase in road miles in the Forest Service since the 1940's. Some of that increase is due to better inventorying and classifying of existing roads, but many were constructed to support commodity needs listed above.

The 1985 Land and Resource Management Plan for the Forest had miles of new roads construction and reconstruction planned on the Forest. Primarily, because of reductions in the timber sale program and lower than expected appropriations for capital investments, many of these roads were never constructed or reconstructed. Over the past decade, road construction has declined significantly.

Road reconstruction and realignment is intended to improve water quality, provide wildlife security areas, and create an efficient transportation system. As a result of decreased and inadequate funding, the condition of many roads on the Forest has fallen below the levels necessary for safety, for resource protection and to efficiently support the traffic volumes being carried. Commercial user contributions, because of fewer activities like timber sales have also decreased maintenance funding. Several county roads that provide access to the Forest are substandard. County governments continue to provide maintenance on some Forest roads, but at reduced levels. Trends indicate that increased volumes in the future; especially from recreation-oriented traffic will continue.

In the past, user created roads were termed “temporary”, “pioneer”, “ghost”, “ways”, and “two-track” roads. Several of these roads were added to the Forest inventory in 1993 to assist in road management and so their future decommissioning could be carried out in a planned manner. With insufficient budgets enforcement, decommissioning, and restoration of these roads has been limited.

The increased urbanization of lands adjacent to the Forest has led to the closing or impairment of several traditional access routes. This is especially true for routes near areas like the urbanized Wasatch Front.

### ***Uinta Planning Area***

Ancient American Indians accessed what is now the Uinta National Forest over a series of foot (and after about 1800, horse) trails. They used these trails to travel through the Forest, and to access particular areas of the Forest used for hunting, plant gathering, ceremonies, and camping. Early European American settlers recognized these trails on maps and in journals, and most were visible on the ground. For example, a trail leading across the western face of Mount Timpanogos and up Provo Canyon (through what is now called Sagebrush Flat) connecting Utah and Heber Valleys was noted on early maps. In some cases these early trails became the template for later European-made roads. In other cases, they have become part of the existing Forest trail system.

Modern descendants of these ancient American Indians include members of the Northern Ute Indian Tribe, the Skull Valley Band of Goshute Indians, and the Confederated Tribes of the Goshute Reservation, at Ibapah. Historic use of roads and trails on the Forest by members of these tribes are documented on old maps and in other historic records. For example, the road through the West Fork of the Duchesne is referred to as the “Indian Trail from Heber City to White Rocks” on a 1904 General Land Office map.

Today Indian peoples come to the Forest for a wide variety of reasons, but do so now on the same network of roads used by other Forest visitors. However, their access to traditional cultural properties and sacred sites is protected by a series of laws and presidential orders. As a result, American Indian Tribes have potential concerns about Forest Road Management that is particular to their status as sovereign nations.

European American settlers arrived in Utah Valley in 1849, the Nephi area in 1851, the Vernon area in 1857, and in Heber Valley in 1859. They were heavily dependent on the wood, water, grazing, stone, mineral, and animal resources available in the adjacent mountains. As a result, they immediately began building very rough wagon roads up nearby canyons. Some of the earliest canyon roads were in American Fork, Hobbie Creek, Payson, Santaquin and Salt Creek Canyons. However, poverty and intermittent skirmishing with Ute and Goshute peoples discouraged any significant road improvements or expansions until the late 1860’s. An exception to this was the 1865 construction of a road up the Hobbie Creek that ultimately went to Denver, Colorado.

California Volunteer soldiers stationed at Fort Douglas in Salt Lake City needed a wagon road over which to bring supplies from the East. They specifically chose the Left Hand Fork of Hobbie Creek in order to avoid the morass of beaver dams and trees in both Provo and Daniel's Canyons. It was completed through Strawberry Valley in 1865, but never became a major Forest travel route. However, it did open Hobbie Creek to additional livestock grazing, logging, and homesteading.

The spread of roads on the Forest proceeded quickly after about 1858. However, the rate of development, and the reasons for that development, varied by area. Generally, road construction was driven by the need to get to particular resources on the Forest. The construction of throughways that connected towns outside the Forest also had a big influence on the rate of road development within the Forest.

One of the earliest major road projects was that of building the road up Provo Canyon. The canyon bottom was filled by the Provo River and dense riparian vegetation. As a result, any early travel through the canyon was done over the old Indian Trail. The first road up the canyon was a daunting task, and was done as a communal project by Provo residents. It was completed in 1859, and was a very narrow wagon road built into the sides of the canyon. This road opened Heber Valley to settlement, as well as setting the stage for homesteading, grazing and logging within Provo Canyon itself. The South Fork of the Provo and Pole Canyon roads were built first (in the 1870's) followed by the North Fork road (1890's).

Silver-lead and gold mining began in the early 1870's in Northern Utah, and this led to the improvement of existing roads and the development of new roads within the American Fork and Silver Lake mining districts. The existing 1870 American Fork Canyon road was very rough and probably went only as far as Mutual Dell (in the main fork) and Dutchman Flat (in the North Fork). It was replaced between 1871 and 1878 by a narrow gauge railroad that went as far as Tibble Fork. By about 1872, miners had constructed improved wagon roads up the North Fork of the American Fork into Mineral Basin, Mary Ellen Gulch, and Major Evans Gulch. Numerous smaller roads continued to be added between these main routes and particular mines. The main canyon route itself became a toll road in 1878, and was built and maintained by the American Fork Wagon Road Company. The toll road ended in 1905, when these lands became part of the Forest Service system. Most mining in the canyon had ended by the early 1950's.

Road building in Spanish Fork Canyon had been hampered by the meandering river and associated beaver dams. However, soldiers leaving Camp Floyd for the Civil War battlefields cut a poor wagon road up the canyon in 1861. Settlers from south Utah Valley pooled their resources in 1864 and added a rough road thirteen miles up Diamond Fork to access much-needed timber. Ultimately, this road also opened the door to homesteading along Diamond Creek. Additional side roads followed in Wanrhodes Canyon, Monk's Hollow, Brimhall Canyon, etc. by the 1890's. These roads were used by even more homesteaders to expand the scope of settlement in the canyon. Eventually many of these homesteads would fail during the Depression in the 1930's.

The discovery of coal at Scofield finally provided the incentive to significantly improve transportation in Spanish Fork Canyon. The Pleasant Valley Coal Company completed a narrow gauge railroad up the canyon in 1877. This was soon replaced by the Denver and Rio Grande transcontinental railroad in 1883, which went all the way to Soldier Summit and beyond. With it came a much better road, and additional roads soon spread up the side-canyons in such places as Tie Fork and the Left and Right Forks of White River, primarily to provide logging access. The first road from Spanish Fork Canyon to connect with Strawberry Valley was probably the Tie Fork road, by the 1890's.

The very rough Diamond Fork road first built in 1864 was significantly improved as a result of the first major trans-basin water development project in the West. Local farmers organized themselves into the Strawberry Water User's Association in 1905 and began lobbying the newly formed Bureau of

Reclamation to build an ambitious dam and tunnel system. They proposed building a reservoir in Strawberry Valley, and diverting its water through the Strawberry Divide into Sixth Water in Diamond Fork.

The Water User's were so anxious to get the project underway in 1905 that they rebuilt the existing Diamond Fork road and its bridges, and extended it up to the West Portal of the proposed tunnel project. This road helped make the Strawberry Valley Project a reality, made Diamond Fork more attractive to settlers, and improved access for livestock operators. This road also became the main travel-way between Strawberry Valley and Spanish Fork Canyon until 1918 when a better road was constructed up the Left Fork of White River.

The main Salt Creek Road connecting Nephi with Sanpete Valley was completed by about 1860. A side road north up Salt Creek was built by 1874 in order to access timber and salt deposits, since both were an important part of Nephi's early economy. The road would also be used early as a haul route for building stone from Andrew's Canyon. A railroad grade was built up Salt Creek to this quarry in 1895; however, this venture was short-lived and the railroad torn out. By 1901 there were also short roads up Red Creek and Pole Canyon from Salt Creek that accessed other stone quarries, as well as more timber and grazing lands.

The Nebo country above Santaquin and Payson Canyons had a network of logging roads by the 1890's, which were also used by stockmen. Another significant impetus for road building was the on-going construction of a series of small dams at Payson Lakes and other locations in order to provide irrigation water for Payson area farmers. In addition, roads were built up Bennie Creek, Nebo Creek, and Spencer Canyon on the eastern flanks of Nebo during the 1880's. These were built by settlers in the Birdseye area, primarily to provide access to logging and grazing lands and water diversions.

Early settlers in Heber Valley also needed access to timber and other resources on what is now the Uinta National Forest. Daniels Canyon had a rough wagon road by 1870, and it replaced Hobble Creek as the main route to Strawberry Valley and the Uintah Basin beyond. There was a road nearly all the way to the Lake Creek Summit by 1881. The high country lands east of the Strawberry Ridge and south of the Duchesne Ridge (including Strawberry Valley) were part of the Uintah-Ouray Ute Indian Reservation, created in 1861. Roads into this area were primarily built by stockmen, who grazed these areas under permit from the Bureau of Indian Affairs.

The road to Soapstone along the Provo River was built in the 1890's. This provided access into the Soapstone area on the Uinta National Forest from the north. Another important route into the area north of Strawberry Valley was the road east of Woodland, completed in the 1880's. It created access into areas such as Bench Creek and the Little South Fork of the Provo by 1891. This road east of Woodland was roughed in all the way to Stockmore by 1900, and it was seen as the future primary connecting road to the Uintah Basin. Lumbermen and stockmen built additional side roads into the high country off this main route that connected with the existing Lake Creek Summit road.

The Vernon area contained a number of rough wagon roads by 1870, built by settlers to access their homesteads and wood in the adjacent hills. Some additional roads were added through the years by miners, who had mines in places such as Harker Canyon and South Oak Brush.

By 1906, the basic road access system we have today was in place. However, there were some areas that still had no roads, a much lower density of roads, or for which the roads were poor enough to seriously restrict access into them. For example, there was no road connecting Ray's Valley with Diamond Fork. The Alpine and Nebo Loop roads did not exist. Both areas contained rough wagon roads, but no good connecting roads. This was particularly the case in the Nebo area, where access was most restricted from

the Salt Creek (south) side. The whole area north of Strawberry Valley contained relatively few roads. For example, there were no roads all the way up either Co-op or Trout Creeks, and the area that now contains Currant Creek Reservoir was accessed from the north and west only.

This era brought some important changes that would strongly affect all subsequent road development. First, most of the lands that are today part of Uinta National Forest were part of the National Forest System by 1906. This includes the areas that had originally been part of the Uintah-Ute Indian Reservation. These lands were returned to the public domain in 1905 as part of a broader effort to significantly reduce the size of the Reservation. Since the Uinta National Forest was created in order to protect the watersheds that supplied local communities, road maintenance and resource access were identified as a part of its mission from the beginning. Congress began allocating funds for road work in the 1910's.

Second, the State of Utah and Juab, Tooele, Utah and Wasatch Counties had identified road construction and maintenance as part of their responsibilities, and had begun to identify key routes as State and County roads. However, they did not have much money to spend on improvements. Eventually, federal money would supplement state and county funds and significant improvements to roads on and adjacent to the Forest would lead to improvements in Forest roads, as well.

Third, automobiles and trucks became increasingly affordable. During the good economic times of the 1920's, many families acquired cars and expected to be able to drive them over the existing road network. In addition, trucks also became more affordable for stockmen and loggers, and these also required better roads, too.

However, there were significant challenges ahead. Many roads had been built without much long-term planning; in many cases the goal was to connect two places with the shortest route and least amount of construction labor necessary. Many roads were in poor condition and passable only during dry weather. Others were so narrow and rough that they could only be used by wagons or small trucks. The rate at which these initial rough wagon roads were improved varied. Many of them would continue to be improved largely to provide better access for logging, water developments, and livestock operations. These activities would also lead to the development of some new roads, as well.

An increasingly important reason for road improvement or construction was recreational use and concerns about public safety. Starting in the mid-1930's, safe access for camping, hunting, fishing, and other recreation would become one of the primary reasons that roads were improved. The other significant issue affecting the improvement of existing roads and addition of others was watershed protection. Many of the original roads were right along streams in canyon bottoms, and/or were built directly on very clayey soils. Most were contributing a lot of sediment into adjacent streams.

Some of these early roads have never been improved, either because of only intermittent use, or because county or federal funding has not been available to do so. Other early roads have been closed through the years. Some of the areas they accessed are now available over other, improved routes. In other cases the original purpose for which they were built no longer exists (as is the case with many mining roads). This process of building and abandoning roads occurred before 1906, as well, for the same reasons.

One of the first road improvements after 1906 was the Woodland to Stockmore Road (now called the Wolf Creek Highway), which was improved in the 1920's with federal funds. However, these funds were insufficient for the task, and it was not until the public work programs of the 1930's that road maintenance and construction was accelerated.

For example, the Daniel's Canyon to Strawberry Valley to Duchesne route became a State Highway in 1921. However, this road was not made a good dirt road passable for all cars until the late 1930's, when the State was able to acquire federal support. An important source of support for roadwork in the 1930's came in the form of Civilian Conservation Corps labor. These men completed a number of important road projects on the Forest.

The CCC completed the Nebo Loop Road and improved the Alpine Loop Road, such that both could be driven in an automobile. They also rebuilt the Springville Crossing Road, between Hobbie and Diamond Creeks, and completed the Squaw Peak Road. The Mirror Lake Highway was created through significant improvement of the existing road, providing better access into the Soapstone area. They also did a great deal of maintenance on existing roads, such as the North Fork Road in American Fork Canyon, and the West Side and Indian Creek roads in Strawberry Valley. They also built a number of new bridges that were heavy enough to take the increasing levels of traffic on Forest Roads.

