ACKNOWLEDGEMENTS

Data collection for this project has been in progress for over a decade and many people have provided support. We would like to thank our field crews including Max Yager, Anita Seda, Carol Harmount, Larry Helberg, Chip Weber, Bob Bozovsky, Tina Canady, Ann Dunphy, and Ron Johnson, for the long hours in the field under conditions that were sometimes pleasant, and sometimes not so pleasant. We also appreciate the contribution of Brad Smith, Gregg Riegel and their crews who provided data (in metric) as part of the Forestry Intensified Research Project. Matthew Fillmore of the Natural Resources Conservation Service and Don Morrison, Umpqua National Forest, provided soils data to support the **plant association** descriptions. Dr. Gene Hickman, also of the NRCS, provided plot data and insight to the vegetation classification. His collaboration is very much appreciated. Many thanks to Peter Gaulke and Ed Gross who assisted with the final editing of this document. Finally, we would like to thank Dave Wheeler. Over the years he served Area Five, he helped set up the data base, collect plot data, input plot data, programmed and modified programs for analysis, classified, taught, and encouraged the rest of us. To the numerous unmentioned others that have helped, we also thank you.

INTRODUCTION

This publication is a field guide to the classification of the **plant series** and **plant associations** on forested land in southwestern Oregon (SWO). The guide facilitates field identification of **plant associations**. It covers the lands of the Umpqua, Rogue River, and Siskiyou National Forests, the Medford District of the Bureau of Land Management, the southern portion of the Roseburg District of the Bureau of Land Management, and areas of Curry County. A more comprehensive office guide will be published subsequently. This Office Guide will include more information on each **plant association**, for example, down woody material levels and productivity values.

The classification is based on the concept of potential natural vegetation. The potential natural vegetation for a site is the vegetation that would be present under climax conditions. In other words, if the site were allowed to grow, undisturbed by fire, insects, diseases, flood, wind, erosion, or humans, in approximately 500 years it would theoretically reach a steady state condition in vegetative composition which would be characteristic of the site potential. The climate of southwestern Oregon favors a frequent fire disturbance regime, resulting in very rare occurrences of climax vegetative conditions. Most forest stands have been burned several times, are multi-aged, and in early or mid-successional stages. The oldest trees are commonly less than 300 years old. As a result, potential natural vegetation has been inferred using younger successional vegetation.

This classification has two-levels, of which the broadest divisions are **plant series** and the finer divisions are **plant associations**. Series is based on the dominant, most shade tolerant, regenerating tree species on the site. This publication presents a classification for the Sitka Spruce (*Picea sitchensis*), Oregon White Oak (*Quercus garryana*), Ponderosa Pine (*Pinus ponderosa*), Tanoak (*Lithocarpus densiflora*), Douglas-fir (*Pseudotsuga menziesii*), Western Hemlock (*Tsuga heterophylla*), Western Redcedar (*Thuja plicata*), Port-Orford-Cedar (*Chamaecyparis lawsoniana*), Jeffrey Pine (*Pinus jefferyi*), White Fir (*Abies concolor*), Lodgepole Pine (*Pinus contorta*), Shasta Red Fir (*Abies magnifica shastensis*), Pacific Silver Fir (*Abies amabilis*), Western White Pine (*Pinus monticola*), and Mountain Hemlock Series (*Tsuga mertensiana*). Each series has been subdivided into **plant associations**. In addition, in the Tanoak Series, an intermediate "subseries" class has been provided. This grouping can be used when series or **plant association** does not provide the desired resolution.

Plant associations are described primarily by the presence or absence, and abundance of **plant species**. Environmental variables, including soil, are also used to classify, and often reflect the pattern of vegetation.

Species presence and abundance result from environmental gradients. Classification attempts to find **plant responses** to natural gradients such as aspect, slope, slope position, soil type, and moisture. For example, north slopes support vegetation that differs from south slopes, so each supports different **plant associations**. This type of natural break is easily recognized and delineated. Conversely, with constant aspect, vegetation often changes from the top of the slope to the bottom, but the change is so gradual that a boundary between **plant associations** is difficult to delineate. Boundaries between **plant associations** may be difficult to recognize where environmental gradients are gradual.

Descriptions of **plant associations**, sometimes based on fewer than ten sample plots (36 percent of the **associations**), will not exactly match a particular site. Therefore, the "best match" of a description should be used. Experience in using the key and guide is helpful for proper **plant association** identification.

DATA COLLECTION

The classification was divided, by Series, among the ecologists in this Area. The lead author is shown at the beginning of each Series chapter.

Analyses are based on over 2500 sample plots. These sample plots provided several data sets. These data sets were made up of: 1) intensive plots collected by the USDA Forest Service Ecology Program, 2) plots installed as part of the Oregon State University Forestry Intensified Research (FIR) Program on Bureau of Land Management (BLM) lands, 3) plots installed by the Natural Resource Conservation Service (NRCS) throughout Curry County, and 4) other plots installed by Oregon State University researchers.

Most data sets included basic vegetation (cover, dominance, etc.) and environmental variables. In addition to vascular species presence and abundance, site variables such as slope, aspect, elevation, and topographic position were collected at each plot.

Average total vascular **plant** species richness (the number of species present) was calculated for each **association** and for each vegetation layer within each **association**. The range of values for richness was divided into five sections and assigned very high, high, intermediate, low, and very low richness ratings. These ratings have a different scale for each Series based on the total range of values. Richness may be helpful in keying **plant associations**.

Forest Service sample plot data estimated percent cover for six vegetation layers. The upper tree layer included cover above 50 feet tall, the middle tree layer included cover between 12 and 50 feet tall, and the lower tree layer, included cover less than 12 feet tall. High shrub cover included shrubs over three feet tall, and low shrub cover, shrubs less than three feet tall. Herb cover included all herbs and grasses.

Data on percent cover of vegetation, by layer, collected by FIR researchers on Bureau of Land Management lands, were stratified differently than the Forest Service data. Data were stratified into five layers. Tree cover was estimated for trees greater than 10 feet tall (3 meters) and less than 10 feet tall. Tall shrubs were greater than 20 inches (50 centimeters) and low shrubs less than 20 inches in height. Herb cover included all herbs and grasses.

Vegetation data collected in the Sky Lakes Wilderness were segregated into cover classes. For the analyses, the midpoint of each cover class was used. The percent cover values were 1, 3, 8, 20, 40, 60, 80, and 95. Aspect codes were also collected and were converted to the midpoint of the range for analyses.

Vegetation data collected by the NRCS in Curry County were collected predominantly on north aspects and were characterized by dominance classes (Anderson and Poulton 1958). Species with a dominance rating of 5 were dominant, 4, codominant, 3,

common, 4, uncommon, and 5, rare. Constancy values were calculated for each species, but percent cover was not collected.

Field identification of *Festuca* species was extremely difficult. In southwestern Oregon, the native dryland fine-leaved fescues with gray-green or blue-tinged leaf color have been called Idaho fescue (*Festuca idahoensis*), red fescue (*Festuca rubra*), Roemer's fescue (*Festuca roemerii*), and sheep fescue (*Festuca ovina*). Field characteristics to discriminate between these species are not useable in southwestern Oregon. Name(s) were attached to these fescues in order to refer to them in this guide. Idaho fescue (*Festuca idahoensis*) is used as the name for all the native, dryland, fine-leaved fescues with gray-green or blue-tinged leaf color. This is not a taxonomic determination (Rolle 1996, pers. comm.).

The tree species white fir (*Abies concolor*) and grand fir (*Abies grandis*) hybridize throughout southwestern Oregon. In this field guide they were identified as white fir. A more thorough explanation is provided in the White Fir Series introduction.

The constancy tables in each **plant association** description show only the most common species for that **association**. Full constancy tables will be provided in the office guide. Due to the format and limited space in this field guide, the BLM vegetative data were stratified from five layers into the overstory-understory categories seen in the tables. This incompatibility of data may have resulted in constancy and cover values for overstory and understory species that may not reflect field conditions.

Soil data were collected on Forest Service and Bureau of Land Management lands. More extensive soil and geology information was summarized from a subset of plots for most **plant associations**, depending on soil plot data availability. A combination of geology maps, exposed bedrock along road cuts, and soil pit rock fragments were used to identify parent material (type of geologic material from which the soil developed). More information in mineralogy and rock types is provided in "Geology of Oregon" (Orr, Orr, Baldwin 1992). Soil data were not collected on NRCS sample plots and are not available for Sky Lakes Wilderness data.

Soil taxonomic classification, moisture regime, and temperature regime have been provided where possible to help identify some of the environmental factors characteristic of each **plant association**. A xeric soil moisture regime identifies soils where winters are moist and cool, the summers are warm and dry, and the soil is dry for more than 45 days of the summer. A udic moisture regime describes areas where some soil moisture is available for **plant** growth throughout the summer. Frigid soils have a mean annual soil temperature less than eight degrees Celsius (C), mesic soils have a mean annual temperature between 8 and 15 degrees C, and isomesic soils maintain a mean annual temperature in the mesic range, but with less fluctuation throughout the year. More soil taxonomy information is provided in the "Keys to Soil Taxonomy" (1996).

To ease the transition from the Draft **Plant Association** classification (Atzet and Wheeler 1984, Atzet and McCrimmon 1990) to the Final **Plant Association** classification, a list is presented at the end of each series introduction showing each draft **association** and listing the possible new **associations** into which it could fall. The percentages following each new **association** reflect the percent of plots from the old **association** that made up the new **association**. For example, the draft Western

Hemlock-Pacific Silver Fir/ Thin-leaved Huckleberry **Association** is described by 11 plots In the final classification, those plots were divided as follows

- 46 percent (5 plots) Western Hemlock-Pacific Silver Fir **Association**
- 27 percent (3 plots) Western Hemlock/Vine Maple-Pacific Rhododendron **Association**
- 18 percent (2 plots) Pacific Silver Fir-Western Hemlock/Thin-leaved Huckleberry **Association**
- 9 percent (1 plot) White Fir-Western Hemlock/Dwarf Oregongrape **Plant Association**

So, if a stand was classified as Western Hemlock-Pacific Silver Fir/Thin-leaved Huckleberry in the past, it is likely (46 percent chance) it will be Western Hemlock-Pacific Silver Fir under the new classification Also note, the draft **plant association** names use the Forest Service Region 6 codes and the final **plant associations** use the national codes provided in the **PLANTS** database (NRCS 1996) It is recommended, when possible, to reclassify the area using the new Field Guide

HOW TO USE THE KEY

There are two levels of keys, the first level is the **plant** series key, the second divides the **plant** series into **plant associations**. **Plant** series are named for the climax dominant trees of a stand At the next level, **plant associations** are named for the two or three consistently occurring species (of a stand) within each series

Steps in Determining **Plant Associations**

To determine **plant series** Series are based on the climax dominant tree species that is successfully regenerating on the site For example, if the overstory cover is 50 percent Douglas-fir and 10 percent western hemlock, and the understory cover is 40 percent western hemlock and 10 percent Douglas-fir, it would fall into the Western Hemlock Series, because western hemlock regeneration would be dominant If there is 49 percent Douglas-fir regeneration and 50 percent western hemlock regeneration it still falls into the Western Hemlock Series

Another characteristic to look for is the distribution of age classes by species For example, it is possible to have a stand dominated by Douglas-fir in the overstory, with no Douglas-fir regeneration, with 25 percent cover of white fir regeneration of all one age class, along with 20 percent western hemlock regeneration If the western hemlock regeneration has many age classes (i.e. a reverse "J" shaped curve of abundance versus age) then it is considered most successful because it has regenerated over many years, and the site would fall into the Western Hemlock Series The high cover of white fir could have been the result of different weather conditions during only one or two years, or the result of a disturbance

Select a uniform site If the area is not uniform, i.e., it has both north and south slopes or it has two soil parent material types, stratify and key both areas or identify the most extensive area and key it Microsite variations, such as rocky areas or draws, may lead to incorrect identification and should be avoided

Select a representative site Select the sites for keying after viewing the entire area. If

the area is mostly pumice, key a pumice site. If the area varies significantly, consider stratifying, particularly if the **association** responses to management are different.

Make a species list. List the most abundant and common species on the site and estimate their cover ocularly by mentally dividing a fifth acre plot into quarters, eighths, etc. For example, if Pacific rhododendron cover could fill about 1/4 of the plot, it averages 25 percent cover.

Use the key sequentially. Always start at the beginning with the series key and note that the distinctions between alternatives are given in order of importance. The first sentence is the most important. Always read all alternatives before choosing. After a series is determined, work through the appropriate key to the **plant association**.

Make a tentative identification. After a **plant association** is determined, read the description to see if it fits the site. Use the constancy tables to see if the characteristic species are present. For example, if a species has 100 percent constancy, it should almost always be present. If the constancy table lists Pacific rhododendron as having 80 percent constancy that means it should be present four out of five times. Also compare the percent cover in the constancy table with the percent cover of your species list from the site. Covers should be similar. Another way to verify identification is to check the location to see if the **association** occurs in the area. The **association** may also occur on adjacent areas or in areas with similar environmental conditions that have not been sampled. If the description does not match the area, return to the first point in the key that was troublesome and take another alternative. Read the description for that **plant association**, see which description best fits the site, and compare it with the first **association**.

Make the final determination. Choose the **plant association** that best reflects site conditions but remember, there will be sites that simply do not fit the key or the classification.

TO KEY DISTURBED SITES

Although the **Plant Association** key was constructed to identify potential natural vegetation, with some adjustment, and greater uncertainty, it can be used for younger sites or those that have been heavily disturbed.

Select an area to key. As described previously, select uniform, representative sites.

Find undisturbed or minimally disturbed vegetation. Find **plants** that characterize the site by using islands of undisturbed vegetation when present. If all areas have been disturbed, use the area with the least disturbance, such as around stumps. Research in southwestern Oregon indicates that even areas that have been clearcut and burned will have about 65 percent of the original species present within two years after burning. The percent cover, of course, will be lower than reported in the **plant association** description.

Check an adjacent stand with the same site characteristics. Adjacent stands can be used to check the **plant association** on the disturbed site. Match the adjacent stand as closely as possible to the aspect, slope, parent material, soil, etc. of the area being keyed.

Read the association descriptions When disturbed sites are keyed, understory occurrence is most important. The list of understory species, especially shrubs, should match the constancy table in the plant association description (covers may be different). Also compare the environmental description.

EXAMPLE

ASSOCIATION NAME WITH COMMON NAMES

Association name with scientific names (Latin standards from NRCS "Plants" data base)

Association name with accepted "Plants" codes (Number of plots, total and by agency)

Picture of representative site

Distribution A summary of where the association is typically found, based on sample locations. Each agency had a different sampling strategy. Distribution was not systematic, nor was it totally random. Coverage was not uniform, therefore, sites may be found at other locations.

Distinguishing Characteristics This section highlights characteristics that help distinguish the association from all others. Often, the differences are too subtle to be distinguished by one or a few characteristics. The plant association key is the best tool for determining plant association membership.

Soils Information on soils and parent material that may help determine association membership is presented.

Environment Environment includes information on physical characteristics of the typical site. It is usually expressed in averages for the particular plant association. Average annual temperature was computed using Brad Smith's program (Deschutes National Forest, Bend Oregon) and average annual precipitation was taken from "Average Annual Precipitation, 1960-1980 in Southwest Oregon", OSU Extension EM 82 20/Nov 1982.

Vegetation Composition and Structure Vegetation composition and structure are specific for each plant association. This section is based on the constancy table, but may also include additional information about environmental indications or relative occurrence.

Common name	Code	Constancy	Cover	Avg Richness
-------------	------	-----------	-------	--------------

Most common names and all plant codes are taken from the standardized NRCS "Plants" data base. In some cases, locally accepted common names are used. Life form, such as tree, shrub, herb, and grass are also established locally. For example, in some areas, vine maple may be considered a tree. Here it is categorized as a shrub.

Constancy is the percent of the time the plant occurs in the sample for the association. For example, if there are 10 samples and the plant occurs in four of them, constancy is 40 percent.

Cover is an ocular estimate of projected vertical cover.

Average richness is calculated by totaling the number of species in each sample by layer and dividing by the number of samples.

KEY TO THE PLANT SERIES

1a	Sitka spruce (PISI) is the dominant regenerating species on the site	SITKA SPRUCE FIRST RED	
1b	Sitka spruce (PISI) is absent or not dominant compared to other regenerating species on the site		2
2a	Oregon white oak (QUGA4) is the dominant regenerating species on the site	OREGON WHITE OAK FIRST BLUE	
2b	Oregon white oak (QUGA4) is absent or not dominant compared to other species regenerating on the site		3
3a	Ponderosa pine (PIPO) is the dominant regenerating species on the site	PONDEROSA PINE FIRST YELLOW	
3b	Ponderosa pine (PIPO) is absent or not dominant compared to other regenerating species on the site		4
4a	Tanoak (LIDE3) is the dominant regenerating species on the site	TANOAK FIRST GREEN	
4b	Tanoak (LIDE3) is absent or subordinate to other regenerating species on the site		5
5a	Douglas-fir (PSME) is the dominant regenerating species on the site	DOUGLAS-FIR FIRST ORANGE	
5b	Douglas-fir (PSME) is absent or subordinate to other species		6
6a	Western hemlock (TSHE) is the dominant regenerating species on the site	WESTERN HEMLOCK FIRST PURPLE

SITKA SPRUCE SERIES

SITKA SPRUCE SERIES

Picea sitchensis

PISI

Paula R Fong

Sitka spruce extends in a narrow band along the west coast of North America from Alaska into northern California. Southwestern Oregon is near the southern end of the species range. Although the species extends further inland along major drainages, most of the Series can be found within one mile of the Pacific Ocean, in the wet and mild climate of the coastal plains and headlands. Tanoak replaces Sitka spruce, as the potential climax species, on inland sites as marine influence wanes. North of Port Orford, the Sitka Spruce Series widens and abuts the Western Hemlock Series on its eastern flank. South of Brookings, tanoak is climax on most sites now dominated by coast redwood, and the Sitka Spruce Series becomes narrow and discontinuous.

Two **plant associations** have been identified for the Series in southwestern Oregon: Sitka Spruce/Salal-Evergreen Huckleberry and Sitka Spruce-White Fir/ Salmonberry. The Sitka Spruce/Salal-Evergreen Huckleberry **Association** is similar to the Sitka Spruce/Salal-Coast **Association** identified in the Siuslaw National Forest **Plant Association** and Management Guide (Hemstrom and Logan 1986), but has much less western hemlock. The Siuslaw Guide's Sitka Spruce/Salal-Coast **Association** may occur on sites immediately north of Port Orford.

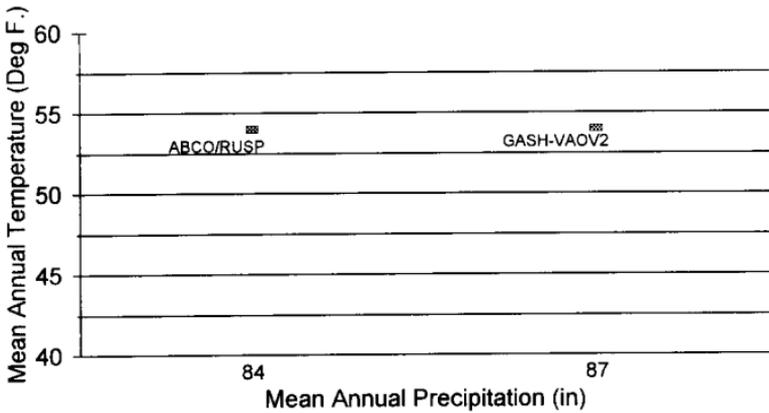

Average annual temperature is 54 degrees F and average annual precipitation is 86 inches, supplemented by fog drip. Average elevation is less than 420 feet. Sample sites are located entirely on private and state-owned land in Curry County. This Series is seldom found on Federal lands.

Soils tend to be deep over siltstone and sandstone parent material. Most of the soils mapped in this portion of the Curry County Soil Survey (18 sites were sampled) include well developed Ultisols mixed with less developed, sandier Inceptisols. Surface texture is loam with 5 to 40 percent gravel and 13 to 27 percent clay. Subsurface texture is loam, sandy loam, or clay loam, with 10 to 40 percent gravel and 7 to 35 percent clay. The Sitka Spruce Series occurs within the isomesic soil temperature regime, where the soil temperature does not vary significantly between summer and winter. Soil moisture regime is udic.

The relative environments of the **plant associations** are shown in the Environmental Graph on page PISI 2. Each **association** is plotted by average annual temperature and average annual precipitation.

Sitka spruce grows in dense stands dominating the overstory, or in **association** with red alder, white fir, and Douglas-fir. Occasionally, dense pockets of lodgepole pine (sometimes called shore pine) are interspersed among the spruce. The shrub layer is often salmonberry, salal, and evergreen huckleberry. Western swordfern is usually present in the herb layer. Average vascular **plant** species richness (total number of vascular species) for the Series ranges between 18 and 23.

Environmental Graph

Although the Series shows relatively little variation in annual precipitation, there may be a difference in soil water availability associated with soil texture. Although the difference may be subtle, it is likely to influence species composition. Greater cover of salal, as opposed to evergreen huckleberry, is usually associated with the drier end of the moisture gradient. Stands dominated by salal with Sitka spruce by itself in the overstory tend to occur on the sandy, well-drained Inceptisols at the southern end of the sample area (Brookings area) where fog drip is less common. Stands with more white fir and alder, and a significant component of salmonberry in the shrub layer, tend to be found in the soils with silt and clay loam in the subsurface, north of Cape Sebastian where fog more often occurs during the summer.

PISI 4

SITKA SPRUCE-WHITE FIR/SALMONBERRY

Picea sitchensis-Abies concolor/Rubus spectabilis

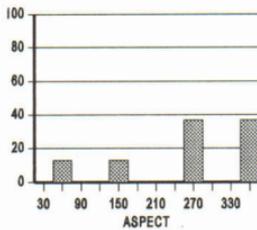

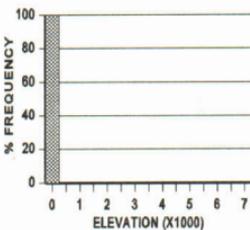

PISI-ABCO/RUSP (N=8; NRCS=8)

Distribution. This Association occurs on lands within one half mile of the Pacific Ocean between the Oregon-California border and Port Orford, Oregon. Most frequently this Association is found north of Cape Sebastian. The Siuslaw National Forest Plant Association Guide should be consulted for sites near Port Orford.

Distinguishing Characteristics. This Association is slightly more diverse and supports slightly more cover than the Sitka Spruce/Salal-Evergreen Huckleberry Association. The overstory usually includes white fir and red alder, as well as Sitka spruce. The shrub layer has high salmonberry cover, with evergreen huckleberry and salal commonly present. Soil textures tend to have higher moisture-holding capacity than the Sitka Spruce/Salal-Evergreen Huckleberry Association.

Soils. The dominant parent material is siltstone, with some sites underlain by sandstone. Surface rock (defined as greater than 7 centimeters in size) cover

Slope position data not available

averages 16 percent, and is mostly gravel. Based on nine plots sampled, soils are deep and moderately well drained to well drained. Surface texture is loam with five to 40 percent gravel and 20 to 27 percent clay. Subsurface texture is clay loam with 10 to 45 percent gravel and cobbles and 30 to 35 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is isomesic.

Environment Elevation averages 412 feet. Slopes average 30 percent with a range of 1 to 50 percent. Both associations average 54 degrees F average annual temperature, but Sitka Spruce-White Fir/Salmonberry averages 84 inches of average annual precipitation.

Vegetation Composition and Structure. Species richness for this Association averages 23 species. The overstory generally includes more white fir, Douglas-fir and red alder than the Sitka Spruce/Salal-Evergreen Huckleberry Association. Western sword-fern and salmonberry dominate the herb and shrub layers respectively, with evergreen huckleberry commonly present on most sites, but at low covers. Salal, poison oak, red elderberry, and red huckleberry are also occasionally present, but at low covers.

SITKA SPRUCE/SALAL-EVERGREEN HUCKLEBERRY

Picea sitchensis/Gaultheria shallon-Vaccinium ovatum

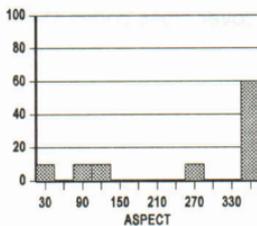

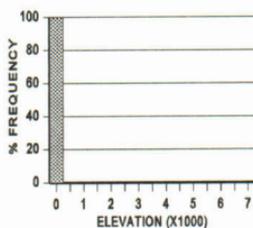

PISI/GASH-VAOV2 (N=10; NRCS=10)

Distribution. This Association occurs on lands within one half mile of the Pacific Ocean between the Oregon-California border and Port Orford, Oregon. Most frequently this Association is found south of Cape Sebastian.

Distinguishing Characteristics. This Association is slightly less diverse and supports slightly less vegetative cover than the Sitka Spruce-White Fir/Salmonberry Association. The overstory and shrub layer are dominated by Sitka spruce and salal, respectively. The soil textures are generally more well drained and have slightly less moisture-holding capacity than the Sitka Spruce-White Fir/Salmonberry Association.

Soils. The predominant parent material is sandstone. Surface rock (defined as greater than 7 centimeters in size) cover averages 3 percent, and is mostly gravel. Based on three pits sampled, soils are deep and well drained. Surface texture is

Slope position data is not available

loam with less than 5 percent gravel and 13 percent clay. Subsurface texture is loam and sandy loam, with 30 to 40 percent gravel and cobbles and 7 to 13 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is isomesic.

Environment Elevation averages 416 feet. Slopes average 20 percent with a range of 1 to 65 percent. This **Association** averages 54 degrees F and 86 inches of precipitation annually.

Vegetation Composition and Structure. Species richness for this **Association** averages 18 species. The overstory is slightly less diverse than the Sitka Spruce-White Fir/Salmonberry **Association**. It is dominated by Sitka spruce, with some red alder and Douglas-fir. Salal dominates the shrub layer. Western sword-fern and evergreen huckleberry are also almost always present but with less cover than salal. Salmonberry is commonly present, but with low cover.

**OREGON WHITE
OAK SERIES**

OREGON WHITE OAK SERIES

Quercus garryana

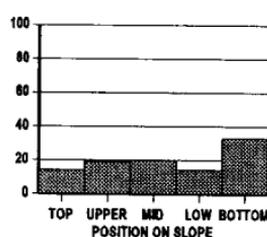

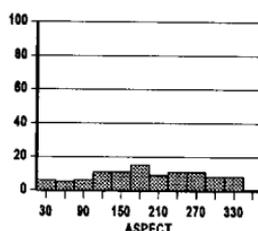

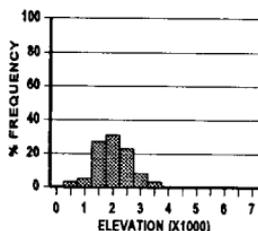

QUGA4

Patricia A. Martinez

Oregon white oak occurs from central California north into Canada and is the most abundant and widely distributed oak in Oregon. Oregon white oak tends to be restricted to islands of shallow soils and hot, dry microclimates. It is usually located on dry to moist, well-drained, gravelly soils, and is shade intolerant. Oregon white oak produces an abundance of acorns and is a vigorous sprouter.

The Oregon White Oak Series is found along the valley floor at low elevations. The Series is discontinuous with isolated pockets on the Tiller Ranger District, Umpqua National Forest and along Bear Camp Road near Agness, Gold Beach Ranger District, Siskiyou National Forest

As shown in the graphs below, this Series ranges in elevation from 500 feet to 3300 feet, with an average elevation of 1980 feet. Although it occurs on all slope positions and aspects, it is more commonly found on southerly aspects and is slightly more common in valley bottoms

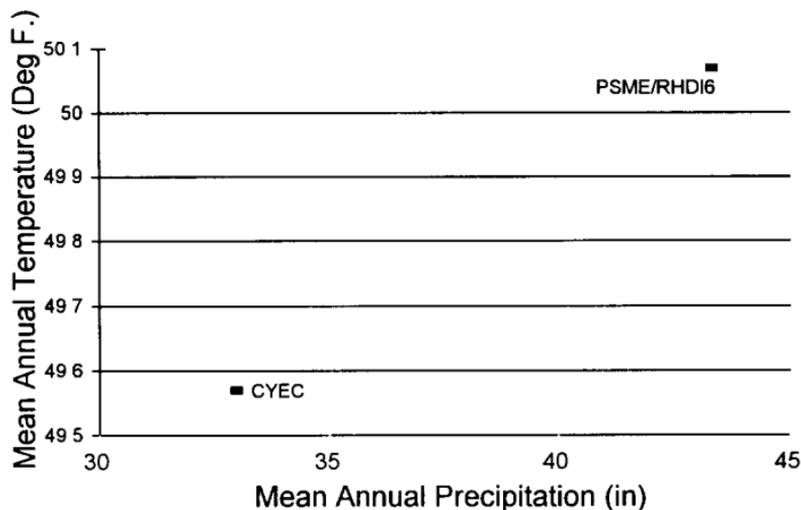

Parent material is variable, consisting of meta-volcanics, serpentine, tuffs, sandstone, mixed sediments, mixed meta-sediments with ultramafics, mixed sediments with ultramafics, mixed ultramafics, welded tuffs, basalt and andesite. Percent cover of rock ranges from 0 to 50 percent, with an average of 6 percent. Percent cover of bedrock ranges from 0 to 30 percent, with an average of 1 percent. Bare ground ranges from 0 to 20 percent, with an average of 3 percent. Litter ranges from 0 to 99 percent, with an average of 41 percent. Moss ranges from 0 to 35 percent, with an average of 4 percent.

Based on eight plots sampled, soils are shallow to deep, and moderately well to well drained. The surface texture is silt loam or loam, with 0 to 25 percent gravel, 0 to 30 percent cobbles, and 20 to 25 percent clay. The subsurface texture is silty clay loam and clay loam, with 0 to 20 percent gravel, 0 to 40 percent cobbles, 0 to 20 percent stones, and 27 to 40 percent clay. The soil moisture regime is probably xeric and

QUGA4 2

the soil temperature regime is probably mesic. Soils classify into the following subgroups: Typic Haploxeroll, Lithic Haploxeroll, Lithic Argixeroll, Lithic Xerochrept, and Typic Xerochrept.

The mean annual temperature for the Oregon White Oak Series is 50 degrees F while the mean annual precipitation ranges from 33 inches to 43 inches. The relative positions of the plant associations in the environment are shown above. Each association is plotted by mean annual temperature and mean annual precipitation.

Average total species richness, based on vascular plants only, is calculated for each association. The average total species richness for the Oregon White Oak Series is 23 species. Average total species richness for the Oregon White Oak-Douglas-fir/Poison Oak Association is 23 species and average total species richness for the Oregon White Oak/Hedgehog Dogtail Association is 24 species.

On Bureau of Land Management sites, tree cover exceeding 10 feet tall (3 meters) averages 46 percent, while tree cover less than 10 feet tall averages 5 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 11 percent, and cover for shrubs less than 20 inches tall averages 19 percent. Herb/grass cover averages 37 percent.

On Forest Service sites, upper layer tree cover averages 6 percent. Mid-layer tree cover averages 13 percent, while lower layer tree cover averages 10 percent. High shrub cover averages 1 percent, while low shrub cover averages 4 percent. Herb/grass cover is high, averaging 91 percent.

Two **plant associations** have been identified for the Oregon White Oak Series Oregon White Oak/Hedgehog Dogtail and Oregon White Oak-Douglas-fir/Poison Oak They were described from 64 plots, 60 on Bureau of Land Management lands and 4 on Forest Service lands Oregon White Oak/Hedgehog Dogtail is drier than Oregon White Oak-Douglas-fir/Poison Oak, Douglas-fir is rarely present and poison oak is usually present, with an average cover of 5 percent. Oregon White Oak - Douglas-fir/Poison Oak is more productive than Oregon White Oak/Hedgehog Dogtail, Douglas-fir is almost always present, and poison oak has an average cover of 18 percent. Oregon White Oak/Hedgehog Dogtail has high herb cover and may have up to 18 grass species present. Hedgehog dogtail is present 85 percent of the time with an average cover of 10 percent, and bur-chervil is present 79 percent of the time with an average cover of 6 percent

The relationship of draft and final **plant associations** in the Oregon White Oak Series is shown below The draft **association** is listed, with the final **associations** below, each in order of most to least common, with the percentage of plots that make up each **association** (refer to Methods section)

QUGA4 4

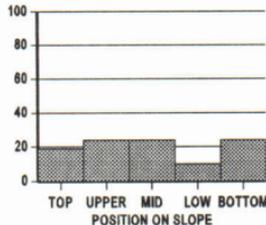

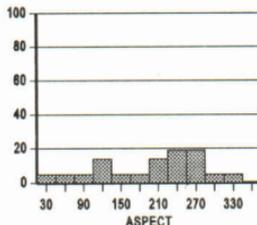

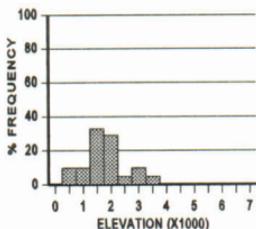

OREGON WHITE OAK-DOUGLAS-FIR/POISON OAK
Quercus garryana-*Pseudotsuga menziesii*/*Rhus diversiloba*
QUGA4-PSME/RHD16 (N=21; BLM=21)

Distribution. This Association is found on the Grants Pass, Butte Falls, and Ashland Resource Areas, Medford District and the Swiftwater Resource Area, Roseburg District, Bureau of Land Management. It may also occur on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, all Ranger Districts of the Rogue River National Forest, and the Tiller and North Umpqua Ranger Districts, Umpqua National Forest.

Distinguishing Characteristics. Douglas-fir is present in the overstory and the understory and poison oak is frequent, with an average cover of 18 percent. The average annual temperature is 50 degrees F and the average annual precipitation is 43 inches, wetter than the Oregon White Oak/Hedgehog Dogtail Association.

Soils. Parent materials found in this Association are meta-volcanics, mixed meta-sediments with ultramafics, basalt, sandstone, mixed sediments with ultramafics, and

mixed ultramafics Surface gravel, rock, and bedrock covers are low, averaging less than 6 percent for each component. Based on four plots sampled, soils are moderately well drained The surface texture is loam and silt loam, with 0 to 25 percent gravel, 0 to 30 percent cobbles, and 20 to 23 percent clay. The subsurface texture is clay loam, with 0 to 20 percent gravel, 5 to 40 percent cobbles, 0 to 20 percent stones, and 27 to 40 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably mesic. Soils classify into the following subgroups: Lithic Haploxeroll, Lithic Xerochrept, and Typic Xerochrept.

Environment. Elevation averages 1810 feet. This **Association** occurs on all aspects, although it is more common on southerly aspects Slope averages 25 percent, and ranges from 3 to 65 percent. Oregon White Oak-Douglas-fir/Poison Oak can be found on all slope positions, but is slightly more common on upper to middle-third slope positions

Vegetation Composition and Structure. Total species richness averages 23 species, slightly lower than the Oregon White Oak/Hedgehog Dogtail **Association** The overstory and understory are both dominated by Oregon white oak with frequent occurrences of Douglas-fir. Poison oak is also frequent. Mountain sweet-root, hedgehog dogtail, and blue wildrye are common. Moss cover averages 5 percent.

Cover for trees greater than 10 feet tall (3 meters) averages 52 percent, while cover for trees less than 10 feet tall averages 3 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 14 percent, while cover for shrubs less than 20 inches tall averages 27 percent. Herb/grass cover averages 27 percent

OREGON WHITE OAK/HEDGEHOG DOGTAIL

Quercus garryana/Cynosurus echinatus

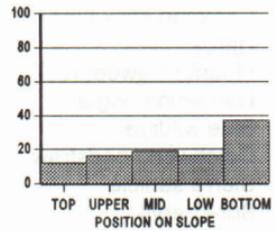

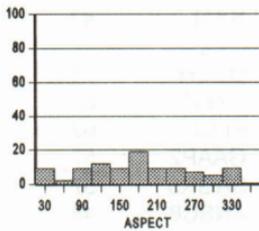

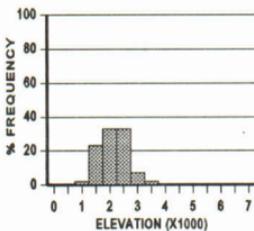

QUGA4/CYEC (N=43; BLM=39, FS=4)

Distribution. This **Association** occurs on the North Umpqua and Tiller Ranger Districts, Umpqua National Forest, the Grants Pass, Ashland, and Butte Falls Resource Areas, Medford District, and the Swiftwater Resource Area, Roseburg District, Bureau of Land Management. It may also occur on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and all Districts of the Rogue River National Forest.

Distinguishing Characteristics. Douglas-fir is generally absent. This **Association** supports high grass species richness (approximately 18 species). Herb/grass cover is high. The average annual temperature is 50 degrees F and the average annual precipitation is 33 inches, drier than the Oregon White Oak-Douglas-fir/Poison Oak **Association**.

Soils. Parent material is variable, consisting of meta-volcanics, serpentine, basalt.

tuffs, sandstone, mixed-sediments, welded tuffs, and andesite. Surface gravel, rock, and bedrock covers are low, averaging less than 6 percent for each component. Based on four plots sampled, soils are shallow to moderately deep and well drained. The surface texture is silt loam or loam, with 0 to 22 percent gravel, 5 to 25 percent cobbles, and 21 to 25 percent clay. Subsurface textures are silty clay loams or clay loams, with 0 to 10 percent gravel, 0 to 25 percent cobbles, and 35 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably mesic. Soils classify to the following subgroups: Typic Haploxeroll, Lithic Haploxeroll, and Lithic Argixeroll.

Environment Elevation averages 2130 feet. This **Association** is present on all aspects, but is most common on southerly aspects. Slope averages 24 percent, ranging from 0 to 65 percent. Oregon White Oak/Hedgehog Dogtail occurs on all slope positions, but is most commonly found on slope bottoms and flats.

Vegetation Composition and Structure Total species richness averages 24, slightly higher than the Oregon White Oak-Douglas-fir/Poison Oak **Association**. The overstory is dominated by Oregon white oak with occasional occurrences of ponderosa pine, California black oak, and Pacific madrone. The understory is dominated by Oregon white oak, with occasional occurrences of Pacific madrone, ponderosa pine, California black oak, and birchleaf mountain-mahogany. In the shrub layer, poison oak is frequent, with an average cover of 5 percent. Hedgehog dogtail and bur-chervil are frequently found in the herb layer. The number of grass species present, along with their covers, are high. Herbs are also plentiful, although covers for individual species are low. Moss cover averages 2 percent.

On Forest Service sites, upper layer tree cover averages 6 percent. Mid-layer tree cover averages 13 percent while lower layer tree cover averages 10 percent. High shrub cover averages 1 percent and low shrub cover averages 4 percent. Herb/grass cover averages 91 percent.

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 39 percent, while cover for trees less than 10 feet tall averages 6 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 8 percent, while cover for shrubs less than 20 inches tall averages 10 percent. Herb/grass cover averages 46 percent.

**PONDEROSA PINE
SERIES**

PONDEROSA PINE SERIES

Pinus ponderosa

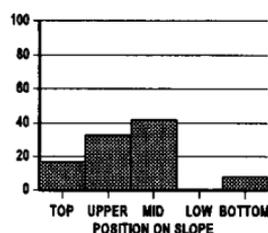

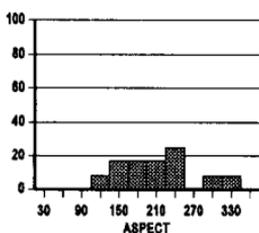

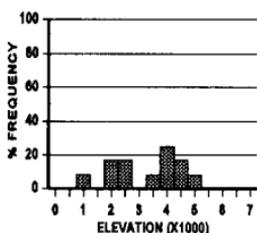

PIPO

Patricia A. Martinez

Ponderosa pine is a widely occurring species in the western United States. It is common in areas with low summer rainfall and is generally tolerant of moisture stress. While ponderosa pine behaves as a fast growing, seral species on hot, dry sites with shallow, droughty soils, it is the climax species on only a few sites in the Klamath and Cascade Province in southwestern Oregon (Atzet 1992). Ponderosa pine can be found in frost pockets and on vertisols, soils with high shrink-swell characteristics. Ponderosa pine regeneration is stimulated by fire, and controlling fires restricts regeneration.

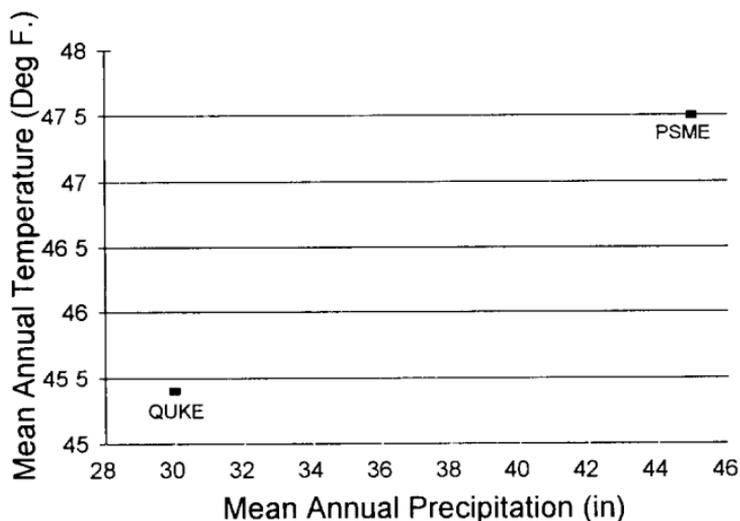

The Ponderosa Pine Series is found near the valley bottom at slightly higher elevations than the Oregon White Oak Series. Small pockets of this Series may occasionally be found at high elevations on south aspects with shallow, rocky soils.

As shown in the graphs below, the Series ranges in elevation from 1050 feet to 5220 feet, with an average elevation of 3310 feet. The Series occurs on all aspects and slope positions, but occurs most frequently at mid-slope positions.

Parent material is variable, consisting of meta-volcanics, basalt, andesite, mixed ultramafics, schist, and diorite. Gravel cover averages 2 percent. Rock cover ranges from 0 to 70 percent, with an average of 7 percent. Bedrock cover ranges from 0 to 45 percent, with an average of 5 percent. Bare ground ranges from 0 to 90 percent, with an average of 9 percent. Soil textures are silty clay loam, loam, or silty clay. Litter ranges from 10 to 99 percent, with an average of 66 percent. Moss is generally absent.

The mean annual temperature for the Ponderosa Pine Series ranges from 45 degrees F to 48 degrees F and the mean annual precipitation ranges from 30 inches to 45 inches. The relative positions of the **plant associations** in the environment are shown on page PIPO 2. Each **association** is plotted by mean annual temperature and mean annual precipitation.

Total species richness, based on vascular **plants** only, is calculated for each **association**. The average total species richness for the Ponderosa Pine Series is 21 species. Total species richness for Ponderosa Pine-Douglas-fir is 23 species and total species richness for Ponderosa Pine-California Black Oak is 19 species.

On Bureau of Land Management sites, tree cover exceeding 10 feet tall (3 meters) averages 60 percent, while cover for trees less than 10 feet tall averages 3 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 11 percent and cover for shrubs less than 20 inches tall averages 1 percent. Herb/grass cover averages 28 percent.

On Forest Service sites, upper layer tree cover averages 23 percent, as does mid-layer tree cover. Lower layer tree cover averages 12 percent. High shrub cover averages 24 percent, while low shrub cover averages 14 percent. Herb/grass cover averages 38 percent.

Two **plant associations** have been identified for the Ponderosa Pine Series in southwestern Oregon. They were described from 12 plots, 10 on Bureau of Land Management lands and 2 on Forest Service lands. The **plant associations** were described using Bureau of Land Management data. Climax ponderosa pine rarely occurs on National Forest Service lands in southwestern Oregon.

The two **associations** in this Series are distinguished by either the presence or absence of Douglas-fir. The Ponderosa Pine-Douglas-fir **Association** has Douglas-fir frequently present with covers usually greater than 5 percent in the overstory and understory combined. Douglas-fir is present in the Ponderosa Pine-California Black Oak **Association**, but covers are less than or equal to 1 percent and California black oak is present, generally with covers greater than 15 percent.

The relationship of draft and final **plant associations** in the Ponderosa Pine Series is shown below. The draft **association** is listed, with the final **association** below it, with the percentage of plots that make up the **association** (refer to Methods).

PIPO 4

PONDEROSA PINE-DOUGLAS-FIR

Pinus ponderosa-Pseudotsuga menziesii

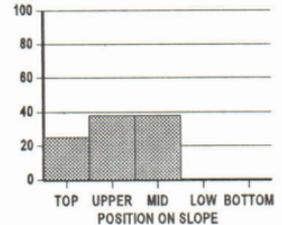

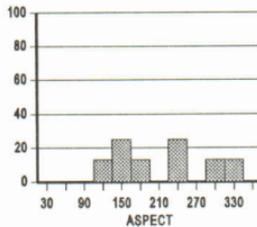

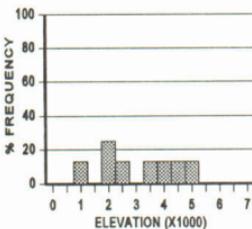

PIPO-PSME (N=8; BLM=6, FS=2)

Distribution. This Association occurs on the Ashland, Butte Falls, Glendale, and Grants Pass Resource Areas, Medford District, Bureau of Land Management. It also occurs on the Applegate Ranger District and may occur on the Ashland, Butte Falls, and Prospect Ranger Districts, Rogue River National Forest and the Galice Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This Association is slightly warmer and wetter than the Ponderosa Pine-California Black Oak Association, averaging 48 degrees F and 45 inches of precipitation annually. Douglas-fir is frequently present with an average cover of 24 percent. California black oak was present on three out of eight plots.

Soils. Parent materials are andesite, basalt, mixed ultramafics, schist, and diorite. Surface rock (defined as greater than 7 centimeters in size) cover averages 9 percent and exposed bedrock averages 2 percent. Bare ground averages 13

percent, significantly higher than the Ponderosa Pine-California Black Oak **Association**. Based on three plots sampled, surface texture is loam, with 20 to 40 percent gravel and cobbles. Subsurface texture is loam, with 60 percent cobbles

Environment. Elevation averages 3050 feet. Aspect is variable, though generally not north. Slopes average 32 percent with a range of 15 to 65 percent. Slope position ranges from mid-slope to ridgetops.

Vegetation Composition and Structure Total species richness averages 23 species, slightly higher than the Ponderosa Pine-California Black Oak **Association**. The overstory is dominated by ponderosa pine and Douglas-fir, both with relatively low covers, 16 and 17 percent respectively. The understory is dominated by ponderosa pine, with Douglas-fir frequently occurring. Incense-cedar, canyon live oak, and sugar pine commonly occur in the understory. Pacific madrone, Oregon white oak, golden chinquapin, and big-leaf maple are rarely present. Poison oak is the only commonly occurring shrub. Woodland tarweed and slender-tubed iris commonly occur while California fescue and woods strawberry occasionally occur. Many grasses may be present. Moss cover averages 4 percent.

On Bureau of Land Management sites, tree cover exceeding 10 feet tall (3 meters) averages 63 percent, while cover for tree species less than 10 feet tall averages 4 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 11 percent and cover for shrubs less than 20 inches tall averages 1 percent. Herb/grass cover averages 15 percent.

On Forest Service sites, upper layer tree cover averages 23 percent. Mid-layer tree cover also averages 23 percent, while lower layer tree cover averages 12 percent. High shrub cover averages 24 percent and low shrub cover averages 14 percent. Herb/grass cover averages 38 percent.

PIPO 6

PONDEROSA PINE-CALIFORNIA BLACK OAK

Pinus ponderosa-Quercus kelloggii

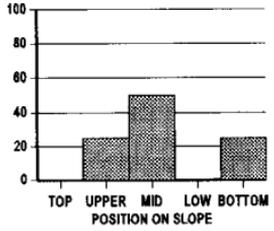

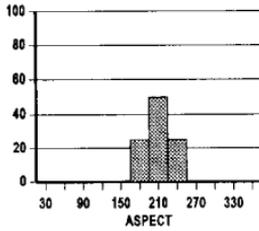

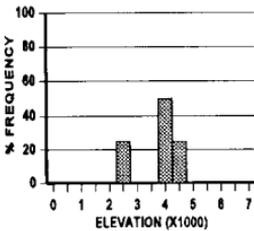

PIPO-QUKE (N=4, BLM=4)

NO PICTURE AVAILABLE

Distribution This **Association** occurs on the Ashland and Butte Falls Resource Areas, Medford District, Bureau of Land Management. It may also occur on all Ranger Districts of the Rogue River National Forest.

Distinguishing Characteristics This **Association** is slightly cooler and drier than the Ponderosa Pine-Douglas-fir **Association**, averaging 45 degrees F and 30 inches of precipitation annually. Douglas-fir, when present, has covers of less than 3 percent in both the overstory and the understory. California black oak is frequently present with covers usually greater than 15 percent.

Soils Parent material is mostly basalt or metavolcanic materials. Surface rock (defined as greater than 7 centimeters in size) cover averages 18 percent and exposed bedrock cover averages less than 1 percent. Bare ground averages less

than 1 percent, considerably less than the Ponderosa Pine-Douglas-fir **Association**. Based on four plots sampled, soil textures are silty clay loam, loam, or silty clay. Average rock fragment content is 13 percent, most of which is cobbles and stones (10 percent).

Environment Elevation averages 3820 feet. This **Association** is generally found on south to southwest aspects. Slopes average 22 percent, with a range of 0 to 45 percent. Slope position ranges from bottoms to the upper one-third.

Vegetation Composition and Structure Total species richness averages 19 species, slightly less than the Ponderosa Pine-Douglas-fir **Association**. The overstory is dominated by California black oak, while the understory is dominated by ponderosa pine and California black oak. California black oak cover averages 22 percent. Douglas-fir is also frequently present, but with covers of less than 3 percent. Deerbrush and common snowberry are common shrubs, while common vetch, woods strawberry, hedgehog dogtail, mountain sweet-root, white-flowered hawkweed, and slender-tubed iris are all frequent herbs. Moss is absent.

Tree cover exceeding 10 feet tall (3 meters) averages 57 percent, while cover for tree species less than 10 feet tall averages 2 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 10 percent, and cover for shrubs less than 20 inches tall is 0 percent. Herb/grass cover averages 40 percent.

TANOAK SERIES

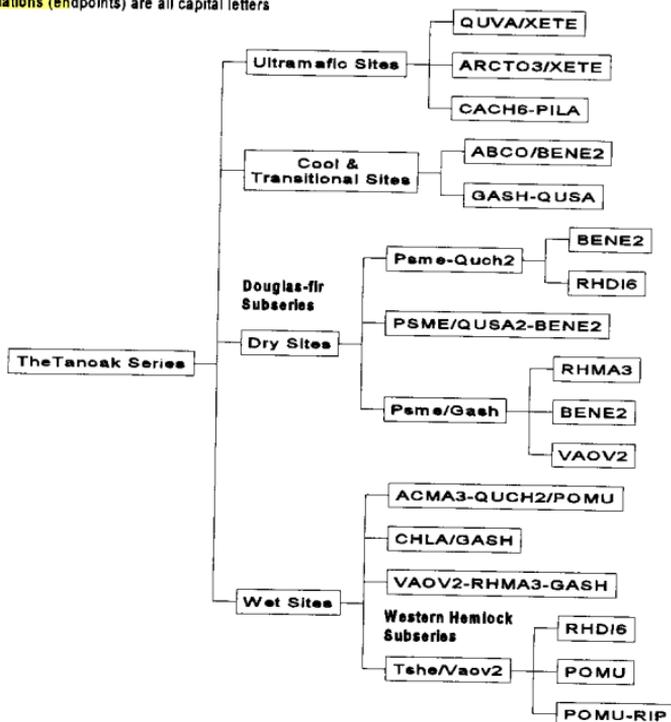

TANOAK SERIES

Lithocarpus densiflorus

LIDE3

Thomas Atzet

Lands climax to tanoak were classified into 17 **plant associations** and two subseries (Their hierarchical relationship is shown in the organizational chart below) Douglas-fir and western hemlock are co-climax with tanoak on the drier and wetter sites, respectively Each condition defines a subseries (a division of the series) Tanoak is climax in the moist middle of southwestern Oregon's environmental gradient The Douglas-fir Series and the Western Hemlock Series bracket tanoak's environmental range The Tanoak-Douglas-fir-Canyon Live Oak/Dwarf Oregongrape **Association** represents the drier end of the gradient Tanoak-Western Hemlock/Evergreen Huckleberry/Western Sword-fern-RIP (Riparian) represents the wet end Other **associations** are **associated** with ultramafic parent material, high elevation, or specific topographic positions, particularly lower slopes, canyon bottoms or riparian zones

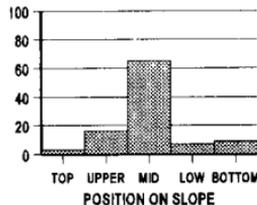

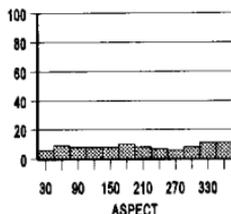

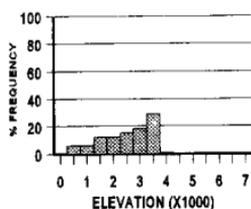

Hierarchical Relationship among the **associations****Associations** (endpoints) are all capital letters

Tanoak's range is limited to southwest Oregon and northwest California. Unlike many of its **associates**, frost, drought, and fire limit its survival and ability to compete. North of Coos Bay, and at elevations above 4000 feet, frost occurs more often and later in the spring, killing or damaging tanoak. To the south and inland, where marine precipitation and fog wane, drought resistant species are better adapted. Fire, like frost, periodically kills or damages tanoak, forcing it to use its root reserves, and keeping it in a reduced competitive condition. In the last 50 years, lack of fire has enhanced tanoak's competitive status. The effects on species composition and stand structure are evident, absolute cover and relative density have increased.

Tanoak is not climax throughout its range. Its major **associates** and competitors, Douglas-fir, Port-Orford-cedar, western hemlock, white fir, and even Jeffrey pine dominate sites well into late successional stages and will maintain dominance, even where tanoak is abundant. Observation, in southwest Oregon, suggests that within 100 years after a major disturbance, the dominant climax species has established itself. After 300 years, keying to the correct series is almost assured.

Tanoak is climax where frost events and drought occur less often: (1) in an inland midslope elevational belt below the high elevation cold, but above cold air accumulation in the valleys (mostly 2000 to 4000 feet, see the three figures below), (2) on the coast where marine air softens severe frosts and reduces summer evapotranspirational demand, (3) in protected inland, often north facing, coves, and (4) on ultramafic sites heavily modified by precipitation or by other normal rock types.

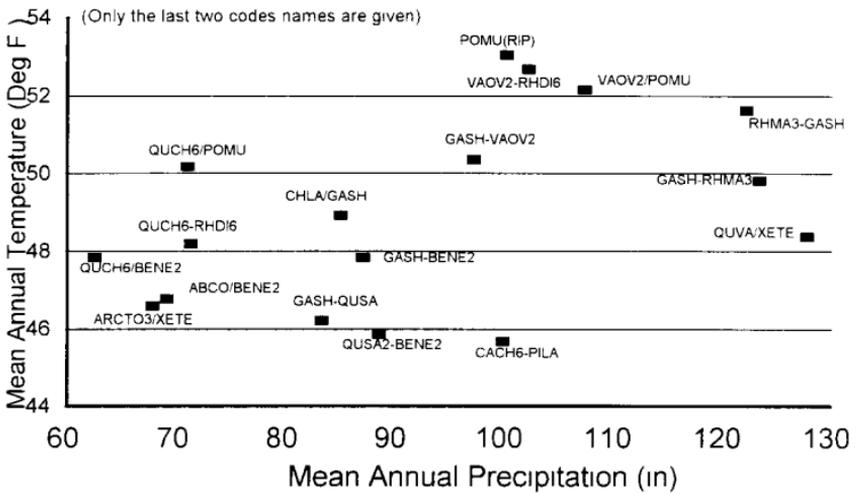

The three graphs below indicate where **associations** occur on the landscape. Few occur above 4000 feet in elevation, about 3000 feet seems optimum. Coastal **associations**, however, average about 1,000 feet. No particular aspect is favored, but a majority of the **associations** can be found on midslope positions. Three **associations**, Tanoak-Huckleberry Oak/Common Beargrass, Tanoak/Manzanita/Common Beargrass, and Tanoak-Golden Chinquapin-Sugar Pine are associated with ultramafic parent rock. Generally deep soils are the rule. Coastal **associations** tend to be **associated** with

sediments since most of the area west of the coast crest is sedimentary.

Relative temperature and precipitation of the **plant associations** are displayed in the Environmental Graph below on page LIDE3 3.

Environmental Graph

The dry inland **associations** are **associated** with low precipitation and generally cooler temperatures. Coastal **associations** appear in the upper right, representing the warm wet side of the gradient. Salal, dwarf Oregon grape, evergreen huckleberry, and Pacific rhododendron commonly occur in the warmer wet **associations** on the coastal side of the Coast Range crest. Except for evergreen huckleberry, they also occur on the east side where coastal influence modifies local climate, or where a combination of climate and topo-edaphic conditions are similar to the coastal climate.

While keying it is important to pay particular attention to the relative cover of evergreen huckleberry, Pacific rhododendron, salal, and dwarf Oregon grape. Each occupies a different environmental niche. Note that evergreen huckleberry is **associated** with warm, wet **plant associations**. It ranges from sea level to about 2500 feet in elevation and reaches maximum cover (most competitive) at about 1000 feet. Salal has a greater range. It occurs throughout southwestern Oregon, is less of a wet indicator, and reaches its maximum development at about 3500 feet in elevation. Dwarf Oregon grape is more competitive inland, particularly at higher elevations. It ranges from sea level to over 5500 feet and can attain greater than 10 percent cover regardless of the elevation. Pacific rhododendron is intermediate between evergreen huckleberry and salal.

Three other species, golden chinquapin, Sadler oak, and canyon live oak are fairly faithful indicators. Sadler oak, ranging from about 3000 to 5500 feet in elevation, usually occurs on cool to cold sites which are often rocky. Canyon live oak, insensitive to elevation, but sensitive to moisture, usually occurs on warm to hot sites. It is often **associated** with golden chinquapin when surface soil rock content is high.

LIDE3 4

The **association** key is constructed to reflect the classification concept. It is divided (hierarchically) into **associations** that occur on ultramafic sites, those that occur in cold or transitional sites, those that occur on inland dry sites, and those that occur west of the Coast Range crest on wetter sites. It is designed so that **associations** can be aggregated into subseries if **association** resolution is not needed. Additional upward aggregation into wet and dry tanoak is also possible.

Associations are part of a gradient that has been teased apart during analysis and made into **associations** at environmental breaks. All breaks are artificial, and may be difficult to recognize in the field. These concepts reflect how ecosystems exist and how they may be managed. Names (particularly long in this Series), are based on the dominant species of each layer, and are designed to highlight the hierarchy, yet reflect the vegetation continuum. Where Douglas-fir is co-climax, its name is used. The Western Hemlock Subseries is divided into three **associations** reflecting their position in the environmental gradient.

When working in the southern end of the Series range, check the "Key to Tanoak **Associations** in Northern California" by Thomas Jimerson in Region Five. A copy may be obtained by contacting the Six Rivers National Forest. The subseries and **associations** are similar and occasionally may describe sites more often found in California.

Plant associations appear in the text in the order they appear in the key. The key deals with **associations** related to ultramafic parent material first and moves through the **associations** generally from dry to wet (see the organization chart on Page LIDE3 1).

White and grand fir hybridize in southwest Oregon. They are difficult to distinguish in the field and at times even with laboratory data. Although coastal individuals have more grand fir morphological characteristics and inland samples appear more like white fir, we have chosen to call it all white fir, knowing there are an infinite variety of intergrades.

