SAM Hydraulic Design Package for Channels

by William A. Thomas, Ronald R. Copeland, Dinah N. McComas

Coastal and Hydraulics Laboratory
U.S. Army Engineer Research and Development Center
3909 Halls Ferry Road
Vicksburg, MS 39180-6199

Final report

Approved for public release; distribution is unlimited

Prepared for U.S. Army Corps of Engineers
Washington, DC 20314-1000

Preface

The SAM Hydraulic Design Package for Channels has been evolving since the late 1980's. The majority of algorithms are a result of research conducted in the Flood Control Channels Research Program in the 1980's and early 1990's. Mr. W.A. Thomas (retired) was one of the driving forces behind the beginnings of SAM. Mr. Thomas, Dr. Ronald Copeland (retired), Dr. Nolan Raphelt, and Mrs. Dinah McComas, all in the former Hydraulics Laboratory (now Coastal and Hydraulics Laboratory (CHL), Engineering Research and Development Center (ERDC), Vicksburg, MS), did most of the original programming for SAM. The package has been debugged, refined and added to from its inception to the present. In 2001, CHL entered into a Cooperative Research and Development Agreement (CRDA) with Owen Ayres & Associates, Inc., Ft. Collins, CO, to put the DOS-based SAM into a more user-friendly interface. Ayres developed a Windows interface which uses the same executable programs, with necessary improvements and fixes, as the earlier DOS-based SAM package. Ayres has exclusive rights to sell and support the SAM package to the private sector and all government agencies except the Corps of Engineers. The Corps of Engineers can receive the new SAM package, and support, through CHL, free with participation in the Numerical Model Maintenance Program at ERDC.

1 Introduction

Purpose and Philosophy

SAM is an integrated system of programs developed through the Flood Damage Reduction and Stream Restoration Research Program to aid engineers in analyses associated with designing, operating, and maintaining flood control channels and stream restoration projects. The package was designed primarily to satisfy the need for qualitative, easy-to-use methodology, especially for use in preliminary screening of alternatives where funds for more extensive investigations are not available.

The SAM package, designed to run on PC computers, is intended to be used primarily as an aid in the design of stable channels. In the past, the design of a stable channel has focused on the erosion process (Simons and Senturk, 1977, and ASCE, 1975). However, erosion is only one of the five fundamental processes--erosion, entrainment, transportation, deposition and compaction--in sedimentation. SAM provides the computational capability to include all these processes except the compaction of the deposited bed sediments in the design of stable channels.

The SAM package is designed to provide hydraulic engineers smooth transition from making hydraulic calculations to calculating sediment transport capacity to making sediment yield determinations. The three main modules of the package can be used in series, as described, or their separate capabilities utilized to aid in various hydraulic design situations. SAM.hyd calculates the width, depth, slope and n-values for stable channels in alluvial material. SAM.sed calculates sediment transport capacity according to a wide range of sediment transport functions, usually using the hydraulic parameters calculated in SAM.hyd. SED.yld uses the sediment transport capacity calculated in SAM.sed to calculate the sediment yield. Channel stability can then be evaluated in terms of the cost of maintaining the constructed channel.

Overview of Manual

This manual describes the fundamental concepts, numerical model capabilities and limitations, computational procedures, input requirements and output descriptions of the various modules in SAM. A brief description of model capabilities and the organization of this manual is presented below.

Theoretical Basis for SAM.hyd, SAM.sed, and SAM.yld calculations (Chapters 2, 3, 4)

These chapters describe the theoretical bases for the hydraulic computations, the sediment transport calculations, and the sediment yield calculations in the SAM.hyd, SAM.sed, and SAM.yld modules, respectively. They present the general capabilities of the modules and describe how the computations are performed.

Theoretical Basis for SAM.aid (Chapter 5)

This chapter describes the general capabilities of this module and describes how the selection of recommended sediment transport equations is made in SAM.aid.

Input Requirements and Program Output for SAM.hyd, SAM.sed, and SAM.yld (Chapters 6, 7, and 8)

These chapters describe the general input data requirements for implementation of specific module capabilities, as well as providing information on the various output tables in each module.

Appendices

The various appendices provide specific instructions on the use of the package. These appendices are:

- A. References
- B. List of Variables
- C. Data Records for Hydraulic Calculations (SAM.hyd)
- D. Data Records for Sediment Transport Functions (SAM.sed)
- E. Data Records for Sediment Yield Calculations (SAM.yld)
- F. SAM.aid – Guidance in Sediment Transport Function Selection

Summary of SAM Capabilities

Geometry

SAM considers only one cross section, not a reach, of a river. However, the geometry of that cross section can be prescribed in several ways. For trapezoidal channels, either a simple or compound channel can be input. Also, an irregular channel can be prescribed with station and elevation coordinates.

SAM.hyd

This module calculates normal depth and composite hydraulic parameters for a cross section with variable roughness. The calculations can be made with a variety of bed roughness predictors. It will also calculate stable channel dimensions--channel width, depth and slope-- for a prescribed discharge and sediment load. The stable channel dimensions calculated in SAM are not constrained by the external hypothesis advocated by Chang (1980) and others. Rather, the designer is able to choose from a family of solutions to meet project constraints. These calculations use analytical equations which include bed material transport and which separate total hydraulic roughness into bank and bed components.

SAM.hyd also provides the option of calculating riprap size, either by the method prescribed in EM 1110-2-1601, "Hydraulic Design of Flood Control Channels" (USACE 1991, 1994), or through testing the results of the normal depth calculations against the Shield's Diagram for particle stability.

SAM.sed

This module calculates the bed material sediment discharge rating curve by size class using hydraulic parameters either calculated in SAM.hyd or user specified. Several sediment transport functions have been programmed into SAM.sed, covering a range of riverine conditions. SAM.sed applies the sediment transport functions at a point thus allowing for no temporal or spatial variability in the size class distribution.

SAM.yld

SAM.yld calculates sediment yield passing a cross-section during a specified period of time using the "Flow-Duration Sediment-Discharge Rating Curve method" described in EM 1110-2-4000, "Sediment Investigations in Rivers and Reservoirs" (USACE 1989). The time period considered can be a single flood event or an entire year. In SAM.yld the flow can be specified by either a flow duration curve or a hydrograph. The sediment discharge rating curve can be specified as either sediment discharge versus water discharge or sediment concentration versus water discharge.

SAM.aid

SAM.aid provides guidance in the selection of a sediment transport function(s) to use with a given project, based on five screening parameters: d_{50} , slope, velocity, width, and depth.

General

The SAM package is a product of the Flood Damage Reduction and Stream Restoration Research Program. The conception and initial development of the package were the results of the efforts of William A. Thomas, Ronald R. Copeland and Nolan Raphelt. However, many workunits and many principal investigators have contributed to the package. The US Government is not responsible for results obtained with this software. However, the office supporting the package would welcome documentation of program errors and should respond if fiscally feasible.

Files

The program operates interactively. However it saves the input data in an ASCII files and uses these files to pass data from module to module.

Theoretical Assumptions and Limitations

SAM is not a package of one-dimensional models. SAM makes calculations based on one cross section at one point in time. There are no provisions in any of the modules for simulating the effects of a hydrograph nor for looking at a reach of a river, except as it might be represented by an average. SAM is designed to be used as a tool during reconnaissance level planning studies. Broad application of SAM results must be made with caution.

Sediment transport functions in SAM must be used with care. Essentially, SAM.sed applies the sediment transport functions at a point, which allows for no variability in the size class distribution over time or space. Considering that the size class distribution of bed material in the natural river changes with discharge, reach, time of year, and other temporal factors, SAM's use of a fixed, non-varying, as-prescribed size class distribution for all calculations presents the possibility that the calculated transport rates are not truly representative of the natural river. The procedure in HEC-6, which integrates processes over several cross sections which describe a reach of the river and provides a continuity equation for sediment movement, will consequently produce a more reliable result than comes from applying a sediment transport function at a single point.

However, SAM will provide reasonable answers if the user is cognizant of the need for the careful prescribing of the bed material gradation.

2 Theoretical Basis for SAM.hyd Calculations

Purpose

The purpose of the hydraulics module, SAM.hyd, is to provide hydraulic design engineers with a systematic method, based on state-of-the-art theory, for rapidly calculating channel size in both fixed and mobile boundary streams.

General

SAM.hyd solves the steady state, normal-depth equation to transform complex geometry into composite, 1-dimensional hydraulic parameters. The program can solve for either depth, width, slope, discharge, or roughness. It allows roughness to be calculated by several different roughness equations within the same cross-section.

SAM.hyd contains an analytical procedure for calculating stable channel dimensions in either sand bed or gravel bed streams. It is based on the Brownlie equations for sediment transport and bed roughness. This calculation provides a table of channel width-depth-slope dimensions which are in equilibrium with the inflowing sediment load. Channel dimensions at minimum stream power are also calculated.

SAM.hyd provides the option of calculating riprap size as described in EM 1110-2-1601, "Hydraulic Design of Flood Control Channels" (USACE 1991, 1994) or through testing the results of the normal depth calculations against the Shield's Diagram for particle stability. The 13 standard riprap sizes from EM 1110-2-1601 are coded into SAM. The user can also specify quarry run riprap.

SAM.hyd offers two procedures for calculating riprap. When flow velocity and depth are known, the riprap size is calculated directly. When water discharge and cross section are given, riprap size is determined by a more complicated calculation since n -value becomes a function of riprap size.

SAM.hyd also has the ability to determine whether or not riprap is required. The program evaluates the calculated bed shear stress and the Shield's critical value. If the calculated bed shear stress is greater than Shield's critical value, SAM.hyd will notify the user that riprap is required. The user may then alter the data file to request riprap calculations.

Regime channel dimensions, determined using the Blench (1970) equations, can be calculated as a function of bed material gradation, bank consistency, and bed-material sediment concentration.

SAM.hyd Options

SAM.hyd can solve for any one of the variables in the uniform flow equation. Water discharge is usually the dependent variable (equation 2-1). However, SAM allows any of the variables on the right hand side to become the dependent variable, except side slope, z . SAM.hyd inspects each input record type in a data set and determines which variables have been prescribed. The variable omitted becomes the dependent variable.

$$Q = f(D, n, W, z, S)$$

Equation 2-1

where

Q = water discharge
D = water depth
n = n-value
W = bottom width
z = side slopes of the channel
S = energy slope

Most of the major calculation options in SAM.hyd rely on the above relationship. For SAMwin, all variables can be prescribed. The user must select the variable to be calculated: normal depth, bottom depth, energy slope, hydraulic roughness (n-values and k_s values), and water discharge. Flow distribution is calculated each time the uniform flow equation is solved, and can be requested during any of the calculations.

Other parameters are also calculated when the uniform flow equation is solved. In SAM.hyd, composite hydraulic parameters can be calculated by four options: alpha method, equal velocity method, total force method and conveyance method.

Bed Form Roughness Prediction is made using Brownlie's (1983) method. It uses velocity, hydraulic radius, slope, particle specific gravity, d_{50} and the geometric standard deviation of the bed sediment mixture.

Cross Section Velocity is printed for comparison with the velocity criteria for stable channel design.

Shear Stress is printed for comparison with the boundary shear stress criteria for stable channel design.

Riprap Size can be requested. If the calculated bed shear stress is greater than Shield's critical value, the program will notify the user.

Effective Width, Depth and Velocity are calculated, printed, and written to an input file for use in sediment transport calculations, SAM.sed.

Equivalent Hydraulic Radius and n-Value are calculated and printed for each subsection in the cross section after the normal depth calculations are completed.

Also, there are two options for coding the cross section. Single or compound channels can be prescribed by defining the bottom width and side slopes for simple triangular, rectangular or trapezoidal shapes. For example, Figure 2.1A shows a low flow channel, a normal flow channel, and a high flow berm. Complex channels can be prescribed by defining the station and elevation coordinates, as on X1 and GR records in HEC-2/HEC-6. Figure 2.1B shows a typical complex cross section as an example of what could be coded in this format.

Normal Depth Calculations

Normal depth is calculated using one of five uniform flow equations, or one of five USDA Soil Conservation Service (SCS) equations for grass-lined channels. Different equations may be used in different panels. An iterative procedure is used to converge on the specified total discharge. Then a composite Manning's roughness coefficient and the effective hydraulic parameters are calculated for the cross section.

Manning Roughness Equation When the hydraulic roughness is prescribed as n-values, the Manning equation is used to determine normal depth.

NOTE: The trapezoidal element 'AB(6)(5)' in this figure is called a "panel" in this document.

1V:ZH -- definition of the side slopes, with the Z as the input parameter

CD1 -- the height of the low flow channel

CD2 -- the incremental height of the normal channel

CD3 -- the incremental height of the high flow channel

BW1 -- the width, toe to toe, of the low flow channel

BW2 -- the width, toe to toe, of the normal channel

BW3 -- the width, toe to toe, of the high flow channel

Note: therefore total depth = CD1+CD2+CD3

Figure 2.1A and 2.1B. Complex Geometry using CT records, top; using X1 and GR records.

$$V = \frac{1.486}{n} R^{2/3} S^{1/2}$$

Equation 2-2

where

- V = velocity, feet per second
- R = hydraulic radius, feet
- S = slope, feet per foot
- n = Manning's roughness coefficient

Hydraulic Roughness Equations Hydraulic roughness can be prescribed directly with n-values (option 0) or it can be related to the physical properties of the cross section by another hydraulic roughness equation. Available roughness equations are given in Table 1.

- 0. Manning's Equation
- 1. Keulegan equations
- 2. Strickler Equation
- 3. Limerinos Equation
- 4. Brownlie Bed Roughness Equations
- 5-9. Five Soil Conservation Service equations for grass lined channels

Table 1. Hydraulic Roughness Options in SAM.hyd.

Note that as each channel problem is unique, no one predictor should be considered as "best."

Effective Surface Roughness Height, k_s

A value for k_s is required when the Keulegan equations or Strickler equation is specified. For the design of concrete channels the suggested values for k_s are shown in EM 1110-2-1601 (USACE 1991, 1994). For the case of channels in natural materials, there are no tables of generally accepted k_s values as there are for Manning's n-values. Moreover, there is no generally accepted technique for measuring this property geometrically. Therefore, unless a specific value of k_s is known, it is recommended that the hydraulic roughness be prescribed with n-values or by another analytical method. When sufficient data are available -- discharge, area, hydraulic radius, and slope -- k_s can be calculated and then used to calculate hydraulic parameters for additional discharges.

Relative Roughness

Relative roughness refers to the ratio of the effective surface roughness height, k_s , to the hydraulic radius, R. The relative roughness parameter is R/k_s . When this parameter is less than 3, which indicates a very rough surface, the logarithmic velocity distribution theory breaks down. For this reason, SAM will

not apply the Keulegan equation when relative roughness is less than 3. Instead, the Strickler equation is automatically substituted.

Keulegan equations, rigid bed

The relative roughness approach based on the Keulegan (1938) equations for velocity distribution is still the state-of-the-art for rigid boundary channel design. Keulegan classified flow types as hydraulically smooth, hydraulically rough, or transitional. His equations can be combined with the Chezy equation to obtain a Chezy roughness coefficient. The equations are written in terms of the Chezy coefficient, C , because the powers are simpler than when the Manning's equation is employed. Chezy's C may then be converted directly to a Manning's n -value.

- (1) The equation for fully rough flow is

$$C = 32.6 \log_{10} \left(\frac{12.2 R}{k_s} \right) \quad \text{Equation 2-3}$$

- (2) For smooth flow the equation is

$$C = 32.6 \log_{10} \left(\frac{5.2 R_n}{C} \right) \quad \text{Equation 2-4}$$

The smooth flow equation is a trial and error solution, best accomplished using a computer program such as SAM.

- (3) The equation for transitional flow is

$$C = -32.6 \log_{10} \left(\frac{C}{5.2 R_n} + \frac{k_s}{12.2 R} \right) \quad \text{Equation 2-5}$$

- (4) The equation showing the relationship of n -value and Chezy C is

$$n = \frac{1.486}{C} R^{1/6} \quad \text{Equation 2-6}$$

where

$$\begin{aligned} R_n &= \text{Reynolds number} \\ &= 4RV/\nu \\ \nu &= \text{kinematic viscosity of water} \end{aligned}$$

and 32.6, 12.2 and 5.2 are empirical coefficients determined from laboratory experiments. These equations, when graphed, produce the Moody-type diagram for open channel flow, Figure B-3, EM 1110-2-1601 (USACE 1991, 1994).

The Iwagaki relationship

Using experimental data obtained from many sources, Iwagaki (Chow, 1959) found that the coefficients 12.2 and 5.2 in equations 2-3, 2-4, 2-5, and 2-6 varied with Froude number. The results of his study disclosed that resistance to turbulent flow in open channels becomes obviously larger with increase in the Froude number. Iwagaki reasoned that this is due to the increased instability of the free surface at high Froude numbers. The Iwagaki relationship is shown in Figure 2.2.