During the 1940's, logging in the areas north of Strawberry Valley increased greatly because of wartime lumber needs. This trend accelerated during the post-war building boom of the 1950's. This led to the creation of miles of additional roads in this area. An important part of this was Congressional authorization to allow part of the receipts from timber sales to be used for road construction for timber sales. Some roads were also created in this area during the mid- to late 1950's as part of a large-scale Forest Service project to treat a massive bark-beetle outbreak.

Another important Forest effort that created opportunities for road improvement in the late 1950's and early 1960's was the PL-566 Watershed Improvement Project. This project was an outgrowth of growing public concern about watershed health that also led to the creating of the Water Quality Act of 1965. Several roads on the Forest were constructed or improved, in order to provide access to project sites, or to contribute to overall water quality. For example, a rough wagon road that connected Ray's Valley and Diamond Fork was improved in the early 1950's, and a new bridge constructed over Sixth Water in order to reduce sedimentation in that stream. The Squaw Peak Road was also improved as part of this project, with an expectation that it would also become an important recreation use road. These funds were also used to close some roads that were degrading the quality of water in their area.

Other roads on the Forest were also improved during this era as the need for recreation access accelerated during the 1950's and 1960's. These include the Alpine Loop, which was paved for the first time in the 1950's, and the Nebo Loop, which was partially reconstructed and paved in the 1980's. In addition, the Cascade Springs Road was completed in 1972.

During the second half of the 20th century the Forest Service also began more long-term road and transportation planning. The result of this effort was to identify key arterial routes through the Forest, and ensure that they were both safe for the level of use for which they were intended, and that they had minimal effects on watershed quality. Several roads in the Strawberry Valley were moved and/or reconstructed in the 1990's as part of this effort, including the Co-op, Clyde, and Indian Creek Roads. The Forest has largely depended on contracts with private companies to complete these projects since the 1970's. An important partner in this effort has been the Utah National Guard, whose Engineering Companies have done road maintenance and reconstruction on the Forest since the 1950's.

As a result of Congressional Acts, such as the Endangered Species Act of 1973, as amended and the National Environmental Policy Act of 1969, the Forest began to look at the affect of roads on a broader range of resources, as well. This effort to balance the need for both public and Forest Service management access to the Forest, and to protect watershed health and other resources, continues.

## Access and Travel Management

Access and travel management is an important aspect of Forest management on the Forest. Most of the private, public and administrative access on the Forest occurs on roads. The transportation system contains National Forest System Roads (NFSR) under Forest Service jurisdiction that provides access to and through National Forest System lands. Roads that are under municipal, county, and state jurisdiction or private roads that provide access to the Forest complete the transportation network. FSRs are authorized primarily for the administration, protection, and utilization of National Forest lands. A travel management plan provides clear, specific direction on the appropriate levels of access to the Forest to be made available and the forms of transportation this access will take.

Presently, travel management across the Forest is identified in the current versions of the MVUM (Motor Vehicle Use Map) by ranger district. Future travel management activities will occur across the national forest by individual ranger districts based on land allocations as identified within the revised forest plans. Travel plans will be updated periodically by the ranger districts and involve public input, and an environmental analysis.

These plans include routes and areas that are designated open to different types of vehicles and vary by location and season. In addition, they address a number of complex travel and access issues including:

- Recreation uses and impacts
- Legal public access to Forest lands
- Legal public access to private in-holdings
- Closed versus open policy
- Economics of transporting commodities
- Law enforcement
- Public health and safety
- Travel way maintenance costs
- Effects and impacts on other Forest resources

## Statistics

**General.** The Road System on the Forest consists of a variety of road standards and jurisdictions. National Forest System Roads (NFSR) are under the jurisdiction of the Forest Service, essential for protection, use and management of National Forest System lands. A road is designated as classified, user created, or temporary. Classified roads are those needed for motor vehicle access, authorized by the Forest Service, designated on the Transportation Atlas, and intended for long-term use. They include local, state, county, private, and NFSRs. Temporary roads are authorized by contract, permit, lease or emergency operation, not intended to be part of the Forest's transportation system and not necessary for long term resource management. User created routes are unplanned roads, abandoned travel ways and off-road vehicle tracks, which have not been designated and managed as a trail. For the purpose of this analysis only data relative to classified roads will be considered.

Road Management Objectives (RMO) are established for all roads and provides criteria for design, operation and management of the road. Design standards such as number of lanes, lane width, surface type, vehicle types, and expected traffic volumes dictate management standards including functional class, maintenance level, and traffic service levels. Access needs, environmental constraints, and economics are considered when determining the appropriate standards to be applied.

**Functional Class.** National Forest System Roads provide access in a branching system of arterial, collector, and local roads. Arterials provide access to large land areas, typically by linking to county

roads, state highways, or communities. They have the highest standards for construction and maintenance, because of a larger volume of traffic they carry. Collector roads disperse traffic from arterials to large forest areas, such as watersheds. Local roads used to access specific project areas or sites are usually short roads of a lower standard of construction. Table RS-1 shows miles of road by functional class as designated in the Forest Service INFRA Database.

| <b>Table RS-1. Miles of Road by Function Class</b> |              |
|--|--------------|
| <b>Functional Class</b>                            | <b>Miles</b> |
| Arterial   | 201          |
| Collector  | 408          |
| Local  | 1975         |

**Maintenance Level (ML).** Operational ML describes the existing condition of the road in terms of current maintenance activities. Objective road ML prescribes the upkeep and restoration work necessary to retain a desired service level. The operational and objective levels are often different due to funding constraints and transportation planning desired conditions. ML 1 is the lowest standard and is physically closed to motor vehicle traffic, while preserving the investment in the road template. ML 2 through 5 are for roads open to high clearance and passenger vehicle traffic. ML 2 is for high-clearance vehicles, such as trucks and four-wheel drive vehicles, and passenger car traffic is discouraged. User comfort and convenience improves as the maintenance level increases up to ML 5, which is normally a double paved facility. Table RS-2 shows miles of road by maintenance level as designated in the Forest Service INFRA Database. Minor adjustments were made to balance numbers where discrepancies existed.

| <b>Table RS-2. Miles of Road by Maintenance Level</b> |                            |                          |
|---|----------------------------|--------------------------|
| <b>ML</b>   | <b>Operational (Miles)</b> | <b>Objective (Miles)</b> |
| 5   | 123                        | 138                      |
| 4   | 139                        | 181                      |
| 3   | 433                        | 492                      |
| 2   | 1673                       | 1568                     |
| 1   | 198                        | 177                      |

**Level of Service.** A description of the road's significant traffic characteristics and operating conditions. The levels reflect a number of factors, such as speed, travel time, traffic interruptions, freedom to maneuver, safety, driver comfort, convenience, and operating cost. In an attempt to follow AASHTO guidelines the Forest Service replaced "Traffic Service Level" with "Level of Service". A forest wide script was performed within the IFRA database to replace the existing levels A-D with levels G-J, G (most efficient and free flowing) through J (Traffic flow is slow and may be blocked, single purpose facility). Although levels A-D are still available, the category is reserved for roads having an average daily traffic (ADT) of > 400. Table RS-3 shows miles of road by level of service as designated in the Forest Service INFRA database.

| Table RS-3. Miles of Road by Level of Service |       |
|---|-------|
| Traffic Service Level                         | Miles |
| G   | 60    |
| H   | 251   |
| I   | 1173  |
| J   | 1082  |

**Surface Type.** The surface type of the road represents the material placed on the road template, which the vehicle tires are in contact. Different surface types are utilized to provide an efficient transportation system in terms of use, maintenance level, traffic service level and maintenance costs. Table RS-4 shows miles of road by traffic service level as designated in the Forest Service INFRA Database. Minor adjustments were made to balance numbers where discrepancies existed.

| Table RS-4. Miles of Road by Surface Type |       |
|---|-------|
| Surface Type                              | Miles |
| Asphalt                                   | 159   |
| Bituminous Surface Treated                | 36    |
| Crushed Aggregate or Gravel               | 305   |
| Improved Native                           | 230   |
| Native                                    | 1836  |

**Highways, Scenic Byways and Backways.** Several roads that access and cross the Forest are Public Lands and Forest Highways, as well as County roads. Forest Highways are under the jurisdiction of and maintained by a public road authority other than the Forest Service and are open to public travel. Several of these roads and NFSRs are designated Forest Service scenic byways and backways. These are important to consider in that they provide access and connectivity to National Forest System lands and complete the Forest Road System. Table RS-5 shows road name, number, jurisdiction and type as designated in the Forest Service INFRA Database.

| Table RS-5. Highways, Byways and Backways     |                       |              |                     |
|---|-----------------------|--------------|---------------------|
| Name  | Number                | Jurisdiction | Type                |
| Wolf Creek                                    | Utah 35 (FH5)         | State        | Highway             |
| U.S. 40                                       | Utah 40 (FH4)         | U.S.         | Highway             |
| Alpine Scenic Loop                            | Utah 92 (FH3)         | State        | Highway/<br>Backway |
| Nebo Scenic Loop                              | FSR 70015             | FS           | Byway               |
| Right Fork White River                        | FSR 70081             | FS           | Backway             |
| Cascade Springs                               | FSR 70114             | FS           | Backway             |
| Left Fork White River/White River Snow Course | FSR 70081 / FSR 70147 | FS           | Backway             |
| Logan Canyon                                  | US 89                 | Federal      | Byway               |
| Ogden River                                   | Utah 39               | State        | Byway               |
| Big Cottonwood                                | Utah 190              | State        | Byway               |

**Table RS-5. Highways, Byways and Backways**

| <b>Name</b>       | <b>Number</b>            | <b>Jurisdiction</b> | <b>Type</b> |
|-------------------|--------------------------|---------------------|-------------|
| Little Cottonwood | Utah 210                 | State               | Byway       |
| Mirror Lake       | Utah 150                 | State               | Byway       |
| Skyline Drive     | FSR 8007,8008, and 80177 | FS                  | Backway     |
| Trappers Loop     | Utah 167                 | State               | Backway     |
| Willard Mountain  | FSR 20084                |                     | Backway     |
| Hardware Ranch    | Utah 101                 | State               | Backway     |
| South Willow      | FS 80171                 | FS                  | Backway     |
| Guardsman Pass    | Utah 224                 | State               | Backway     |
| Pioneer Memorial  | Utah 65                  | State               | Backway     |
| North Slope       | FSR 80058, 40058, 80072  | FS                  | Backway     |
| Broadhead Meadow  | FSR 80416                | FS                  | Backway     |

**Federal Land Transportation Program (FLTP).** Due to inadequate road maintenance funding and the need for a safe and efficient road system, the agency has implemented the Transportation Rule to determine a minimum road system, as well as pursue outside funding (non – U.S. General Treasury Funds). As a part of oversight for TEA-21 bill, the House Transportation Committee has requested that the Federal Highway Administration (FHWA) and the Forest Service submit a report concerning advantages and disadvantages of managing a significant portion of the agencies road system as public roads. This may lead to funding needed for improvements on FSR identified as public roads from the Highway Trust Fund (gas tax). FHWA supports creation of a Forest Service Public Road System and proposes it be included in the Federal Lands Highways Program (Hernandez, C. 2002). The Forest submitted a list of proposed roads to the Intermountain Region. Table RS-7 shows the Forest's highest priority (Regional Sub-Set) listed in order of ranking based on the Region's Recreation and Economic Generator Filter. The list below accounts for 225.7 miles of the 501.4 total miles of proposed roads.

**Table RS-7. Federal Land Transportation Program**

| <b>Road Name</b>             | <b>NFSR Number</b> |
|------------------------------|--------------------|
| Cascade Springs Scenic Drive | 70114              |
| Nebo Loop Scenic Byway       | 70015              |
| South Strawberry Access      | 70051/70042/70131  |
| Unicorn Ridge-Indian Creek   | 70042              |
| China Meadows                | 80072              |
| China Meadows                | 40072              |
| Sinks                        | 20055              |
| Soldier Creek Rec Complex    | 70480              |
| Cemetery Point               | 20096              |
| Sheep Creek-Rays Valley      | 70051              |
| Strawberry Bay Complex       | 70452              |
| Hobble Fork Canyon           | 70058              |
| Granite Flat Campground      | 70010              |

| Table RS-7. Federal Land Transportation Program (cont.) |             |
|---|-------------|
| Road Name   | NFSR Number |
| Diamond Fork  | 70029       |
| Farmington Canyon                                       | 80007       |
| Skyline Drive   | 80008       |
| Ward Canyon   | 80177       |
| Coop Creek  | 70082       |
| Tony Grove Lake   | 20003       |

| North Slope   | 40058       |
| North Slope   | 80058       |
| Squaw Peak  | 70027       |

**Revised Statute (RS) 2477.** Revised Statute (RS) 2477 roads are public routes constructed across public lands prior to the date of National Forest reservation, have some form of construction, and have been used as a public highway. The numbers of roads on the Forest that meet this definition is unknown, but it is believed to be minimal. The Forest Service does not have a definitive regulatory mechanism by which it can administratively recognize public roads under RS 2477. Typically, a legal determination usually through a court action can establish a RS 2477 right-of-way.

**User Created Routes.** These are non-system, travel ways that are usually not necessary for the administration of or access to NFS lands. They include old timber, range or mining roads that may or may not have been closed or obliterated to eliminate vehicular traffic, or created by unapproved use. Off-road vehicle use is occurring on the Forest in the more accessible areas, creating “user created routes”, “two track” or “ghost” roads. Because many of these travelways appear on the landscape as a road and in many cases cause significant resource damage, there is a critical need to assess their condition and make a decision to retain or close them as funding allows.