KEY TO THE TANOAK PLANT ASSOCIATIONS

Ultramafic parent material influenced associations

- 1a Ultramafic parent material or soils with ultramafic influence (serpentine/peridotite), western white pine (PIMO3) greater than 10 percent cover in the overstory and understory combined LIDE3-PIMO3/QUVA/XETE
Page LIDE3 10
- 1b Ultramafic parent material or soils with ultramafic influence (serpentine/peridotite), manzanita (ARCTO3) species dominating the shrub layer, Jeffrey pine (PIJE) absent. LIDE3/ARCTO3/XETE
Page LIDE3 12
- 1c Ultramafic parent rock or soils with ultramafic influence (serpentine/peridotite), Jeffrey pine (PIJE) usually present, golden chinquapin (CACH6) cover usually greater than 30 percent LIDE3-CACH6-PILA
Page LIDE3 14
- 1d Not as above 2
- 2a Drier sites usually east of the coastal crest at higher elevations and usually dominated by Douglas-fir (PSME) in the regeneration layer Canyon live oak (QUCH2), Pacific madrone (ARME), Golden chinquapin (CACH6), poison oak (RHD16), hairy honeysuckle (LOHI2), and common snowberry (SYMO) usually present in some combination "Dry associations" 3
- 2b Wetter sites usually west of the coastal crest or in inland coves on northerly aspects usually less than 2000 feet elevation Usually dominated by salal (GASH), and Pacific rhododendron (RHMA3) Western hemlock (TSHE), evergreen huckleberry (VAOV2), red alder (ALRU2), Oregon oxalis (OXOR), or western sword-fern (POMU) often present in some combination "Wet associations" 6
- 2c A mix of moist and dry, on lower slopes or in protected canyon bottoms Big-leaf maple (ACMA3) usually present with high cover (about 30 percent) LIDE3-ACMA3-QUCH2/POMU
Page LIDE3 16

“Dry **associations**” including part of the *Tanoak-Douglas-fir Subseries*
(see the flow chart on Page LIDE3 Tanoak 1)

- 3a Sadler oak (QUSA2) cover greater than 20 percent
LIDE3-PSME/QUSA2-BENE2
Page LIDE3 18
- 3b Sadler oak (QUSA2) absent or cover less than 20 percent 4
- 4a White fir (ABCO) frequently present in both the overstory and understory Poison oak (RHD16) canyon live oak (QUCH2), and sugar pine (PILA) absent or less than one percent cover
LIDE3-ABCO/BENE2
Page LIDE3 20
- 4b White fir (ABCO) regeneration rarely present or less than five percent cover Canyon live oak (QUCH2) frequently present at greater than 10 percent cover 5
- 5a Dwarf Oregongrape (BENE2) cover frequently greater than 10 percent, Douglas-fir regeneration cover less than 10 percent
LIDE3-PSME-QUCH2/BENE2
Page LIDE3 22
- 5b Dwarf Oregongrape (BENE2) cover frequently less than 10 percent and Douglas-fir (PSME) regeneration cover greater than 10 percent
LIDE3-PSME-QUCH2/RHD16
Page LIDE3 24

“Wet **associations**” including the *Tanoak-Western hemlock Subseries*

- 6a Salal (GASH) dominated Usually more than three miles from the coast Sugar pine (PILA), western twinflower (LIBOL), Port-Orford-cedar (CHLA) golden chinquapin (CACH6), common prince's-pine (CHUM), or Sadler oak (QUSA2) may be present 7
- 6b Evergreen huckleberry (VAOV2) dominated Usually coastal Western hemlock (TSHE), red alder (ALRU2), California-laurel (UMCA), salmonberry (RUSP), western sword-fern (POMU), or Oregon oxalis (OXOR) may be present or common 9

LIDE3 8

- 6c Big-leaf maple (ACMA3) and vine maple (ACCI) dominate, often riparian or lower slope positions LIDE3-ACMA3-QUCH2/POMU
Page LIDE3 16
- 7a Port-Orford-cedar (CHLA) often present in the overstory and co-dominant with tanoak (LIDE3) in the understory LIDE3-CHLA/GASH
Page LIDE3 26
- 7b Sadler oak (QUSA2) present, usually cover greater than 30 percent LIDE3-CACH6/GASH-QUSA2
Page LIDE3 28
- 7c Not as above Douglas-fir (PSME) coclimax with tanoak (LIDE3) 8

Wetter sites of the *Tanoak-Douglas-fir Subseries* (8a, 8b, 8c)
(Douglas-fir competes well with tanoak regeneration in the understory, salal (GASH) dominates the shrub layer)

- 8a Pacific rhododendron (RHMA3) is the most dominant secondary shrub, usually the driest sites of the three (8a, 8b 8c) LIDE3-PSME/GASH-RHMA3
Page LIDE3 30
- 8b Dwarf Oregongrape (BENE2) is the most dominant secondary shrub, usually higher elevation LIDE3-PSME/GASH-BENE2
Page LIDE3 32
- 8c Evergreen huckleberry (VAOV2) is the most dominant secondary shrub, moister sites of the three (8a, 8b, 8c) LIDE3-PSME/GASH-VAOV2
Page LIDE3 34

9a Evergreen huckleberry (VAOV2) dominates the shrub layer, Pacific rhododendron (RHMA3) with greater cover than salal (GASH) Driest coastal sites Poison oak (RHDI6), hairy honeysuckle (LOHI2), or California hazel (COCOC) may be present, western hemlock (TSHE) absent, and western sword-fern (POMU) less than five percent cover. LIDE3/VAOV2-RHMA3-GASH
Page LIDE3 36

9b Western hemlock (TSHE) present and co-dominant or subdominant to tanoak (LIDE3) Wet indicators such as red alder (ALRU2), salmonberry (RUSP), western sword-fern (POMU), Pacific yew (TABR2), and Oregon oxalis (OXOR) are often present and with high covers

10

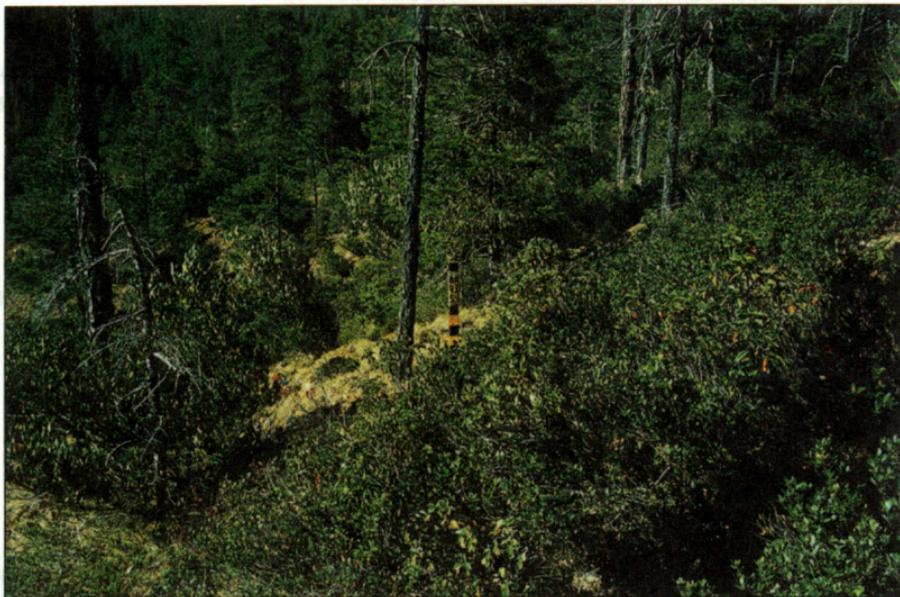

Tanoak-Western hemlock Subseries (10a, 10b, 10c)
Western hemlock (TSHE) competes with tanoak regeneration but remains subordinate or rarely co-climax The subseries is a gradient from dry (10a) to wet sites (10c)

10a Driest of the subseries Poison oak (RHDI6) present, usually with low cover LIDE3-TSHE/VAOV2-RHDI6
Page LIDE3 38

10b Moist sites, often north aspects and lower slope positions Western sword-fern (POMU) cover less than 35 percent, Oregon oxalis (OXOR) cover usually less than 5 percent LIDE3-TSHE/VAOV2/POMU
Page LIDE3 40

10c Wettest sites of the tanoak series, often riparian or adjacent to riparian sites Western hemlock (TSHE), western sword-fern (POMU), Oregon oxalis (OXOR), salmonberry (RUSP), red alder (ALRU2), and occasionally western redcedar (THPL) present Western sword-fern (POMU) cover greater than 50 percent, Oregon oxalis (OXOR) cover often greater than 20 percent LIDE3-TSHE/VAOV2/POMU-RIP
Page LIDE3 42

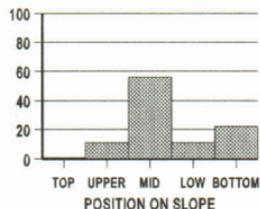

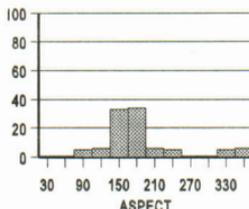

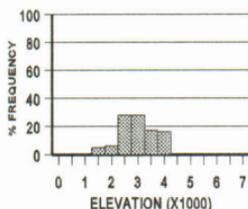

TANOAK-WESTERN WHITE PINE/HUCKLEBERRY OAK/COMMON BEARGRASS
Lithocarpus densiflorus-*Pinus monticola*/*Quercus vaccinifolia*/*Xerophyllum tenax*
 LIDE3-PIMO3/QUVA/XETE (N=9; FS=9)

Distribution. Although this Association is found throughout the Oregon range of the Tanoak Series, it is associated with ultramafic parent material or metamorphosed rocks influenced by ultramafics. Therefore, its distribution is dependent on the distribution of the host parent material. Also, it occurs on sites that are moderated by the Oceanic influence.

Distinguishing Characteristics. Ultramafic parent material, and a preference for south aspects, distinguishes this Association from all but two others in the Series, Tanoak/Manzanita/Beargrass and Tanoak-Golden Chinquapin-Sugar Pine. However, the constant presence and high cover of huckleberry oak is unique to this Association.

Soils. Parent material is usually ultramafic or the more basic rocks such as basalt or hornblend. Soils are usually shallow. Average depth is frequently greater than 10

inches Surface rock cover averages 34 percent Eight percent of the ground surface is commonly bare and an additional four percent is usually exposed bedrock

Environment Average elevation is 2600 feet Slopes average 30 percent Average annual temperature is about 48 degrees F and average annual precipitation is about 128 inches, the highest rate for the Tanoak Series Litter cover is relatively low (67 percent) and moss only covers 3 percent of the forest floor

Vegetation Composition and Structure Total species richness, very high for the Series is 30 The **Association** ranges on both sides of the coastal crest and has high niche diversity Western white pine, typical on open ultramafic sites, dominates the overstory but is subordinate to tanoak as regeneration Lodgepole pine is rarely present The typical species complement on ultramafic parent material includes western white pine, huckleberry oak, coffeeberry, box-leaved silk-tassel, red huckleberry, and common beargrass Because this **Association** can occur near the coast and moisture modifies the nutrient imbalance, it may include species more typical of normal parent material, such as evergreen huckleberry and salal Various species of manzanita may also be present, particularly on disturbed sites Iris species are often found with common beargrass, whipplevine, and toothleaf pyrola

<u>Herbs</u>				11
Common beargrass	XETE	100	4	
Whipplevine	WHMO	78	1	
Toothleaf pyrola	PYDE	78	1	

TANOAK/MANZANITA/COMMON BEARGRASS

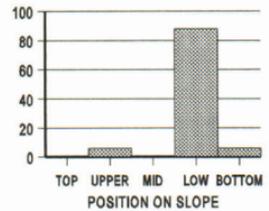

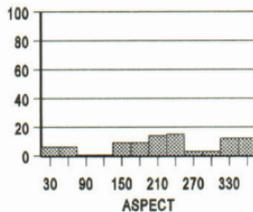

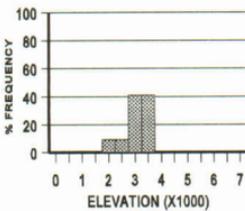

Lithocarpus densiflorus/*Arctostaphylos*/*Xerophyllum tenax*
LIDE3/ARCTO3/XETE (N=17; BLM=17)

Distribution. This Association is found east of the coastal crest in the Grants Pass Resource Area, Medford District, Bureau of Land Management, and the Illinois Valley and Galice Ranger Districts, Siskiyou National Forest. It rarely occurs in the Glendale Resource Area. All other known occurrences are east of Range 11 West.

Distinguishing Characteristics. The complement of species indicates that soils, although not always ultramafic, are at the basic end of the gradient, or may be mixed with ultramafics such as serpentine, dunite, or peridotite. This Association occurs at relatively high elevations for the Series (3300 feet) and has a small elevational range. It is one of the coolest and driest tanoak associations.

Soils. Soils are often reddish and basic. Based on 17 samples, average depth is at least greater than 16 inches. Textures are silt loams and sandy loams with some sandy clay loams. Rock fragment content, mostly gravel, averages 56 percent.

Environment Variability in elevation is low. About 70 percent of the sites occur between about 3000 and 3700 feet. Slopes average about 40 percent. Sites occur on all aspects, but slightly more often on those facing north. Average annual temperature is about 47 degrees F and average annual precipitation is about 68 inches, the second lowest rate for the Series. Manzanita species indicate dry sites, but they can also invade severely disturbed moist sites. In this case, they indicate the site's lack of available moisture, as the precipitation rate reflects.

Vegetation Composition and Structure Total species richness, very low for the Series, is 16. Site productivity is limited by the influence of basic (occasionally ultramafic) parent material and shallow soils. Douglas-fir usually dominates the overstory and ponderosa pine may also be present. Its presence indicates that the ultramafic influence is weak. On serpentine, a common ultramafic parent material, Jeffrey pine is almost exclusively the dominant pine. The reddish soils and the occurrence of squawcarpet on nearby cutbanks is an indication of the high iron and magnesium content of the soil. The shrub layer is dominated by manzanita species. Manzanita species are indicative of hot, dry sites. They may also be a result of repeated or intense disturbance. Although many sites have been burned or disturbed, the integration of parent materials and climate support a unique complement of species in this Association. Common beargrass is the most constant herb present. Common prince's-pine and whipplevine are commonly present.

TANOAK-GOLDEN CHINQUAPIN-SUGAR PINE

Lithocarpus densiflorus-Castanopsis chrysophylla-Pinus lambertiana

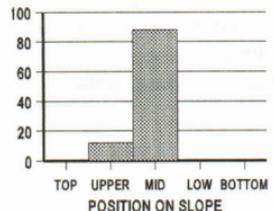

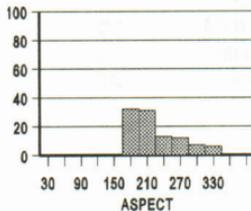

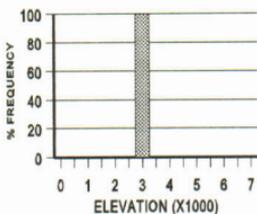

LIDE3-CACH6-PILA (N=8; BLM=8)

Distribution. This unusual **Association** is found only in the Grants Pass Resource Area, Medford District, Bureau of Land Management. It seems to be confined to Township 35 South, Range 9 West. It may be found elsewhere on high elevation, south aspects, if the soils are ultramafic or basic. Validation of its presence in other townships is welcome.

Distinguishing Characteristics. This **Association** has only been found in a limited area. Average elevation is 3600 feet. Sites are located between 3200 and 3800 feet. Aspects are usually south to southwest and sites are **associated** with mid to upper slope topographic positions. Ultramafic parent material, and **associated** flora, such as huckleberry oak and coffeeberry characterize the **Association**.

Soils. Parent material is usually a mix of granodiorite, ultramafics, and mixed volcanic. Samples occur on an *aureole* (an area where granodiorite was intruded

through serpentine) and rock types are well mixed. Average depth is at least greater than 14 inches, based on nine samples. Textures are sandy loams. Rock fragment content averages 73 percent, most of which is cobbles and stones (41 percent).

Environment Elevation averages 3600 feet. Slopes average about 37 percent. Sites occur predominately on southwest aspects, but occasionally may occur on northwest aspects. Average annual temperature is a cool 46 degrees F (lowest for the Series) and average annual precipitation is 100 inches.

Vegetation Composition and Structure Total species richness, very low for the Series, is 14. Although this **Association** is limited in extent, ultramafic sites usually have a high herbaceous diversity. Herbs are often ephemeral and difficult to find, particularly where soil surface moisture is quickly depleted. Diversity estimates are subject to seasonal variation, and a one time sample, if taken late in the season, may be inaccurate. Jeffrey pine dominates the overstory, but tanoak regeneration is much more abundant in the understory. Typical ultramafic flora evenly dominates the shrub layer. Dwarf Oregongrape is the least tolerant of the calcium/magnesium imbalance characteristic of ultramafic soil, and is rarely found with cover greater than 5 percent. The manzanitas and bracken may also partly reflect repeated low intensity disturbance.

TANOAK-BIG-LEAF MAPLE-CANYON LIVE OAK/WESTERN SWORD-FERN
Lithocarpus densiflorus-*Acer macrophyllum*-*Quercus chrysolepis*/*Polystichum munitum*
 LIDE3-ACMA3-QUCH2/POMU (N=9; BLM=9)

Distribution. This Association is found east of the coastal crest (east of Range 11 West) in the Grants Pass and Glendale Resource Areas, Medford District, Bureau of Land Management, and in the Illinois Valley and Galice Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. Associated with inland sites, this Association occurs on all aspects, slightly more often on milder north and east faces, and below the upper third topographic positions. It also occurs across a wide range of elevations, from near the valley floor to over 3500 feet. The flora is a combination of "wet" and "dry" species, since it commonly occupies steep canyon walls with shallow soils or soils with high amounts of gravel (soils can dry quickly). However, these sites are protected from the wind and sun, and maintain high humidity throughout the day.

Soils Parent material can be metavolcanic, metasediment, ultramafic and sandstone. Soils are usually deep. Based on nine samples average soil depth is at least greater than 20 inches. Textures are silt loams, or sandy loams with some clay loams and loamy sand. Rock fragment content, mostly gravel (67 percent), averages 74 percent.

Environment Elevation ranges from about 500 feet to over 3500 feet and averages over 1900 feet. Slopes average 66 percent. Sites occur on all aspects, but slightly more often on those facing north. Average annual temperature is a warm 50 degrees F and average annual precipitation is only 71 inches, well into the dry end of the moisture gradient. Wet species are supported by atmospheric moisture, fog, and high humidity. See the Environmental Graph on page LIDE3 3.

Vegetation Composition and Structure Total species richness, low for the Series, is 18. Douglas-fir dominates the overstory, but is less than half as abundant in the understory. Nearly 30 percent cover of big-leaf maple is unusual for the Series. Big-leaf maple is less common in the southern third of Oregon. It occurs sporadically and total cover rarely exceeds 10 percent. The highest density and cover of big-leaf maple occurs at 3600 feet in elevation. Even at its elevational peak, average cover for the Siskiyou Mountain Province is only one percent. It is most common in riparian topography, where it competes well with tanoak. Oregon ash may be present, an indication of lower slope, wet soils. Rather than the four most common species (evergreen huckleberry, salal, Pacific rhododendron, and dwarf Oregongrape) of the wetter sites of the Series, the shrub layer is dominated by three shrubs that characterize the drier end of the moisture gradient, hairy honeysuckle, poison oak and California hazel. Western sword-fern will almost always be present, but averages less than 10 percent cover. Whipplevine cover increases on drier sites. Rattlesnake-plantain is ever present, as in every wooded site.

TANOAK-DOUGLAS-FIR/SADLER OAK-DWARF OREGONGRAPE

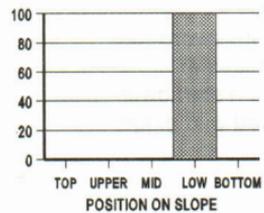

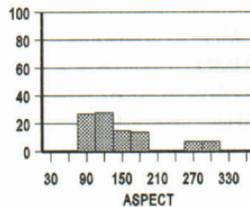

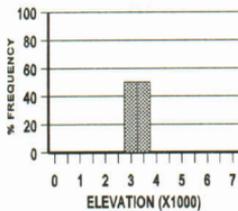

Lithocarpus densiflorus-*Pseudotsuga menziesii*/*Quercus sadleriana*-*Berberis nervosa*
LIDE3-PSME/QUSA2-BENE2 (N=7; BLM=7)

Distribution. This **Association's** range is limited to the northwest corner of the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may be found elsewhere in the immediate vicinity at similar elevations on similar parent material. However, it is a separate **association** because of its unique complement of flora and potential differences in management response.

Distinguishing Characteristics. This **Association** most often occurs on sandstone. Soils are shallower than other tanoak **associations**. Aspects are more often southerly, and sites are **associated** with lower slope positions. The average elevation is high (3600 feet) and lacks variability; the standard deviation is less than 300 feet. The occurrence and high cover (43 percent) of Sadler oak is its most distinguishing characteristic.

Soils. This **Association** occurs on sandstone where soils are usually moderately

deep Average depth is at least greater than 14 inches (pits were not dug to bedrock) Soil textures are mostly sandy loam Based on seven samples average rock fragment content is 52 percent, 50 percent is in the gravel size class

Environment Elevation averages about 3600 feet Average annual temperature is about 46 degrees F Average annual precipitation is about 87 inches, the lowest for the Series (cool and relatively dry) Slopes average 45 percent and are usually steeper than most other associations See the graph on page LIDE3 3

Vegetation Composition and Structure Total species richness is the second lowest of the Series (15) All layers lack richness The Association is not extensive and often has high surface rock content, a condition that may depress survival of shallow rooted species Although typically dominated by Douglas-fir and less so, by sugar pine, this Association may often have some early seral species, most typically knobcone pine Competition in the understory is usually high among tanoak, golden chinquapin, and Douglas-fir Canyon live oak is commonly present and sugar pine is occasional Sadler oak dominates the shrub layer, but dwarf Oregongrape is usually present Red huckleberry, a widely occurring forest species lacking indicator value in the Tanoak Series, is common Little prince's-pine and common prince's-pine are the dominant herbs They are also common and seem to lack indicator value Rattlesnake-plantain, present in almost every forest stand, is also present Oregon fairybell may be found in the spring before moisture stress limits growth and survival

TANOAK-WHITE FIR/DWARF OREGONGRAPE
Lithocarpus densiflorus-Abies concolor/Berberis nervosa
 LIDE3-ABCO/BENE2 (N=41; BLM=41)

Distribution. This Association occurs on the east side of the coastal crest (western Glendale Resource Area and eastern Galice Ranger District), mostly north of Township 37 South. It occurs less often in the Illinois Valley (southern Grants Pass Resource Area and eastern Illinois Valley Ranger District).

Distinguishing Characteristics. This Association is the driest and coolest on normal or non ultramafic parent material. White fir is occasional in the overstory. Average elevation (3300 feet) is higher than most other tanoak associations (about 85 percent of sites occur above 2700 feet). Like most other tanoak associations, however, it occurs on all aspects. It occurs on lower third and bottom topographic positions.

Soils Parent material varies from metavolcanic to metasediment, often sandstone, averaging at least 16 inches. Based on 34 samples, textures are silt loams, with some silty clay loams and sandy loams.

Environment Average elevation is about 3300 feet. The **Association** occurs on all aspects. Slopes average 42 percent, but occurrence is mostly limited to the bottom and lower slope topographic positions. Average annual temperature is about 47 degrees (F), and average annual precipitation is approximately 69 inches.

Vegetation Composition and Structure Total species richness, low for the Series, is 20. Although the tree and shrub layer are below average, the herb layer is rich. Douglas-fir dominates the overstory, white fir is occasional. Douglas-fir, and tanoak, will continue to thrive but not dominate the understory. White fir regeneration, averaging 22 percent cover, indicates the cooler tanoak sites. Pacific madrone, common within the Series, is an indicator of disturbance. Western redcedar, Port-Orford-cedar, and incense-cedar rarely occur. Dwarf Oregongrape, common throughout the Series and this **Association**, indicates deep soils which are common in the Series. Western twinflower and western sword-fern occasionally occur.

TANOAK-DOUGLAS-FIR-CANYON LIVE OAK/DWARF OREGONGRAPE
Lithocarpus densiflorus-Pseudotsuga menziesii-Quercus chrysolepis/Berberis nervosa
 LIDE3-PSME-QUCH2/BENE2 (N=72; BLM=52, FS=20)

Distribution. This Association occurs on the western Glendale Resource Area, eastern Galice Ranger District, southwestern Grants Pass Resource Area and east Illinois Valley Ranger District. It is evenly distributed throughout the area, however, most sites are east of Range 11 West, east side of the coastal crest.

Distinguishing Characteristics. This Association commonly occurs on all parent materials, all aspects, and on a variety of slope positions. Its elevational range is also wide. There are no key distinguishing environmental characteristics. Species presence and relative abundance are the basis for keying this Association.

Soils. Parent material can be metavolcanic, metasediment, sandstone, andesite, basalt, greywacke and less commonly, diorite or gabbro. Based on 52 plots, soil depth averages greater than 42 inches. Textures are silt loams with some silty clay

loams and sandy loams. Rock fragment content, mostly gravel, averages 38 percent. Surface rock cover averages 13 percent.

Environment Elevation averages about 2900 feet. The average is slightly higher on Bureau of Land Management lands (3100 feet) compared to Forest Service lands (2700 feet). Average annual temperature is about 48 degrees F, cool for the Series, and average annual precipitation is about 63 inches, the driest of the Series. Slopes average about 49 percent, litter cover averages 88 percent and moss cover averages 17 percent. See graph on page LIDE3 3.

Vegetation Composition and Structure Total species richness, highest for the Series, is 35. This **Association** has an extensive environmental range, which helps to diversify the tree layers. Sugar pine is far less abundant than Douglas-fir, but is typical in inland sites of the Series. Jeffrey pine, ponderosa pine, and California black oak are rarely found, and Port-Orford-cedar is rare on the wetter, sometimes ultramafic, sites. Dwarf Oregongrape, common on inland, higher elevation sites, is the most frequently occurring shrub, but may be less abundant than salal on some sites. Poison oak cover is low, and it most commonly occurs on the drier sites. Red huckleberry, conversely, is more common on the wetter sites. Similarly, whipplevine and western twinflower represent drier and wetter sites, respectively. Western sword-fern may also be present, but the inland, dry site variety usually found in this **Association** is not an indication of high soil moisture.

TANOAK-DOUGLAS-FIR-CANYON LIVE OAK/POISON OAK

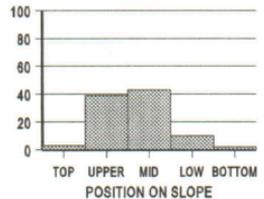

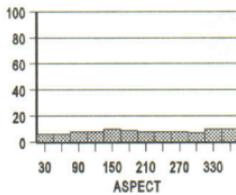

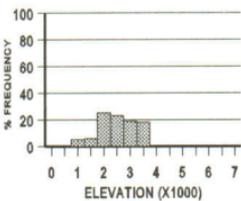

Lithocarpus densiflorus-*Pseudotsuga menziesii*-*Quercus chrysolepis*/*Rhus diversiloba*
 LIDE3-PSME-QUCH2/RHDI6 (N=89; FS=75, BLM=14)

Distribution. This **Association** occurs on the east side of the coastal crest (western Glendale Resource Area, eastern Galice Ranger District, southwest Grants Pass Resource Area and east Illinois Valley Ranger District). It may be found closer to the coast on the Chetco and Gold Beach Ranger Districts. It most commonly occurs on the northeast Galice Ranger District and the northwest Grants Pass Resource Area.

Distinguishing Characteristics. Although this **Association** occurs on a variety of parent materials, slope positions and aspects, it most often occurs between 2000 and 4000 feet in elevation. It occurs on inland sites in combination with poison oak and hairy honeysuckle. It is one of the drier tanoak **associations** and rarely occurs in bottom positions.

Soils. This **Association** occurs on any parent material, including ultramafics. Surface

rock is usually high, varying from 7 percent to higher than 63 percent. Based on seven samples, average depth is greater than 36 inches. Surface textures are mostly loam to silty clay loam, with 20 to 90 percent gravel, cobbles and stones.

Environment. Elevation averages about 2600 feet. Average annual temperature is about 48 degrees F and average annual precipitation is about 71 inches. This **Association** occurs on all aspects, but is most common on the mid to upper slopes. Slopes average about 55 percent. Moss cover, typically positively related to increasing temperature and atmospheric moisture, averages only 16 percent.

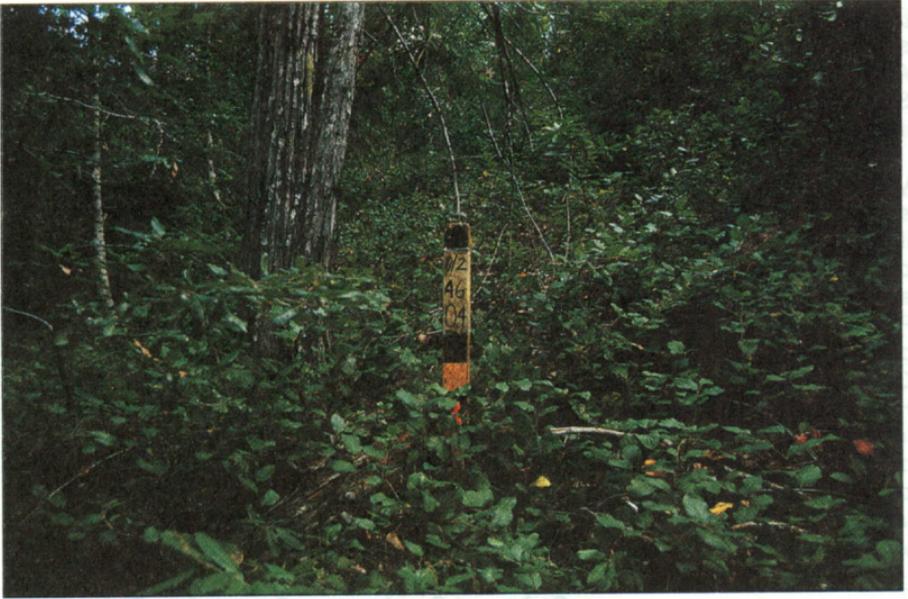

Vegetation Composition and Structure. Total species richness, intermediate for the series, is 26. This **Association's** range is limited. Thus, niche diversity may be limited, but the understory supports more species than the Series average. Sugar pine rivals Douglas-fir in constancy, but not cover. The drier sites may rarely support Oregon white oak, and California-laurel may be found on the wetter sites. Rarely will knobcone pine or Port-Orford-cedar be present. Typically, baldhip rose is present at low cover. In this **Association**, salal indicates the wetter sites, while California hazel and creeping snowberry are occasional to rare on the drier sites. Hairy honeysuckle and poison oak, both common shrubs, are particularly faithful indicators of dry sites. The strength of their indication is greatest when they co-occur. Although western starflower, pathfinder, Scouler's harebell, and catchweed bedstraw are often present, they wither in early summer and may not be evident later. These ephemeral species may not be evident when keying late in the Fall. Whipplevine, the most common herb, however, is evident most of the year.

TANOAK-PORT-ORFORD-CEDAR/SALAL

Lithocarpus densiflorus-Chamaecyparis lawsoniana/Gaultheria shallon

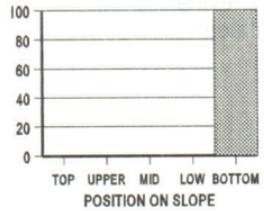

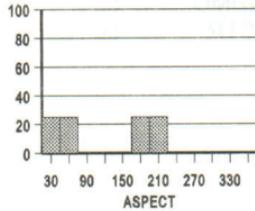

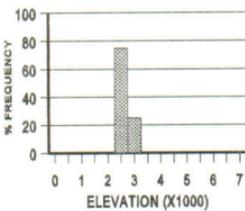

LIDE3-CHLA/GASH (N=4; FS=4)

Distribution. This uncommon **Association** is scattered throughout the Siskiyou National Forest and possibly the Medford District, Bureau of Land Management. It is closely **associated** with bottoms, concavities, or streams. It occurs on the Gold Beach, Illinois Valley, and Galice Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. Although uncommon on the general landscape, this **Association** occurs in drainage concavities of lower slopes. It is the transition between the Port-Orford-cedar and Tanoak Series. In deeper, primary drainages, Port-Orford-cedar is usually the climax dominant. Because it occurs in protected topography, it may be found on all aspects. Several other tanoak **associations** contain Port-Orford-cedar, but with lower cover and constancy. The presence and relative cover of Port-Orford-cedar is the most reliable key characteristic.

Soils. Parent material is usually andesite, basalt or schist. Soil depth averages at

least 31 inches deep Surface rock and gravel average 8 percent and 19 percent respectively

Environment The average elevation is about 2400 feet Aspects may vary It is, however, exclusively a bottomland **association** Slope averages 29 percent with a range of 11 to 48 percent Average annual temperature is about 49 degrees F, moderate for the Series Average annual precipitation is approximately 85 inches, also moderate for the Series

Vegetation Composition and Structure Total species richness, high for the Series is 29 Although the **Association** is based on a few samples (N=4), it is the third most rich, possibly because it is extensively distributed Douglas-fir dominates the overstory, Port-Orford-cedar occurs in both the overstory and understory and is co-climax with tanoak Canyon live oak occurs in the driest sites Conversely, red alder occurs on disturbed, moist sites Salal, dwarf Oregongrape, evergreen huckleberry Pacific blackberry, common prince's-pine, and rattlesnake-plantain frequently occur Sedge is occasional, but abundant, where soils are commonly moist As distance to the coast decreases, bottoms are more likely to be climax to Port-Orford-cedar

TANOAK-GOLDEN CHINQUAPIN/SALAL-SADLER OAK

Lithocarpus densiflorus-Castanopsis chrysophylla/Gaultheria shallon-Quercus sadleriana

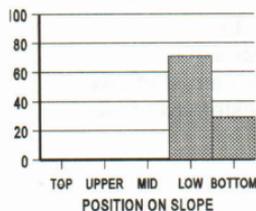

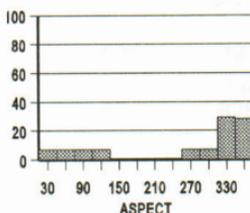

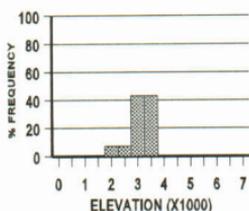

LIDE3-CACH6/GASH-QUSA2 (N=7; BLM=7)

Distribution. This Association occurs within the Grants Pass Resource Area and is associated with a mix of parent materials. Relatively high in elevation for the coastal crest area, it may host ice age relics (see the office guide discussion). It occurs in Township 34 South, Range 8 West, and Township 35 South, Range 9 West but may be found in the general vicinity.

Distinguishing Characteristics. This Association, like Tanoak-Golden Chinquapin-Sugar Pine, occurs on high elevation, inland sites. Average elevation is 3300 feet. Unlike, Tanoak-Golden Chinquapin-Sugar Pine, it is associated with normal soils, avoids south aspects and is on lower slope and bottomland topographic positions. Although golden chinquapin is common to both associations, Sadler oak dominates the shrub layer of this Association.

Soils. Parent material can be granodiorite, mixed metavolcanic, intrusive volcanic,

or even ultramafic. Average depth is greater than 18 inches, based on seven plots. Textures are silt loam or sandy loams. Rock fragment content, mostly gravel (30 percent is of gravel size), averages 38 percent.

Environment Elevation averages 3300 feet. Slopes average 50 percent. Sites predominately occur on north aspects. Average annual temperature is a cool 46 degrees F and average annual precipitation is 83 inches.

Vegetation Composition and Structure Total species richness, low for the Series, is 16. Niche diversity is very low. Typically, Douglas-fir and sugar pine comprise the majority of the overstory cover. The understory sustains a variety of species. Golden chinquapin, competitive with tanoak, often indicates rocky soils. Rarely, western hemlock or Port-Orford-cedar may be present in the understory, but only on the wettest sites. Sadler oak and golden chinquapin indicate a variation in the salal dominated **associations**. Both species are usually **associated** with rocky sites. Cover in the herb layer is usually lacking, possibly a result of rocky well drained soil.

TANOAK-DOUGLAS-FIR/SALAL-PACIFIC RHODODENDRON

Lithocarpus densiflorus-Pseudotsuga menziesii/Gaultheria shallon-Rhododendron macrophyllum

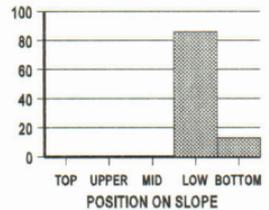

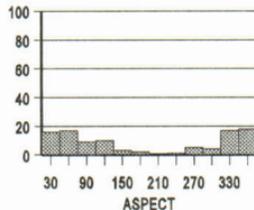

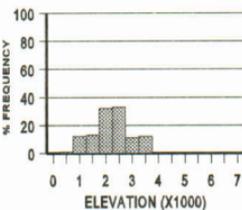

LIDE3-PSME/GASH-RHMA3 (N=80; NRCS=46, BLM=34)

Distribution. This common **Association** occurs on both sides of the coastal crest. It is common throughout the western Siskiyou National Forest and the Myrtlewood Resource Area of the Coos Bay District, Bureau of Land Management. It is also commonly found east of the coastal crest, north of Township 36 South. It only rarely occurs in the Illinois Valley area.

Distinguishing Characteristics. Sites occur on both sides of the coastal crest, mostly on lower slope or bottom topographic positions. Most sites occur on sandstone. North aspects are favored, particularly on inland sites. Like other **associations** that straddle the crest, relative cover of species can be used to distinguish among the **associations**.

Soils. Sandstone is the most common parent material. However, sites can also be

ultramafic or gabbro. Based on 34 samples, average soil depth is greater than 39 inches. Textures are mostly sandy loam, less often silt loam and silty clay loam. Average rock fragment content is 48 percent, mostly gravel (averaging 41 percent) in size.

Environment Elevation averages about 2500 feet. Average annual temperature is about 50 degrees F. Average annual precipitation is about 123 inches, the second highest rate for the Series. Slopes average 34 percent, but can be steeper, particularly on inland sites. Pacific rhododendron and evergreen huckleberry are subordinate to salal, since elevation is near the high end of the Series range. Evergreen huckleberry cover is highest at approximately 1000 feet in elevation.

Vegetation Composition and Structure Species richness, low for the Series, is 26. Occurrence of this Association is localized, therefore, environmental variation is low. Shrub and herb richness are below the Series average. The overstory is the usual complement of species including golden chinquapin, sugar pine, Pacific madrone, and tanoak. Rarely, white fir and western white pine may be found, particularly at the higher elevations. Typically, tanoak dominates the regeneration layer. Douglas-fir is a common competitor. Golden chinquapin, common in this Association, often indicates rockier soils. Rarely, wet site indicators such as western hemlock, western redcedar, Pacific yew, and red alder may be present at low cover. Salal and Pacific rhododendron totally dominate the shrub layer. Rarely, on the driest sites, poison oak or hair honeysuckle may be present. Common beargrass is more abundant on the drier sites, while western sword-fern characterizes the wettest sites. Braken rarely occurs, but when present, it is often abundant.

TANOAK-DOUGLAS-FIR/SALAL-DWARF OREGONGRAPE

Lithocarpus densiflorus-*Pseudotsuga menziesii*/*Gaultheria shallon*-*Berberis nervosa*
LIDE3-PSME/GASH-BENE2 (N=71; BLM=45, NRCS=26)

Distribution. Except for several sites just west of the coastal crest, this **Association** occurs mostly on the east side. Medford Bureau of Land Management District sites straddle the Grants Pass and Glendale Resource Areas. Only a few sites were found south of Township 36 South in the Grants Pass Resource Area. Most Forest Service sites are on the Gold Beach Ranger District, Siskiyou National Forest, although the **Association** may be found further south.

Distinguishing Characteristics. Most sites occur east of the coastal crest on lower slope or bottom positions. Soils are usually sandstone. Climate is slightly cooler and drier than the average tanoak site, thus its difficult to key in the field. Dwarf Oregongrape's consistent presence, at cover greater than 5 percent, contrasted with the relative lack of evergreen huckleberry and Pacific rhododendron, separate this **association** from others in the Series.

Soils Sandstone is the most common parent material. Less often sites are diorite or ultramafic. Based on 45 samples, average soil depth is greater than 38 inches. Textures are mostly sandy loam and silt loam, less often sandy clay loam. Average rock fragment content is 44 percent, mostly gravel size.

Environment Elevation averages about 2800 feet, coastal sites are slightly lower. Average annual temperature is about 48 degrees F. Average annual precipitation is about 87 inches. This combination seems to favor dwarf Oregon grape over salal, evergreen huckleberry, and Pacific rhododendron, the three most common shrubs associated with tanoak. Dwarf Oregon grape, however, has a greater elevational range than any of the three. It is more common on higher sites. Slopes average 39 percent, but can be greater than 60 percent. See the graph on page LIDE3 3.

Vegetation Composition and Structure. Total species richness, high for the Series, is 26. Tree layers are richer than most other associations. As usual, the overstory is dominated by Douglas-fir. Golden chinquapin is found in both tree layers, while western hemlock is rarely present. In addition to the species listed in the table below, the wetter site indicators, Pacific yew, red alder, and big-leaf maple may also be present. Salal dominates most sites and baldhip rose is usually present (it is of limited use, however as it only indicates that you are in the woods). Evergreen huckleberry is present on the wettest sites and occasionally poison oak or hairy honeysuckle may be present (consistent indicators of the driest sites). Common beargrass and whipplevine are the more abundant herbs, but some of the more ephemeral species, such as western starflower and vanillaleaf, may also be present.

TANOAK-DOUGLAS-FIR/SALAL-EVERGREEN HUCKLEBERRY

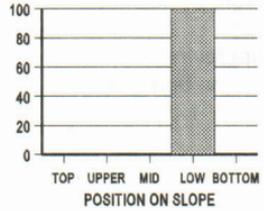

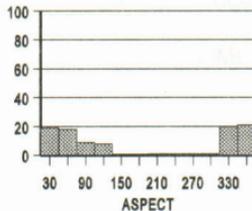

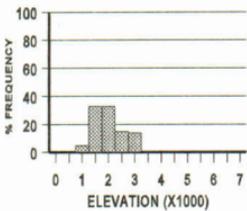

Lithocarpus densiflorus-Pseudotsuga menziesii/Gaultheria shallon-Vaccinium ovatum

LIDE3-PSME/GASH-VAOV2 (N=41; NRCS=28, BLM=13)

Distribution. This Association straddles the coastal crest, but is mostly confined to the Glendale Resource Area and the Gold Beach Ranger District. Most sites are north of Township 37 South, only a few occur further south. The most westerly known occurrence is less than a mile from the Pacific Ocean. The northern Grants Pass Resource Area is likely to support this Association.

Distinguishing Characteristics. Because most coastal associations are on sediment, geologic material is not often an effective discriminator. This Association is highly associated with the lower third slope positions and is rarely found on south aspects. Its elevational range is high for coastal associations, but low for inland sites. Climate is moderate, mostly warm and wet. Evergreen huckleberry and salal are greater in relative abundance than dwarf Oregon grape and Pacific rhododendron.

Soils Parent material is mostly metasediment and sandstone. Based on 13 samples, average soil depth is greater than 52 inches. Textures are mostly silt loam and sandy loam. Average rock fragment content is 53 percent, mostly gravel size.

Environment Elevation averages about 1750 feet and variability is low. Slopes average about 45 percent. Coastal sites are less steep, but highly variable. Average annual temperature is 50 degrees F and average annual precipitation averages 97 inches. This **Association** is in the warm, wet quadrant of the environmental grid. See the Environmental Graph on page LIDE3 3.

Vegetation Composition and Structure Total species richness, low for the Series, is 20. There are few understory species and the number of herbaceous species is low. The drier sites of this **Association** may support canyon live oak and creambush ocean-spray, while Pacific yew, western redcedar, red alder, or salmonberry (salmonberry usually occurs on the very wettest sites) may be present at very low cover. Typically, tanoak and Douglas-fir dominate the regeneration layer. Canyon live oak and creambush ocean-spray, together, indicate the drier sites. Pacific rhododendron is low in cover compared to other Tanoak-Douglas-fir **associations** dominated by salal. Pacific rhododendron seems to be less competitive with evergreen huckleberry and salal closer to the coast. Conversely, western sword-fern and Oregon oxalis increase in cover toward the coast. They are the dominant herbs, while evergreen violet is commonly present, but averages only one percent cover.

TANOAK/EVERGREEN HUCKLEBERRY-PACIFIC RHODODENDRON-SALAL
Lithocarpus densiflorus/Vaccinium ovatum-Rhododendron macrophyllum-Gaultheria shallon
 LIDE3/VAOV2-RHMA3-GASH (N=36; FS=36)

Distribution. Found entirely west of Range 11 West, this **Association** is confined to the Myrtlewood Resource Area, Medford District, Bureau of Land Management and Gold Beach and Chetco Ranger Districts, Siskiyou National Forest. It is not likely to occur north of Township 34 South.

Distinguishing Characteristics. Mostly **associated** with coastal sediments, this extensive **Association** occurs on all aspects and all but ridgetop slope positions. It also occurs over a wide range of elevations. The relative cover of the four most common shrubs, evergreen huckleberry, salal, Pacific rhododendron, and dwarf Oregongrape, is the most discriminating key characteristic.

Soils. Parent material is usually sedimentary, often sandstone and less often siltstone, mudstone, conglomerate or shale. Soils are moderately deep to deep. Average depth is greater than 44 inches. Surface rock cover averages 10 percent.

Environment Elevation ranges from about 500 feet to over 3000 feet, and averages about 1400 feet Slopes average 38 percent Sites occur on all aspects, but slightly more often on those facing north Average annual temperature is about 52 degrees F and average annual precipitation is about 122 inches, the third highest rate for the Series Litter cover on the forest floor averages 95 percent Moss cover averages 20 percent See the Environmental Graph on page LIDE3 3

Vegetation Composition and Structure Total species richness, very low for the Series, is 17 Site domination by tanoak, evergreen huckleberry, Pacific rhododendron, and salal seem to limit herbaceous diversity Douglas-fir is the only overstory species to attain greater than 50 percent cover Diversity for the tree layer is low (richness averages one) Microsite temperature and moisture differences in the herb layer can be contrasted using western sword-fern and common beargrass as opposite extremes Braken is usually an early seral, opportunistic species invading disturbed ground Once established, however, it is persistent

TANOAK-WESTERN HEMLOCK/EVERGREEN HUCKLEBERRY-POISON OAK

Lithocarpus densiflorus-Tsuga heterophylla/Vaccinium ovatum-Rhus diversiloba

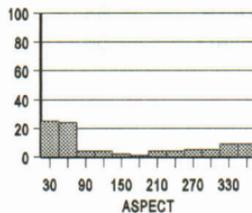

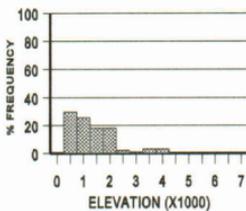

LIDE3-TSHE/VAOV2-RHDI6 (N=39; NRCS=39)

Distribution. This widely occurring **Association** is found mostly west of Range 10 West, scattered inland within two miles of the Pacific Ocean (Myrtlewood Resource Area, Gold Beach, Chetco, and Powers Ranger District. Its most eastern extent is up the Rogue River canyon. Only rare disjunct occurrences can be found in the eastern Glendale Resource Area.

Distinguishing Characteristics. This is the driest of the coastal **associations**. It is relatively low in elevation and tends to occur more often on north than south aspects. Although low in cover, poison oak and hairy honeysuckle are important discriminators, since together they are faithful indicators of soils that can develop severe moisture stress.

Soils. Soil data are not available.

Slope position data are not available.

Environment Elevation averages about 950 feet and variability is high. Slopes average about 32 percent. Average annual temperature is 53 degrees F and average annual precipitation averages 102 inches. This Association is one of the three warm, moist associations of the Western Hemlock Subseries.

Vegetation Composition and Structure Total species richness, high for the Series, is 28. This Association's range is extensive, environments vary, and only the understory tree layer is below the average Series richness. California-laurel and Pacific madrone indicate opposing ends of the moisture gradient, but they also can be effective pioneers, thus unreliable as environmental indicators. Oregon white oak, although rare (one percent cover), consistently indicates hot, dry environments. The understory regeneration is dominated by tanoak, but western hemlock is the next most shade tolerant tree species present. Because western hemlock's presence, although uncommon, indicates the transition from the Tanoak to the Western Hemlock Series, western hemlock was included in the Association name. Additionally, as indicated by the complement of vegetation, the Association belongs to the Western Hemlock Subseries. California-laurel is common and canyon live oak is occasional. Poison oak is the most consistent indicator of the drier sites of the Association, but evergreen huckleberry is more dominant and occurs more often. As the driest of the Tanoak-western hemlock Subseries (a division of the Series), this Association supports hairy honeysuckle and California hazel. The most frequently occurring herbs are low in cover (western sword-fern, bearded fescue and evergreen violet). Oregon oxalis and whipplevine can be used to indicate contrasts in local site moisture availability.

TANOAK-WESTERN HEMLOCK/EVERGREEN HUCKLEBERRY/WESTERN SWORDFERN
Lithocarpus densiflorus-Tsuga heterophylla/Vaccinium ovatum/Polystichum munitum
 LIDE3-TSHE/VAOV2/POMU (N=37; NRCS=28, FS=9)

Distribution. This widely occurring **Association** is found mostly west of the coastal crest (Myrtlewood Resource Area, Gold Beach, Chetco, and Powers Ranger Districts). Like other coastal **associations**, it can be found within the Rogue River corridor further east, where the coastal influence is funneled up canyon. It may be occasionally found east of the crest only in areas where summer fog is common.

Distinguishing Characteristics. Parent material is typically coastal sediments. Sites are usually on mid-slope topographic positions and elevation is usually less than 1500 feet. This **Association** is often found on northerly aspects and less in the southeast quadrant. This **Association** is one of the three warm, moist **associations** of the Western Hemlock Subseries.

Soils. Parent material is mostly sediment, (sandstone and siltstone), and rarely

granite Soil depth averages greater than 50 inches Average surface rock cover is 11 percent Average gravel cover is 28 percent

Environment Elevation averages 1100 feet and variability is low Slopes average 40 percent, but range from 15 to 95 percent Average annual temperature is 52 degrees F and average annual precipitation averages 107 inches Moss cover averages 30 percent over a dense litter cover of greater than 90 percent Western hemlock and western sword-fern cover indicate that high humidity and fog are common See the Environmental Graph on page LIDE3 3

Vegetation Composition and Structure Total species richness, low for the series, is 22 The tree layers are slightly below average in species richness The presence of western hemlock indicates the cooler, more uniform temperatures of the coast Western hemlock's presence, along with the complement of wet site indicators, is also an indication that the **Association** belongs to the Western Hemlock Subseries Inland, drier sites support higher cover of madrone and Douglas-fir regeneration Typically, evergreen huckleberry becomes increasingly abundant with increasing coastal influence Red alder and California-laurel also become more abundant as site moisture becomes more abundant These indicators can be contrasted with the cover of poison oak and hairy honeysuckle Western sword-fern dominates the herb layer Along with Oregon oxalis, it is present throughout the year Western starflower, fragrant bedstraw and vanillaleaf, all ephemeral, may be difficult to find during late summer (another reason why herbs are not often used as key species)

TANOAK-WESTERN HEMLOCK/EVERGREEN HUCKLEBERRY/WESTERN SWORD-FERN (RIP)
Lithocarpus densiflorus-*Tsuga heterophylla*/*Vaccinium ovatum*/*Polystichum munitum* (Rip)
 LIDE3-TSHE/VAOV2/POMU-RIP (N=43; NRCS=40, FS=3)

Distribution. This widely occurring **Association** occurs almost entirely west of Range12 West (Myrtlewood Resource Area, Gold Beach, Chetco, and Powers Ranger Districts). It is more common in the northern townships. It is not likely to be found inland.

Distinguishing Characteristics. This **Association** is mostly coastal, but a few sites may be found immediately west of the crest on lower concavities along the Rogue River canyon. The most frequently occurring parent material is sandstone. Most sites occur below 1500 feet in elevation and on bottom positions. Although south facing slopes occasionally support this complement of species, it is more highly **associated** with north aspects. It is a member of the Western Hemlock Subseries.

Soils. Parent material is frequently sandstone, and rarely mixed metamorphic. Soil depth averages greater than 37 inches. Surface rock cover averages 33 percent,

2 percent in the gravel size class

Environment The average elevation is about 1000 feet, the lowest average for the Series. Slopes average 36 percent. Average annual temperature is 53 degrees F and average annual precipitation is 100 inches. Exposed surface rock, often colluvial, is common in these riparian systems, moss cover is usually greater than 50 percent. These sites are often protected from wind and radiation by topography, and a complement of wet species, **associated** with the Western Hemlock Subseries, is usually present.

Vegetation Composition and Structure Total species richness, intermediate for the Series, is 23. All layers are near average Series richness. Western hemlock and California-laurel indicate the coastal influence. Tanoak dominates the regeneration layer. Western hemlock will continue to be a part of the species complement through all successional stages (Western Hemlock Subseries). Big-leaf maple commonly occurs on these riparian sites. Rarely, white fir (grand fir mix), red alder, western redcedar, Port-Orford-cedar, and California-laurel are present. Occasionally, salmonberry occurs on the wettest coastal sites, but evergreen huckleberry, red huckleberry and Pacific rhododendron dominate. As with other **associations** in the Tanoak-Western Hemlock Subseries, western sword-fern is the dominant herb and Oregon oxalis cover is high.

DOUGLAS-FIR SERIES

DOUGLAS-FIR SERIES

Pseudotsuga menziesii

PSME

Patricia A. Martinez
Thomas Atzet

The latitudinal range of Douglas-fir is the greatest of any commercial conifer of western North America. Nearly pure stands of Douglas-fir continue south from their northern limit on Vancouver Island through western Washington, Oregon, and the Klamath and Coast Ranges of northern California as far south as the Santa Cruz Mountains.

Douglas-fir behaves as a drought tolerant pioneer, with moderate tolerance to shade. It is best described as a generalist. Douglas-fir occurs in all series and at elevations ranging from sea level to 5600 feet. Rather than any particular parent material, soil depth, or aspect, Douglas-fir regeneration is associated with recently disturbed ground. Overstory presence of Douglas-fir indicates disturbance, while presence and dominance in the understory can indicate hot, dry conditions characteristic of the Series. Ponderosa pine and incense-cedar are the only major conifers with greater tolerance to drought (Minore 1979). Douglas-fir reproduces well in temperatures near 80 degrees F (Cleary and Waring 1969) and survives in less than two percent of full sunlight for at least several decades (Atzet and Waring 1970). Douglas-fir is not known, however, for its frost tolerance. Except for the isolated occurrences of climax stands of Oregon white oak and ponderosa pine, the Series occurs in the hottest, driest forest environments in southwestern Oregon.

Douglas-fir grows under a wide variety of climatic conditions. Douglas-fir typically dominates the overstory in early, mid, and late seral successional stages in Temperate and Mediterranean ecosystems throughout the Pacific Northwest. The coastal region of the Pacific Northwest has a maritime climate characterized by mild, wet winters and cool, relatively dry summers, a long frost-free season, and narrow diurnal fluctuations of temperature. Precipitation, mostly in the form of rain, is concentrated in the winter months. Climate in the Cascade range tends to be more severe, colder, shorter frost-free period, and more snow (Hermann and Lavender 1990).

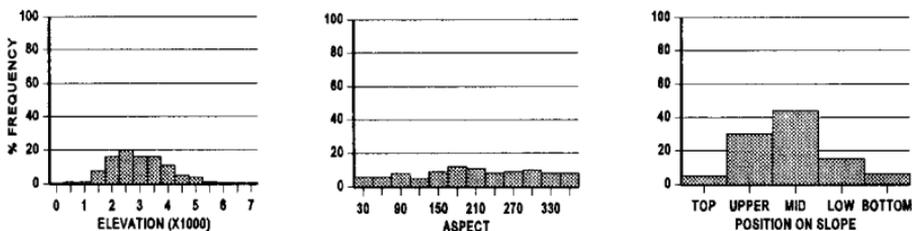

On most Temperate sites, Douglas-fir is succeeded by more shade tolerant species in the late stages of succession, and rarely attains climax status. In the southern extreme of the Temperate Zone, where it mixes with Mediterranean ecosystems, isolated stands, potentially climax to Douglas-fir, become increasingly common. These stands are usually associated with shallow, skeletal soils on south aspects. This localized hot, dry microclimate gives Douglas-fir a competitive advantage. This advantage is similar to the advantage it has immediately after disturbance, when sites are exposed to radiation, night-time re-radiation, extreme heat and cold, and desiccating winds.

Because Mediterranean ecosystems are hotter, drier, and have more clear days and nights (temperature extremes not dampened by cloud cover or high humidity) than

PSME 2

Temperate systems, Douglas-fir has the potential to attain climax status (is the climax dominant) on a wide variety of soil conditions across the landscape. Yet, the Series distribution is not totally associated with a particular elevational band or continuum, like the White Fir Series. Instead, the Douglas-fir Series can be found on the hotter, drier sites at high elevations or on the coastal side of the Coastal Crest mixed with the Western Hemlock or Tanoak Series.

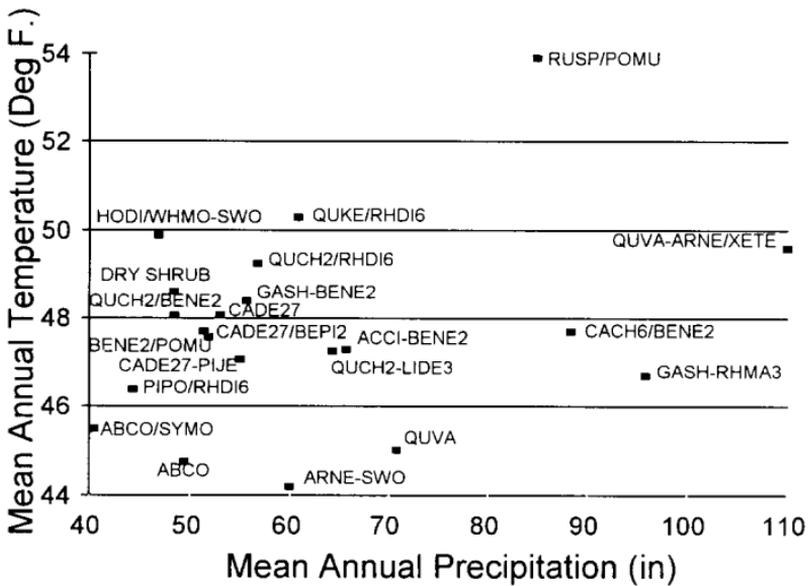

As shown in the graphs below, the Douglas-fir Series covers a wide elevational band, from 180 feet to 5620 feet with an average elevation of 2830 feet. It occurs on all aspects. Although this Series occurs on all slope positions, it is more commonly found on upper and middle-third slope positions.

Parent material is variable, consisting of basalt, andesite, sandstone, mudstone, siltstone, shale, serpentine, peridotite, or other ultramafic materials, metavolcanic materials, granodiorite, diorite, mixed metamorphic materials, sedimentary materials, schist, greywacke, welded tuff, amphibolite, granite, gabbro, pumice, rhyolite, tephra, ash, breccia, and chert. Gravel cover ranges from 4 to 29 percent, with an average of 14 percent. Rock cover ranges from 1 to 42 percent, with an average of 10 percent. Bedrock cover ranges from 0 to 10 percent, with an average of 2 percent. Litter ranges from 47 to 98 percent, with an average of 78 percent, while bare ground ranges from 0 to 12 percent, with an average of 3 percent. Moss cover ranges from 2 to 29 percent, with an average of 12 percent.

Based on 298 plots sampled, soils are shallow to deep. Surface texture is clay loam, loam, silty clay loam, sandy clay loam, silt loam, sandy loam, silty clay, loamy sand, and clay. Average rock fragment content is 44 percent, most of which is gravel (average of 34 percent).

The mean annual temperature for the Douglas-fir Series ranges from 44 degrees F to 54 degrees F and the mean annual precipitation ranges from 40 inches to 121 inches. The relative positions of the plant associations in the environment are shown on page PSME 3. Each association is plotted by mean annual temperature and mean annual precipitation.

Average species richness, based on vascular **plants** only, is calculated for each **association**. The average richness for the Douglas-fir Series ranges between 19 and 58 species per **association**. Richness is rated as very low, 19 to 26 species, low, 27 to 34 species, intermediate, 35 to 42 species, high, 43 to 50 species, and very high, anything greater than 51 species.

The overstory is dominated by Douglas-fir. Many other species, conifer and hardwoods alike, will be found in the overstory. The understory is dominated by Douglas-fir, with common occurrences of Pacific madrone. Canyon live oak, incense-cedar, and sugar pine occur occasionally. As in the overstory, many other species, conifers and hardwoods alike, may be present. Common shrubs include baldhip rose, dwarf Oregongrape, poison oak, creambush, ocean-spray, California hazel, hairy honeysuckle, Pacific blackberry, salal, and creeping snowberry. Common herbs include white-flowered hawkweed, western starflower, rattlesnake-plantain, whipplevine, western sword-fern, pathfinder, snow-queen, braken, mountain sweet-root, vanillaleaf, slender-tubed iris, Scouler's harebell, common beargrass, and western twinflower.

For Forest Service sites, upper layer tree cover ranges from 48 to 75 percent, with an average of 62 percent. Mid-layer tree cover ranges from 27 to 52 percent, with an average of 41 percent while lower layer tree cover ranges from 16 to 56 percent, with an average of 29 percent. High shrub cover ranges from 2 to 58 percent, with an average of 18 percent, while low shrub cover ranges from 8 to 71 percent, and averages 30 percent. Herb cover ranges between 7 and 66 percent, and averages 27 percent. Low, intermediate, and high canopy covers are defined as the lower, middle, and upper thirds of the total range of average covers for each layer.

PSME 4

For Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) ranges from 54 to 78 percent, and averages 71 percent, while cover for trees less than 10 feet tall ranges from 5 to 26 percent, and averages 11 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) ranges from 3 to 44 percent, and averages 20 percent, and cover for shrubs less than 20 inches tall ranges from 7 to 58 percent, and averages 29 percent. Herb cover ranges from 6 to 44 percent, and averages 18 percent.