Figure 2.2. The Iwagaki relationship (Chow, 1959), used with permission from McGraw-Hill Book Company, Inc.

Keulegan's equations can be modified to incorporate Iwagaki's results.

(1) Chow (1959) presents Keulegan's equation for the average flow velocity V in the following form

$$V = U_* \left[6.25 + 5.75 \log_{10} \left(\frac{R}{k_s} \right) \right] \quad \text{Equation 2-7}$$

where

$U_* = \sqrt{gRS}$ = boundary shear velocity

g = acceleration of gravity

6.25 = empirical constant for fully rough flow

(2) The equation for rough flow may be obtained by substituting a variable, A_r , for the constant, 6.25, and \sqrt{gRS} for U_* , and then combining with the Chezy equation.

$$\frac{V}{U_*} = \frac{C}{\sqrt{g}} = A_r + 5.75 \log_{10} \left(\frac{R}{k_s} \right) \quad \text{Equation 2-8}$$

$$C = \sqrt{g} \left[A_r + 5.75 \log_{10} \left(\frac{R}{k_s} \right) \right] \quad \text{Equation 2-9}$$

$$C = 32.6 \log_{10} \left[10^{\frac{A_r \sqrt{g}}{32.6}} \left(\frac{R}{k_s} \right) \right] \quad \text{Equation 2-10}$$

where A_r is the Iwagaki variable for rough flow. From Keulegan's study of Bazin's data, the value of A_r was found to have a wide range, varying from 3.23 to 16.92. Keulegan used a mean value of 6.25 for A_r .

(3) The comparable form of the equation for smooth flow is

$$C = 32.6 \log_{10} \left[10^{\frac{A_s \sqrt{g}}{32.6}} \left(\frac{\sqrt{g} R_n}{4C} \right) \right] \quad \text{Equation 2-11}$$

where A_s is the Iwagaki variable for smooth flow.

(4) The roughness equation in the transition zone is a combination of the equations for smooth and fully rough flow as follows:

$$C = -32.6 \log_{10} \left(\frac{4C}{\sqrt{g} R_n 10^{\frac{A_s \sqrt{g}}{32.6}}} + \frac{k_s}{R 10^{\frac{A_r \sqrt{g}}{32.6}}} \right) \quad \text{Equation 2-12}$$

A_r and A_s variables The A_r and A_s variables are shown graphically in Figure 2.2. An equation for A_r is

$$A_r = -27.058 \log_{10}(F + 9) + 34.289 \quad \text{Equation 2-13}$$

where F is the Froude number. Data ranges from $0.2 < F < 8.0$.

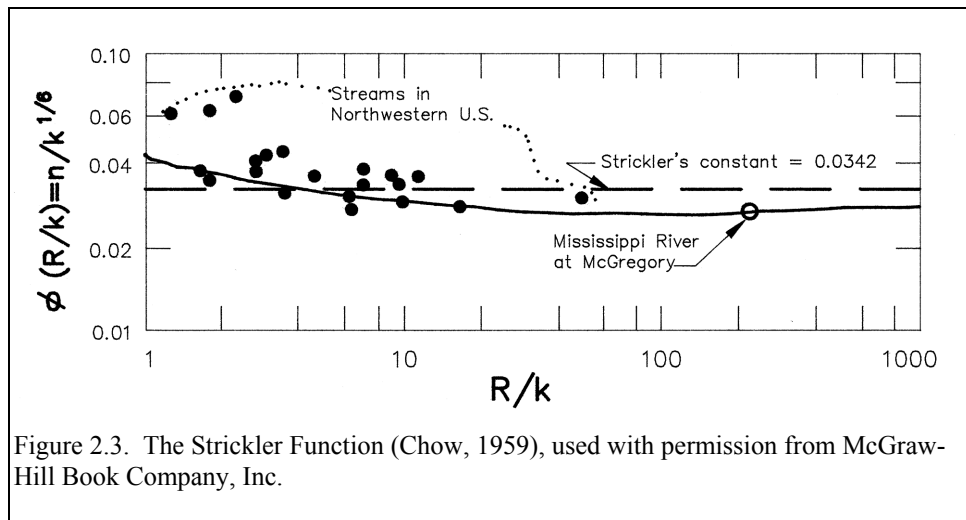

Using an equation of the same form, the relationship for A_s is

$$A_s = -24.739 \log_{10}(F + 10) + 29.349 \quad \text{Equation 2-14}$$

Equations 2-6, 2-10, 2-12, 2-13 and 2-14 are used in SAM.hyd to calculate the roughness coefficient when the Keulegan equations are specified.

Strickler Equation

The Strickler function is compared to measured data in Figure 2.3. (Chow, 1959) This figure shows that for a wide range in relative roughness, R/k_s , the variability of the Strickler function $\phi R/k_s$ is small. Strickler assumed this to be a constant, 0.0342 when k_s and R were expressed in feet. The effective surface roughness height, k_s , is the d_{50} of the bed sediment in this figure. However, k_s can be correlated with other measures of the surface roughness, depending on what is representative of the surface roughness height of the boundary materials. For example, riprap research at WES (Maynard 1991, 1992) has shown that the Strickler equation will give satisfactory n -values when k_s is taken to be the d_{90} of the stone.

$$n = \phi \frac{R}{k_s} k_s^{1/6} \quad \text{Equation 2-15}$$

where, in SAM,

k_s = effective surface roughness, ft
 $\phi R/k_s = 0.0342$ for natural channels,
 where $k_s = d_{50}$
 = 0.0342 for velocity and stone size calculations in riprap design,
 where $k_s = d_{90}$
 = 0.038 for discharge capacity calculations in riprap design,
 where $k_s = d_{90}$

SAM uses different values for the Strickler function, depending on the calculations to be made. Chow (1959) recommends the use of 0.0342 for natural sediment, so that is the default value. In accordance with EM 1110-2-1601 (USACE 1991, 1994), 0.0342 is also used for velocity and stone size calculations. Thus, the same Strickler function is used in specified panels for cross-sections where some panels have riprap and others have natural sediment. Also in accordance with EM 1110-2-1601, 0.038 is used for water surface calculations after riprap has been calculated. In this case, n-values for all panels in the cross section will use this constant whether riprap was prescribed for that panel or not, possibly calculating some n-values incorrectly. Problems can be avoided by using another roughness equation in panels without riprap.

Limerinos n-value Predictor

Limerinos (1970) developed an empirical relative roughness equation for coarse, mobile bed streams using field data. He correlated n-values with hydraulic radius and bed sediment size. The resulting equation is shown below.

$$n = \frac{0.0926 R^{1/6}}{1.16 + 2.0 \log_{10} \left(\frac{R}{d_{84}} \right)} \quad \text{Equation 2-16}$$

where

d_{84} = the particle size, ft, for which 84% of the sediment mixture is finer.
 Data ranged from 1.5 mm to 250 mm.
 n = Manning's n value. Data ranged from .02 to 0.10.
 R = Hydraulic radius, ft. Data ranged from 1 to 6 ft.

Grain sizes in Limerinos's data ranged from very course sand to large cobbles. Consequently, it follows that this equation is applicable to gravel/cobble bed streams and to bed regimes similar to those found in such streams and within the energy spectrum contained in Limerinos' field data. n-values predicted with the Limerinos equation are sufficiently larger than those predicted by the Strickler equation indicating that some loss other than grain roughness must have been present. The Limerinos equation is not applicable to lower regime flow nor does it forecast the transition between upper and lower regimes.

Burkham and Dawdy (1976) showed that the Limerinos equation could be used in sand bed streams provided the regime was plane bed. In their analysis they extended the range of the relative roughness parameter as follows.

$$600 < \frac{R}{d_{84}} < 10,000$$

Equation 2-17

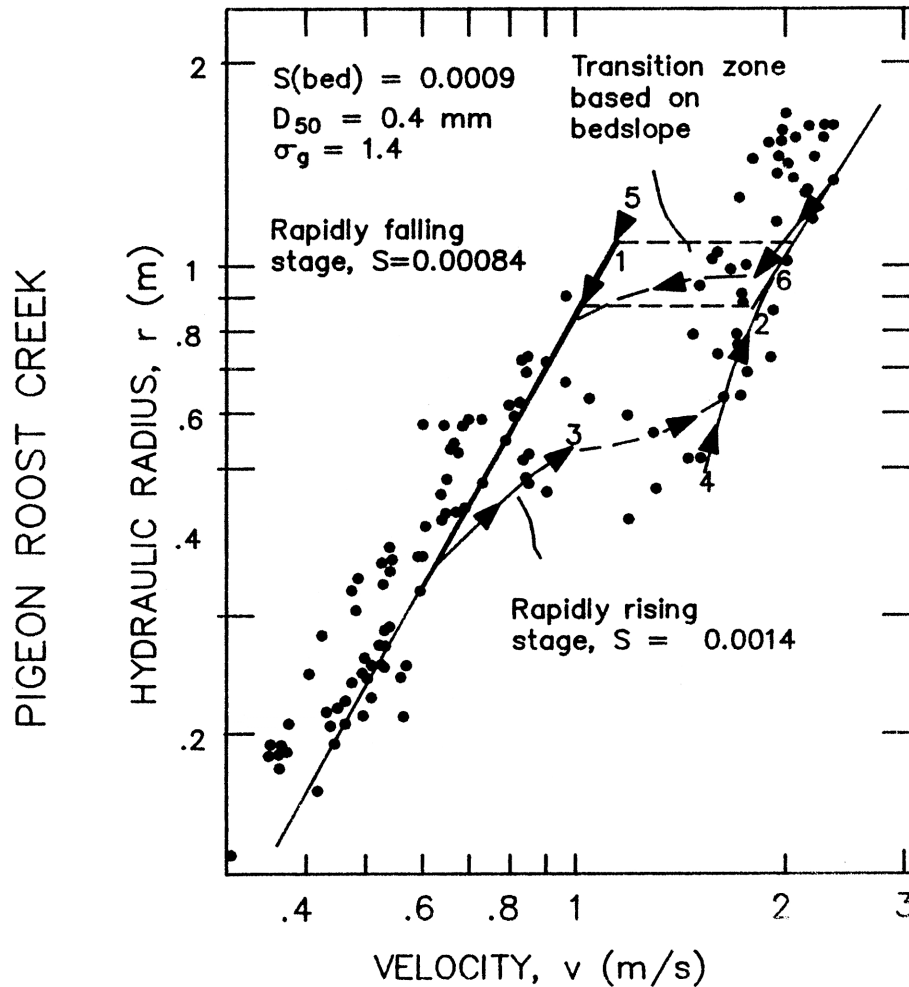

Figure 2.4. Velocity versus hydraulic radius in a mobile bed stream, used with permission of California Institute of Technology.

Brownlie (1983) Bed-roughness Predictor

In sediment transport calculations it is important to link n -values to the bed regime. This is particularly true when hydraulic conditions shift between upper regime and lower regime flow.

Brownlie sought to reconstitute the discontinuity in the graph of hydraulic radius versus velocity, Figure 2.4. (Brownlie 1983) In the process of his research, Brownlie collected the known sediment data sets, 77 in all, containing 7027 data points. Of the total, 75 percent were from flume studies and 25 percent from field tests. He used 22 of these data sets and demonstrated a significant agreement with both field and laboratory data.

Brownlie's basic equations were modified for SAM to display bed roughness as a coefficient times the grain roughness. Any consistent set of units are applicable.

$$n = [\text{Bedform Roughness}] * [\text{Strickler Grain Roughness}] \quad \text{Equation 2-18}$$

The resulting form of the equations for lower and upper regime are:

LOWER REGIME FLOW:

$$n = \left(1.6940 \left(\frac{R}{d_{50}} \right)^{0.1374} S^{0.1112} \sigma^{0.1605} \right) 0.034 (d_{50})^{0.167} \quad \text{Equation 2-19}$$

UPPER REGIME FLOW:

$$n = \left(1.0213 \left(\frac{R}{d_{50}} \right)^{0.0662} S^{0.0395} \sigma^{0.1282} \right) 0.034 (d_{50})^{0.167} \quad \text{Equation 2-20}$$

where

d_{50} = the particle size for which 50% of the sediment mixture is finer.

R = hydraulic radius of the bed portion of the cross section.

S = bed slope; probably the energy slope would be more representative if flow is non-uniform.

σ = the geometric standard deviation of the sediment mixture, where

$$\sigma = 0.5 \left(\frac{d_{84}}{d_{50}} + \frac{d_{50}}{d_{16}} \right) \quad \text{Equation 2-21}$$

TRANSITION FUNCTION:

If the slope is greater than 0.006, flow is always UPPER REGIME.
Otherwise, the transition is correlated with the grain Froude number as follows:

$$F_g = \frac{V}{\sqrt{(s_s - 1) g d_{50}}} \quad \text{Equation 2-22}$$

$$F_g' = \frac{1.74}{S^{1/3}} \quad \text{Equation 2-23}$$

if $F_g < F_g'$ Lower Regime Flow

if $0.8 F_g' < F_g < 1.25 F_g'$ Transition Flow

if $F_g > F_g'$ Upper Regime Flow

where

F_g = grain Froude number.
 s_s = specific gravity of sediment particles.
 V = velocity of flow.
 S = bed slope.

The transition occurs over a range of hydraulic radii and not at a point. Over this range, then, it is a double-valued function, and the transition test will give different regimes depending on which equation is being solved for roughness at that iteration. That is realistic since one expects the rising side of a hydrograph to trigger the transition at a different discharge than does the falling side. This can cause the calculations to fail to converge in the transition zone, and the program will notify the user. **If convergence fails**, inspect the maximum and minimum values printed. Usually, the depths are the same whereas the discharges are significantly different. This signifies that the transition has been located from both the upper regime and the lower regime curves, and the results are the best that can be achieved.

Soil Conservation Service (SCS) Roughness for Grass Cover

Hydraulic roughness curves for five types of grass cover were published by SCS (US Department of Agriculture 1954), Figure 2.5. Each curve type, A through E, refers to grass conditions described in Table 4. EM 1110-2-1601 (USACE 1991, 1994) presents an example of the use of these curves.

Figure 2.5. n-value relationships for grass cover.

Distribution of Hydraulic Roughness

Hydraulic roughness should be prescribed between each pair of coordinates, i.e., for each panel, as shown in Figure 2.6. It is important to establish which portion of the channel cross section is bed and which is bank because the bed roughness predictors apply only to the channel bed. That is, typically the vegetation roughness and bank angle do not permit the bed load to move along the face of the banks. Therefore, the Limerinos and Brownlie n-value equations should not be used to forecast bank roughness, i.e., should not be assigned to the channel banks.

On the other hand, the point bar is a natural source-sink zone for sediment transport. Consequently, it is a location at which Limerinos and Brownlie equations would apply.

Table 4. Characteristics of Grass Cover.

Type	Cover	Condition
A	Weeping lovegrass.....	Excellent stand, tall (average 30 in.)
	Yellow bluestem Ischaemum....	Excellent stand, tall (average 36 in.)
B	Kudzu.....	Very dense growth, uncut
	Bermudagrass.....	Good stand, tall (average 12 in.)
	Native grass mixture (little bluestem, blue grama, other long and short midwest grasses)	Good stand, unmowed
	Weeping lovegrass.....	Good stand, tall (average 24 in.)
	Lespedeza serices.....	Good stand, not woody, tall (average 19 in.)
	Alfalfa.....	Good stand uncut (average 11 in.)
	Weeping lovegrass.....	Good stand, mowed (average 13 in.)
	Kudzu.....	Dense growth, uncut
	Blue grama.....	Good stand, uncut (average 13 in.)
C	Crabgrass.....	Fair stand, uncut (10 to 48 in.)
	Bermudagrass.....	Good stand, mowed
	Common lespedeza.....	Good stand, uncut (average 11 in.)
	Grass-legume mixture--summer (orchard grass, redtop, Italian ryegrass and common lespedeza)	Good stand, uncut (6 to 8 in.)
	Centipedegrass.....	Very dense cover (average 6 in.)
	Kentucky bluegrass.....	Good stand headed (6 to 12 in.)
D	Bermudagrass.....	Good stand, cut to 2.5-inch height
	Common lespedeza.....	Excellent stand, uncut (average 4.5 in.)
	Buffalograss.....	Good stand, uncut (3 to 6 in.)
	Grass-legume mixture--fall, spring (Orchardgrass, redtop, Italian ryegrass, and common lespedeza)	Good stand, uncut (4 to 5 in.)
	Lespedeza sericea.....	After cutting to 2-inch height; very good stand before cutting
E	Bermudagrass.....	Good stand, cut to 1.5-inch height
	Bermudagrass.....	Burned stubble

None of the n-value equations account for momentum or bend losses. Presently, the only technique to account for bend losses is to increase the n-values by some factor. Chow (1959) presents the Cowan method for including bend losses. This method requires the user to input the n-values directly, thus this method could be applied by the user to the SAM input.