“User Created Routes” and the exact status of them is unknown since a detailed inventory has yet to be completed. The only data that exists for these “user created” roads results from what can be discerned from the 7½-minute orthographic/orthophoto maps showing these routes as lines and corridors. This information has been digitized onto a GIS layer and now is part of a GIS dataset. This information has not been field verified.

In the past, the Forest has attempted to manage “user created” travel routes at the local level with limited success. This is due to the dynamic nature of these routes, since many public users of the Forest indiscriminately travel off designated routes for various reasons. The Forests routes are currently being managed as “closed unless designated open.” This management strategy has been implemented through documentation on the Motorized Vehicle Use Maps, along with signage on the ground. It should be noted that this practice is consistent with State of Utah legislation, where lands within the state are “closed unless posted and/or signed open.”

Additional direction regarding roads and travel corridors can be found in the 2003 forest plans and amendments to these plans.

## Accomplishments and Funding

**General.** Commercial use of the transportation system has declined in the 1990s and this trend is expected to continue in the coming decades. On the other hand, recreation traffic has increased substantially. This shift in traffic composition and user types has dramatically affected road maintenance, operation and management activities. The change in management activities has included a reduction in road construction, an emphasis on reconstruction to improve and/or relocate roads away from riparian areas, and maintain roads that are suitable for passenger car traffic.

Historic funding for road construction, reconstruction, maintenance and operations has declined but in recent years has been flat due to passing of multiple continuing resolutions.

**Capital Improvements.** Capital Improvement can be defined as an activity that expands the capacity of a road or transportation system, or otherwise upgrades it to serve a different purpose from, or significantly greater than, that originally intended. Road construction and reconstruction are usually associated with development related to timber harvest, utility lines, mineral and energy development, recreation facilities, and public safety. New road construction on the Forest has been on a decline. This trend is expected to continue due to having needed infrastructure in place, fluctuation in appropriated funds, and concentrated management efforts to maintain existing infrastructure. Reconstruction activities were also lower than expected primarily due to lack of funding and unanticipated time frames associated with NEPA compliance. Reconstruction activities are expected to continue to meet road management objectives, but will be dependent of funding.

In addition to appropriated road funding, the former Purchaser Credit Program (PCP) and the current sawtimber sale funds have resulted in construction and reconstruction of roads. The Forest has sold an average of 20,000 ccf per year. Timber harvest road construction and reconstruction were well above projections, primarily due to salvage of insect and disease material not accounted for in the quantities above. A level or decline in trend is expected to continue.

**Maintenance.** Annual maintenance of a road is the act of keeping the asset in an acceptable condition. It includes preventative, annual and cyclical activities needed to preserve the road so that it continues to provide acceptable service and achieves expected life. Deferred maintenance occurs when required and scheduled maintenance activities are not performed and delayed until a later date. A road is considered fully maintained when after all activities, annual or deferred, are completed and the road meets established RMO standards.

In order to better track our infrastructure and its current condition, INFRA (Forest Service infrastructure database) was implemented. A primary portion of this system is Route Basics, which tracks classified FSRs with all their features (linear events) and work items (annual and deferred). In order to populate work items a Road Condition Survey program was implemented in 1999. Utilizing a Region 2 program, which collected existing road condition data via a GPS unit, 100% of objective maintenance level 3, 4 and 5 roads were surveyed. In 2000, a new program was utilized, Electronic Road Log (ERL). The roads surveyed in 2000 were generated from a random list of objective ML 1 and 2. In 2001, the remaining roads were surveyed and data from previous years were validated. Utilizing existing annual cost data and a default cost per mile based on Operational Level, dollars needed to maintain the road system have been generated. The current system used to collect this data is based on a random sample of maintenance level 2, 3, 4, and 5. Although this data is used by the WO to report cost, the data is usually not enough to give local forest a good representation of the overall annual cost of the road system.

The *Analysis and Recommendation for the Paved Road Network* report dated February 2014, provided a full analysis and development of a pavement management system (PMS) for the Forest. It provided a complete GIS-based physical inventory and condition survey of the pavement network; a needs assessment process; analyses of root causes of pavement deterioration; analysis of current road maintenance programs; recommended maintenance and preservation treatments; treatment costs and budget proposals; and a method to evaluate alternate funding scenarios to maximize the average remaining service life (RSL) of the road network.

Pavement Condition Index (PCI) rates pavement on a scale of 0 to 100 based on structural capacity of the pavement. RSL is a scale based upon a 20 year lifespan and serves as an indicator of the remaining time that a pavement will meet the minimum performance standard. After 8 years of service (approximately RSL 12, or PCI 76), most asphalt pavements will deteriorate to just inside the “satisfactory” condition rating. This relates to a thirty percent drop in the service life of the pavement and is the optimal point in time at which a global (full surface) preventative maintenance should be performed.

The report determined paved surface roads on the Forest had an average Pavement Condition Index (PCI) of 73 and Remaining Service Life (RSL) of 11. Thirty-five percent of road network surface area below satisfactory and six percent has no service life left (terminal serviceability) or PCI <40 (RSL 0). In addition, analyses of the distress information of the paved road network showed twelve significant distress types prevalent in the asphalt pavement network. Of these distress types, alligator cracking was the most significant in terms of total PCI deduct.

Annual accomplishment reporting indicates that the Forest road maintenance program achieved maintenance on an average of 19% of the transportation system annually since 2010. It has been steady over the last 5 years, but declined significantly (from 32%) when the two Forests merged and CMRD allocations were reduced. Individual Forest maintenance activities prior to merge are described in associated Forest Roads Analysis Reports. Maintenance is accomplished using various sources including Forest Service personnel, Schedule A agreements with counties, public works contracting, and timber sales activities.

Recurrent maintenance has focused on stabilizing and removing public safety hazards on system roads, pavement preservation, providing facilities with varying standards for various types of vehicles, reducing the affects to water resources, and allowing access to and through appropriate areas of the Forest. With road maintenance budgets fluctuating and traffic volumes on the Forest road system dramatically increasing, many roads have not been maintained to the levels established in road management objectives. Historically (prior to Forest merge), the Forests had received less then 30% of the estimated funding needed to maintain the existing road infrastructure. This means that a large number of miles of road are in a deteriorating condition and some are causing resource damage, particularly related to surface erosion control problems. Many are rutted, rough and often impassible. Many local roads (ML2) are primitive, inappropriately located and difficult or impossible to maintain. They are the largest contributors to surface erosion problems and become safety hazards needing realignment or reconstruction. This reduction in ability to maintain the road system to standard as identified in the road management objective is a direct correlation to the large backlog of deferred maintenance.

**Decommissioning.** Decommissioning a road includes stabilization, restoration or conversion of an existing roadbed to a more natural state. In general, the Forest has a well-established road system, with minimal numbers of miles planned for decommissioning. The focus in recent years is the closure or obliteration of user-created routes. There has not been adequate funding to decommission user-created routes, so the Forest has focused on obtaining outside funding through grants associated with watershed restoration to support these efforts. The cost to decommission a road varies greatly by the standard and location of the road as well as the level of needed treatments. Cost estimates should be based on a case-by-case basis.

## ISSUE IDENTIFICATION

### Process

Issue identification is based on present and future anticipated access needs, current road condition, impacts on the environment due to existing and planned roads and associated activities, current and projected funding and social consideration such as historic, existing and desired future uses.

Public involvement in issue identification was assessed from previous *Roads Analysis*, and input to *Forest Plan* revisions, and access and travel management. Public scoping has shown that many of the roads are of interest and value to some users. A portion of the public wants roads improved for travel by standard passenger vehicle, unimproved and open (or re-opened) for motorized and mechanized recreation opportunities, and closed to protect roadless, wildlife and watershed values. Contact with local Counties has shown interest in maintaining mutually beneficial partnerships for road maintenance and the need to provide access and connectivity of the transportation network.

The extent of issues range in scale from Forest-wide to district, watershed and project level. Issues at the project level are not necessarily appropriate to address at the Forest level and vice-versa. Since this analysis is to provide specific management opportunities and recommendation for the transportation system in terms of individual road segments, issues relative to the Forest-scale will be assessed. The other intent is to provide direction for future roads analysis of classified and user created roads at district, watershed and project level. Issues raised relative to those levels are also listed for consideration at the appropriate sub-Forest scale.

### Identified Issues

The issues below have been identified internally as well as externally through the scoping process for a variety of resource related projects as well as in the development of alternatives for the Forest Plan revision.

***Forest Service Final Roads Rule*** - This rule addresses the agency's need to ensure that transportation facilities are managed at a minimum level while maintaining ecosystem health and providing for the needs and desires of the public for access. It also states that agency should work towards balanced funding levels to ensure roads are adequately maintained.

***Budget Allocation for Maintenance of Existing Facilities.*** The annual funding received for maintaining roads and bridges on the Forest is less than 18% of needed funding to maintain roads to road management objectives.

***Forest Service Roadless Area Conservation Rule (RACR)*** - This rule limits road construction and reconstruction activities within inventoried roadless areas with certain exemptions. Issues raised include protection of these areas; potential for environmental damage resulting from roads; and others expressed concern that there is already sufficient land allocated for non-motorized use.

***Riparian Habitat Conservation Areas (RHCAs)*** - Riparian areas are an important component of ecosystems and provide habitat for a variety of aquatic and terrestrial plants and animals. Many forest roads are located along or within riparian areas and are contributors to erosion and sediment contributors.

***Watershed management*** – Roads located within riparian areas and through areas of hill slope instability may contribute to sediment transport to adjacent streams potentially reducing water quality.

***Terrestrial wildlife habitat management*** – Roads affect wildlife in a variety of ways. Effects from roads include direct mortality from vehicle strikes, loss of habitat from the road footprint, habitat fragmentation, loss of habitat effectiveness because of avoidance behavior, loss of habitat connectivity, and indirectly by increasing human access and activity. Effects of Forest roads on wildlife species depend on road density, types of habitats traversed by roads, and roads that travel through areas of high habitat diversity.

***Timber harvest activities*** – Many areas being actively managed through timber sale activity have been accessed at one time or another for similar reasons. New roads associated with timber sales generally tend to be temporary; existing roads may be maintained or upgraded slightly to accommodate transportation of logs from the sale area without causing resource damage.

***Non-Forested Vegetation*** – Roads eliminate vegetation across road prisms and associated cut and fill slopes when constructed. Roads located in riparian areas also create a potential loss of recruitment for large woody material and detritus into stream channels.

***Noxious weed management*** – Roads serve as corridors for the introduction of noxious weeds and, subsequently, can have dramatic indirect effects on both riparian and upland vegetation. Weed infestations can spread from travel corridors into adjacent areas where plant diversity and even soil stability can be reduced.

***Air quality*** – Native surface and aggregate surface roads can contribute to fine particles in the air that affect air quality and visibility. Air quality impacts from forest roads are associated with vehicle emissions, dust from traffic on unpaved roads, and dust from road construction and maintenance activities.

***Recreation Opportunity Spectrum (ROS)*** – The change from one road maintenance level to next level could change the physical, social and managerial characteristics of the ROS setting and could have an effect on the desire experience of recreation users.

***Recreation*** - Roads provide access to both the interior and exterior of Forest Service system lands for recreation users. The dominate use on Forest Service system lands managed by the Uinta-Wasatch-Cache National Forests is recreation. Access that is convenient to the Forest visitor is critical as they seek varying activities and experiences within the Forests. Recreation use will continue to grow as the population growth along the Wasatch Front continues. Because roads provide a defined access to Forest Service system lands for a variety of recreation user groups there are several issues that can result from the management of roads, such as conflicts between users and the reduction of motorized routes and so forth.

***Scenic Integrity*** – Motorized routes are one of the ways people see the Forest and its diverse scenic character. Constructed road prism location and size can affect the character of the landscape being seen by either being the platform from how people see the landscape or by effecting the viewed landscape in a positive or negative manor. Viewing scenery is one of the top recreation activities throughout the Forest Service.

***Right-of-ways*** - There is a demonstrated public interest and need to protect historic access (roads and trails) to the Forest. In addition to directly negotiating with landowners to acquire legal access state, county and local governments are utilizing methods to protect access. R.S. 2477 will continue to be a driving issue by local and state government agencies to maintain the existence of Forest roads and trails.

***Coordination of County, State, and Others*** - Roads to and through the Forest are to be seamless (implying that the traveling public would not notice significant boundary differences of roads between land owners) and provide connectivity with roads and highways under other jurisdictions. Roads having

the existing or potential designation under the Federal Aid Highway project as part of the Public Forest Service Roads (PFSR) network should be identified as well as assess the costs and/or benefits.

## ASSESSING BENEFITS, PROBLEMS AND RISKS

To evaluate the current road system, the IDT evaluated the existing condition and identified issues. The following are items of discussion on resources that were considered in developing and analyzing the effects of roads for this analysis. Problems, risks and benefits associated with roads management are addressed.

### Issue Assessment

***Forest Service Final Roads Rule*** -This rule addresses the agency's need to ensure that transportation facilities are managed at a minimum level while maintaining ecosystem health and providing for the needs and desires of the public for access. It also states that the agency should work towards balanced funding levels to ensure roads are adequately maintained. This analysis is intended to address this agency need relative to the Uinta National Forest's transportation system.