Twenty-one **plant associations** have been classified for the Douglas-fir Series in southwestern Oregon. They were described from 601 plots, 245 from Forest Service data, 337 from Bureau of Land Management data, and 19 from Natural Resources Conservation Service data. There may be some additional types on the Illinois Valley, Galice, and Chetco Ranger Districts of the Siskiyou National Forest not covered in this guide. If the southwestern Oregon key fails to work in these areas, try the Douglas-fir key in the guide "A Field Guide to the Tanoak and Douglas-fir **Plant Associations** in Northwestern California" (R5-ECOL-TP-009) by Thomas M. Jimerson, et. al. 1996.

The relationship of draft and final **plant associations** in the Douglas-fir Series is shown below. The draft **associations** are listed, with the final **associations** below, each in order of most to least common, with the percentage of plots that make up each **association** (refer to Methods section).

DOUGLAS-FIR/SALMONBERRY/WESTERN SWORD-FERN

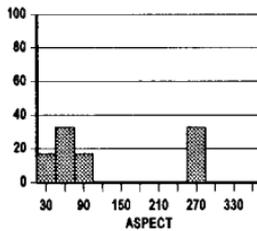

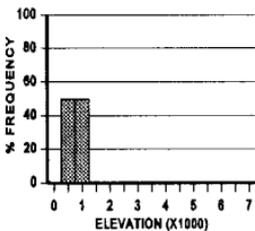

Pseudotsuga menziesii/Rubus spectabilis/Polystichum munitum
PSME/RUSP/POMU (N=6, NRCS=6)

Distribution This Association is coastal and is found primarily in Curry County. It may be found on the Gold Beach, Chetco, and Powers Ranger Districts, Siskiyou National Forest, and on adjacent Bureau of Land Management lands.

Distinguishing Characteristics This Association is moist, as suggested by the presence of salmonberry, red alder, and Sitka spruce. Tanoak is also frequently present. This is the warmest Douglas-fir Association.

Soils No soils data are available.

No slope position data available.

Environment Elevation averages 520 feet Aspects are northerly, however, sampling was biased towards northern aspects Slope averages 24 percent and ranges from 1 to 50 percent

Vegetation Composition and Structure Total species richness is low for the Series, averaging 27 species. The overstory is dominated by Douglas-fir and red alder Sitka spruce and tanoak are common Understory species frequently found include Douglas-fir and tanoak Port-Orford-cedar is found occasionally. Salmonberry is frequently found in the shrub layer, while evergreen huckleberry, red huckleberry, creambush ocean-spray, salal, and red elderberry are all common Frequent herbs include western sword-fern, redwoods violet, braken, and iris Nettle-leaf horse-mint, Oregon oxalis, fragrant bedstraw, white inside-out-flower, foxglove, Oregon bigroot, and bearded fescue are common All herbs, with the exception of western sword-fern, have low covers

PSME 16

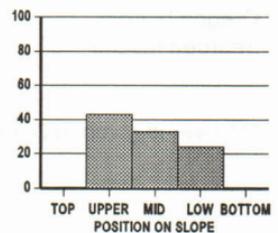

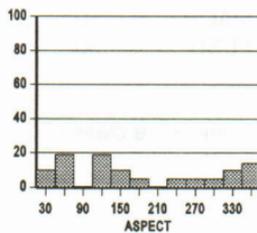

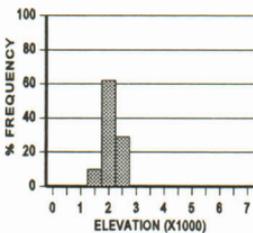

DOUGLAS-FIR/HUCKLEBERRY OAK-PINEMAT MANZANITA/COMMON BEARGRASS
Pseudotsuga menziesii/Quercus vaccinifolia-Arctostaphylos nevadensis/Xerophyllum tenax
PSME/QUVA-ARNE/XETE (N=21; FS=21)

Distribution. This Association occurs on the Chetco Ranger District, Siskiyou National Forest. Twenty of the 21 plots occurred in the Lemmingsworth Gulch Research Natural Area, but this Association may also occur elsewhere.

Distinguishing Characteristics. This Association is coastal and is the only Douglas-fir Association that occurs exclusively on serpentine and peridotite parent materials. This Association is similar to the Douglas-fir/Pinemat Manzanita Association, except huckleberry oak is present in this Association, generally with high covers. This is the wettest Douglas-fir Association.

Soils. Parent material is serpentine (80 percent constancy) and peridotite (20 percent constancy). Surface gravel cover averages 20 percent and surface rock cover averages 42 percent. Exposed bedrock averages 1 percent. Bare ground averages 4 percent, while litter averages 64 percent.

Environment Elevation averages 2110 feet Aspects vary Slope averages 45 percent and ranges from 26 to 64 percent Slope position ranges from the lower one-third to the upper one-third

Vegetation Composition and Structure Total species richness is very high for the Series, averaging 57 species The overstory is dominated by Douglas-fir Knobcone pine, western white pine, and Jeffrey pine are common, all with low covers. The understory is dominated by Douglas-fir and California-laurel Douglas-fir covers are low, while California-laurel covers are high, generally greater than 10 percent Tanoak (shrub form), huckleberry oak, pinemat manzanita, coffeeberry, red huckleberry, dwarf ceanothus, box-leaved silk-tassel, and baldhip rose are frequent shrubs In the herb/grass layer, common beargrass, sedge, slender-tubed iris, obscure bedstraw, Oregon trillium, Howell's biscuit-root, common yarrow, yellow inside-out-flower, leafy erigeron, toothleaf pyrola, few-fruited biscuit-root, rock fern, nodding arnica, variable morning-glory, and whipplevine are all frequent, most with low covers Moss cover averages 5 percent

Upper layer tree cover has the lowest cover of the Series, averaging 1 percent. Mid-layer tree cover is also low, averaging 27 percent, while lower layer tree cover is high, averaging 56 percent High shrub cover is low for the Series, averaging 12 percent, while low shrub cover is intermediate, averaging 34 percent Herb/grass cover is also intermediate, averaging 38 percent.

DOUGLAS-FIR/HUCKLEBERRY OAK
Pseudotsuga menziesii/Quercus vaccinifolia
 PSME/QUVA (N=13; BLM=13)

Distribution. This Association is scattered east of the Coast Range crest on dry sites. It occurs on the Grants Pass and Glendale Resource Areas, Medford District, Bureau of Land Management and is common on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. There may be occasional occurrences on the west half of the Butte Falls Resource Area, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association only occurs in the Siskiyou east of the coastal crest and does not occur in the Cascades. The presence of huckleberry oak and ultramafic parent materials indicate poor sites, but they are not preemptive key characteristics. The occasional presence of Sadler oak and/or knobcone pine may help key to this Association.

Soils. Parent material varies from sandstone, mixed sediment, and mixed

metavolcanic to ultramafic. Based on 13 samples, soils average at least 12 inches deep. Textures are mostly sandy loam, silt loam, and silty clay loam. Average rock fragment content is 62 percent. Most fragments (49 percent) are of gravel size.

Environment. Elevation ranges from about 3000 feet to over 5000 feet. The average is 3900 feet. This **Association** occurs equally on all aspects, but usually occupies midslope topographic positions. Slopes average about 32 percent. Average annual temperature is about 45 degrees F (cool for the Series) and average annual precipitation is about 71 inches. Approximately 4 percent of the forest floor is exposed bedrock, 53 percent is covered with litter, 12 percent is bare ground, and 2 percent is covered with moss.

Vegetation Composition and Structure. Total species richness, very low for the Series, is 22. The herb layer particularly lacks richness, hosting an average of eight species. Cover greater than 10 feet (3 meters) tall, usually trees, averages 54 percent. Tree cover less than 10 feet tall averages 12 percent, tall shrubs, greater than 20 inches (50 centimeters) tall, average 43 percent cover, low shrubs, less than 20 inches tall, average 31 percent cover, herb cover averages 7 percent. When sugar pine occurs in the overstory it can be an indication of early growing season water availability, however, only dwarf Oregongrape in the shrub layer supports such an interpretation. Dwarf Oregongrape covers are too low, however, to add more surity. Knobcone pine, golden chinquapin, and the two manzanita species often indicate disturbance, usually fire. On sites with ultramafic rocks, huckleberry oak and common beargrass are often present with relatively high cover.

DOUGLAS-FIR-INCENSE-CEDAR-JEFFREY PINE
Pseudotsuga menziesii-Calocedrus decurrens-Pinus jeffreyi
 PSME-CADE27-PIJE (N=6; FS=6)

Distribution. This Association occurs on the Illinois Valley Ranger District, Siskiyou National Forest and the Diamond Lake Ranger District, Umpqua National Forest. It may also occur on adjacent districts of both Forests, along with adjacent lands of the Bureau of Land Management.

Distinguishing Characteristics. This Association is generally found on serpentine and peridotite. Jeffrey pine and incense-cedar are frequent. Douglas-fir-Incense-cedar-Jeffrey Pine is one of the drier, cooler associations. This Association is found mainly on upper slope positions.

Soils. Parent material is serpentine and peridotite, with some ash and granite. Average surface rock cover is 13 percent, with 11 percent gravel and 3 percent bare ground exposure. Soils are generally shallow to moderately deep, with an average depth of 21 inches.

Environment Elevation averages 3080 feet Aspects are most frequently northeast and south Slope averages 48 percent and ranges between 33 and 60 percent This **Association** is generally found on upper third slope positions

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 31 species. The overstory is dominated by Douglas-fir, Jeffrey pine, and incense-cedar. Sugar pine rarely occurs. The understory is dominated by Douglas-fir and incense-cedar. Tanoak and canyon live oak are frequent, while Jeffrey pine, Pacific madrone, and sugar pine are common. White fir will occasionally be found. Baldhip rose is a frequent shrub, while poison oak, hairy honeysuckle, and Piper's Oregongrape are common. White-flowered hawkweed and slender-tubed iris are frequent herbs, while whipplevine, imbricate sword-fern, rattlesnake-plantain, slender bittercress, common yarrow, California harebell, and western starflower are common herbs. Moss cover averages 19 percent.

Upper layer tree cover is low, averaging 53 percent. Mid-layer tree cover is high for the Series, averaging 47 percent, and lower layer tree cover is intermediate, averaging 36 percent. High and low shrub covers are both low for the Series, averaging 2 and 20 percent, respectively. Herb/grass cover is high for the Series, averaging 66 percent.

DOUGLAS-FIR-INCENSE-CEDAR
Pseudotsuga menziesii/Calocedrus decurrens
PSME-CADE27 (N=13; BLM=13)

Distribution. This Association is scattered east of the Coast Range crest on dry sites. It occurs on the Grants Pass and Glendale Resource Areas, Medford District, Bureau of Land Management, and on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association is not likely to occur in the Cascades or west of the Coast Range crest. It is highly associated with, but not exclusively found on, ultramafic parent material. Soils are usually shallow and rocky. Jeffrey pine and rock fern, highly reliable indicators of ultramafics, are important key species for distinguishing this Association from others in the Series.

Soils. Parent material is generally ultramafic, mostly serpentine, or metavolcanic material. Based on 13 samples, soil depth averages at least 16 inches. Textures

are mostly silty clay loam, silt loam, or clay loam. Average rock fragment content is 36 percent. Most fragments (24 percent) are of gravel size.

Environment Elevation ranges from about 2000 to over 4000 feet. The average is 2700 feet and frequency lessens at higher elevations. The mode, however, at only 2000 feet, indicates the distribution is not normal. This **Association** occurs on all aspects, but most often faces south. Douglas-fir-incense-cedar occurs from midslopes to ridgetops, but rarely occupies bottomland positions. Slopes average about 45 percent. Average annual temperature is about 48 degrees F and average annual precipitation is about 53 inches. Approximately 2 percent of the forest floor is exposed bedrock, 50 percent is covered with litter, 6 percent is bare ground, and 8 percent is covered with moss.

Vegetation Composition and Structure Total species richness, very low for the Series, is 20. The shrub layer, particularly depauperate, averages only three species. Cover greater than 10 feet (3 meters) tall, usually trees, averages 58 percent. Tree cover less than 10 feet tall averages 7 percent. Tall shrubs, greater than 20 inches (50 centimeters) tall, average 10 percent cover, low shrubs, less than 20 inches tall, average 7 percent cover. Herb cover averages 44 percent, high for drier sites of the Series. Jeffrey pine is a prominent species in both the overstory and understory. Together with rock fern, Jeffrey pine is almost a sure indication of ultramafic soils. Incense-cedar tolerates ultramafics well, but it also tolerates every other parent material type. Canyon live oak and the lack of shrubs and herbs are likely an indication of both a dry environment and the nutrient imbalance **associated** with ultramafics. Grasses survive and grow well on most imbalanced sites. Fescue is commonly found **associated** with ultramafic parent material.

DOUGLAS-FIR/PINEMAT MANZANITA-SWO

Pseudotsuga menziesii/*Arctostaphylos nevadensis*

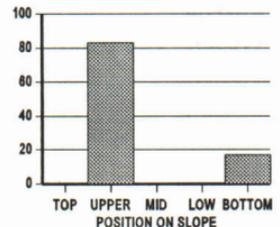

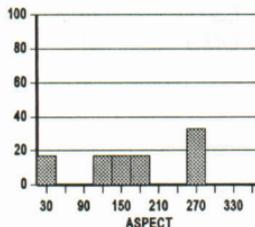

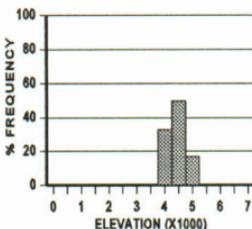

PSME/ARNE-SWO (N=6; FS=6)

Distribution. This Association occurs on the Applegate and Prospect Ranger Districts, Rogue River National Forest, the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and the Tiller and North Umpqua Ranger Districts, Umpqua National Forest. Douglas-fir/Pinemat Manzanita-SWO may also occur on adjacent lands of the Bureau of Land Management.

Distinguishing Characteristics. This is a high elevation association, averaging 4270 feet. This Association is similar to Douglas-fir/Huckleberry Oak-Pinemat Manzanita/Common Beargrass except huckleberry oak is rarely present and parent material is not ultramafic. This is the coolest Association of the Series.

Soils. Parent material is highly variable. Plots occur on rhyolite, pumice, gabbro, schist, and metavolcanic materials. Average surface rock cover is 16 percent, with 18 percent gravel. Soils are generally moderately deep, but can be shallow or deep,

with an average depth of greater than 36 inches. Based on two plots sampled, surface textures are loam and sandy loam, with 15 percent cobbles and up to 60 percent gravel. Subsurface textures are silty clay loam and clay, with 60 to 90 percent cobbles.

Environment Elevation averages 4270 feet. This **Association** occurs on all aspects. Slope averages 33 percent and ranges from 3 to 57 percent. Douglas-fir/Pinemat Manzanita-SWO is mostly found on upper one-third slope positions, and will occasionally occur on benches and narrow flats.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 28 species. The overstory is dominated by Douglas-fir, with incense-cedar, sugar pine, and western white pine common. The understory is dominated by Douglas-fir, with incense-cedar, white fir, golden chinquapin, western white pine, and sugar pine common, most with low covers. Pinemat manzanita and baldhip rose are frequent shrubs, while dwarf Oregongrape and western serviceberry are common. Common prince's-pine frequently occurs in the herb/grass layer while common beargrass, whipplevine, western sword-fern, and whitevein pyrola commonly occur. All have low covers. Moss cover averages 5 percent.

Upper layer tree cover is low for the Series, averaging 48 percent. Mid-layer tree cover is high, averaging 51 percent while lower layer tree cover is intermediate, averaging 37 percent. High shrub and low shrub covers are also intermediate for the Series, averaging 34 and 44 percent, respectively. Herb/grass cover is low, with an average of 13 percent.

DOUGLAS-FIR/VINE MAPLE-DWARF OREGONGRAPE
Pseudotsuga menziesii/Acer circinatum-Berberis nervosa
PSME/ACCI-BENE2 (N=16; FS=16)

Distribution. This Association occurs on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest and all Districts of the Umpqua National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is one of the cooler, drier Douglas-fir associations. It is the only association where vine maple is consistently present.

Soils. Parent material is highly variable. Plots occur on andesite, basalt, diorite, welded tuff, pumice, and metavolcanic bedrock. Soils are moderately deep to deep, with an average depth of greater than 37 inches. Average surface rock cover is 11 percent, with 19 percent gravel and 3 percent bare ground. Based on one plot sampled, surface and subsurface textures are loam with little to no gravel or cobbles, and a few boulders.

Environment Elevation averages 3030 feet No one aspect dominates over another Slope averages 43 percent and ranges between 0 and 80 percent This Association may be found on any slope position

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 41 species The overstory is dominated by Douglas-fir Sugar pine, incense-cedar, white fir, and western hemlock are occasionally found The understory is dominated by Douglas-fir Pacific yew and western hemlock are frequently found Golden chinquapin and incense-cedar are common Vine maple, dwarf Oregongrape, red huckleberry, baldhip rose, and Pacific blackberry are frequently found shrubs Vine maple covers are high, averaging 43 percent and dwarf Oregongrape covers are generally greater than 10 percent Western sword-fern, vanillaleaf, whipplevine, white trillium, western twinflower, common prince's-pine, western starflower, snow-queen, round-leaved violet, Oregon fairybell, white-flowered hawkweed, and rattlesnake-plantain are frequently found, all with low covers Moss cover averages 19 percent

Upper layer tree cover is high for the Series, averaging 68 percent Mid-layer and lower layer tree covers are intermediate, averaging 43 and 42 percent, respectively High shrub, low shrub, and herb/grass covers are also intermediate for the Series, averaging 34, 49, and 30 percent, respectively

DOUGLAS-FIR-GOLDEN CHINQUAPIN/DWARF OREGONGRAPE
Pseudotsuga menziesii-Castanopsis chrysophylla/Berberis nervosa
PSME-CACH6/BENE2 (N=16; FS=16)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest, all ranger districts of the Siskiyou National Forest, and the Tiller and North Umpqua Ranger Districts, Umpqua National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is one of the lower elevation Douglas-fir associations. Golden chinquapin, a rocky site indicator, is common, generally with covers greater than 15 percent. This Association is moist and cool.

Soils. Parent material is mostly sandstone, pumice, or andesite, with some breccia and mudstone. Average surface rock cover is 3 percent, with 19 percent gravel. Soils are generally deep but can be shallow, with an average depth of greater than

32 inches Based on two plots sampled, surface texture is loam with 90 percent stones or cobbles. Subsurface texture is loam with 95 percent stones

Environment Elevation averages 2910 feet Aspects vary, though tend not to be northwest. Slope averages 35 percent and ranges from 7 to 67 percent This Association may be found on any slope position.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 28 species. The overstory is dominated by Douglas-fir and sugar pine. The understory is dominated by Douglas-fir and golden chinquapin, both with covers generally greater than 15 percent. Tanoak, Pacific madrone, canyon live oak, white fir, and sugar pine are common associates. Western hemlock, incense-cedar, Pacific yew, and Pacific dogwood are common. Dwarf Oregongrape, baldhip rose, and red huckleberry are frequent shrubs, while salal, Pacific blackberry, Pacific rhododendron, and vine maple are common Rattlesnake-plantain and common beargrass are frequently occurring herbs, while common prince's-pine, western twinflower, and braken are common Moss cover averages 11 percent

Upper layer tree cover is high, averaging 71 percent Mid-layer tree cover is intermediate for the Series, averaging 36 percent, while lower layer tree cover is low, averaging 27 percent High shrub and low shrub covers are intermediate for the Series, averaging 28 and 47 percent, respectively Herb/grass cover is low, averaging 16 percent

DOUGLAS-FIR/SALAL-PACIFIC RHODODENDRON

Pseudotsuga menziesii/Gaultheria shallon-Rhododendron macrophyllum

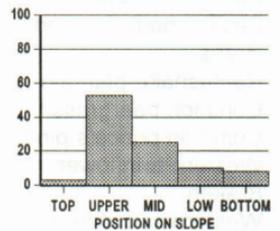

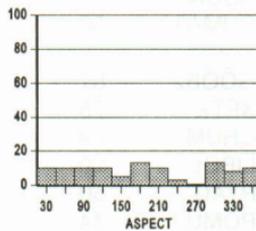

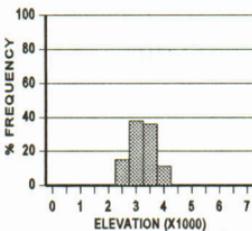

PSME/GASH-RHMA3 (N=53; FS=21, BLM=19, NRCS=13)

Distribution. This **Association** occurs on all districts of the Siskiyou National Forest and the Tiller and North Umpqua Ranger Districts, Umpqua National Forest. It also occurs on the Grants Pass and Glendale Resource Areas, Medford District, and the South River Resource Area, Roseburg District, Bureau of Land Management, and in Curry County.

Distinguishing Characteristics. This **Association** is the second wettest of the Series, averaging 96 inches of precipitation annually. Salal and Pacific rhododendron both frequently occur with high covers (average 61 and 39 percent, respectively). Dwarf Oregon grape and common beargrass also frequently occur.

Soils. Parent material is mostly sandstone, pumice, or andesite, with some mudstone, breccia, mixed metamorphic materials, diorite, and serpentine. Based on 19 samples, soil textures are mostly silt loam or sandy loam. Average rock fragment

content is 37 percent, most of which is gravel (average 30 percent)

Environment Elevation averages 3230 feet Aspects vary Slope averages 35 percent and ranges from 9 to 80 percent This **Association** occurs on all slope positions Average annual precipitation is 96 inches and average annual temperature is 47 degrees F

Vegetation Composition and Structure Total species richness is very low for the Series, averaging 20 species The overstory is dominated by Douglas-fir The understory is dominated by Douglas-fir and golden chinquapin Golden chinquapin cover averages 18 percent Tanoak is common Frequent shrubs include salal, Pacific rhododendron, and dwarf Oregongrape Pacific rhododendron and salal both have high covers, averaging 39 and 61 percent, respectively Common beargrass and braken frequently occur, and rattlesnake-plantain is common Moss cover averages 6 percent

On Forest Service sites, upper layer tree cover is high, averaging 68 percent Mid-layer and lower layer tree covers are low, averaging 30 and 25 percent, respectively High shrub and low shrub covers are high, averaging 58 and 71 percent, respectively This **Association** has the highest shrub covers of the Series Herb/grass cover is low, with an average of 10 percent

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 75 percent, while cover for trees less than 10 feet tall averages 11 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 36 percent, and cover for shrubs less than 20 inches tall averages 58 percent Herb/grass cover averages 6 percent

DOUGLAS-FIR/SALAL-DWARF OREGONGRAPE

Pseudotsuga menziesii/Gaultheria shallon-Berberis nervosa

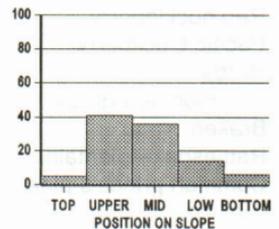

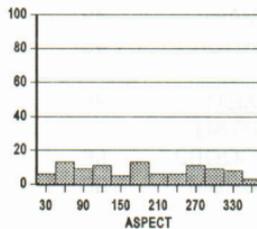

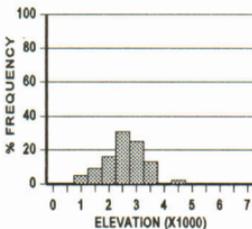

PSME/GASH-BENE2 (N=64; BLM=47, FS=17)

Distribution. This Association occurs on all districts of the Umpqua National Forest, and all Resource Areas, Medford and Roseburg Districts, Bureau of Land Management.

Distinguishing Characteristics. This Association is one of the drier, cooler plant associations of the Douglas-fir Series. Pacific rhododendron is rarely present. Salal is frequently found, with high covers.

Soils. Parent material is variable, with occurrences of mudstone, sandstone, andesite, diorite, basalt, granite, rhyolite, tephra, and ash. Average surface rock cover is 6 percent, with 16 percent gravel. Based on 47 plots sampled, soil textures are mostly loam and sandy loam, with some silt loam, sandy clay loam, silty clay loam, and silty clay. Average rock fragment content is 35 percent, most of which is gravel (average 30 percent).

Environment Elevation averages 2550 feet Aspects vary Slope averages 43 percent and ranges from 2 to 80 percent This **Association** may be found on all slope positions

Vegetation Composition and Structure Total species richness is low for the Series, averaging 33 species The overstory is dominated by Douglas-fir, with incense-cedar and sugar pine commonly occurring The understory is dominated by Douglas-fir Incense-cedar, golden chinquapin, and Pacific madrone are common, while white fir, Pacific dogwood, bigleaf-maple, and sugar pine are occasionally found Salal, dwarf Oregongrape, and baldhip rose are frequently found in the shrub layer Salal and dwarf Oregongrape may have high covers, salal averaging 43 percent, while dwarf Oregongrape averages 7 percent Creambush ocean-spray, Pacific blackberry, and creeping snowberry are common In the herb/grass layer, whipplevine, western sword-fern, and western starflower are frequent, while pathfinder, vanillaleaf, and western twinflower are common All have relatively low covers Moss cover averages 12 percent

On Forest Service sites, upper layer tree cover is high for the Series, averaging 71 percent Mid-layer tree cover is intermediate for the Series, averaging 40 percent, while lower layer tree cover is low, averaging 16 percent High shrub cover is low, averaging 21 percent, and low shrub cover is intermediate, averaging 47 percent Herb/grass cover is also intermediate for the Series, averaging 32 percent

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 73 percent, while cover for trees less than 10 feet tall averages 5 percent Cover for shrubs greater than 20 inches tall (50 centimeters) averages 16 percent, and cover averages 58 percent for shrubs less than 20 inches tall Herb/grass cover averages 12 percent

DOUGLAS-FIR/DWARF OREGONGRAPE/WESTERN SWORD-FERN
Pseudotsuga menziesii/Berberis nervosa/Polystichum munitum
 PSME/BENE2/POMU (N=37; BLM=37)

Distribution. This **Association** is scattered east of the Coast Range crest on dry sites. It occurs within the Glendale Resource Area, Medford District, Bureau of Land Management and on the Galice Ranger District, Siskiyou National Forest. This **Association** may also occur on the Illinois Valley Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This **Association** is difficult to distinguish from other Douglas-fir **associations**. Douglas-fir **associations** have a consistently similar complement of vegetation, since the environmental range of the Series is narrow. Except for the occasional presence of Pacific yew and dwarf Oregongrape indicating more moist sites, using relative cover provides the best discrimination among the **associations**. Douglas-fir/Dwarf Oregongrape/Western Sword-fern only occurs in the Siskiyou east of the coastal crest and is not likely to be found in the Cascades. It occurs on all aspects, but rarely above 3300 feet in elevation or on ridgetops.

Soils Parent material varies among sandstone, mudstone, serpentine and peridotite. Soil depth averages at least 14 inches. Textures are mostly sandy loam, loam, or clay loam. Average rock fragment content is 41 percent. Most fragments (29 percent) are of gravel size.

Environment Elevation ranges from about 1000 feet to about 3500 feet. The average is 2700 feet. The mode, slightly less, is about 2500 feet. This **Association** occurs on all aspects, but less often on south faces. This **Association** is normally distributed on all slope positions, with midslopes as the definitive mode. Slopes average about 46 percent. Average annual temperature is about 48 degrees F and average annual precipitation is about 51 inches. Approximately 4 percent of the forest floor is exposed bedrock, 50 percent is covered with litter, 6 percent is bare ground, and 8 percent is covered with moss.

Vegetation Composition and Structure Total species richness, low for the Series, is 29. The range for all layers is 16 to 48 species. Cover greater than 10 feet (3 meters) tall, usually trees, averages 74 percent. Tree cover less than 10 feet tall averages 11 percent, tall shrubs, greater than 20 inches (50 centimeters) tall, average 19 percent cover, low shrubs, less than 20 inches tall, average 35 percent cover, herb cover averages 22 percent. Douglas-fir and incense-cedar dominate the overstory, but because of their wide ecological amplitude do not specifically indicate site environment. Pacific madrone, with low cover and constancy, indicates the site is cool for the Series. Pacific yew and salal indicate cooler sites. Covers of species usually related to hotter, warmer sites (creambush ocean-spray and less so, California hazel) are relatively low in cover. Except for whipplevine, usually **associated** with warmer sites, vanillaleaf, western twinflower, western starflower, and pathfinder support the interpretation that this is one of the more mild **associations** of the Series.

DOUGLAS-FIR-CANYON LIVE OAK-TANOAK

Pseudotsuga menziesii-Quercus chrysolepis-Lithocarpus densiflora

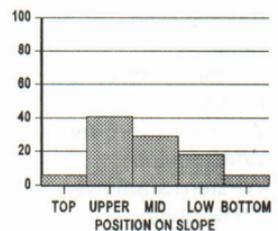

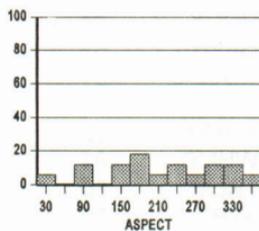

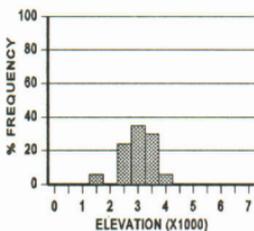

PSME-QUCH2-LIDE3 (N=17; FS=17)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association is similar to Douglas-fir-Golden Chinquapin/Dwarf Oregongrape, except this Association is drier, has more canyon live oak, tanoak, and poison oak, and less golden chinquapin and dwarf Oregongrape.

Soils. Parent material is mostly mudstone or basalt, with some sandstone, chert, schist, and diorite. Average surface rock cover is 10 percent, with 20 percent gravel and 5 percent exposed bare ground. Soils are generally shallow to moderately deep, but can be deep. Average depth to bedrock is greater than 27 inches.

Environment Elevation averages 3030 feet Aspects vary. Slopes average 49 percent and range between 15 and 85 percent This **Association** may be present on all slope positions

Vegetation Composition and Structure Total species richness is low for the Series, averaging 28 species The overstory is dominated by Douglas-fir with sugar pine occurring frequently The understory is dominated by Douglas-fir and canyon live oak, both with relatively high covers Pacific madrone, tanoak, and sugar pine are also frequent Tanoak cover is generally greater than 10 percent. Golden chinquapin is common Baldhip rose is the only frequently occurring shrub Poison oak, dwarf Oregongrape, and hairy honeysuckle are common Rattlesnake-plantain is the only frequently occurring herb, while western starflower, common prince's-pine, white-flowered hawkweed, braken, and little prince's-pine are common Imbricate sword-fern, vanillaleaf, and ground-cone are occasionally found All shrubs and herbs have low covers Moss cover averages 18 percent

Upper layer tree cover is low for the Series, averaging 55 percent. Mid-layer and lower layer tree covers are intermediate for the Series, averaging 42 and 41 percent, respectively High shrub and low shrub covers are low, averaging 4 and 12 percent, respectively. Herb/grass cover is also low for the Series, averaging 7 percent

DOUGLAS-FIR-CANYON LIVE OAK/POISON OAK

Pseudotsuga menziesii-Quercus chrysolepis/Rhus diversiloba

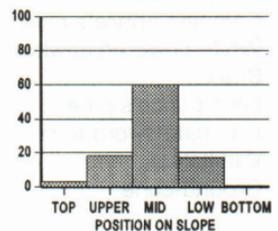

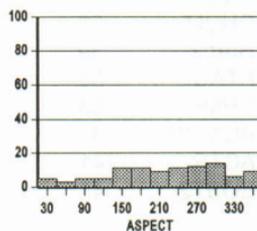

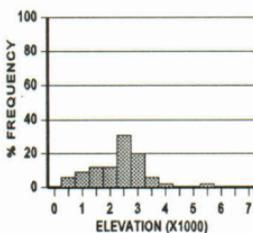

PSME-QUCH2/RHDI6 (N=65; BLM=39, FS=26)

Distribution. This **Association** occurs on the Applegate Ranger District, Rogue River National Forest and the Galice, Gold Beach, and Illinois Valley Ranger Districts, and possibly the Chetco Ranger District, Siskiyou National Forest. It also occurs on all Resource Areas, Medford District and the South River Resource Area, Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This is one of the warmer, drier **associations** of the Douglas-fir Series. Canyon live oak and poison oak are frequently present, with high covers. Both indicate rocky, dry conditions.

Soils. Parent material is highly variable. Plots occur on sandstone, andesite, mudstone, schist, granite, and gabbro, with some plots underlain by metavolcanics, mixed sedimentary, or ultramafic materials. Based on 39 plots sampled, soil textures are mostly sandy loam, with some silt loam, loam, silty clay loam, or loamy sand.

Average rock fragment content is 69 percent, most of which is gravel (average 50 percent)

Environment Elevation averages 2280 feet Aspects vary Slope averages 62 percent and ranges between 10 and 110 percent This **Association** may occur on all slope positions, but most frequently occurs mid-slope Average annual precipitation is 57 inches and average annual temperature is 49 degrees F

Vegetation Composition and Structure Total species richness is very low for the Series, averaging 26 species The overstory is dominated by Douglas-fir The understory is dominated by Douglas-fir and canyon live oak, with Pacific madrone commonly occurring Frequently occurring shrubs include poison oak and hairy honeysuckle; poison oak with high covers and hairy honeysuckle with low covers Baldhip rose is common White-flowered hawkweed, western sword-fern, and western starflower are commonly occurring herbs Moss cover averages 23 percent

On Forest Service sites, upper layer tree cover is low for the Series, averaging 49 percent, while mid-layer tree cover is high, averaging 52 percent Lower layer tree cover is intermediate, averaging 31 percent High shrub cover is low for the Series, averaging 10 percent, and low shrub cover is intermediate, averaging 31 percent Herb/grass cover is low for the Series, averaging 27 percent

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 74 percent, while cover for trees less than 10 feet tall averages 26 percent Cover for shrubs greater than 20 inches tall (50 centimeters) averages 12 percent and cover for shrubs less than 20 inches tall averages 14 percent Herb/grass cover averages 12 percent

DOUGLAS-FIR-CALIFORNIA BLACK OAK/POISON OAK
Pseudotsuga menziesii-Quercus kelloggii/Rhus diversiloba
 PSME-QUKE/RHD16 (N=11; FS=11)

Distribution. This **Association** occurs on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is a dry, warm **Association**, the warmest of the Douglas-fir dry **associations**, and is one of the lowest in elevation. California black oak and poison oak, both dry site indicators, are frequently found.

Soils. Parent material is mostly mudstone, sandstone, and siltstone, with tephra and metavolcanics occurring occasionally. Average surface rock cover is less than 1 percent, with 4 percent each of gravel and bare ground exposure. Soils are generally moderately deep, but can be shallow or deep, with an average depth of 32 inches. Based on one plot sampled, surface texture is loam with 40 percent gravel. Subsurface texture is silty clay loam with 40 to 60 percent cobbles and stones.

Environment Average elevation is 2000 feet This **Association** is generally found on southerly aspects Slope averages 39 percent and ranges between 20 and 57 percent Slope position ranges from the lower one-third to the upper one-third of the slope.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 25 species. The overstory is dominated by Douglas-fir and sugar pine. The understory is dominated by Douglas-fir, California black oak, and Pacific madrone Sugar pine, tanoak, and canyon live oak are all frequent. Ponderosa pine is common. Poison oak and baldhip rose are frequent shrubs, while hairy honeysuckle is common Scouler's harebell, white-flowered hawkweed, slender-tubed iris, braken, and rattlesnake-plantain are common All shrubs and herbs have low cover values. Moss cover averages 7 percent

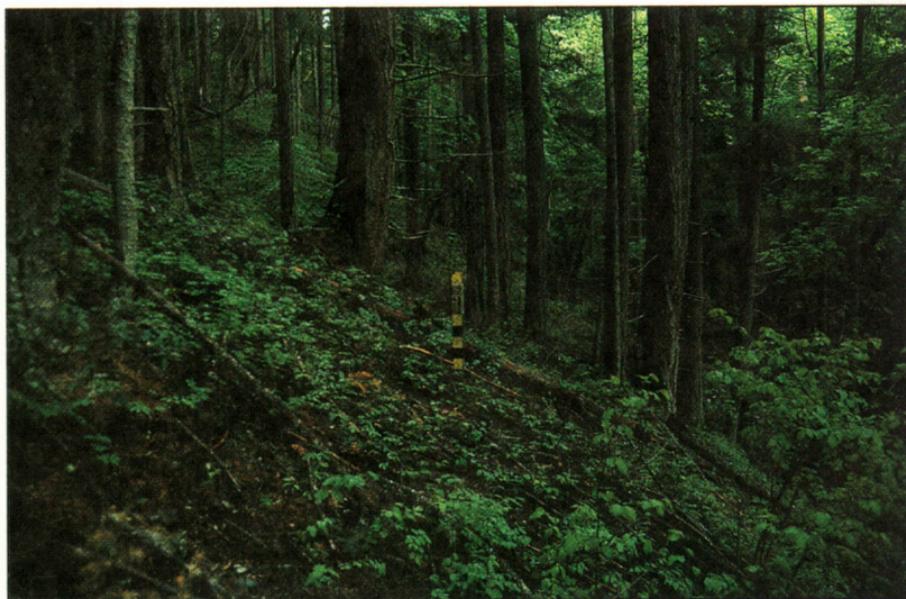

Upper layer and mid-layer tree covers are intermediate for the Series, averaging 60 and 44 percent, respectively. Lower layer tree cover is low, averaging 28 percent. High shrub and low shrub covers are low for the Series, averaging 5 and 8 percent, respectively. Herb/shrub cover is also low for the Series, averaging 15 percent.

DOUGLAS-FIR-CANYON LIVE OAK/DWARF OREGONGRAPE

Pseudotsuga menziesii-Quercus chrysolepis/Berberis nervosa

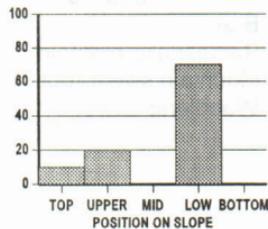

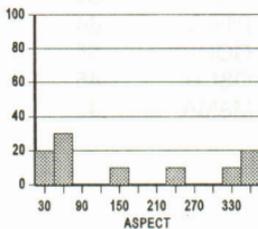

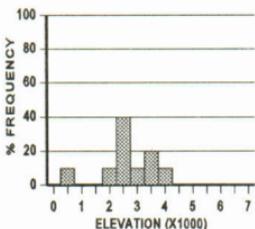

PSME-QUCH2/BENE2 (N=10; FS=10)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest, the Tiller Ranger District, Umpqua National Forest, and the Gold Beach Ranger District, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association is one of the cooler, drier associations in the Douglas-fir Series. Ponderosa pine and sugar pine are very rarely found.

Soils. Parent material is mostly schist and andesite, with some diorite, greywacke, and welded tuff. Average surface rock cover is 3 percent, with 10 percent gravel. Soils are generally deep but may be moderately deep, with an average depth of greater than 32 inches.

Environment Elevation averages 2610 feet Aspects vary, though, in general, tend to be northerly Slope averages 56 percent and ranges from 18 to 70 percent Slope position ranges from ridgetops to the lower one-third of the slope Generally, however, this **Association** is found on the lower one-third of the slope

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 41 species The overstory is dominated by Douglas-fir. The understory is dominated by Douglas-fir and Pacific madrone Canyon live oak and big-leaf maple are frequent, while California black oak and white fir are common Dwarf Oregongrape, creambush ocean-spray, creeping snowberry, and poison oak are frequent shrubs, generally with covers greater than 5 percent Hairy honeysuckle, baldhip rose, and Piper's Oregongrape are also frequent shrubs, but generally have covers less than 5 percent Western serviceberry, California hazel, thimbleberry, and common snowberry are common Frequent herbs include western sword-fern, western starflower, rattlesnake-plantain, and pathfinder, all with low covers Moss cover averages 22 percent

Upper layer tree cover is intermediate for the Series, averaging 64 percent Mid-layer tree cover is also intermediate, averaging 40 percent, while lower layer tree cover is low, averaging 17 percent High shrub cover is low for the Series, averaging 18 percent, while low shrub cover is intermediate, averaging 40 percent Herb/grass cover is also intermediate, averaging 35 percent

DOUGLAS-FIR-PONDEROSA PINE/POISON OAK
Pseudotsuga menziesii-*Pinus ponderosa*/*Rhus diversiloba*
 PSME-PIPO/RHD16 (N=17; FS=17)

Distribution. This Association occurs on the Applegate and Ashland Ranger Districts, Rogue River National Forest, the Chetco Ranger District, Siskiyou National Forest, and the Tiller Ranger District, Umpqua National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is one of the drier, cooler Douglas-fir associations. Ponderosa pine, California black oak, and poison oak, all dry site indicators, are usually present.

Soils. Parent material is mostly granite, gabbro or schist. Average surface rock cover is 7 percent, with 8 percent gravel. Soils are moderately deep to deep, with an average depth of greater than 39 inches. Based on one plot sampled, surface texture is loam with 45 percent gravel. Subsurface texture is sand with 65 to 85 percent gravel and cobbles.

Environment Elevation averages 3450 feet Aspects vary, though tend not to be northeast Slope averages 47 percent and ranges from 22 to 80 percent Slope position ranges from the lower one-third of the slope up to ridgetops

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 38 species. The overstory is dominated by Douglas-fir and ponderosa pine. Sugar pine is common. The understory is dominated by Douglas-fir Pacific madrone, ponderosa pine, and California black oak are frequent. Sugar pine is common Poison oak and Piper's Oregongrape are frequent shrubs, while creeping snowberry, deerbrush, western serviceberry, creambush ocean-spray, and hairy honeysuckle are common. Woodland tarweed, white-flowered hawkweed, and spreading dogbane are frequently occurring herbs, while woods strawberry, slender-tubed iris, mountain sweet-root, and American vetch are common Moss cover averages 3 percent.

Upper layer tree cover is low for the Series, averaging 49 percent Mid-layer tree cover is intermediate, averaging 40 percent, while lower layer tree cover is low, averaging 22 percent High shrub and low shrub covers are low for the Series, averaging 8 and 11 percent, respectively. Herb/grass cover is intermediate, averaging 35 percent

DOUGLAS-FIR-INCENSE-CEDAR/PIPER'S OREGONGRAPE
Pseudotsuga menziesii-Calocedrus decurrens/Berberis piperiana
 PSME-CADE27/BEPI2 (N=18; FS=18)

Distribution. This Association occurs on the Applegate, Ashland, and Prospect Ranger Districts, Rogue River National Forest, and the Tiller and North Umpqua Ranger Districts, Umpqua National Forest. It may also occur on the Butte Falls Ranger District, Rogue River National Forest and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is a drier, cooler Douglas-fir association. White fir is frequently present, but with relatively low covers. Piper's Oregongrape and poison oak, dry site indicators, are also frequently present.

Soils. Parent material is mostly schist, welded tuff, and basalt, with some andesite, diorite, and amphibolite. Average surface rock cover is 8 percent, with 8 percent gravel. Soils are generally deep, but may be moderately deep, with an average depth of greater than 40 inches.

Environment Elevation averages 3000 feet Aspects vary Slope averages 35 percent and ranges between 12 and 62 percent Slope position ranges from the upper one-third of the slope down to the lower one-third of the slope This

Association may also occur on benches and narrow flats

Vegetation Composition and Structure Total species richness is high for the Series, averaging 44 percent The overstory is dominated by Douglas-fir and ponderosa pine, with sugar pine and incense-cedar common **associates** Douglas-fir dominates the understory. Incense-cedar, white fir, and Pacific madrone frequently occur, generally with covers greater than 5 percent Sugar pine is common Frequently occurring shrubs include Piper's Oregongrape, baldhip rose, poison oak, creeping snowberry, and Pacific blackberry All have low covers except poison oak, which averages 12 percent cover Pathfinder, slender-tubed iris, rattlesnake-plantain, woods strawberry, white-flowered hawkweed, western starflower, and western sword-fern are all frequent herbs All generally have low cover values Moss cover averages 11 percent.

Upper layer tree cover is intermediate for the Series, averaging 64 percent Mid-layer tree cover is high, averaging 50 percent, while lower layer tree cover is low, averaging 21 percent Both high shrub and low shrub covers are low for the Series, averaging 10 and 28 percent, respectively Herb/grass cover is intermediate, averaging 35 percent

DOUGLAS-FIR-WHITE FIR/CREeping SNOWBERRY

Pseudotsuga menziesii-Abies concolor/Symphoricarpos mollis

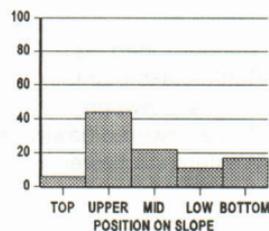

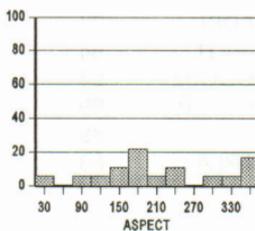

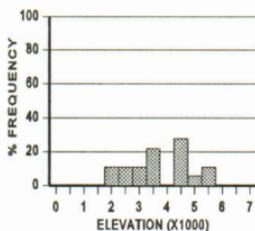

PSME-ABCO/SYMO (N=18; FS=18)

Distribution. This **Association** occurs on the Applegate and Ashland Ranger Districts, Rogue River National Forest and the Galice Ranger District, Siskiyou National Forest. It may also occur on the Illinois Valley Ranger District, Siskiyou National Forest and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is the driest Douglas-fir **Association**. It is also one of the coolest. White fir is frequently present, indicating a more productive site. Western sword-fern is generally absent.

Soils. Parent material is mostly schist, andesite, basalt, and granite. Soils are moderately deep to deep, with an average depth of greater than 40 inches. Average surface rock cover is 4 percent, with 6 percent gravel.

Environment Elevation averages 3730 feet This **Association** occurs on all aspects. Slopes average 38 percent and range from 3 to 76 percent This **Association** may occur on any slope position

Vegetation Composition and Structure Total species richness is low for the Series, averaging 33 species The overstory is dominated by Douglas-fir and ponderosa pine. The understory is dominated by Douglas-fir. White fir is frequent, while California black oak and Pacific madrone are common Frequent shrubs include creeping snowberry, baldhip rose, and Piper's Oregongrape Creambush ocean-spray and western snowberry are common All have very low covers Western starflower and white-flowered hawkweed are frequently occurring herbs, while Scouler's harebell, rattlesnake-plantain, mountain sweet-root, woods strawberry, pathfinder, catchweed bedstraw, and snowqueen are common All also have very low covers Moss cover averages 1 percent

Upper layer tree cover is high for the Series, averaging 71 percent. Mid-layer tree cover is intermediate, averaging 41 percent Lower layer tree cover, high and low shrub cover, and herb/grass cover are all low for the Series, averaging 18, 11, 16, and 19 percent, respectively

DOUGLAS-FIR-WHITE FIR

Pseudotsuga menziesii-Abies concolor

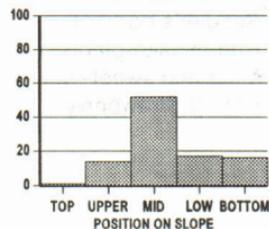

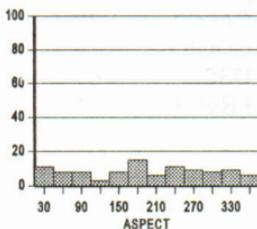

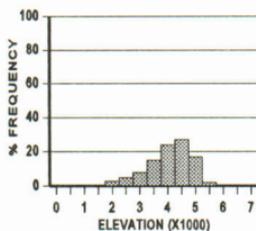

PSME-ABCO (N=66; BLM=41, FS=25)

Distribution. This Association occurs on the Applegate, Ashland, Prospect, and probably Butte Falls Ranger Districts, Rogue River National Forest, the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and all Districts of the Umpqua National Forest. It also occurs on the South River Resource Area, Roseburg District, the Klamath Falls Resource Area, Lakeview District, and all Resource Areas, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association is characterized by the frequent presence of white fir in both the overstory and the understory. Dwarf Oregongrape is also frequently found. This is one of the higher elevation, cooler Douglas-fir associations. The presence of white fir and sugar pine indicate more productive sites. This Association is probably transitional to the White Fir Series.

Soils. Parent material is mostly basalt, andesite, and granodiorite, with some gabbro

schist, and sandstone. Soils are mostly deep, but can be shallow, with an average depth of greater than 38 inches. Based on 40 plots sampled, soil textures are mostly sandy loam, with some silt loam, loam, and clay loam. Average rock fragment content is 37 percent, most of which is gravel (average 24 percent). Average surface rock cover is 7 percent, with 10 percent gravel.

Environment Elevation averages 4040 feet. Aspects vary. Slope averages 35 percent and ranges from 0 to 80 percent. This **Association** occurs on all slope positions. Average annual temperature is 45 degrees F and average annual precipitation is 49 inches.

Vegetation Composition and Structure Total species richness is low for the Series, averaging 32 species. The overstory is dominated by Douglas-fir, with white fir common. The understory is dominated by Douglas-fir with frequent occurrences of white fir. Dwarf Oregongrape frequently occurs in the shrub layer, while baldhip rose and creeping snowberry are common. Pacific blackberry and creambush ocean-spray are occasionally found. Western twinflower, common prince's-pine, white-flowered hawkweed, pathfinder, and Oregon fairybell are all commonly found. Moss cover averages 8 percent.

On Forest Service sites, upper layer tree cover is high for the Series, averaging 75 percent, while mid-layer tree cover is low, averaging 35 percent. Lower layer tree cover is also low for the Series, averaging 17 percent. High shrub and low shrub covers are both low for the Series, averaging 13 and 27 percent, respectively. Herb/grass cover is intermediate, averaging 30 percent.

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 76 percent, while cover for trees less than 10 feet tall averages 12 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 3 percent, and cover for shrubs less than 20 inches tall averages 13 percent. Herb/grass cover averages 19 percent.

DOUGLAS-FIR/CREAMBUSH OCEAN-SPRAY/WHIPPLEVINE-SWO
Pseudotsuga menziesii/Holodiscus discolor/Whipplea modesta
 PSME/HODI/WHMO-SWO (N=42; BLM=42)

Distribution. This Association is scattered east of the Coast Range crest on dry sites. It occurs within the Grants Pass and Glendale Resource Areas, Medford District, Bureau of Land Management, and is common on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. There may be occasional occurrences within the Butte Falls Resource Area, Medford District, Bureau of Land Management, and the Applegate Ranger District, Rogue River National Forest.

Distinguishing Characteristics. This Association occurs in the Siskiyou east of the coastal crest and possibly in the Cascades. Except for Pacific dogwood and big-leaf maple, the complement of species is characteristic of the dry side of the environmental gradient. Poison oak and whipplevine, at covers greater than 10 percent, are fairly faithful indicators of drier sites.

Soils Parent material is generally mixed sediment or metavolcanic. Based on 41 samples, soil depth averages at least 15 inches. Textures are mostly loam and less often clay loam, silt loam, or sandy loam. Average rock fragment content is 41 percent. Most fragments (33 percent) are of gravel size.

Environment. Elevation ranges from about 500 to 3500 feet. The average is 2000 feet with a peaked distribution around the mean. This **Association** occurs equally on all aspects, but overwhelmingly occupies midslope topographic positions. Rarely does it occur on ridgetops or bottomland topographic positions. Slopes average about 58 percent. Average annual temperature is about 50 degrees F and average annual precipitation is about 47 inches. Approximately 1 percent of the forest floor is exposed bedrock, 57 percent is covered with litter, 3 percent is bare ground, and 16 percent is covered with moss.

Vegetation Composition and Structure. Total species richness, low for the Series, is 32. The average number of species in all layers ranges from 27 to 41. Cover greater than 10 feet (3 meters) tall, usually trees, averages 74 percent. Tree cover less than 10 feet tall averages 8 percent, tall shrubs, greater than 20 inches (50 centimeters) tall, average 28 percent cover, low shrubs, less than 20 inches tall, average 30 percent cover, herb cover averages 8 percent. Douglas-fir dominates the overstory and understory layers. Both big-leaf maple and Pacific dogwood are notable as indicators of high atmospheric moisture usually **associated** with bottom slope positions. Canyon live oak, on the other hand, would be expected to occupy the upper slope positions. The shrub layer is dominated by dry site indicators (poison oak, hairy honeysuckle, creambush ocean-spray, and California hazel). Dwarf Oregongrape is the only contradictory indicator. It is found with higher cover on the sites with deeper soils. The herb/grass layer is also dominated by a dry site indicator, whipplevine. Although there are some herbs more commonly found on more moist sites, they are comparatively low in cover.

DOUGLAS-FIR/DRY SHRUB

Pseudotsuga menziesii/Dry shrub

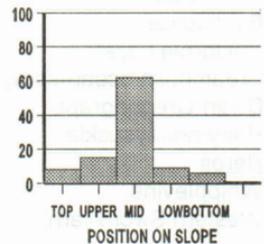

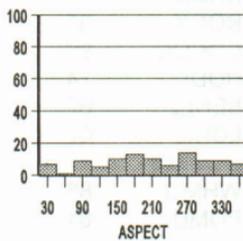

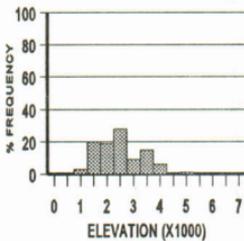

PSME/DRY SHRUB (N=86; BLM=86)

Distribution. This Association is scattered east of the Coast Range crest on dry sites. It occurs within the Grants Pass and Glendale Resource Areas, Medford District, Bureau of Land Management, and less often within the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and the Applegate Ranger District, Rogue River National Forest. There may be occasional occurrences in the west half of the Butte Falls Resource Area, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association only occurs in the Siskiyou east of the coastal crest and is not likely to occur in the Cascades. The presence of several dry shrubs (none have achieved dominance) is indicative of the hot, dry environment. Poison oak may have slightly more cover, but the overall combination of shrubs is better used to key to the associations.

Soils. Parent material varies from sandstone, mudstone, siltstone, shale, and mixed

metavolcanics to basalt. Based on 40 samples, soil depth averages at least 15 inches. Textures are mostly sandy clay loam, silt loam, sandy loam, or silty clay loam. Average rock fragment content is 42 percent. Most fragments (42 percent) are of gravel size.

Environment Elevation ranges from about 1000 feet to over 4000 feet. The average, somewhat normally distributed, is 2500 feet. This **Association** occurs on all aspects, but slightly more often in the southwest quadrant. It occurs on all slope positions, but usually occupies midslopes. Slopes average about 43 percent. Average annual temperature is about 49 degrees F and average annual precipitation is about 48 inches. Approximately 1 percent of the forest floor is exposed bedrock, 58 percent is covered with litter, 7 percent is bare ground, and 14 percent is covered with moss.

Vegetation Composition and Structure Total species richness, very low for the Series, is 26. The shrub layer, slightly depauperate, averages six species. Seven to 43 is the range for all layers of the **Association**. Cover greater than 10 feet (3 meters) tall, usually trees, averages 78 percent. Tree cover less than 10 feet tall, averages 8 percent, tall shrubs, greater than 20 inches (50 centimeters) tall, average 9 percent cover, low shrubs, less than 20 inches tall, average 13 percent cover, herb cover averages 18 percent. Madrone and sugar pine in a Douglas-fir dominated canopy are an indication that soils can be relatively deep. Both require high amounts of spring soil moisture. They may be contradicted as indicators by canyon live oak and California black oak in the understory. In this Series the complement of species alone is not enough to assess site environment. Interpretations must be balanced by considering relative cover and microsite differences. As the number and cover of dry site indicators increases, their indicator reliability increases. The shrub layer, for example, is a complement of dry indicators, all low in cover, but equal in value. White-flowered hawkweed and whipplevine support indications of dry microsites.

**WESTERN
HEMLOCK SERIES**

WESTERN HEMLOCK SERIES

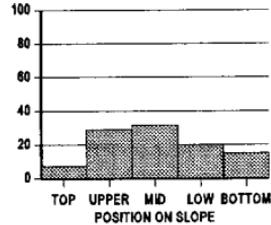

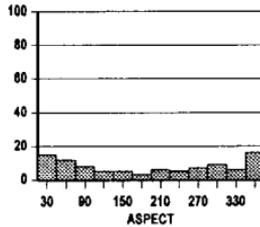

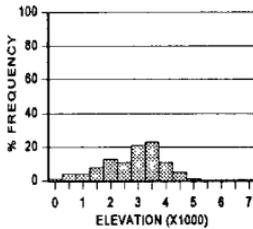

Tsuga heterophylla

TSHE

Diane E. White

Southwestern Oregon is the southern end of the range of the Western Hemlock Series. In the Cascade Mountains, this Series is abundant on the Cottage Grove and North Umpqua Ranger Districts and adjacent Bureau of Land Management lands. It extends south through the Umpqua National Forest to the Butte Falls Ranger District of the Rogue River National Forest. It is likely limited by dry conditions and is replaced by the White Fir Series to the south. In the Coast Range, the Western Hemlock Series extends south into the Gold Beach Ranger District of the Siskiyou National Forest and adjacent lands, and is replaced by the Tanoak Series where temperatures are warmer. The Douglas-fir Series occurs on hotter, drier sites, and the Pacific Silver Fir and Shasta Red Fir Series occur at higher elevations on cooler sites.

The Series covers a wide elevational band, though the average is approximately 3000 feet. It occurs on many types of soils. All aspects except south are well represented, and upper, middle, lower and valley bottom slope positions are more common than ridge tops. The Series includes highly productive lands, and has a high **plant** species diversity.

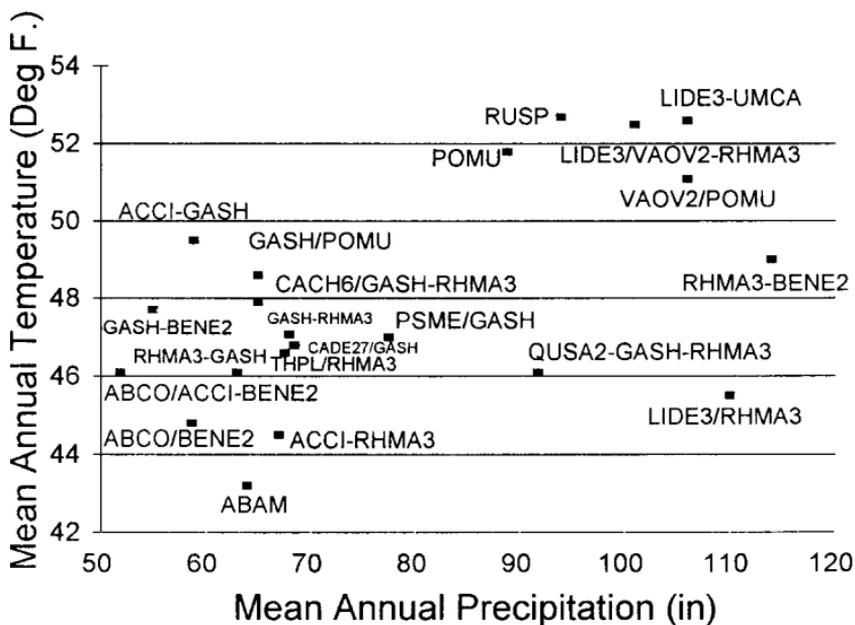

The Western Hemlock Series generally occurs in areas that are warm. Average annual temperatures range from 43 degrees F in the High Cascades to 53 degrees F in coastal areas. Average annual rainfall varies between 50 inches in drier areas of the Cascades to 115 inches near the coast.

Parent material is highly variable, although andesite and basalt are the most common. Soils range from shallow to deep, although moderately deep to deep are the most frequently encountered conditions. They are generally moderately to excessively well drained. Surface textures range from sand, sandy loam, loam, and loamy sand to sandy clay loam, silt loam, and clay loam. Rock fragments range from 5 to 80 percent, and clay content ranges from 1 to 60 percent. Subsurface textures range from sandy loam, loam, and silt loam, to sandy clay loam, clay loam, and occasionally clay. Rock fragments are between 2 and 90 percent. The soil moisture regime is either udic or xeric, the former being the most common. The temperature regime is frequently mesic and occasionally frigid. Samples include 95 soil pits.

TSHE 2

The relative environments of the **plant associations** are shown below. Each **association** is plotted by mean annual temperature and mean annual rainfall

As a result of frequent disturbances in southwestern Oregon, Douglas-fir, an early seral species, is the dominant overstory tree in the Western Hemlock Series. Western hemlock is the dominant tree species in the understory, and is particularly abundant in older stands with a low frequency of disturbance. In wetter areas of the Cascades, western redcedar is present, and at higher elevation, cooler areas, white fir or Pacific silver fir are present. In the coastal Siskiyou Mountains, tanoak may be present, and in areas that tend toward ultramafic soils, Port-Orford-cedar is common. Salal is widespread throughout the Series, absent only from the high elevation, cooler areas, and the lowest elevation wet sites. Pacific rhododendron is common, but less widespread than salal, and tends to reflect low productivity areas. Golden chinquapin and whipplevine are present on dry, rocky sites.

Average vascular **plant** species richness for the Western Hemlock Series ranges between 18 and 38. In this series, richness is rated as very low, 18 to 21 species, low, 22 to 25 species, intermediate, 26 to 29 species, high, 30 to 33 species, and very high, 34 to 38 species.