Figure 2.6. Prescribing hydraulic roughness.

Composite Hydraulic Properties

The compositing routines in SAM calculate representative hydraulic parameters for cross sections with complex geometry and variable roughness. Representative hydraulic parameters are used to calculate the same normal depth that would be calculated by a more rigorous analysis that analyzed each homogeneous cross-section subarea separately. Due to the obfuscated relationships between variables that can occur in compound and complex channels, parameter definition for a composite variable may be different than normally employed for that variable. For example, in the alpha compositing method, the composite hydraulic radius is not defined as the total area divided by the wetted perimeter; rather it includes, in addition to the usual geometric element property, the variation of both depth and n-values. There are several methods in the literature for compositing. The alpha method was selected as the default for SAM. Three other methods are provided as options: equal velocity, total force, and conveyance methods.

Alpha Method

The discussion of the derivation and use of hydraulic properties by the Alpha method appears in Appendix C, EM 1110-2-1601 (USACE 1991, 1994). A cross section is subdivided into panels between coordinate points. The divisions between panels are assumed to be vertical. The cross section is not subdivided between channel and overbanks for this calculation.

A water-surface elevation is either assigned or assumed, and calculations begin at the first wet panel in the cross section. The geometric properties of area and wetted perimeter are calculated, and the panel's hydraulic radius is calculated from them. The assigned roughness for the panel is converted to a Chezy C, and a panel conveyance is calculated. Computations move panel by panel to the end of the cross section. The composite cross-sectional area is defined as the sum of all the panel subareas and is the true area. The composite velocity is defined as the total discharge divided by the area, conserving continuity. The composite hydraulic radius is conveyance weighted as given by the following equation:

$$\bar{R} = \frac{\sum_{i=1}^k R_i C_i A_i \sqrt{R_i}}{\sum_{i=1}^k C_i A_i \sqrt{R_i}} \quad \text{Equation 2-24}$$

where:

\bar{R} = the composite hydraulic radius
k = the number of panels
i = the panel number
 $R_i = A_i / P_i$

C_i = the panel Chezy roughness coefficient
 A_i = the panel cross-sectional area
 P_i = Wetted perimeter in wet panel i

The composite roughness coefficient, \bar{n} , is calculated using the composite \bar{R} in the Manning equation.

$$\bar{n} = \frac{1.486 \bar{R}^{\frac{2}{3}} S^{\frac{1}{2}} \sum_{i=1}^k A_i}{Q} \quad \text{Equation 2-25}$$

where:

S = energy slope
 Q = total discharge

The alpha method ignores roughness on vertical walls, and renders roughness contributions negligible when there are steep side slopes. When significant roughness is contributed by vertical or steep side slopes, one of the other compositing methods should be employed.

Equal Velocity Method

A more rational compositing method for cross-sections with rough vertical walls or steep side slopes is the equal velocity method. It was proposed independently by both Horton and Einstein (Chow, 1959) and assumes that the velocity is equal in all panels. All hydraulic variables are calculated in the normal fashion except the Manning roughness coefficient, which is calculated using the following equation.

$$\bar{n} = \frac{\left(\sum_{i=1}^{k-1} P_i n_i^{1.5} \right)^{2/3}}{\left(\sum_{i=1}^{k-1} P_i \right)^{2/3}} \quad \text{Equation 2-26}$$

where

\bar{n} = the composite n-value for the total section
 n_i = n-value in wet panel i
 k = number of panels

Since only wetted perimeter, and not hydraulic radius, appears in this equation, it is always well behaved. EM 1110-2-1601 (USACE 1991, 1994) discusses two other equal velocity methods. However, Horton's method was

retained in SAM.hyd because of its simplicity. It is adequate for simple cross-section shapes, and it is programmable for complex cross-section shapes.

Total Force Method

This method was proposed by Pavlovskii, by Muhlhofer, and by Einstein and Banks (Chow, 1959). It is based on the hypothesis that the total force resisting the flow is equal to the sum of the forces resisting the flow in each panel. The resulting composite n-value is

$$\bar{n} = \frac{\left(\sum_{i=1}^k P_i n_i^2 \right)^{1/2}}{\left(\sum_{i=1}^k P_i \right)^{1/2}} \quad \text{Equation 2-27}$$

where

- P_i = Wetted perimeter in wet panel i
- n_i = n-value in wet panel i
- P = Total wetted perimeter in cross section

Conveyance Method

With the conveyance method, a composite roughness coefficient is calculated based on weighted conveyances in three subsections. The conveyance method separates the overbanks from the channel so the calculations can be confined to strips, or subsections within the cross section, having similar hydraulic properties. The conveyance for each subsection can be calculated and the values summed to provide the conveyance for the entire cross section. The Manning equation is used to calculate conveyance instead of the Chezy equation used in the alpha method. Composite hydraulic radius is calculated as total area divided by total wetted perimeter, rather than as a conveyance weighted parameter -- thus the compositing characteristics are concentrated in the Manning's roughness coefficient. Conveyance for the overbanks and channel are calculated in English units using the following equations:

$$K_{LOB} = \frac{1.486 A_{LOB} \left(\frac{A_{LOB}}{P_{LOB}} \right)^{2/3}}{\sum_{i=1}^{i=LCB} P_i n_i}$$

$$K_{CH} = \frac{1.486 A_{CH} \left(\frac{A_{CH}}{P_{CH}} \right)^{2/3}}{\sum_{i=LCB}^{i=RCB} P_i n_i}$$

$$K_{ROB} = \frac{1.486 A_{ROB} \left(\frac{A_{ROB}}{P_{ROB}} \right)^{2/3}}{\sum_{i=LCB}^k P_i n_i}$$

Equation 2-28

$$K_{TOTAL} = K_{LOB} + K_{CH} + K_{ROB}$$

where:

K = conveyance
 LOB = Left overbank
 CH = channel
 ROB = right overbank
 LCB = left channel bank
 RCB = right channel bank

The composite hydraulic radius is calculated using the following equation:

$$\bar{R} = \frac{\sum_{i=1}^k A_i}{\sum_{i=1}^k P_i} \quad \text{Equation 2-29}$$

$$\bar{n} = \frac{1.486 A_{TOTAL} \bar{R}^{2/3}}{K_{TOTAL}} \quad \text{Equation 2-30}$$

The composite Manning's roughness coefficient for the total channel is calculated using the following equation:

Compositing in a narrow-deep channel

The importance of accounting for the roughness of the side slopes in the calculation of normal depth is illustrated by the following example. A proposed trapezoidal channel has a 60 ft base width, 1V:2H side slopes, a slope of 0.001, and a design discharge of 5000 cfs. Assuming that the sides slopes have a roughness coefficient of 0.08 and the bed has a roughness coefficient of 0.030, normal depth and composited hydraulic parameters, calculated using the four compositing methods in SAM, are shown in the following tabulation:

Comparison of Calculated Composite Hydraulic Parameters Deep-Narrow Channel with High Side Slope Roughness					
Method	Depth ft	Area sq ft	\bar{R} ft	Velocity ft/sec	\bar{n}
Alpha	10.4	839	10.0	6.0	0.037
Equal Velocity	14.7	1312	10.4	3.8	0.059
Total Force	15.0	1356	10.6	3.7	0.062
Conveyance	14.3	1262	10.2	4.0	0.056

The calculated depth is significantly lower with the alpha method because the side slope roughness is inadequately accounted for due to the assumption of vertical divisions between panels. If the side slopes had been vertical the alpha method would have completely neglected their contribution to roughness.

Compositing compound channels and overbanks

Variable roughness and depth across the cross-section introduce turbulence into the flow which results in additional energy loss due to the momentum transfer. Existing theory is currently inadequate to properly quantify the magnitude of these losses. However, it is important that these losses be recognized and considered when choosing a compositing technique.

Compositing by the equal velocity and total force methods can overemphasize the contribution to roughness of channel subareas in cases where homogeneous flow conditions do not exist, such as on irregular overbanks. The same effect can occur with the conveyance method in SAM when only a single subsection is considered. James and Brown (1977) reported that without adjustments to either the resistance coefficient or the hydraulic radius, using composite hydraulic parameters in the Manning or Chezy equations did not accurately predict the stage-discharge relation in a channel-floodplain configuration when there were shallow depths on the floodplain-- $1.0 < Y/D < 1.4$, where Y is water depth in the channel and D is the bank height. However, the effects of geometry seemed to disappear at the higher stages, i.e., for $Y/D > 1.4$, when it no longer became necessary to make any correction to the basic equations. Figure 2.7 summarizes that finding, stressing that the conveyance (separate-channels) method is the best choice if Y/D falls within the 1.0 to 1.4 range and that another method should be used if $Y/D > 1.4$.

Figure 2.7. Comparison of measured data and theoretical methods.

Effective Hydraulic Parameters for Sediment Transport

The problem of obtaining representative hydraulic parameters is critical when making sediment transport calculations involving complex cross sections. The velocity, depth, width and slope are needed for subsections having similar hydraulic properties. This requirement leads to a compositing technique that

produces an EFFECTIVE WIDTH and an EFFECTIVE DEPTH. Variables in the following equations are illustrated in Figure 2.8.

$$EFD = \frac{\sum D_i A_i D_i^{2/3}}{\sum A_i D_i^{2/3}} \quad \text{Equation 2-31}$$

$$EFW = \frac{\sum A_i D_i^{2/3}}{EFD^{5/3}} \quad \text{Equation 2-32}$$

where

A_i = Area of panel i , $\Delta X D_i$
 D_i = Average depth of panel i , $1/2 (A+B)$
 EFD = Effective Depth of the cross section
 EFW = Effective Width of the cross section

Figure 2.8. Calculating effective depths and widths.

In SAM the slope can be either the bed slope, water surface slope, or energy slope since all are parallel in normal depth computations. Effective values are calculated in SAM after the normal depth has been determined. Although effective values are calculated for both overbanks and the channel, only the channel values are written into the sediment transport input file for sediment transport calculations.

Flow Distribution Across the Cross Section

Flow distribution across the cross section will be calculated when all the variables in the uniform flow equation are prescribed. In addition, flow distribution will be calculated after the uniform flow equation is solved for an unknown variable. A conveyance weighted discharge, Q_i , is calculated for each panel using the following equation:

$$Q_i = Q \left(\frac{C_i A_i \sqrt{R_i}}{\sum C_i A_i \sqrt{R_i}} \right) \quad \text{Equation 2-33}$$

where

Q = total discharge
C = Chezy coefficient
A = area
R = hydraulic radius
i = panel number

Bottom Width Calculation-Fixed Bed

This option allows bottom width to become the dependent variable in the uniform flow equation:

$$W = f(Q, n, D, z, S) \quad \text{Equation 2-34}$$

where

Q = water discharge
D = water depth
z = side slopes of the channel
n = n-value
S = energy slope

This bottom width calculation is strictly a solution of the uniform flow equation for a fixed bed and does not consider sediment transport requirements. This option can only be used when a trapezoidal channel is specified on a CT-record. The compound channel may have up to 3 trapezoidal-shaped templates. The solution technique begins by sizing the low flow channel first, then solving for the main channel and then the overbank channel.

Energy Slope Calculation

This option allows the energy slope to become the dependent variable in the uniform flow equation:

$$S = f(Q, n, W, D, z) \quad \text{Equation 2-35}$$

The calculations are trial and error and convergence may be difficult. The Brownlie n-value relationships may result in convergence failure due to the discontinuity at the transition between lower and upper regime flow. SAM.hyd prints a message to the output file when convergence fails.

Hydraulic Roughness Calculation

This option allows the n-value to become the dependent variable in the uniform flow equation.

$$n = f(Q, W, D, z, S) \quad \text{Equation 2-36}$$

It is especially useful for calculating unknown roughness for one section of the cross-section when roughness is known for other sections of the cross-section.

This calculation, like the other solutions of the uniform flow equation which involve compositing, is trial and error. A simple solution of the Manning equation for the total cross section is used to calculate the first trial roughness. Roughness can be specified in some panels and calculated for others. If a roughness in a panel is input, the program will convert it to a k_s using the Keulegan equation for fully rough flow unless the equation specified is Strickler. However, only the Keulegan or Strickler equations can be used to calculate roughness. If the program is asked to calculate roughness using the Manning's equation option then it automatically uses the Strickler equation. If the program is asked to calculate roughness using the Brownlie or Limerinos equation then there is nothing to calculate because the roughness has been implicitly determined by the bed gradation used. If the program is asked to calculate roughness using the Grass equations then there is still nothing to calculate because the roughness is again implicitly determined by the Grass equation chosen.

NOTE: Limerinos, Brownlie and the Grass equations are not to be used with negative roughness values because there is nothing to calculate — the roughness is implicitly determined by the bed gradation or the grass.

Roughness in the remaining panels will be calculated as a specified proportion of k_s for the Manning, Strickler, and Keulegan equations. The iterative solution for k_s uses the secant method for convergence as follows.

$$X_3 = X_2 - \left(\frac{f(X_2)}{f(X_2) - f(X_1)} \right) (X_2 - X_1) \quad \text{Equation 2-37}$$

where

- X_1 = is the first trial value of k_s
- $f(X_1)$ = is the difference between Q_{true} and the calculated Q for X_1
- X_2 = is the second trial value of k_s
- $f(X_2)$ = is the difference between Q_{true} and calculated Q for X_2
- X_3 = is the next trial value of k_s .

Of the several equations for hydraulic roughness, the Strickler equation is the most likely to converge. The Limerinos, Brownlie, and grass equations are independent of k_s and therefore cannot be used to solve for k_s . This algorithm is primarily intended for use with equations using k_s . Expect convergence problems with other equations.

Water Discharge Calculation

This option allows the water discharge to become the dependent variable in the uniform flow equation.

$$Q = f(Q, W, D, z, S) \quad \text{Equation 2-38}$$

This calculation, like the other solutions of the uniform flow equation which involve compositing, is trial and error. It also uses the secant method for convergence. When convergence fails, assume a range of discharges and use the normal depth calculations to arrive at the correct value.

Riprap Size for a Given Velocity and Depth

When flow velocity and depth are known, the riprap size is calculated using the following equation, taken from EM 1110-2-1601(1991,1994):

$$d_{30cr} = S_f C_S C_V C_T D \left[\left(\frac{\gamma_w}{\gamma_s - \gamma_w} \right)^{0.5} \frac{V_{AVE} C_B}{\sqrt{K_I g D}} \right]^{2.5} \quad \text{Equation 2-39}$$

where

d_{30CR} = Critical d_{30} (i.e. minimum d_{30}) size for stable riprap

S_f = Safety factor

C_S = Coefficient of incipient failure

C_V = vertical velocity coefficient

C_T = coefficient for riprap thickness

D = local water depth

γ_w = unit weight of water

γ_s = unit weight of riprap

V_{AVE} = average channel velocity

C_B = bend correction for average velocity (V_{SS}/V_{AVE})

K_I = Correction for side slope steepness

g = Acceleration of gravity

Required input data for simple riprap calculations are: average channel velocity, depth at the toe of the riprap, channel width, side slope, bend radius, bend angle, riprap specific weight, and whether the cross-section is trapezoidal or natural.

Riprap Gradation Tables

Size and specific gravity of available riprap are needed for this calculation, and the 13 standard riprap sizes shown in EM 1110-2-1601 are encoded into SAM.hyd as shown in the Table 6. Calculations begin with the smallest size stone and continue until a stable size is reached.

Quarry-Run Stone

A known riprap gradation table may be specified in SAM. This input is not currently available in SAMwin. This option is useful for quarry-run riprap where the gradation is known. Up to 5 sizes of quarry run riprap can be encoded. These gradations should be entered one size per record starting with the smallest and ending with the largest size. When this information is present, riprap size computations use the quarry run stone. When quarry run stone is prescribed, those stone sizes are used in lieu of the gradation tables encoded in SAM.

Table 6. Graded Riprap Sizes.

Low Turbulence zones, placed in the dry, $\gamma_s = 165 \text{ lbs/cuft}$

Layer No.	DMAX ¹ in	D30 ¹ ft	D50 ¹ ft	D90 ¹ ft	POROSITY ² %
1	9	0.37	0.43	0.53	38
2	12	0.48	0.58	0.70	38
3	15	0.61	0.73	0.88	38
4	18	0.73	0.88	1.06	38
5	21	0.85	1.03	1.23	38
6	24	0.97	1.17	1.40	38
7	27	1.10	1.32	1.59	38
8	30	1.22	1.46	1.77	38
9	33	1.34	1.61	1.94	38
10	36	1.46	1.75	2.11	38
11	42	1.70	2.05	2.47	38
12	48	1.95	2.34	2.82	38
13	54	2.19	2.63	3.17	38

Notes:

¹ These values were taken from EM 1110-2-1601.

² These values are estimated from one set of field data.