***Budget Allocation for Maintenance of Existing Facilities*** -The annual funding received for maintaining roads and bridges on the Forest is less than 18% of needed funding to maintain roads to road management objectives. The Forest Service has historically received less funding than necessary to address maintenance needs and subsequently has fallen behind. This situation is reflected in the Forest Service Transportation Rule, which limits new construction in light of existing maintenance needs. The inability to maintain existing roads makes it difficult to justify construction of new facilities. As reported to Congress, deferred maintenance of Forest Service roads is estimated to be in the billions of dollars. It would take an increase in annual allocations of funds over a period of several years before the Forest has an opportunity to catch up on all the backlogged heavy maintenance needs, while still providing the required annual maintenance to address public safety and resource related issues. Any potential sources for external funding and its associated costs and benefits should be evaluated.

***Forest Service Roadless Area Conservation Rule (RACR)*** – The Forest Service is required to get concurrence from either the regional office or the Washington office for activities that are proposed in inventoried roadless areas.

***Riparian Habitat Conservation Areas (RHCAs)*** - Riparian areas are an important component of ecosystems and provide habitat for a variety of aquatic and terrestrial plants and animals. Many forest roads are located along or within riparian areas, as these were the routes followed when the settlers first accessed the forest. Many of the existing roads lie in much the same location as the original wagon trails. The public values riparian areas as preferred sites for dispersed recreation activities including hunting, fishing, and camping. Roads within RHCAs can be major contributor to erosion and to sediment transport to stream courses. Dealing with water quality issues tends to be a primary focus of road management in RHCAs for this reason. Impacts to roads would focus road management activities on protecting watershed and water quality, and public health and safety.

RHCA corridors can include road prism by virtue of their proximity to the stream courses. When this situation occurs, increased emphasis is placed on management of the road facility and uses thereon, to ensure riparian habitat and associated resources are not adversely impacted by the use of the facility. In some cases, it may be preferable to relocate the road out of the RHCAs to address some issues. This

follows the basic philosophy of the current Forest Plan and Forest plan management standards and guidelines emphasize restricting activities within RHCAs to minimize resource impacts.

***Watershed management*** – The Watershed Condition Framework (WCF) is used for identifying priority watersheds for restoration. This analysis will be used in conjunction with the WCF to identify priority areas to improve watershed conditions and provide a manageable road system. Roads located within riparian areas have a higher potential to transport sediment to adjacent streams. Water quality conditions can be directly related to erosion from travelways, and roads are believed to be major contributor to water quality problems in streams on the Forest. In addition, road location relative to hill slope stability should be evaluated. Information on RHCA should be incorporated into factors to be evaluated for watershed health.

***Terrestrial wildlife habitat management*** – Many species of wildlife and their habitats are affected by roads on the Uinta Wasatch Cache National Forests. Maintaining the integrity of wildlife and their habitats, while also maintaining public access is important.

The configuration and distribution of roads influence the degree of effects on wildlife. Greater road densities have greater impacts than isolated roads or roads not located in crucial habitat. Direct habitat loss is limited to the actual road and road right-of-way, but habitat effectiveness can be lost due to avoidance behavior or through habitat fragmentation. For example, many large mammal species are known to avoid roads including cougars, deer, elk, pronghorn, bears, wolves, and others. Elk are among the most sensitive to roads and exhibit avoidance behavior as far as 800 meters or more away from roads throughout the year. These avoidance behaviors reduce “habitat effectiveness,” because otherwise suitable habitats close to roads are not used. Roads can also fragment wildlife populations and habitat. For example, many amphibians and small mammals altogether avoid crossing roads which effectively fragments their habitat and isolates them from other populations. Greater road densities have been associated with crashes in amphibian populations. Evaluating road density has been used broadly as a metric to evaluate the effect roads have on patch size, habitat effectiveness, and habitat fragmentation.

Although analysis of road density addresses many effects of roads, it does not perform well to evaluate roads in key or important habitats. For example, a single road in a key or crucial habitat would have a larger negative effect compared to roads in a low value habitat regardless of overall road density. Habitat types that would qualify as key or important habitats would be those that have higher biodiversity, those that are rare on a landscape, or those that are crucial to rare or declining species.

Many wildlife species select the edges between habitat types because each habitat provides different characteristics that contribute the needs of the species. For example, some species may select to use the edges between two habitats because they use one habitat as a food source, and the other for hiding cover. Because many wildlife species use edges, roads that traverse many habitat types over short distances would have greater effects than roads traveling through monotypic habitats.

Regardless, measures for the conservation of TES species are included in projects as standard operating procedures. The Biological Evaluation and Biological Assessment processes further ensure that appropriate measures are included in management decisions. The impact of these measures varies widely dependent upon the site-specific situations. These measures do, however, tend to restrict when, where, or how construction, reconstruction, operation, and maintenance activities would be applied. In some cases, these measures may restrict road management activities and affect the timing of project implementation. Application of timing restrictions would be required in critical big game winter range. These restrictions limit road activities including operation and maintenance work during critical areas when wildlife can be stressed.

**Timber harvest activities** – Many areas being actively managed through timber sale activity have been accessed at one time or another for similar reasons. New roads associated with timber sales generally tend to be temporary; existing roads may be maintained or upgraded slightly to accommodate transportation of logs from the sale area without causing resource damage. Generally, the Forest offers commercial timber sales every year that involve road construction and reconstruction activities. Within the last 15 years road activities with timber sale areas have been relatively light. Most road construction is less than one half mile per year. Reconstruction has averaged approximately one to two miles per year, which includes improving and upgrading drainage structures, hauling and placing gravel, installing signs, and reconditioning existing road prisms. Road construction and reconstruction is anticipated to remain at the same level as in the past, slightly lower perhaps with the implementation of RACR and other management area allocations. The strategy is to continue emphasizing stabilizing road surfaces with gravel and drainage and address safety issues and concerns. Timber management activities should be addressed in terms of commercial users, shared road maintenance opportunities and vegetation management.

**Non-Forested Vegetation** - The most obvious direct effect of travel management is the loss of vegetation from road prisms and associated cut and fill slopes when constructed. Roads located in riparian areas also create a potential loss of recruitment for large woody material and detritus into stream channels. Maintenance activities such as brushing and drainage reconstruction can impact additional vegetation along roadsides. Runoff from the road prism, where concentrated and focused, can cause soil erosion and damage plants.

Direct effects from roads and trails are greatest in riparian areas. Road construction and maintenance can remove a large proportion of the vegetation within these narrow zones. Runoff from the road prism can erode soils and reduce vegetative cover. Roads typically have only minor direct impacts on upland vegetation because they occupy only a small proportion of the landscape.

**Noxious weed management** –Roads serve as corridors for the introduction of noxious weeds and, subsequently, can have dramatic indirect effects on both riparian and upland vegetation. Roadside areas are prime sites for establishment of noxious weeds that might be transported onto the Forest by vehicles. Noxious weed management is essential in order to abate or slow the spread of undesirable plant species.

The repeated use of roads provides a continual supply of seed. Soil disturbances associated with the construction, reconstruction, and maintenance of roads create potential habitat for weed invasion. Weed seeds can be carried long distances on heavy equipment, on the undercarriage of vehicles (including all-terrain vehicles), and in the hair and digestive tract of saddle and pack stock. As roads are maintained, scarification of the roadbed provides a prime site for weed establishment. Once established, weed infestations can spread from travel corridors into adjacent areas. Relocation of roads can result in new corridors for weed introduction, while leaving existing weed infestation along closed portions of roads difficult to access for treatment.

Closure of roads without revegetation reduces the movement of seed but does little to reduce the potential weed habitat or prevent establishment once seed enters the area. Revegetating closed roads can further reduce the risk of noxious weed establishment by stabilizing the site and providing competition. Roads also provide access for weed treatment activities. The most cost-effective way to apply herbicide is from a truck, tractor, or ATV.

The relationship of roads and noxious weeds is best addressed through Forest Planning by establishing standards, guidelines, and monitoring requirements that can be implemented at the project level. No further assessment of noxious weeds will be carried through this analysis.

**Air quality** – Native surface and aggregate surface roads can contribute to fine particles in the air that affect air quality and visibility. Air quality impacts from forest roads are associated with vehicle

emissions, dust from traffic on unpaved roads, and dust from road construction and maintenance activities. Most effects are localized and temporary; however, during the winter, climatic inversions occur. These inversions can trap pollutants causing concentrations to exceed National Ambient Air Quality Standards (NAAQS). The vast majority of vehicle use in counties encompassing the Forest occurs off-forest.

Most classified roads (about 2408 of 2567 miles, or 94 percent) on the Forest are unpaved, with the exception of roads that access or cross the Forest that are under jurisdiction of a public road authority. Most use of Forest roads is associated with recreation. The extent of the impact depends on the amount of roads, and on the amount of traffic or disturbance involved. Dust from unpaved roads increases with dryness and vehicle weight. Vehicles using improved road surfaces often generate less dust.

In order to accommodate increasing use, reduce maintenance costs, and improve water quality and fisheries habitat, some roads are being relocated and/or surfaced. Equipment used to relocate or surface roads generate emissions and dust, but only temporarily and the effects are localized.

Motorized recreation occurs year-round. Motorized travel generates emissions and dust on unpaved surfaces. Although this dust can be significant immediately adjacent to a road, it is temporary and very minor on a Forest-wide, county, or even a drainage scale. Little difference in the amount of hunting, fishing, hiking, biking, and sightseeing is expected to occur. Consequently, the amount of road traffic and air quality impacts associated with these activities would vary little.

In localized areas on the Forest, vehicular travel on unpaved roads can be heavy where activities such as timber harvest, mining, and oil and gas development occur. Such use often requires dust abatement measures to mitigate the air quality impacts of sustained and heavy traffic use. The effects of these activities on road dust and resultant air quality are best addressed at the Forest Planning level in terms of standards and guidelines for implementation at the project level relative to specific time and location. No further assessment of air quality will be carried through this analysis.

### ***Recreation Opportunity Spectrum (ROS)***

Recreation managers generally concern themselves with managing settings and with determining what types of activities may be appropriate within each setting. To match the diversity of recreation interests with appropriate opportunities, the Uinta-Wasatch-Cache National Forests offer a variety of recreation settings. These settings are differentiated by remoteness, human modification, social interaction between users, managerial presence and information that are incorporated into a recreation-planning tool called the Recreation Opportunity Spectrum (ROS).

The Forest Service uses this classification system to distinguish between different types of recreation settings in the Forests. The ROS system provides a way to help managers and recreation users understand the general characteristics of the physical, social and managerial attributes of the managed for setting. By using these general characteristic the recreation user can identify the setting that would best support the type of experience they are seeking.

### ***Problems, risks and benefits associated with roads management are addressed.***

The relationship between ROS settings and Travel Management Plans must be addressed because each has some effect on the other.

The Uinta-Wasatch-Cache National Forests are being managed by 9 different ROS setting categories. Three of the categories are associated with Wilderness management and would be non-motorized, one setting manages none motorized Forest Service system lands and the other 6 include roads as part of their management direction.

The management of ROS categories has a direct relationship to roads and their management. If a road is eliminated off or added to the system, the physical, social and managerial part of the ROS setting are

affected and would change and effect recreation users. By eliminating or increasing motorized access the remoteness in and the lack of human modification could change the recreation used experience. The social interaction between users would go from vehicular to biological or from biological to vehicular interaction. The elimination or inclusion of signs and other vehicular control devices would reduce or increase the managerial presence in the landscape thus changing the setting and the recreation user's experience.

Change in the road maintenance level could affect the three characteristics of an ROS setting by moving from primitive prism of maintenance level 2 roads (ROS, Semi-Primitive Motorized) to the 3 and higher maintenance levels road prisms. The increase or decrease of development of the road prism has a direct effect on the ROS setting being managed for and could change the desire experience of users in a positive or negative manor depending on what experience the recreation user is seeking.

Biological, social, and socio-economic considerations are necessary in the decision process for any future road decommissioning, construction or reconstruction activity. These considerations are important when it comes to the operation and maintenance of roads as well.

Social impacts from road decommissioning are also a driving force in transportation management activities. Some visitors would like a more primitive experience with less roads and others want access to Forest Service system lands and consider reduction in roads a direct effect to their desire experience. . Public education and information sharing has been and would continue to be critical in helping the public understand why certain decisions in transportation management are made.

**Recreation** - Recreational use is the dominant activity that occurs on the Forest. Access that is safe and convenient to the Forest visitor is critical to ensure a positive experience. Recreation use will continue to grow as the population growth along the Wasatch Front continues. In addition, Utah is a destination of choice to many outside the state who are interested in the diversity of opportunities that exist.

New recreation road construction is expected to be minimal. It is also anticipated that some reconstruction will occur, which will also be minimal as most of the infrastructure is already in place. Any reconstruction will be commensurate with any planned recreation improvements. Road operation and maintenance activities will continue to be essential in providing safe and convenient transportation facilities.

Road operation and maintenance will continue, along with the challenge to secure funds. Most of the 159 miles of asphalt surfaces are arterial routes and/or provide access to campgrounds. Maintaining these surfaces will range from \$20,000 to \$35,000 per mile for surface treatment. Most road damage, particularly to native surface roads, occurs in the spring and fall when roads are more susceptible to damage by vehicle travel.

The Forest provides a diverse array of recreational experiences, which in turn creates diversity in travel management. Presently, many roads on the Forest have been designated open to ATV use, creating long-loop routes which conflict with other types of vehicle use. Managing these activities would not significantly change under any alternative as related to existing roads.

**Scenery** – Because roads represent one of the major viewing platforms for recreation users on the Forests the reduction of roads would have an effect on recreation users viewing scenery. Through the reduction of roads viewing platforms would be eliminated, but through re-contouring and environment mitigation of the decommission roads the viewed landscape would begin the process of returning to a desire natural appearing landscape. So reduction of roads is a possible negative and positive effect for a varied range of users on the Forests.