Upper layer tree canopy cover ranges from 58 percent in the Western Hemlock-Douglas-fir/Salal **Association**, to 84 percent in the coastal Western Hemlock/Pacific Rhododendron-Dwarf Oregongrape **Association**. The mid-layer tree canopy cover ranges between 39 and 65 percent. The lower layer tree canopy cover ranges

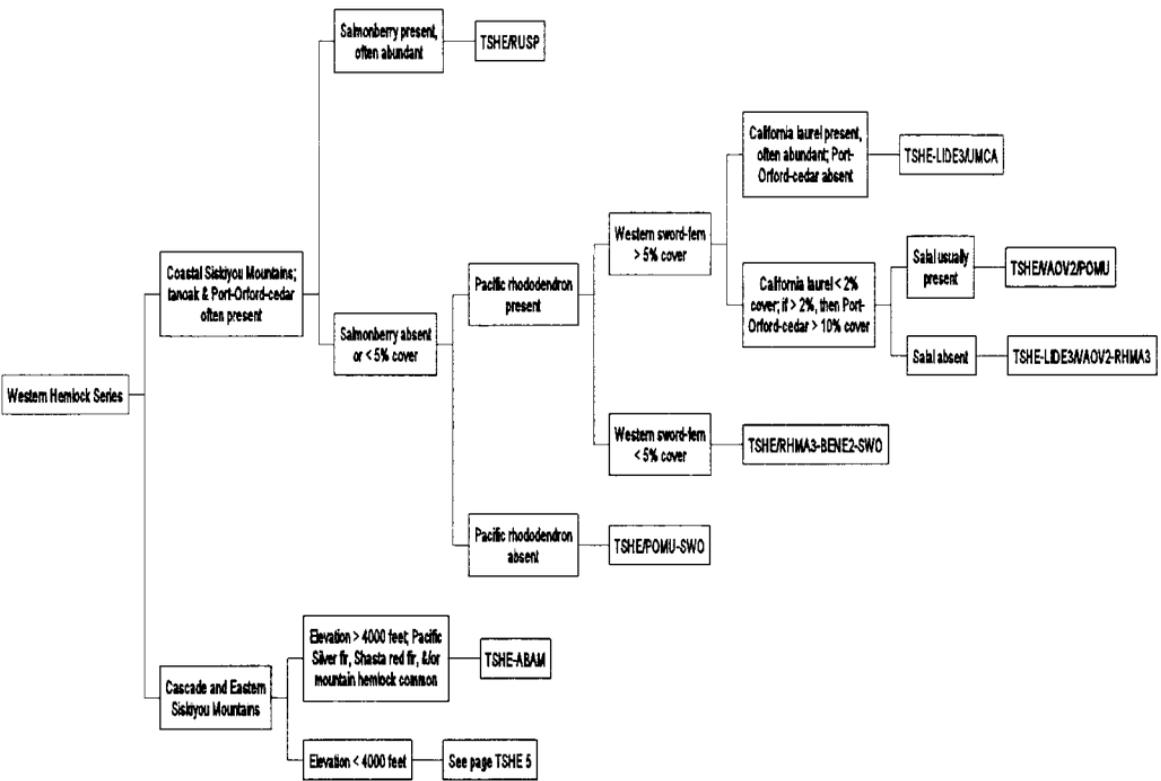

between 24 and 56 percent. High shrub cover ranges between 1 and 44 percent, and low shrub cover ranges between 10 and 81 percent. Herb/grass layer cover ranges between 10 and 85 percent.

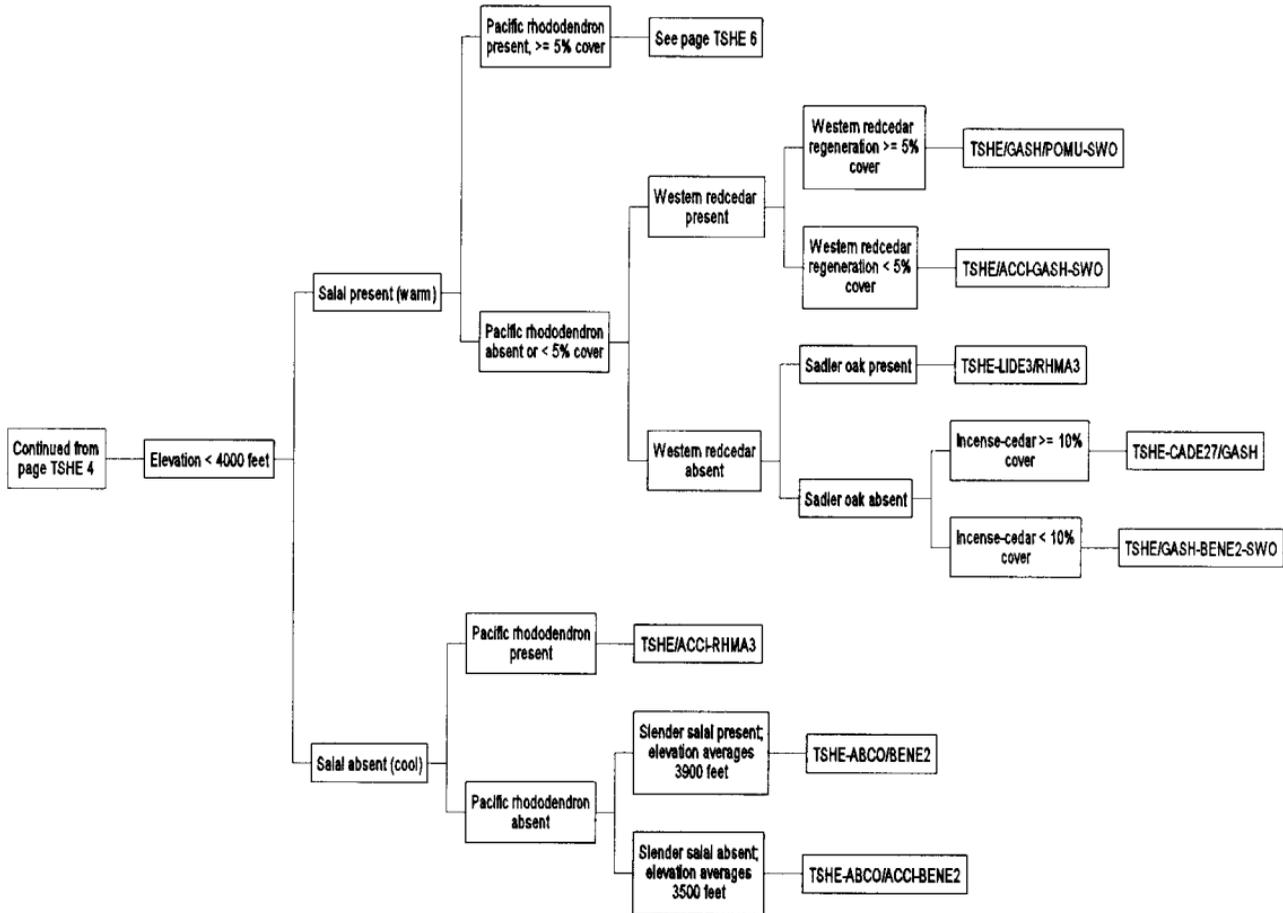

Twenty-one **plant associations** have been identified for the Series in southwestern Oregon. They were described from 272 plots (178 Forest Service, 76 Natural Resource Conservation Service, and 18 Bureau of Land Management). In addition, on the Cottage Grove Ranger District, the Western Hemlock/Dwarf Oregongrape and Western Hemlock/Oregon Oxalis **Plant Associations**, described on the Willamette National Forest, may occur. Complete descriptions of these **plant associations** may be found in the **Plant Association and Management Guide, Willamette National Forest** (Hemstrom, Logan, and Pavlat, 1987).

WESTERN HEMLOCK/SALMONBERRY

Tsuga heterophylla/Rubus spectabilis

TSHE/RUSP (N=28; NRCS=28)

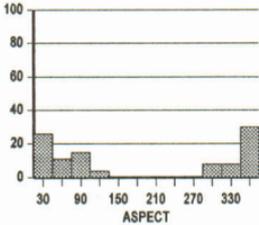

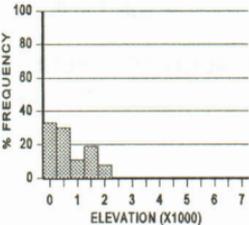

Distribution. This Association is found on the west side of the Siskiyou Mountains and adjacent coastal areas. Occurrence is likely on the Coos Bay District, Bureau of Land Management.

Distinguishing Characteristics. The shrub layer of this Association is dominated by salmonberry. This Association occurs on north aspects at low elevations. It is wet, and is the warmest Association of the Western Hemlock Series.

Soils. Soil data are not available.

Environment. This Association averages 855 feet in elevation. Aspect is primarily north, however sampling was biased to north slopes. Slope averages 30 percent and ranges between 1 and 60 percent.

No slope position data available

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 26. The overstory is dominated by Douglas-fir, and western hemlock is commonly present. Red alder is frequently encountered and white fir is common. In the understory, western hemlock is frequently encountered and Port-Orford-cedar and tanoak are common. Hardwoods can be dense in some areas. In the shrub layer, salmonberry and red huckleberry are usually present. Evergreen huckleberry, dwarf Oregongrape, and Pacific blackberry are commonly encountered. In the herb/grass layer, western sword-fern and candyflower are frequently present, and Oregon oxalis, fragrant bedstraw, and bearded fescue are common associates.

WESTERN HEMLOCK/SWORDFERN-SWO
Tsuga heterophylla/Polystichum munitum
TSHE/POMU-SWO (N=7; FS=7)

Distribution. The Western Hemlock/Western Sword-fern-SWO Association is found on the Powers and Gold Beach Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs on sites that are wet and warm during the winter months, and humid during the summer. Big-leaf maple and Port-Orford-cedar are indicators of these environmental conditions.

Soils. Parent material is most commonly sandstone, with one occurrence each of breccia and schist. Based on three pits sampled, soils are moderately deep and well drained. Surface textures are loams with 30 to 65 percent rock fragments and 15 to 20 percent clay. Subsurface textures are loams and clay loams with 65 to 75 percent rock fragments and 25 to 30 percent clay. The soil moisture regime is probably udic and the soil temperature regime is probably frigid. These soils classify into the following great groups: Typic Haplumbrepts and Typic Dystochrepts.

Environment Elevation averages 1210 feet in elevation and aspect is primarily north Slope averages 42 percent and ranges between 11 and 80 percent This Association occurs predominantly on lower slopes to valley bottoms

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 28. The overstory is dominated by Douglas-fir, western hemlock is present, and white fir may have high cover in some areas. Port-Orford-cedar is frequent, though at low covers. In the understory, in addition to western hemlock, big-leaf maple, tanoak, and Port-Orford-cedar are frequent, while California-laurel is common. In some areas, vine maple may be dense, with up to 50 percent cover. Shrubs are a small component of this Association. Red huckleberry and dwarf Oregongrape are frequently encountered, but at low covers. Evergreen huckleberry and salmonberry are common. The herbaceous layer is diverse. Western sword-fern is the most dominant species, with up to 90 percent cover in some areas. Oregon oxalis is present with covers ranging from 1 to 40 percent. Fern diversity is high. Moss cover is intermediate for the Series, averaging 26 percent.

Upper layer tree cover is high for the Series, averaging 76 percent. Mid-layer and lower layer tree covers are intermediate, averaging 55 and 39 percent, respectively. Shrub cover is low, with high shrubs averaging 5 percent cover and low shrubs 10 percent cover. This Association has, by far, the highest total herb/grass cover for the Series, averaging 85 percent.

WESTERN HEMLOCK-TANOAK-CALIFORNIA-LAUREL
Tsuga heterophylla-Lithocarpus densiflorus-Umbellularia californica
 TSHE-LIDE3-UMCA (N=9; NRCS=9)

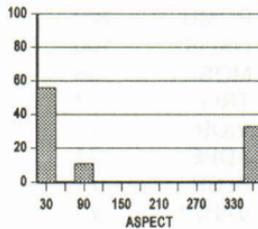

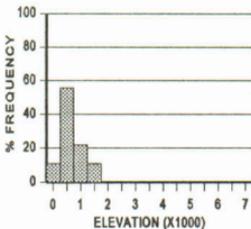

Distribution. This Association is found on the west side of the Siskiyou Mountains near the coast. This Association is likely found on the Coos Bay District, Bureau of Land Management.

Distinguishing Characteristics. This Association is found on north aspects at low elevations. It differs from the Western Hemlock-Tanoak/Evergreen Huckleberry-Pacific Rhododendron Association by the occurrence of California-laurel.

Soils. Soil data are not available.

Environment. This Association averages 850 feet in elevation and aspect is primarily north, although sampling was primarily on north slopes. Slope averages 51 percent and ranges between 30 and 65 percent.

No slope position data available

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 29. The overstory is dominated by western hemlock, while Douglas-fir and tanoak are frequently encountered. The understory is dominated by western hemlock. California-laurel is common. The hardwood component may be represented by tanoak, California-laurel, big-leaf maple, or vine maple. Evergreen huckleberry is frequently encountered in the shrub layer, and Pacific rhododendron may be abundant in some areas. Dwarf Oregongrape is frequently encountered. Western sword-fern is present in the herb/grass layer and may be dominant. Oregon oxalis is frequent.

WESTERN HEMLOCK/EVERGREEN HUCKLEBERRY/WESTERN SWORD-FERN
Tsuga heterophylla/Vaccinium ovatum/Polystichum munitum
TSHE/VAOV2/POMU (N=12; FS=12)

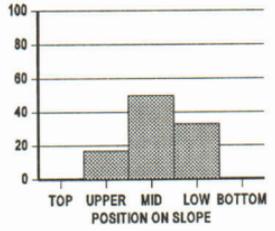

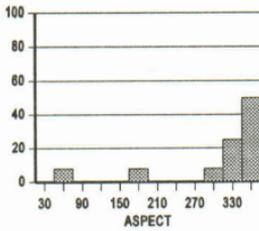

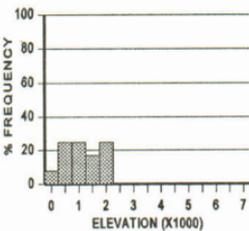

Distribution. This Association is found on the Gold Beach and Powers Ranger Districts, Siskiyou National Forest and may be present on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association is found in the warm, wet environments of the Western Hemlock Series. Elevation is generally low. Multiple species of ferns may be encountered, and Oregon oxalis is a common species.

Soils. Parent materials are predominantly sandstone. Based on nine plots sampled, soil is moderately deep to deep. Surface rock content ranges from 0 to 80 percent, and averages 12 percent.

Environment. This Association averages 1370 feet in elevation. Slopes are often steep, with an average of 62 percent, and a range between 20 and 80 percent. North aspects predominate. This Association rarely occurs on ridge tops or valleys.

Vegetation Composition and Structure Total species richness is low for the Series, averaging 24. The overstory tree layer is dominated by Douglas-fir, and western hemlock and Port-Orford-cedar are common. The understory is dominated by western hemlock. Tanoak is frequently present, but only with low cover. Hardwoods are common to occasional, and may include vine maple, big-leaf maple, red alder, Pacific madrone, golden chinquapin, Pacific dogwood, tanoak, and California-laurel. Pacific rhododendron, red huckleberry, dwarf Oregongrape, salal, and evergreen huckleberry are frequent components of the shrub layer. The herb/grass layer is dominated by western sword-fern while Oregon oxalis is a frequent component. Moss cover is high for the Series, averaging 34 percent.

Upper and mid-layer tree covers are at intermediate and high for the Series, averaging 72 and 63 percent, respectively. Lower layer tree cover is high, averaging 48 percent. Shrub covers are also intermediate, with high shrubs averaging 23 percent and low shrubs, 32 percent. Total herb/grass cover averages 44 percent, but ranges from 6 to 95 percent.

Common name	Code	Constancy	Cover	Avg Richness

TSHE 20

WESTERN HEMLOCK-TANOAK/EVERGREEN HUCKLEBERRY-PACIFIC RHODODENDRON
Tsuga heterophylla-Lithocarpus densiflorus/Vaccinium ovatum-Rhododendron macrophyllum
TSHE-LIDE3/VAOV2-RHMA3 (N=10; NRCS=10)

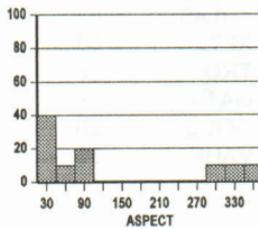

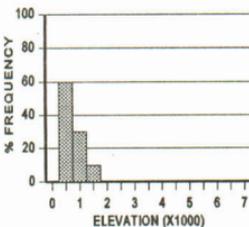

Distribution. This Association occurs on the west slopes of the Siskiyou Mountains near the coast. This Association likely occurs on the Coos Bay District, Bureau of Land Management.

Distinguishing Characteristics. Salmonberry is usually absent and tanoak is usually abundant. This Association is generally found at higher elevations and averages higher precipitation and slightly cooler temperatures than the Western Hemlock/ Salmonberry Association.

Soils. Soil data are not available.

Environment. This Association averages 960 feet in elevation and occurs primarily on northern aspects (although only north slopes were sampled). Slope averages 32 percent and ranges between 10 and 60 percent.

No slope position data available

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging only 19. The overstory is dominated by western hemlock and tanoak. Douglas-fir is frequently encountered and often abundant. Port-Orford-cedar and red alder are common. In the understory, tanoak and western hemlock are frequent, and Port-Orford-cedar common. The hardwood component, represented solely by tanoak, can be abundant. Evergreen huckleberry is present in the shrub layer. Pacific rhododendron is frequently found and can be abundant in some areas. Dwarf Oregon grape is common. Redwoods violet is present in the herb/grass layer. Western sword-fern is frequent and can be abundant. Oregon oxalis is a common **associate**.

WESTERN HEMLOCK/PACIFIC RHODODENDRON-DWARF OREGONGRAPE-SWO
Tsuga heterophylla/Rhododendron macrophyllum-Berberis nervosa
 TSHE/RHMA3-BENE2-SWO (N=34; NRCS=29, FS=5)

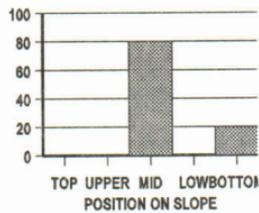

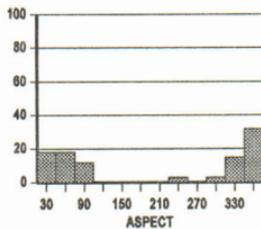

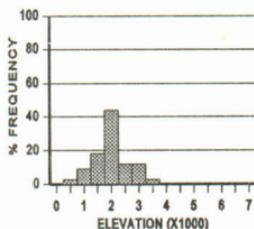

Distribution. This Association occurs in the western portion of the Siskiyou National Forest and adjacent coastal areas. It may also be present on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This is a coastal Siskiyou Mountain plant association. It is the wettest of the Western Hemlock Series and the coolest of the coastal Western Hemlock Associations. This Association has a dense shrub layer consisting of Pacific rhododendron and salal.

Soils. Parent material is sandstone. Based on four plots sampled, soils are deep. Surface rock averages 3 percent and ranges from 0 to 10 percent.

Environment. This Association averages 2250 feet in elevation and aspect is primarily north, although sampling was biased toward north slopes. Slope averages

37 percent and ranges between 5 and 65 percent. This **Association** occurs primarily on middle thirds of slopes (based on data available only from the Forest Service plots)

Vegetation Composition and Structure Total species richness is the lowest for the Series, averaging only 18. The overstory is dominated by Douglas-fir, western hemlock is frequent, and Port-Orford-cedar is occasional. The understory is dominated by western hemlock, while tanoak, Douglas-fir, and Port-Orford-cedar are also frequently encountered. In the shrub layer, Pacific rhododendron, red huckleberry, salal, and dwarf Oregongrape are frequent. Salal may be quite dense in some areas. The most frequently found herbs are round-leaved violet and braken.

Upper layer tree cover is the highest for the Series, averaging 84 percent. Mid-layer tree cover and low layer tree cover are intermediate, averaging 52 and 36 percent, respectively. Shrub cover is also intermediate with high shrub averaging 32 percent and low shrub 59 percent. Herb cover is second lowest for the Series, averaging only 13 percent.

WESTERN HEMLOCK-DOUGLAS-FIR/SALAL-SWO
Tsuga heterophylla-Pseudotsuga menziesii/Gaultheria shallon
TSHE-PSME/GASH-SWO (N=5; FS=5)

Distribution. This Association is found on the Cottage Grove and North Umpqua Ranger Districts, Umpqua National Forest and the Illinois Valley and Powers Ranger Districts, Siskiyou National Forest. It is likely found on the Swiftwater Resource Area of the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This Association often occurs on dry, rocky sites on upper to middle-third slope positions. It is transitional to the Douglas-fir Series, as evidenced by the constancy and abundance of Douglas-fir regeneration and golden chinquapin cover.

Soils. Parent material is highly variable and may include chert, breccia, tephra, andesite, and granite. Based on four plots sampled, soils are moderately deep to deep, and well drained. Surface textures are loams with 30 to 60 percent rock fragments and 12 to 20 percent clay. Subsurface textures are loams and clay loams

with

with 30 to 60 percent rock fragments. The soil moisture regime is probably xeric and soil temperature regime is probably mesic. Soils classify into the following subgroups: Typic Xerumbrepts and Typic Xerochrepts.

Environment. This **Association** averages 3160 feet in elevation and aspect is variable. Slope averages 33 percent and ranges between 13 and 45 percent. This **Association** occurs on middle to upper thirds of slopes.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 23. The overstory tree cover is dominated by Douglas-fir. Western hemlock is frequent, but at lower covers. The understory is dominated by western hemlock. It includes golden chinquapin and Douglas-fir regeneration averaging 14 percent and 11 percent cover, respectively. The hardwood component is dominated by the evergreen species, golden chinquapin, tanoak, and canyon live oak. Other hardwoods that may be present are vine maple, big-leaf maple, and Pacific dogwood. The shrub layer is dominated by salal and Pacific rhododendron. Dwarf Oregongrape is frequent at low covers, and red huckleberry and baldhip rose are common. Herbaceous species presence is variable, though whitevein pyrola and braken are frequently encountered. Moss cover is low for the Series, averaging only 9 percent.

Upper layer tree cover is lowest of the Series, averaging only 58 percent. Mid-layer tree cover is intermediate, averaging 55 percent and lower layer tree cover is very high, averaging 52 percent. Shrubs are a significant component of the structure in this **Association**. High shrubs average 40 percent cover, while low shrubs average 81 percent cover, the highest of the Series. Herb/grass cover ranges from 5 to 35 percent, and averages 16 percent.

WESTERN HEMLOCK/SALAL-PACIFIC RHODODENDRON-SWO
Tsuga heterophylla/Gaultheria shallon-Rhododendron macrophyllum
 TSHE/GASH-RHMA3-SWO (N=20; FS=20)

Distribution. This **Association** occurs on the Cottage Grove, North Umpqua, and Tiller Ranger Districts, Umpqua National Forest. It is likely to occur on the Swiftwater Resource Area of the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This **Association** is on warm sites, although not as harsh as the Western Hemlock-Golden Chinquapin/Salal-Pacific Rhododendron **Association**. On the Tiller Ranger District it occurs at elevations over 3500 feet. Whipplevine, a rocky site indicator, is generally present.

Soils. Parent material is primarily andesite or basalt, however, occasionally pumice, tephra, andesite, gabbro, sandstone, breccia, or granite may be present. Based on nine plots sampled, soils are moderately deep to deep, and well to moderately well drained. Surface textures are loams and clay loams with 15 to 70 percent rock fragments and 15 to 25 percent clay. Subsurface textures are loams, clay loams,

and clays, with 20 to 70 percent rock fragments. The soil moisture regime is probably udic and the soil temperature regime is probably mesic. Subgroups include. Typic Haplumbrepts, Typic Udorthents, and Mollic Hapludalfs.

Environment. This **Association** averages 3010 feet in elevation and aspect is variable, though often east or north. Slope averages 34 percent and ranges between 7 and 67 percent. This **Association** is commonly on upper slopes.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 35. The overstory tree layer is dominated by Douglas-fir, and Douglas-fir and golden chinquapin are frequent in the understory. Hardwoods include Rocky Mountain maple, big-leaf maple, red alder, and tanoak; average covers are very low. The shrub layer is dominated by salal, Pacific rhododendron, and dwarf Oregongrape. Whipplevine and twinflower are frequent in the herb/grass layer, the latter at fairly high covers. Rattlesnake-plantain, western sword-fern, common prince's-pine, and round-leaved violet are also frequent, and western starflower, Oregon fairybell, white-flowered hawkweed, and white trillium are common **associates**. Moss cover is moderate for the Series, averaging 18 percent.

Upper, middle, and lower layer tree covers are about average for the Western Hemlock Series averaging 68, 55, and 41 percent, respectively. High shrubs average 28 percent cover and low shrubs 57 percent cover. Herb/grass cover averages 26 percent.

WESTERN HEMLOCK-PACIFIC SILVER FIR

Tsuga heterophylla-Abies amabilis

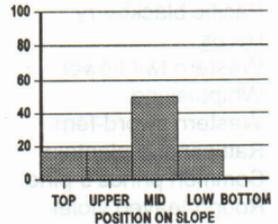

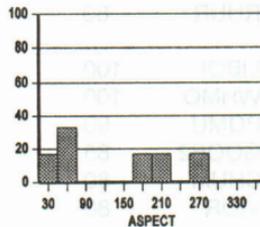

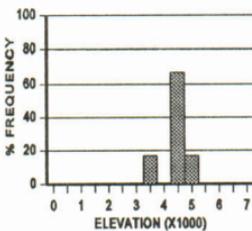

TSHE-ABAM (N=6; FS=6)

Distribution. This Association occurs on the Umpqua National Forest, primarily on the Diamond Lake Ranger District, but also on the Cottage Grove and North Umpqua Ranger Districts.

Distinguishing Characteristics. This Association is present at the highest elevations of the Series, on cool, moist sites. It is bounded at higher elevations by the Pacific Silver Fir Series and at lower elevations by other Western Hemlock Associations.

Soils. Parent material is most commonly basalt, andesite, or pumice mixed with ash. Based on five plots sampled, soils are deep and somewhat excessively well drained. Surface textures are loams and loamy sands with 10 to 80 percent rock fragments and 1 to 17 percent clay. Subsurface textures are loams and sandy loams with 20 to 90 percent rock fragments. The soil moisture regime is probably udic and the soil temperature regime is probably frigid. Soils classify into the following subgroups:

Dystrochrepts and Typic Udorthents.

Environment. This **Association** occurs at high elevations, averaging 3930 feet, and on variable aspects. Slope averages 32 percent and ranges between 3 and 77 percent. This **Association** is commonly found on middle-third slope positions.

Vegetation Composition and Structure. Total species richness for the Series is low compared with other **plant associations** in the Series, averaging 24. The overstory tree layer is dominated by Douglas-fir and western hemlock, with a significant component of Pacific silver fir in both the overstory and understory. Thin-leaved huckleberry is a frequent component of the shrub layer. Shrubs are generally not dominant, compared with other western hemlock **associations**. Vanillaleaf, common prince's-pine, western twinflower, one-sided pyrola, and coolwort foamflower are frequent in the herb/grass layer. Moss cover averages 9 percent.

Upper layer tree cover is relatively high for the Series, averaging 73 percent. Mid-layer tree cover averages 39 percent, and lower layer tree cover averages 24 percent. High shrub cover is very low (1 percent), but low shrub cover averages close to 10 percent. The herbaceous layer is quite variable, ranging from 2 to 85 percent cover, and averaging 30 percent.

WESTERN HEMLOCK-GOLDEN CHINQUAPIN/SALAL-PACIFIC RHODODENDRON
Tsuga heterophylla-*Castanopsis chrysophylla*/*Gaultheria shallon*-*Rhododendron macrophyllum*
TSHE-CACH6/GASH-RHMA3 (N=6; FS=6)

Distribution. This Association occurs on the Cottage Grove, North Umpqua, and Tiller Ranger Districts of the Umpqua National Forest.

Distinguishing Characteristics. This Association occurs on rocky sites. The climate is warmer compared with other Cascade Mountain western hemlock associations. Dry site indicators golden chinquapin and whipplevine are present, and honeysuckle and poison oak may be present occasionally.

Soils. Parent material is most commonly andesite, basalt, or sandstone, with infrequent occurrences of tephra. Based on five plots sampled, soils are moderately deep and well drained. Surface texture is loam with 45 to 70 percent rock fragments and 20 to 30 percent clay. Subsurface texture is loam and clay loam with 35 to 75 percent rock fragments. The soil moisture regime is probably xeric, and the soil temperature regime is probably mesic. Soils classify into the following subgroups:

Typic Xerochrepts and Typic Haploxeralfs.

Environment. This Association averages 2900 feet in elevation and occurs predominantly on south aspects. Slopes average 42 percent and range between 20 and 75 percent. This Association occurs primarily on middle to upper thirds of slopes.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 35. The overstory tree layer is dominated by Douglas-fir. Incense-cedar, sugar pine, and western hemlock are almost always present. Understory tree cover is rich, with western hemlock, Douglas-fir, golden chinquapin, incense-cedar, and Pacific yew frequent, and Pacific madrone common. Hardwoods include big-leaf maple, vine maple, red alder, and Pacific dogwood. Dwarf Oregongrape, salal, and Pacific rhododendron are frequent, with high covers of salal and Pacific rhododendron. The dry site indicators silk-tassel (*Garrya*) and honeysuckle (*Lonicera*) are sometimes present. The most frequent herbs are vanillaleaf, whipplevine, and western twinflower. Moss cover averages 19 percent.

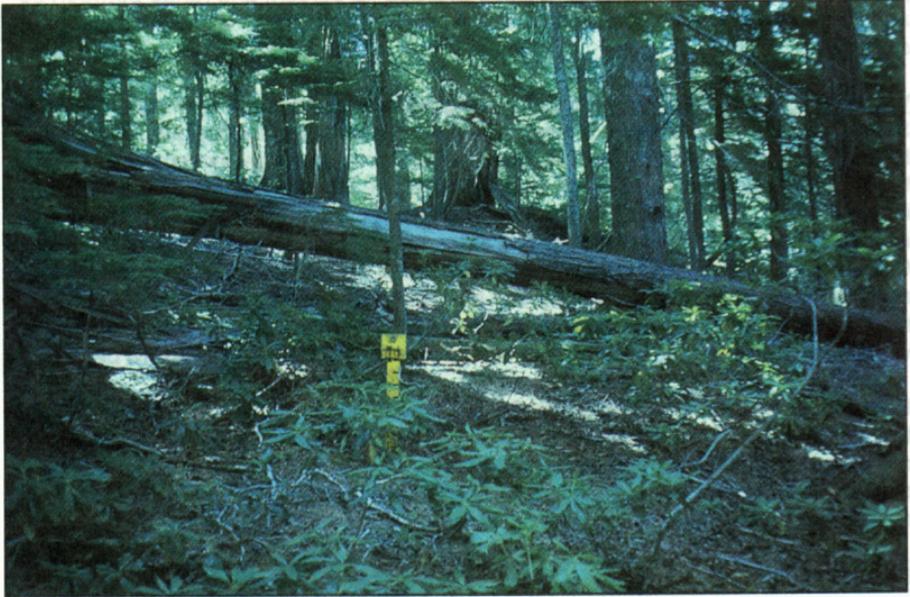

Upper layer tree cover is low for the Series, averaging 66 percent. Middle and lower tree layer covers are moderate with 52 and 43 percent cover, respectively. Shrub covers are high; high shrubs average 36 percent cover and low shrubs 62 percent cover. Herb/grass cover is fairly low for the Series, averaging 20 percent, and ranges between 10 and 45 percent cover.

WESTERN HEMLOCK-TANOAK/PACIFIC RHODODENDRON

Tsuga heterophylla-Lithocarpus densiflorus/Rhododendron macrophyllum

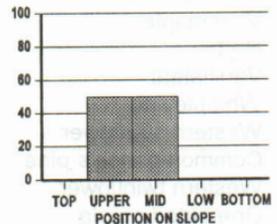

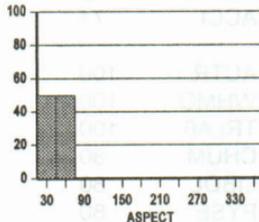

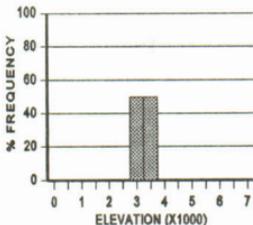

TSHE-LIDE3/RHMA3 (N=2; FS=2)

Distribution. This **Association** occurs on the Galice Ranger District, Siskiyou National Forest. It may also be present on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This **Association** occurs at intermediate elevations, on cold aspects, in very wet areas. Tanoak and Sadler oak, in addition to Pacific rhododendron and common beargrass, are the characteristic species.

Soils. Parent material is sandstone. Based on two plots sampled, soils are moderately deep and well drained. Surface and subsurface textures are sandy clay loam with 60 to 80 percent rock fragments and 20 to 35 percent clay. The soil moisture regime may be udic or xeric and the soil temperature regime may be mesic or frigid. Soils classify into the following subgroups: Typic and Mollic Hapludalfs.

Environment. This **Association** averages 3490 feet in elevation and aspect is northerly. Slope averages 62 percent and ranges between 38 and 85 percent. This **Association** occurs on middle to upper thirds of slopes.

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 29. The overstory is dominated by western hemlock and Douglas-fir. White fir is also present, and incense-cedar is common. In addition to the overstory species, the understory includes tanoak, Pacific yew and western redcedar, all at low covers. Hardwoods are not a dominant component. The shrub layer is characterized by vine maple, Pacific rhododendron, and sometimes Sadler oak. Most other shrubs are present at very low covers. The herbaceous layer also has low cover. Moss cover exceeds herb cover, averaging 18 percent.

Upper layer tree cover averages 80 percent and is exceeded only by the Western Hemlock/Pacific Rhododendron-Dwarf Oregongrape-SWO **Association**. Mid-layer tree cover is intermediate, averaging 63 percent, and lower layer tree cover is sparse, averaging only 30 percent. High shrub and low shrub layers average only 13 and 18 percent cover, respectively. Total herb/grass cover, lowest of the Series, averages 10 percent.

WESTERN HEMLOCK-WESTERN REDCEDAR/PACIFIC RHODODENDRON
Tsuga heterophylla-Thuja plicata/Rhododendron macrophyllum
 TSHE-THPL/RHMA3 (N=6; FS=6)

Distribution. This Association occurs on the Cottage Grove, North Umpqua, and Diamond Lake Ranger Districts, Umpqua National Forest. It is likely to occur on the Swiftwater Resource Area, Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs at moderate elevations in the Cascade Mountains. It occurs in moist environments, although not quite as moist as the Western Hemlock/Salal/Western Sword-fern-SWO Association. Western redcedar is an important component, and Pacific yew, a humid site indicator, is present.

Soils. Parent material is highly variable and may include gabbro, tephra, rhyolite, pumice, andesite, sandstone, and breccia. Based on five plots sampled, soils are moderately deep to deep and well drained. Surface textures are loams and loamy sands with 45 to 80 percent rock fragments and 10 to 20 percent clay. Subsurface

textures are sandy loams, clay loams, and clays, with 30 to 85 percent rock fragments. The soil moisture regime is probably udic and the soil temperature regime is probably mesic. The soils classify into the following subgroups: Typic Dystrachrepts and Mollic Hapludalfs.

Environment. This **Association** averages 3110 feet in elevation and aspects are north and west. Slope averages 31 percent, and ranges between 14 and 60 percent. This **Association** occurs predominantly on lower slopes.

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 28. The overstory is dominated by Douglas-fir, and western hemlock and western redcedar are also frequent. The understory may have abundant western redcedar. Pacific yew and golden chinquapin are frequent, however, the covers are low. Hardwoods are not a significant component of the stand. Vine maple and golden chinquapin are present, but average only 2 and 3 percent cover, respectively. The shrub layer is dominated by Pacific rhododendron. Salal and dwarf Oregongrape are frequent and may also be abundant. Red huckleberry is also frequent, but at low cover. Western twinflower and whitevein pyrola are frequent in the herb/grass layer. Western sword-fern is frequent, but at very low cover. Moss cover is intermediate for the Series, and averages 23 percent.

Upper layer tree cover is high for the Series, averaging 73 percent. Middle and lower layer tree covers average 57 and 40 percent, respectively. Shrub cover is dominant in this **association**. High shrubs average 44 percent cover, the highest in the Series, and low shrubs average 60 percent cover. Total herb/grass cover is intermediate for the Series, averaging 23 percent, and ranges from 5 to 55 percent.

WESTERN HEMLOCK/PACIFIC RHODODENDRON-SALAL-SWO
Tsuga heterophylla/Rhododendron macrophyllum-Gaultheria shallon
 TSHE/RHMA3-GASH-SWO (N=14; FS=14)

Distribution. This Association occurs on the Cottage Grove, North Umpqua, and Tiller Ranger Districts, Umpqua National Forest and is likely found on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. The Western Hemlock/Pacific Rhododendron-Salal-SWO Association is similar to the Western Hemlock-Western Redcedar/Pacific Rhododendron Association, only drier.

Soils. Parent material is most commonly andesite and basalt, with occasional occurrences of granite, breccia, sandstone, and tephra. Based on six plots sampled, soils are moderately deep and well drained. Surface soil textures are loam with 30 to 55 percent rock fragments and 15 to 25 percent clay. Subsurface textures are clay loams and loams with 30 to 60 percent rock fragments. The soil moisture regime is probably udic; the soil temperature regime may be mesic or frigid. Soils

classify into the following subgroups: Typic Dystrochrepts and Typic Hapludalfs.

Environment. This Association averages 3430 feet in elevation and aspect is variable, though rarely directly south. Slope averages 36 percent and ranges between 3 and 89 percent. This Association often occurs on upper slopes.

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 27. The overstory is dominated by Douglas-fir. Western hemlock is frequently found and western white pine is commonly encountered. The understory is predominantly western hemlock. Douglas-fir and Pacific yew are common, while golden chinquapin is frequently encountered. The shrub layer is dominated by Pacific rhododendron, which in some areas can be very dense. Salal, dwarf Oregongrape, Pacific blackberry, and red huckleberry are frequently encountered. Common prince's-pine, western twinflower, and western sword-fern are frequently encountered in the herb/grass layer. Moss cover is intermediate for the Series, averaging 20 percent cover.

Upper and mid-layer tree covers are intermediate for the Series, averaging 70 and 56 percent, respectively. Lower layer tree cover is low, averaging only 29 percent. High shrub cover is high, averaging 42 percent, and low shrub cover is intermediate, averaging 54 percent. Total herb/grass cover is very low for the Series, averaging 15 percent.

WESTERN HEMLOCK/SADLER OAK-SALAL-PACIFIC RHODODENDRON

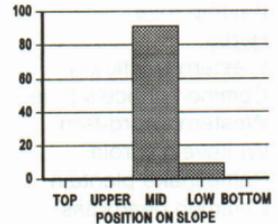

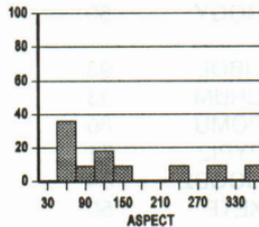

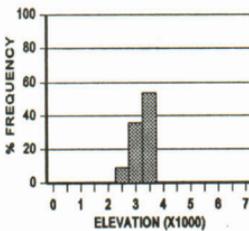

Tsuga heterophylla/Quercus sadleriana-Gaultheria shallon-Rhododendron macrophyllum
 TSHE/QUSA2-GASH-RHMA3 (N=11; BLM=11)

Distribution. This Association occurs in the Grants Pass Resource Area of the Medford District, Bureau of Land Management and may be present on adjacent Forest Service lands.

Distinguishing Characteristics. This Association is characterized by high elevations, high precipitation, and cool temperatures. Pacific rhododendron, Sadler oak, and salal are present. This Association resembles the Western Hemlock-Tanoak/Pacific Rhododendron Association, which has higher precipitation.

Soils. Parent material is most commonly granite, diorite, or sandstone. Based on seven plots sampled, soils are well drained. Textures are sandy loams, sandy clay loams, and silt loams, with 15 to 75 percent rock fragments.

Environment. This **Association** averages 3420 feet in elevation and aspect is predominantly, though not exclusively, east Slope averages 49 percent and ranges between 25 and 72 percent. This **Association** occurs primarily on middle third slope positions.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 20 species. The tree layer is dominated by Douglas-fir. Western hemlock, white fir, and sugar pine are frequently present. Port-Orford-cedar is a common **associate**. The hardwood species are common to occasional, and may consist of golden chinquapin and tanoak. The shrub layer can be dense and may include Pacific rhododendron, salal, Sadler oak, and dwarf Oregongrape. The herbaceous species presence is variable and does not support high cover. Western twinflower is frequently found. Moss cover ranges from 0 to 35 percent, but averages 3 percent

Stratification of total tree and shrub layer covers differs in this **Association** (refer to the Methods section). Total tree cover averages 74 percent, and cover of trees less than 10 feet tall (3 meters) averages 24 percent. Shrubs, both greater and less than 20 inches (50 centimeters) tall, average 61 percent cover. Total herb/grass cover averages only 12 percent, but ranges from 2 to 35 percent.

TSHE 40

WESTERN HEMLOCK-INCENSE-CEDAR/SALAL

Tsuga heterophylla-Calocedrus decurrens/Gaultheria shallon

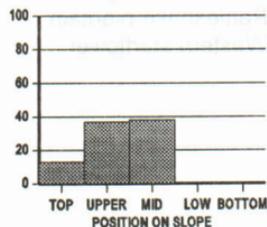

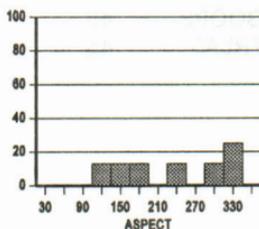

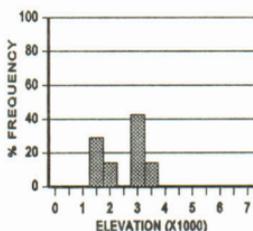

TSHE-CADE27/GASH (N=7; BLM=7)

Distribution. This **Association** occurs on the Medford District, Bureau of Land Management and may be present on adjacent Forest Service lands.

Distinguishing Characteristics. The presence of both salal and incense-cedar, and absence of Pacific rhododendron, characterize this **Association**. Whipplevine occurrence suggests rocky soil, yet the relatively high cover of western sword-fern indicates moist conditions.

Soils. Parent materials include metasediments, metavolcanics, and andesite. Based on six plots sampled, soils are well drained to moderately well drained. Textures are silty loams, sandy loams, and silty clays, with 15 to 45 percent rock fragments.

Environment. This **Association** averages 2760 feet in elevation and occurs predominantly on east, south, and west aspects. Slopes average 39 percent and ranges from 12 to 89 percent. This **Association** occurs mostly on middle to upper slopes.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 25. The tree layer is dominated by Douglas-fir. Incense-cedar is present and may be abundant, while western hemlock cover is often low. Golden chinquapin is commonly encountered. The shrub layer is often dominated by salal, although occasionally it is not present. Dwarf Oregongrape and baldhip rose are frequent, and Pacific blackberry is common. Western twinflower is present in the herb/grass layer, and western sword-fern, white inside-out-flower, and whipplevine are common.

Stratification of tree and shrub layer covers differs in this **Association** (refer to Methods section). Total tree cover averages 74 percent, and cover of trees less than 10 feet (3 meters) tall averages 16 percent. Shrubs greater than 20 inches tall (50 centimeters) averages 18 percent cover and shrubs less than 20 inches tall average 38 percent cover. Total herb/grass cover averages 33 percent and ranges between 10 and 70 percent.

WESTERN HEMLOCK/SALAL-DWARF OREGONGRAPE-SWO
Tsuga heterophylla/Gaultheria shallon-Berberis nervosa
 TSHE/GASH-BENE2-SWO (N=17; FS=17)

Distribution. This Association occurs on all Ranger Districts of the Umpqua National Forest and may occur on the South River Resource Area of the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs at low elevations, on warm, dry sites with gentle slopes. Whiplavine, a rocky site indicator, is often present. Other dry site indicators may also be present such as, canyon live oak, Piper's Oregongrape, and hairy honeysuckle. This Association is similar to the Western Hemlock/Dwarf Oregongrape and the Western Hemlock/Oregon Oxalis; both are described in the Willamette National Forest Plant Association Guide (Hemstrom, et. al. 1987).

Soils. This Association was found on 10 different parent materials and may be the most variable of the Series. Based on seven plots sampled, soils are shallow to

deep, and well drained to moderately well drained. Surface textures vary from loamy sand to clay loam, while four of the soils have a heavy clay layer beginning at 3 to 17 inches. Rock fragment content is also variable, from 0 to 60 percent. Subsurface textures include loamy sands, silt loams, and sandy loams. Subsurface rock fragments varied from 0 to 55 percent. The soil moisture regime is probably udic, and the soil temperature regime is probably mesic. Soils classify into the following subgroups: Typic Hapludalfs, Haploxeralfs and Paleixeralfs, Typic Xerochrepts and Dystrochrepts.

Environment. This **Association** averages 2870 feet in elevation and occurs predominantly on north, east, and west aspects. Slope averages 35 percent and ranges from 5 to 70 percent. This **Association** occurs on all slope positions.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 36. Douglas-fir and western hemlock are present in the overstory. White fir and incense-cedar are common, while sugar pine is occasional. Pacific yew, Douglas-fir, golden chinquapin, western hemlock, and white fir are frequently encountered in the understory. Vine maple may be dense in some areas. Other hardwoods include big-leaf maple, Pacific madrone, Pacific dogwood, and canyon live oak. In the shrub layer, dwarf Oregongrape and salal are present. Red huckleberry, baldhip rose, and Pacific blackberry are frequent. Western twinflower, western sword-fern, and round-leaved violet are almost always present. Moss cover is fairly high for the Series, averaging 20 percent.

Upper and mid-layer tree covers are high for the Series, averaging 74 and 65 percent cover, respectively. Lower layer tree cover averages 39 percent. Shrub cover is low to intermediate, with high shrub cover averaging only 5 percent and low shrub cover 34 percent. Herb/grass cover ranges from 8 to 90 percent and averages 22 percent.

WESTERN HEMLOCK/SALAL/WESTERN SWORD-FERN-SWO
Tsuga heterophylla/Gaultheria shallon/Polystichum munitum
 TSHE/GASH/POMU-SWO (N=14; FS=14)

Distribution. This Association occurs predominantly on the Cottage Grove and North Umpqua Ranger Districts, and occasionally on the Tiller Ranger District, Umpqua National Forest. It is likely to occur on the Swiftwater Resource Area of the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. The Western Hemlock/Salal/Western Sword-fern-SWO Association is present at moderately low elevations. It occurs on warm sites that are often adjacent to streams and moist most of the year. Western redcedar is frequent in the overstory. It is also present, and often abundant, in the understory. Pacific yew, also an indicator of humid conditions, is often present along with several fern species. This Association is similar to the Western Hemlock/Dwarf Oregongrape and the Western Hemlock/Oregon Oxalis Plant Associations on the Willamette National Forest (Hemstrom, et. al. 1987).

Soils. Parent material is most commonly andesite and basalt, and occasionally breccia, sandstone, or tephra. Based on eight plots sampled, soils are moderately deep to deep and well drained. Surface textures are loams with 5 to 65 percent rock fragments and 15 to 25 percent clay. Subsurface textures are loams, clay loams, and some clays, with 5 to 80 percent rock fragments. The soil moisture regime may be either udic or xeric and the soil temperature regime is probably mesic. Soils classify into the following subgroups: Typic Hapludalfs, Typic Haploxeralfs, and Typic Haplumbrepts.

Environment. This **Association** averages 2430 feet in elevation, and aspect is highly variable. Slope averages 52 percent and ranges from 12 to 80 percent. This **Association** occurs predominantly on lower slopes.

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 30 species. The overstory layer is dominated by Douglas-fir, with western hemlock occurring frequently. Western redcedar is common. All species in the overstory are reproducing in the understory. Additional understory species include Pacific yew and the hardwoods big-leaf maple, red alder, golden chinquapin, and Pacific dogwood. Vine maple is frequently encountered in the shrub layer and is sometimes abundant. Salal and dwarf Oregongrape are also frequent. Western sword-fern is the only herb consistently present. Moss cover is high for the Series, averaging 34 percent.

Upper layer tree cover averages 71 percent. Middle and lower layer tree covers were the highest for the Series, averaging 65 and 56 percent cover, respectively. Shrub cover was low with only 8 percent high shrub cover and 24 percent low shrub cover. Herb/grass cover averages 36 percent.

WESTERN HEMLOCK/VINE MAPLE-SALAL-SWO
Tsuga heterophylla/Acer circinatum-Gaultheria shallon
 TSHE/ACCI-GASH-SWO (N=10; FS=10)

Distribution. This **Association** is found on all Ranger Districts, Umpqua National Forest and is likely to occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This **Association** is present at moderately low elevations. Temperatures are relatively mild. The presence of whiplavine suggests the sites are moderately dry and somewhat rocky.

Soils. Parent material is predominantly basalt and andesite, but may also be rhyolite, tephra, or mixed metamorphosed or sedimentary material. Based on nine plots sampled, soils are deep and well drained. Surface textures are loams and sandy loam with 20 to 60 percent rock fragments and 10 to 23 percent clay. Subsurface textures are clay loam and silt loam with 10 to 75 percent rock fragments. The soil moisture regime can be both udic and xeric and the soil temperature regime is probably mesic. Soils classify into the following subgroups:

Typic and Mollic Haploxeralfs, Typic Udorthents, and Dystric Xerorthents

Environment This **Association** averages 2180 feet in elevation and aspect is highly variable. Slope is variable and averages 43 percent. The **Association** occurs predominantly on middle slope positions.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 35. The overstory is dominated by Douglas-fir. Western hemlock has low cover. The understory is dominated by western hemlock with a small amount of western redcedar and Douglas-fir. Golden chinquapin and Pacific dogwood are frequent. Vine maple may be an abundant shrub on some sites. In the shrub layer, dwarf Oregongrape, salal, Pacific blackberry, and baldhip rose are frequent. Western sword-fern, western twinflower, vanillaleaf, cutleaf goldthread, white trillium, and white inside-out-flower are frequent in the herb/grass layer. Moss cover is the highest of the Series, averaging over 40 percent.

Upper layer tree cover is very low for the Series, 65 percent; while mid-layer cover is high at 64 percent. Lower layer tree cover is about average. High shrub cover and low shrub cover average 11 and 40 percent, respectively. Herb/grass cover is moderate for the Series at about 22 percent

WESTERN HEMLOCK/VINE MAPLE-PACIFIC RHODODENDRON
Tsuga heterophylla/Acer circinatum-Rhododendron macrophyllum
 TSHE/ACCI-RHMA3 (N=28; FS=28)

Distribution. This **Association** occurs on all Ranger Districts of the Umpqua National Forest and on the Prospect Ranger District, Rogue River National Forest.

Distinguishing Characteristics. This **Association** is present at high elevations which are cool into the spring months. Salal is rarely present, but Pacific rhododendron is almost always present; abundance varies. The cool site indicators white fir and thin-leaved huckleberry are frequently encountered.

Soils. Parent material is most commonly andesite, but may also be basalt, tephra, breccia, highly weathered sandstone, granite, gabbro, or rhyolite. Based on four plots sampled, soils are moderately deep and well drained. Surface textures are loams and silt loams with 10 to 20 percent rock fragments and 10 to 20 percent clay. The subsurface textures are silt loams with 20 to 50 percent rock fragments. The soil moisture regime is probably udic, and the soil temperature regime may be

either mesic or frigid. Soils classify into the following subgroups. Typic Dystrochrepts and Typic Haplumbrepts.

Environment. This **Association** averages 4040 feet and occurs on most aspects, although rarely on south aspects. Slope averages 36 percent and ranges from 0 to 75 percent. This **Association** occurs frequently on upper slope positions.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 37 species. The overstory tree layer is dominated by Douglas-fir, with lesser amounts of western hemlock and white fir. Pacific silver fir, incense-cedar, sugar pine, white pine and western redcedar may also be present. In addition to those species in the overstory, Shasta red fir and Pacific yew are also present in the understory. The hardwood component is rich; vine maple, Rocky Mountain maple, Pacific madrone, golden chinquapin, and Pacific dogwood may be present. Vine maple may be dense in some areas. Dwarf Oregongrape, Pacific rhododendron, thin-leaved huckleberry, baldhip rose, and Pacific blackberry are high in constancy. Western twinflower and common prince's-pine occur frequently. In some areas, Oregon oxalis may have high cover, up to 75 percent. Moss cover is very low for the Series, averaging only 7 percent.

Upper layer tree cover is moderate for the Series, averaging 72 percent. Mid-layer tree cover averages 54 percent, and lower layer tree cover 40 percent. High shrub cover is fairly sparse, averaging 18 percent, as is low shrub cover with 28 percent. Herb/grass cover ranges from 3 to 98 percent, with an average of 37 percent.

WESTERN HEMLOCK-WHITE FIR/DWARF OREGONGRAPE

Tsuga heterophylla-Abies concolor/Berberis nervosa

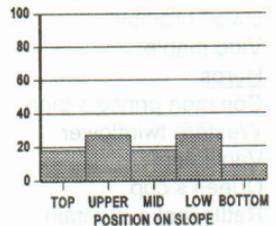

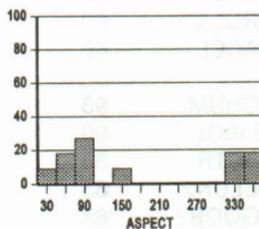

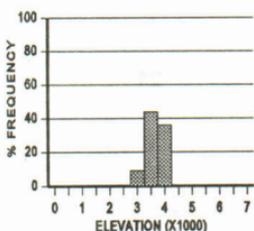

TSHE-ABCO/BENE2 (N=11; FS=11)

Distribution. This Association occurs on the North Umpqua and Diamond Lake Ranger Districts, Umpqua National Forest, and the Prospect and Butte Falls Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. This is a cool, dry, high elevation western hemlock association. The cool site indicators thin-leaved huckleberry and slender salal are common. This Association is often adjacent to the White Fir Series.

Soils. The predominant parent material is either basalt or andesite, while ash, pumice, breccia, sandstone, and tephra may be present occasionally. Based on nine plots sampled, soils are moderately deep and well drained. Surface and subsurface textures are loams, sandy loams, and silt loams with 20 to 70 percent rock fragments and 10 to 20 percent clay. The soil moisture regime may be udic or xeric and the soil moisture regime may be mesic or frigid. Soils classify into the

following subgroups: Typic Xerochrepts and Dystrochrepts, Typic Udorthents and Xerorthents.

Environment. This **Association** averages 3930 feet in elevation and is found predominantly on north and east aspects. Slope averages 30 percent and ranges from 3 to 50 percent. The **Association** occurs on all slope positions.

Vegetation Composition and Structure. This **Association** has very high total species richness for the Series, averaging 38. The overstory is dominated by Douglas-fir; western hemlock, white fir, and white pine are common. The understory is dominated by western hemlock, although Douglas-fir is also present. White fir and Pacific yew occur frequently. The most frequently encountered hardwood is golden chinquapin. Vine maple may have up to 30 percent cover. The shrub layer is dominated by dwarf Oregongrape, which may be dense. Slender salal, snow bramble, and creeping snowberry are common; and thin-leaved huckleberry, Pacific blackberry, Oregon boxwood, and baldhip rose are frequent. Western twinflower and common prince's-pine are present in the herb layer. Vanillaleaf and rattlesnake-plantain are frequent, and queen's cup, western starflower, white inside-out-flower, and round-leaved violet are common. Moss cover is low for the Series, averaging 6 percent.

Upper and mid-layer tree cover is relatively low for the Series, averaging 69 and 50 percent cover respectively. Lower layer tree cover is intermediate, averaging 44 percent. High shrub cover is low, averaging only 3 percent while low shrubs are more abundant with 37 percent cover. Total herb cover is intermediate for the Series, averaging 31 percent

WESTERN HEMLOCK-WHITE FIR/VINE MAPLE-DWARF OREGONGRAPE

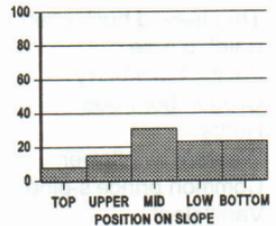

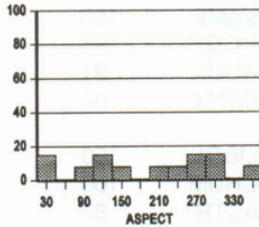

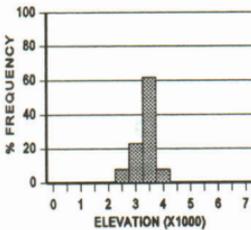

Tsuga heterophylla-Abies concolor/Acer circinatum-Berberis nervosa
 TSHE-ABCO/ACCI-BENE2 (N=13; FS=13)

Distribution. This Association is located on the Butte Falls and Prospect Ranger Districts, Rogue River National Forest and on the Diamond Lake Ranger District, Umpqua National Forest.

Distinguishing Characteristics. This is a cool, high elevation plant association. Neither salal, slender salal, nor Pacific rhododendron are present.

Soils. Parent material is most commonly andesite, although basalt, diorite, pumice, ash, and tephra occur occasionally. Based on five plots sampled, soils are moderately deep and well to somewhat excessively well drained. Surface textures are loams and sands, with 5 to 40 percent rock fragments and 3 to 17 percent clay. Subsurface textures are sandy loams and silt loams with 2 to 40 percent rock fragments. The soil moisture regime is probably xeric and the soil temperature

regime can be mesic or frigid. Soils classify into the following subgroups. Typic Xerumbrepts, Typic Xerorthents, and Typic Xeropsamments.

Environment. This **Association** averages 3500 feet in elevation and aspect is highly variable. Slope averages 28 percent and ranges from 2 to 60 percent. Occurrence is most often on middle to lower slopes and valley bottoms.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 37 species. The overstory is dominated by Douglas-fir and white fir is encountered on most plots. Sugar pine is common. The understory contains western hemlock and white fir. Incense-cedar is common and Pacific yew frequent. In some areas hardwoods are abundant; for example, vine maple can be very dense. Pacific dogwood is frequent, and golden chinquapin is commonly encountered. The shrub layer is dominated by dwarf Oregongrape. California hazel, baldhip rose, and Pacific blackberry are frequently encountered. Western twinflower can reach up to 30 percent cover in the herb layer. Moss cover averages 10 percent.

Upper layer tree cover is intermediate for the Series averaging 67 percent, mid-layer cover, 49 percent, and lower layer tree cover, 32 percent. High shrub and low shrub covers are intermediate for the Series, averaging 23 and 43 percent, respectively. Total herb/grass cover averages 32 percent.

**WESTERN
REDCEDAR
SERIES**

WESTERN REDCEDAR SERIES

Thuja plicata

THPL

Diane E. White

The Western Redcedar Series has both an interior range and a coastal range in western North America. The interior range includes the north half of Idaho, fringes of western Montana west of the continental divide, and the southeastern corner of British Columbia. The coast range extends further, both north and south. It begins at the southern-most tip of southeastern Alaska, and continues through western Washington and Oregon west of the Cascade Mountain crest. In southwestern Oregon, the Series occurs on the Cottage Grove, North Umpqua, and Diamond Lake Ranger Districts, Umpqua National Forest.

In southwestern Oregon, the Western Redcedar Series nearly always has a major component of western hemlock. This Series occurs in areas that average 48 F in temperature and 64 inches in rainfall.

The Western Redcedar Series in southwestern Oregon is represented by one **plant association**, the Western Redcedar/Dwarf Oregongrape/Western Sword-fern **Association**.

The relationship of draft and final **plant associations** in the Western Redcedar Series is shown below. The draft **associations** are listed, with the final **associations** below each, in order of most to least common, with the percentage of plots that make up each **association**.

WESTERN REDCEDAR/DWARF OREGONGRAPE/WESTERN SWORD-FERN
Thuja plicata/*Berberis nervosa*/*Polystichum munitum*
THPL/BENE2/POMU (N=7; FS=7)

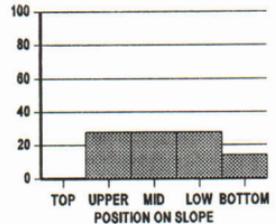

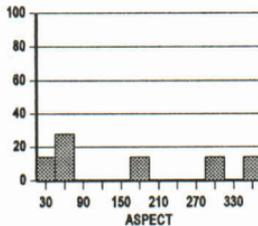

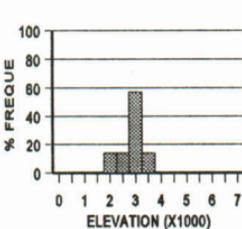

Distribution. This Association occurs on the Cottage Grove, North Umpqua, and Diamond Lake Ranger Districts, Umpqua National Forest and probably the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs at low to intermediate elevations in moist areas.

Soils. Parent material is primarily basalt, with infrequent occurrences on breccia and rhyolite. Soil data are not available.