Riprap Size for a Given Discharge and Cross-Section Shape

Riprap size is a more complicated calculation when water discharge and cross section are given than it is when the flow velocity and depth are given because n -value becomes a function of riprap size. The computational procedure in SAM.hyd is as follows.

The computations begin with the unprotected channel. The bed sediment size is determined as the d_{50} calculated from the given bed gradation. Input must include hydraulic roughness equations and either n -values or k_s values, as required for normal depth computations. If the Strickler equation is selected for hydraulic roughness, the Strickler coefficient is 0.034, which is the value for natural sediment where $k_s = d_{50}$ (Chow, 1959). Normal depth is calculated using the alpha method, and flow is distributed across the section. Stability of the bed sediment is then calculated at each cross section coordinate using the distributed velocity and the depth at that point. Shield's Diagram is used to test for particle stability. The calculated shear stress is compared to the critical shear stress determined from Shield's diagram.

$$\tau_c = \Theta (\gamma_s - \gamma_w) d_{50}$$

Equation 2-40

where:

τ_c = critical shear stress

Θ = Shield's parameter

If this test shows that the actual bed shear stress exceeds the critical value then the bed sediment is diagnosed as unstable. If the panel is designated as a panel where riprap computations are desired, SAM will solve the riprap equation to find the smallest riprap size that will be stable. If the panel is not so designated, the program prints a message to the output file concerning the instability.

Considerable care must be employed when applying the cross-section shape option because flow conditions may be outside the range of conditions used to develop the riprap equations. When this option is used, it is important that the side slope protection be defined as a single panel in the geometry input. SAM will use 0.8 times the maximum depth in the panel for the local flow depth in the riprap equation. When a bend radius is specified, SAM uses the average velocity in the cross section for V_{AVE} in the riprap equation. Therefore, it is important that the input geometry include only channel geometry and discharge. When a bend radius is not specified, SAM uses the calculated panel velocity for V_{AVE} in the riprap equation. This calculation may provide useful information for compound channels in straight river reaches, but it is an extension of the procedure outlined in EM 1110-2-1601. Careful study of the recommendations and guidelines described in EM 1110-2-1601 should be considered essential.

In SAM, riprap computations begin with the smallest rock size. The hydraulic roughness equation, in each panel designated as having riprap, is automatically changed to the Strickler equation and the Strickler coefficient, is set equal to 0.034. Normal depth is calculated for the resulting n-values. The alpha method is used to calculate normal depth and flow is distributed across the section. The riprap size equation is solved for each panel. When the resulting size is stable in each panel, riprap computations are finished. Otherwise, computations move to the next larger riprap size and the procedure is repeated.

After the stable stone size is determined, a stage discharge curve is calculated for the riprapped channel. The Strickler coefficient, which was 0.034 when determining stone size, is increased to 0.038 in this calculation for flow capacity. This calculation determines the rating curve with the selected riprap in place.

Blench Regime Equations

Stable channel dimensions may be calculated using the Blench (1970) regime equations. These regime equations are also shown in ASCE Manual 54 (ASCE 1975). The equations were intended for design of canals with sand beds. The basic three channel dimensions, width, depth and slope, are calculated as a

function of bed-material grain size, channel-forming discharge, bed-material sediment concentration, and bank composition.

$$W = \left(\frac{F_B Q}{F_S} \right)^{0.5} \quad \text{Equation 2-41}$$

$$F_B = 1.9 \sqrt{d_{50}} \quad \text{Equation 2-42}$$

$$D = \left(\frac{F_S Q}{F_B^2} \right)^{\frac{1}{3}} \quad \text{Equation 2-43}$$

$$S = \frac{F_B^{0.875}}{\frac{3.63 g}{\nu^{0.25}} W^{0.25} D^{0.125} \left(1 + \frac{C}{2,330} \right)} \quad \text{Equation 2-44}$$

where

W = channel width - ft
 F_B = bed factor
 F_S = side factor
 Q = water discharge -cfs
 d_{50} = median grain size of bed material - mm
 D = depth - ft
 S = slope
 C = bed-material sediment concentration - in parts per million
 g = acceleration of gravity - ft/sec²
 ν = kinematic viscosity - ft²/sec

The results are true regime values only if Q is the channel forming discharge. However, a width, depth and slope will be calculated for any discharge by these equations.

Blench suggests that the following values be used for the side factor:

$F_S = 0.10$ for friable banks
 $F_S = 0.20$ for silty, clay, loam banks
 $F_S = 0.30$ for tough clay banks

In order to calculate the Blench regime dimensions, the side factor, bed-material sediment concentration, and the bed-material gradation should be input. SAM.hyd sets default values for the Blench variables if none are specified: $F_S = 0.20$, $C = 0.0$, and $d_{50} = 0.25$ mm.

Stable Channel Dimensions

SAM may be used to calculate stable channel dimensions that will pass a prescribed sediment load without deposition or erosion. This analytical approach (Copeland, 1994) determines dependent design variables of width, slope, and depth from the independent variables of discharge, sediment inflow, and bed material composition. It involves the solution of flow resistance and sediment transport equations, leaving one dependent variable optional. Minimum stream power is used as a third equation for an optional unique solution. This method is based on a typical trapezoidal cross section and assumes steady uniform flow. The method is especially applicable to small streams because it accounts for transporting the bed material sediment discharge in the water above the bed, not the banks, and because it separates total hydraulic roughness into bed and bank components.

Basic Equations for Sand-bed Streams

If the sand-bed option is selected, SAM uses the sediment transport and resistance equations developed by Brownlie (1981). There are separate resistance equations for upper and lower regime flow. The equations are dimensionless and can be used with any consistent set of units.

Upper regime:

$$R_b = 0.2836 d_{50} q_*^{0.6248} S^{-0.2877} \sigma^{0.0813} \quad \text{Equation 2-45}$$

Lower regime:

$$R_b = 0.3742 d_{50} q_*^{0.6539} S^{-0.2542} \sigma^{0.1050} \quad \text{Equation 2-46}$$

$$q_* = \frac{V D}{\sqrt{g d_{50}^3}}$$

where:

- R_b = hydraulic radius associated with the bed
- d_{50} = median grain size
- S = slope
- σ = geometric bed material gradation coefficient

V = average velocity
 D = water depth
 g = acceleration of gravity

To determine if upper or lower regime flow exists for a given set of hydraulic conditions, a grain Froude number F_g and a variable F'_g were defined by Brownlie. According to Brownlie, upper regime occurs if $S > 0.006$ or if $F_g > 1.25 F'_g$, and lower regime occurs if $F_g < 0.8 F'_g$. Between these limits is the transition zone. In the analytical method, $F_g = F'_g$ is used to distinguish between upper and lower regime flow. The program will inform the user which regime is being assumed in the calculations and if the bed forms are in the transition zone.

$$F_g = \frac{V}{\sqrt{g d_{50} \left(\frac{\gamma_s - \gamma}{\gamma} \right)}}$$

Equation 2-47

$$F'_g = \frac{1.74}{S^{0.3333}}$$

where:

γ_s = specific weight of sediment
 γ = specific weight of water

The hydraulic radius of the side slope is calculated using Manning's equation:

$$R_s = \left(\frac{V n_s}{1.486 S^{0.5}} \right)^{1.5}$$

Equation 2-48

where:

R_s = hydraulic radius associated with the side slopes, ft
 V = average velocity, fps
 n_s = Manning's roughness coefficient for the bank

If the roughness height k_s of the bank is known, then it can be used instead of Manning's roughness coefficient to define bank roughness. The model uses Strickler's equation to calculate the bank roughness coefficient:

$$n_s = 0.039 k_s^{\frac{1}{6}} \quad \text{Equation 2-49}$$

where k_s is the roughness height, in ft. For riprap, k_s should be set equal to the minimum design d_{90} .

Composite hydraulic parameters are partitioned in the manner proposed by Einstein (1950):

$$A = R_b P_b + R_s P_s \quad \text{Equation 2-50}$$

where:

A = total cross-sectional area
 P_b = perimeter of the bed
 P_s = perimeter of the side slopes

This method assumes that the average velocity for the total cross section is representative of the average velocity in each subsection.

Concentration, C, in ppm, is calculated using the Brownlie sediment transport equation, which is also a regression equation and is based on the same extensive set of flume and field data used to develop his resistance equations. This equation was chosen because of its compatibility with the resistance equations, which are coupled with the sediment transport equation in the numerical solution:

$$C = 9022 (F_g - F_{go})^{1.978} S^{0.6601} \left(\frac{R_b}{d_{50}} \right)^{-0.3301} \quad \text{Equation 2-51}$$

$$F_{go} = \frac{4.596 \tau_{*o}^{0.5293}}{S^{0.1405} \sigma^{0.1606}} \quad \text{Equation 2-52}$$

$$\tau_{*o} = 0.22 Y + 0.06 (10)^{-7.7 Y} \quad \text{Equation 2-53}$$

where

$$Y = \left(\sqrt{\frac{\gamma_s - \gamma}{\gamma}} \right)^{-0.6}$$

and

$$R_g = \frac{\sqrt{g d_{50}^3}}{\nu}$$

Basic Equations for Gravel-bed Streams

If the gravel-bed option is selected, SAM uses equations more appropriate for coarse bed streams. Sam uses the Limerinos (1970) equation to calculate grain roughness on the bed. The Manning equation is used to calculate the roughness on the channel side slope. Additional roughness may be added in the manner suggested by Cowan (1956). Sediment transport is calculated using the Meyer-Peter and Muller (1948) equation.

The Limerinos equation accounts for the grain roughness in a uniform reach of a gravel-bed stream that is relatively free of bed forms. The Limerinos equation may be presented in dimensionless units as:

$$\frac{V}{U'_*} = 5.66 \log \left(3.80 \frac{R'_b}{d_{84}} \right)$$

where:

V = average velocity

U'_* = shear velocity associated with grain roughness

R'_b = hydraulic radius associated with grain roughness

d_{84} = grain size for which 84% of the bed is finer.

Manning's roughness coefficient associated with grain roughness can be determined from the Limerinos equation:

$$n'_b = \frac{CME R_b'^{1/6}}{g 5.66 \log \left(3.80 \frac{R'_b}{d_{84}} \right)}$$

where:

n'_b = roughness coefficient associated with bed

CME = 1.486 English units

1.0 SI units

R'_b = bed hydraulic radius associated with grain roughness (ft or m)
 g = acceleration of gravity (ft/s or m/s)
 d_{84} = grain size for which 84% of the bed is finer (ft or m)

Additional bed roughness may be added to the grain bed roughness using the Cowan (1956) method. Roughness may be added to account for factors such as surface irregularities, variability in channel shape, obstructions, vegetation and meandering. Meandering is accounted for with a meandering coefficient, m . In a straight channel the meandering coefficient is 1.0. Appropriate values for the meandering coefficient and additions to the grain roughness n -value can be found in Cowan (1956) and Chow (1959). Using the Cowan equation the total bed roughness coefficient is:

$$n_b = m(n''_b + n'_b)$$

where:

n_b = total bed roughness coefficient
 m = Cowan meander coefficient
 n''_b = bed roughness other than grain roughness.

Using the Manning equation the hydraulic radius associated with the bed is calculated

$$R_b = \left(\frac{V n_b}{S^{1/2} CME} \right)^{3/2}$$

where:

S = channel slope.

The hydraulic radius associated with the bank or side slope is

$$R_s = \left(\frac{V n_s}{S^{1/2} CME} \right)^{3/2}$$

where:

n_s = the roughness coefficient associated with the side slope.

Values for m , n''_b , and n_s must be selected by the user and provided as program input.

If the roughness height, k_s , of the bank is known, then it can be used instead of Manning's roughness coefficient to define bank roughness. The model uses Strickler's equation to calculate the bank roughness coefficient

$$n_s = 0.039 k_s^{1/6}$$

where k_s is the roughness height in feet.

Composite hydraulic parameters are partitioned in the manner proposed by Einstein (1950),

$$A = R_b P_b + R_s P_s$$

where:

- A = total cross-sectional area
- P_b = perimeter of the bed
- P_s = perimeter of the side slopes.

This method assumes that the average velocity for the total cross section is representative of the average velocity in each subsection (equal velocity method of compositing).

Sediment transport for the gravel-bed option is calculated using the Meyer-Peter Muller equation:

$$\left(\frac{k_r}{k'_r} \right)^{3/2} \gamma_w R_b S = 0.047 (\gamma_s - \gamma_w) d_m + 0.25 \left(\frac{\gamma_w}{g} \right)^{1/3} \left(\frac{\gamma_s - \gamma_w}{\gamma_s} \right)^{2/3} g_s^{2/3}$$

where:

- k_r = total bed roughness = $1/n_b$
- k'_r = particle roughness = $1/n'_b$
- γ_w = specific weight of water, lbs/ft³ or N/m³
- γ_s = specific weight of sediment
- d_m = median sediment size, ft or m
- g_s = sediment transport in lbs/sec-ft or N/sec-m
- R_b = bed hydraulic radius in ft or m

and

$$\left(\frac{k_r}{k'_r}\right)^{3/2} R_b = R'_b$$

and

$$d_m = \sum_{i=1}^n f_i d_i$$

where:

f_i = fraction of size class “i” in bed

d_i = geometric mean diameter of size class “i” in bed.

Calculating sediment discharge and concentration

A typical cross section, with the critical hydraulic parameters labeled, is shown in Figure 2.9. The concentration calculated from the sediment transport equation applies only vertically above the bed. Total sediment transport in weight per unit time is calculated by the following equation:

$$Q_s = \gamma C B D V \quad \text{Equation 2-54}$$

where:

Q_s = sediment transport in weight/time

B = base width

$$\bar{C} = \frac{Q_s}{0.0027 Q} \quad \text{Equation 2-55}$$

An average concentration for the total discharge is then calculated:

where:

\bar{C} = concentration using the total discharge, in ppm

Q_s = sediment transport in tons/day

Q = discharge in cfs

Figure 2.9. Typical cross section used in analytical method.

Input Requirements

Required input data are sediment inflow concentration, side slope, bank roughness coefficient, bed material d_{50} , bed material gradation coefficient, and water discharge. If sediment inflow is to be calculated, which is the recommended procedure, then additional data are required for the supply reach. These are: base width, side slope, bank roughness coefficient, bed-material median grain size, geometric gradation coefficient, average slope, and discharge. It is important that the base width be representative of the total movable-bed width of the channel. The bank roughness should serve as a composite of all additional roughness factors, i.e., channel irregularities, variations of channel cross-section shape, and the relative effect of obstructions, vegetation, and sinuosity. Only flow that is vertical above the bed is considered capable of transporting the bed material sediment load. If the gravel bed calculations are to be made, the user has the option of inputting the added roughness and meander multiplier for the Cowan option.

Water Discharge

The design discharge is critical in determining appropriate dimensions for the channel. Investigators have proposed different methods for estimating that design discharge. The 2-year frequency flood is sometimes used for perennial streams. For ephemeral streams the 10-year frequency is sometimes used. The "bankfull" discharge is sometimes suggested. Others prefer using the "effective" discharge, which is the discharge that transports the most bed material sediment. Currently, there is no generally accepted method for determining the channel-forming discharge. It is recommended that a range of discharges be used in the analysis to test sensitivity of the solution.

Inflowing Sediment Discharge

This is the concentration of the inflowing bed material load. It is best if SAM.hyd is allowed to calculate the sediment concentration based on hydraulic conditions in the sediment supply reach. The bed material composition is defined by the median grain size and the gradation coefficient.

Valley Slope

Valley slope is the maximum possible slope for the channel invert. This value is used in the test for sediment deposition. If the required slope exceeds the prescribed valley slope, the following message is printed:

```
>>>>MINIMUM SLOPE IS GREATER THAN VALLEY SLOPE - THIS IS A SEDIMENT TRAP <<<<
```

Bank Slopes and Roughness

The analytical method assumes that all bed material transport occurs over the bed of the cross section and that none occurs above the side slopes. Therefore, the portion of water conveyed above the side slopes expends energy but does not transport sediment, making "Flow Distribution" an extremely important calculation. The input parameters for flow distribution are bank angle and bank roughness. The recommended procedure to use for this is discussed in Chapter 5 of EM 1110-2-1601 (USACE 1991, 1994). Any roughness input for the bed will be disregarded by the calculations as bed roughness is calculated using the Brownlie equations. For maximum transport of sediment, use the steepest bank angle allowed by bank stability requirements.

Range of Solutions

Stable channel dimensions are calculated for a range of widths. For each combination of slope and base width, a unique value of depth is calculated. This can be used to evaluate stability in an existing channel or in a proposed design channel. It is important to consider river morphology when interpreting these calculated values. It is also important to be consistent in the selection of channel dimensions. That is, once a width is selected, the depth and slope are fixed. This allows the designer to select specific project constraints, such as right-of-way or bank height or minimum bed slope, and then arrive at a consistent set of channel dimensions.