**Access and Travel Management** – Presently, travel management across the Forest is identified in the current versions of the MVUM (Motor Vehicle Use Map) by ranger district. Future travel management

activities will occur across the forest by individual ranger districts based on land allocations as identified within the revised Forest Plan. Any alternative selected will have an effect on travel management planning, which would include, but not be limited to, road management objective changes based on new management prescriptions and the implementation of the Recreational Opportunities Spectrum (ROS) and Scenery Management System (SMS).

Varying opinions exist regarding roads and access. Some people view roads as having an adverse impact to natural resources. Any closure or decommissioning will have some affect by displacing users elsewhere and even limiting their historical use of National Forest System lands. Additionally, Forest Service managers would be affected if roads were closed or decommissioned by limiting access to perform their administrative duties.

Site-specific issues to be addressed would include seasonal road closures, wildlife and fisheries, access to dispersed recreation sites, and designated off-highway vehicle routes. It is appropriate to utilize this analysis during access and travel management as well as adapt for other route systems such as trails.

***Right-of-ways*** - There is a demonstrated public interest and need to protect historic access (roads and trails) to the Forest. In addition to directly negotiating with landowners to acquire legal access state, county and local governments are utilizing methods to protect access. The Forest continues to acquire and identify potential right of ways for acquisition, of which some will be perfected by entities other than the Forest Service.

R.S. 2477 will continue to be a driving issue by local and state government agencies to maintain the existence of Forest roads and trails. Some travelways that are not designated Forest roads may become public travelways under R.S. 2477.

Benefits realized from road management activities include right-of-way and easement acquisition, and coordination of roads activities with adjacent landowners and local, state and tribal governments. The RS2477 issue poses constant challenges to management of the National Forest roads system. It also poses opportunities to clarify management responsibilities, and can facilitate identification of right of ways needed to provide or maintain public access.

Reasonable access to private inholdings would continue as required by agency policy. Also, existing and future right-of-ways and/or easements would continue to ensure that public access to National Forest System lands is maintained. These issues will be assessed in this analysis.

***Coordination of County, State, and Others*** - Roads to and through the Forest are to be seamless (implying that the traveling public would not notice significant boundary differences of roads between land owners) with roads and highways under other jurisdictions. This is the direction under the *Final Roads Rule*, and many roads on this Forest currently meet this direction. Several Forest roads have the potential of becoming part of the Federal Aid Highway project (Flap or FLIP). Other roads are being considered for designation as part of FLTP network – the connotation being that the standard is potentially high enough to be considered for other funding sources. This would help to preserve infrastructure and to maintain public access to and through National Forest System lands.

Local governments are concerned that changes in the Forest's management of roads and the emphasis on protection of roadless areas could threaten rights they hope to assert in the management of roads they believe predate the establishment of the National Forest (commonly referred to as R.S. 2477 roads). There is concern that the Forest Service is usurping local authority by gradually implementing restrictions on the use of federal lands through road closures, wilderness designations, and other measures without adequately informing and involving local officials.

Most of the Forest Service's classified roads are generally continuously open to the public for access. They can, however, be seasonally closed for protection of infrastructure values and environmental needs.

Continual coordination and collaboration with state and county officials in the management of transportation facilities to and through the Forest would be continued to ensure that access is maintained, standards are consistent, safety issues are addressed, and efficiency is considered at all times.

## **Factors to Be Evaluated**

To evaluate the current road system the IDT evaluated the assessed issues. The primary areas that the IDT determined could be adequately evaluated at the Forest-scale include watershed health, riparian habitat, aquatic species; terrestrial wildlife; access; and maintenance cost. Each issue has multiple factors. Each factor contributing to the evaluation of the associated issue includes a description of indicator and associated measurement parameters. The indicator is a specific description of how the factor will be evaluated relative to the road system. The measurement parameter includes a value rating for each factor based on range of results available from the developed indicator. Issues with multiple factors are evaluated based on weighted values and given an overall rating (low, medium or high).

## **Watershed Health, Riparian Habitat and Aquatic Species**

In analyzing the impacts of roads to watershed health, riparian function and aquatic species for the Uinta National Forest, four major factors should be reviewed. These are:

- (1) Potential loss of riparian function;
- (2) Potential for sediment loading generated from roads;
- (3) Potential loss of connectivity and accessibility to habitat as a result of incompatible design or location of road culverts with aquatic species; and
- (4) Potential for hill slope instability caused by road location.

A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix A.

## **Terrestrial Wildlife**

Factor identified for evaluation:

- (1) Road Density (miles of road/square mile) by watershed
- (2) Road segments located near or through habitats that contribute disproportionately to biodiversity
- (3) Road segments that travel through areas with many habitats in close proximity, evaluated as the number of habitats crossed per mile.
- (4) Together, these three factors were combined to provide a high, medium or low classification for each segment.

A full description of indicator, its associated measurement parameters, data limitations and analysis results are available in Appendix B.

## **Access**

Four factors were identified for evaluation:

- (1) Private Access;
- (2) Public Access;
- (3) Administrative Access; and
- (4) Connectivity.

A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix C.

## Maintenance Costs

Five factors were identified for evaluation:

- (1) Commercial use and contributing funds;
- (2) Shared road maintenance agreements;
- (3) Byway Backway designation;
- (4) Public Forest Service Roads (PFSR);
- (5) Annual maintenance costs

A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix D.

# MANAGEMENT OPPORTUNITIES AND PRIORITIES

## Evaluation Process

To provide management opportunities and set priorities the IDT assessed issues and determined which were costs and benefits associated to the road system. The ratings of each issue were combined to provide an overall cost and benefit rating of low, moderate or high for each road. Based on those results priorities are made regarding each road segment.

After review by line officers, incorporation of local factors, and any subsequent evaluation, the combined cost/risk and benefit ratings are placed within a Road Cost-Benefit Matrix. A primary management opportunity (PMO) is then assessed to each road segment based on where it is located in the matrix.

## Road Related Costs, Benefits and Priorities

**Costs.** The cost of a road segment includes threats, problems and risks associated with issues identified under watershed health, riparian function, aquatic species (WRA) and terrestrial wildlife (TW). In general, WRA rating is considered twice the risk as TW. A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix E. Overall cost/risk rating for each road segment is visually displayed and listed in Appendix E (Table E.4).

**Benefits.** The overall benefit of a road segment includes issues identified under access (ACCESS) and road maintenance costs (RM). In general, overall access rating is considered equivalent to maintenance costs. A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix E. Overall benefit rating for each road segment is visually displayed and listed in Appendix E (Table E.4).

**Priorities.** A priority for action or evaluation of primary and secondary management opportunities is assigned to each road segment based on overall cost and benefit rating. A full description of indicators, their associated measurement parameters, data limitations and analysis results are available in Appendix E. A priority for each road segment is visually displayed and listed in Appendix E (Table E.4).

## Primary Management Opportunities (PMO)

Primary Management Opportunities (PMO) are based on combined cost and benefit rating for a road segment. PMOs include “Likely Needed” or “Likely Not Needed”. The following are the definitions of primary management opportunities (PMO) and their associated criteria for each road segment based on location within a Road Cost-Benefit Matrix. Each PMO is visually displayed on the matrix below. PMOs have been identified at the Forest scale as opportunities for change. Site specific analysis, in accordance with NEPA, will be required to further evaluate cost/risks and benefits to determine future management direction of road segments.

**Likely Needed (N)** – Road is deemed essential for Forest access and management.

**Likely Not Needed (NN)** – Road is not deemed essential for Forest access and management.

**Road Benefit-Cost Matrix.** This matrix places the results from analysis in one of nine boxes that shows the relationship between overall benefit and cost associated with each road segment evaluated. Values in matrix are shown as Benefit, Cost (i.e. H,L = High Benefit with Low Cost).

|         |          | Cost |          |      |   |
|---------|----------|------|----------|------|---|
|         |          | Low  | Moderate | High |   |
| Benefit | High     | H,L  | H,M      | H,H  | <b>PMO</b><br> Likely Needed<br> Likely Not Needed |
|         | Moderate | M,L  | M,M      | M,H  |   |
|         | Low      | L,L  | L,M      | L,H  |   |

## RECOMMENDATIONS

It is anticipated that over the next decade the miles of classified roads will likely remain relatively unchanged. This is due to the fact that the Forest is presently well accessible with many roads in-place and functioning. Many of these roads (particularly arterial and collector roads) have been maintained or reconstructed to a standard that provides a safe economical facility. Most of the local roads on the Forest have been in-place for a number of years and will remain to provide access to and through the area. However, ecosystem integrity, public safety, and available funding must be balanced with access needs and desires to define a minimum road system. Recommendations to achieve a safe, efficient, environmentally sound minimum road system include standardizing a process to identify road management objectives, providing input for Forest management direction, and outlining the direction for future sub-Forest scale analysis.

## **Road Management Objectives (RMO)**

Upon completion of this analysis the Deciding Official through recommendation of the IDT and line officers will evaluate the management opportunities and priorities. After concurrence or modification of these recommendations, an updated Road Management Objective (RMO) will be prepared for each road segment for signature by the appropriate line officers. The RMO form is generated through Microsoft Access which queries data from road attributes in the INFRA database (see Appendix E) and Management Opportunities and Priorities as a result of this analysis (Appendix E). Adjustments or modification to RMO's should occur if/when original data is found to be inaccurate, further analysis is completed at the sub-Forest scale or implementation of access and travel management plans.

## **Forest Management Direction**

The IDT was directed to provide any available specific information that may be needed to support/inform the current Forest Plan Revision. The National Forest Management Act (NFMA, 36CFR 219.11) requires that management direction be developed for each management area to include multiple-use goals and objectives, a description of the desired future condition, multiple-use prescriptions and standards and guidelines. Each of these may be expressed at one or more scales from forest-wide to a specific management area or watershed. All of these components together comprise management direction.

All roads will be designed, operated and maintained to accomplish and meet the goals and objectives of the associated Forest Plans. Standards and guidelines, as appropriate, will be applied and incorporated into the road analysis process. Safe and efficient facilities will be operated and maintained consistent with the implementation of agency policies and executive or congressional mandates.

This transportation analysis concentrated on Forest-wide issues and therefore will provide input to future Forest Plan Revisions. Recommendations were developed from analysis of specific road management opportunities and issues or factors in terms of portions of the road system. The following recommendations may be appropriate to most alternatives in the Forest Plan Revision, but they will need to be tailored in order to implement any given alternative in terms of forestwide allocations and specific management area direction.

- Future sub-Forest roads analysis should concentrate on district, watershed or project level analysis. Analysis will be completed at the discretion of land managers in conjunction with agency direction based on validity of this analysis for the appropriate scale.

## **Watershed Function, Riparian Habitat and Aquatic Species**

- A large majority (86 percent) of roads on the Forest are located within 6th Order HUCs that have a moderate or high rate of loss in recruitment of large woody material and detritus. The segments contributing to high and moderate risk ratings should be evaluated for relocation.
- The majority of road segments, 86 percent (or 2197 miles) are in the lower rating category for sediment loading. This conclusion supports considerable efforts in the last 15 years to relocate roads out of riparian areas and harden surface of those that remain.
- Approximately 3 percent of segments have stream crossings where stream gradients exceed 4 percent or where field surveys indicates at least one crossing is impassible. Areas where the stream gradient exceeds 4 percent should be further analyzed at a watershed or project level for the existence of cross drainage structures and the potential for loss of connectivity.
- A small percentage (8 percent) of road segments analyzed have greater than 75 percent of their lengths located in landslide prone areas. These roads should be assessed for current condition and long-term maintenance issues.

- Approximately 22 percent of road segments received high or moderate risk rating. Of these, only 5 percent (426 miles) received a high risk rating. These segments should be carefully weighted with road benefit and consideration in change in location and or hardening surfaces should be considered.

### **Terrestrial Wildlife**

- The 340 miles of roads (approximately 30 percent of road segments) that received high risk classification should be evaluated for management. Management may include closure, relocation, seasonal closures, decisions on maintenance levels, or other related actions. Consideration for location of new roads should consider road density, and avoid placement when possible, in habitats identified in this document as having high value to wildlife, and avoid when possible, traveling through areas of high habitat diversity. Existing seasonal road closures were not evaluated and should be at the sub-Forest scale to determine extent of potential risk. Priority for consideration should be for the 30 percent that received high risk ratings because these will be segments that fall within watersheds that have higher road densities and also fall within important habitats and/or diverse areas.

### **Access**

- Maintain access to and through National Forest System lands to meet private, public and administrative access needs. Use of the road system has confirmed trends that recreation is the primary use of the road system followed by administrative and then private access needs.
- The existing road system is well connected (greater than 94%). As funding allows, concentrate heavy maintenance activity on roads where objective maintenance levels can be achieved.
- Utilize RAP data to determine priority to acquire access rights and allocate funding when available.
- Coordinate with local public road authorities on roads that are to be identified as having potential perspective right. Current data was not requested or available from local Utah Counties.
- Of the roads analyzed 10 miles (or 1% of road segments) were identified as having low access benefit. These segments should be individually analyzed to determine accuracy of results and then determine long term access needs.

### **Road Maintenance**

- Identify the 17 percent of roads segments that have existing or potential commercial users and collect funds where appropriate.
- Utilize results that identified an additional 1 percent of road segments for potential for shared road maintenance agreements and coordinate with local Counties to develop comprehensive road agreements. Roads also identified as potential PFSR and Connectivity rating = 3 (objective ML = operational ML) should be included for consideration.
- Identify potential roads to be designated as Byway and Backways. It is not anticipated that these percentages will increase dramatically, but potential designation was not analyzed. As use continues to increase on the Forest, during future analysis or access and travel management revisions, roads should be evaluated for potential designation.
- Determine why annual maintenance costs vary dramatically for road segments with same objective maintenance level. Roads that have annual maintenance costs that are greater than 125 percent of average per mile include 1426 miles (or 40% of segments). The existing cost data needs to be reevaluated and updated in the INFRA database in order to be more accurate.
- The Public Forest Service Roads (PFSR) designation is out-dated. A more accurate representation of public road status would be designation of roads identified under Federal Lands Transportation Program (FLTP). Future analysis at all levels should incorporate this change.