Environment. This Association averages 2970 feet in elevation and aspect is predominantly north and east. Slope averages 37 percent and ranges between 5 and 52 percent. This Association rarely occurs on ridge top slope positions.

Vegetation Composition and Structure Total species richness is very high compared with **associations** in the Western Hemlock Series, and averages 36. The overstory is dominated by Douglas-fir, while western hemlock and western redcedar are common. Western redcedar is dominant in the understory. Western hemlock is present, but at lower covers. Small amounts of Pacific yew are common. Hardwoods may be abundant, vine maple, for example, is frequently encountered and may be dense in some areas. Bigleaf maple, golden chinquapin, and Pacific dogwood are common. Dwarf Oregongrape, salal, and Pacific rhododendron are present in the shrub layer. Any of these species can be dense in an area. Red huckleberry is a frequent **associate**. Western sword-fern, three-leaf anemone, and Oregon fairybell are consistently present in the herb/grass layer, but at low covers. Moss cover is very high compared with **plant associations** in the Western Hemlock Series, averaging 42 percent.

Upper layer tree cover is high compared with **plant associations** in the Western Hemlock Series, averaging 75 percent. Mid-layer tree cover is intermediate averaging 60 percent cover, and lower layer tree cover is very high, averaging 58 percent. High shrub cover averages 23 percent and low shrub cover is dense, averaging 64 percent. Herb/grass cover is intermediate, averaging 24 percent.

PORT-ORFORD- CEDAR SERIES

PORT-ORFORD-CEDAR SERIES

Chamaecyparis lawsoniana

CHLA

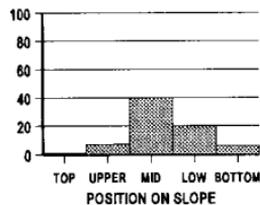

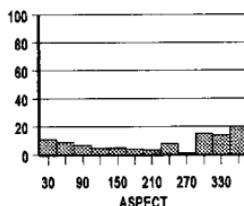

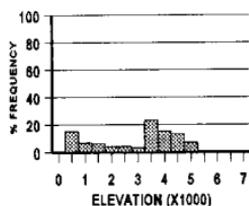

Vince Randall

Lands climax to Port-Orford-cedar were classified into eight **plant associations**. Most plots were located in Oregon. However, observations indicate that application in northern California is limited. Thomas Jimerson's (1994) Port-Orford-cedar guide should be consulted for areas south of the Siskiyou crest that divides the Rogue and Klamath basins.

Port-Orford-cedar, a member of the Cupressaceae family, occupies a restricted range, compared to most northwest conifers. Its range somewhat coincides with the Klamath Geological Province, which roughly forms a square with Coos Bay, Eureka, Redding, and Roseburg as the corners. Except for an isolated population near Mount Shasta, inland stands, east of the Coast Range crest are uncommon. They occur where moisture stress is dampened by summer fog (topographically protected drainages, on north aspects).

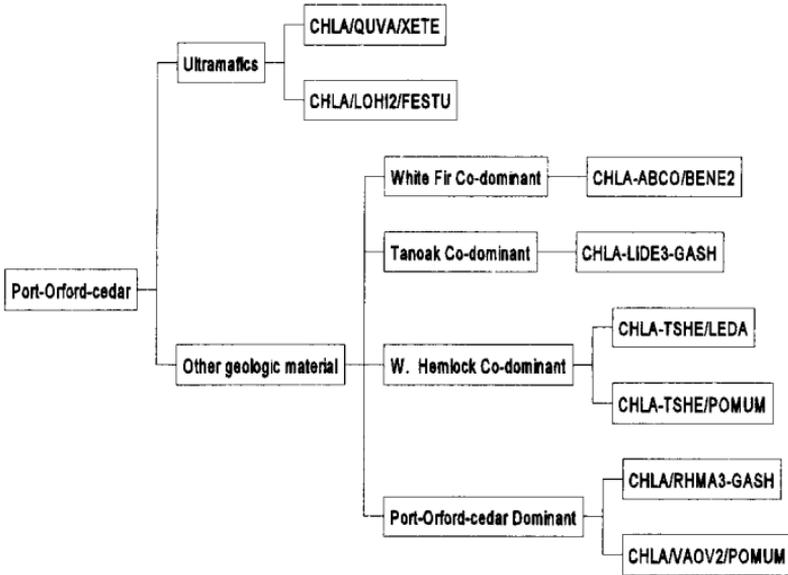

North of the California border, Port-Orford-cedar occurs throughout the landscape. In the Powers, Coos Bay area, it commonly occurs on upper slope topographic positions. Inland it is rarely found on ridges or upper slope positions, density increases toward the lower slope positions and bottoms. In northern California, populations are mostly **associated** with bottoms and lower slope positions (Jimerson, 1994). Throughout its range, Port-Orford-cedar occurs on ultramafic parent material, particularly where the water table is close to the surface (perched). Scattered, perched water tables are characteristic of ultramafic parent material. The Port-Orford-Cedar/Huckleberry Oak/Common Beargrass and the Port-Orford-Cedar/Hairy Honeysuckle/Fescue **Associations** often occur on perched water tables.

The Port-Orford-Cedar Series is most common west of the Coast Range crest, but is **associated** with lower third to bottoms or moist ultrabasic material inland. Coastal sites are low, averaging less than 1500 feet, inland sites average about 3500 feet.

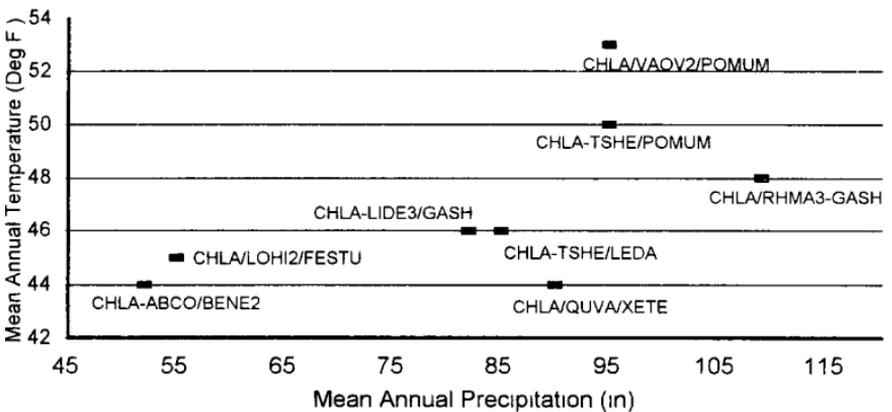

CHLA 2

The Series can be divided into **associations** occurring on ultramafic parent material, those co-climax with other species, and those dominated by Port-Orford-cedar. The diagram below illustrates the relationship among the **associations**.

The "Other geologic material" fork is arranged from cold, dry to warm, wet. The Port-Orford-cedar-White Fir/Dwarf Oregongrape **Association** is at the upper limits of the Series, where cold limits survival, growth, and reproduction. The Port-Orford-cedar-Tanoak/Salal **Association** intergrades with the Tanoak Series in the hotter, drier

Environmental Graph

environments The Western Hemlock group, including the Port-Orford-cedar-Western Hemlock/Sierra-laurel **Association**, and the Port-Orford-cedar-Western Hemlock/Western Sword-fern **Association**, intergrades with the Western Hemlock Series at the warm, wet extreme for the Port-Orford-Cedar Series

Port-Orford-cedar root rot, *Phytophthora lateralis*, introduced into the northwest early in this century (infections were first found in southwest Oregon about 40 years ago) is thought to be fatal to Port-Orford-cedar Infected trees occur along streams, roads, and are sparsely scattered throughout the landscape However, survivors are often found within infected areas, indicating the possibility of resistance or uneven distribution of the pathogen (spores) We have not yet determined the reasons for the existence of these survivors, but resistance, if it does exist, may be related to **plant association** For example, the drier **associations** seem to be less susceptible to infection

Page CHLA 3 below shows the relationship of draft and final **plant associations** Draft **associations** are underlined and final **associations** are listed below in the order they most likely fall into the final **associations** This cross reference could be used to determine how sites keyed with the draft should fall into the final classification However re-keying in the field or running existing species information through the final key is recommended

KEY TO THE PORT-ORFORD-CEDAR PLANT ASSOCIATIONS

- 1a Vegetation dominated by ultramafic parent material, or soils with ultramafic influence (Serpentine, Peridotite) 2
- 1b Vegetation not as above 3
- 2a Huckleberry oak (QUVA), common beargrass, and whitevein pyrola (PYPI2) present CHLA/QUVA/XETE
Page CHLA 6
- 2b Huckleberry oak (QUVA), common beargrass (XETE), and whitevein pyrola (PYPI2) absent Hairy honeysuckle (LOHI2) and fescue (FESTU) present (Usually found on shallow ultramafic soils) CHLA/LOHI2/FESTU
Page CHLA 8
- 3a Area usually between the Pistol River and 4 Mile Creek within twenty miles of the ocean, at less than 1,000 feet elevation Western sword-fern (POMUM) present with at least 25% cover Fragrant bedstraw (GATR3) usually present at 5% cover Salmonberry (RUSP) is common CHLA/VAOV2/POMUM
Page CHLA 10
- 3b Western hemlock (TSHE), tanoak (LIDE3), or white fir (ABCO) seldom codominant or subdominant to Port-Orford-cedar (CHLA) in the understory and/or overstory layers Pacific rhododendron (RHMA3) and salal (GASH) frequently dominate the shrub layer (Areas are mainly found scattered along the western flank of the coastal crest, although they can occasionally be seen widely scattered on the east side of the Siskiyou) CHLA/RHMA3-GASH
Page CHLA 12
- 3c Western hemlock (TSHE), tanoak (LIDE3), or white fir (ABCO) present and codominant or subdominant to Port-Orford-cedar (CHLA) in the understory and/or overstory layer 4
- 4a Tanoak (LIDE3) found codominant or subdominant to Port-Orford-cedar in the understory Salal (GASH), dwarf Oregongrape (BENE2), and red huckleberry (VAPA) frequently found in the shrub layer (Areas are usually found east of the coastal crest between 2,400 and 4,100 feet elevation) CHLA-LIDE3/GASH
Page CHLA 14

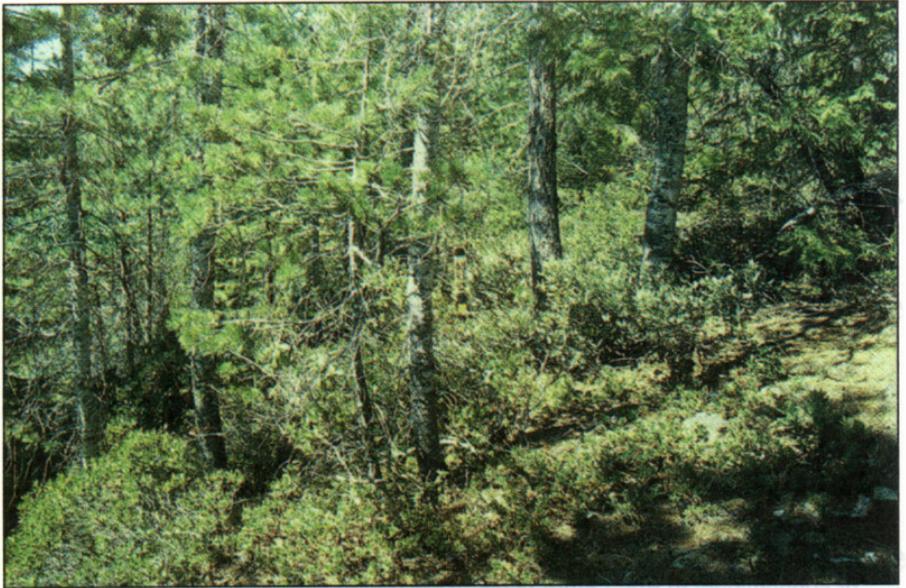

- 4b White fir (ABCO) present and codominant or subdominant to Port-Orford-cedar (CHLA) in the understory Dwarf Oregongrape (BENE2) present, rattlesnake-plantain (GOOB2), western twinflower (LIBOL), and western starflower (TRLA6) frequently present. (Areas are usually found in or near the eastern half of the Illinois Valley Ranger District of the Siskiyou National Forest above 3,000 feet elevation) CHLA-ABCO/BENE2
Page CHLA16
- 4c Western hemlock (TSHE) codominant or subdominant to Port-Orford-cedar (CHLA) in the understory and/or the overstory 5
- 5a Western hemlock (TSHE) present and codominant or subdominant to Port-Orford-cedar in the understory Western swordfern (POMUM), Oregon oxallis (OXOR), dwarf Oregongrape (BENE2), and salal (GASH) present (Area is usually in or near the Powers Ranger District of the Siskiyou National Forest, less than 3,200 feet elevation) CHLA-TSHE/POMUM
Page CHLA 18
- 5b Western hemlock (TSHE) frequently present and codominant or subdominant to Port-Orford-cedar in the understory Sierra-laurel (LEDA) and salal (GASH) frequently present (Area is usually within the upper reaches of Silver Creek and Howard Creek on the Siskiyou National Forest, above 3,200 feet) CHLA-TSHE/LEDA

CHLA 6

PORT-ORFORD-CEDAR/HUCKLEBERRY OAK/COMMON BEARGRASS

Chamaecyparis lawsoniana/Quercus vaccinifolia/Xerophyllum tenax

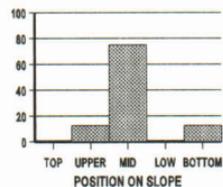

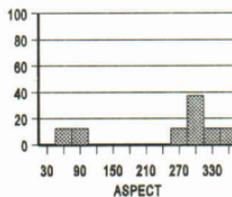

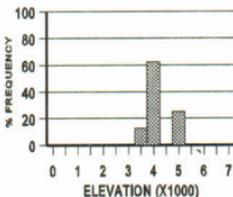

CHLA/QUVA/XETE (N=8; BLM=5, FS=3)

Distribution. This **Association** occurs along Chrome Ridge on the Galice Ranger District, near Black Butte on the Illinois Valley Ranger District, and near Snow Camp Meadow on the Gold Beach Ranger District, Siskiyou National Forest. It may also be found on other ultramafically influenced areas within southwest Oregon.

Distinguishing Characteristics. This **Association** is one of the highest in elevation. It is moist and cool with a mean annual temperature of 44 degrees F and mean annual precipitation of 90 inches. Huckleberry oak, common beargrass, and whitevein pyrola are consistently present.

Soils. Parent material is a mixture of intrusive volcanics and ultramafics. Average surface rock fragment cover is 32 percent, with 14 percent gravel and 4 percent bareground exposed. Soils are shallow to deep, with an average depth of greater than 28 inches. Soil texture is silt loam or sandy loam, with some silty clay. Average

rock fragment content is 58 percent, with 21 percent gravel and up to 46 percent cobbles and stones

Environment Elevation averages 4150 feet This **Association** is found primarily in northwest aspects Slopes average 43 percent and range from 15 to 65 percent The dominant slope position is midslope, but this **Association** is also found in lower slope positions, as well as upper slopes with perched water tables

Vegetation Composition and Structure Total species richness, intermediate for the series, averages 28 species The overstory is dominated by Douglas-fir and Port-Orford-cedar The understory is dominated by Port-Orford-cedar Douglas-fir, white fir, and western white pine are frequently present Jeffery pine is less common Huckleberry oak, red huckleberry, common beargrass, and whitevein pyrola are frequently present Moss cover averages 5 percent

On the Forest Service sites, upper layer tree cover is low, averaging 50 percent Mid-layer tree cover is intermediate, averaging 50 percent while the lower layer tree cover averages 15 percent, also intermediate for the Series High shrub cover is low, averaging 17 percent and low shrub cover is high, averaging 31 percent Total herb cover is low, averaging 18 percent

On the Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) averages 39 percent, while cover for trees less than 10 feet tall averages 10 percent Cover for shrubs greater than 20 inches tall (50 centimeters) averages 58 percent, with cover for shrubs less than 20 inches tall averaging 49 percent Herb cover averages 13 percent

CHLA 8

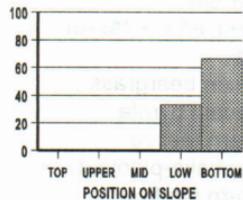

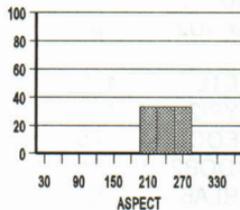

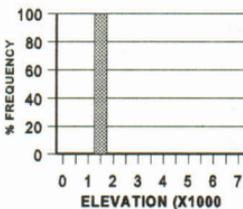

PORT-ORFORD-CEDAR/HAIRY HONEYSUCKLE-FESCUE
Chamaecyparis lawsoniana/Lonicera hispidula/Festuca
CHLA/LOHI2/FESTU (N=3; BLM=3)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest and the Ashland Resource Area of the Medford District, Bureau of Land Management. This Association may also occur on the Ashland Ranger District, Rogue River National Forest.

Distinguishing Characteristics. This is a relatively low elevation Port-Orford-cedar Association found solely on shallow soils derived from ultramafic parent material. It is dry and warm with a mean annual temperature of 45 degrees F and mean annual precipitation of 55 inches. Port-Orford-cedar is present in both the overstory and understory, with a combined cover exceeding 28 percent.

Soils. Parent material consists of ultramafic materials. Soils are mostly shallow, with an average depth of 11 inches. Based on three plots sampled, soil texture is silty clay, with 12 percent rock fragments, most of which is gravel (averaging 8 percent).

Environment Elevation averages 1690 feet. This **Association** is found primarily on southwest aspects, near or in wetlands. Slopes average 22 percent and range from 14 to 35 percent. This **Association** may also be found on the lower third of slopes in areas with perched water tables.

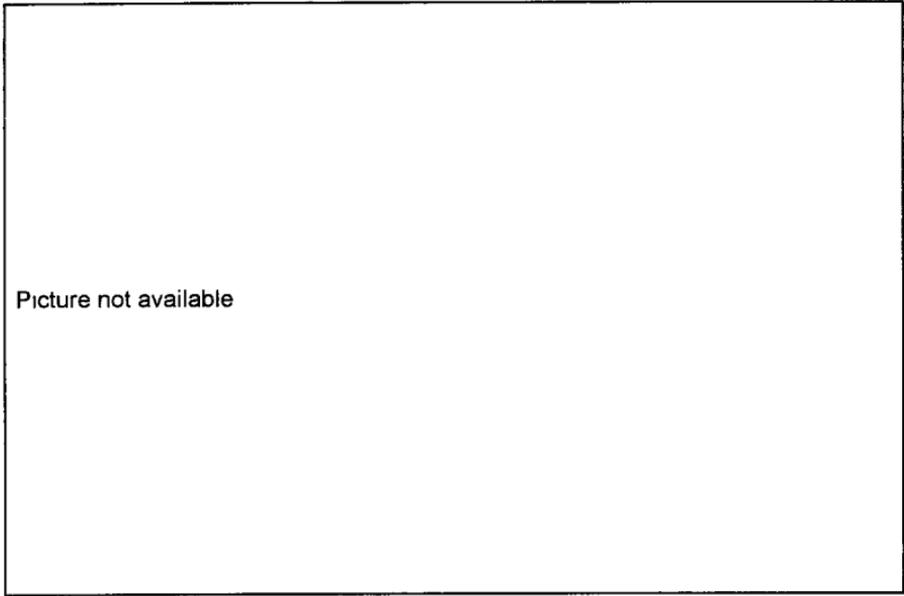

Vegetation Composition and Structure Total richness, low for the series, averages 18 species. The overstory is dominated by Port-Orford-cedar. The understory is dominated by Port-Orford-cedar, with Douglas-fir, Jeffrey pine and sugar pine common. California black oak occurs on about 30 percent of the sites. Fescue dominates the herbaceous layer with an average of 45 percent cover. Hairy honeysuckle, sickleleaf onion, and obscure bedstraw are frequently found with individual species averaging two percent cover. Western azalea is common, averaging greater than 30 percent cover. California pitcher-plant is occasionally found, averaging greater than 20 percent cover. Moss cover averages nine percent.

Cover for trees greater than 10 feet tall (3 meters) averages 57 percent, while cover for trees less than 10 feet tall averages 23 percent. Cover for shrubs greater than 20 inches (50 centimeters) tall averages three percent. Cover for shrubs less than 20 inches tall averages 38 percent. Herb cover averages 59 percent.

PORT-ORFORD-CEDAR/EVERGREEN HUCKLEBERRY/WESTERN SWORD-FERN
Chamaecyparis lawsoniana/Vaccinium ovatum/Polystichum munitum munitum
CHLA/VAOV2/POMUM (N=15, NRCS=15)

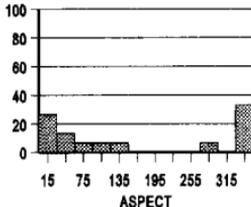

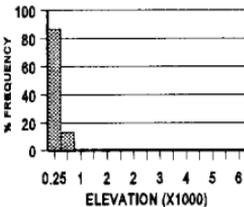

Distribution This Association occurs on the Coos Bay District, Bureau of Land Management, and the Gold Beach Ranger District, Siskiyou National Forest

Distinguishing Characteristics This Association is the lowest and furthest west of all Port-Orford-cedar associations. Sites are located near the coast between the Pistol River and 4 Mile Creek. Only one site greater than 10 miles inland of the Pacific Ocean is known. This Association is the warmest, averaging 53 degrees F, and among the wettest, with 95 inches of precipitation annually.

Soils Soils data are not available

Environment Elevation averages 265 feet, with a range from 32 to 853 feet. This Association is generally found on northerly aspects with slopes averaging 28 percent, between a range of 1 to 60 percent.

Soils data are not available

Vegetation Composition and Structure Total species richness, intermediate for the series, averages 23 species. The overstory is dominated by Douglas-fir. Port-Orford-cedar dominates the understory with an average of 16 percent cover. California-laurel, western hemlock, and tanoak are also common, but with low covers. Western sword-fern is present with classes* averaging greater than 25 percent. Fragrant bedstraw, evergreen huckleberry, salmonberry, and western starflower are frequently found with individual species covers averaging greater than ten percent.

PORT-ORFORD-CEDAR/PACIFIC RHODODENDRON-SALAL

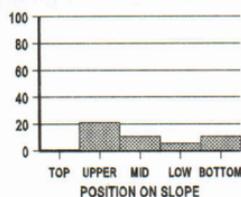

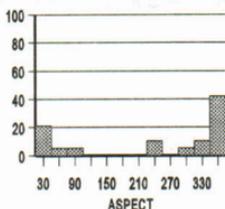

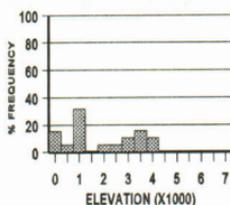

Chamaecyparis lawsoniana/Rhododendron macrophyllum-Gaultheria shallon
 CHLA/RHMA3-GASH (N=19; NRCS=10, FS=9)

Distribution. This Association has the widest distribution of the Series. Sites are scattered from the coastal town of Langlois, Oregon, to Number 8 Gulch on the east side of the Illinois Valley Ranger District, Siskiyou National Forest. However, about 80 percent of the sites are located west of the coastal crest.

Distinguishing Characteristics. This Association is the wettest of the Series, with a mean annual precipitation of 109 inches. It is also among the warmest, with a mean annual temperature of 48 degrees F. A dense shrub layer of Pacific rhododendron, salal, dwarf Oregongrape, and/or evergreen huckleberry often dominate this Association with their high covers.

Soils. Forest Service plot data indicates variable parent material including andesite, basalt, schist, diorite, sandstone, conglomerate, and serpentine. Average surface rock fragment cover is 23 percent, with 12 percent gravel. Soils are moderately deep to deep, with an average depth of greater than 41 inches.

Environment Elevation averages 1834 feet. This **Association** is found primarily on northerly aspects. Slopes average 30 percent and range from one to 70 percent. The dominant slope position is upper slope, but this **Association** occurs on lower slope positions as well.

Vegetation Composition and Structure Total species richness, intermediate for the series, averages 22 species. The overstory is dominated by Douglas-fir, Port-Orford-cedar is common. The understory is dominated by Port-Orford-cedar with tanoak and Douglas-fir common. Pacific rhododendron and salal occur frequently with dwarf Oregongrape, red huckleberry, and evergreen huckleberry common. Common beargrass often has the highest cover on the site. Moss cover averages 22 percent.

Forest Service data indicate that upper layer tree cover is high for the Series, averaging 70 percent. Mid-layer cover is high, averaging 48 percent while lower layer tree cover averages 42 percent, also high for the Series. High shrub cover is intermediate, averaging 36 percent and low shrub cover is high, averaging 76 percent. Total herb cover is low, averaging 10 percent.

PORT-ORFORD-CEDAR-TANOAK/SALAL

Chamaecyparis lawsoniana-Lithocarpus densiflorus/Gaultheria shallon

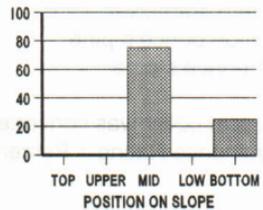

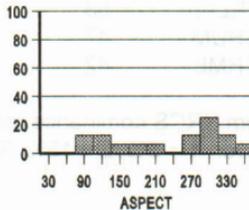

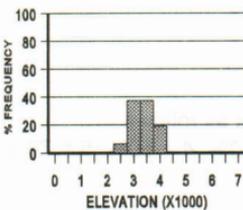

CHLA-LIDE3/GASH (N=16; BLM=16)

Distribution. This Association occurs in the upper reaches of Silver and Howard Creek watersheds in the Grants Pass Resource Area, Medford District, Bureau of Land Management and in the Galice Ranger District, Siskiyou National Forest. Sites can also be found near Little Sugarloaf Peak on the Illinois Valley Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This Association is environmentally similar to the Port-Orford-cedar-Western hemlock/Sierra-laurel Association, averaging 46 degrees F and 82 inches of precipitation annually. It is the only Association where tanoak is codominant with Port-Orford-cedar in the understory, and western hemlock is absent in the overstory.

Soils. The dominant parent material is a mixture of intrusive volcanic, metavolcanic, (including ultrabasics), and metasediments. Soils are moderately deep, averaging

more than 15 inches in depth. Soil texture is mainly silt loam, with some sandy loam, and clay loam. Average rock fragment content is 51 percent, 33 percent of which is gravel.

Environment Elevation averages 3330 feet. This **Association** is generally found at mid-slope on all aspects, except northeast. Slopes average 38 percent with a range of 15 to 77 percent.

Vegetation Composition and Structure Total species richness, intermediate for the series, averages 22 species. The overstory is dominated by Douglas-fir and Port-Orford-cedar. Port-Orford-cedar dominates the understory with an average of 22 percent cover. Tanoak is the next most common species, averaging 15 percent cover. Douglas-fir and white fir are commonly found in the understory, but with low covers. Salal is frequently found, cover averages 46 percent. Dwarf Oregon grape and red huckleberry are frequently present with covers averaging four percent. Western twinflower, western starflower, little prince's-pine and whipplevine are common, with low covers. Moss cover averages 6 percent.

Tree cover exceeding 10 feet (3 meters) averages 86 percent while cover for tree species less than ten feet tall averages 28 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 43 percent and cover for shrubs less than 20 inches tall averages 27 percent. Herb cover averages 11 percent.

PORT-ORFORD-CEDAR-WHITE FIR/DWARF OREGONGRAPE

Chamaecyparis lawsoniana-*Abies concolor*/*Berberis nervosa*

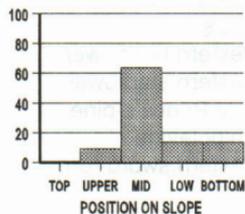

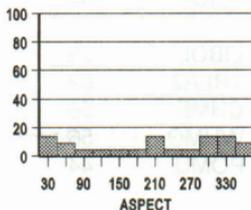

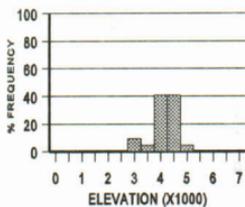

CHLA-ABCO/BENE2 (N=22; FS=13, BLM=9)

Distribution. This Association occurs in the eastern half, Illinois Valley Ranger District, Siskiyou National Forest, and the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may also occur on the Applegate Ranger District, Rogue River National Forest, and the Happy Camp Ranger District, Klamath National Forest.

Distinguishing Characteristics. This high elevation Association is the coolest and driest of the Port-Orford-cedar associations, averaging 44 degrees F and 52 inches of precipitation annually. It is the only association in which white fir is codominant with Port-Orford-cedar in the understory.

Soils. Parent material is a mix of andesite and basalt, granitics and diorite. Soils can be shallow to deep, averaging 30 inches in depth. Soil textures are mainly silty

clay and sandy loam, with some silty clay loam Average rock fragment content is 32 percent; gravel size particles average 32 percent

Environment Elevation averages 4165 feet This **Association** is found on all aspects Slopes average 34 percent, ranging from 8 to 68 percent The slope position is mainly midslope, although it ranges from upper thirds to bottoms

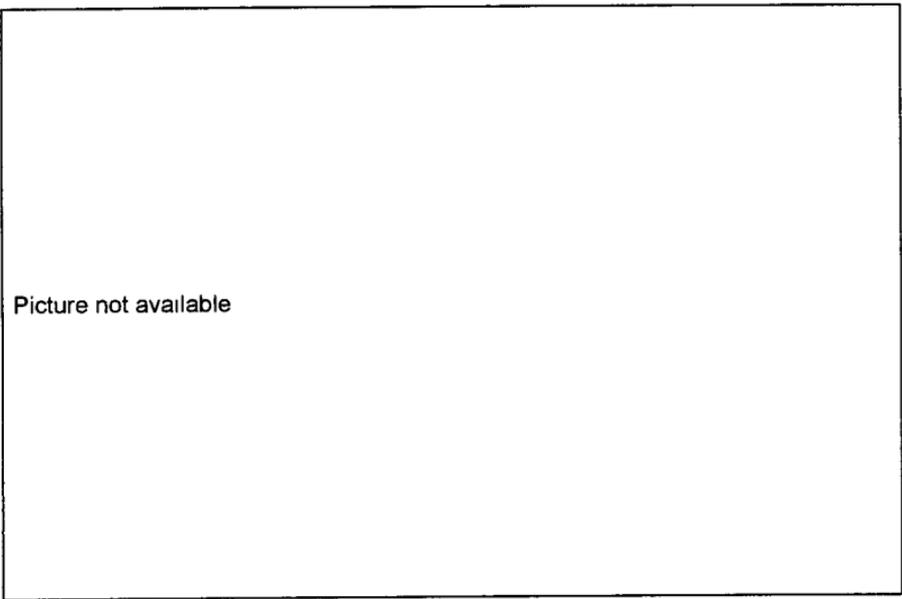

Vegetation Composition and Structure Total richness, high for the series, averages 32 species The overstory is dominated by Douglas-fir and Port-Orford-cedar Port-Orford-cedar and white fir dominate the understory with an average cover of 30 and 10 percent, respectively Dwarf Oregongrape averages four percent cover Rattlesnake-plantain, western twinflower, and western starflower are frequently present in the species-rich herbaceous layer Moss cover averages 11 percent

On Forest Service sites upper layer tree cover is high, for the series, averaging 70 percent Mid-layer tree cover is also high, averaging 51 percent, while lower layer tree cover is intermediate, averaging 32 percent High shrub cover is low, averaging three percent, and low shrub cover is intermediate, averaging 11 percent Herb cover averages 32 percent

On Bureau of Land Management sites, tree cover exceeding 10 feet (3 meters) tall averages 80 percent, while cover for tree species less than 10 feet tall, averages 27 percent Cover for shrubs greater than 20 inches (50 centimeters) tall averages 6 percent, and cover for shrubs less than 20 inches tall averages 20 percent Herb cover averages 27 percent

PORT-ORFORD-CEDAR-WESTERN HEMLOCK/WESTERN SWORD-FERN
Chamaecyparis lawsoniana-Tsuga heterophylla/Polystichum munitum
CHLA-TSHE/POMU (N=6, FS=6)

Distribution This **Association** occurs on the Powers Ranger District, Siskiyou National Forest. It may also be found on the Myrtlewood Resource Area, Coos Bay District, Bureau of Land Management, and the Gold Beach Ranger District, Siskiyou National Forest.

Distinguishing Characteristics This **Association** is warmer and wetter than most Port-Orford-cedar **associations**, averaging 50 degrees F and 95 inches of precipitation annually. It is the only **association** dominated by western sword-fern in the herb layer.

Soils The dominant parent material is sandstone, and occasionally diorite. Average surface rock fragment cover is 19 percent, with 6 percent gravel. Soils are moderately deep to deep, averaging greater than 45 inches.

Environment Elevation averages 1810 feet This Association is generally found on northerly aspects with slopes averaging 43 percent, with a range of 10 to 80 percent Slope position ranges from midslope to bottoms

Vegetation Composition and Structure Total species richness, high for the series, averages 30 species The overstory is dominated by Douglas-fir and Port-Orford-cedar Port-Orford-cedar, western hemlock, and Douglas-fir dominate the understory with an average cover of 33, 13, and 3 percent, respectively Tanoak is frequently found, averaging 6 percent cover Dwarf Oregongrape, salal, and red huckleberry are all present with moderate to low covers Pacific rhododendron and evergreen huckleberry are frequently found as well Western sword-fern and Oregon oxalis are present, usually dominating the herbaceous layer Moss cover averages 28 percent

Upper layer tree cover is high for the series, averaging 77 percent Mid-layer tree cover is high, averaging 61 percent, while the lower layer tree cover is intermediate, averaging 43 percent High shrub cover is low, averaging 13 percent and low shrub cover is intermediate, averaging 23 percent Herb cover averages 66 percent

PORT-ORFORD-CEDAR-WESTERN HEMLOCK/SIERRA-LAUREL
Chamaecyparis lawsoniana-Tsuga heterophylla/Leucothoe davisiae
 CHLA-TSHE/LEDA (N=11; BLM=11)

Distribution. This Association occurs in the upper reaches of Silver and Howard Creek watersheds in the Grants Pass Resource Area, Medford District, Bureau of Land Management, and the Galice Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This Association is slightly cooler and drier than most other Port-Orford-cedar associations, averaging 46 degrees F and 85 inches of precipitation annually. It is the only Association with Sierra-laurel as a major component of the shrub layer.

Soils. The dominant parent material is grano-diorite with some metavolcanic material. Soils are mostly moderately deep, with an average depth of greater than 15 inches. Based on 11 plots, soil texture is highly variable including sand, sandy loam, silt loam, sandy clay loam, and clay loam. Average rock fragment content is 6 percent, most of which is gravel (32 percent).

Environment Elevation averages 3700 feet. This **Association** is generally found on westerly aspects with slopes averaging 20 percent, and a range of 7 to 39 percent. Slope position is mainly bottoms and basins, but this **Association** is also found midslope, or even on ridgetops **associated** with perched water tables.

Vegetation Composition and Structure Total species richness, low for the Series, averages 18 species. The overstory is dominated by Port-Orford-cedar and western hemlock. Port-Orford-cedar and western hemlock also dominate the understory with an average of 20 percent cover. Pacific yew and Douglas-fir are also present, but with low covers. Sierra-laurel and salal are frequently found with their covers averaging 30 and 15 percent respectively. Pacific rhododendron, red huckleberry, and rattlesnake-plantain are common with covers averaging 30, 2 and 1 percent respectively. Moss cover averages 6 percent.

Tree cover exceeding 10 feet tall (3 meters), averages 94 percent, while cover for tree species less than 10 feet tall averages 22 percent. Cover for shrubs greater than 20 inches (50 centimeters) tall, averages 39 percent, and cover for shrubs less than 20 inches tall averages 37 percent. Herb cover averages 5 percent.

JEFFREY PINE
SERIES

JEFFREY PINE SERIES

Pinus jeffreyii

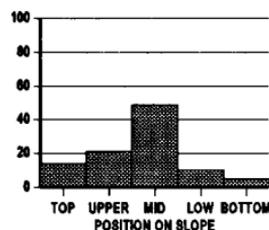

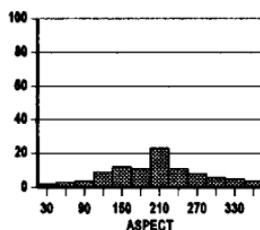

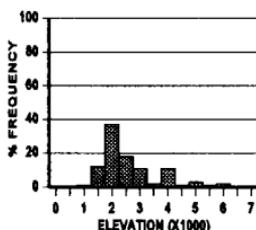

PIJE

Patricia A. Martinez

Southwestern Oregon is the northern extent of the range of Jeffrey pine. This species is scattered throughout Curry, Josephine, Jackson, and Douglas counties, with the heaviest concentrations in Josephine and Jackson counties. It usually occurs on ultramafic parent material. Jeffrey pine is often the dominant tree species on soils derived from ultramafic parent material, especially in interior valleys and foothills. Tanoak (*Lithocarpus densiflora*), western hemlock (*Tsuga heterophylla*), or Port-Orford-cedar (*Chamaecyparis lawsoniana*) may replace Jeffrey pine as the stand dominant near the coast.

Ultramafic bedrock, mainly serpentine and peridotite, is high in ferromagnesium silicate minerals with an unusually high proportion of nickel and chromium. This chemical composition, toxic to most plants, results in a unique and diverse flora. Soils weathered from ultramafic rock strongly reflect the elemental composition of the parent rock with high concentrations of magnesium, iron, and silica (Kruckeberg 1984).

As shown in the graphs below, the Jeffrey Pine Series covers a wide elevational band, from 1200 feet to 6000 feet, with a concentration near 2000 feet, and an average elevation of 2586 feet. Although this Series occurs on all aspects and slope positions, it is more commonly found on southerly aspects and mid-slope positions.

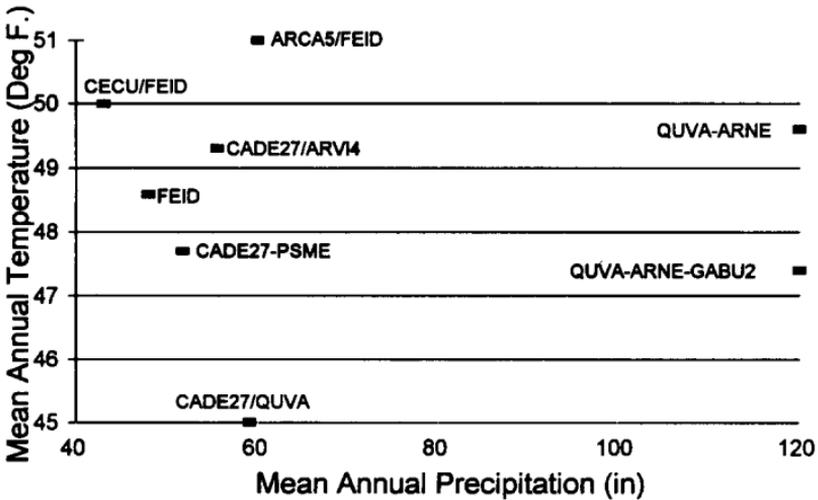

Parent material is either pure serpentine or peridotite (66 percent of the time) or a mixture of undifferentiated ultramafic material with other rock types. The Series rarely occurs on grano-diorite or meta-volcanic soils that apparently do not have any ultramafic influence.

The Jeffrey Pine Series tends to have high exposed gravel, surface rock, and bedrock components. Gravel cover ranges from 3 to 95 percent, with an average of 28 percent. Rock cover ranges from 5 to 75 percent, with an average of 39 percent. Bedrock cover ranges from 0 to 15 percent, with an average of 4 percent. Moss cover, however, is low compared to other Series, ranging from 0 to 50 percent, with an average of 3 percent. This reflects the dry surface soil conditions typical of the Series.

PIJE 2

Based on ten plots sampled, soils are shallow to deep, and moderately well to well drained. Surface texture is clay loam, loam, or silty clay loam, with 0 to 33 percent gravel, 0 to 50 percent cobbles and stones, and 25 to 32 percent clay. Subsurface textures are clay, clay loam, loam, and silty clay loam, with 0 to 50 percent gravel, 5 to 70 percent cobbles and stones, and 20 to 50 percent clay. The soil moisture regimes are xeric or udic and the soil temperature regimes are mesic or frigid. Soils classify to the following subgroups: Lithic Xerochrept, Typic Xerochrept, Dystric Xerochrept, Lithic Haploxeralf, Typic Haploxeralf, and Typic Palixeralf.

The mean annual temperature for the Jeffrey Pine Series ranges from 45 degrees F to 51 degrees F and the mean annual precipitation ranges from 43 inches to 120 inches. The relative positions of the plant associations in the environment are shown below. Each association is plotted by mean annual temperature and mean annual precipitation.

As a result of the serpentine/peridotite parent material influence, there are many unique species found in this Series, i.e., Jeffrey pine, rock fern, dwarf ceanothus, Tolmie's mariposa, and box-leaved silk-tassel. These species will be frequently found, yet will usually have low covers. Jeffrey pine was present in every association in both the overstory and the understory. Douglas-fir and incense-cedar are consistently found in most associations in both the overstory and the understory. Coffeeberry and dwarf ceanothus are frequently found along with rock fern, huckleberry oak, and common beargrass.

Average total species richness, based on vascular plants only, is calculated for each association. The average total species richness for the Jeffrey Pine Series ranges from 15 to 49 species per plot. Richness is rated as very low, 15 to 21 species; low, 22 to 29 species; intermediate, 30 to 36 species; high, 37 to 43 species; and very high, greater than 44 species.

A characteristic feature of the Series is an open canopy of trees, shrubs, and herbs. On Forest Service sites, upper layer tree cover ranges from 6 to 25 percent, and averages 17 percent. Mid-layer tree cover ranges from 23 to 31 percent, and averages 27 percent, while lower layer tree cover ranges from 21 to 45 percent, and averages 35 percent. High shrub cover ranges from 3 to 18 percent, and averages 9 percent, while low shrub cover ranges from 21 to 56 percent, and averages 32 percent. Herb/grass cover ranges from 28 to 74 percent, and averages 49 percent. Low, intermediate, and high canopy covers are defined as the lower, middle, and upper thirds of the total range of average covers for each layer.

On Bureau of Land Management sites, cover for trees greater than 10 feet tall (3 meters) ranges from 12 to 50 percent, and averages 30 percent, while cover for trees less than 10 feet tall ranges from 1 to 11 percent, and averages 5 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) ranges from 3 to 46 percent, and averages 25 percent, while cover for shrubs less than 20 inches tall ranges from 3 to 32 percent, and averages 13 percent. Herb/grass cover ranges from 31 to 62 percent, and averages 48 percent.

Eight **plant associations** have been classified for the Jeffrey Pine Series in southwestern Oregon. They were described from 91 plots, 54 from Bureau of Land Management data and 37 from Forest Service data. There may be some additional types on the Illinois Valley, Galice, and Chetco Ranger Districts of the Siskiyou National Forest not detected by sampling. If the southwestern Oregon key fails, try the Jeffrey Pine Series Key from "A Field Guide to Serpentine **Plant Associations** and Sensitive **Plants** in Northwestern California" by Thomas M. Jimerson et. al. (R5-ECOL-TP-006, 1995).

SPECIES TO KNOW

There are several species used in the **plant association** key that are easily confused with similar species. A general description of each of these occurs below.

Idaho fescue (FEID) - In southwestern Oregon, the native dryland fine-leaved fescues with gray-green or blue-tinged leaf color have been called Idaho fescue (*Festuca idahoensis*), red fescue (*Festuca rubra*), Roemer's fescue (*Festuca roemer*), and sheep fescue (*Festuca ovina*). Field characteristics to discriminate between these species are not usable in southwestern Oregon. Name(s) were attached to these fescues in order to refer to them in this guide. Idaho fescue (*Festuca idahoensis*) is used as the name in this publication for all the native dryland fine-leaved fescues with gray-green or blue-tinged leaf color. It is not a taxonomic determination (Rolle 1996).

Hoary manzanita (ARCA5) - An erect or spreading shrub, 1 to 3 (or to 6) feet high, without a basal burl. Bark is smooth, dark red-brown; densely soft white-pubescent branchlets, and peduncles. Leaves are pale green and gray pubescent or canescent on both surfaces; ovate to roundish; 1.25 to 2 inches long. Flowers about 0.25 inches long, in short racemes or panicles, white or pinkish; bracts large and foliaceous. Fruit is depressed-globular, 0.25 to 0.38 inches broad, usually pubescent, sometimes slightly glandular or glabrate and glaucous. Easily confused with whiteleaf manzanita (ARVI4) (Munz 1968).

PIJE 4

Whiteleaf manzanita (ARVI4) - Evergreen, erect shrub; 3.3 to 13.0 feet high, without a basal burl. Bark is smooth, reddish-brown. Leaves are pale, glaucous, whitish-green, sticky; ovate or elliptic, rounded at the tip; 1 - 1.5 inches long. Flowers urn-shaped, pink to whitish; 0.2 - 0.3 inches long. Fruit is light brown or red berry, smooth or glandular, 0.2 - 0.3 inches in diameter. Whiteleaf manzanita is capable of inhabiting low elevation, dry sites. It can withstand extremely high moisture stress levels and is capable of extracting water from bedrock (Zwieniecki and Newton 1996). Easily confused with hoary manzanita (ARCA5) (Seda, Atzet, and Wheeler 1989).

Box-leaved silk-tassel (GABU) - Low, evergreen shrub, 2 - 6.5 feet tall. Young twigs are stiffly hairy. This species is dioecious (male and female plants). Leaves are oblong-elliptic to roundish, 0.4 - 1.6 inches long, glabrous on upper surface, densely pubescent below, with petiole 0.1 - 0.2 inches long. Flowers - male catkins 2 - 2.8 inches long, in clusters of 2 - 4, female flowers 1.2 - 3.5 inches long. Fruit are blue-black, subglabrous berries, 0.1 - 0.2 inches. Be careful not to assume this is a manzanita at first glance. Silk-tassels have opposite leaves (Seda, Atzet, and Wheeler 1989).

Squaw carpet (CEPR) - Evergreen trailing shrub forming dark green mats. Leaves opposite, leathery, with toothed margins. Flowers showy, blue to white clusters. Fruit capsules, 0.2 - 0.4 inches broad, with three lobes. Dwarf ceanothus (CEPU) is very similar, but the leaves are smaller and it grows in ultrabasic soils, such as serpentine (Seda, Atzet, and Wheeler 1989).

Dwarf ceanothus (CEPU) - Low, mat-forming, creeping shrub. Leaves opposite, persistent, wedge-shaped to oblong-lanceolate; 0.2 - 0.6 inches long on petioles less than 0.1 inches long, often with few teeth on the margins. Flowers blue to white, borne in few-flowered umbels. Fruit globose capsules, 0.2 inches in diameter, containing shiny, flattened seeds. Similar to squaw carpet (CEPR) (Seda, Atzet, and Wheeler 1989).

The relationship of draft and final plant associations in the Jeffrey Pine Series is shown below. The draft associations are listed, with the final associations below, each in order of most to least common, with the percentage of plots that make up each association (refer to Methods section).

JEFFREY PINE/HOARY MANZANITA/IDAHO FESCUE
Pinus jeffreyi/*Arctostaphylos canescens*/*Festuca idahoensis*
 PIJE/ARCA5/FEID (N=6; BLM=6)

Distribution. This Association occurs on the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may also occur on the Illinois Valley and Galice Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This is a low elevation Jeffrey pine association and is one of the warmer, drier Jeffrey pine associations. Hoary manzanita and Idaho fescue are frequently present, both with covers greater than 30 percent. Dwarf ceanothus is also frequently present with covers usually greater than 5 percent.

Soils. Parent material consists of mixed-ultramafics, serpentine, and peridotite. Surface rock (defined as greater than 7 centimeters in size) cover averages 8 percent, while exposed bedrock cover averages 6 percent. Bare ground averages 19 percent.

Environment. Elevation averages 1730 feet. Aspects vary, though this **Association** is rarely found on north aspects. Slope averages 44 percent, with a range of 35 to 60 percent. Slope position ranges from mid-slope to lower slope and rolling topography is common.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 19 species. The overstory is dominated by Jeffrey pine. The only understory species commonly found is Jeffrey pine, although incense-cedar is occasionally found. Hoary manzanita and dwarf ceanothus are frequently present in the shrub layer. Hoary manzanita covers are generally greater than 30 percent and Dwarf ceanothus covers are generally greater than 5 percent. Brewers oak is common. In the herb/grass layer, Idaho fescue is frequently found, with high covers Buttercup and common eriophyllum are also frequently found, but with low covers. Applegate's paintbrush, sickleleaf onion, locoweed, and ookow are all common, also with low covers. Moss is absent.

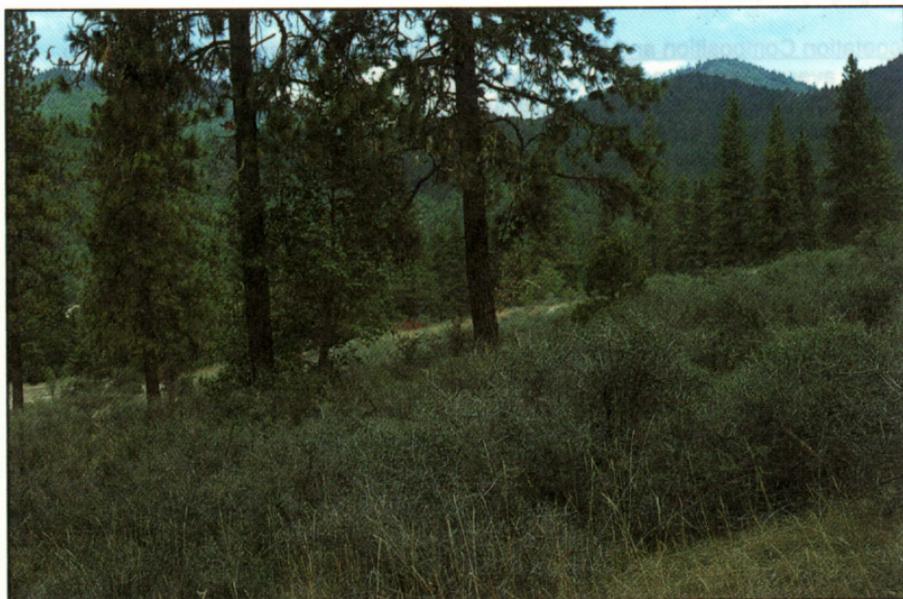

Cover for trees greater than 10 feet tall (3 meters) averages 12 percent, while cover for trees less than 10 feet tall averages 1 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 46 percent, and cover for shrubs less than 20 inches tall averages 8 percent. Herb/grass cover averages 47 percent

JEFFREY PINE/BUCKBRUSH/IDAHO FESCUE

Pinus jeffreyi/Ceanothus cuneatus/Fescue idahoensis

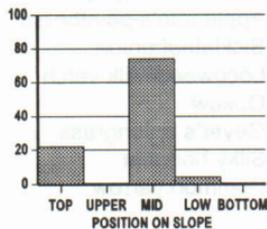

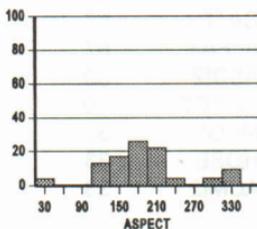

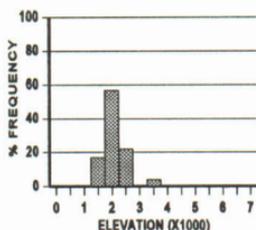

PIJE/CECU/FEID (N=23; BLM=23)

Distribution. This Association occurs on the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may also be found on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs at low elevations and is the driest Jeffrey pine association. Buckbrush, a dry site indicator, occurred on 21 out of 23 plots, with an average cover of 37 percent. Buckbrush is abundant only in this Jeffrey Pine Association. Idaho fescue and whiteleaf manzanita occur frequently, with average covers of 53 and 20 percent, respectively.

Soils. The predominant parent material is mixed ultramafics, with serpentine and granodiorite occurring occasionally. Surface rock (defined as greater than 7 centimeters in size) cover averages 18 percent with less than 1 percent exposed bedrock present.

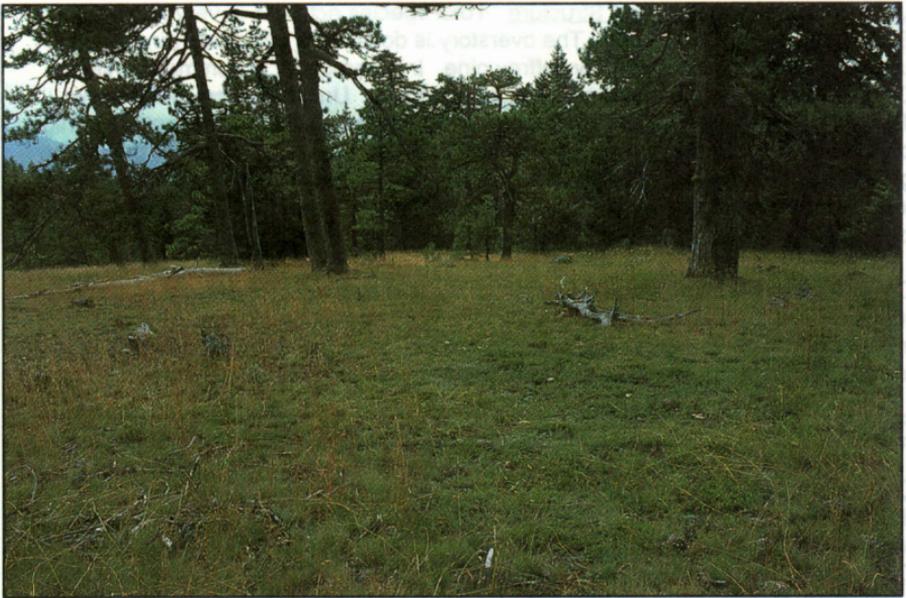

Environment. Elevation averages 2080 feet. Aspect is variable, though generally south, southeast, or southwest. Slope averages 43 percent and ranges from 0 to 60 percent. This **Association** occurs on all slope positions, but mostly mid-slope.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 15 species. The overstory is dominated by Jeffrey pine. The understory is also dominated by Jeffrey pine. Incense-cedar is common, while Douglas-fir and Pacific madrone occur occasionally. Understory covers are low. The shrub layer is dominated by buckbrush and whiteleaf manzanita, both with high covers. The herb/grass layer is dominated by Idaho fescue, with covers generally greater than 30 percent. Sulphurflower and rock fern are frequent, Pacific hound's-tongue is common, and bluegrass, big squirreltail, and common yarrow are occasional, all with low covers. Moss cover averages less than 1 percent.

Cover for trees greater than 10 feet tall (3 meters) averages 27 percent while cover for trees less than 10 feet tall averages 4 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 25 percent, while cover for shrubs less than 20 inches tall averages 32 percent. Herb/grass cover averages 52 percent.

JEFFREY PINE/IDAHO FESCUE
Pinus jeffreyi/Festuca idahoensis
PIJE/FEID (N=13; BLM=13)

Distribution. This Association occurs on the Grants Pass, Glendale, and Butte Falls Resource Areas, Medford District, Bureau of Land Management and the Galice Ranger District, Siskiyou National Forest. This Association may also occur on the Illinois Valley Ranger District, Siskiyou National Forest and the Tiller Ranger District, Umpqua National Forest.

Distinguishing Characteristics. Jeffrey Pine/Idaho Fescue is one of the warmer, drier Jeffrey pine associations. Idaho fescue is frequently present with covers ranging from 10 to 90 percent and averaging 44 percent.

Soils. Parent materials consist of serpentine (the most predominant), peridotite, mixed ultramafics, and mixed ultramafics with metavolcanics. Surface rock (defined as greater than 7 centimeters in size) cover averages 9 percent while exposed bedrock cover averages 5 percent. Bare ground also averages 5 percent.

Based on two plots sampled, soils are moderately well drained. The surface texture is clay loam, with 0 to 15 percent gravel, 0 to 25 percent cobbles, and 25 to 29 percent clay. The subsurface texture is clay, with 10 percent gravel, 50 to 60 percent cobbles, and 40 to 50 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably mesic. Soils classify to the following subgroups: Lithic Haploxeralf or Typic Palexeralf.

Environment. Elevation averages 2570 feet. Aspect is variable. The average slope is 31 percent with a range of 12 to 45 percent. All slope positions are represented, with mid-slopes being the most common.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 18 species. The overstory is dominated by Jeffrey pine. The understory is dominated by Jeffrey pine with common occurrences of incense-cedar and Douglas-fir. Idaho fescue is frequently found, usually with high covers. Common eriophyllum and rock fern are common, while prairie junegrass, spreading phlox, common yarrow, and sulphurflower are occasional, all with low covers. Moss cover averages 5 percent.

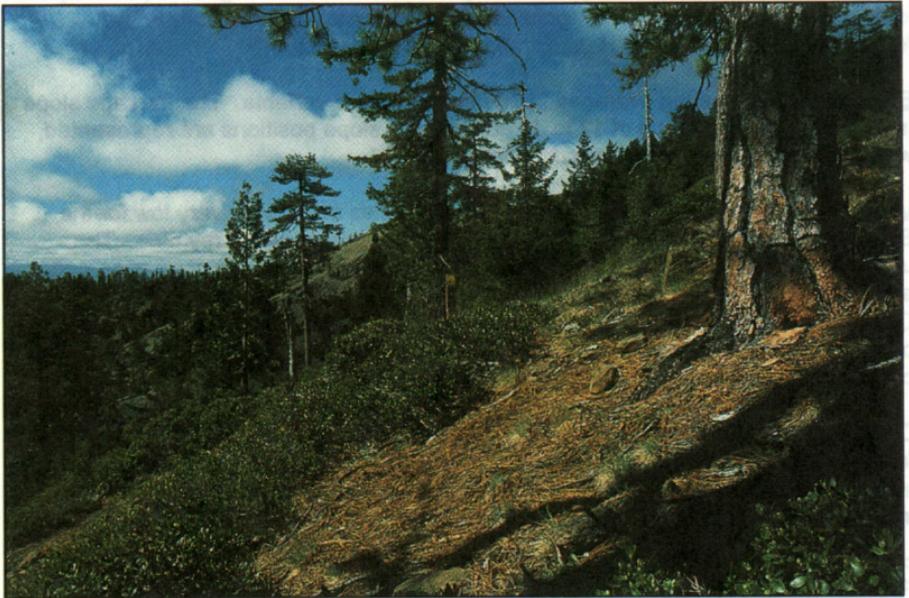

Cover for trees greater than 10 feet tall (3 meters) averages 30 percent while cover for trees less than 10 feet tall averages 4 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 3 percent and cover for shrubs less than 20 inches tall averages 3 percent. Herb/grass cover averages 62 percent.

JEFFREY PINE-INCENSE-CEDAR/HUCKLEBERRY OAK

Pinus jeffreyi-Calocedrus decurrens/Quercus vaccinifolia

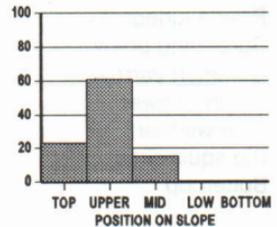

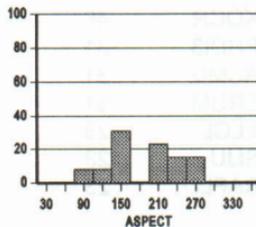

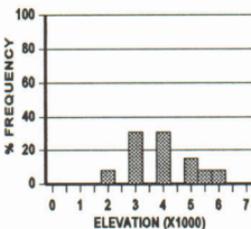

PIJE-CADE27/QUVA (N=13; FS=13)

Distribution. This **Association** occurs on the Applegate and Ashland Ranger Districts, Rogue River National Forest and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on the Ashland and Grants Pass Resource Areas, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This is a relatively high elevation Jeffrey pine **association** and is the coolest of the Jeffrey pine **associations**. Huckleberry oak and incense-cedar are usually present.

Soils. Parent material is serpentine, with one occurrence of peridotite. Surface gravel and rock content averages 26 and 36 percent cover, respectively, while exposed bedrock cover averages 5 percent. Based on two plots sampled, soils are deep (greater than 40 inches) and well drained. Surface texture is silty clay loam, with 8 to 25 percent gravel, 35 to 50 percent cobbles and stones, and 32 percent

clay. Subsurface texture is silty clay loam, with 5 percent gravel, 40 percent cobbles and stones, and 32 to 35 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably frigid. Soils classify to the following subgroups: Dystric Xerochrept and Typic Xerochrept.

Environment. Elevation averages 3990 feet. Aspect is variable, although generally not northerly. Slope averages 33 percent with a range of 5 to 68 percent. Slope position ranges from ridgetops down to the middle one-third of the slope.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 27 species. The overstory is dominated by Jeffrey pine. Incense-cedar is frequently present but with low covers. Douglas-fir is common in the overstory, although covers are low. The understory is dominated by Jeffrey pine, with frequent occurrences of incense-cedar and Douglas-fir. White fir occurred on one plot. Hardwoods found in this **Association**, although rare and with low covers, consist of Pacific madrone, golden chinquapin, canyon live oak, Oregon white oak, and California-laurel. The shrub layer is dominated by box-leaved silk-tassel and huckleberry oak, both with fairly high covers. Whiteleaf manzanita, buckbrush, and dwarf ceanothus commonly occur, while pinemat manzanita and pygmy Oregongrape are occasionally present. Rock fern is frequently found while common beargrass and common yarrow are common; all had low covers. Moss cover averages 1 percent.