If the calculations indicate that the slope of the project channel needs to be less than the natural terrain, the slopes in the table can be used to aid in spacing drop structures or in introducing sinuosity into the project alignment.

An example of a family of slope-width solutions that satisfy the resistance and sediment transport equations for the design discharge is illustrated by Figure 2.11. Any combination of slope and base width from this curve will be stable for the prescribed channel design discharge. Combinations of width and slope that

plot above the stability curve will result in degradation, and combinations below the curve will result in aggradation. The greater the distance from the curve, the more severe the instability.

Constraints on this wide range of solutions may result from a maximum possible slope, or a width constraint due to right-of-way. Maximum allowable depth could also be a constraint. Depth is not plotted in Figure 2.10, but it is calculated for each slope and width combination determined. With constraints, the range of solutions is reduced.

Different water and sediment discharges will produce different stability curves. First, the stable channel solution is obtained for the channel-forming discharge. Then, stability curves are calculated for a range of discharges to determine how sensitive the channel dimensions are to variations in water and sediment inflow events.

The stable channel dimensions are calculated for a range of widths on either side of a prescribed median value. If no median value is prescribed, the program assigns a value based on the hydraulic geometry equation proposed in EM 1110-2-1418 (USACE 1994).

$$B = 2.0 Q^{0.5}$$

Equation 2-56

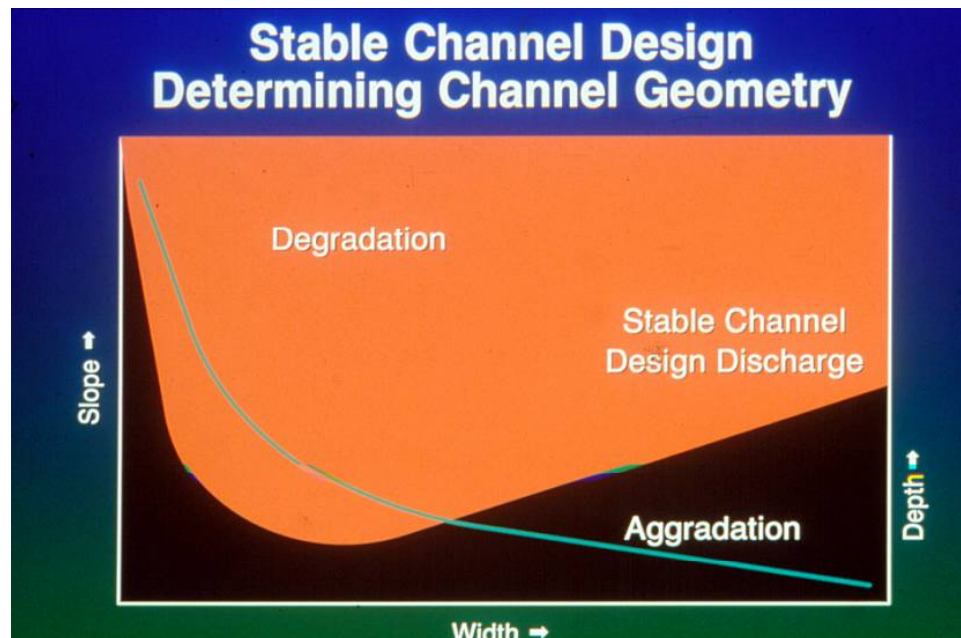

Figure 2.10. Graph of a family of slope-width solutions.

The SAM program assigns 20 base widths for the calculation, each with an increment of 0.1B. Calculations for these conditions are displayed as output. Stability curves can then be plotted from these data.

A solution for minimum stream power is also calculated by the model. This solution represents the minimum slope that will transport the incoming sediment load. Solution for minimum slope is obtained by using a second-order Lagrangian interpolation scheme. Opinions are divided regarding the use of minimum stream power to uniquely define channel stability.

An optional use of the analytical method is to assign a value for slope, thereby obtaining unique solutions for width and depth. Typically there will be two solutions for each slope.

Meander Program

Langbein and Leopold (1966) proposed the sine-generated curve as an analytical descriptor for meander planform in sand-bed rivers. Their “theory of minimum variance” is based on the hypothesis that the river will seek the most probable path between two fixed points, which is described by the following equation:

$$\phi = \omega \cos \frac{2 s \pi}{M}$$

Equation 2-57

where:

- ϕ = angle of the meander path with the mean longitudinal axis
- ω = maximum angle a path makes with the mean longitudinal axis
- s = the curvilinear coordinate along the meander path
- M = the meander arc length

These variables are shown in Figure 2.11.

Meander planform may thus be described with a shape parameter, ω , and a scale parameter, M . The sine generated curve has been shown to effectively replicate meander patterns in a wide variety of natural rivers. (Langbein and Leopold, 1966)

The purpose of the meander algorithm in SAM is to provide both curvilinear and Cartesian coordinates for a meander planform based on the sine-generated curve. Required input are the meander arc length, M , and the meander wave length, λ . The meander arc length can be determined from the valley slope, the meander wave length, and the design stable channel slope.

Figure 2.11. Variable definitions for the Meander Program.

$$M = \frac{\lambda * \text{valley slope}}{\text{channel slope}} \quad \text{Equation 2-58}$$

The meander wavelength can be determined using hydraulic geometry relationships or the analogy methodology. Generalized hydraulic geometry relationships for meander wavelength can be found in EM 1110-2-1418 and Copeland et al 2001. The analogy method is described in Chapter 5 of Copeland et al, 2001.

3 Theoretical Basis for SAM.sed Calculations

Purpose

Sediment transport functions can be used to calculate the bed material portion of the sediment discharge rating curve. This rating curve can then be used in the Flow-Duration Sediment-Discharge Rating Curve Method, programmed in SAM.yld, to calculate the bed-material sediment yield. Various sediment transport equations have been programmed into SAM.sed.

EM 1110-2-4000, "Sediment Investigations of Rivers and Reservoirs," provides a good description of the mechanics of sediment transport (USACE 1989).

General

SAM.sed will calculate a sediment discharge rating curve based on hydraulic conditions and the bed gradation. The hydraulic input data for SAM.sed can be calculated using SAM.hyd or it can be determined external to the program and input directly (SAM.m95 can be used only in DOS mode). SAM.sed will create a partial input data set for SAM.yld. There is also a module, SAM.aid, which provides guidance on the selection of transport functions.

Sediment transport functions in SAM must be used with care. There is no allowance for variability in the size class distribution over time or space. In natural rivers the size class distribution of bed material varies with discharge, reach, time of year, and other temporal factors. SAM's use of a fixed, average size class distribution for all calculations presents the possibility that the calculated transport rates are not truly representative of the natural river. The procedure in HEC-6, which integrates processes over several cross sections and provides a continuity equation for sediment movement, will consequently produce a more reliable result. SAM provides reasonable time-averaged results in cases where the river is in general equilibrium; that is, it is neither aggrading or degrading. It is very important that the user correctly prescribe a representative bed material gradation.

Sediment Transport Functions

The following sediment transport functions have been incorporated into SAM. Except for Brownlie, these functions are also available in HEC-6. Some are identified as "d₅₀" which means the original version was for a single grain size. That capability is provided in SAM.sed. The HEC-6 versions of the functions calculate by grain size class and that capability is also in SAM.sed.

Table 7. Sediment Transport Functions available in SAM.sed.

ACKERS-WHITE.	MPM (1948), D50
ACKERS-WHITE, D50	PARKER
BROWNLIE, D50	PROFITT (SUTHERLAND)
COLBY	SCHOKLITSCH
EINSTEIN (BED-LOAD)	TOFFALETI.

ENGELUND-HANSEN	TOFFALETI-SCHOKLITSCH
LAURSEN (COPELAND)	YANG
LAURSEN (MADDEN), 1985	YANG, D50
MEYER-PETER and MULLER (MPM) (1948)	VAN RIJN

Ackers-White is a version of Ackers-White (1973) which has been modified, at WES, for multiple grain size calculations on sand and/or gravel bed streams. Modifications made by Ackers (1993) have been incorporated.

Ackers-White, D50 is a single grain size function.

Brownlie (1981) is a single grain size function for sand transport.

Colby (1964) is a version of Colby's single grain size function which has been modified at WES for multiple grain size calculations. It is valid for sand transport in streams and small rivers.

Einstein (Bed-load) (1950) is a multiple grain size function used to calculate the bed-load discharge of sand and/or gravel bed streams. The hiding factor has been modified at WES, incorporating the work of Pemberton (1972) and Shen and Lu (1983).

Einstein (Total-load) (1950) is a function that extends the Einstein bed-load calculations to include suspended load by grain size classes and sums them to get the total load.

Engelund (Hansen) (1967) is a version of Engelund-Hansen D₅₀ which has been modified at WES for multiple grain size calculations on sand bed streams.

Laursen (Copeland) (Copeland and Thomas, 1989) is a modification to Laursen's (1958) multiple grain size function, extending its range to larger gravel sizes.

Laursen (Madden) (Madden, 1993) is a multiple grain size function modified by Madden for sand bed transport. It has been used for mixtures of sand and gravel. There is a 1963 modification in HEC-6 that is not available in SAM.

MPM – Meyer-Peter and Muller (1948) is a multiple grain size function for gravel bed rivers. It is not valid when appreciable suspended load is present.

MPM, D50 -- Meyer-Peter and Muller (1948), D50 is a version of the multiple grain size function MPM which has been modified, at WES, using a single grain size function.

Parker (1990) is a version of Parker's multiple grain size function. It can be applied to poorly sorted gravel bed streams. Finer sizes, less than 2 mm, must be excluded from the specified surface size distribution and the gradation must be 100% defined, i.e., there must be a size for which 0% of the material is finer. The bed material sizes used must be representative of the coarse upper layer of the bed.

Profitt (Sutherland) (1983) is a multiple grain size function modification of the Ackers-White formula. It can be used on sand and/or gravel bed streams.

Schoklitsch (1930) is a version of the Schoklitsch single grain size function that has been modified at WES for multiple grain size calculations. It is applicable to sand and gravel bed streams which do not have considerable amounts of suspended sediment transport.

Toffaletti (1968) is a multiple grain size function for sand bed rivers. It is not valid for gravel transport.

Toffaletti-MPM is a combined function for sand and gravel bed streams. Sediment transport is calculated using both functions by size class. Calculated bed load from the Toffaletti function is compared to the total calculated by MPM and the larger is used for bed load. Suspended load is then calculated using Toffaletti.

Toffaletti-Schoklitsch is a combined function for sand and gravel bed streams. Sediment transport is calculated using both functions by size class. Calculated bed load from the Toffaletti function is compared to the total calculated by Schoklitsch and the larger is used for bed load. Suspended load is then calculated using Toffaletti.

- Van Rijn is based on Van Rijn (1984 a, b). Some of the modifications made by Spasojevic and Holly (1994) for CH3D-SED are incorporated. The most significant change is the multiple-grain grain size treatment. A hiding factor is applied to the bed load transport, but not the suspended load transport. Shield's parameter is calculated using Van Rijn's equations. The suspended sediment concentration profile is calculated using equations proposed in Van Rijn's paper (1984b). Recommended use is for grain sizes between 0.1 and 0.5 mm.
- Yang (1973, 1984) is a version of Yang, D50, which has been modified, at WES, for multiple grain size calculations in sand and gravel bed streams (less than 10 mm).
- Yang, D50 is a single grain size function for sand and gravel transport in streams and small rivers.

This is not an exhaustive list of transport functions. These were selected based on both corporate experience and recommendations from the literature. There is no implication that those not selected are deficient. The objective in SAM.sed was to provide designers with a "few" acceptable methods whose use could be supported. The criteria for selection were

- a. to cover a broad range of particle sizes;
- b. to cover a broad range of hydraulic conditions;
- c. to calculate sediment transport by partitioning the mixture into size classes and summing the rate of each to get the total, except when d_{50} functions are requested; and
- d. to have a history of being reliable when used within the range of data for which each was calibrated.

The Brownlie function is included here because it is used in the analytical method for calculating channel width, depth and slope in SAM.hyd. It is a single grain size function.

Calculations

The functional form for sediment transport equations is

$$GS_i = \ddot{u} (V, D, S_e, B_e, d_e, \rho_s, G_{sf}, d_s, i_b, \rho_f, T) \quad \text{Equation 3-1}$$

where

GS_i = transport rate for size class i
 V = average flow velocity
 D = effective depth of flow
 S_e = energy slope
 B_e = effective width of flow (width of portion of cross section which is transporting bed material sediment)
 d_e = effective particle size for the mixture
 ρ_s = density of sediment particles
 G_{sf} = grain shape factor
 d_s = geometric mean of particles in size class i
 i_b = fraction of size class i in bed
 ρ_f = density of fluid
 T = temperature of fluid

Of particular interest are the groupings of terms: hydraulic parameters (V , D , S_e , B_e), sediment particle parameters (d_e , ρ_s , G_{sf}), sediment mixture parameters (d_s , i_b) and fluid properties (ρ_f , T).

Not all listed parameters are used in all sediment transport functions. In SAM.sed, the specific gravity of sediment defaults to 2.65, and the particle shape factor defaults to 0.667. However, these defaults can be over-ridden.

Procedure for Calculating Sediment-Discharge Rating Curve

The steps in calculating a sediment-discharge rating curve from the bed-material gradation are:

1. assemble field data (cross sections and bed gradations)
2. develop representative values for roughness coefficients, geometry, and bed gradation from the field measurements
3. calculate the stage-discharge rating curve accounting for possible regime shifts due to bed-form change
4. calculate the bed-material sediment-discharge rating curve using hydraulic parameters from the stage-discharge calculation.

SAM.sed can be used for step 4. The input information required by SAM.sed, from step 3, can be obtained from SAM.hyd or HEC-2.

Data Ranges used in Development of Sediment Transport Functions

The range of data used in the development of the sediment transport functions that have been included in SAM.sed are summarized in Tables 9 through 21. These summaries are based on the authors' stated ranges when presented in their original papers. Otherwise, the summaries were determined based on the author's description of his data base in combination with the data listings of Brownlie (1981) or Toffaleti (1968).

Correction for Sand Transport in High Concentration of Fines

Colby (1964) showed a significant increase in the transport capacity of sands when high concentrations ($C_f > 10,000$ ppm) of fine sediments (wash load) were present. The correction factor ranged up to 100 times the normal transport as the water depth and fines-concentration increased. The range of parameters tested is given in the following table.

Parameter	Range of data
concentrations	up to 200,000 ppm
velocities	up to 10 fps
depths	up to 100 ft
grain sizes	up to 0.9 mm.

At present, only the Colby function contains a correction for fines in SAM. In HEC-6, the Colby correction factor is applied to all sediment transport equations except Toffaleti, when Toffaleti is not combined with other equations.

Importance of Bed-material Gradation Designation

In the calculation of sediment transport, the designated bed gradation controls the calculated sediment discharge. The rate of transport increases exponentially as the grain size decreases, as shown in Figure 3.1. Therefore, bed-material gradations must be determined carefully. Techniques for selecting a representative sample are discussed in EM 1110-2-4000 (USACE 1989). Due to the sensitivity of transport calculations to the grain size, especially the finer sizes, Einstein (1950) recommended excluding the finest 10 percent of the sampled bed gradation from calculation of the total bed-material load.

Figure 3-1. Variation of sediment transport with grain size (from EM 1110-2-4000 (USACE 1989), Figure 10-7)

4 Theoretical Basis for SAM.yld Calculations

Purpose

Sediment yield is the total sediment outflow from a watershed or drainage basin, measurable at a cross section of reference and in a specified period of time (ASCE, 1975). Sources of the total sediment yield include the watershed surface, rills and gullies, streambanks, and degrading streambeds. Sediment yield can be subdivided based on the method of transport. The finer portion of the sediment yield is continuously maintained in suspension by flow turbulence and is called the washload. The coarser fraction of the sediment yield is actively exchanged with the sediment on the bed and is called the bed-material sediment yield. SAM.yld provides hydraulic design engineers a systematic method for rapidly calculating sediment yield. If sediment transport is calculated using sediment transport *equations*, only the bed-material sediment yield is calculated. If sediment transport is determined from total load *measurements*, then the total sediment yield (washload and bed-material load) is calculated.

General

SAM.yld calculates sediment yield passing a cross-section during a specified period of time. The time period considered can be a single flood event or an entire year. In SAM.yld the flow can be specified by either a flow duration curve or a hydrograph. The sediment discharge curve can be specified as either sediment discharge versus water discharge or as sediment concentration versus water discharge. Calculations are based on the flow-duration sediment-discharge rating curve method.

Flow-Duration Sediment-Discharge Rating Curve Method

This is a simple integration of the flow duration curve with the sediment discharge rating curve at the outflow point from the drainage basin. This method

is widely used in the Corps of Engineers for two reasons. First, both the flow duration curve and the sediment discharge rating curve are process-based and can be changed from the historical values needed for hindcasting to values needed for forecasting water and sediment yield in the future. Also, the curves can be defined to reflect specific components of the sediment runoff process, i.e., a sediment discharge rating curve can be calculated for sand and gravels when those are the types of sediment of most interest to project performance.