- The analysis showed that 26 percent of the road segments received a low overall rating. Since one of the primary purposes of these roads analysis is to provide a cost efficient road system, careful comparison of road segments receiving a low benefit rating to other benefits and costs should be evaluated.

## Direction for Future Transportation Analysis

**General.** The transportation analysis incorporates a six-step process that provides framework for periodic reevaluation of the road system and management strategies appropriate to scale. It provides interdisciplinary teams and decision makers context for finer and sub-Forest scale analysis; sets priorities for more detailed analysis and program planning; and identifies issues requiring further evaluation for both existing roads and roads planned for the future. It also provides direction and consistency in the evaluation of the road system and road segments at the sub-Forest scale independent of project team assigned to analysis. Although the analysis consists of specific steps, the process will require feedback and iteration over time as the analysis matures and is evaluated at various scales.

Prior to making specific road management decisions teams assigned to sub-Forest analysis will have to validate data and opportunities as well as consider additional localized issues. Some additional issues with associated factors, as well as primary management opportunities (PMO) can be provided for consideration during sub-Forest scale analysis.

The Transportation Analysis, in terms of Forest Plan direction, should apply all of the Forest-wide guidance in an integrated way to the specific area of land involved. The intention of the analysis is to take the broad conceptual goals, allocations, etc. for a number of resources and uses and fit them together in a clear complementary way, given that particular area's land capabilities, needs, and opportunities. Projects are to be developed consistent with these. While no one project is likely to achieve all of the goals, objectives and desired future conditions, the aggregate of multiple projects over time should move toward them.

**Forestwide Analysis.** Due to limited timeframes associated with this analysis the following items should be incorporated if and when this analysis is re-evaluated.

- Utilize transportation atlas to continue evaluation of accuracy of INFRA database (i.e. map roads based on jurisdiction to identify errors)
- Collect any needed data from field or outside sources
- Incorporate Forest access and travel management plan(s)

It is not the intention of this analysis to re-analyze at this level in the future, but instead concentrate analysis at the sub-Forest scale such as district, watershed or project scales. The items listed above should be incorporated at all scales on any future roads analysis.

**Sub-Forest Analysis.** District, watershed or project level analysis includes a rather in-depth analysis of the road system and individual road segments in terms of specific costs and benefits, rather than trends. Typical sub-forest scale analysis could be included as part of watershed assessments and district access and travel management plans. In addition to a cost and benefit analysis completed at the Forest scale: priorities, PMOs, suggestions listed above, and a strategy to map, evaluate and analyze user created roads should be addressed.

Any modifications to the management opportunities listed in this report would be identified in the Road Management Objectives.

User created roads were not evaluated in the Forest-scale roads analysis. The following are specific recommendations for the user created road system.

- Prioritize potential user created layer by priority watersheds or implementation of watershed assessments
- Inventory/ground truth potential user created road layer in GIS during field season prior to start of watershed assessment.
- Continue updating the data through more accurate mapping and ground truthing.
- Include all user created roads in sub-Forest scale roads analysis.

Access and travel management plans should incorporate this analysis. Additional analysis may be required at the appropriate scale after evaluation of issues, factors and management opportunities consider local factors. The inclusion of the trail system under this process is appropriate.

## Appendix Description

Names and numbers of the Uinta Wasatch Cache N.F ranger districts are as follows:

- D1- Salt Lake Ranger District
- D2- Pleasant Grove Ranger District
- D3-Heber-Kamas Ranger District
- D4- Evanston-Mountain View Ranger District
- D6- Ogden Ranger District
- D7- Logan Ranger District
- D8- Spanish Fork Ranger District

Tables A.3, B.2, C.2, D.1, and E.4 have all been sorted by district then by route number. An alphabetized appendix of road names has been provided in appendix F in order to cross-reference name to route id and district number.

## APPENDIX A

### WATERSHED HEALTH, RIPARIAN FUNCTION AND AQUATIC SPECIES

In analyzing the impacts of roads to watershed health, riparian function and aquatic species for the Uinta National Forest, four major factors should be reviewed. These are:

- (1) Potential loss of riparian function;
- (2) Potential for sediment loading generated from roads;
- (3) Potential loss of connectivity and accessibility to habitat as a result of incompatible design or location of road culverts with aquatic species; and
- (4) Potential for hill slope instability caused by road location.

Each factor is important to a different degree; therefore they are weighed based on each factors contributing potential. The degree to which each factor has potential is identified by numeric values listed under their associated measurement indicator. It is understood that minor factors should be considered at the watershed or project scale. These could include unstable soils, the potential for pollutants to enter the stream from hazardous material transport, fishing and stocking ability, etc. These factors are important but the above four major factors are over-riding at the forest scale.

#### Loss of Connectivity and Accessible Habitat

**Description of Indicator.** The number of stream crossings was identified to analyze the loss of connectivity and accessible habitat for aquatic species. This analysis used the 2006-2007 fish passage data collected across the Forest. Culverts identified as a fish passage barrier were used for this analysis.

3 = Road segment has at least one stream crossing and stream slope is greater than 4 percent.

2 = Road segment has at least one stream crossing and stream slope is between 2 and 4 percent.

1 = Road segment/stream crossing has at least one stream crossing and stream slope is between 0 and 2 percent.

0 = Road segment has no stream crossings

These results were adjusted using field data as follows.

3 = If field surveys indicates at least one crossing is impassible.

2 = If there is one segment was rated as 3 and contained only one crossing but there was no field evidence to suggest that it was impassible.

***Data Limitations.***

Fish passage data was not collected in two watersheds which do not support cutthroat trout. Stream crossings are limited in these drainages and will be treated as a barrier.

***Analysis Results.*** The analysis shows that 87 percent of the road segments analyzed do not have stream crossings. Approximately 11 percent of road segments have stream crossings with greater than 2 percent stream gradients. About 8 percent of road segments have at least one stream crossing and stream slope is between 2 and 4 percent, or there road segments were rated as 3 and contained only one crossing but there was no field evidence to suggest that it was impassible. Approximately 3 percent of segments have stream crossings where stream gradients exceed 4 percent or where field surveys indicates at least one crossing is impassible. Areas where the stream gradient exceeds 4 percent should be further analyzed at a watershed or project level for the existence of cross drainage structures and the potential for loss of connectivity.

## **Loss of Riparian Function**

***Description of Indicator.*** To address the loss of riparian function, the amount of riparian vegetation that has been removed by roads was analyzed. The analysis looked at the area of the riparian zone that has had a travel corridor constructed over it. To make this more uniform across the forest, the analysis considered the riparian zone 300 feet on each side of the stream corridor.

Roads within 300 feet of a stream were included in the analysis because the most stringent protection of riparian areas in the 2003 Uinta National Forest and the 2003 Wasatch-Cache National Forest Land and Resource Management Plans. Roads within riparian areas eliminate the potential for new plant growth. Roads confine stream channels, causing them to down-cut and lose interaction with their floodplain. Riparian vegetation has a hard time establishing in confined channel situations where an established floodplain is not present. Many streams with roads next to them are rip-rapped or armored to protect the road infrastructure. Large wood that does fall into the stream is often pulled out to eliminate stream bank erosion and road undercutting. These actions all impact current and future large woody debris and detritus recruitment into the stream channels across the forest.

The road layer in the Uinta-Wasatch-Cache National Forests GIS database was used to identify existing classified FSRs and other non-Forest Service (e.g. city, county, state) roads. The percentage of roads within 300 feet of streams within individual sixth order Hydrologic Unit Codes (HUCs) was analyzed. The percent of the 300 feet from the stream that has been taken out of properly functioning condition because of roads, on the forest, ranged from 0 to 4.35 percent.

***Measurement Indicator.*** The rating for loss of recruitment potential for large woody material and detritus into the stream from riparian area is based on the percentage of land within 300 feet of streams that has been taken out of naturally functioning condition. A list of ratings for each road segment is in Table A.3.

6 = Majority of road segment is located in 6<sup>th</sup> level HUCs with a Rds%300 Variable value greater than 1.0

4= Majority of road segment is located in 6<sup>th</sup> level HUCs with a Rds%300 Variable value between 0.25 and 1.0

2 = Majority of road segment is located in 6<sup>th</sup> level HUCs with a Rds%300 Variable value less than 0.25

**Data Limitations.** Limitation of data and analysis included actual road disturbance width, user created road impacts, and actual riparian forest width. For the analysis, all roads were assumed to be 12 feet wide and all riparian areas were assumed to be 300 feet wide. It is recognized that a number of paved roads are wider, but the barrow non-paved sections would be close to the 12 feet. It is also recognized that riparian areas on the forest are less than 300 feet as well as greater than 300 feet in size. The forest does not currently have an inventory of user created roads, and therefore, geographic data for these was not available for this analysis.

**Analysis Results.** The analysis showed that 51 percent of road segments are primarily located within a 6<sup>th</sup> Order HUC having greater than 1.0 percent of the area within 300 feet of streams occupied by roads (Rds%300). Close to 22 percent of road segments are primarily located within 6<sup>th</sup> Order HUC having an Rds%300 between 0.25 and 1.0 percent. The remaining 28 percent of roads are located within a 6<sup>th</sup> Order HUC having an Rds%300 less the 0.25 percent. According to the analysis, the majority (86 percent) of roads on the Forest are located within 6<sup>th</sup> Order HUCs that have a moderate or high rate of loss in recruitment of large woody material and detritus.

## Hill Slope Stability

**Description of Indicator.** The percentage of road segment that crosses through landslide prone areas was identified to analyze hill slope stability. Building roads through landslide prone areas can trigger soil creep as well as deep-seated and shallow seated landslides. Although landslides are natural processes, landslides caused by anthropogenic activity, such as road building, can accelerate impacts to aquatic resources by adding large quantities of sediment to a river or stream system.

**Measurement Indicator.** The rating for hill slope stability is based on the percentage of road segment that passes through landslide prone areas as delineated by the Uinta National Forest GIS database. A list of hill slope ratings for each road segment is in Table A.3.

4 = Greater than or equal to 75 percent of the road segment crosses through landslide prone areas.

3 = Less than 75 percent or greater than or equal to 50 percent of the road segment crosses through landslide prone areas.

2 = Less than 50 percent or greater than or equal to 25 percent of the road segment crosses through landslide prone areas.

1 = Less than 25 percent but greater than 0 percent of the road segment crosses through landslide prone areas.

0 = Road segment does not cross through landslide prone areas.

**Data Limitations.** All landslides delineated on the GIS data layer were assumed to have the same risk. Risk to aquatic environments as related to landslides varies. The results of this analysis will locate areas where more in depth analysis will be necessary at the project or watershed scale. Unclassified roads were not assessed in this analysis.

**Analysis Results.** The analysis showed that approximately 80 percent of the road segments analyzed do not cross through landslide prone areas. Approximately 6 percent of the road segments have between 0 and 25 percent of their lengths crossing landslide prone areas. Approximately 5 percent of the segments have between 25 and 75 percent of their lengths crossing landslide prone areas. Only, 8 percent of the 2,851 road segments analyzed have greater than 75 percent of their lengths located in landslide prone areas.

## Sediment Loading

**Description of Indicator.** To address sediment loading produced from roads, the key factors to look at include road surface material, proximity of the road to the stream and slope of the land from the road edge to the stream. Road surface types on the Uinta National Forest are native, improved native, aggregate (includes crushed aggregate base or gravel), or paved (includes asphalt or bituminous surface treatment). Surface type is a major consideration in the analysis of sediment produced by the road prism. Forest Service Water Erosion Prediction Project (WEPP) modeling shows that gravelling or paving a road can reduce sediment production by 79 to 92 percent (USDA, Forest Service, 1999b). Roads within 300 feet of a stream reduce the natural functions provided by riparian vegetation, prevent the filtering of sediment, and provide direct routes for sediment to enter watercourses. In addition, drainage from the road prism is a factor in sediment loading. Roads located on steep side slopes or grades tend to concentrate flows more than those on gentler side slopes, reducing the success of the streamside buffer.

**Measurement Indicator.** The rating for sediment loading from roads is based on surface type, stream proximity to the road, and slope of the land from the edge of the road to the stream. For this analysis, road segments that are greater than 300 feet from the stream were considered to have no effect on the stream channel relative to sediment loading. A list of ratings for each road segment is found in Table A.1.

| Table A.1 Sediment Loading Criteria for the Uinta NF and Wasatch-Cache NF Travel Analyses. |   |        |
|--|---|--------|
| Surface Type   | Percent of road segment within 300 feet of stream | Rating |
| Native   | >50%  | 9      |
|  | <50%  | 6      |
| Improved Native  | >50%  | 6      |
|  | <50%  | 3      |
| Aggregate  | >50%  | 3      |
|  | <50%  | 1      |
| Any surface  | 0%  | 0      |

**Data Limitations.** Additional considerations at the watershed or project scale could include more detailed sediment transport modeling (i.e.-WEPP). These models consider additional factors in more detail including, soil type; type and percentage of vegetative cover; road grade and width; and travelway and embankment cross slopes. This type of modeling would produce information that could be used to analyze the amount of sediment generated by the road and amount of sediment leaving the buffer and entering the stream environment. These values could then be converted to sediment loading per mile of road for comparison between individual road segments. However, this level of assessment is not appropriate for the scale of this analysis.