Upper layer tree cover is high for the Series, averaging 25 percent, while mid-layer tree cover is low, averaging 23 percent. Lower layer tree cover averages 36 percent, intermediate for the Series. High shrub and low shrub covers are low for the Series, averaging 3 and 30 percent, respectively. Herb/grass cover is intermediate for the Series, averaging 47 percent.

JEFFREY PINE/HUCKLEBERRY OAK-PINEMAT MANZANITA

Pinus jeffreyi/Quercus vaccinifolia-Arctostaphylos nevadensis

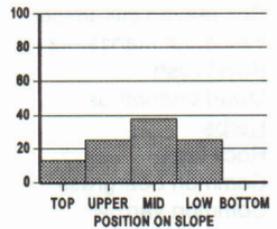

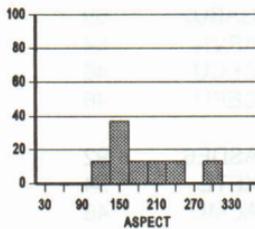

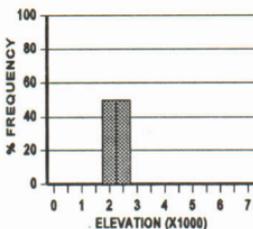

PIJE/QUVA-ARNE (N=8; FS=8)

Distribution. This Association occurs on the Chetco Ranger District, Siskiyou National Forest. All plots were located in the Lemmingsworth Gulch Research Natural Area.

Distinguishing Characteristics. This Association is a coastal expression of vegetation on ultramafics. It is the only warm, wet Jeffrey pine association, with an average annual temperature of 50 degrees F and average annual precipitation of 120 inches. Jeffrey Pine/Huckleberry Oak-Pinemat Manzanita-Box-Leaved Silk-Tassel is cooler but also averages 120 inches of precipitation per year. Both associations are by far the wettest of the Series.

Soils. Parent material is serpentinite. Surface gravel averages 24 percent, while surface rock averages 27 percent. Average exposed bedrock cover is 1 percent. Based on two plots sampled, soils are shallow to moderately deep (10 to 30 inches)

and well drained. Surface texture is loam, with 25 to 33 percent gravel, 2 percent cobbles, and 25 percent clay. Subsurface textures are loam and clay loam, with 0 to 50 percent gravel, 5 to 50 percent cobbles, and 20 to 35 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably mesic. Soils classify to the following subgroups: Lithic Xerochrept and Typic Haploxerafl.

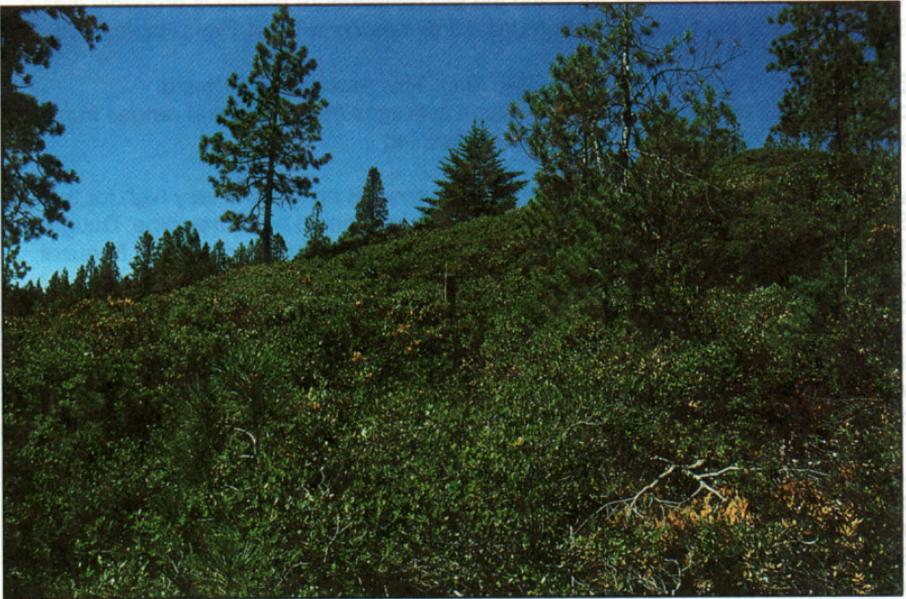

Environment. Elevation averages 2240 feet. This **Association** is found predominantly on southern aspects. Slope averages 41 percent and ranges from 13 to 60 percent. All slope positions are represented.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 49 species. The overstory is dominated by Jeffrey pine, Douglas-fir, and knobcone pine. The understory is dominated by Jeffrey pine, with frequent occurrences of Douglas-fir and California-laurel. Huckleberry oak is frequently present with an average cover of 22 percent. The shrub form of tanoak is commonly found. Pinemat manzanita, dwarf ceanothus, and coffeeberry are frequently present, as is rock fern, obscure bedstraw, few-fruited biscuit-root, death camas, common yarrow, variable morning-glory, slender-tubed iris, and spreading phlox, all with low covers. Moss cover averages 2 percent.

Upper layer tree cover is low for the Series, averaging 6 percent. Mid-layer tree cover is high for the Series, averaging 31 percent, while lower layer tree cover is intermediate, averaging 38 percent. High shrub and low shrub covers are low for the Series, averaging 5 and 21 percent, respectively. Herb/grass cover is intermediate for the Series, with an average of 48 percent.

JEFFREY PINE/HUCKLEBERRY OAK-PINEMAT MANZANITA-BOX-LEAVED SILK-TASSEL
Pinus jeffreyi/Quercus vaccinifolia-Arctostaphylos nevadensis-Garrya buxifolia
 PIJE/QUVA-ARNE-GABU2 (N=5; FS=5)

Distribution. This Association occurs on the Chetco, Gold Beach, Galice, and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on the Grants Pass Resource Area, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association, along with the Jeffrey Pine/Huckleberry Oak-Pinemat Manzanita Association, is the wettest of the Series, averaging 120 inches of precipitation annually. This Association differs from the Jeffrey Pine/Huckleberry Oak-Pinemat Manzanita Association by the presence of box-leaved silk-tassel, generally with covers greater than 20 percent. It is also cooler, averaging 47 degrees F, annually.

Soils. The predominant parent material is serpentine, with one occurrence of peridotite. Surface gravel averages 24 percent cover and surface rock averages 51

percent cover. Exposed bedrock averages 6 percent cover. Based on two plots sampled, soils are moderately deep (27 inches) and well drained. Surface texture is clay loam, with 20 percent gravel, 5 percent cobbles, and 25 percent clay. Subsurface texture is also clay loam, with 25 percent gravel, 20 percent cobbles, and 35 percent clay. The soil moisture regime can be either xeric or udic and the soil temperature regime is probably frigid. Soils classify to the following subgroup: Dystric Xerochrept.

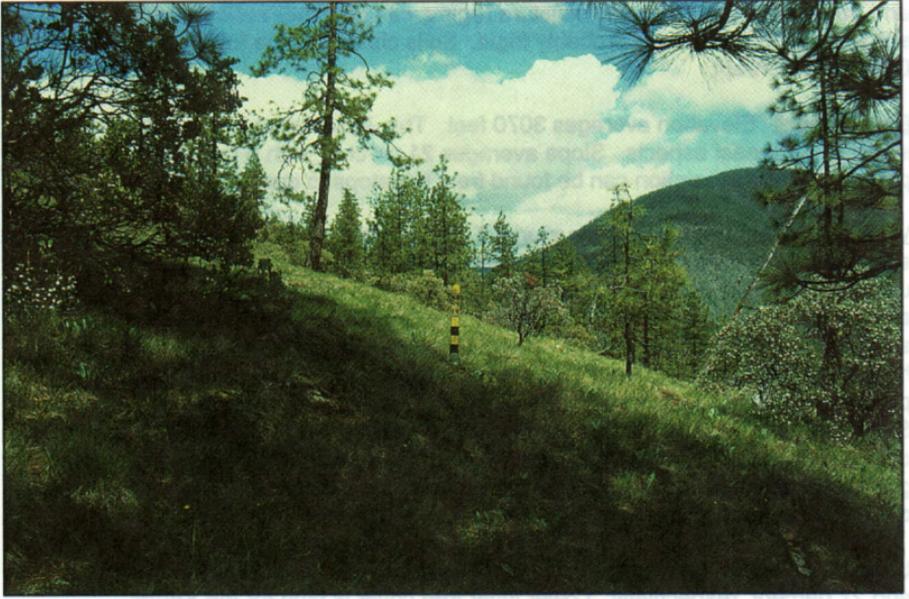

Environment. Elevation averages 3070 feet. This **Association** is generally found on south to southeast aspects. Slope averages 21 percent, with a range of 8 to 35 percent. This **Association** can be found from ridgetops to draws.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 27 species. The dominant overstory species is Jeffrey pine. The understory is also dominated by Jeffrey pine with Douglas-fir frequently present, although with low covers. Knobcone pine, western white pine, and California-laurel are common, but with low covers. Pinemat manzanita, box-leaved silk-tassel, and huckleberry oak are frequently present with covers averaging greater than 20 percent. Pygmy Oregongrape is also frequently present, but with low covers. Slender-tubed iris, common juniper, dwarf ceanothus, rock fern, whipplevine, and common beargrass are common with low covers. Squaw carpet, variable morning-glory, coffeeberry, red huckleberry, and Horkelia are occasional, also with low covers. Moss cover averages less than 1 percent.

Upper layer and mid-layer tree covers are intermediate for the Series, averaging 15 and 27 percent, respectively. Lower layer tree cover is high for the Series, averaging 45 percent. High shrub cover is low, averaging 8 percent, while low shrub cover averages 56 percent, highest for the Series. Herb/grass cover averages 28 percent, lowest for the Series.

JEFFREY PINE-INCENSE-CEDAR/WHITELEAF MANZANITA
Pinus jeffreyi-Calocedrus decurrens/Arctostaphylos viscida
 PIJE-CADE27/ARVI4 (N=11; FS=11)

Distribution. This **Association** occurs on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and the Applegate Ranger District, Rogue River National Forest. It may also occur on the Grants Pass and Ashland Resource Areas, Medford District, Bureau of Land Management.

Distinguishing Characteristics. This is one of the warmer, drier Jeffrey pine **associations**. Whiteleaf manzanita is frequently present with high covers, usually greater than 30 percent. Huckleberry oak is usually absent.

Soils. Parent material is serpentine, with one occurrence of diorite. Surface gravel averages 35 percent cover while surface rock averages 42 percent cover. Exposed bedrock averages 1 percent cover. Based on two plots sampled, soils are shallow to moderately deep (18 to 23 inches), and moderately well drained. Surface texture is clay loam, with 15 to 25 percent gravel, 10 to 25 percent cobbles, and 25 percent

clay. Subsurface textures are clay loam and clay, with 15 percent gravel, 30 to 70 percent cobbles and stones, and 35 to 45 percent clay. The soil moisture regime is probably xeric and the soil temperature regime is probably mesic. Soils classify to the following subgroups: Lithic Xerochrept and Typic Xerochrept.

Environment. Elevation averages 2310 feet. Aspects vary. Slope averages 33 percent and ranges from 15 to 45 percent. Slope position ranges from the lower one-third to the ridgetop. This **Association** can also be found on narrow flats and benches.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 29 species. The overstory is dominated by Jeffrey pine, with incense-cedar and Douglas-fir common. Incense-cedar and Douglas-fir generally have low cover values. The understory is dominated by Jeffrey pine and incense-cedar, with Douglas-fir occurring occasionally. All have low covers. In the shrub layer, whiteleaf manzanita is frequently present, with covers usually greater than 30 percent. Dwarf ceanothus is common, but with covers of less than 10 percent. Coffeeberry occurs occasionally, but with low covers. In the herb/grass layer, rock fern is common, again with very low covers. Tolmie's mariposa and western buttercup are common, while slender-tubed iris, common eriophyllum, and sickleleaf onion are occasionally present, all with low covers. Moss cover averages 3 percent.

Upper layer tree cover is high for the Series, averaging 23 percent. Mid-layer tree cover is intermediate, averaging 27 percent, while lower layer tree cover is low for the Series, averaging 21 percent. High shrub cover is high for the Series, averaging 18 percent, and low shrub cover is low, averaging 22 percent. Herb/grass cover is one of the highest of the Series, averaging 74 percent (mostly grasses).

JEFFREY PINE-INCENSE-CEDAR-DOUGLAS-FIR

Pinus jeffreyi-Calocedrus decurrens-Pseudotsuga menziesii

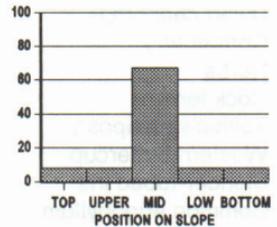

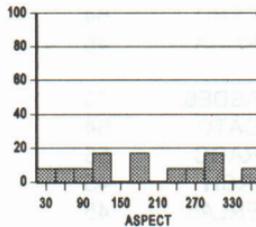

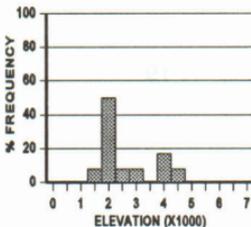

PIJE-CADE27-PSME (N=12; BLM=12)

Distribution. This Association occurs on the Grants Pass and Butte Falls Resource Areas, Medford District, Bureau of Land Management. It may also occur on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association is highly variable in both vegetation and environment and is one of the warmer, drier Jeffrey pine associations. Based on the presence of Douglas-fir and non-serpentine species such as tanoak, hairy honeysuckle, and western starflower, this Association may represent a transition to the Douglas-fir Series.

Soils. Parent materials consist of serpentine, peridotite, and mixed ultramafics, with one occurrence of sandstone. Surface rock (defined as greater than 7 centimeters in size) cover averages 7 percent and exposed bedrock cover averages 3 percent.

Environment. Elevation averages 2700 feet. Aspects vary. Slope averages 36 percent with a range of 4 to 65 percent. All slope positions are represented, with mid-slope most predominant.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 21 species. The overstory is dominated by Jeffrey pine, with Douglas-fir and incense-cedar common. The understory is dominated by Jeffrey pine, with incense-cedar and Douglas-fir occurring frequently. All have low covers. Pacific madrone and canyon live oak occur occasionally. The shrub and herb/grass layers may have a large variety of species, but rarely one individual species that occurs frequently. Coffeeberry, western twinflower, and golden iris occur most frequently. Moss cover averages 10 percent, the highest for the Series.

Tree cover exceeding 10 feet tall (3 meters) averages 50 percent while cover for tree species less than 10 feet tall averages 11 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 24 percent and cover for shrubs less than 20 inches tall averages 8 percent. Herb/grass cover averages 31 percent.

WHITE FIR SERIES

WHITE FIR SERIES

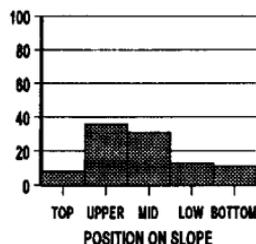

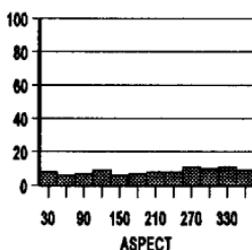

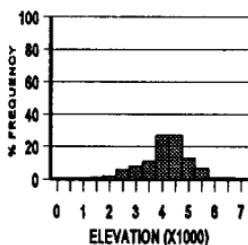

Abies concolor

ABCO

Diane E. White

As a species, white fir is abundant in southwestern Oregon. On the west side of the Cascade Mountains, southwestern Oregon is the approximate northern extent. White fir extends south throughout California. Grand fir (*Abies grandis*) also occurs in the area, but it interbreeds with white fir and is difficult to distinguish. Zobel (1973, 1974) has described a zone of morphological and physiological intergradation between the two species. The overlap occurs in a diagonal band extending from the Klamath Mountain Province (northwest California and southwest Oregon) through the southern Oregon Cascades into the Blue Mountains (northeast Oregon and west-central Idaho). Individuals exhibiting characteristics of both species are often referred to as *Abies grandicolor* (sic). All references in this guide will be to white fir (*A. concolor*), although some individuals in the field may exhibit more grand fir characteristics. The ecological and silvicultural differences are not significant enough to warrant any distinctions within the context of this guide.

The White Fir Series occurs on environmentally varied sites throughout southwestern Oregon. It covers a wide elevational band, with an average of approximately 4300 feet. The Series occurs evenly across all aspects, and upper and middle slope positions are more common than ridge tops or bottoms. The Series includes highly productive lands, and has a high vascular **plant** species diversity.

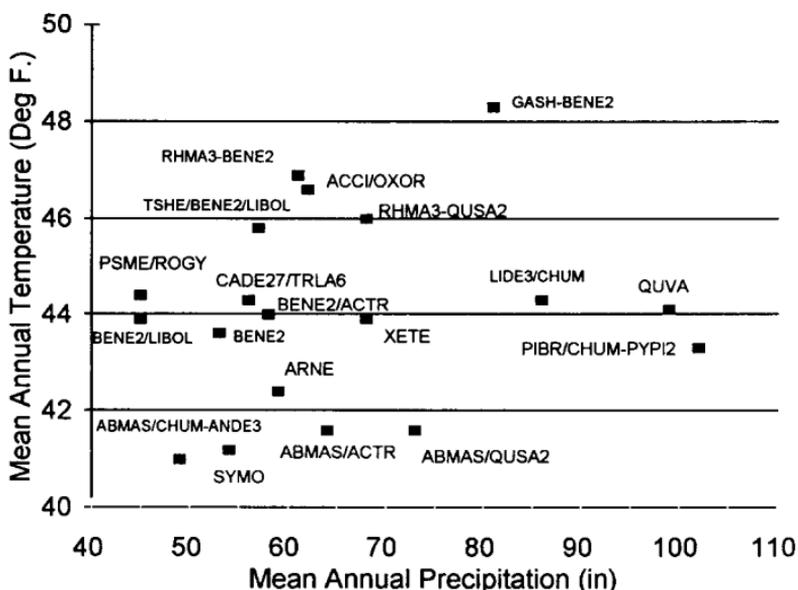

Many different soils occur in the White Fir Series. Parent material is variable, although occurrence on diorite is frequent. Soils range from shallow to deep, although moderately deep to deep are the most frequently encountered conditions. Surface textures range from sand, sandy loam, loam, and loamy sand to sand, clay loam, silt loam, and clay loam. Rock fragments range from 15 to 70 percent, and clay content ranges from 5 to 26 percent. Subsurface textures range from sand, sandy loam, loam, and loamy sand, through sandy clay loam and clay loam. Rock fragments are between 10 and 75 percent, and clay content ranges between 0 and 50 percent. Soil data were collected on all plots, with a sub-sample of 75 intensively described soil pits.

The White Fir Series generally occurs on cool sites. Average annual temperature ranges from 41 degrees F in the High Cascades and Siskiyou to 48 degrees F in lower elevation areas. Average annual rainfall varies between 45 inches in drier areas of the Cascades to 102 inches near the coast.

ABCO 2

The relative environments of the **plant associations** are shown below. Each **association** is plotted by mean annual temperature and mean annual precipitation.

As a result of the frequent disturbance in southwestern Oregon, Douglas-fir, an early seral species, is the dominant overstory tree in the White Fir Series. In colder areas, Shasta red fir may be the dominant overstory pioneer species. White fir is the dominant tree species in the understory, and is particularly abundant in older stands with a low frequency of disturbance. In wetter areas of the Cascades and Siskiyou, western hemlock is present, and on higher elevation, cooler areas, Pacific silver fir, mountain hemlock, Shasta red fir, and lodgepole pine may be present. In cold, dry areas of the Siskiyou, Brewer spruce may be part of the stand. In the Siskiyou tanoak may be present, and in areas that tend toward ultramafic soils, Port-Orford-cedar may be common. Dwarf Oregon-grape and common prince's-pine are widespread throughout the Series. Pacific rhododendron and salal are common in moist, high productivity areas. Incense-cedar, golden chinquapin, ponderosa pine, and whipplevine are present on dry sites.

Average total vascular **plant** species richness for the White Fir Series ranges between 19 and 44. In this Series, richness is rated as very low, less than or equal to 20 species; low, 21 to 29 species; intermediate, 30 to 35 species; high, 36 to 41 species, and very high, greater than 41 species.

Upper layer tree canopy cover ranges from 55 percent in the White Fir-Shasta Red Fir/Vanillaleaf Association, to 78 percent in the White Fir/Pacific Rhododendron-Sadler Oak Association. The mid-layer tree cover ranges between 33 and 63 percent. The lower layer tree cover ranges between 8 and 68 percent. High shrub cover ranges between 1 and 60 percent, and low shrub cover ranges between 2 and 55 percent. Herb/grass cover ranges between 10 and 98 percent.

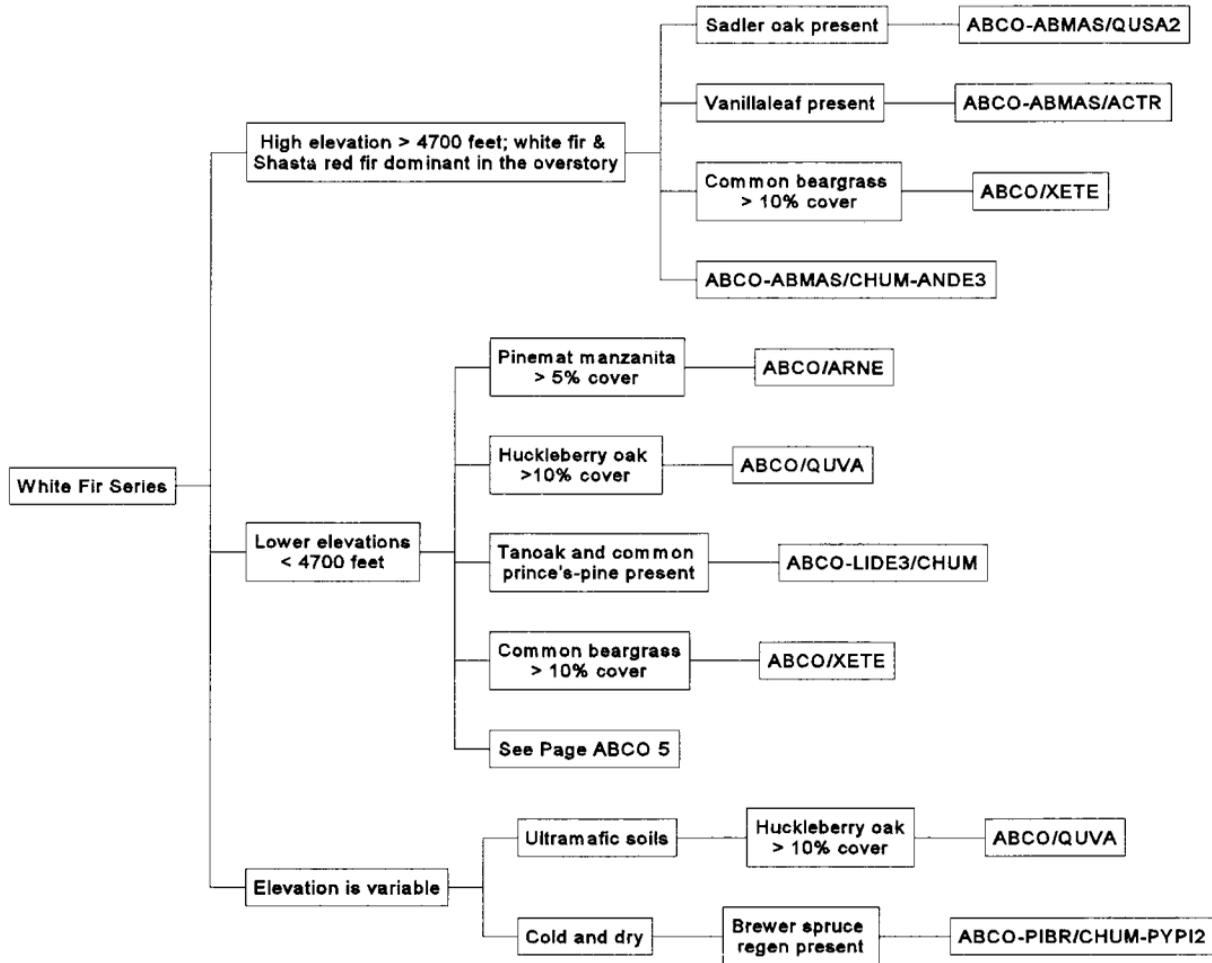

Nineteen plant associations have been classified for the Series in southwestern Oregon. They were described from 521 plots; 454 from Forest Service and 67 from Bureau of Land Management lands.

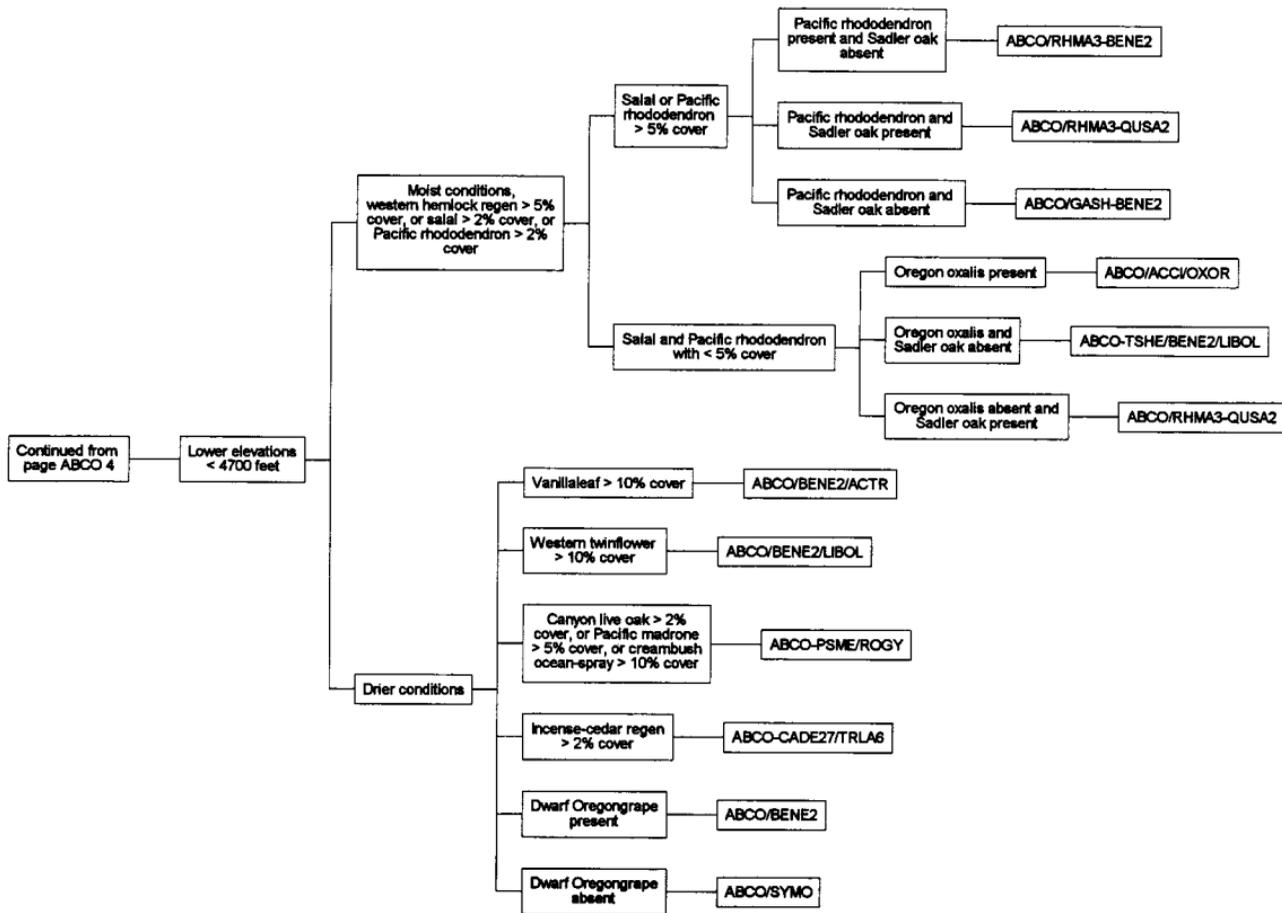

The flow chart on the following pages shows a graphical presentation of the classification and the relationships between the plant associations.

ABCO 12

WHITE FIR-SHASTA RED FIR/SADLER OAK

Abies concolor-Abies magnifica shastensis/Quercus sadleriana

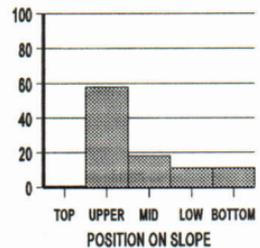

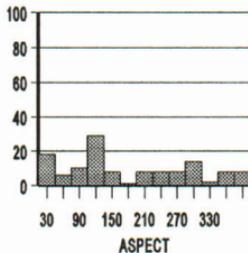

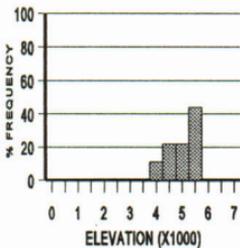

ABCO-ABMAS/QUSA2 (N=17; FS=7)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs on cold sites at high elevations. This Association is wetter than White Fir-Shasta Red Fir/Vanillaleaf and White Fir-Shasta Red Fir/Common Prince's-pine-Threeleaf Anemone. Overstory tree canopy cover is often low.

Soils. Parent material is mostly diorite, granodiorite, and sandstone, with some quartz diorite and gabbro. Average surface rock cover is 16 percent, with 9 percent gravel, and 3 percent bare ground exposure. Soils are moderately deep to deep, with an average depth of more than 49 inches. Based on two plots sampled, surface texture is loam and sand, with 20 to 45 percent gravel, and 0 to 17 percent clay.

Subsurface texture is loam and sand, with 10 to 25 percent gravel, 20 to 75 percent cobbles, and 0 to 20 percent clay

Environment This **Association** averages 5220 feet in elevation and occurs on aspects that are predominantly north, east and west Slope averages 42 percent and ranges from 12 to 80 percent This **Association** occurs predominantly on upper third slope positions

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 30 White fir and Shasta red fir are frequent, and Douglas-fir common in the overstory White fir and Shasta red fir are present in the understory, Douglas-fir is common Hardwoods include Douglas maple, big-leaf maple, red alder, golden chinquapin, Pacific dogwood, tanoak, and canyon live oak In the shrub layer, Sadler oak is frequent Dwarf Oregongrape, baldhip rose, dwarf bramble, Pacific blackberry, Sitka mountain-ash, and creeping snowberry are common shrubs Common prince's-pine, whitevein pyrola, and one-sided pyrola are frequent in the herb/grass layer Vanillaleaf, threelife anemone, little prince's-pine, white-flowered hawkweed, and western false Solomon's-seal are common Moss cover is very low for the Series, averaging only 2 percent

Upper and middle layer tree covers are low to intermediate for the Series, averaging 59 and 40 percent cover, respectively Lower layer tree cover averages 14 percent cover Shrub cover is low to very low, with high shrub cover averaging 17 percent and low shrub cover 13 percent Herb/grass cover ranges from 1 to 65 percent, and averages 29 percent

ABCO 14

WHITE FIR-SHASTA RED FIR/VANILLALEAF

Abies concolor-*Abies magnifica shastensis*/*Achlys triphylla*

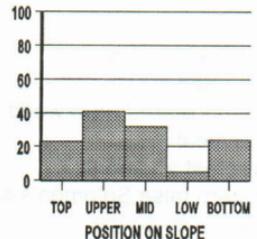

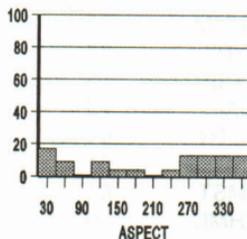

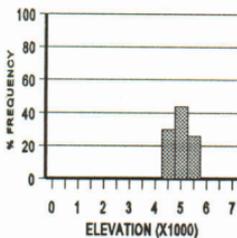

ABCO-ABMAS/ACTR (N=22; FS=22)

Distribution. This Association occurs on the Diamond Lake Ranger District, Umpqua National Forest, the Applegate and Prospect Ranger Districts, Rogue River National Forest, and the Illinois Valley Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs on very high elevation, cold sites. Overstory tree cover is low and herbs are abundant. This Association receives less precipitation than White Fir-Shasta Red Fir/Sadler Oak and more precipitation than White Fir-Shasta Red Fir/Common Prince's-pine-Threeleaf Anemone or White Fir/Creeping Snowberry.

Soils. Parent material is mostly a mix of igneous materials including diorite, granodiorite, granite, gabbro, andesite, and basalt. Average surface rock cover is 5 percent, with 7 percent gravel and 5 percent bare ground exposure. Soils are moderately deep to deep, with an average depth greater than 44 inches.

Based on one plot sampled, surface textures are loam with 15 to 45 percent gravel, 40 percent cobbles, and 19 percent clay. Subsurface textures are loam with 15 percent gravel, 50 percent cobbles, and 23 percent clay.

Environment. This **Association** averages 5190 feet in elevation and the aspect is predominantly north and west. Slope averages 35 percent and ranges from 6 to 65 percent. This **Association** occurs predominantly upper or middle-thirds of slopes or ridge tops.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 44. White fir and Shasta red fir are frequent in the overstory, and Douglas-fir is common. White fir and Shasta red fir are frequent in the regeneration layer, and incense-cedar is common. Mountain hemlock occurs occasionally. Hardwoods include Douglas maple, big-leaf maple, Sitka alder, Pacific dogwood, and canyon live oak. Baldhip rose, creeping snowberry, and dwarf Oregongrape are common. Vanillaleaf, white inside-out-flower, trail-plant, threeleaf anemone, bigleaf sandwort, Scouler's harebell, queen's cup, Oregon fairybell, woods strawberry, white-flowered hawkweed, starry false Solomon's-seal, western starflower, white trillium, and stream violet are frequent herbs. Moss cover averages 2 percent.

Upper and mid layer tree covers are low for the Series, averaging 55 and 33 percent cover, respectively. Lower layer tree cover averages 15 percent. Shrub cover is low to very low, with high shrub cover averaging 3 percent and low shrub cover 15 percent. Herb/grass cover is high for the Series, ranging from 45 to 95 percent, and averaging 71 percent.

WHITE FIR/COMMON BEARGRASS

Abies concolor/Xerophyllum tenax

ABCO/XETE (N=5; BLM=5)

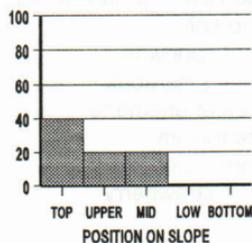

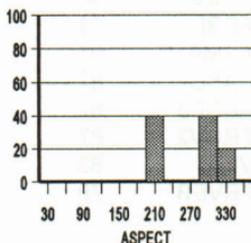

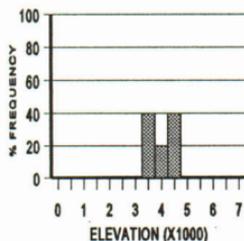

Distribution. This Association occurs on the Grants Pass and Glendale Resource Areas of the Medford District, Bureau of Land Management. It may also occur on adjacent Forest Service lands.

Distinguishing Characteristics. This Association occurs at moderate elevations, on moist warm sites. Common beargrass cover is high.

Soils. Parent material can be schist, serpentine, or peridotite. Average surface rock cover is 34 percent, with 28 percent gravel, and 3 percent bare ground exposure. The depth on one sample plot was 30 inches.

Environment. This Association averages 4310 feet in elevation and occurs on northwest and southwest aspects. Slope averages 26 percent and ranges from 8 to 48 percent. This Association occurs predominately on ridge top positions.

Vegetation Composition and Structure Total species richness is low for the Series, averaging 25 Douglas-fir and white fir are frequent overstory White fir is frequent in the understory and Douglas-fir is common Hardwoods may include golden chinquapin In the shrub layer, baldhip rose and dwarf Oregongrape are frequent, and creambush ocean-spray is common Common beargrass is likely present, and western fescue, white-flowered hawkweed, and snow-queen are common Moss cover is low for the Series, averaging 4 percent.

Cover of trees exceeding 10 feet tall (3 meters) averages 68 percent, while trees less than 10 feet tall average 8 percent cover Cover of shrubs greater than 20 inches tall (50 centimeters) averages only 1 percent, and cover of shrubs less than 20 inches tall averages 2 percent Herb/grass cover ranges from 30 to 85 percent, and averages 46 percent

ABCO 18

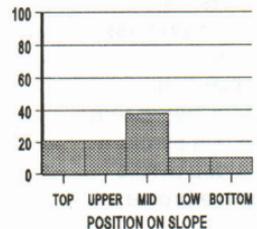

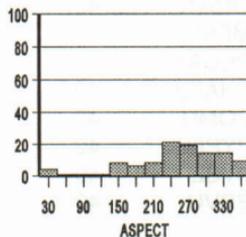

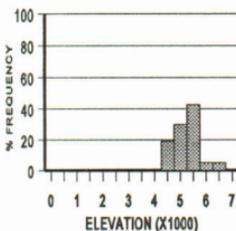

WHITE FIR-SHASTA RED FIR/COMMON PRINCE'S-PINE-THREELEAF ANEMONE
Abies concolor-*Abies magnifica shastensis*/*Chimaphila umbellata*-*Anemone deltoidea*
ABCO-ABMAS/CHUM-ANDE3 (N=27; FS=27)

Distribution. This Association occurs on the Diamond Lake Ranger District, Umpqua National Forest, the Ashland, Applegate, and Butte Falls Ranger Districts, Rogue River National Forest, and the Illinois Valley Ranger District, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs at high elevations on cold sites. Shasta red fir is a major component of the stand. The number of herb species is about half that of the White Fir-Shasta Red Fir/Vanillaleaf Association. This Association is slightly colder and much drier than the White Fir-Shasta Red Fir/Vanillaleaf or White Fir-Shasta Red Fir/Sadler Oak Plant Associations.

Soils. Parent material varies from andesite and basalt to diorite and granite. The average surface rock cover is 12 percent, with 9 percent surface gravel. Based on three plots sampled, soils can be shallow to deep (average depth of greater than 40

inches and very well drained. The surface textures are fine loamy sand and loamy sand, with an average of 15 percent gravel and 5 percent clay. Subsurface textures are loamy sand, with an average of 21percent gravel, 5 percent cobbles, and 3 percent clay.

Environment This **Association** averages 5420 feet in elevation and the aspect is predominantly west to northwest. Slope averages 24 percent and ranges from 3 to 50 percent. This **Association** occurs on ridge tops and upper and middle thirds of slopes.

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 33. White fir, Shasta red fir, and Douglas-fir are frequent in the overstory and understory. Pacific yew, golden chinquapin, and lodgepole pine may have high cover. Additional hardwoods include Douglas maple, red alder, and Pacific dogwood. In the shrub layer, baldhip rose is frequent, and Oregon boxwood and creeping snowberry are common. Threeleaf anemone, bigleaf sandwort, Scouler's harebell, common prince's-pine, woods strawberry, white-flowered hawkweed, and whitevein pyrola are frequently encountered herbs. Moss cover is very low for the Series, averaging 3 percent.

Upper and mid layer tree covers are low to intermediate for the Series, averaging 56 and 44 percent, respectively. Lower layer tree cover averages 21 percent. Shrub cover is very low to low, with high shrub cover averaging only 2 percent and low shrub cover 23 percent. Herb/grass cover ranges from 1 to 65 percent, and averages 31 percent.

WHITE FIR/HUCKLEBERRY OAK
Abies concolor/Quercus vaccinifolia
ABCO/QUVA (N=13; FS=10, BLM=3)

Distribution. This Association occurs on the Applegate Ranger District, Rogue River National Forest, the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and the Grants Pass Resource Area of the Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs on wet sites with ultramafic soils. Huckleberry oak is an indicator of this soil type. This Association is slightly drier and slightly warmer than the White Fir-Brewer Spruce/Common Prince's-pine-Whitevein Pyrola Association.

Soils. Parent material is mostly diorite or granite, with some andesite, sandstone, and a mix of metamorphosed volcanic materials. Average surface rock cover is 29 percent, with 22 percent gravel, and 3 to 4 percent each of bedrock and bare ground exposure. Based on one plot sampled, soils are moderately deep to deep (pit depth

was greater than 28 inches) Surface texture is sandy loam with 30 to 35 percent gravel, 25 to 30 percent cobbles, and 5 percent clay Subsurface texture is sandy loam, with 15 to 30 percent gravel, 25 to 70 percent cobbles, and 8 to 14 percent clay

Environment This Association averages 4250 feet in elevation Occurrence on south aspects is not common Slope averages 43 percent and ranges from 20 to 75 percent This Association occurs on all slope positions, except valley bottoms

Vegetation Composition and Structure Species richness is low for the Series, averaging 29 Douglas-fir is frequent in both the overstory and understory Sugar pine is frequent in the overstory White fir, sugar pine, and incense-cedar are frequent in the understory, and Shasta red fir, golden chinquapin, tanoak, and brewer spruce are common Hardwoods may include vine maple, Douglas maple, Pacific madrone, Pacific dogwood, and canyon live oak In the shrub layer, dwarf Oregongrape, huckleberry oak, and baldhip rose are frequent Pinemat manzanita, Pacific blackberry, and red huckleberry are common Common prince's-pine, little prince's-pine, rattlesnake-plantain, western sword-fern, whitevein pyrola, and whipplevine are frequent in the herb/grass layer Vanillaleaf, western twinflower, western starflower, and common beargrass are common Moss cover is intermediate for the Series, averaging 9 percent

Upper and mid layer tree covers are low to intermediate for the Series, averaging 56 and 48 percent cover, respectively Lower layer tree cover averages 47 percent Shrub cover is low to intermediate, with high shrub cover averaging only 9 percent and low shrub cover 38 percent Herb/grass cover ranges from 7 to 60 percent, and averages 18 percent

Abies concolor-Picea breweriana/Chimaphila umbellata-Pyrola picta
 ABCO-PIBR/CHUM-PYPI2 (N=11; FS=11)

Distribution. This Association occurs on the Applegate Ranger District of the Rogue River National Forest, and the Illinois Valley Ranger District of the Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs on the coldest, wettest sites of the Series. It occurs in a narrow elevational band between 4000 and 4500 feet.

Soils. Parent material is mostly a mix of igneous materials, including diorite and gabbro, andesite, basalt, and granite. Average surface rock cover is 19 percent, with 17 percent gravel, 7 percent surface bedrock, and 3 percent bare ground exposure. Soils are shallow to deep, with an average depth of greater than 30 inches. Based on one plot sampled, surface textures are loam, with 60 percent gravel, 5 percent cobbles, and 18 percent clay. Subsurface textures are sandy loam and loamy sand, with 45 percent gravel, 5 to 10 percent cobbles, and 6 to

16 percent clay

Environment This Association averages 4490 feet in elevation and occurs on generally north aspects. Slope averages 38 percent and ranges from 12 to 70 percent. It occurs on all slope positions, with the exception of bottoms or valleys.

Vegetation Composition and Structure Total species richness is intermediate, averaging 32. Douglas-fir is present in the overstory and understory. White fir is frequent in the overstory and present in the understory. Shasta red fir and Brewer spruce are also present in the understory. Golden chinquapin and incense-cedar are common. Other hardwoods may include Douglas maple, red alder, tanoak, canyon live oak, and Oregon white oak. In the shrub layer, dwarf Oregongrape and Sadler oak are frequent. Western serviceberry, pinemat manzanita, baldhip rose, and red huckleberry are common. Common prince's-pine is present in the herb layer, whitevein pyrola and rattlesnake-plantain are frequent. Western twinflower, one-sided pyrola, little prince's-pine, whipplevine, and common beargrass are common. Moss cover is low, averaging 4 percent.

Upper and middle layer tree covers are intermediate to high, averaging 63 and 56 percent cover, respectively. Lower layer tree cover averages 51 percent. Shrub cover is very low to intermediate, with high shrub cover averaging only 5 percent and low shrub cover 36 percent. Herb cover ranges from 1 to 70 percent, and averages 25 percent.

WHITE FIR/PINEMAT MANZANITA

Abies concolor/*Arctostaphylos nevadensis*

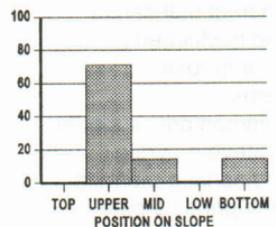

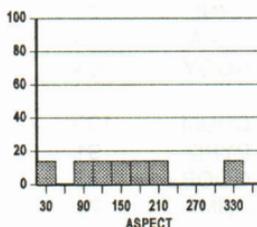

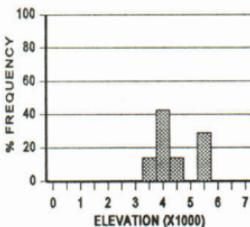

ABCO/ARNE (N=7; FS=7)

Distribution. This **Association** occurs on the Butte Falls and Ashland Ranger Districts, Rogue River National Forest and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This **Association** occurs at intermediate elevations and on cool sites with moderate amounts of precipitation. Sugar pine and Douglas-fir are well represented. Soils are well drained.

Soils. Parent material is highly variable. The **Association** occurs over granitic and quartz diorite, gabbro, rhyolite, metamorphosed schist, slate, and siltstone. Average surface rock cover is 10 percent, with 12 percent gravel. Based on seven plots sampled, soils are moderately deep to deep (average depth 35 inches) and well drained to very well drained. The surface textures are mostly loamy sand or sandy loam, with some loam. Surface horizons have an average of 33 percent gravel, 33

percent cobbles and stone, and 13 percent clay. Subsurface texture is mostly sand, with some sandy loam and loam. Subsurface horizons have an average of 34 percent gravel, 26 percent cobbles or stones, and 14 percent clay. Soil temperature regime can be either mesic or frigid, and the soil moisture regime is probably xeric.

Environment. This Association averages 4740 feet in elevation and occurs on all aspects except perhaps west. Slope averages 31 percent and ranges from 20 to 40 percent. This Association occurs predominantly on upper third slope positions.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 19. Douglas-fir, sugar pine, and white fir are frequent in the overstory and in the understory. Hardwoods that may be present include golden chinquapin, tanoak, and canyon live oak. In the shrub layer, pinemat manzanita is frequent. Dwarf Oregongrape is common. Rattlesnake-plantain and common prince's-pine are frequent, and little prince's-pine, white-flowered hawkweed, western twinflower, one-sided pyrola, and whitevein pyrola are common in the herb/gass layer. Moss cover is very low for the Series, averaging 2 percent.

Upper and mid layer tree covers are intermediate for the Series, averaging 65 and 49 percent cover, respectively. Lower layer tree cover averages 43 percent. Shrub cover is very low to low, with high shrub cover averaging only 2 percent and low shrub cover 25 percent. Herb/grass cover ranges from 1 to 60 percent, and averages 23 percent.

WHITE FIR-TANOAK/COMMON PRINCE'S-PINE

Abies concolor-Lithocarpus densiflorus/Chimaphila umbellata

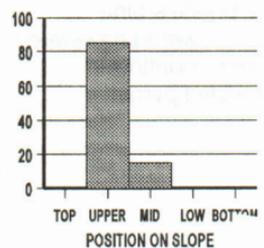

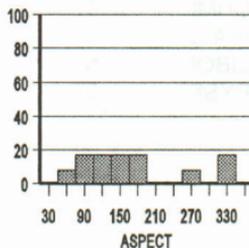

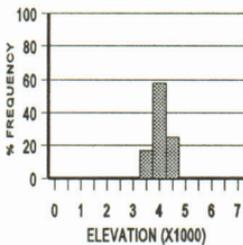

ABCO-LIDE3/CHUM (N=17; FS=7)

Distribution. This Association occurs on the Galice, Gold Beach, and Illinois Valley Ranger Districts, Siskiyou National Forest.

Distinguishing Characteristics. This Association occurs at moderate elevations on moderately steep, wet, warm sites. It is exceeded only by White Fir/Huckleberry Oak and White Fir-Brewer Spruce/Common Prince's-pine-Whitevein Pyrola in annual rainfall.

Soils. Parent material is variable, including granite and diorite, andesite and basalt, with some siltstone and sandstone. Average surface rock cover is 9 percent, with 21 percent gravel, and 3 percent bare ground exposure. Soils are shallow to moderately deep, with an average depth of greater than 36 inches. Based on three plots, surface texture is sandy loam, with 30 to 65 percent gravel, 10 to 15 percent cobbles, and 10 to 17 percent clay. Subsurface texture is sandy loam and loam, with

30 to 75 percent gravel, 0 to 30 percent cobbles, and 12 to 17 percent clay.

Environment. This **Association** averages 4170 feet in elevation and occurs predominantly on south and east aspects. Slope averages 42 percent and ranges from 20 to 62 percent. This **Association** frequently occurs on upper third slope positions.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 24. White fir and Douglas-fir are frequent in the overstory and understory. Sugar pine is common in the overstory. Tanoak is frequent in the understory, and canyon live oak and incense-cedar are common. Other hardwoods may include vine maple, Douglas maple, big-leaf maple, red alder, Pacific madrone, golden chinquapin, and Pacific dogwood. In the shrub layer, dwarf Oregongrape and baldhip rose are frequent, and Pacific blackberry and creeping snowberry are common. Little prince's-pine, common prince's-pine, vanillaleaf, rattlesnake-plantain, and whitevein pyrola are frequent in the herb/grass layer; and Scouler's harebell, whipplevine, and Oregon fairybell are common. Moss cover is intermediate for the Series, averaging 12 percent.

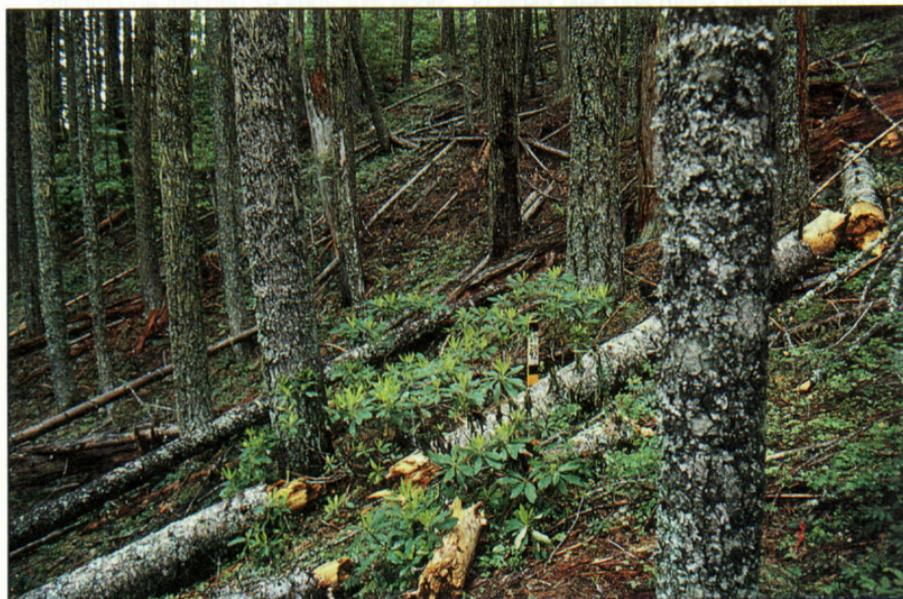

Upper and mid layer tree covers are intermediate to low for the Series, averaging 68 and 33 percent cover, respectively. Lower layer tree cover also averages 33 percent cover. Shrub cover is very low, with high shrub cover averaging only 3 percent and low shrub cover 13 percent. Herb/grass cover ranges from 2 to 76 percent, but averages only 15 percent.

WHITE FIR/PACIFIC RHODODENDRON-DWARF OREGONGRAPE

Abies concolor/Rhododendron macrophyllum-Berberis nervosa

ABCO/RHMA3-BENE2 (N=31; FS=31)

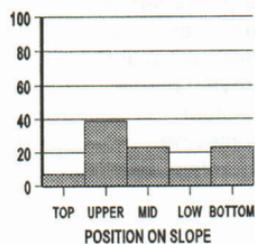

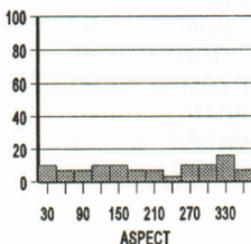

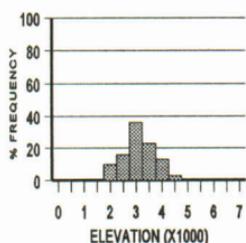

Distribution. This Association occurs on all Ranger Districts of the Umpqua National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association occurs at moderate elevations on very warm, moderately wet sites. This Association has dense shrub cover. It is environmentally similar to White Fir/Vine Maple/Oregon Oxalis.

Soils. Parent material is mostly andesite, basalt, diorite, or granite, with some welded tuff and pumice. Average surface rock cover is 9 percent, with 13 percent gravel. Soils are mostly moderately deep to deep, with an average depth of greater than 43 inches.

Environment. Elevation averages 3350 feet. This Association occurs on all aspects. Slope averages 34 percent and ranges from 9 to 69 percent. This Association

occurs on all slope positions, although ridge tops are less common

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 36. Douglas-fir is frequent in the overstory, and white fir and sugar pine are common. White fir, Douglas-fir, western hemlock, and Pacific yew are frequent, and incense-cedar and golden chinquapin are common in the understory. Other hardwoods may include vine maple, Douglas maple, big-leaf maple, red alder, Pacific madrone, canyon live oak, and Pacific dogwood. In the shrub layer, dwarf Oregongrape, Pacific rhododendron, baldhip rose and Pacific blackberry are frequent. Vine maple, salal, creambush ocean-spray, creeping snowberry, and red huckleberry are common. Salal may be dense in some areas. Vanillaleaf, common prince's-pine, rattlesnake-plantain, western sword-fern, round-leaved violet, western twinflower and whipplevine are frequent herbs. Moss cover is highest for the Series, averaging 19 percent.

Upper and mid layer tree covers are high and intermediate for the Series, averaging 71 and 48 percent cover, respectively. Lower layer tree cover averages 33 percent. Shrub cover is intermediate to high, with high shrub cover averaging 27 percent and low shrub cover 55 percent. Herb/grass cover ranges from 5 to 85 percent, and averages 28 percent

WHITE FIR/PACIFIC RHODODENDRON-SADLER OAK

Abies concolor/Rhododendron macrophyllum-Quercus sadleriana

ABCO/RHMA3-QUSA2 (N=13; BLM=13)

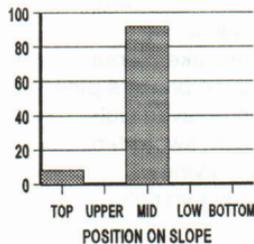

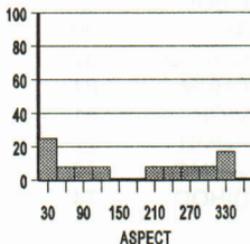

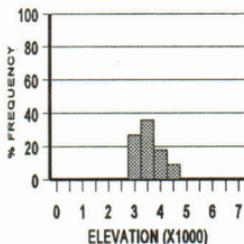

Distribution. This Association occurs on the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association occurs on warm, moist sites with gentle slopes. It is similar to White Fir/Pacific Rhododendron-Dwarf Oregongrape, with the inclusion of Sadler oak.

Soils. This Association may occur on many types of parent material including mixed sediments and intrusives, intrusive volcanics, gabbro, granodiorite, and metasediments. Soils are generally moderately deep to deep. Textures are sandy loams. Total coarse fragments average 43 percent.

Environment. This Association averages 3790 feet in elevation and occurs on all

aspects Slope averages 36 percent and ranges from 12 to 62 percent. This **Association** occurs predominantly on middle slope positions

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 19. Douglas-fir and sugar pine are frequent in the overstory. White fir is frequent in the understory, and golden chinquapin, sugar pine, Douglas-fir, and western hemlock are common. Golden chinquapin may be dense in some areas. Other hardwoods may include vine maple, Pacific madrone, and canyon live oak. In the shrub layer, Sadler oak, dwarf Oregongrape, Pacific rhododendron, and red huckleberry are frequent. Salal may be dense in some areas. Common prince's-pine and western twinflower are frequent, while other herb/grass species are transient. Moss cover is lowest of the Series, averaging less than 1 percent.

Cover of trees exceeding 10 feet tall (3 meters) is very high, averaging 78 percent. Cover of trees less than 10 feet tall is low, averaging 20 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 60 percent, the highest for the Series, and cover of shrubs less than 20 inches tall averages 39 percent. Herb/grass cover ranges from 1 to 30 percent, and averages 20 percent

WHITE FIR/SALAL-DWARF OREGONGRAPE
Abies concolor/Gaultheria shallon-Berberis nervosa
ABCO/GASH-BENE2 (N=41; BLM=31, FS=10)

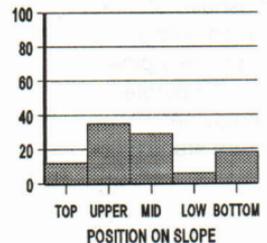

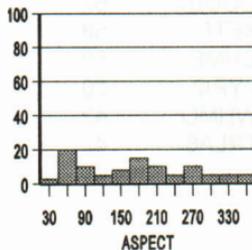

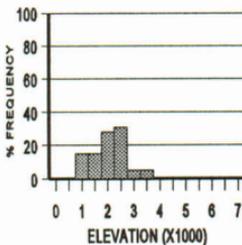

Distribution. This Association occurs on the Tiller and North Umpqua Ranger Districts, Umpqua National Forest, the Swiftwater and South River Resource Areas, Roseburg District, Bureau of Land Management, and may occur on adjacent lands.

Distinguishing Characteristics. This Association occurs at low elevations with high amounts of precipitation. It occurs on the warmest sites of the Series.

Soils. Parent material is variable, including granite, gabbro, dacite, andesite, and basalt, welded tuff, ash, and sandstone. Average surface rock cover is 8 percent, with 8 percent gravel. Soils are shallow to deep, with an average depth of greater than 35 inches. Based on one plot sampled, surface and subsurface texture is sand, with 20 to 40 percent gravel, and 2 to 7 percent clay.

Environment. The elevation of this Association averages 2300 feet and the

Association occurs on all aspects. Slope averages 33 percent and ranges from 3 to 65 percent. This **Association** occurs predominantly on upper and middle slope positions.

Vegetation Composition and Structure Total species richness is high for the Series, averaging 41. Douglas-fir is frequent in the overstory and understory. White fir and incense-cedar are frequent in the overstory and present in the understory. In the understory, golden chinquapin and Pacific madrone are frequent, and sugar pine is common. Other hardwoods may include vine maple, big-leaf maple, red alder, Pacific dogwood, tanoak, canyon live oak, and California black oak. In the shrub layer, dwarf Oregongrape, creeping snowberry, salal, hairy honeysuckle, baldhip rose, and Pacific blackberry are frequent. Piper's Oregongrape is common. Fairy-slipper, Oregon fairybell, catchweed bedstraw, rattlesnake-plantain, white-flowered hawkweed, western twinflower, whipplevine, white inside-out-flower, trail-plant, western starflower, and round-leaved violet are frequent. Moss cover is high for the Series, averaging 17 percent.

Upper and mid layer tree covers are high to intermediate for the Series, averaging 77 and 48 percent cover, respectively. Lower layer tree cover averages 25 percent cover. Shrub cover is low to high, with high shrub cover averaging only 8 percent and low shrub cover 53 percent. Herb/grass cover is between 1 and 50 percent, and averages 22 percent.

ABCO 34

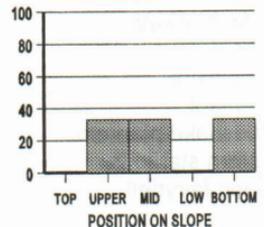

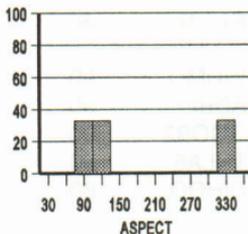

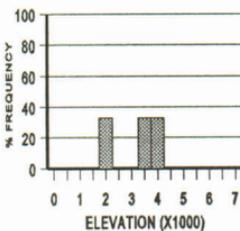

WHITE FIR/VINE MAPLE/OREGON OXALIS
Abies concolor/Acer circinatum/Oxalis oregana
ABCO/ACCI/OXOR (N=3; FS=3)

Distribution. This Association occurs on the North Umpqua Ranger District, Umpqua National Forest and may occur on the Swiftwater Resource Area of the Roseburg District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs at intermediate elevations, on warm sites with moderate amounts of precipitation. Western hemlock regeneration is nearly equal to that of white fir. Western sword-fern may be abundant. This is a transition plant association between the White Fir and Western Hemlock Series.

Soils. Parent material can be rhyolite and basalt. Average surface rock cover is 3 percent, with 12 percent gravel. The average depth on three plots is greater than 43 inches.

Environment. This **Association** averages 3250 feet in elevation and occurs on aspects that are predominantly east and north. Slope averages 32 percent and ranges from 1 to 75 percent. This **Association** occurs on upper, middle third, and valley bottom slope positions.