Sediment discharge rating curve

The sediment discharge rating curve is a relationship between water discharge and sediment discharge as discussed in chapter 3. SAM.sed calculates the bed-material sediment discharge rating curve needed for SAM.yld. SAM.sed will create this rating curve in terms of sediment concentration. However, the sediment discharge rating curve may be described in terms of tons/day by direct input to SAM.yld. If total sediment yield is required, the sediment discharge rating curve must be determined from measurements and directly input to SAM.yld.

Flow duration curve

The flow duration curve is a relationship between water discharge and the cumulative frequency each discharge occurs over a given time. It is a graphic description of a hydrologic event. The discharge magnitudes are plotted as the ordinates with the corresponding percents of time exceeded as the abscissas. Care should be taken in developing this curve.

Often the flow duration curve is calculated from historical databases containing the USGS mean daily records. If this data is used as the basis for a flow duration curve, efforts must be made to ensure that the peak flows are represented. This may be important in smaller streams where peak flow durations are considerably shorter than one day. Discharge durations for events larger than those in the mean daily record can be determined by one of several methods. If there are flood hydrographs on record, they can be the basis for calculating the discharge duration for the high flow events. If there is no recorded hydrograph for a flood event that has a published peak discharge, then the discharge durations can be determined assuming that the hydrograph had the same shape as a flood hydrograph of record or as a synthetic hydrograph calculated using HEC-1 or another hydrologic method. In any case, to ensure reasonable results the peak discharges of record should be incorporated into the flow duration curve, or the hydrograph, used in SAM.yld.

Calculations

Class intervals of water discharge are used in the integration of the flow-duration and sediment discharge rating curves. The percent exceedance is tabulated at each ordinate in user-defined increments that should be sufficiently

small so the exceedance curve is approximated by straight line segments. The value of the discharge at the midpoint of each segment and its incremental time in percent is then calculated. The representative value of the sediment discharge is calculated as the geometric mean of the sediment discharges corresponding to the water discharges that bound the increment. The daily average discharge is calculated by multiplying the water discharge by the incremental exceedance fraction and summing all increments. The daily average sediment discharge is calculated similarly, by summing all results of multiplying the incremental sediment load by the incremental exceedance fractions. The average annual sediment yield is the product of the mean daily value times 365 days.

Points of caution

The sediment discharge rating curve is plotted as water discharge (Q) versus sediment discharge (QS) on a log-log grid. The typical scatter in such plots demonstrates that sediment discharge is not a simple function of water discharge. When the water discharge in cfs is plotted versus the sediment concentration in ppm, scatter is more apparent than when water discharge is plotted versus sediment discharge in tons/day. This is due to the spurious correlation between Q and QS resulting from the dependency of QS on Q . The engineer should investigate and evaluate any regional and watershed characteristics which might contribute to scatter. This can be accomplished by testing for homogeneity with respect to season of the year, systematic changes in land use, type of sediment load, and type of erosive mechanisms. A multiple correlation approach coupled with good engineering judgement may be employed to establish the dominant factors influencing historical concentrations. It is important to predict how these factors might change in the future and how such changes would impact sediment concentrations and particle sizes.

Additional factors contributing to scatter include washload concentration and temperature. The percent of the sediment load that is washload influences the amount of scatter in the data because the washload depends on its availability from source areas and not upon hydraulics of flow at the point of interest. Also, as the concentration of fines increases above 10,000 ppm, the transport rate of sands and gravels increases significantly. Water temperature may cause a significant variation in transport capacity of the bed material load. Thus water temperature variations, when coupled with seasonal changes in land use, may require that separate warm and cold weather sediment discharge rating curves be used to achieve acceptable accuracy in the calculated results.

It is usually necessary to extrapolate the sediment discharge rating curve to water discharges well above the range of measured data. Straight-line extrapolations typically over-estimate sediment load at high discharges. Extrapolating the relationship for total concentrations does not guarantee the proper behavior of individual size classes. Typically, the rating curves for finer size classes tend to flatten with increasing discharge.

Flow Hydrograph Method

This modification of the flow-duration--sediment discharge rating curve method substitutes water discharges from a hydrograph for the flow-duration curve. Those ordinates are integrated with the sediment discharge rating curve to produce the sediment yield for that event.

5 Theoretical Basis for SAM.aid — Guidance in Sediment Transport Function Selection

Purpose

SAM.aid is a module of the SAM package that provides guidance in the selection of the most applicable sediment transport function(s) to use for given hydraulic conditions for a specified river or stream. The traditional approach for selecting a function has involved collecting field data, including both suspended sediment measurements and bed material gradations; processing and testing that data with a number of sediment transport functions; and then selecting the function that best matched the field measurements. Because many of today's projects are on small ungaged streams and because field data are often too limited for this approach to be satisfactorily applied, SAM.aid was developed to provide an alternative in which only bed-material gradations and hydraulic parameters are required.

General

Different functions may give widely differing results for a specified channel. Therefore it is important to test the predictive capability of a sediment transport function against measured data in the project stream or in a similar stream before its adoption for use in a sediment study. Also, different functions were developed from different sets of field and laboratory data and are better suited to some applications than others.

Most sediment transport functions predict a rate of sediment transport for a given set of steady-state hydraulic and bed material conditions. Typically, hydraulic variables are laterally averaged. Some sediment transport functions were developed for calculation of bed-load only, and others were developed for calculation of total bed-material load. This distinction can be critical in sand-bed streams, where the suspended bed-material load may be orders of magnitude greater than the bed-load. Another important difference in sediment transport functions is the manner in which grain size is treated. Most sediment transport functions were developed as single-grain-size functions, usually using the median

bed material size to represent the total bed. Single-grain-size functions are most appropriate in cases where equilibrium sediment transport can be assumed, i.e., when the project will not significantly change the existing hydraulic or sediment conditions. When the purpose of the sediment study is to evaluate the effect of a project on sediment transport characteristics, i.e., the project or a flood will introduce non-equilibrium conditions, then a multiple-grain-size sediment transport function should be used. Multiple-grain-size functions are very sensitive to the grain-size distribution of the bed material. Extreme care must be exercised in order to ensure that the fine component of the bed-material gradation is representative of the bed surface for the specified discharge. This is very difficult without measured data. For this reason Einstein (1950) recommended ignoring the finest 10 percent of the bed material sample for computation of bed-material load with a multiple-grain-size function. In HEC-6 and SAM, single-grain-size functions are converted to multiple-grain-size functions simply by calculating sediment transport using geometric mean diameters for each size class in the bed (sediment transport potential) and then assuming that transport of that size class (sediment transport capacity) can be obtained by multiplying the sediment transport potential by the bed fraction. This can produce unreliable results since the assumption is that each size class fraction in the bed acts independent of other size classes on the bed, thus ignoring the effects of hiding.

Description

SAM.aid is based on the premise that a sediment transport function that accurately predicts measured sediment in a gaged stream would be an appropriate predictor in an ungaged stream with similar characteristics. SAM.aid compares calculated "screening parameters" for a given river to the same screening parameters from a database of rivers (Brownlie, 1981) that have sufficient sediment data to determine an appropriate sediment transport function. The "screening parameters" are velocity, depth, slope, width, and d_{50} . It should be noted that Brownlie reduced measured bed material gradations to median grain sizes and geometric standard deviations. This means that this guidance is not applicable to rivers that have bed gradations that are not log-normally distributed.

When the user inputs velocity, depth, slope, width and d_{50} for an ungaged river, SAM.aid compares each of these screening parameters with those of each river in the Brownlie database. A "match" is identified when a parameter falls within the range of data for a database river. The d_{50} must fall within the range for a river in the database before SAM.aid will examine the other parameters. The three best sediment transport functions for each database river is then listed, along with the type of parameter(s) that matched and the name of the data set matched.

After the matches are displayed, the user can check the description of the rivers on which SAM.aid based its choices to see how close those descriptions match the user's river or stream. This is an essential step in ensuring that the sediment transport functions will actually provide the best predictive capability for the river in question. This will also narrow the choices when SAM.aid

displays several data sets that "matched" a user's data, all with the same matching screening parameters.

Criteria for selecting sediment transport functions

Discrepancy ratios were calculated for each measured discharge. Raphael (1996) describes the discrepancy ratio that Yang (1984), van Rijn (1984) and others have used as

$$\frac{q_s \text{ computed}}{q_s \text{ measured}}$$

For each data base, the percentage of discrepancy ratios between 0.5 and 2.0¹ was determined, and the average discrepancy ratio was calculated. The five to eight sediment transport functions with the highest percentage of discrepancy ratios within the selected range were selected first. From these, the functions were ranked by average discrepancy ratio. The function with the discrepancy ratio closest to 1.0 was ranked highest.

Only one of the Toffaleti function combinations was considered in each ranking. For instance, if both the Toffaleti and the Toffaleti-Schoklitsch functions ranked in the top three, only the function with the highest ranking would be included in the final recommendations. For some functions, sediment transport is calculated two ways: 1) assuming a median grain size and 2) making calculations by size class fractions. For these functions only the multiple grain size option was considered in the rankings. Since the Brownlie function calculates sediment transport using only the median grain size, it is included in the rankings.

In some cases, when the data is clearly outside the range for which a sediment transport function was developed, a function was excluded from the rankings.

The rankings for all the sediment transport functions in SAM.sed, for all the data sets in SAM.aid, are given in tables 5.2 through 5.21. They are also available onscreen in SAM.aid as part of the site description, allowing the user to apply personal engineering judgement and experience. This is an important feature to remember since the results of SAM.aid are meant only as suggestions, for guidance.

¹ This range, 0.5 to 2.0 was chosen because it is the range that is used in many other researchers in this field: van Rijn (1984a), Alonso (1980), White, Milli and Crabbe (1975), among others.

Data Ranges of the Data Sets used in SAM.aid

The data sets used in SAM.aid for comparison of user-input data each have a range of values for the five selection parameters: d_{50} , velocity, depth, width, and slope. These ranges are given in Table 5.22. However, in the SAM.aid program the upper and lower limits of the ranges for D_{50} have been extended to the next size class boundary, according to the American Geophysical Union standard size classes. This allows a somewhat wider range of choices to be offered to the user without compromising the theory behind SAM.aid.

Table 5.22. Data ranges of the data sets referenced in SAM.aid.

6 Input Requirements and Program Output for SAM.hyd

Purpose

SAM.hyd has four main calculation options, with variations within each of these. While some of the input and output are consistent for all options, each calculation option also has specific input data requirements as well as varying output. This chapter will address these specific input data requirements and present an overview of associated output, option by option.

General

SAM.hyd expects an input file designated as *x.hi*, with **no embedded spaces**. SAM.hyd will write a corresponding file *x.ho*, which is the hydraulic calculations output file. All SAM.hyd options except the stable channel calculations also create an *x.si* file, which is an input file to SAM.sed.

SAM.hyd's four calculation options are briefly described below. The first option allows for determination of the unknown variable in the Manning equation, i.e., depth, bottom width in a trapezoidal channel, slope, roughness or discharge. Detailed discussions of the various input requirements follow.

Normal Depth Calculations and Variations offers the user the option of calculating normal depth, bottom width, discharge, energy slope, hydraulic roughness, and flow distribution. Four compositing methods are available. Riprap can be added to most of these calculations.

Stable Channel Dimensions (Copeland Method) will calculate the dependent design variables of width, slope and depth from the independent variables of discharge, sediment inflow and bed material composition using the analytical approach known as the Copeland Method.

Meander Geometry Calculations will provide both curvilinear and Cartesian coordinates for a meander planform based on the sine-generated curve.

Riprap Size, Known Velocity and Depth, will calculate riprap size according to the procedure in EM 1110-2-1601 (USACE 1991, 1994) for cases when the velocity and depth are given.

Most of the above calculation options have additional options within. These are briefly described below. The input required to trigger these options will be discussed in detail in following sections.

In the uniform flow calculations hydraulic parameters can be calculated by one of four compositing methods: (1) alpha method, (2) equal velocity method, (3) total force method or (4) conveyance method.

Bed-form roughness prediction may be accounted for by using Brownlie's method, which uses velocity, hydraulic radius, slope, particle specific gravity, D_{50} and the geometric standard deviation of the bed sediment mixture.

Regime dimensions using the Blench equation can be calculated when requested with specific input, but this option is not available in SAMwin. (An editor can be used to alter an input file – see Appendix C.) Channel width, depth and slope are calculated as a function of bed-material grain size, channel-forming discharge, bed-material sediment concentration, and bank composition.

Geometry can be simple, as defined by a Channel Template (CT record), or complex, as prescribed by multiple CT records, or with station/elevation data, as in X1/GR-record data sets from HEC-2/HEC-6. In either case the geometry will be transformed into effective hydraulic parameters for sediment transport calculations.

Riprap can be added to most options.

The installation CD contains an example application, and discussion, in the LWV folder. This folder is not copied to the CD during installation, so to review the example application, see the CD.

Program execution

The hydraulic calculations can be made in SAMwin by selecting a calculation type from the “Edit” dropdown menu, inputting the data, and selecting “solve,” or from the “Run” dropdown menu, see Figure 6.1. This second option is useful if a ready-to-run data set exists.

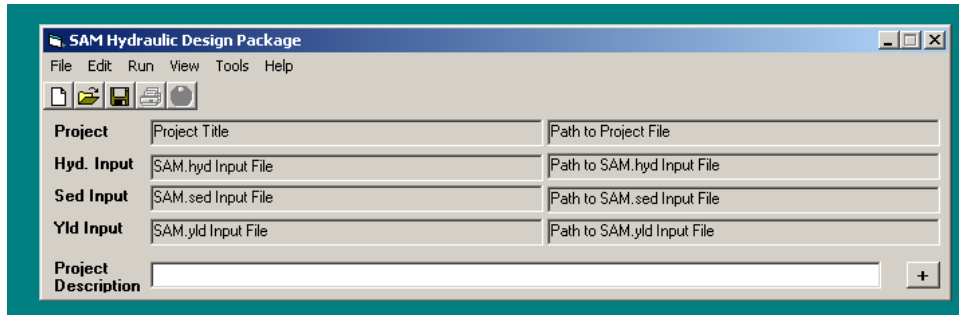

Figure 6.1. Opening window of SAMwin.

Normal Depth Calculations

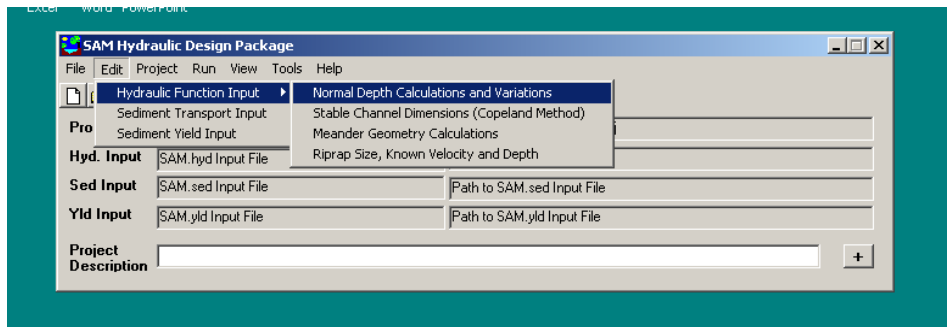

Figure 6.2. Choosing Normal Depth Calculations and Variations.

Input

“Normal Depth Calculations and Variations” selected from within the “Hydraulics Functions Input” menu of the “Edit” drop-down menu is shown in Figure 6.2. This selection will open the screen in Figure 6.3.

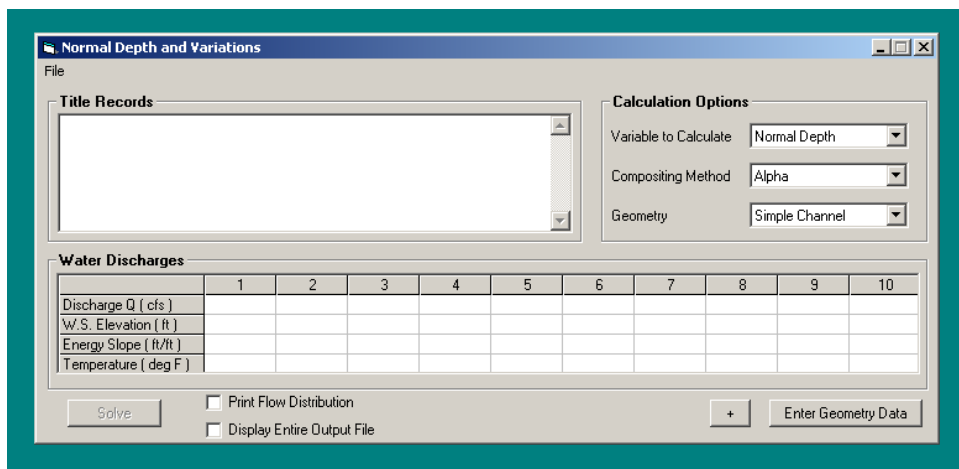

Figure 6.3. Normal Depth and Variations window of SAMwin.