Another additional consideration would be the condition of the road (rutted, unrutted, outsloped, insloped, crowned, etc.). When doing this analysis, it was assumed that each road was in the same condition and has the same intensity of management. Maintenance of roads plays a large role in sediment loading but that data was not available for the analysis.

As in loss of recruitment, unclassified roads were not assessed due to the lack of data.

**Analysis Results.** The analyses showed that 2,044 miles of road (or 80 percent of the road segments) on the Uinta National Forest are not within 300 feet of any stream channel. Approximately 78 miles (or 11 percent of the road segments) received a value of one; 76 miles (or 3 percent) received a value of three; 269 miles (or 11 percent) received a value of six; and 88 miles (or 3 percent) received a value of nine. The majority of roads (2,197 miles, or 86 percent of segments) are in the lower rating category for sediment loading.

## Overall Rating

**Description of Indicator.** The overall watershed health, riparian habitat, and aquatic species rating for each road segment incorporates four factors, loss of riparian function; sediment loading associated with road surface and location relative to slope and stream proximity; loss of connectivity and accessible habitat as a result of improper installation of road culverts; and the percentage of road segment that crosses through hill slope instability areas. Each of these factors are important but to a different degree.

Relative to this analysis, the largest most consistent and chronic impacts at the forest scale are associated with loss of riparian function and sediment loading. In contrast, the loss of connectivity and hill slope stability, while essential at the site-specific or project scale, are only a moderate concern when considered at the forest scale.

**Measurement Indicator.** The overall road segment rating weighs each of the four factors based on values assigned through analysis: Loss of recruitment was assessed using numeric values of six, four, or two; sediment loading was assessed using numeric values of nine, six, three, one, or zero; loss of connectivity was assessed using numeric values of three, two, one, or zero; and hill slope stability was assessed using numeric values of four, three, two, one, or zero. Numeric values were indicators of low, moderate, and high risk for each factor, respectively. An overall rating was then derived for each road segment based on the cumulative value of the risk factors listed as follows:

High = Total value is between 15 and 22

Moderate = Total value is between 9 and 14

Low = Total value is between 2 and 8

**Data Limitations.** Due to the scope of this analysis and identified limitations of the parameters used to complete the assessment, the derived rating values are relatively general in nature and may not necessarily reflect site-specific or watershed scale conditions. Because of this, these rating values should only be used as a general guide in making road management and maintenance decisions on a Forest-wide basis.

**Analysis Results.** Results of the analysis show that 136 miles of road (or 5 percent of the road segments) analyzed are rated as high risk, 426 miles (or 17 percent) are rated moderate risk, and 1,993 miles (or 78 percent) are rated as a low risk to watershed health, riparian function, and aquatic species. A table of overall ratings for each road segment is available in Table A.2.

| Table A.2 - Watershed Health, Riparian Function, and Aquatic Species |         |        |                  |          |              |                |              |              |   |                   |                      |                  |         |        |
|--|---------|--------|------------------|----------|--------------|----------------|--------------|--------------|---|-------------------|----------------------|------------------|---------|--------|
| FSR  | SEGMENT |        | Functional Class | District | Objective ML | Operational ML | SERVICE LIFE | Surface Type | Loss of Connectivity and Accessible Habitat | Riparian Function | Hill Slope Stability | Sediment Loading | OVERALL |        |

## APPENDIX B

### TERRESTRIAL WILDLIFE

Roads affect wildlife in a variety of ways. Effects from roads include direct mortality from vehicle strikes, loss of habitat from the road footprint, habitat fragmentation, loss of habitat effectiveness because of avoidance behavior, loss of habitat connectivity, and indirectly by increasing human access and activity. Human activity can greatly impact wildlife habitat and populations. Impacts of human activity are influenced by road density, intensity of use, road location, and types of habitats traversed by roads (Wisdom et al. 2000). Some of the habitat impacts include spread of noxious or invasive plants, snag/down log reduction through firewood gathering, vegetation trampling, erosion, and increase in additional roads (unauthorized routes). Impacts of human activity on individuals or populations of wildlife species include hunting, poaching, trapping, disturbing or harassing, and road kill. In general, higher road densities are harmful to wildlife because most of the human activity associated with roads negatively impacts wildlife habitat and populations. There are approximately 74 mammal species, 190 bird species, 6 amphibians, and 18 reptile species that occur on the Uinta-Wasatch-Cache National Forests. Most if not all of these species are impacted by roads to varying degrees.

The configuration and distribution of roads influence the degree of effects. Greater road densities have greater impacts than isolated roads or roads not located in crucial habitat. Direct habitat loss is limited to the actual road and road right-of-way, but habitat effectiveness can be lost due to avoidance behavior or through habitat fragmentation. For example, many large mammal species are known to avoid roads including cougars, deer, elk, pronghorn, bears, wolves, and others. Elk are among the most sensitive to roads and exhibit avoidance behavior as far as 800 meters or more away from roads throughout the year. These avoidance behaviors reduce “habitat effectiveness,” because otherwise suitable habitats close to roads are not used. Roads can also fragment wildlife populations and habitat. For example, many amphibians and small mammals altogether avoid crossing roads which effectively fragments their habitat and isolates them from other populations. Greater road densities have been associated with crashes in amphibian populations. Evaluating road density has been used broadly as a metric to evaluate the effect roads have on patch size, habitat effectiveness, and habitat fragmentation.

Although analysis of road density addresses many effects of roads, it does not perform well to evaluate roads in key or important habitats. For example, a single road in a key or crucial habitat would have a larger negative effect compared to roads in a low value habitat regardless of overall road density. Habitat types that would qualify as key or important habitats would be those that have higher biodiversity, those that are rare on a landscape, or those that are crucial to rare or declining species.

Many wildlife species select the edges between habitat types because each habitat provides different characteristics that contribute the needs of the species. For example, some species may select to use the edges between two habitats because they use one habitat as a food source, and the other for hiding cover. Because many wildlife species use edges, roads that

traverse many habitat types over short distances would have greater effects than roads traveling through monotypic habitats.

## Indicators

A number of indicators were considered for use in this analysis. The indicators had to differentiate the relative effect that existing road segments have on wildlife and assign a value of risk to each road segment that would inform future decisions on the Forest's road system. The indicators chosen for wildlife had to address the effects of roads on the broadest number of species possible, address as many of the ways that roads affect wildlife as possible, and be applicable at the forest-wide scale. Several indicators used in past analyses did not meet the above criteria.

We chose three indicators that would address the broadest number of wildlife species and address the most ways in which roads affect wildlife. Indicators chosen were road density within HUC 10 watersheds expressed as miles of road/square mile, roads located in key habitats expressed as percentage of area of key habitat affected within a 200 m buffer, and roads that occur within areas of high habitat diversity expressed as the number of habitat types crossed/mile of road. We used landfire data as the basis to identify habitat types for the diversity indicator and the key habitats indicator. Percentiles were used to assign relative values to each road segment for each indicator. These three scores were then added together to assign a final score for their relative effect on wildlife for each road segment.

## Road Density Indicator

**Description of Indicator** The road density indicator was assessed at the HUC 10 watershed scale and the units of measurement were miles of road/square mile. This indicator only included densities of roads administered by the Forest Service, and thus only on Forest Lands. The road density indicator addresses loss of habitat from the road footprint, habitat fragmentation, loss of habitat effectiveness, loss of habitat connectivity, and to some extent human influences. Lower road densities are better for a broad variety of wildlife species. Risk scores were assessed by percentile relative to road density existing on the forest.

**Measurement Indicator.** The relative risk rating for road densities is described below. Road densities (FS roads only) fell between 1.96 miles/square mile to 0.000713 miles/square mile. Road segments whose longest lengths fell within watersheds with the highest road densities (75<sup>th</sup> percentile or greater) were assigned a high value of 3 (or high risk), road segments whose longest lengths fell within watersheds that had road densities between 25<sup>th</sup>-75<sup>th</sup> percentiles were assigned a medium value of 2 (medium risk), and those that fell within watersheds whose road densities were lower than the 25<sup>th</sup> percentile were assigned a low score of 1 (low risk). A list of ratings for individual watersheds is available in Table B.2.

High Risk (3) = All segments falling within watersheds that had road densities of 0.669 miles of road/square mile and higher (up to 1.96 miles/square mile).

Medium Risk (2) = All segments falling within watersheds that had road densities between 0.668 miles/square mile and 0.3122 miles/square mile.

Low Risk (1) = Road densities less than 0.312 miles of road/square mile.

**Data Limitations.** This analysis included only authorized roads administered by the Forest Service, which also limited the analysis to Forest Lands. An evaluation of road density that included all ownerships would have resulted in different risk scores, and would have likely resulted in the selection of watersheds along the Wasatch front as higher risk. Unauthorized routes also contribute to road densities, but these were not evaluated in this analysis because spatial data is lacking on unauthorized routes. An evaluation of road density is scale dependent, and the scale at which road densities are evaluated influenced the outcome. The scale of this analysis was at the HUC 10 size. Some areas have much higher road densities locally, even though road densities within the HUC 10 are lower overall. This is true in some watersheds that contain designated Roadless and Wilderness areas.

**Analysis Results,** for this indicator, 640 segments were identified as high risk, 1422 were identified as medium risk, and 789 segments were identified as low risk. A total of 652 miles were identified as high risk, 1248 miles were identified as medium risk, and 667 miles were identified as low risk. Because this indicator was based on road densities within watersheds, every segment within each watershed received the same density classification, and thus the same indicator score. The average lengths of the road segments rated high, medium and low risk ratings were 1.01 miles, 0.877 miles and 0.845 miles respectively.

| Watershed Name                            | Road Density | Rank   |

## Important Habitats Indicator

**Description of Indicator.** The important habitats indicator identifies roads located within or adjacent to important habitats expressed as the percentage of area the habitat affected within a 200 m buffer of the road segment. The important habitat indicator addresses impacts to high value habitats, which are not addressed by the road density indicator. Important habitats were identified because they are known to either support high biodiversity, are relatively rare on the landscape, are sensitive to disturbance, recovers slowly, or may be highly important to some species, especially declining, rare or sensitive species. Table B.1 shows habitats that were identified as important and the reason why they were selected as shown below:

**Table B.1**

| Habitat Type  | Reason Selected as Key Habitat Type   |
|---|---|
| Inter-Mountain Basins Montane Riparian Systems          | Rare on landscape, supports high biodiversity, important to the life cycle of some species                    |
| Rocky Mountain Alpine Turf                              | Rare on landscape, sensitive to disturbance, recover slowly, critical to species using the highest elevations |
| Rocky Mountain Montane Riparian Systems                 | Supports high biodiversity, critical to the life cycle of some species  |
| Rocky Mountain Subalpine/Upper Montane Riparian Systems | Rare on landscape, Supports high biodiversity, critical to the life cycle of some species                     |
| Rocky Mountain Subalpine-Montane Mesic Meadow           | Supports high biodiversity, Important foraging habitat, important to the life cycle of some species.          |
| Rocky Mountain Wetland-Herbaceous                       | rare on landscape, supports high biodiversity, important to the life cycle of some species.                   |
| Southern Rocky Mountain Montane-Subalpine Grassland     | Supports high biodiversity, important foraging habitat, important to the life cycle of some species.          |

**Measurement Indicator.** Road segments were evaluated by applying a 200 meter buffer to all road segments, identifying road segments that included any of the key habitat types, and then calculating a percentage of the buffer area that contained that habitat type. Once the

percentages were determined, we then ascribed a relative risk score for each segment based on the percentage of habitat affected for each habitat type. Road segments that affected the greatest percentages of each key habitat were rated highest while those that affected lower percentages were rated lower. We used percentiles to determine break points.

Segments that affected a high percentage of a key habitat were rated as high (score of 3) if their percent affected area was at or above the 75<sup>th</sup> percentile, a medium risk score (score of 2) was assigned if the segment ranked out between 75<sup>th</sup>-25<sup>th</sup> percentile, and a low score if they rated out below the 25<sup>th</sup> percentile of area affected.

High Risk (3) = All segments falling within the 75<sup>th</sup> percentile or above for percentage of the 200 m area affected for each habitat type.

Medium Risk (2) = All segments falling between the 75<sup>th</sup> percentile and the 25<sup>th</sup> percentile for percentage of the 200 m area affected for each habitat type.

Low Risk (1) = All segments falling below the 25<sup>th</sup> percentile for percentage of the 200 m area affected for each habitat type.

Table B.2 below shows the breaks for percentage of habitat affected within the 200 meter buffers, broken to show risk break points.

**Table B.2**

| VegType   | High Values  | Medium values | Low Values |
|---|--------------|---------------|------------|
| Inter-Mountain Basins Montane Riparian Systems          | 25.42-8.45   | 7.3-0.96      | 0.95-0     |
| Rocky Mountain Alpine Turf                              | 11.67-0.60   | 0.533-0.16    | 0.09-0     |
| Rocky Mountain Montane Riparian Systems                 | 57.31-11.74  | 11.69-1.49    | 1.49-0     |
| Rocky Mountain Subalpine/Upper Montane Riparian Systems | 1.794-0.497  | 0.4796-0.079  | 0.07-0     |
| Rocky Mountain Subalpine-Montane Mesic Meadow           | 89.48-8.525  | 8.5-1.13      | 1.13-0     |
| Rocky Mountain Wetland-Herbaceous                       | 38.112-3.964 | 3.95-0.449    | 0.445-0    |
| Southern Rocky Mountain Montane-Subalpine Grassland     | 74.32-3.369  | 3.336-0.4139  | 0.411-0    |

**Data Limitations** A number of other habitat types were evaluated but were eliminated because they were common and widespread on the landscape, and therefore had lower differentiating ability. For example even though aspen habitats support high biodiversity and is important to the lifecycle of many species, aspen is so common and widespread that it would have identified too many segments to be useful as an important habitat. Likewise, some habitat types lacked enough data or had detailed enough data to be useful to identifying segments at risk. Examples of where data is lacking include old growth (or forests with old growth characteristics), sage grouse nesting habitats and brood rearing habitats, and deer and elk fawning areas, etc. So although these habitats were not used, they may still be important to consider when evaluating the Forest's road system.