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 37. Douglas-fir and white fir are frequent in the overstory. Western hemlock is common. White fir, Pacific yew, and western hemlock are frequent in the understory. Big-leaf maple and Douglas-fir are common. Other hardwoods include vine maple, Pacific dogwood and red alder. In the shrub layer, dwarf Oregongrape, baldhip rose, vine maple, and Pacific blackberry are frequent. Snow bramble and red huckleberry are common. Trail-plant, Oregon fairybell, Oregon oxalis, and starry false Solomon's-seal are frequent herbs. Moss cover is high for the Series, averaging 18 percent.

Upper and mid layer tree covers are high to very high for the Series, averaging 73 and 63 percent, respectively. Lower layer tree cover averages 68 percent. Shrub cover is very low to low, with high shrub cover averaging only 2 percent and low shrub cover 23 percent. Herb/grass cover ranges between 90 and 95 percent, and averages 92 percent, the highest for the Series.

WHITE FIR-WESTERN HEMLOCK/DWARF OREGONGRAPE/WESTERN TWINFLOWER
Abies concolor-Tsuga heterophylla/Berberis nervosa/Linnaea borealis longiflora
ABCO-TSHE/BENE2/LIBOL (N=38; FS=38)

Distribution. This Association occurs on all Ranger Districts of the Umpqua National Forest, the Applegate, Prospect, and Butte Falls Ranger Districts, Rogue River National Forest, and the Galice Ranger District, Siskiyou National Forest. It may also occur on the Butte Falls Resource Area of the Medford District, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs on moist sites, often in the transition between the Western Hemlock and White Fir Series.

Soils. Parent material is variable, including andesite, basalt, diorite, pumice, sandstone, and welded tuff. Average surface rock cover is 10 percent, with 13 percent gravel, and 3 percent surface bedrock. Soils can be shallow to deep, with an average depth of greater than 37 inches. Based on four plots sampled, surface texture is loam and sandy loam, with 0 to 65 percent gravel, 0 to 5 percent cobbles, and 10 to 26 percent clay. Subsurface texture is clay loam, sandy loam, and loamy

sand, with 5 to 65 percent gravel, 0 to 30 percent cobbles, and 3 to 32 percent clay

Environment This **Association** occurs at an average elevation of 3610 feet and may occur on any aspect Slope averages 35 percent and ranges from 0 to 77 percent This **Association** is commonly on upper to middle third slope positions

Vegetation Composition and Structure Total species richness is high for the Series, averaging 39. Douglas-fir is frequent in the overstory, and white fir is common. White fir, Douglas-fir, golden chinquapin, incense-cedar, western hemlock, and Pacific yew are frequent in the understory. Vine maple may be dense in some areas Other hardwoods may include Douglas maple, big-leaf maple, Pacific madrone, Pacific dogwood, and canyon live oak. WHITE FIR/DWARF OREGONGRAPE/VANILLALEAF

Abies concolor/Berberis nervosa/Achlys triphylla

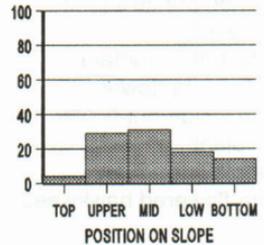

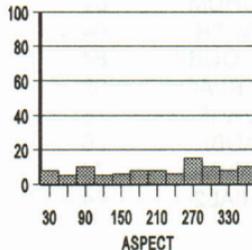

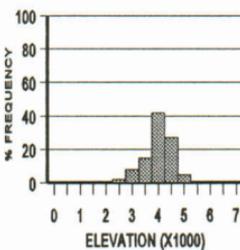

ABCO/BENE2/ACTR (N=67; FS=49, BLM=18)

Distribution. This Association occurs on the Tiller, Diamond Lake, and North Umpqua Ranger Districts, Umpqua National Forest, the Applegate and Prospect Ranger Districts, Rogue River National Forest, and the Illinois Valley Ranger District, Siskiyou National Forest. It also occurs on the Swiftwater and South River Resource Areas, Bureau of Land Management.

Distinguishing Characteristics. This Association occurs at intermediate elevations on sites with moderate amounts of precipitation. This Association receives more precipitation than the White Fir/Dwarf Oregongrape Association, which is reflected by the presence of vanillaleaf.

Soils. Parent material can be variable, from mixed metavolcanics and diorite, to andesite, basalt, schist, and gabbro. The average surface rock cover is 8 percent, with 11 percent surface gravel. Based on nine plots sampled, soils are moderately

deep to deep (average depth of greater than 40 inches), and well drained to very well drained. Surface textures are loams, with 37 percent gravel, 14 percent cobbles and stones, and 14 percent clay. Subsurface textures are mostly loams and sandy loams, with two occurrences of clay and clay loam. Subsurface horizons have 32 percent gravel, 23 percent cobbles, and 18 percent clay.

Environment. This **Association** averages 4310 feet in elevation and occurs on all aspects. Slope averages 35 percent and ranges from 0 to 65 percent. This **Association** occurs on all slope positions.

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 40. Douglas-fir and white fir are frequent in the overstory and understory. Incense-cedar and golden chinquapin are common in the understory. Other hardwoods may include vine maple, Douglas maple, big-leaf maple, red alder, Pacific madrone, Pacific dogwood, tanoak, and canyon live oak. In the shrub layer, dwarf Oregongrape, baldhip rose, Pacific blackberry, and creeping snowberry are frequent. California hazel and creambush ocean-spray are common. In the herb/grass layer vanillaleaf, trail-plant, threeleaf anemone, common prince's-pine, Oregon fairybell, rattlesnake-plantain, western starflower, and white inside-out-flower are frequent. Moss cover is low for the Series, averaging 6 percent.

Upper and mid layer tree covers are high and low for the Series, averaging 73 and 38 percent cover, respectively. Lower layer tree cover averages 23 percent. Shrub cover is very low to low, with high shrub cover averaging only 7 percent and low shrub cover 25 percent. Herb/grass cover is between 25 and 95 percent, and averages 55 percent

ABCO 40

WHITE FIR/DWARF OREGONGRAPE/WESTERN TWINFLOWER

Abies concolor/Berberis nervosa/Linnaea borealis longiflora

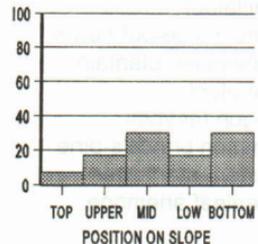

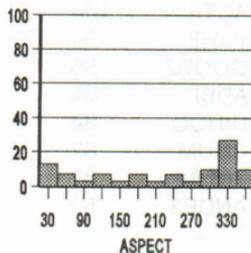

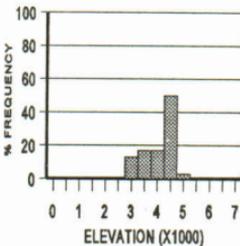

ABCO/BENE2/LIBOL (N=30; FS=30)

Distribution. This Association occurs on the North Umpqua Ranger District, Umpqua National Forest, and on all Ranger Districts, Rogue River National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association occurs at intermediate elevations. It is drier than the White Fir/Dwarf Oregongrape and White Fir/Dwarf Oregongrape/Vanillaleaf Associations.

Soils. Parent material varies from andesite, basalt, and pumice, to granite and schist. The average surface rock cover is 9 percent, with 8 percent surface gravel. Based on four plots sampled, soils are moderately deep to deep (average depth of greater than 45 inches) and well drained. Surface textures include sand, sandy loam, and sandy clay loam, with 10 to 35 percent gravel, 5 percent cobbles, and 17 percent clay. Subsurface textures include loamy sand, sand, and sandy clay loam,

with 20 to 30 percent gravel, 3 to 20 percent cobbles and stones, and 22 percent clay

Environment This **Association** averages 4300 feet in elevation and occurs on all aspects, with northwest being the most common aspect. Slope averages 21 percent and ranges from 1 to 65 percent. This **Association** commonly occurs on middle third and valley bottom slope positions.

Vegetation Composition and Structure Total species richness is high for the Series, averaging 39. Douglas-fir and white fir are frequent in the overstory present. In the understory, white fir, golden chinquapin, Douglas-fir, and Pacific yew are frequent. Other hardwoods may include vine maple, Douglas maple, big-leaf maple, Pacific madrone, Pacific dogwood, and California black oak. In the shrub layer, dwarf Oregongrape, Oregon boxwood, baldhip rose, and creeping snowberry are frequent. Western twinflower is frequent in the herb/grass layer. Trail-plant, threeleaf anemone, common prince's-pine, queen's cup, rattlesnake-plantain, white-flowered hawkweed, mountain sweet-root, western false Solomon's-seal, snow-queen, western starflower, and white trillium are also frequent. Moss cover is intermediate for the Series, averaging 13 percent.

Upper and mid layer tree covers are intermediate and low for the Series, averaging 69 and 36 percent cover, respectively. Lower layer tree cover averages 24 percent. Shrub cover is low to intermediate, with high shrub cover averaging 8 percent and low shrub cover 40 percent. Herb/grass cover ranges from 10 to 90 percent, and averages 56 percent.

WHITE FIR-DOUGLAS-FIR/BALDHIP ROSE

Abies concolor-Pseudotsuga menziesii/Rosa gymnocarpa

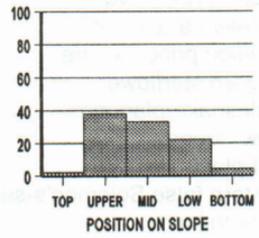

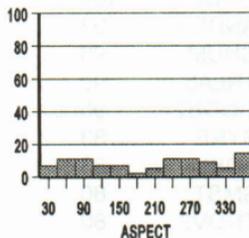

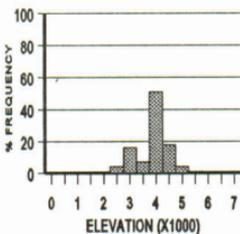

ABCO-PSME/ROGY (N=45; FS=45)

Distribution. This **Association** occurs on the North Umpqua Ranger District, Umpqua National Forest, the Applegate, Ashland, and Prospect Ranger Districts, Rogue River National Forest, and the Illinois Valley Ranger District, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This **Association** occurs at moderate elevations on dry sites. It has significant levels of Douglas-fir regeneration and is a transitional **plant association** between the White Fir and Douglas-fir Series. The White Fir/Dwarf Oregongrape/Western Twinflower **Association** occurs on equally dry sites, however, the White Fir-Douglas-fir/Baldhip Rose **Association** occurs on warmer sites. These two **associations** are the driest of the Series.

Soils. Parent material is mostly schist with some basalt, andesite, and granodiorite. Average surface rock cover is 23 percent, with 18 percent gravel, and 6 percent

exposed bedrock. Based on seven plots sampled, soils are moderately deep to deep (average depth 39 inches), and well drained. The surface textures are loam, sandy loam, and loamy sand, with 10 to 50 percent gravel and cobbles, and 10 percent clay. Subsurface textures are sandy loam and loam, with some clay loam and sand. Subsurface horizons have an average of 20 to 40 percent gravel, 10 to 70 percent cobbles, and 16 percent clay.

Environment. This **Association** averages 4090 feet in elevation and occurs on all aspects. Slope averages 52 percent and ranges from 0 to 84 percent. This **Association** commonly occurs on upper, middle, and lower third slope positions.

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 37. Douglas-fir is frequent in the overstory, and white fir, sugar pine, and ponderosa pine are common. White fir, Douglas-fir and Pacific madrone are frequent in the understory. Golden chinquapin, incense-cedar, and canyon live oak are common. Other hardwoods may include vine maple, Douglas maple, big-leaf maple, red alder, Pacific dogwood, tanoak, and California black oak. In the shrub layer, dwarf Oregongrape, creambush ocean-spray, baldhip rose, and creeping snowberry are frequent. Western serviceberry, Piper's Oregongrape, and Pacific blackberry are common. Rattlesnake-plantain and western starflower are frequent herbs. Trail-plant, common prince's-pine, Oregon fairybell, woods strawberry, white-flowered hawkweed, western false Solomon's-seal, snow-queen, whipplevine, and white trillium are common herbs. Moss cover is intermediate for the Series, averaging 10 percent.

Upper and mid layer tree covers are intermediate for the Series, averaging 64 and 45 percent cover, respectively. Lower layer tree cover averages 23 percent. Shrub cover is low, with high shrub cover averaging 12 percent and low shrub cover 29 percent. Herb/grass cover ranges between 0 and 70 percent, and averages 26 percent.

WHITE FIR-INCENSE-CEDAR/WESTERN STARFLOWER
Abies concolor-Calocedrus decurrens/Trientalis latifolia
ABCO-CADE27/TRLA6 (N=31; FS=31)

Distribution. This Association occurs on the North Umpqua, Diamond Lake, and Tiller Ranger Districts, Umpqua National Forest, all Ranger Districts of the Rogue River National Forest, and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also be present on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association occurs at intermediate elevations on sites that receive moderate amounts of precipitation.

Soils. Parent material is variable, including andesite, basalt, granodiorite, diorite, and gabbro, with some schist, rhyolite, and breccia, and, rarely serpentine. Average surface rock cover is 12 percent, with 13 percent gravel, 6 percent bare ground exposure, and 3 percent surface bedrock. Based on three plots sampled, surface texture is sandy loam and loam, with 20 to 39 percent gravel, 0 to 10 percent

cobbles, and 10 to 18 percent clay. Subsurface texture is sandy loam, sandy clay, loam and clay loam, with 10 to 42 percent gravel, 0 to 20 percent cobbles, and 18 to 35 percent clay.

Environment This Association averages 4230 feet in elevation and occurs on predominantly north, east, and west aspects. Slope averages 35 percent and ranges from 3 to 60 percent. This Association occurs on all slope positions

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 35. Douglas-fir, white fir, and incense-cedar are frequent in the overstory, and sugar pine common. White fir, incense-cedar, and Douglas-fir are frequent in the understory. Hardwoods may include vine maple, Douglas maple, big-leaf maple, Pacific madrone, golden chinquapin, Pacific dogwood, canyon live oak, Oregon white oak, and California black oak. In the shrub layer, dwarf Oregongrape, baldhip rose, and creeping snowberry are frequent, and California hazel, creambush ocean-spray, and Pacific blackberry are common. Western starflower is frequent in the herb/grass layer, and vanillaleaf, trail-plant, threeleaf anemone, bigleaf sandwort, Scouler's harebell, common prince's-pine, woods strawberry, catchweed bedstraw, rattlesnake-plantain, white-flowered hawkweed, whipplevine, braken, and starry false Solomon's-seal are common. Moss cover is low for the Series, averaging 5 percent

Upper and mid layer tree covers are high and intermediate for the Series, averaging 72 and 46 percent cover, respectively. Lower layer tree cover averages 18 percent. Shrub cover is low, with high shrub cover averaging only 10 percent and low shrub cover 24 percent. Herb/grass cover ranges from 3 to 75 percent, and averages 32 percent

ABCO 46

WHITE FIR/DWARF OREGONGRAPE

Abies concolor/Berberis nervosa

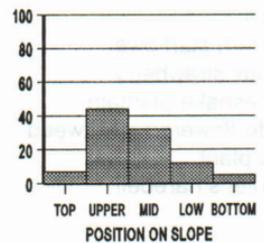

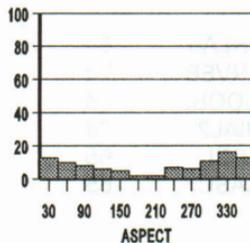

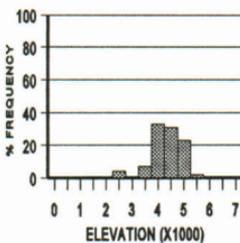

ABCO/BENE2 (N=84; FS=84)

Distribution. This **Association** occurs on the Cottage Grove, North Umpqua, and Tiller Ranger Districts, Umpqua National Forest, all Ranger Districts of the Rogue River National Forest, and the Galice, Gold Beach, and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This **Association** occurs over a wide range of elevations. It is found on drier sites with moderate temperatures. The presence of dwarf Oregongrape suggests higher productivity.

Soils. Parent material is highly variable. This **Association** occurs over granitics, quartz diorite, andesite, basalt, sandstone, and schist. Surface rock cover averages 12 percent, with 11 percent gravel. Soils are moderately deep to deep, with an average depth of greater than 40 inches. Based on 25 plots sampled, surface

texture is mostly loamy sand or sandy loam, with some loam and sandy clay loam. Surface horizons have 15 to 40 percent gravel and cobbles, and 13 percent clay. Subsurface horizons have 20 to 60 percent gravel and cobbles, and 14 percent clay. Soil temperature regime can be either mesic or frigid, and the soil moisture regime is probably xeric.

Environment. This **Association** averages 4570 feet in elevation and occurs on all aspects, although slightly more frequently on north aspects. Slope averages 40 percent and ranges from 7 to 75 percent. This **Association** is common on upper and middle third slope positions.

Vegetation Composition and Structure. Species richness is intermediate for the Series, averaging 35. White fir and Douglas-fir are almost always present in the overstory. White fir and Douglas-fir are present in the understory. Vine maple may be dense in some areas. Other hardwoods may include Douglas maple, big-leaf maple, red alder, Pacific madrone, golden chinquapin, Pacific dogwood, tanoak, canyon live oak, and California black oak. In the shrub layer, dwarf Oregongrape, baldhip rose, and creeping snowberry are frequent, and creambush ocean-spray and Pacific blackberry are common. Threelobed anemone, rattlesnake-plantain, and western starflower are frequently encountered in the herb/grass layer; common prince's-pine and little prince's-pine are common. Moss cover is low for the Series, averaging 6 percent.

Upper and mid layer tree covers are high and low for the Series, averaging 72 and 37 percent cover, respectively. Lower layer tree cover averages 18 percent. Shrub cover is low, with high shrub cover averaging 10 percent and low shrub cover 24 percent. Herb/grass cover ranges from 2 to 85 percent, and averages 30 percent.

WHITE FIR/CREeping SNOWBERRY

Abies concolor/Symphoricarpus mollis

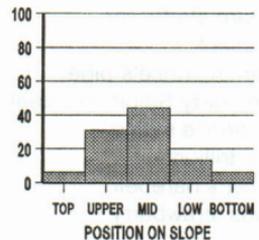

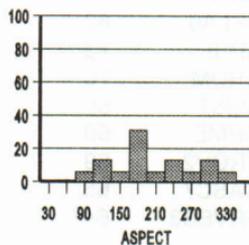

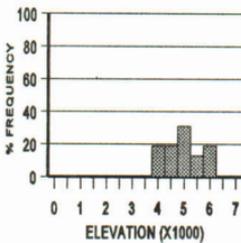

ABCO/SYMO (N=16; FS=16)

Distribution. This Association occurs on the Diamond Lake Ranger District, Umpqua National Forest, the Applegate and Ashland Ranger Districts, Rogue River National Forest, and the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. This Association occurs on high elevation sites. It is exceeded only by White Fir-Shasta Red Fir/Common Prince's-pine-Threeleaf Anemone in cold, dry conditions. Shasta red fir is not dominant in the stand as it is in the White Fir-Shasta Red Fir/Common Prince's-pine-Threeleaf Anemone Association.

Soils. Occurrence of this Association is most often on granodiorite, but it may also occur on gabbro or mixed metamorphosed volcanics. Soils are generally deep.

Environment This **Association** averages 5180 feet in elevation and occurs on predominately east, south, and west aspects Occurrence on north aspects is not likely Slope averages 40 percent and ranges from 18 to 65 percent This **Association** occurs commonly on upper and middle third slope positions

Vegetation Composition and Structure Total species richness is low for the Series, averaging 28 In the overstory, white fir and Douglas-fir are frequent Ponderosa pine is common in the overstory White fir, Douglas-fir, and golden chinquapin are frequent in the understory Other hardwoods may include vine maple, Douglas maple, Pacific madrone, Pacific dogwood, canyon live oak, and California black oak In the shrub layer, creeping snowberry and baldhip rose are frequent, and western serviceberry, creambush ocean-spray, and Oregon boxwood are common In the herb/grass layer, Scouler's harebell and little prince's-pine are frequent, and trail-plant, threeleaf anemone, bigleaf sandwort, common prince's-pine, woods strawberry, rattlesnake-plantain, white-flowered hawkweed, mountain sweet-root, whitevein pyrola, starry false Solomon's-seal, western starflower, and white trillium are common Moss cover is very low for the Series, averaging 2 percent

Upper and mid layer tree covers are intermediate and low for the Series, averaging 68 and 36 percent cover, respectively Lower layer tree cover averages 14 percent Shrub cover is very low, with high shrub cover averaging only 4 percent and low shrub cover 12 percent Herb/grass cover ranges from 0 to 95 percent, and averages 19 percent

LOGGEPOLE PINE SERIES

LODGEPOLE PINE SERIES

Pinus contorta

PICO

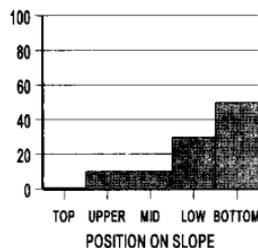

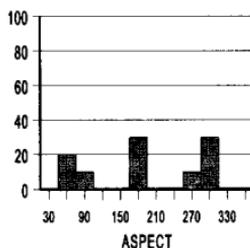

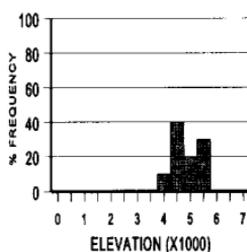

Lisa A. McCrimmon

Lodgepole pine grows throughout the western United States in a wide variety of environments. In the southern Oregon Cascades it occurs as a pioneer on young soils developed from deep pumice in cold environments. Lodgepole pine is usually succeeded by more tolerant species, such as white fir, as the increasing canopy ameliorates the frosty conditions. In areas with deep pumice soils, cold air ponding and frequent frosts, lodgepole pine remains the dominant climax tree species due to its tolerance of cold temperatures, resistance to drought, and minimal need for mineralized elements.

The Lodgepole Pine Series is found on the Mt. Mazama pumice and ash deposits in the broad, flat valley bottoms surrounding Diamond Lake and the Rogue River and its major tributaries east of Prospect. Around Diamond Lake the Series is more continuous, but along the Rogue River it is fragmented, found only in the areas of greatest cold air accumulation and deepest pumice. The Series also occurs on higher elevation flats adjacent to Crater Lake National Park and in isolated frost pockets. Without the cold air accumulation of the valley bottoms and flats, the Lodgepole Pine Series is replaced at lower elevations by the White Fir or Western Hemlock Series, and at upper elevations, by the Shasta Red Fir or Mountain Hemlock Series.

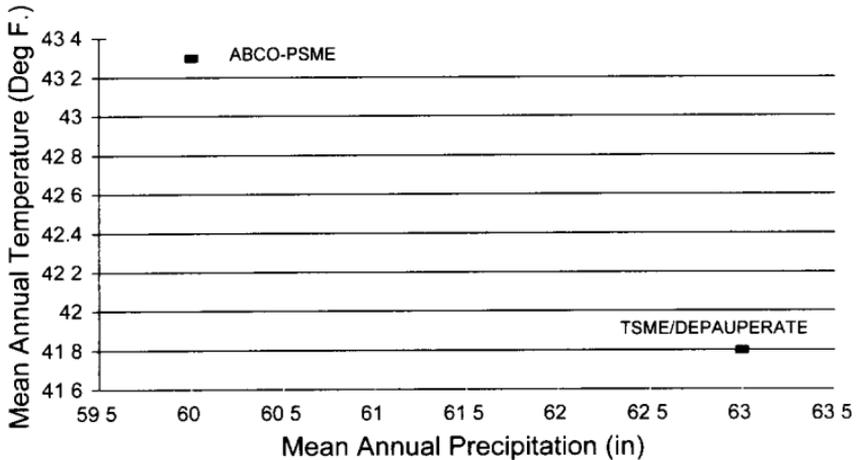

In the Siskiyou there are only a few small scattered sites where lodgepole pine continues to succeed itself. Areas with shallow soils, or standing water through most of the growing season, keep other species from regenerating. Due to the uniqueness and small acreage of each site, **plant associations** were not developed for lodgepole pine in the Siskiyou.

Elevation ranges from approximately 4400 feet to 5800 feet in the Cascades. Most aspects are represented and slopes are flat, ranging from 1 to 7 percent, though occasionally may be as steep as 15 percent. Due to the flat or gentle slopes, aspect does little to change the environmental conditions of the sites, so it is of lesser importance in this Series in differentiating between **plant associations**. Topographic position is mostly bottoms (valley bottoms and flats), but this Series can also be found higher on the slope when the slopes are gentle.

PICO 2

The Lodgepole Pine Series generally occurs in areas that are relatively cold and wet for the Cascades. Average annual temperature ranges from 41 degrees F to 44 degrees F with an average of 43 degrees F. Average annual precipitation ranges from 40 inches to 70 inches with an average of 61 inches. The relative environments of the **plant associations** are shown below. Each **association** is plotted by average annual temperature and average annual precipitation. Climate data for Lodgepole Pine/Thin-leaved Huckleberry-Grouse Huckleberry is unavailable.

Parent material is pumice and ash. Samples include two soil pits. Soils range from shallow to deep. Average surface rock cover is 2 percent with 15 percent gravel. Surface texture is sandy loam with 10 to 15 percent cobbles. Subsurface texture is also sandy loam with 15 to 90 percent cobbles. Pumice soils are generally young, shallow, infertile, and droughty. With time, organic matter accumulates, decomposes, and physical structure changes resulting in increases in soil fertility and water holding capacity, and changes in thermal properties.

Surface gravel cover ranges from 1 to 85 percent, with an average of 15 percent. Surface rock cover ranges from 0 to 5 percent, with an average of 2 percent. Exposed bedrock cover is 0 percent. Bare ground ranges from 1 to 2 percent, with an average of 1 percent. Litter cover ranges from 93 to 99 percent, with an average of 96 percent. Moss cover, however, is low, ranging from 0 to 20 percent, with an average of 4 percent. This reflects the cold, dry soil conditions typical of the Series.

Lodgepole pine is the dominant species in the overstory of the Lodgepole Pine Series. Lodgepole pine is also abundant in the understory. On warmer sites, white fir and/or western hemlock are present and on cooler sites, mountain hemlock and/or Shasta red fir are present. Grouse huckleberry and pinemat manzanita occur frequently throughout the Series with western serviceberry common.

Total species richness (the number of species of vascular **plants**) is calculated for each **Association**. The average total species richness for the Lodgepole Pine Series ranges between six and 24. Very low richness is six to nine species, low, 10 to 13.

species, intermediate, 14 to 17 species, high, 18 to 21 species, and very high, 22 to 24 species

Estimates of total cover by vegetation layer were made for wildlife interpretations. Upper layer tree cover ranges from 26 percent in Lodgepole Pine-White Fir-Douglas-fir to 45 percent in Lodgepole Pine-Mountain Hemlock/Depauperate and averages 34 percent for the Series. Mid-layer tree cover ranges from 19 to 33 percent and averages 27 percent. Lower layer tree cover averages 30 percent. High shrub cover ranges from 0 to 3 percent and averages 1 percent. Low shrub cover ranges from 0 to 26 percent and averages 15 percent. Herb/grass layer cover ranges from 1 to 20 percent and averages 12 percent.

Three final **plant associations** have been identified for the Series in southwestern Oregon. They were described from 10 plots: seven Forest Service plots and three Sky Lakes Wilderness plots. The following shows the relationship of draft and final **plant associations**. The draft **associations** are listed, with final **associations** below, each in order of most to least common, with the percentage of plots that make up each **association** (refer to Methods section).

PICO 4

LODGEPOLE PINE-WHITE FIR-DOUGLAS-FIR

Pinus contorta-Abies concolor-Pseudotsuga menziesii

PICO-ABCO-PSME (N=4; FS=4)

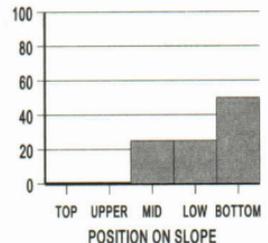

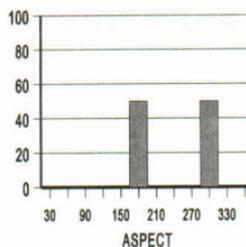

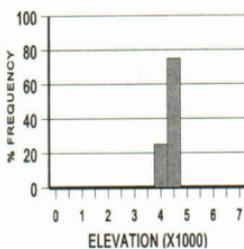

Distribution. Lodgepole Pine-White Fir-Douglas-fir occurs on the Diamond Lake Ranger District, Umpqua National Forest, and the Prospect, Ashland, and, likely, the Butte Falls Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Lodgepole Pine-White Fir-Douglas-fir is the warmest **association** of the Series. The presence of white fir and Douglas-fir in the understory and the relatively rich shrub and herb layers indicate these warmer conditions.

Soils. Parent material is pumice or andesite. Soils are shallow to deep, with an average depth of greater than 38 inches. Average surface rock cover and gravel cover is 2 percent each. Based on one plot sampled, surface texture is sandy loam with 10 percent cobbles. Subsurface texture is sandy loam with 80 to 90 percent cobbles.

Environment. Elevation averages 4610 feet. Lodgepole Pine-White Fir-Douglas-fir

likely occurs on all aspects Slope averages 4 percent and ranges from 1 to 5 percent Slope positions range from middle one-third to valley bottom

Vegetation Composition and Structure Total species richness is very high for the Series, averaging 24 species. Overstory tree layer is dominated by lodgepole pine, with occasional Shasta red fir, Douglas-fir, and western white pine Lodgepole pine dominates the understory, with white fir, Douglas-fir, and western white pine occurring frequently with low covers. Shasta red fir and mountain hemlock occur commonly with low covers Pinemat manzanita, squaw carpet, and western serviceberry occur frequently in the shrub layer, with grouse huckleberry, squaw currant, green rabbit-brush, and Oregon boxwood occurring commonly. In the herb/grass layer, common prince's-pine, bottlebrush squirreltail, white-flowered hawkweed, and fireweed occur frequently, and woods strawberry, whitevein pyrola, woodland pinedrops, and bigleaf sandwort are common. Moss cover averages 6 percent

Upper layer tree cover, low for the Series, averages 26 percent. Mid-layer tree cover is high, averaging 33 percent, and lower layer tree cover is intermediate, averaging 30 percent High and low shrub cover are both high, averaging 3 and 26 percent, respectively. Herb/grass cover is high, ranging from 1 to 40 percent, with an average of 20 percent

PICO 6

LOGEPOLE PINE/THIN-LEAVED HUCKLEBERRY-GROUSE HUCKLEBERRY

Pinus contorta/Vaccinium membranaceum-Vaccinium scoparium

PICO/VAME-VASC (N=3; Sky Lakes=3)

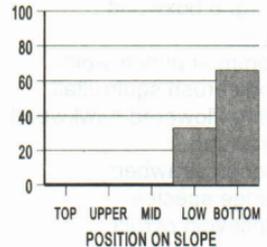

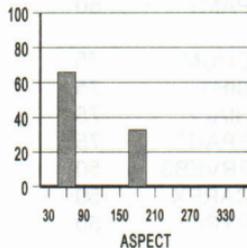

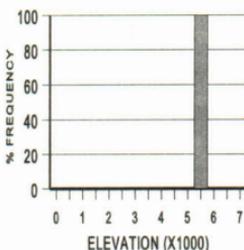

Distribution. Lodgepole Pine/Thin-leaved Huckleberry-Grouse Huckleberry occurs in the Sky Lakes Wilderness and may also occur on the Prospect and Butte Falls Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Lodgepole Pine/Thin-leaved Huckleberry-Grouse Huckleberry is present at high elevations on cold flats with cold air drainage. Similar to Lodgepole Pine-Mountain Hemlock/Depauperate, Lodgepole Pine/Thin-leaved Huckleberry-Grouse Huckleberry has lower cover and constancy of mountain hemlock, and increased shrub and herb layers with high covers of thin-leaved huckleberry and grouse huckleberry, indicating it is a relatively warmer association.

Soils. Soil data are not available.

Environment. Elevation averages 5660 feet. Lodgepole Pine/Thin-leaved Huckleberry-Grouse Huckleberry occurs on northeast and south aspects, but likely

occurs on all aspects Slope averages 8 percent and ranges from 1 to 15 percent Lower one-third and valley bottom slope positions predominate

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 15 species Overstory tree layer is dominated by lodgepole pine Understory is dominated by lodgepole pine, with mountain hemlock occurring commonly, and western white pine, Shasta red fir, and golden chinquapin occurring occasionally In the shrub layer, thin-leaved huckleberry and grouse huckleberry occur frequently with moderate to high covers Pinemat manzanita, subalpine spirea, and western serviceberry occur commonly Pinemat manzanita may have moderate covers In the herb/grass layer, sickle-keeled lupine, long-stalked clover, and spreading phlox occur commonly Moss cover averages 2 percent

Vegetation layer cover data are not available.

PICO 8

LOGEPOLE PINE-MOUNTAIN HEMLOCK/DEPAUPERATE

Pinus contorta-Tsuga mertensiana/Depauperate

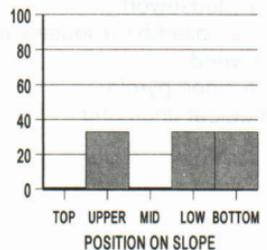

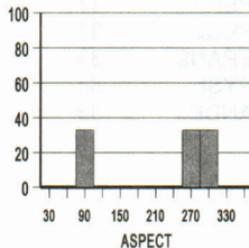

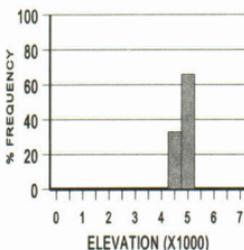

PICO-TSME/DEP (N=3; FS=3)

Distribution. Lodgepole Pine-Mountain Hemlock/Depauperate occurs on the Diamond Lake Ranger District, Umpqua National Forest, and may also occur on the Prospect or Butte Falls Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Lodgepole Pine-Mountain Hemlock/Depauperate occurs on pumice/ash flats above 4500 feet in elevation or in depressions, at lower elevations, that collect cold air. Lodgepole Pine-Mountain Hemlock/Depauperate is the coldest **association** of the Series. Lodgepole pine and mountain hemlock in the regeneration layer and the lack of, or minimal, shrub and/or herb/grass layers indicate the cold conditions of this **Association**.

Soils. Parent material is pumice. Soils are moderately deep to deep, with an average depth of greater than 32 inches. Average surface rock cover is 1 percent, with 32 percent gravel. Based on one plot sampled, surface texture is sandy loam with 15 percent cobbles. Subsurface texture is sandy loam with 15 to 25 percent

cobbles

Environment Elevation averages 5170 feet. Lodgepole Pine-Mountain Hemlock/Depauperate occurs on northeast and west aspects but it is likely to occur on any aspect. Slope averages 4 percent and ranges from 2 to 7 percent. Lower slope positions predominate

Vegetation Composition and Structure Total species richness is very low for the Series, averaging six species. Lodgepole pine dominates the overstory with occasional Shasta red fir and mountain hemlock, both with low covers. Lodgepole pine dominates the understory and mountain hemlock occurs frequently with low cover. Shasta red fir and western white pine occur occasionally. Shrub richness is very low for the Series with grouse huckleberry occurring occasionally. Herb/grass richness is also very low for the Series with long stolon sedge, velvet lupine, two-colored lupine, and slender hairgrass occurring occasionally with very low covers. Moss cover averages less than 1 percent.

Upper layer tree cover is high for the Series, averaging 45 percent. Mid-layer tree cover is low, averaging 19 percent. Lower layer tree cover is intermediate, averaging 30 percent. High shrub, low shrub, and herb covers are all low for the Series, averaging 0, less than 1, and 1 percent, respectively.

SHASTA RED FIR SERIES

SHASTA RED FIR SERIES

Abies magnifica shastensis

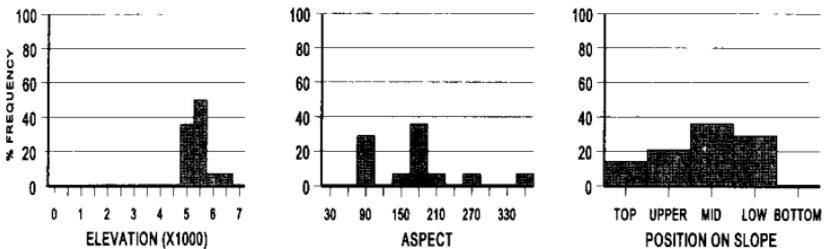

ABMAS

Lisa A McCrimmon

Shasta red fir (*Abies magnifica* A. Murr. var. *shastensis* Lemm.) is a variety of California red fir (*Abies magnifica* A. Murr.) that is found in southwest Oregon and northern California. It is interfertile with noble fir (*Abies procera* Rehd.) and California red fir. Morphological and genetic characteristics of the trio are similar, thus complicating identification in southwest Oregon. Populations north of the McKenzie River are recognizable as noble fir and south of Mt. Lassen as California red fir. Shasta red fir is generally found at high elevations where the climate is cool to cold and moist, however, it is able to tolerate summer dry spells common to the Mediterranean environment of southwest Oregon.

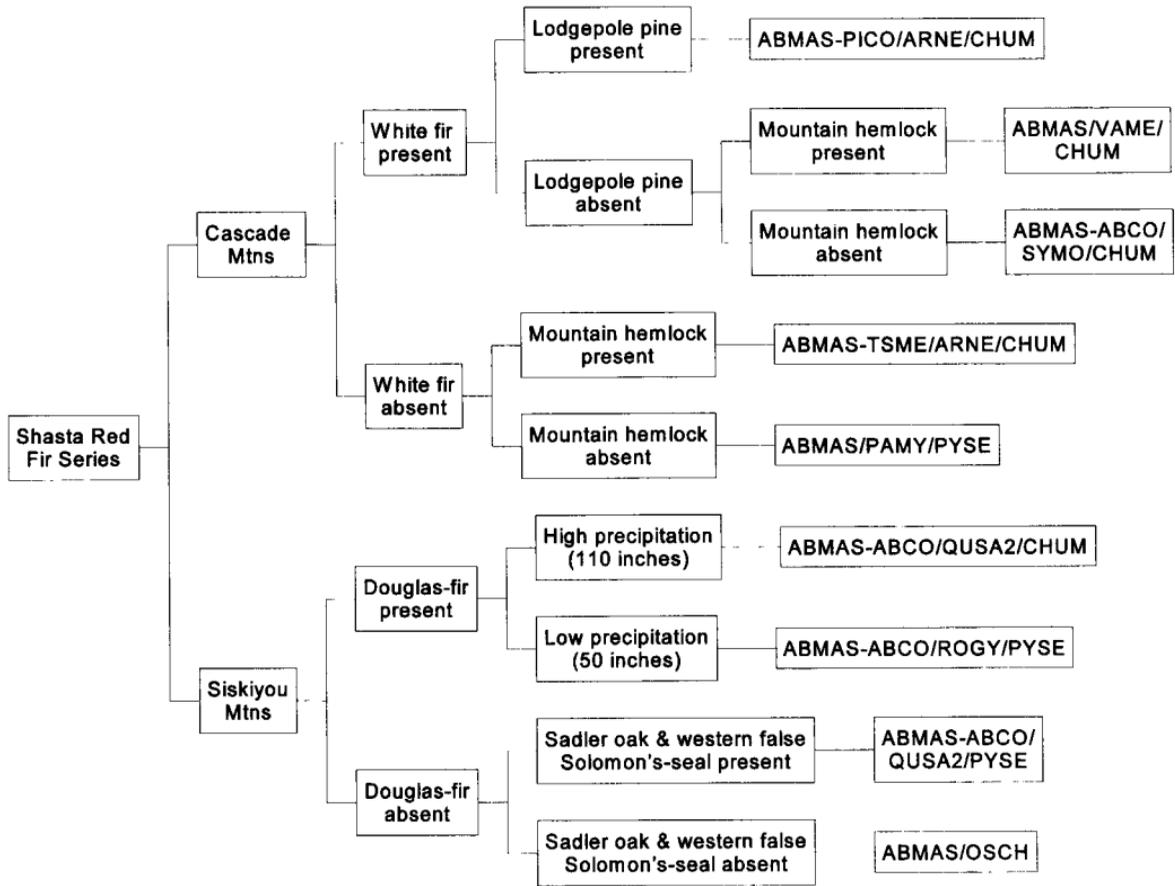

The Shasta Red Fir Series occurs in a narrow elevational band centered around 5700 feet. It is replaced by the White Fir Series at lower elevations and the Mountain Hemlock Series at higher elevations. The flowchart on page ABMAS 2 shows a graphical presentation of the classification and the relationships between **plant associations** in the Shasta Red Fir Series.

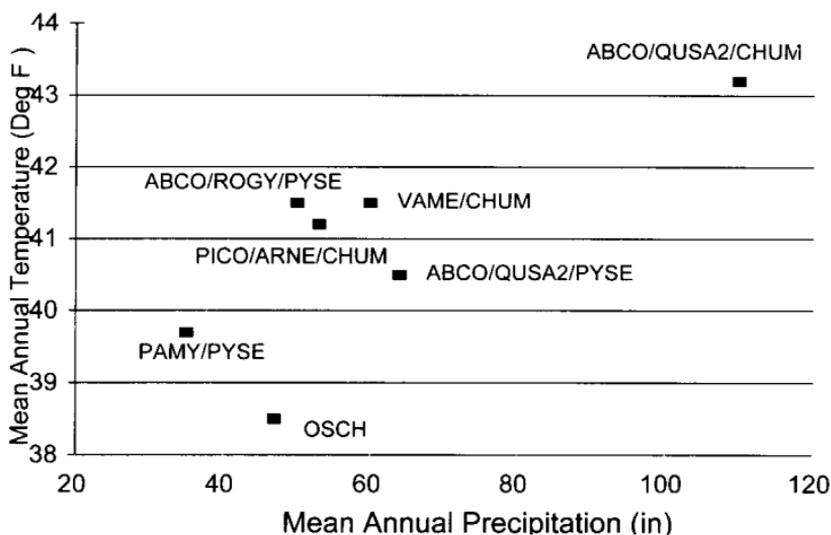

Elevation ranges from approximately 4000 feet to 6900 feet. All aspects are represented with fewer occurrences on the southwest and west. Slope can range from flat to very steep. Topographic position ranges from ridge tops to valley bottoms, but the Series is most frequently found between upper and lower one-third slope positions.

The Shasta Red Fir Series generally occurs in areas that are cool to cold and moist. Average annual temperature ranges from 37 degrees F to 44 degrees F, averaging 40 degrees F. Average annual precipitation varies between 35 inches and 120 inches and averages 60 inches. The relative environments of the **plant associations** are shown on page ABMAS 3. Each **association** is plotted by average annual temperature and average annual precipitation. Climate data is not available for Shasta Red Fir-White Fir/Creeping Snowberry/Common Prince's-pine and Shasta Red Fir-Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine.

Parent material is highly variable, but most often is composed of igneous materials. Soils range from shallow to deep. Surface rock cover ranges from 5 to 38 percent,

with an average of 15 percent. Surface gravel cover ranges from 3 to 18 percent, with an average of 8 percent. Exposed bedrock cover ranges from 0 to 2 percent, with an average of 1 percent. Bare ground ranges from 1 to 5 percent, with an average of 2 percent. Litter cover ranges from 50 to 99 percent, with an average of 84 percent. Moss cover ranges from 1 to 10 percent, with an average of 2 percent.

Shasta red fir is generally the dominant tree in the overstory of the Shasta Red Fir Series and is abundant in the understory. On warmer sites, white fir is present, and on cooler sites, mountain hemlock is present.

Total species richness (the number of species of vascular plants) is calculated for each association. The average total species richness for the Shasta Red Fir Series ranges from 15 to 34. Richness is rated as very low, 15 to 18 species; low, 19 to 22 species; intermediate, 23 to 26 species; high, 27 to 30 species; and very high, 31 to 34 species.

Estimates of total cover by vegetation layer were made for wildlife interpretations. Upper-layer tree cover ranges from 39 percent in Shasta Red Fir-Lodgepole Pine/Pinemat Manzanita/Common Prince's-pine to 72 percent in Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine and averages 58 percent for the Series. Mid-layer tree cover ranges from 25 to 47 percent and averages 34 percent. Lower layer tree cover ranges from 15 to 67 percent and averages 23 percent. High shrub cover ranges from 0 to 19 percent and averages 4 percent. Low shrub cover ranges from 6 to 48 percent and averages 18 percent. Herb/grass layer cover ranges from 6 to 45 percent and averages 30 percent.

Nine final plant associations have been identified for the Series in southwestern Oregon. They were described from 97 plots: 50 Forest Service plots, 33 Sky Lakes Wilderness plots, 8 Bureau of Land Management plots, and 6 Curry County Natural

ABMAS 4

Resources Conservation Service plots. The following shows the relationship of draft and final **plant associations**. The draft **associations** are listed, with final **associations** below, each in order of most to least common, with the percentage of plots that make up each **association** (refer to Methods section).

ABMAS 8

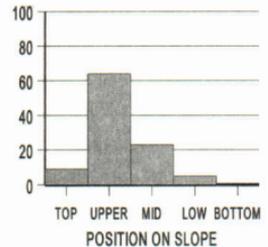

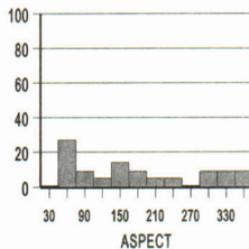

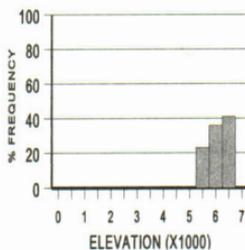

SHASTA RED FIR/MOUNTAIN SWEET-ROOT
Abies magnifica shastensis/Osmorhiza chilensis
ABMAS/OSCH (N=22; FS=22)

Distribution. Shasta Red Fir/Mountain Sweet-root occurs in the Siskiyou Mountains on the Ashland and Applegate Ranger Districts, Rogue River National Forest. It may also occur on the Illinois Valley Ranger District, Siskiyou National Forest, and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Shasta Red Fir/Mountain Sweet-root is found at cool temperatures and low precipitation relative to other associations in the Series. Shasta red fir dominates both the overstory and understory, with white fir the only other commonly occurring tree species. The shrub layer is sparse, but the herb layer is rich with a wide variety of species, few having a constancy greater than 75 percent.

Soils. Parent material is mostly one of a variety of igneous materials - granite, granodiorite, diorite, or gabbro, with some slate or schist. Soils are mostly

moderately deep to deep, with an average depth of 39 inches. Average surface rock cover is 6 percent, with 10 percent gravel and 5 percent bare ground exposure. Based on six plots sampled, surface texture is sandy loam or loamy sand, with 15 to 40 percent gravel or cobbles. Subsurface texture is loamy sand, sand, or sandy loam, with 25 to 50 percent gravel and cobbles.

Environment Elevation averages 6360 feet. Shasta Red Fir/Mountain Sweet-root occurs on all aspects. Slope averages 30 percent and ranges from 1 to 45 percent. Upper and middle one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 26 species. Overstory and understory are dominated by Shasta red fir, with white fir occurring occasionally in the overstory and commonly in the understory. The shrub layer is sparse, with creeping snowberry and mountain balm occurring commonly, and Siskiyou gooseberry, sticky currant, and greenleaf manzanita occurring occasionally, all at low covers. Herb/grass richness is very high for the Series, however, few species occur with regularity. White-flowered hawkweed and mountain sweet-root occur frequently, with bigleaf sandwort, whitevein pyrola, one-sided pyrola, stream violet, Sitka valerian, and starry false Solomon's-seal occurring commonly, all at low covers. Moss cover averages 1 percent.

Upper layer tree cover is high for the Series, averaging 64 percent. Mid-layer and lower layer tree covers are low, averaging 28 and 18 percent, respectively. High shrub cover is low, averaging 1 percent, as is low shrub cover, averaging 6 percent. Herb/grass cover is high for the Series, ranging from 1 to 90 percent, with an average of 38 percent.

ABMAS 10

SHASTA RED FIR-WHITE FIR/BALDHIP ROSE/ONE-SIDED PYROLA
Abies magnifica shastensis-Abies concolor/Rosa gymnocarpa/Pyrola secunda
 ABMAS-ABCO/ROGY/PYSE (N=9; FS=6, BLM=3)

Distribution. Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola occurs in the Siskiyou Mountains on the Ashland Ranger District, Rogue River National Forest, the Illinois Valley Ranger District, Siskiyou National Forest, and the Grants Pass Resource Area, Medford District, Bureau of Land Management. It may also occur on the Applegate Ranger District, Rogue River National Forest.

Distinguishing Characteristics. Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola is very similar to Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine. Both have Douglas-fir present in the overstory and/or understory. Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola is found in areas with an average annual precipitation of 50 inches and has a greater constancy and cover of one-sided pyrola. Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine is found in areas with an average annual precipitation of 110 inches and has a greater constancy and cover of Sadler oak.

Soils. Parent material is mostly granodiorite, quartz diorite, or diorite. Soils are shallow to moderately deep, with an average depth of greater than 27 inches. Average surface rock cover is 8 percent, with 4 percent gravel.

Environment. Elevation averages 5150 feet. Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola occurs mostly on west, north, and east aspects and rarely on south aspects. Slope averages 32 percent and ranges from 8 to 53 percent. Slope positions range from ridge tops to valley bottoms.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 32 species. Overstory and understory tree layers are dominated by Shasta red fir, with Douglas-fir and white fir frequently occurring. In the understory, golden chinquapin, western white pine, and Pacific yew occur occasionally. In the shrub layer, baldhip rose occurs frequently, and thin-leaved huckleberry and dwarf Oregongrape commonly. Herb/grass richness is very high for the Series. One-sided pyrola and common prince's-pine occur frequently, and rattlesnake-plantain, white-flowered hawkweed, whitevein pyrola, queen's cup, threeleaf anemone, and white trillium occur commonly. Moss cover averages 3 percent.

On Forest Service sites, upper layer tree cover is intermediate for the Series, averaging 51 percent. Mid-layer tree cover is high, averaging 44 percent. Lower layer tree cover is low, averaging 27 percent. High shrub cover is high, averaging 19 percent, and low shrub cover is intermediate, averaging 28 percent. Herb/grass cover is high, ranging from 10 to 70 percent, with an average of 45 percent.

On Bureau of Land Management sites, tree cover exceeding 10 feet tall (3 meters) averages 83 percent, while cover for tree species less than 10 feet tall averages 6 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) averages 8 percent, and cover for shrubs less than 20 inches tall averages 38 percent. Herb cover ranges from 3 to 30 percent, with an average of 18 percent.

SHASTA RED FIR-WHITE FIR/SADLER OAK/COMMON PRINCE'S-PINE
Abies magnifica shastensis-Abies concolor/Quercus sadleriana/Chimaphila umbellata
 ABMAS-ABCO/QUSA2/CHUM (N=10; NRCS=6, FS=4)

Distribution. Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine occurs in the Siskiyou Mountains on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest, and in Curry County. It may also occur on the Chetco and Gold Beach Ranger Districts, Siskiyou National Forest, and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine is very similar to Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola. Both have Douglas-fir present in the overstory and/or understory. Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine is found in areas with an average annual precipitation of 110 inches and has a greater constancy and cover of Sadler oak. Shasta Red Fir-White Fir/Baldhip Rose/One-sided Pyrola is found in areas with an average annual precipitation of 50 inches and has a greater constancy and cover of one-sided pyrola.

Soils Parent material can be granodiorite, andesite, or sandstone. Soils are shallow to deep, with an average depth of 23 inches. Average surface rock cover is 38 percent, with 22 percent gravel.

Environment Elevation averages 4500 feet, the lowest of the Series. Shasta Red Fir-White Fir/Sadler Oak/Common Prince's-pine occurs mostly on northwest to northeast aspects, though this may be due to the sampling bias to north aspects for the Natural Resources Conservation Service plots. Slope averages 44 percent and ranges from 30 to 60 percent. Upper one-third slope positions predominate.

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 26 species. Overstory tree layer is dominated by Douglas-fir, with Shasta red fir occurring frequently and white fir commonly. Understory is dominated by Shasta red fir, with white fir occurring frequently. Douglas-fir occurs commonly, and Pacific yew, canyon live oak, Brewer spruce, golden chinquapin, and sugar pine occur occasionally. In the shrub layer, Sadler oak occurs frequently at high covers, and dwarf Oregongrape, thin-leaved huckleberry, and baldhip rose occur commonly. In the herb/grass layer, common prince's-pine, vanillaleaf, and common beargrass occur frequently. Toothleaf pyrola, whitevein pyrola, little prince's-pine, Oregon fairybell, rattlesnake-plantain, and white-flowered hawkweed occur commonly. Moss cover averages 5 percent.

Upper layer tree cover is high for the Series, averaging 72 percent. Mid-layer and lower layer tree covers are both high, averaging 41 and 67 percent, respectively. High shrub cover is absent (Sadler oak was included in the lower layer tree cover), with low shrub cover low, averaging 15 percent. Herb/grass cover is also low for the Series, ranging from 2 to 25 percent, with an average of 9 percent.

SHASTA RED FIR-WHITE FIR/SADLER OAK/ONE-SIDED PYROLA
Abies magnifica shastensis-Abies concolor/Quercus sadleriana/Pyrola secunda
 ABMAS-ABCO/QUSA2/PYSE (N=6; FS=6)

Distribution. Shasta Red Fir-White Fir/Sadler Oak/One-sided Pyrola occurs in the Siskiyou Mountains on the Applegate Ranger District, Rogue River National Forest, and the Illinois Valley Ranger District, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Shasta Red Fir-White Fir/Sadler Oak/One-sided Pyrola is found at moderate temperatures and precipitation for the Series. It is characterized by the absence of Douglas-fir in the overstory and understory, and the presence of Sadler oak.

Soils. Parent material is mostly one of a variety of igneous materials - granodiorite, gabbro, diorite, or granite. Soils are moderately deep to deep, with an average depth of greater than 42 inches. Average surface rock cover is 5 percent, with 7 percent gravel, and 6 percent bare ground exposure.

Environment Elevation averages 5720 feet. Shasta Red Fir-White Fir/Sadler Oak/One-sided Pyrola likely occurs on all aspects. Slope averages 42 percent and ranges from 30 to 55 percent. Upper one-third slope positions predominate

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 33 species. Overstory and understory tree layers are both dominated by Shasta red fir, with white fir occurring frequently. Incense-cedar is frequently present in the understory. The shrub layer is dominated by Sadler oak, with dwarf bramble and Sitka mountain-ash occurring frequently. Creeping snowberry, gummy gooseberry, purple-flowered honeysuckle, baldhip rose, sticky currant, and thimbleberry commonly occur. Herb/grass richness is very high for the Series with one-sided pyrola, white-flowered hawkweed, western false Solomon's-seal, whitevein pyrola, common prince's-pine, and catchweed bedstraw occurring frequently. Columbia brome, vanillaleaf, coffee fern, spotted coral-root, threeleaf anemone, little prince's-pine, Scouler's harebell, white inside-out-flower, and bigleaf sandwort occur commonly. Moss cover averages 2 percent

Upper layer tree cover is low for the Series, averaging 47 percent. Mid-layer tree cover is high, averaging 41 percent, and lower layer tree cover is low, averaging 24 percent. High and low shrub cover are low, averaging 6 and 9 percent, respectively. Sadler oak was included in the lower layer tree cover. Herb/grass cover is low for the Series, ranging from 3 to 50 percent, with an average of 27 percent.

SHASTA RED FIR-WHITE FIR/CREEPING SNOWBERRY/COMMON PRINCE'S-PINE
Abies magnifica shastensis-Abies concolor/Symphoricarpos mollis/Chimaphila umbellata
ABMAS-ABCO/SYMO/CHUM (N=14; Sky Lakes=14)

Distribution. Shasta Red Fir-White Fir/Creeping Snowberry/Common Prince's-pine occurs in the southern Oregon Cascades in the Sky Lakes Wilderness. It may also occur on the Butte Falls or Prospect Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Shasta Red Fir-White Fir/Creeping Snowberry/Common Prince's-pine is found at high elevations. Shasta red fir and white fir are frequently present in the understory, and mountain hemlock and lodgepole pine are usually absent.

Soils. Soil data are not available.

Environment. Elevation averages 5740 feet. Shasta Red Fir-White Fir/Creeping Snowberry/Common Prince's-pine occurs on most aspects, although rarely on southwest to northeast aspects. Slope averages 14 percent and ranges from 2 to 33 percent. Slope positions range from ridge tops to lower one-third.

Vegetation Composition and Structure. Total species richness is low for the Series, averaging 20 species. Overstory tree layer is dominated by Shasta red fir, with white fir occurring frequently, and western white pine and Douglas-fir commonly. The understory is dominated by Shasta red fir, with white fir frequent. Golden chinquapin and western white pine occur commonly and Douglas-fir occasionally. Shrub richness is very low for the Series, with creeping snowberry and Oregon boxwood occurring commonly. In the herb/grass layer, common prince's-pine and long stolon sedge occur frequently, and whitevein pyrola, one-sided pyrola, and starry false Solomon's-seal occur commonly. Moss cover averages less than 1 percent.

Vegetation layer cover data are not available.

SHASTA RED FIR/THIN-LEAVED HUCKLEBERRY/COMMON PRINCE'S-PINE
Abies magnifica shastensis/Vaccinium membranaceum/Chimaphila umbellata
 ABMAS/VAME/CHUM (N=8; FS=8)

Distribution. Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine occurs in the southern Oregon Cascades on the Butte Falls and Prospect Ranger Districts, Rogue River National Forest, and on the Diamond Lake and North Umpqua Ranger Districts, Umpqua National Forest.

Distinguishing Characteristics. Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine is found at moderate temperatures and precipitation relative to the other **plant associations** in the Series. White fir and mountain hemlock are usually present and lodgepole pine is mostly absent. Thin-leaved huckleberry, common prince's-pine, queen's cup, and white-flowered hawkweed are usually present.

Soils. Parent material is mostly andesite or basalt, with some tephra. Soils are moderately deep to deep, with an average depth of greater than 41 inches. Average surface rock cover is 10 percent, with 3 percent gravel.

Environment Elevation averages 5250 feet. Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine generally occurs on southwest to north aspects. Slope averages 21 percent and ranges from 5 to 30 percent. It is found on all slope positions

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 34 species. Overstory tree layer is dominated by Shasta red fir, with Douglas-fir and western white pine common. Shasta red fir dominates the understory, with mountain hemlock and white fir occurring frequently. Golden chinquapin and western white pine occur commonly, and Douglas-fir and western hemlock occur occasionally. Shrub richness is very high for the Series. Thin-leaved huckleberry dominates the shrub layer with high covers common. Dwarf bramble and dwarf Oregongrape occur frequently. Oregon boxwood, pinemat manzanita, and creeping snowberry occur commonly. Herb/grass richness is high for the Series, with common prince's-pine, queen's cup, white-flowered hawkweed, one-sided pyrola, threeleaf anemone, and rattlesnake-plantain occurring frequently. Vanillaleaf, western twinflower, leafy lousewort, round-leaved violet, bigleaf sandwort, and starry false Solomon's-seal occur commonly. Moss cover averages 4 percent.

Upper layer tree cover is intermediate for the Series, averaging 55 percent. Mid-layer and lower layer tree covers are low, averaging 25 and 15 percent, respectively. High shrub cover is low, averaging 1 percent, however, low shrub cover is high averaging 48 percent. Herb/grass cover is intermediate for the Series, ranging from 8 to 70 percent, with an average of 22 percent

SHASTA RED FIR-LOGDEPOLE PINE/PINEMAT MANZANITA/COMMON PRINCE'S-PINE
Abies magnifica shastensis-*Pinus contorta*/*Arctostaphylos nevadensis*/*Chimaphila umbellata*
 ABMAS-PICO/ARNE/CHUM (N=4; FS=4)

Distribution. Shasta Red Fir-Lodgepole Pine/Pinemat Manzanita/Common Prince's-pine occurs in the southern Oregon Cascades on the Ashland Ranger District, Rogue River National Forest, and on the Diamond Lake Ranger District, Umpqua National Forest. It may also occur on the Butte Falls and Prospect Ranger Districts, Rogue River National Forest, and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Shasta Red Fir-Lodgepole Pine/Pinemat Manzanita/Common Prince's-pine is found at moderate temperatures and precipitation relative to the other **plant associations** in the Series. The slopes are relatively flat, averaging 5 percent. The presence of lodgepole pine in the understory indicates cold air accumulation.

Soils. Parent material is mostly pumice or andesite. Soils are shallow to deep, with an average depth of greater than 26 inches. Average surface rock cover is 5 percent, with 3 percent gravel.