Title Records.

This area allows the user to input descriptive strings, up to about 80 characters long, for use in identifying data sets. Extra characters will be truncated, not wrapped.

Calculation Options.

Variable to Calculate. The dropdown menu allows the user to choose the variable to be calculated without having to leave data blank for that particular variable. Choices are: normal depth, bottom width, energy slope, hydraulic roughness, and water discharge.

Compositing Method. SAM offers four compositing methods: alpha, equal velocity, total force, and conveyance.

Geometry. The three choices here are simple channel (single trapezoidal channel), compound channel (up to three, 'stacked,' trapezoidal channels), and station-elevation.

Flow Data

Water Discharges.

SAM data records accept a maximum of 10 data points per data type. This area allows the user to input discharge (cfs), water surface elevation (ft), energy slope (ft/ft), and temperature (F°)

Enter Geometry Data

This button opens the screen for geometry input according to the choice made in the Calculation Options box. Geometry input will be discussed later.

+ “ Box.

This button toggles, opens/closes, a small window which will receive selected output. The output coming to this window cannot be selected by the user.

Print Flow Distribution

When this box is checked, SAM will add the results of the flow distribution calculations to the output file.

Display Entire Output File

When this box is checked the output file will open in its own window (using Notepad) after calculations are complete. If this button is not checked, some input will echo to the screen in an area that will drop down below this entire “Normal Depth and Variations” window. The entire output file can also be viewed by checking the View menu of the SAM main window and selecting “Hydraulic Output File.”

Solve

This button causes SAM.hyd to execute. However, SAMwin often “forces” the user to check the geometry. If the Solve button is “greyed out,” click on the Geometry button to check the geometry. Be sure to click OK to have the Solve button operational after the Geometry screen closes.

Geometry

The screen that opens here is determined by the Geometry type chosen in the Calculation Options of the screen in Figure 6.3.

Channel Template Input

Figure 6-4. Simple Channel screen – showing data for a not composite channel

Simple and Compound Channel. A simple channel is described on either the “Channel Template Input” screen, shown in Figure 6.4, or the “Compound Channel Template” screen, shown in Figure 6.5. The Channel Geometry section of these screens prescribes bottom width, bank height and side slopes for a simple triangular, rectangular, or trapezoidal shape. A plot of the cross-section is

available by clicking the View menu and selecting “Cross Section.” The Compound Channel Template can describe up to three, “stacked” shapes in one channel. For example, a low flow channel can be coded on the first tab, followed by a normal flow channel and a high flow berm, as shown in Figure 1A, Chapter 2. **NOTE:** The Compound Channel option requires the discharges to be input in a specific way. See Appendix C, CT Record. Also note that if bottom width calculations are prescribed, the cross section is not sufficiently defined by the input to be plotted by the View menu.

Low Flow Channel Geometry. Bank height must be input even if water surface elevation is being calculated.

Low Flow Channel Type and Low Flow Roughness Input – Simple (or Composite) Channel. These are linked inputs. If the channel described by the geometry in this window has uniform roughness, then that channel is not a composite channel, and only one roughness equation and value are required, as shown in Figure 7.4. However, if the channel and banks either have different roughness values or require different roughness equations, then the channel is a composite channel. Clicking the “yes” button in answer to the “Type” question causes the “Low Flow Roughness” area to change to request the required input, Figure 6.5.

The screenshot shows the 'Compound Channel Template' window with the 'View' menu open. The 'Low Flow' tab is selected. The 'Low Flow Channel Geometry' section contains input fields for Bottom Width (140), Bank Height (15), Left Side Slope (Horiz. to 1) (2), and Right Side Slope (Horiz. to 1) (2). The 'Low Flow Channel Type' section asks 'Is this a composite channel?' with 'Yes' selected. The 'Low Flow Roughness Input -- Composite Channel' section shows three columns for Left Bank, Bed, and Right Bank, each with a 'Roughness Equation' dropdown (all set to 'Manning') and a 'Roughness Value' input field (the Bed field contains '.025'). 'Cancel' and 'OK' buttons are at the bottom right.

Figure 6.5. Channel template window showing composite channel input.

In addition, if the Limerinos or Brownlie equations are selected, the window further changes to request the “Bed Material Gradation,” as shown in Figure 6.6. DMAX is a required input whereas the specific gravity of sediment is optional (the value shown is the default value). The program will accept up to 18 points on the bed material gradation, and they **must** be input from largest grain size to smallest. However, a grain size for 100% finer and for 0% finer is not required.

The screenshot shows the 'Compound Channel Template' dialog box with the 'View' tab selected. The 'Low Flow' tab is active. The 'Low Flow Channel Geometry' section has 'Bottom Width' set to 140 and 'Bank Height' set to 15. The 'Left Side Slope (Horiz. to 1)' and 'Right Side Slope (Horiz. to 1)' are both set to 2. The 'Low Flow Channel Type' section has 'Is this a composite channel?' set to 'No'. The 'Low Flow Roughness Input -- Composite Channel' section has 'Roughness Equation' set to 'Manning' for the 'Left Bank' and 'Right Bank', and 'Limerinos' for the 'Bed'. The 'Roughness Value' for the 'Bed' is set to .025. The 'Bed Material Gradation' section has 'DMAX (mm)' set to 1 and 'Specific Gravity of Sediment' set to 2.65. Below this is a table for 'Particle Size (mm)' and 'Percent Finer (%)' with columns 1 through 9.

	1	2	3	4	5	6	7	8	9
Particle Size (mm)									
Percent Finer (%)									

Figure 6.6. Bed Material Gradation input area of the Compound Channel Template.

Station Elevation. Complex channels can be prescribed by station and elevation coordinates. This format is the same as that in HEC-2 and HEC-6. Figure 1B in Chapter 2 shows a typical complex cross section that would be coded in this format. Figure 6.7 shows the input window for this geometry option.

Cross Section Characteristics. River mile is an optional input. The Left and Right bank stations designate the moveable bed and must be points on the cross section, but are also optional in SAM.hyd.

X-Y Coordinates of Channel Cross Section. The user can input up to 100 points. The “Edit” pull down menu offers typical editing functions, including inserting and deleting rows. These edit commands allow the user to cut to or from a columnar spreadsheet, i.e., Microsoft Excel.

Roughness Equations and Roughness Values for Panels. This area will define panels by their station/elevation endpoints and allow the user to input both the roughness equation and value to use for each panel. Roughness equation

choices are listed to the right of the input area. To have hydraulic roughness calculated, put a negative number in the panels involved. Generally a “-1” is used, but the roughness can be prorated by panel. See Appendix C, KS Record, for details of this option.

Sample Output Data

Selected results are printed to the drop down notebook area of the “Normal Depth and Variations” screen. The user has no control over what prints to this display. The complete output is saved in the appropriate default output file. This file will open upon program execution completion if the “Display Entire Output File” box is checked. Otherwise, the View option on the main screen can be used.

The hydraulic parameters needed for sediment transport calculations are written into the default sediment input file along with the other data needed for calculating sediment transport capacity.

The following output description is from TEST 1C, as given. Note that the Flow Distribution information was requested.

NOTE: The table numbers may change in other output files, depending on the calculation option chosen.

...END OF JOB...

General Tables The banner will reflect the version and date of the particular code being used. Table 1 simply echoes the input. Table 2-1 gives information on the cross-section properties before any calculations are made. Table 2-2 shows the acceleration of gravity. Table 2-3 shows the properties of water as calculated from the specified temperature and assuming sea level elevation.

Normal Depth Table Table 8-1 gives the normal depth calculated using the specified compositing method, which in this example is the alpha method. Also given are composite variables for the entire cross section. Since the alpha method is specified, the composite hydraulic radius, \bar{R} , is calculated by a conveyance weighted procedure using the panels between every point defining the cross section. For the conveyance, equal velocity, and total force methods,

the composite hydraulic radius is calculated as the total area divided by the total wetted perimeter.

For the alpha method:

$$\bar{R} = \frac{\sum_{i=1}^k R_i C_i A_i \sqrt{R_i}}{\sum_{i=1}^k C_i A_i \sqrt{R_i}}$$

For the conveyance, equal velocity, and total force methods:

$$\bar{R} = \frac{\sum_{i=1}^k A_i}{\sum_{i=1}^k P_i}$$

where:

- k = the number of panels
- i = the panel number
- \bar{R} = the composite hydraulic radius
- $R_i = A_i / P_i$
- C_i = the panel Chezy roughness coefficient
- A_i = the panel cross-sectional area
- P_i = the wetted perimeter

The composite roughness coefficient, \bar{n} , is calculated using the composite \bar{R} in the Manning equation:

$$\bar{n} = \frac{1.486 \bar{R}^{\frac{2}{3}} S^{\frac{1}{2}} \sum_{i=1}^k A_i}{Q}$$

where:

- S = energy slope
- Q = total discharge

Other results in Table 8-1 are calculated as follows:

$$\bar{V} = \frac{Q}{\sum A_i}$$

$$Froude\ Number = \frac{\bar{V}}{\sqrt{EFD * g}}$$

$$\tau = \gamma \bar{R} S$$

where:

\bar{V} = average velocity
 EFD = effective depth
 g = acceleration of gravity
 τ = bed shear stress
 γ = unit weight of water

Flow Distribution Table. Table 8-2 gives the flow distribution for each panel of the cross section. The conveyance weighted discharge percentage for each panel, Q_i , is calculated by the following equation:

$$Q_i = 100 Q \left(\frac{C_i A_i \sqrt{R_i}}{\sum C_i A_i \sqrt{R_i}} \right)$$

Area, wetted perimeter, and hydraulic radius are reported for each panel. Panel hydraulic radius, R_i , is defined as A_i/P_i . k_s and n are calculated or given for each panel. Velocity, V_i , is defined as Q_i/A_i . If no bed gradation is specified:

$$\tau = \gamma D_i S$$

where:

D_i = average depth in the panel

If a bed gradation is specified, then τ in the table is the grain shear stress calculated using a combination of the Manning and Limerinos equations, where R' is the hydraulic radius associated with grain roughness and is determined from the following:

$$\frac{V_i}{\sqrt{g R'_i S}} = 3.28 + 5.75 \log \frac{R'_i}{d 84}$$

and the grain shear stress is calculated as:

$$\tau'_i = \gamma R'_i S$$

The **CMT column** consists of 6 columns of single letter codes. The first 3 columns define the flow type, which is considered to be rough if

$$\frac{\frac{4 R_i V_i}{C_i R_i} k_{si}}{v} \geq 50$$

where:

v = kinematic viscosity

If the flow is rough, an R appears in the third column. Otherwise T/S, standing for transitional to smooth flow, appears in **columns 1 through 3**.

Other nomenclature in **columns 1 through 3** are "V:O", indicating that this panel has a vertical wall, and "DRY", indicating that there is no water in this panel.

The **fourth column** is used to define the flow regime, if the Brownlie equations are specified, or to identify that the SCS grass equations are being used.

U - upper bed regime

T - transitional

L - lower bed regime

G - indicates the equation flagged in column 6 is a grass equation.

The **last column** indicates the roughness equation used for the panel.

B - Brownlie

K - Keulegan

L - Limerinos

M - Strickler (Manning)

A,B,C,D,E - various grass equations if the fourth column was a "G".

At the bottom of the table are summaries. The numbers below the solid line are totals for the column. The numbers below the dashed line are composite values for the cross-section, calculated the same as in Table 8-1.

In the output for TEST 1C, notice that for $Q = 100$, the panel between stations 50.0 and 80.0 has a calculated n-value of 0.0305. The comment column for this panel shows "R S", indicating rough flow and that the Strickler method was used. The input data requested Keulegan, but, **NOTE**, SAM will not apply Keulegan if $k_s/R < 3$. It automatically substitutes Strickler.

The Normal depth Table 8-1 and the Flow Distribution Table 8-2 are repeated for every discharge prescribed on the QW-record. The composite hydraulic parameters for each discharge are highlighted between the flow distribution tables, with "*****". In the example output included in this chapter, the printout for discharges 4 and 5 have been omitted.

Hydraulic Parameters for Sediment Transport Table The results printed in Table 8-4 are representative hydraulic parameters for making sediment transport calculations. The effective velocity, depth, width and slope are calculated for both overbanks and the channel. EFFECTIVE WIDTH, EFW, and EFFECTIVE DEPTH, EFD are defined by the following equations:

$$EFD = \frac{\sum d_i A_i d_i^{2/3}}{\sum A_i d_i^{2/3}}$$

$$EFW = \frac{\sum A_i d_i^{2/3}}{EFD^{5/3}}$$

where:

A_i = flow area of each trapezoidal element
 d_i = average water depth of each trapezoidal element

Equivalent Hydraulic Properties for overbanks and channel Flow distribution and conveyance-weighted hydraulic parameters are calculated for the overbanks and channel and listed in Table 8-5. The water-surface elevation that was calculated using the specified compositing method determines channel and overbank subareas and wetted perimeters. Conveyance for each subarea is calculated using the Chezy equation and conveyance weighted discharges determined. Using the area, wetted perimeter, discharge, and slope for the three subareas, a composite n value is calculated for the channel and both overbanks.

Plotting The following hydraulic output plots should be available: stage versus n-value; stage versus average velocity in cross section; stage versus effective velocity; stage versus discharge; stage versus width; stage versus effective width; stage versus hydraulic radius; cross section geometry; and, slope versus width.

- 1V:ZH -- definition of the side slopes, with the Z as the input parameter
 CD1 -- the height of the low flow channel
 CD2 -- the incremental height of the normal channel
 CD3 -- the incremental height of the high flow channel
 BW1 -- the width, toe to toe, of the low flow channel
 BW2 -- the width, toe to toe, of the normal channel
 BW3 -- the width, toe to toe, of the high flow channel
 Note: therefore total depth = CD1+CD2+CD3

Figure 6.9. Definition of input for bottom calculations for compound channels.

Bottom Width Calculations: Input and Output

Bottom width of a simple or compound channel can be determined with this option. Roughness and compositing are handled the same as described for normal depth calculations. Bottom width becomes the dependant variable in the Manning equation:

$$W = f(Q, n, D, z, S)$$

where

- W = bottom width
 Q = water discharge
 n = n-value
 D = water depth
 z = side slopes of the channel
 S = energy slope

Bottom Width must be selected in the “Variable to Calculate” drop down box on the “Normal Depth and Variations” screen, Figure 6-3.

Geometry input

Either the “Simple Channel” or the “Compound Channel” method for inputting geometry is permitted in this calculation; but not the station/elevation method. Note that the water surface elevation, on the “Normal Depth and Variations” screen does not have to be given a value for the bottom width calculations. The bank height input on the “Compound Channel Template” screen sets a limiting depth on the channel.

Simple Channel. To calculate bottom width for a simple channel, put only 1 discharge in the “Flow Data” area, Figure 6-3.

Compound Channel. To calculate bottom width for a compound channel, use the “Compound ChannelTemplate” screen, Figure 6-6. The number of discharges input on the “Flow Data” area **must** match the number of “tabs” filled out. Also, the discharges must be in low-normal-high flow channel order. **NOTE:** The requirements for discharge input in this calculation are different from those for all other hydraulic calculations.

Input for Compound Channel Calculations. The ‘bank heights’ requested on the “Compound Channel Template” screen are the heights represented by CD1, CD2, and CD3 in Figure 6.9. Each of these heights is *incremental*; each is for its own section of the channel (see Figure 6.9). For example, in Test 2B, below, the maximum depth for the normal channel is 13 ft (3+10); the maximum depth in the high flow channel is 28 ft (3+10+15). The program will increase the calculated bottom width to convey the prescribed discharge rather than increase the depth beyond that 28 ft. The calculated water surface, and depth, is the distance from the low flow channel invert to the water surface. The discharge input is the *total* discharge (input on the “Flow Data” area of the “Normal Depth and Variations” screen).

Sample Input Data

The following example shows input data when calculating bottom width. The difference between this input and that required to calculate normal depth is bottom width, CT record field 1, is left blank by SAMwin. Also note no water surface is prescribed.

Sample Output Data

The following output is taken from the output from Test 2A, above. The general output tables from these calculations are described earlier. However, note that table series "8-x" has become "5-x". The information contained in the two series of tables is the same, with the title of the "x-1" table flagging both the calculation performed and the compositing method used. **NOTE:** The calculated bottom width is shown in Table 5-1 as "Bottom Width" and is not flagged as having been calculated.

TABLE 5-1. CALCULATE BOTTOM WIDTH; COMPOSITE PROPERTIES BY ALPHA METHOD.