The analysis favored smaller segments because we used the percentage of disturbed area rather than total acres of disturbance. There were some instances when long segments of road scored lower for risk, yet affected greater acreage than segments that ranked out higher

because they had a lower percentage of affected habitats. Some of the longer road segments should be evaluated for the total amount of key habitats they affect in addition to their proportion affected. Naturally, longer road segments cover more distance, and when buffered cover more area. The effects of road segment lengths on the analysis are an important consideration when attempting future analysis of the road system. Some segments were ranked for more than one habitat type. In cases where segments were ranked for more than one habitat type, we used the value of the higher ranking to assign a risk score. Thus we did not evaluate the cumulative area affected by the segment for all habitat types combined. In future analysis, it may be important to evaluate the additive percentage of all key habitat affected by individual segments rather than evaluate the segment's effect on each habitat individually to account for instances where a segment affects some percentages of more than one key habitat.

***Analysis Results.*** There were 2059 segments ranked in this analysis, some of which were ranked under more than one habitat type. In total 888 segments were ranked high, 749 segments were ranked medium, and 1214 segments were ranked low. The miles of road that was ranked high was approximately 602 miles ranked high, 564 ranked medium, and 1388 miles were ranked low. Average segment lengths for High medium and low were 0.68 miles, 0.75 miles, and 1.14 miles respectively.

## **Habitat Diversity Indicator**

***Description of Indicator.*** The habitat diversity indicator identifies how many habitats each road segment passes through per mile. The habitat diversity indicator identifies road segments that pass through areas of relatively higher biodiversity. Neither the road density indicator, nor the key habitats indicator takes into account landscape heterogeneity. High habitat diversity (or landscape heterogeneity) is known to support more species, and because many species use habitat edges, many species are affected when roads pass through many habitat types over short distances.

The number of habitat types each road segment passes through were counted and then divided by the length of the road in miles to determine how many different habitats were crossed per mile. Once habitats/mile were determined, we then ascribed a relative risk score for each segment based on percentiles, where in the highest 75<sup>th</sup> percentile of habitats crossed/mile were identified as high (score of 3), the 75-25 percentile was identified as medium (score of 2), and segments that rated below the 25<sup>th</sup> percentile were identified as low (score of 1).

High Risk (3) = All segments falling above the 75<sup>th</sup> percentile for number of habitats crossed per mile (above 20 habitats/mile).

Medium Risk (2) = All segments falling between the 75<sup>th</sup> percentile and the 25<sup>th</sup> percentile for number of habitats crossed per mile (between 5 and 19/mile).

Low Risk (1) = All segments falling below the 25<sup>th</sup> percentile for the number of habitats crossed per mile.

**Data Limitations:** This indicator tended to select segments that were short and that passed through more than one habitat type. In some cases, segments passed through two different habitat types multiple times, even though they habitat types were the same, each time the segment changed habitat types it was counted.

**Analysis Results.** In total 676 segments were ranked high, 1406 segments were ranked medium, and 769 segments were ranked low. The miles of road that was ranked high under the diversity indicator was approximately 98.6 miles, 972 miles ranked medium, and 1496.1 miles were ranked low. Average segment lengths for High medium and low were 0.146 miles, 0.6913 miles, and 1.95 miles respectively.

## Overall Rating

**Description of Indicator.** Three factors were evaluated, Density of Forest Roads within HUC 10, Disturbance to Important Habitats, and Roads located in areas of High Diversity.

**Measurement Indicator.** A table of individual road ratings is available in Table B.5.

**Data Limitations.** This analysis included only classified roads. User created or unauthorized roads also contribute to disturbance of wildlife, and wildlife habitats. It also did not evaluate non-forest system roads which also may have effects on wildlife that use Forest Lands. This analysis took into account road density, impacts from roads to key habitats, and disturbances to edge areas and diverse areas. The analysis did not directly evaluate habitat fragmentation due to roads, habitat patch size, noise disturbance, vehicle strikes, or the actual footprint of habitat lost, some of the indicators did capture some of these effects. Factors not considered, but which may have adverse effects on wildlife include average speed of each vehicles that use each segment, intensity of use, and seasonality of road use. We also did not evaluate proximity of road locations to known wildlife features such as goshawk nests, crucial habitats such as crucial big game winter habitat, migration routes, areas important seasonally to some wildlife, or known locations of TES species. These types of analysis are more appropriate for evaluations of individual road segments, or at a smaller local scale.

**Analysis Results.** Based on the above rating system, each segment received a final score numbering from 3-9 which were the scores from each individual indicators added together. A score of 9 represents the highest, while a score of 3 represents the lowest risk. Table.5 shows the number of segments, the average length and total mileage for each risk score. The scores were then assigned a high, medium, or low risk designation based on the risk scores. Road segments who's risk score was 7 to 9 were classified as high, those scoring 5 to 6 were classified as medium, and those that scored 3 to 4 were classified as low risk. Tables B.3 and B.4. show the number of segments, average length and total miles of each classification. The final classification breaks were chosen because a score between 7-9 required one or more of the individual risk indicators to receive the highest score ( a score of 3) and the other indicators to at least be medium (an individual risk score of 2) or to have a score of two high (individual indicators of 3) and only one low . A score between 5-6 would only be achieved if

either the individual scores were all less than or equal to 2's, or if only one indicator ranked 3 and the other indicators both ranked lows (an individual risk scores of 1). A final risk score of 3-4 would be achieved only if only one individual indicator risk score was 2 and both other indicators were ranked 1 or lower. Based on the analysis results, and considering indicators for other resources, a range of management actions may be appropriate in the management of the Forest's Road System. Management actions may include closures, seasonal closures, road relocations, decisions on maintenance levels, evaluation of proposed new roads, or other related actions.

**Table B.3**

| <b>Risk Score</b> | <b>Number of Segments</b> | <b>Average Length</b> | <b>Total Miles</b> |
|-------------------|---------------------------|-----------------------|--------------------|
| 3                 | 77                        | 2.59                  | 199                |
| 4                 | 376                       | 1.6                   | 603                |
| 5                 | 761                       | 1.06                  | 807                |
| 6                 | 780                       | 0.79                  | 618                |
| 7                 | 566                       | 0.47                  | 268                |
| 8                 | 263                       | 0.26                  | 69                 |
| 9                 | 28                        | 0.12                  | 3.4                |

## APPENDIX C

### ACCESS

The road system serves many different types of needs and provides opportunities. In addition it can provide connectivity to county, state, and Federal roads and highways. The benefit of roads to access for the Uinta National Forests includes five major factors to be analyzed. These are:

- (1) Private Access;
- (2) Public Access;
- (3) Administrative Access; and
- (4) Connectivity

Each factor is important but to a different degree, therefore they are weighed based on existing access as identified on transportation plans. The degree to which each factor is associated to overall access is identified by numeric values listed under their associated measurement indicator. A numeric value is assigned to each road segment based on the factors listed below. Access ratings as described below for each road segment is listed in Table C.1.

#### Private Access

**Description of Indicator.** Private access includes roads to private property and in holdings, utility lines, mineral and material sources, drill sites, communication sites, agreements and other permitted roads or sites.

**Measurement Indicator.** The level of private access is evaluated by functional class and identification of route as primary or secondary, in terms of non-Forest managed land, existing agreement or permit.

3 = Road segment is classified AND serves as the primary access to non-Forest Service managed land.

2 = Road segment is classified AND serves as the primary access to agreement or permit.

1 = Road segment is classified as an arterial or collector AND serves as a secondary access to non-Forest Service managed land, agreement or permit.

0 = Road segment is classified as a local route AND serves as a secondary access to non-Forest Service managed land, agreement or permit OR does not contribute in anyway to non-Forest lands and is not included agreement or permit.

**Data Limitations.** None

**Analysis Results.** The results of the analysis conclude that access to the indicators listed above is a primary function of the road system. Approximately 1033 miles, or 30 % of the road segments, sampled provide primary access to either non-Forest Service managed land (433 miles, 11%) or an existing agreement or permit (600 miles, 19%).

## Public Access

**Description of Indicator.** Public access is based on the extent of use by various types of vehicles including passenger cars, 4-wheel drives, and motor homes, as well as, the type of use the road segment serves including trailheads, dispersed and developed recreation sites.

**Measurement Indicator.** The level of public access is evaluated by functional class and identification of route as primary or secondary in terms of developed recreation site (campground or trailhead) or dispersed recreation opportunities.

- 3 = Road segment is a classified route AND serves as primary access to developed recreation site.
- 2 = Road segment is classified as an arterial route AND serves as secondary access to developed recreation site OR is classified AND serves as primary access to a dispersed recreation opportunity.
- 1 = Road segment is classified as a collector or local route AND serves as secondary access to developed recreation site OR is classified as an arterial AND serves as secondary access for dispersed recreation.
- 0 = Road segment is classified as a collector or local route AND serves as secondary access for dispersed recreation OR is blocked to use by passenger cars and only provides access for dispersed recreation.

**Data Limitations.** Currently the Forest is utilizing existing travel maps. As districts create and update transportation plans they will need to re-evaluate public needs based on scoping.

**Analysis Results:** The results of the analysis conclude that access for recreation is the number one use of the road system. Approximately 2141 miles of road, or 64 percent of road segments, sampled provide primary access for recreation opportunities including developed recreation sites (541 miles, 21%) or dispersed recreation opportunities (1600 miles, 44%).

## Administrative Access

**Description of Indicator.** Administrative access includes the extent that the Forest Service uses road segment to access administrative sites, material sources, and management of natural resource programs including range, watershed, wildlife, fire suppression, etc.

**Measurement Indicator.** The level of administrative access is best measured by functional class, identification of route as primary or secondary, and existing or needed access to specific resource functions.

- 3 = Road segment is a classified road AND serves as primary access to a Forest Service administrative site.
- 2 = Road segment is classified as an arterial or collector route AND serves as secondary access to a Forest Service administrative site OR is a classified route AND serves as primary access to Forest Service land management.
- 1 = Road segment is classified as a local route AND serves as secondary access to Forest Service administrative site OR is classified as an arterial or collector AND serves as secondary access to Forest Service land management.
- 0 = Road segment is classified as a local route AND serves as a secondary route to Forest Service land management OR is a classified route AND does not contribute in any way to access Forest Service administrative sites or land management.

**Data Limitations.** None

**Analysis Results.** The results of the analysis conclude that access for administration is a major use of the road system. Approximately 1491 miles of road (41 percent of the road segments) sampled provide primary access to an administrative site (307 miles, 13%) or land management (1184 miles, 28%).

## Connectivity

**Description of Indicator.** Connectivity includes the free flowing nature of the road within its transportation system and associated public roads. Ask the question - does the road meet intended and expected access for the user. For instance, is there a change in maintenance level or surface type where appropriate within the road system? Does the system inter-relate to the associated public road system?

**Measurement Indicator.** The level of connectivity is best measured by evaluating existing and planned road management objectives in terms of maintenance level (ML).

- 3 = Road segment has the same existing and planned road management objectives in terms of maintenance level (objective ML = operational ML).
- 2 = Road segment has different existing and planned road management objectives in terms of maintenance level (objective ML = operational ML +/- 1).
- 0 = Road segment has different existing and planned road management objectives in terms of maintenance level (objective ML > operational ML +/- 1).

**Data Limitation.** Do to the time frames associated with this analysis, limited input to the connectivity of the road system with the associated public road system.

**Analysis Results.** The results of the analysis conclude that the majority (94%) of road segments sampled provide connectivity. The remaining segments do not meet objective maintenance level (ML). Of these, 136 road segments have a difference of 1 between operational and objective ML and 40 road segments have a difference of 2 or more.

## Overall Access Rating

**Description of Indicator.** The overall access rating for each road segment incorporates analysis of five factors, which are existing private, public, and administrative access needs, connectivity, and outstanding rights. Each factor is important but to a different degree. The largest impact is associated with access to private property, developed recreation and administrative sites. It is also critical to provide a free flowing system that properly connects to a public road system and have legal rights for this access.

**Measurement Indicator.** The overall road segment rating weighs each of the three factors based on values assigned through analysis. Private, public, and administrative access needs are each assessed numeric values of 0, 1, 2 or 3. Connectivity and outstanding rights are assessed a numeric value of 0-1, 2, 3. Numeric values were indicators of non-existent and/or low, moderate, and high benefit for each factor, respectively. An overall rating is then assessed for each road segment as described below. An overall rating for each road segment is available in Table C.1.

|            |  |
|------------|--|
| High =     | Cumulative value is greater than 10 OR<br>Private >1 or Public = 3 or Admin = 3 AND Connectivity > 2 |
| Moderate = | Cumulative value is between 3 and 7 OR<br>Private, Public, or Admin > 1 AND Connectivity > 0         |
| Low =      | Cumulative value is less than 2 OR<br>Private, Public and Admin < 2                                  |

**Analysis Results.** The overall rating for access shows that 2557 miles of road, or 99% of the road segments, sampled provide needed access by receiving a high (1211 miles, 46%) or moderate (1345 miles, 53%) rating. Only 10 miles, or 1% of the roads analyzed received a low access benefit rating. These roads should be evaluated further at the sub-Forest scale when appropriate.