Environment Elevation averages 5390 feet Shasta Red Fir-Lodgepole Pine/Pinemat Manzanita/Common Prince's-pine probably occurs on all aspects Slope averages 5 percent and ranges from 0 to 12 percent Slope positions are mostly valley bottoms, though may also be ridge top or middle one-third of gentle slopes

Vegetation Composition and Structure Total species richness is intermediate for the Series, averaging 25 species Overstory tree layer is dominated by Shasta red fir, with western white pine occurring frequently Lodgepole pine and Douglas-fir are also common in the overstory White fir and mountain hemlock occur occasionally Shasta red fir dominates the understory, with lodgepole pine, white fir, and western white pine occurring frequently, and mountain hemlock commonly Douglas-fir, Pacific silver fir, and golden chinquapin occur occasionally In the shrub layer, pinemat manzanita and Oregon boxwood occur frequently Western serviceberry and thin-leaved huckleberry occur commonly In the herb/grass layer, common prince's-pine, woods strawberry, queen's cup, and one-sided pyrola occur frequently Moss cover averages 2 percent

Upper layer tree cover is low for the Series, averaging 39 percent. Mid-layer tree cover is high, averaging 47 percent Lower layer tree and high shrub covers are low, averaging 20 and 1 percent, respectively. Low shrub cover is intermediate, averaging 20 percent Herb/grass cover is low for the Series, ranging from 5 to 8 percent, with an average of 6 percent

ABMAS 22

SHASTA RED FIR-MOUNTAIN HEMLOCK/PINEMAT MANZANITA/COMMON PRINCE'S-PINE
Abies magnifica shastensis-Tsuga mertensiana/Arctostaphylos nevadensis/Chimaphila umbellata
ABMAS-TSME/ARNE/CHUM (N=19; Sky Lakes=19)

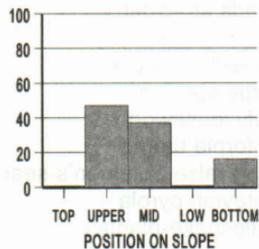

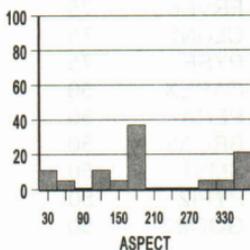

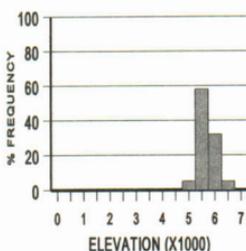

Distribution. Shasta Red Fir-Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine occurs in the southern Oregon Cascades in the Sky Lakes Wilderness. It may also occur on the Butte Falls or Prospect Ranger Districts, Rogue River National Forest, or the Diamond Lake Ranger District, Umpqua National Forest.

Distinguishing Characteristics. Shasta Red Fir-Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine occurs at high elevations and is one of the coldest of the Shasta Red Fir Series. Mountain hemlock is present in the understory and white fir is generally absent, both indicating the cold environment.

Soils. Soil data are not available.

Environment. Elevation averages 6050 feet. Shasta Red Fir-Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine occurs on most aspects, although rarely on southwest and west aspects. Slope averages 16 percent and ranges from 1 to

35 percent. Upper and middle one-third slope positions predominate, although Shasta Red Fir-Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine can also occur in the valley bottoms

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 15 species. Overstory and understory tree layers are dominated by Shasta red fir, with mountain hemlock occurring frequently, lodgepole pine commonly, and western white pine occasionally. In the understory, golden chinquapin occurs occasionally. Shrub richness is very low for the Series, with pinemat manzanita occurring commonly, and grouse huckleberry occasionally. Herb/grass richness is also very low for the Series, with common prince's-pine and long stolon sedge occurring frequently, and one-sided pyrola commonly. Moss cover averages 1 percent

Vegetation layer cover data is not available

SHASTA RED FIR/OREGON BOXWOOD/ONE-SIDED PYROLA
Abies magnifica shastensis/Pachistima myrsinites/Pyrola secunda
ABMAS/PAMY/PYSE (N=5; BLM=5)

Distribution. Shasta Red Fir/Oregon Boxwood/One-sided Pyrola occurs in the southern Oregon Cascades on the Ashland Resource Area, Medford District, and the Klamath Falls Resource Area, Lakeview District, Bureau of Land Management. It may also occur on the Butte Falls and Ashland Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Shasta Red Fir/Oregon Boxwood/One-sided Pyrola is found at cool temperatures and low precipitation relative to the other **plant associations** in the Series. Shasta red fir is generally the only species found in the overstory and the dominant species in the understory, with golden chinquapin occurring commonly, and sugar pine and western white pine rarely.

Soils. Parent material is mostly andesite or basalt. Based on five plots sampled, soil textures are loam or silty loam. Average rock fragment content is 18 percent, most of which is gravel (average 12 percent).

Environment Elevation averages 5910 feet Shasta Red Fir/Oregon Boxwood/One-sided Pyrola generally occurs on north, east, and southeast aspects Slope averages 17 percent and ranges from 2 to 28 percent Slope positions include upper, middle one-third, and valley bottom

Vegetation Composition and Structure Total species richness is low for the Series, averaging 20 species Overstory and understory tree layers are dominated by Shasta red fir Golden chinquapin occurs commonly in the understory The shrub layer is very low in richness for the Series, with Oregon boxwood occurring commonly. In the herb/grass layer, sticky starwort and one-sided pyrola occur frequently Common prince's-pine, northwest listera, threeleaf anemone, California brome, starry false Solomon's-seal, white trillium, Pacific bleedingheart, and white-flowered hawkweed occur commonly Moss cover averages 2 percent

Tree cover exceeding 10 feet tall (3 meters) averages 75 percent while cover for tree species less than 10 feet tall averages 20 percent Cover for shrubs greater than 20 inches tall (50 centimeters) averages 10 percent and cover for shrubs less than 20 inches tall averages 16 percent Herb cover ranges from 2 to 99 percent, with an average of 24 percent

PACIFIC SILVER FIR SERIES

PACIFIC SILVER FIR SERIES

Abies amabilis

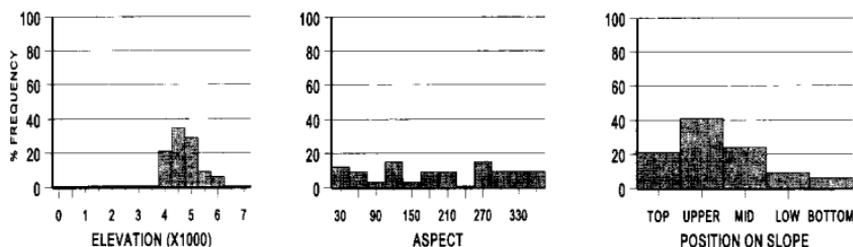

ABAM

Lisa A McCrimmon

Pacific silver fir grows along the Pacific coast from southeastern Alaska to the northern Oregon Coast Range. It is also found in the upper elevations of the Washington and Oregon Cascades. In the Cascades, Pacific silver fir reaches its southern limits near the Prospect and Butte Falls Ranger Districts of the Rogue River National Forest and the Sky Lakes Wilderness. Isolated stands, relics from the Ice-age, are found in cirques in the Klamath Geological Province of southern Oregon and northern California. Pacific silver fir is likely limited by the Mediterranean environment of southwestern Oregon, its droughty summers, and frequent fires.

The Pacific Silver Fir Series extends through the higher elevations of the Umpqua National Forest, ending in the northeastern corner of the Prospect Ranger District of the Rogue River National Forest. Its topographical and vegetational characteristics overlap with other Series. At lower elevations, the Pacific Silver Fir Series is replaced by the Western Hemlock and White Fir Series, and at higher elevations by the Shasta Red Fir and Mountain Hemlock Series.

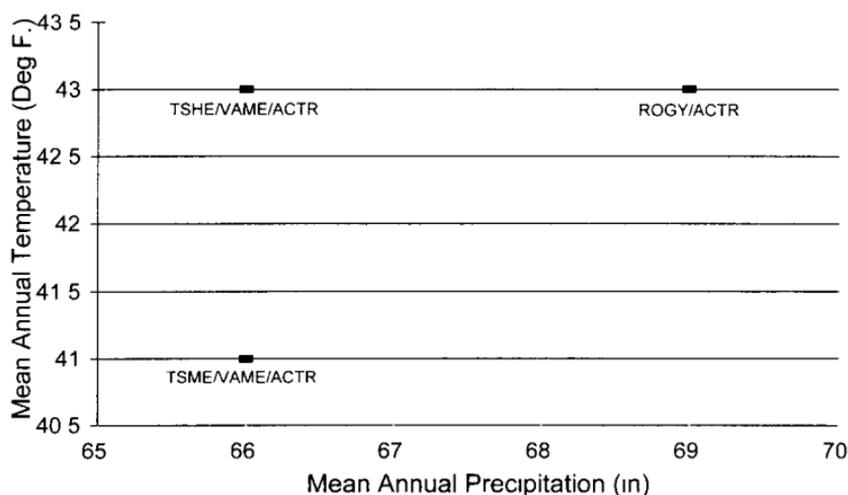

Elevation for the Pacific Silver Fir Series ranges from approximately 4000 feet to 6150 feet in the southern Oregon Cascades. All aspects are represented and slopes range from flat to very steep. Topographical position ranges from ridge tops to the valley bottoms, but the Series is most frequently found between ridge tops and the middle one-third of the slope.

The Pacific Silver Fir Series generally occurs in areas that are cool and wet. Average annual temperature ranges from 39 degrees F to 45 degrees F with an average of 42 degrees F. Average annual precipitation varies between 60 inches and 80 inches with an average of 68 inches. The relative environments of the **plant associations** are shown on page ABAM 2. Each **association** is plotted by average annual temperature and average annual precipitation.

Parent material is highly variable. Although andesite and basalt are the most common, diorite, pumice, ash, and tephra are occasionally found. Soils range from moderately deep to deep.

Surface gravel cover ranges from 0 to 50 percent, with an average of 7 percent. Surface rock cover ranges from 0 to 25 percent, with an average of 5 percent.

Exposed bedrock cover ranges from 0 to 15 percent, with an average of 2 percent. Bare ground ranges from 0 to 7 percent, with an average of 1 percent. Litter cover ranges from 85 to 99 percent, with an average of 98 percent. Moss cover ranges from 1 to 20 percent, with an average of 5 percent.

Due to frequent disturbance regimes in southwest Oregon, Douglas-fir, an early seral species, is the dominant tree in the overstory of the Pacific Silver Fir Series. Pacific silver fir regeneration is abundant in the understory. On warmer sites, western hemlock is present, and on cooler sites, mountain hemlock is present. Dwarf bramble and thin-leaved huckleberry occur frequently throughout the Series, with baldhip rose, dwarf Oregongrape, and Pacific blackberry common.

Total species richness (number of species of vascular plants) was calculated for each association. The average total species richness for the Pacific Silver Fir Series ranges between 25 and 36 species. Richness is rated as very low, 25 to 26 species; low, 27 to 29 species; intermediate, 30 to 31 species; high, 32 to 34 species, and very high, 35 to 36 species.

Estimates of total cover by vegetation layer were made for wildlife interpretations. Upper layer tree cover ranges from 62 percent in Pacific Silver Fir-Mountain Hemlock/Thin-leaved Huckleberry/Vanillaleaf to 74 percent in Pacific Silver Fir-Western Hemlock/Thin-leaved Huckleberry/Vanillaleaf and averages 70 percent for the Series. Mid-layer tree cover ranges from 32 to 38 percent and averages 35 percent. Lower layer tree cover ranges from 30 to 41 percent and averages 32 percent. High shrub cover ranges from 1 to 10 percent and averages 5 percent. Low shrub cover ranges from 14 to 19 percent and averages 16 percent. Herb/grass cover ranges from 25 to 37 percent and averages 29 percent.

Three final plant associations have been identified for the Series in southwestern Oregon. They were described from 34 Forest Service plots. The following shows the relationship between draft and final plant associations. The draft associations are listed, with final associations below, each in order of most to least common, with

the percentage of plots that make up each **association** (refer to Methods section)

ABAM 6

PACIFIC SILVER FIR-MOUNTAIN HEMLOCK/THIN-LEAVED HUCKLEBERRY/VANILLALEAF
Abies amabilis-*Tsuga mertensiana*/*Vaccinium membranaceum*/*Achlys triphylla*
ABAM-TSME/VAME/ACTR (N=10; FS=10)

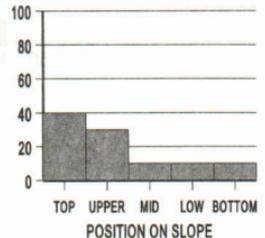

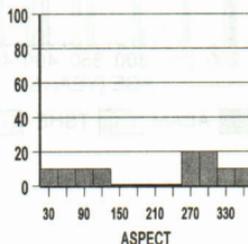

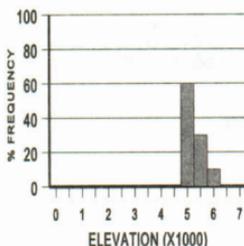

Distribution. Pacific Silver Fir-Mountain Hemlock/Thin-leaved Huckleberry/Vanillaleaf occurs on the Diamond Lake and North Umpqua Ranger Districts, Umpqua National Forest, and the Prospect Ranger District, Rogue River National Forest.

Distinguishing Characteristics. Pacific Silver Fir-Mountain Hemlock/Thin-leaved Huckleberry/Vanillaleaf is present at the highest elevations and the coldest temperatures of the Series. Mountain hemlock and thin-leaved huckleberry are frequently present, both indicators of the cold environment.

Soils. Parent material is most commonly basalt and andesite, pumice or tephra. Soils are moderately deep to deep, with an average depth of greater than 40 inches. Average surface rock cover is 4 percent, with 6 percent gravel.

Environment. Elevation averages 5390 feet. Pacific Silver Fir-Mountain Hemlock/

Thin-leaved Huckleberry/Vanillaleaf occurs predominantly on west, north, and east aspects and rarely on south aspects. Slope averages 25 percent and ranges from 6 to 48 percent. Ridge top and upper one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging 25 species. Shasta red fir generally dominates the overstory, with Pacific silver fir frequent, mountain hemlock and western white pine common, and Douglas-fir occasional. Pacific silver fir dominates the understory, with mountain hemlock occurring frequently with low to moderate covers. Shasta red fir occurs frequently in the understory, with western white pine common, and white fir occasional. Shrub richness is very low for the Series. Thin-leaved huckleberry and dwarf bramble are found frequently, with baldhip rose and Oregon boxwood occasional. In the herb/grass layer, vanillaleaf and queen's cup occur frequently. One-sided pyrola, white inside-out-flower, northwest listera, starry false Solomon's-seal, common prince's-pine, leafy lousewort, and whitevein pyrola occur commonly. Moss cover averages 4 percent.

Upper layer tree cover is low for the Series, averaging 62 percent. Mid-layer and lower layer tree covers are both low, averaging 32 and 30 percent, respectively. High shrub cover is low, averaging 1 percent, but low shrub cover is high, averaging 19 percent. Herb/grass cover is also low, ranging from 0 to 60 percent, and averaging 25 percent.

ABAM 8

PACIFIC SILVER FIR/BALDHIP ROSE/VANILLALEAF

Abies amabilis/Rosa gymnocarpa/Achlys triphylla

ABAM/ROGY/ACTR (N=17; FS=17)

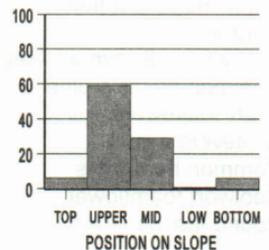

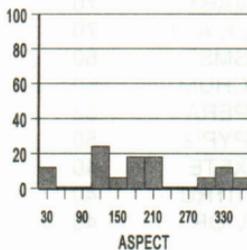

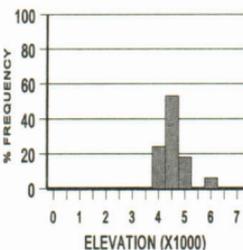

Distribution. Pacific Silver Fir/Baldhip Rose/Vanillaleaf occurs on all Ranger Districts of the Umpqua National Forest and may also occur on the Prospect Ranger District, Rogue River National Forest.

Distinguishing Characteristics. Pacific Silver Fir/Baldhip Rose/Vanillaleaf is found at warm temperatures and high precipitation relative to the other plant associations in the Series. Douglas-fir and white fir are frequently found in the understory, with western hemlock and mountain hemlock occurring occasionally and only with low covers. Western hemlock indicates warmer sites and mountain hemlock cooler sites.

Soils. Parent materials are commonly andesite or tephra, with some diorite. Soils are moderately deep to deep, with an average depth of greater than 45 inches. Average surface rock cover is 6 percent, with 6 percent gravel.

Environment. Elevation averages 4830 feet. Pacific Silver Fir/Baldhip Rose/

Vanillaleaf occurs on most aspects, although rarely on east and west aspects. Slope averages 39 percent and ranges from 19 to 65 percent. Upper and middle one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 36 species. Overstory tree layer is dominated by Douglas-fir, with Pacific silver fir and white fir common. Western white pine, Shasta red fir, and western hemlock occur occasionally. Pacific silver fir dominates the understory with Douglas-fir and white fir occurring frequently, and western hemlock, Shasta red fir, and Pacific yew occasionally. Vine maple occurs commonly, and often in abundance. Baldhip rose, dwarf Oregongrape, dwarf bramble, and Pacific blackberry frequently occur in the shrub layer. Vanillaleaf, western twinflower, starry false Solomon's-seal, rattlesnake-plantain, white inside-out-flower, threeleaf anemone, queen's cup, common prince's-pine, and Oregon fairybell are frequently occurring herbs. Moss cover averages 5 percent.

Upper layer tree cover is high for the Series, averaging 73 percent. Mid-layer tree cover is also high, averaging 38 percent, and lower layer tree cover is low, averaging 30 percent. High shrub cover is intermediate, averaging 6 percent, and low shrub cover is low, averaging 14 percent. Herb/grass cover is intermediate for the Series, ranging from 5 to 95 percent, with an average of 28 percent.

ABAM 10

PACIFIC SILVER FIR-WESTERN HEMLOCK/THIN-LEAVED HUCKLEBERRY/VANILLALEAF
Abies amabilis-Tsuga heterophylla/Vaccinium membranaceum/Achlys triphylla
ABAM-TSHE/VAME/ACTR (N=7; FS=7)

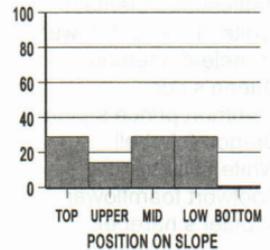

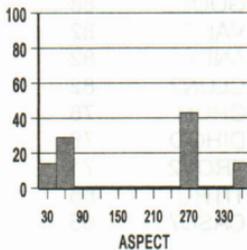

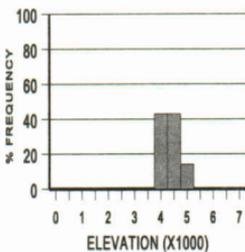

Distribution. Pacific Silver Fir-Western Hemlock/Thin-leaved Huckleberry/Vanillaleaf occurs on the Cottage Grove and Diamond Lake Ranger Districts, and likely, the North Umpqua Ranger District, Umpqua National Forest.

Distinguishing Characteristics. Pacific Silver Fir-Western Hemlock/Thin-leaved Huckleberry/Vanillaleaf is the lowest in elevation and one of the warmer associations of the Series. Western hemlock is frequently present at moderate covers in both the overstory and understory, indicating relatively warm conditions.

Soils. Parent material is mostly andesite, with some diorite and ash. Soils are moderately deep to deep, with an average depth of greater than 47 inches. Average surface rock cover is 6 percent, with 10 percent gravel.

Environment. Elevation averages 4600 feet. Pacific Silver Fir-Western Hemlock/Thin-leaved Huckleberry/Vanillaleaf occurs on west and north aspects and rarely

on south aspects. Slope averages 28 percent and ranges from 3 to 50 percent. Slope position ranges from ridge top down to the lower one-third slope.

Vegetation Composition and Structure Total species richness is high for the Series, averaging 33 species. Overstory tree layer is dominated by Douglas-fir, with western hemlock occurring frequently, and Pacific silver fir commonly. White fir, western white pine, and Engelmann spruce occur occasionally. Understory is dominated by Pacific silver fir, with western hemlock occurring frequently at low covers. Pacific yew, Douglas-fir, white fir, and western white pine occur occasionally. Vine maple, though occasional, may be dense in some areas. In the shrub layer, thin-leaved huckleberry and dwarf bramble occur frequently. In the herb/grass layer, vanillaleaf, coolwort foamflower, western twinflower, rattlesnake-plantain, common prince's-pine, white trillium, and Oregon fairybell occur frequently. Moss cover averages 7 percent.

Upper layer tree cover is high for the Series, averaging 74 percent. Mid-layer tree cover is low, averaging 33 percent. Lower layer tree, high shrub, and low shrub covers are all high, averaging 41, 10, and 18 percent, respectively. Herb/grass cover is also high for the Series, ranging from 3 to 90 percent, with an average of 37 percent.

WESTERN WHITE PINE SERIES

WESTERN WHITE PINE SERIES

Pinus monticola

PIMO3

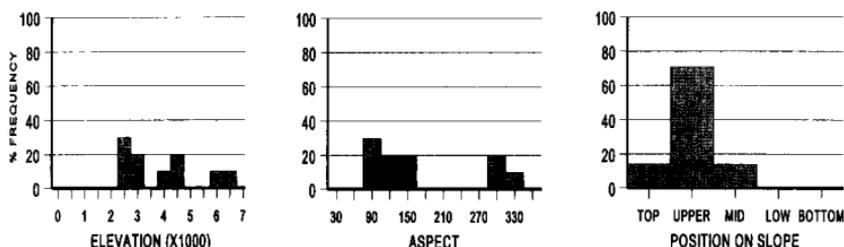

Lisa A McCrimmon

Western white pine grows along the Pacific coast from coastal British Columbia southward through Washington and Oregon to the Siskiyou Mountains along the Coast. It also grows from the Washington Cascades to the Sierra Nevada. In the Siskiyou Mountains and the southern Oregon Cascades, western white pine occurs occasionally in many stands.

The Western White Pine Series is found in the Siskiyou Mountains primarily on ultramafic soils. Its occurrences are rare, disjunct, and generally limited in acreage. Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass is intermixed with the Tanoak Series and Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass is intermixed with the Jeffrey Pine Series. Western White Pine/Common Beargrass grades into the Shasta Red Fir Series. The combination of western white pine blister rust, mountain pine beetles, drought, and fire suppression may result in the reduction or loss of western white pine as a dominant climax species in parts of the Siskiyou.

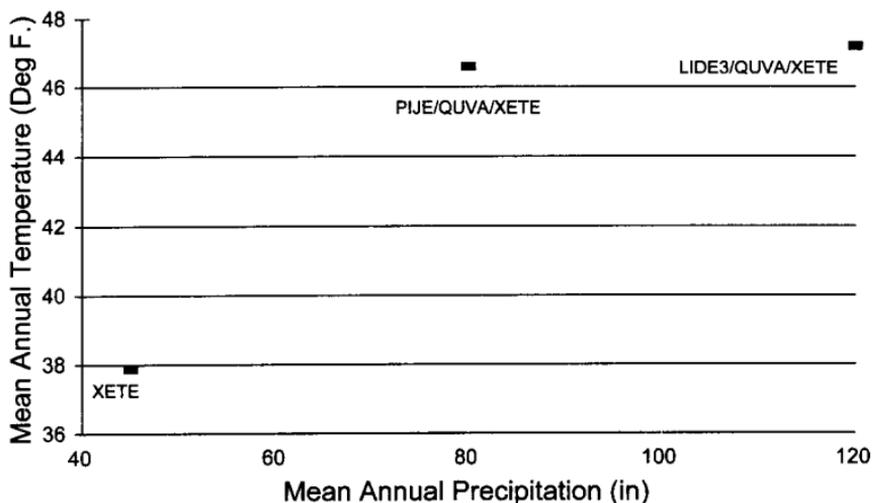

In the southern Oregon Cascades, western white pine is only found as an **associate** in stands and not as a dominant species in the regeneration layer, so there are no **associations** described.

Elevation ranges from approximately 2640 feet to 6680 feet in the Siskiyou. All aspects are represented, and slope ranges from flat to steep. Position ranges from ridge tops to the middle one-third of the slope.

The Western White Pine Series can occur in a variety of climates ranging from warm/wet to cool/dry. Average annual temperature ranges from 38 degrees F to 49 degrees F and averages 44 degrees F. Average annual precipitation ranges from 45 inches to 130 inches and averages 90 inches. The relative environments of the **plant associations** are shown on page PIMO3 2. Each **association** is plotted by average annual temperature and average annual precipitation.

Parent material is serpentine, peridotite, hornblend, or basalt. Soils range from shallow to moderately deep. Surface gravel cover ranges from 0 to 30 percent, averaging 11 percent. Surface rock cover ranges from 5 to 80 percent, averaging

41 percent. Exposed bedrock cover ranges from 0 to 7 percent, averaging 4 percent. Bare ground ranges from 0 to 10 percent, averaging 3 percent. Litter cover ranges from 40 to 99 percent, averaging 81 percent. Moss cover ranges from 0 to 20 percent, averaging 4 percent.

Either western white pine or Jeffrey pine may be the dominant species in the overstory of the Western White Pine Series. Western white pine regeneration is abundant in the understory. On warmer, wetter sites, tanoak is present, and on warmer, drier sites, tanoak is absent. On the cooler, drier sites, Shasta red fir and white fir are present. Huckleberry oak, red huckleberry, pinemat manzanita, pygmy Oregon grape, and box-leaved silk-tassel occur frequently throughout the Series on warmer sites, with pinemat manzanita and western serviceberry occurring frequently on cooler sites. Common beargrass occurs frequently on all **associations**.

Total species richness (the number of species of vascular **plants**) is calculated for each **Association**. The average total species richness for the Western White Pine Series ranges between 29 and 34, with an average of 32 species. Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass and Western White Pine/Beargrass both have an average total species richness of 34 species. Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass has an average total species richness of 29 species.

Estimates of total cover by vegetation layer were made for wildlife interpretations. Upper layer tree cover ranges from 10 percent in Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass to 30 percent in Western White Pine/Beargrass and averages 17 percent for the Series. Mid-layer tree cover ranges from 23 to 35 percent and averages 30 percent. Lower layer tree cover ranges from 10 to 73 percent and averages 49 percent. High shrub cover ranges from 0 to 28 percent and averages 14 percent. Low shrub cover ranges from 3 to 45 percent and averages 28 percent. Herb/grass layer cover ranges from 13 to 88 percent and averages 37 percent.

Three final **plant associations** have been identified for the Series in the Siskiyou. They were described from 10 Forest Service plots. The following shows the relationship of draft and final **plant associations**. The draft **associations** are listed, with final **associations** below, each in order of most to least common, with the percentage of plots that make up each **association** (refer to Methods section)

WESTERN WHITE PINE/Common BEARGRASS

Pinus monticola/Xerophyllum tenax

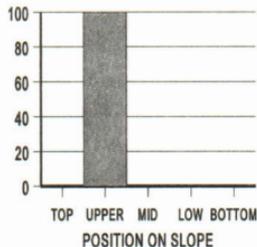

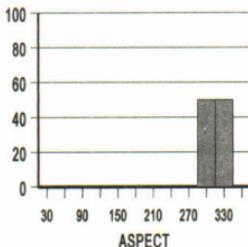

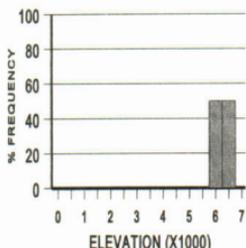

PIMO3/XETE (N=2; FS=2)

Distribution. Western White Pine/Common Beargrass occurs on Red Mountain on the Applegate Ranger District, Rogue River National Forest, and may also occur on outcrops of peridotite in the Siskiyou Mountains.

Distinguishing Characteristics. Western White Pine/Common Beargrass is found at low temperatures and low precipitation relative to other associations in the Series. Western white pine dominates the overstory and understory with Shasta red fir present, and common beargrass dominates the shrub/herb/grass layer with covers averaging 60 percent.

Soils. Parent material is usually peridotite. Soils are shallow to moderately deep, with an average depth of 18 inches. Average surface rock cover is 27 percent, with 6 percent gravel. Bare ground exposure and surface bedrock both average 5 percent on two plots.

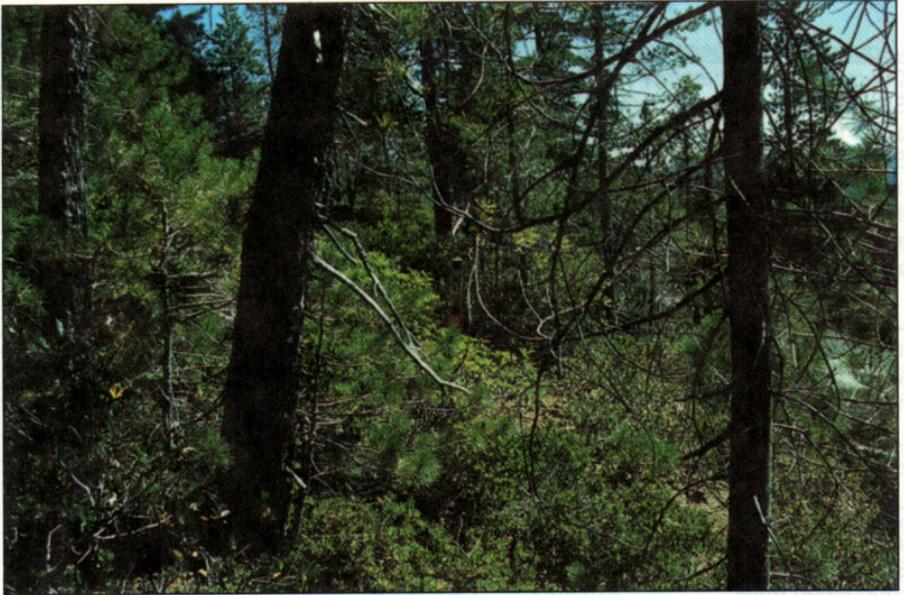

Environment Elevation averages 6580 feet Western White Pine/Common Beargrass occurs on west to northwest aspects, but may occur on other aspects Slope averages 40 percent and ranges from 23 to 57 percent Upper one-third slope positions predominate

Vegetation Composition and Structure Total species richness averages 34 species Overstory and understory are dominated by western white pine In the overstory, Shasta red fir occurs commonly, and in the understory, white fir and Shasta red fir occur frequently Mountain hemlock, Douglas-fir, and incense-cedar are common Shrub richness is very low for the Series, with western serviceberry and pinemat manzanita frequently occurring with low covers Herb/grass richness is very high for the Series Common beargrass, sedge species, common yarrow, leafy pedicularis, and mountain monardella frequently occur Common beargrass has high cover, averaging 60 percent Moss cover averages 1 percent

Upper layer tree cover is high for the Series, averaging 30 percent Mid-layer and lower layer tree covers are low, averaging 23 and 10 percent, respectively High shrub cover is absent, and low shrub cover is low at 3 percent Herb/grass cover is high, ranging from 80 to 95 percent, with an average of 88 percent

WESTERN WHITE PINE-TANOAK/HUCKLEBERRY OAK/COMMON BEARGRASS
Pinus monticola-Lithocarpus densiflorus/Quercus vaccinifolia/Xerophyllum tenax
PIMO3-LIDE3/QUVA/XETE (N=3; FS=3)

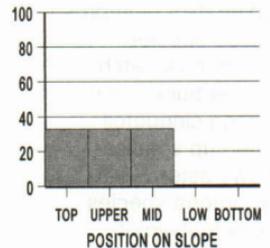

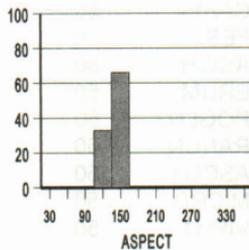

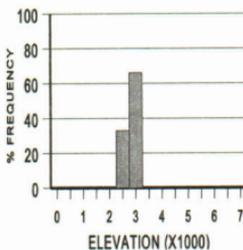

Distribution. Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass occurs on the Chetco and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass is found at warm temperatures and high precipitation relative to other **associations** in the Series. The presence of tanoak and California laurel both indicate moist conditions.

Soils. Parent materials can be serpentine, hornblend, or basalt. Soils are shallow to moderately deep, with an average depth of 18 inches. Average surface rock cover is 18 percent, with 16 percent gravel, and 4 percent exposed bedrock.

Environment. Elevation averages 3160 feet. Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass occurs on southeast aspects. Slope averages

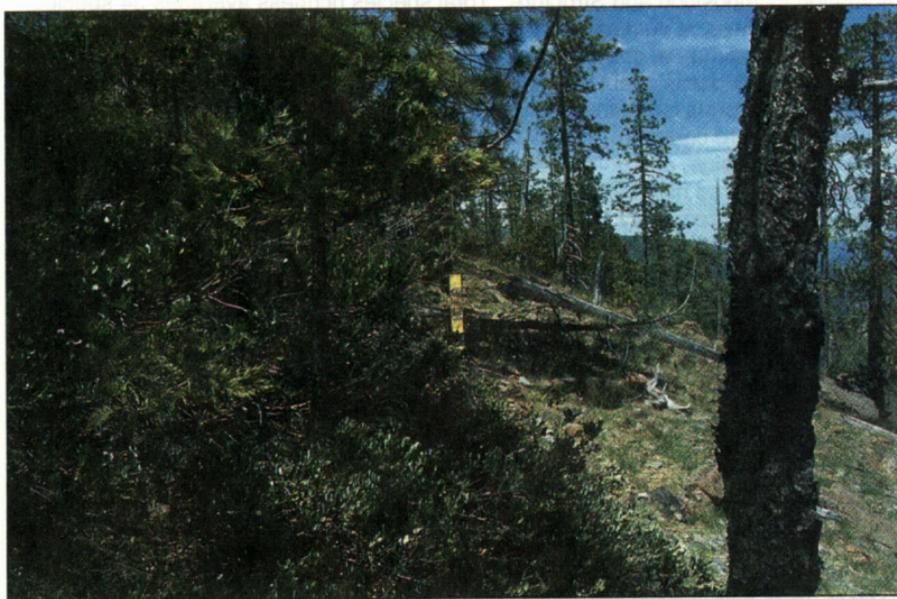

23 percent and ranges from 7 to 50 percent. Ridge top to middle one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness averages 34 species. Overstory tree layer is dominated by western white pine, with Douglas-fir and knobcone pine common, and sugar pine, Jeffrey pine, Port-Orford-cedar, and western hemlock occasional. Western white pine dominates the understory, with tanoak and California laurel frequently occurring. Port-Orford-cedar, Douglas-fir, and knobcone pine are common. Jeffrey pine, incense-cedar, sugar pine, lodgepole pine, ponderosa pine, and golden chinquapin occur occasionally. In the shrub layer, huckleberry oak, red huckleberry, common juniper, pinemat manzanita, and pygmy Oregongrape are frequently found. In the herb/grass layer, common beargrass, toothleaf pyrola, and whipplevine are frequently found. Sedge species, slender-tubed iris, obscure bedstraw, and western starflower are common. Moss cover averages 8 percent.

Upper layer tree cover is low for the Series, averaging 10 percent. Mid-layer tree cover is intermediate, averaging 32 percent, and lower layer tree cover is high, averaging 60 percent. High shrub and low shrub cover are both intermediate, averaging 28 and 32 percent, respectively. Herb/grass cover is low, ranging from 7 to 17 percent, with an average of 13 percent.

WESTERN WHITE PINE-JEFFREY PINE/HUCKLEBERRY OAK/Common BEARGRASS
Pinus monticola-*Pinus jeffreyi*/*Quercus vaccinifolia*/*Xerophyllum tenax*
 PIMO3-PIJE/QUVA/XETE (N=5; FS=5)

Distribution. Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass occurs on the Galice and Illinois Valley Ranger Districts, Siskiyou National Forest. It may also occur on adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass is found at warm temperatures and moderate precipitation relative to other associations in the Series. Average annual temperature is slightly less than Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass, however, average annual precipitation is much less, 80 inches for this Association as compared to 120 inches for Western White Pine-Tanoak/Huckleberry Oak/Common Beargrass. Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass lacks tanoak and has less constancy and cover of other high moisture indicators.

Soils. Parent material is serpentine or peridotite. Soils are moderately deep, with an average depth of 24 inches. Average surface rock cover is 59 percent, with 8

percent gravel One plot has 10 percent bare ground cover

Environment Elevation averages 3800 feet Western White Pine-Jeffrey Pine/Huckleberry Oak/Common Beargrass occurs on east, southeast, and west aspects, but may occur on other aspects as well Slope averages 27 percent and ranges from 5 to 50 percent Upper one-third slope positions predominate

Vegetation Composition and Structure. Total species richness averages 29 species Overstory tree layer is dominated by Jeffrey pine, with incense-cedar, western white pine, and Douglas-fir frequently occurring. The understory is dominated by western white pine, with incense-cedar, Jeffrey pine, and Douglas-fir frequently occurring. California laurel, Port-Orford-cedar, and white fir occur occasionally The shrub layer is dominated by huckleberry oak with moderate to high covers. Box-leaved silk-tassel, pinemat manzanita, pale serviceberry, and pygmy Oregongrape are frequent Squaw carpet and red huckleberry are common In the herb/grass layer, common beargrass and western starflower are frequent, with Oregon trillium, rock fern, slender-tubed iris, and woodland tarweed common Moss cover averages 3 percent

Upper layer and mid-layer tree covers are intermediate for the Series, averaging 15 and 35 percent, respectively Lower layer tree cover is high, averaging 73 percent High shrub cover is low, averaging 8 percent, however, low shrub cover is high, averaging 45 percent Herb/grass cover is low for the Series, ranging from 15 to 30 percent, with an average of 23 percent

**MOUNTAIN
HEMLOCK SERIES**

MOUNTAIN HEMLOCK SERIES

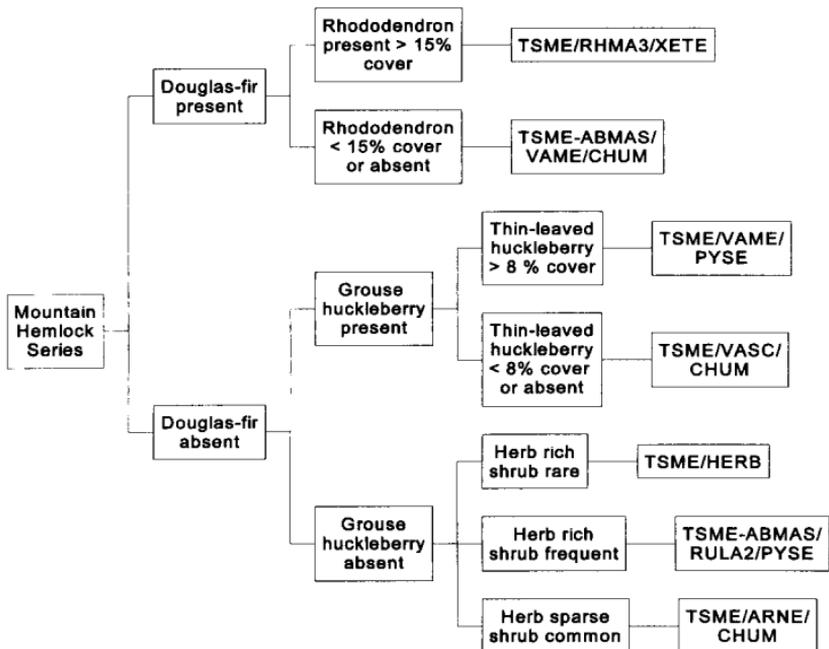

Tsuga mertensiana

TSME

Lisa A. McCrimmon

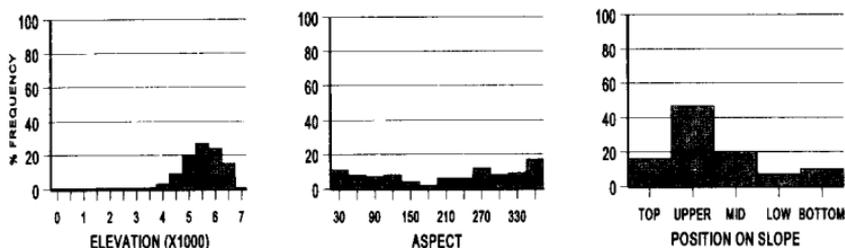

Mountain hemlock ranges from southeast Alaska, south through the Cascade Mountains, to the Sierra Nevada in California. In southwestern Oregon mountain hemlock occurs at high elevations with cold temperatures and moderate precipitation.

The Mountain Hemlock Series is the highest elevation forested series in southern Oregon. In the southern Oregon Cascades it occurs as a fairly continuous band, but in the Siskiyou Mountains it is fragmented, found only on northerly aspects of the higher peaks and ridges. The Mountain Hemlock Series is replaced at lower elevations by the Shasta Red Fir Series and at higher elevations by subalpine meadows. The flowchart below shows a graphical presentation of the classification and the relationship between **associations**.

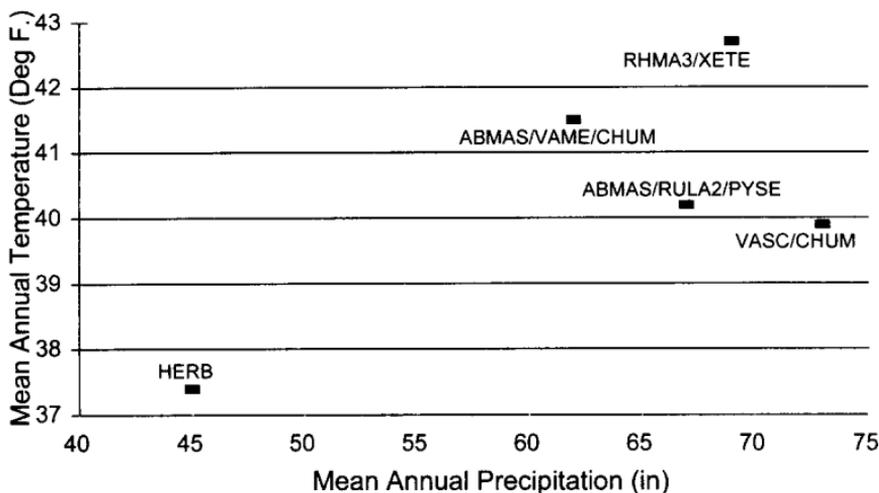

TSME 2

Elevation ranges from approximately 3950 feet to 6790 feet in the Cascades and from 5330 feet to 7340 feet in the Siskiyou. All aspects are represented and slope can range from flat to very steep. Topographic position can range from ridge tops to valley bottoms, but most frequently occurs between ridge tops and middle one-third slope.

The Mountain Hemlock Series generally occurs in areas that are cool to cold, and wet. Average annual temperature ranges from 36 degrees F to 45 degrees F with an average of 40 degrees F. Average annual precipitation ranges from 40 inches to 80 inches with an average of 63 inches. The relative environments of the plant associations are shown below. Each association is plotted by average annual temperature and average annual precipitation. No climatic data is available for Mountain Hemlock/Thin-leaved Huckleberry/One-sided Pyrola and Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine.

Parent material is highly variable, although pumice, andesite, and basalt are the most common, with schist, granodiorite, and mixed metamorphic materials occurring less frequently. Soils range from shallow to deep. Surface gravel cover ranges from 0 to 60 percent, with an average of 5 percent. Surface rock cover ranges from 0 to 85 percent, with an average of 9 percent. Exposed bedrock cover ranges from 0 to 15 percent, with an average of 2 percent. Bare ground ranges from 0 to 15 percent,

with an average of 1 percent Litter cover ranges from 30 to 100 percent, with an average of 92 percent Moss cover, however, is low, ranging from 0 to 15 percent, with an average of 2 percent This reflects the cold soil conditions typical of the Series.

Mountain hemlock and Shasta red fir are dominant tree species in the overstory, with western white pine and Douglas-fir occurring occasionally. Mountain hemlock is dominant in the understory, with Shasta red fir occurring frequently. On warmer sites, Douglas-fir, white fir, and western hemlock may be present Thin-leaved huckleberry, one-sided pyrola, and common prince's-pine occur commonly.

Total species richness (the average number of species of vascular plants) is calculated for each Association. The average total species richness for the Mountain Hemlock Series ranges between 9 and 28 Richness is rated as very low, 9 to 12 species, low, 13 to 16 species; intermediate, 17 to 20 species, high, 21 to 24 species, and very high, 25 to 28 species.

Estimates of total cover by vegetation layer were made for wildlife interpretations. Upper layer tree cover ranges from 50 percent in Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine to 61 percent in Mountain Hemlock/Herb and averages 57 percent for the Series Mid-layer tree cover ranges from 25 to 55 percent and averages 31 percent. Lower layer tree cover ranges from 14 to 28 percent and averages 20 percent. High shrub cover ranges from 0 to 71 percent and averages 9 percent Low shrub cover ranges from 0 to 38 percent and averages 26 percent Herb/grass layer cover ranges from 1 to 33 percent and averages 18 percent.

Seven final plant associations have been classified for the Series in southwestern Oregon. They were described from 98 plots: 62 Forest Service, 32 Sky Lakes Wilderness, and 4 Bureau of Land Management. The following shows the relationship of draft and final plant associations The draft associations are listed, with final associations below, each in order of most to least common, with the percentage of plots that make up each association (refer to Methods section)

TSME 6

MOUNTAIN HEMLOCK/PACIFIC RHODODENDRON/COMMON BEARGRASS
Tsuga mertensiana/Rhododendron macrophyllum/Xerophyllum tenax
TSME/RHMA3/XETE (N=6; FS=6)

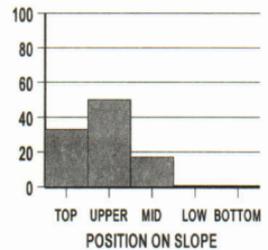

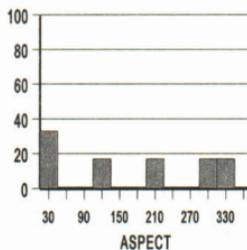

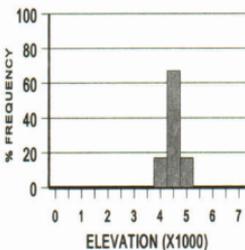

Distribution. Mountain Hemlock/Pacific Rhododendron/Common Beargrass occurs on the Cottage Grove, Diamond Lake, and North Umpqua Ranger Districts, Umpqua National Forest.

Distinguishing Characteristics. Mountain Hemlock/Pacific Rhododendron/Common Beargrass is found at warm temperatures and high precipitation relative to the other plant associations in the Series. The frequent occurrence of Douglas-fir and Pacific rhododendron indicate the warmer conditions.

Soils. Parent material is generally one of a variety of igneous materials, including andesite, pumice, tephra, or rhyolite. Soils can be shallow to deep, with an average depth of greater than 31 inches. Average surface rock cover is 25 percent, with 9 percent gravel.

Environment. Elevation averages 4770 feet. Mountain Hemlock/Pacific

Rhododendron/Common Beargrass occurs on most aspects, although rarely on southeast and south aspects. Slope averages 39 percent and ranges from 15 to 62 percent. Ridge top and upper one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is high for the Series, averaging 23 species. Overstory tree layer is dominated by Douglas-fir. Western white pine, mountain hemlock, and Shasta red fir frequently occur, Pacific silver fir is common, and white fir is occasional. Understory is dominated by mountain hemlock, with western hemlock, Pacific silver fir, Shasta red fir, golden chinquapin, and western white pine common. Pacific rhododendron dominates the shrub layer with high covers, thin-leaved huckleberry is frequent, and slender salal, dwarf Oregongrape, and Oregon boxwood are common. In the herb/grass layer, rattlesnake-plantain, common beargrass, and western twinflower are common. Common beargrass may have high cover. Moss cover averages 5 percent.

Upper layer tree cover is low for the Series, averaging 51 percent. Mid-layer tree cover is high, averaging 55 percent, and lower layer tree cover is low, averaging 16 percent. High and low shrub covers are both high, averaging 71 and 26 percent, respectively. Herb/grass cover is also high for the Series, ranging from 1 to 80 percent, with an average of 33 percent.

MOUNTAIN HEMLOCK-SHASTA RED FIR/THIN-LEAVED HUCKLEBERRY/COMMON PRINCE'S-PINE
Tsuga mertensiana-Abies magnifica shastensis/Vaccinium membranaceum/Chimaphila umbellata
TSME-ABMAS/VAME/CHUM (N=28; FS=25, Sky Lakes=3)

Distribution. Mountain Hemlock-Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine occurs mostly in the southern Oregon Cascades, but occasionally in the Siskiyou. It is found on all Ranger Districts of the Rogue River National Forest, the Diamond Lake Ranger District of the Umpqua National Forest, and in the Sky Lakes Wilderness.

Distinguishing Characteristics. Mountain Hemlock-Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine is found at low elevations with warm temperatures and moderate precipitation relative to the other **plant associations** in the Series. The presence of Douglas-fir, white fir, and western hemlock are all indicative of the warmer conditions.

Soils. Parent material is mostly pumice, andesite, and basalt. Soils are deep to moderately deep, with an average depth of greater than 41 inches. Average surface rock cover is 7 percent, with 2 percent gravel. Based on six plots sampled, surface

textures are sandy loam, loam, or clay loam, with 0 to 30 percent gravel and up to 40 percent cobbles. Subsurface textures are sandy loam, clay loam, or loam, with 10 to 95 percent cobbles.

Environment. Elevation averages 5260 feet. Mountain Hemlock-Shasta Red Fir/Thin-leaved Huckleberry/Common Prince's-pine occurs on all aspects. Slope averages 21 percent and ranges from 3 to 60 percent. Upper, middle one-third, and valley bottom slope positions predominate.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 28 species. Overstory tree layer is dominated by Shasta red fir, with mountain hemlock and Douglas-fir frequent, western white pine common, and white fir occasional. Understory tree layer is dominated by mountain hemlock, with Shasta red fir and western white pine frequent, white fir and Douglas-fir common, and golden chinquapin and lodgepole pine occasional. Shrub richness is very high for the Series, with thin-leaved huckleberry occurring frequently, occasionally with high covers. Oregon boxwood and dwarf bramble occur commonly. In the herb/grass layer, common prince's-pine and one-sided pyrola occur frequently, and queen's cup, threeleaf anemone, western twayblade, and rattlesnake-plantain commonly. Moss cover averages 3 percent.

Upper layer tree cover is high for the Series, averaging 59 percent. Mid-layer tree cover is low, averaging 30 percent, and lower layer tree cover is high, averaging 28 percent. High shrub cover is low, averaging 4 percent, and low shrub cover is high, averaging 28 percent. Herb/grass cover is intermediate, ranging from 0 to 90 percent, with an average of 18 percent.

MOUNTAIN HEMLOCK-SHASTA RED FIR/DWARF BRAMBLE/ONE-SIDED PYROLA
Tsuga mertensiana-Abies magnifica shastensis/Rubus lasiococcus/Pyrola secunda
 TSME-ABMAS/RULA2/PYSE (N=17; FS=13, BLM=4)

Distribution. In the Cascades, Mountain Hemlock-Shasta Red Fir/Dwarf Bramble/One-sided Pyrola is found on the Butte Falls and Prospect Ranger Districts, Rogue River National Forest, and the Tiller, Diamond Lake, and North Umpqua Ranger Districts, Umpqua National Forest. In the Siskiyou, it is found on the Applegate Ranger District, Rogue River National Forest, the Illinois Valley Ranger District, Siskiyou National Forest, and the Grants Pass Resource Area, Medford District, Bureau of Land Management.

Distinguishing Characteristics. Mountain Hemlock-Shasta Red Fir/Dwarf Bramble/One-sided Pyrola is found at moderate temperatures and precipitation relative to the other **plant associations** in the Series. The frequent occurrence of dwarf bramble and the occasional occurrence of white fir indicate the warmer conditions.

Soils. Parent material is mostly pumice, andesite and basalt, with some dacite, ash, and mixed metamorphic materials. Soils are mostly moderately deep and deep, with

an average depth of 40 inches. Average surface rock cover is 6 percent, with 6 percent gravel. Based on three plots sampled, surface textures are loam, silt loam, or sandy loam, with 0 to 25 percent gravel and cobbles. Subsurface textures are loam, sand, or loamy sand with 20 to 25 percent gravel and cobbles and up to 40 percent stones.

Environment. Elevation averages 5780 feet. Mountain Hemlock-Shasta Red Fir/Dwarf Bramble/One-sided Pyrola occurs on most aspects, although rarely on south aspects. Slope averages 27 percent and ranges from 5 to 55 percent. Upper and middle one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is very high for the Series, averaging 25 species. Overstory tree layer is dominated by Shasta red fir, with mountain hemlock frequent, and white fir occasional. Understory is dominated by mountain hemlock, with Shasta red fir frequent, and white fir and Pacific silver fir occasional. In the shrub layer, dwarf bramble frequently occurs, and thin-leaved huckleberry is common, occasionally with high covers. Herb/grass richness is very high for the Series, with one-sided pyrola frequent, and common prince's-pine, queen's cup, leafy pedicularis, western twayblade, and whitevein pyrola common. Moss cover averages 2 percent.

On Forest Service sites, upper layer tree cover is high for the Series, averaging 58 percent. Mid-layer and lower layer tree cover are both low, averaging 25 and 14 percent, respectively. High shrub cover is low, averaging 1 percent. Low shrub cover is intermediate, averaging 24 percent. Herb/grass cover is high for the Series, ranging from 1 to 90 percent, with an average of 26 percent.

On Bureau of Land Management sites, tree cover exceeding 10 feet tall (3 meters) averages 76 percent while tree cover less than 10 feet tall averages 9 percent. Cover for shrubs greater than 20 inches tall (50 centimeters) was absent and cover for shrubs less than 20 inches tall averages 2 percent. Herb cover ranges from 2 to 30 percent, with an average of 13 percent.

MOUNTAIN HEMLOCK/THIN-LEAVED HUCKLEBERRY/ONE-SIDED PYROLA
Tsuga mertensiana/Vaccinium membranaceum/Pyrola secunda
 TSME/VAME/PYSE (N=7; Sky Lakes=7)

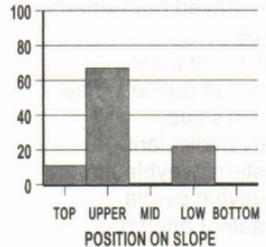

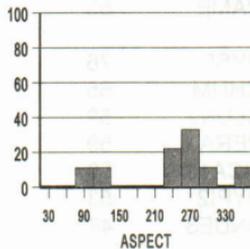

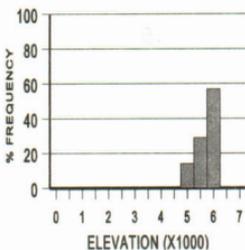

Distribution. Mountain Hemlock/Thin-leaved Huckleberry/One-sided Pyrola occurs in the Sky Lakes Wilderness in the southern Oregon Cascades. It may also occur on the Prospect, Butte Falls, or Ashland Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Mountain Hemlock/Thin-leaved Huckleberry/One-sided Pyrola is found at moderate elevations relative to the other plant associations in the Series. Warmer species, such as Douglas-fir and white fir, are rare in the overstory and understory.

Soils. Soil data are not available.

Environment. Elevation averages 5980 feet. Mountain Hemlock/Thin-leaved Huckleberry/One-sided Pyrola occurs on most aspects, although rarely on northeast and south aspects. Slope averages 17 percent and ranges from 10 to 29 percent. Upper and middle one-third slope positions predominate.

Vegetation Composition and Structure Total species richness is very low for the Series, averaging 12 species. Overstory tree layer is dominated by Shasta red fir, with mountain hemlock common, and western white pine and lodgepole pine occasional. Understory is dominated by mountain hemlock, with Shasta red fir occurring frequently. In the shrub layer, thin-leaved huckleberry is frequent and often at high covers, and grouse huckleberry is common. Herb/grass richness is very low for the Series, with one-sided pyrola and little prince's-pine frequent, and woods strawberry common. Moss cover averages 1 percent.

Vegetation layer cover data is not available

MOUNTAIN HEMLOCK/GROUSE HUCKLEBERRY/COMMON PRINCE'S-PINE
Tsuga mertensiana/Vaccinium scoparium/Chimaphila umbellata
 TSME/VASC/CHUM (N=20; Sky Lakes=13, FS=7)

Distribution. Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine occurs in the southern Oregon Cascades on the Tiller and Diamond Lake Ranger Districts, Umpqua National Forest, the Prospect Ranger District, Rogue River National Forest, and in the Sky Lakes Wilderness.

Distinguishing Characteristics. Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine is found at moderate temperatures and high precipitation relative to the other plant associations in the Series. It is the coldest of the mountain hemlock plant associations in the Cascades. The lack of warm species, such as Douglas-fir and white fir, indicate cold temperatures as does the common occurrence of lodgepole pine on the flatter sites.

Soils. Parent material is mostly pumice or andesite. Soils are moderately deep to deep, with an average depth of greater than 39 inches. Average surface rock cover

is 7 percent, with 9 percent gravel. Based on two plots sampled, surface texture is sand, sandy loam, or loam, with 0 to 15 percent cobbles. Subsurface textures are sand or sandy loam, with 25 to 90 percent cobbles.

Environment. Elevation averages 6120 feet. Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine occurs on all aspects. Slope averages 11 percent and ranges from 1 to 33 percent. Ridge top, upper, and middle one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is very low for the Series, averaging nine species. Overstory tree layer is dominated by mountain hemlock, with Shasta red fir and lodgepole pine occasional. Understory is dominated by mountain hemlock, with Shasta red fir common, and lodgepole pine and western white pine occasional. In the shrub layer, grouse huckleberry occurs frequently, and thin-leaved huckleberry occurs occasionally. Herb/grass richness is very low for the Series, with long stolon sedge and common prince's-pine common and one-sided pyrola and smooth woodrush occasional. Moss cover averages 2 percent.

Upper layer tree cover is low for the Series, averaging 50 percent. Mid-layer and lower layer tree covers are both low, averaging 31 and 15 percent, respectively. High shrub cover is absent, and low shrub cover is intermediate, averaging 23 percent. Herb/grass cover is low for the Series, ranging from 0 to 3 percent, with an average of 1 percent.

MOUNTAIN HEMLOCK/PINEMAT MANZANITA/COMMON PRINCE'S-PINE
Tsuga mertensiana/*Arctostaphylos nevadensis*/*Chimaphila umbellata*
 TSME/ARNE/CHUM (N=9; Sky Lakes=9)

Distribution. Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine occurs in the Sky Lakes Wilderness in the southern Oregon Cascades. It may also occur on the Ashland, Butte Falls, or Prospect Ranger Districts, Rogue River National Forest.

Distinguishing Characteristics. Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine and Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine are found at the highest elevations of the Mountain Hemlock Series. Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine generally occurs on relatively steeper slopes (20 percent), with lodgepole pine and grouse huckleberry rarely occurring. Mountain Hemlock/Grouse Huckleberry/Common Prince's-pine is found on relatively flatter slopes (11 percent), and grouse huckleberry is frequently present with lodgepole pine commonly present.

Soils. Soil data are not available.

Environment Elevation averages 6130 feet Mountain Hemlock/Pinemat Manzanita/Common Prince's-pine occurs on most aspects, although rarely on southeast and south aspects Slope averages 20 percent and ranges from 8 to 55 percent Upper one-third slope positions predominate

Vegetation Composition and Structure Total species richness is very low for the Series, averaging 11 species. Overstory tree layer is dominated by Shasta red fir, with mountain hemlock occurring frequently, and western white pine occasionally Understory is dominated by mountain hemlock, with Shasta red fir frequent, and western white pine occasional In the shrub layer, pinemat manzanita is common Herb/grass richness is very low for the Series, with common prince's-pine, long stolon sedge, and one-sided pyrola frequent, and white-flowered hawkweed occasional. Moss cover averages less than 1 percent.

Vegetation layer cover data are not available.

MOUNTAIN HEMLOCK/HERB
Tsuga mertensiana/Herb
TSME/HERB (N=11; FS=11)

Distribution. Mountain Hemlock/Herb occurs in the Siskiyou Mountain Province on the Ashland and Applegate Ranger Districts, Rogue River National Forest. It may also occur on the Illinois Valley Ranger District, Siskiyou National Forest, and adjacent Bureau of Land Management lands.

Distinguishing Characteristics. Mountain Hemlock/Herb is found at cold temperatures and low precipitation relative to the other **plant associations** in the Series. The lack of species indicating warmer conditions, such as white fir and Douglas-fir, indicate these conditions.

Soils. Parent material is mostly schist or granodiorite, with some mixed metamorphic or igneous materials. Soils can be shallow or deep, with an average depth of greater than 34 inches. Average surface rock cover is 10 percent, with 4 percent gravel. Based on six plots sampled, surface textures are loam, sandy loam, or loamy

sand, with 15 to 40 percent gravel and cobbles. Subsurface textures are loam, sand, sandy loam, or loamy sand, with 25 to 50 percent gravel and up to 85 percent cobbles.

Environment Elevation averages 6710 feet. Mountain Hemlock/Herb occurs on northwest to east aspects. Slope averages 33 percent and ranges from 8 to 59 percent. Ridge top and upper one-third slope positions predominate.

Vegetation Composition and Structure. Total species richness is intermediate for the Series, averaging 17 species. Overstory and understory tree layers are dominated by mountain hemlock, with Shasta red fir frequently occurring. Shrub richness is very low for the Series, with shrub species occurring rarely. Herb/grass richness is high for the Series, with mountain heliotrope, skunkleaf polemonium, mountain bunchgrass, and Ross's sedge found commonly. Moss cover averages 1 percent.

Upper layer tree cover is high for the Series, averaging 61 percent. Mid-layer and lower layer tree cover are both low, averaging 28 and 14 percent, respectively. High and low shrub covers are absent on most plots. Herb/grass cover is intermediate for the Series, ranging from 3 to 35 percent, with an average of 15 percent