**** N	Q	WS ELEV FT	BOTTOM WIDTH FT	R FT	SLOPE ft/ft	n Value	VEL FPS	FROUDE NUMBER	SHEAR STRESS #/SF
**** 1	6000.	3.00	153.1	2.97	0.005000	0.0175	12.34	1.27	0.92

1	1	2.83	0.0170	6000.00	486.35	12.34

The following output is from Test 2B, above. Note the "**** 1" lines from the example above and the example below – the bottom widths are very different, because the discharges prescribed are very different and the maximum depth is 3, as prescribed by the bank height input in both. Also note that the "WS ELEV FT" in Table 5-1 is cumulative (the distance from the low flow channel invert to

the water surface), i.e., the 85,000 cfs discharge fills the 28 ft of depth prescribed by the bank heights, causing the high flow channel to gain width. Each bottom width given in Table 5-1 is the width of that channel, from toe of slope to toe of slope, as shown in Figure 6.9.

Occasionally the following warning message will appear:

ABNORMAL TERMINATION OF WIDTH CALCULATION.
SUCCESSIVE ITERATIONS ARE NOT IMPROVING THE CONVERGENCE.

The program will then print values on the “****” lines anyway. The warning indicates problems encountered when trying to converge on an appropriate width. To check the answer for reasonableness, use the calculated bottom width as input to the water surface elevation calculations. If the water surface then calculated is close to that the bottom width calculations printed, then the answer is reasonable.

TABLE 5-1. CALCULATE BOTTOM WIDTH; COMPOSITE PROPERTIES BY ALPHA METHOD.

Energy Slope Calculation: Input and Output

Energy slope can be determined with this option, where slope becomes the dependant variable in the Manning equation:

$$S = f (W, Q, n, D, z, S)$$

Geometry, roughness, compositing, and plotting are handled the same as described for the normal depth calculations. Choose “Energy Slope” as the “Variable to Calculate.”

Sample Input Data

The following example shows input data when calculating energy slope. Notice that it is the same as shown for Normal Depth except that the WS-record is present and the ES-record is missing. The missing ES-record tells SAM to calculate the slope.

```

TI    TEST NO. 4  CALCULATE ENERGY SLOPE

Hydraulic Roughness Calculations: Input and Output

In this calculation roughness becomes the dependant variable in the Manning equation, thus calculating that variable:

$$W = f(Q, n, D, z, S)$$

Geometry, compositing and plotting are handled as described for normal depth calculations. This calculation, like the other solutions of the Manning equation which involve compositing, is trial and error. A simple solution of the Manning equation is used to calculate the first trial roughness coefficient. Of the several equations for hydraulic roughness, the Strickler (Manning) equation is the most likely to converge. The Brownlie equation may have trouble converging due to the discontinuity associated with the transition zone.

Sample Input Data

The following example shows input data when calculating k_s . Note the KN record in Test 4B, and field 6 on the CT record in Test 4A. The negative values flag the program to make the hydraulic roughness calculations. The absolute value, i.e., 0.5 in Test 4B, tells the program the ratio of roughness in that element to the composite roughness. For example, if the values are -1, as on the KS-record fields 3, 4, 5, and 6, or as on the CT record in field 6 in Test 4A, then the roughness in each of these panels would be calculated as equal proportions of the composite. The program is supposed to supply “missing” values on a record by repeating the data in the previous fields; i.e., on the CT record, the data for fields 7 and 8, and 9 and 10, would be repeated from fields 5 and 6 (see Appendix C).

Note, however, that currently this does not work for the KN record, and data for all fields should be supplied by the user.

Output Data

The information contained in the output tables is the same as that described in the normal depth calculation output.

Water Discharge Calculations: Input and Output

This option allows water discharge to become the dependant variable in the Manning equation.

$$W = f(Q, n, D, z, S)$$

Geometry, roughness, compositing, and plotting are all handled as in the normal depth calculations.

Note, when convergence fails, assume a range of discharges and use the normal depth calculations to arrive at the correct value.

Riprap Size for a Given Velocity and Depth (RS-Record) Calculations

Input and Output

The input window for these calculations is accessed from the SAMwin main menu – Edit – Hydraulic Function Input – Riprap size, Known Velocity and Depth, Figure 6.10.

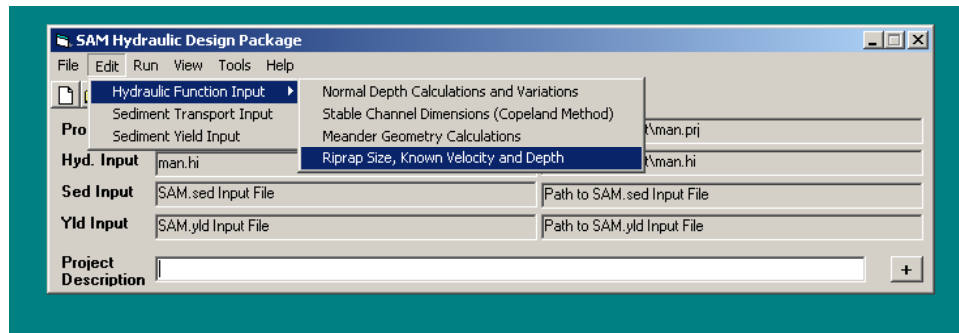

Figure 6.10. Finding the Riprap Calculations input screen.

When flow velocity and depth are known, the riprap size is calculated using the equation described in EM 1110-2-1601 (USACE 1991, 1994). Since the size and specific gravity of available riprap are needed for this calculation, the 13 standard riprap sizes (shown in EM 1110-2-1601 and in Chapter 2) are available in the program by default. The riprap design equation is:

$$d_{30} = S_f C_s C_v C_T D \left[\left(\frac{\gamma_w}{\gamma_s - \gamma_w} \right)^{0.5} \frac{V_{AVE} C_B}{\sqrt{K_1 g D}} \right]^{2.5}$$

where

d_{30} = characteristic riprap size of which 30 percent is finer by weight

S_f = Safety factor

C_s = Coefficient of incipient failure

C_v = vertical velocity coefficient

C_T = coefficient for riprap thickness

D = local water depth

γ_w = unit weight of water

γ_s = unit weight of riprap

V_{AVE} = average channel velocity

C_B = bend correction for average velocity (V_{SS}/V_{AVE})

K_1 = Correction for side slope steepness

g = Acceleration of gravity

Up to five sizes of quarry run riprap can be specified and will be used in the calculations instead of the default if they appear in the data set. This capability is not available in SAMwin at this time. However, the quarry run riprap data can be input on the RQ record with an editor; see Appendix C. That data set can then be run with the “Run” option of the SAMwin main menu. No plots are available from these calculations.

The safety factor, S_f , accounts for variability and uncertainty in calculated hydrodynamic and non-hydrodynamic imposed forces and/or for uncontrollable physical conditions. The minimum safety factor recommended in EM 1110-2-1601 (USACE 1991, 1994) is 1.1. This is the default value used in SAM. However, a larger value may be specified on the riprap input screen. A discussion of appropriate values for the safety factor is presented in EM 1110-2-1601 (USACE 1991, 1994).

The thickness coefficient, C_T , accounts for the increase in stability that occurs when riprap is placed thicker than the minimum thickness. Minimum thickness is the greater of $d_{100 \text{ MAX}}$ and $1.5 d_{50 \text{ MAX}}$. If minimum thickness is desired, then $C_T = 1.0$. EM 1110-2-1601 (USACE 1991, 1994) provides three curves for determining C_T as a function of the ratio d_{85}/d_{15} and the ratio of design thickness to minimum thickness -- T_R/T_{MIN} . Currently, SAM uses the curve that results in the least reduction in design riprap size:

$$C_T = 1.44 - 0.58 \frac{T_R}{T_{\text{MIN}}} + 0.14 \frac{T_R}{T_{\text{MIN}}} \quad 1 \leq \frac{T_R}{T_{\text{MIN}}} \leq 2$$

where:

T_R = riprap thickness
 T_{MIN} = $d_{100 \text{ MAX}}$ or $1.5 d_{50 \text{ MAX}}$, whichever is greater.

This equation is appropriate when the gradation uniformity coefficient, d_{85}/d_{15} , = 1.7, which corresponds to the gradations recommended in EM 1110-2-1601 (USACE 1991, 1994). Larger gradation uniformity coefficients would result in a smaller value for C_T . In SAM, the default value for T_R/T_{MIN} is 1.0. A different ratio may be prescribed as variable RSEC on the RS record or a variable RT(i) of the RT record. T_R/T_{MIN} ratios usually range between 1.0 and 1.5.

NOTE: THIS DESCRIPTION AND CODING FOR C_T REFLECTS 1991 GUIDANCE.

The stability coefficient for incipient failure, C_S , has been determined to be 0.030 for angular rock, and 0.0375 for rounded stone. These values have been demonstrated for riprap gradations where $1.7 < d_{85}/d_{15} < 5.2$. The default in SAM is for the angular rock. The rounded stone coefficient may be used by specifying a negative thickness ratio, T_R/T_{MIN} , for the variable RSEC on the RS record or for variable RT(L) on the RT record. The stability coefficient for incipient failure may also be changed by changing the variable CIFRRS on the RR record and

using negative values for T_R/T_{MIN} . $C_S = 0.30$ is multiplied by CIFRSS when T_R/T_{MIN} is negative -- the default for CIFRSS is 1.25 which yields $C_S = 0.375$.

The vertical velocity distribution coefficient, C_V , varies as a function of the ratio of bend radius, R , to channel width, W . $C_V = 1.0$ in straight channels, for the inside of bends, and for bends where R/W is ≥ 26 . The equation for C_V when $R/W < 26$ is:

$$C_V = 1.283 - 0.2 \log_{10} \left(\frac{R}{W} \right)$$

The maximum value allowed for C_V is 1.283. C_V is determined in SAM using either a calculated water-surface width or a water-surface width prescribed on record RS, and a bend radius prescribed as variable on the RR record.

The side slope correction factor, K_1 , is calculated by SAM from geometric input and the empirical side slope correction graph in EM 1110-2-1601. The side slope steepness angle is calculated for each panel. When the steepness is milder than 1V:3H the side slope correction factor is 1.0. The steepest side slope allowed is 1V:1.5H.

The bend correction factor, C_B , which is the same as V_{SS} / V_{AVE} in EM 1110-2-1601, is determined differently depending on whether the channel is a natural channel or a trapezoidal channel. In SAM, a trapezoidal cross section is identified by setting NTRAP on the RR record equal to 1. If no value is assigned a natural channel is assumed. C_B is calculated in SAM as a function of the R/W ratio. For trapezoidal channels:

$$C_B = 1.71 - 0.78 \log_{10} \left(\frac{R}{W} \right) \quad 1.48 \leq C_B \leq 0.82$$

and for natural channels:

$$C_B = 1.74 - 0.52 \log_{10} \left(\frac{R}{W} \right) \quad 1.58 \leq C_B \leq 0.90$$

NOTE: THESE DESCRIPTIONS AND CODING FOR CB REFLECT 1991 GUIDANCE.

When riprap calculations are made using known velocity and depth, care must be taken in defining the input variables. Depth is the depth of water at the toe of the riprap. SAM will adjust the depth to 0.8 D as prescribed in EM 1110-2-1601 (USACE 1991, 1994). If the local depth averaged velocity at 20 percent up-slope

from the riprap toe is input, then no bend radius should be prescribed. On the other hand, if the average channel velocity upstream of the bend is input, then a bend radius should also be prescribed. The bend radius, R , is defined as the centerline radius of the bend, considering only the main channel. The water-surface width, W , is defined as the main channel water-surface width at the upstream end of the bend.

Figure 6.11. Input screen for riprap calculations for known velocity and depth.

Sample Input Data

The required input data for simple riprap calculations are shown in Figure 6.11. Again, if quarry run riprap gradations are to be specified, they must be added to the data set with an editor, and should be entered one size per record, starting with the smallest. This record is currently not available in SAMwin.

Various input data sets are given in the following examples.

Sample Output Data

The following example is taken from the output from Test 6A. The general tables, Tables 1 and 0-3, are described in the normal depth calculation output. The output shown below is the additional, riprap output. The first line describes the calculation being performed. The next line states the source of the riprap sizes tested. It would have stated "USING QUARRY RUN RIPRAP" had that been prescribed. The first table shown describes the necessary riprap size as determined by the calculations. The second, longer table describes both the riprap and some of its effects as well as some of the factors used in the calculations. The cross section properties are echoed, and there is a table with the "Hydraulic properties with riprap in place." The standard tables, 8-4 and 8-5, are repeated but contain the parameters as calculated with the stated riprap size in place.

...END OF JOB...

Riprap Size for a Given Discharge and Cross Section Shape: Input and Output

Riprap size calculations are more complicated when the water discharge and cross section are given than when the flow velocity and depth are given because n-value becomes a function of riprap size. The computational procedure is described in detail in Chapter 2. The stone size gradation table is the default for riprap sizes, but quarry run stone can be prescribed, as noted above, although that option is currently not available in SAMwin. Riprap size is determined automatically when the RR-, RT-, and PF-records are included in a data set for normal depth, bottom width, energy slope or water discharge calculations. The

PF record is required for riprap calculations because the program tests bed particles against the Shield's diagram to determine whether or not riprap is needed.

Considerable care must be employed when applying the cross-section shape option because flow conditions may be outside the range of conditions used to develop the riprap equations. When these calculations are made, it is important that the user define the side slope protection as a single panel in the geometry input. SAM will use 0.8 times the maximum depth in the panel for the local flow depth in the riprap equation. When a bend radius is specified, SAM uses the average velocity in the cross section for V_{AVE} in the riprap equation. Therefore, it is important that the input geometry include only channel geometry and discharge. When a bend radius is not specified, SAM uses the calculated panel velocity for V_{AVE} in the riprap equation. This calculation may provide useful information for compound channels in straight river reaches, but it is an extension of the procedure outlined in EM 1110-2-1601 (USACE 1991, 1994). Careful study of the recommendations and guidelines described in that EM are considered essential.

Figure 6-12. Additional input needed when riprap requested on the Station-Elevation normal depth input screen.

Sample Input Data

These calculations can be accessed through the “Normal Depth” input, as described earlier. Figure 6-12 shows some of the required input data for riprap size calculations when station elevation geometry is input. Figure 6-13 shows some of the required input data for riprap size calculations when channel template geometry is input. Other required data are particle size on the channel bed and thickness of the riprap by panel (the RT record). The RT record also tells the calculations in which panel to put riprap. This record is not available in SAMwin at this time and must be manually made and put in the input file. The

other data in this calculation-type file are required to perform the normal depth calculations and produce the water velocity and depth in each panel.

Geometry, roughness, compositing and plotting are handled the same as described for normal depth calculations without riprap.

Sample Output Data

The following example is taken from the output from Test 7C. The general output tables from these calculations are described in the normal depth output

section. However, the output for these calculations is threefold. The first set of normal depth tables show the results of the normal depth, or other, calculations without riprap. The next set of output, starting with "DETERMINE RIPRAP SIZE FOR A GIVEN WATER DISCHARGE," describes the results of the riprap calculations using the hydraulic parameters shown in the first set of tables. The third set of output is a second set of normal depth calculations showing the hydraulic parameters calculated with the given riprap in place. The parameters written to the sediment transport, SAM.sed, input file are taken from this second set of normal depth calculations.

If there is no RT record in the data set and riprap is required, the following message appears:

```

DETERMINE RIPRAP SIZE FOR A GIVEN WATER DISCHARGE
USING GRADED RIPRAP TABLES FROM EM 1110-2-1601

NO LOCATIONS WERE SPECIFIED FOR RIPRAP.
N, Q(N), AND WS(N) =      1      6000.      3.00

```

(This message was produced by adding only an RR record to Test 2A. With no RT record SAM had no idea where to put the riprap.)

Blench Regime Equations

Stable channel dimensions may be calculated using the Blench (1970) regime equations. These regime equations are also shown in ASCE Manual 54 (ASCE 1975). The equations were intended for design of canals with sand beds. The basic three channel dimensions, width, depth and slope, are calculated as a function of bed-material grain size, channel-forming discharge, bed-material sediment concentration, and bank composition.

$$W = \left(\frac{F_B Q}{F_S} \right)^{0.5}$$

$$F_B = 1.9 \sqrt{d_{50}}$$

$$D = \left(\frac{F_S Q}{F_B^2} \right)^{\frac{1}{3}}$$

$$S = \frac{F_B^{0.875}}{\frac{3.63 \text{ g}}{\nu^{0.25}} W^{0.25} d^{0.125} \left(1 + \frac{C}{2,330} \right)}$$

where

W = channel width - ft

F_B = bed factor

F_S = side factor

Q = water discharge -cfs

d₅₀ = median grain size of bed material - mm

D = depth - ft

S = slope

C = bed-material sediment concentration - in parts per million

g = acceleration of gravity - ft/sec²

ν = kinematic viscosity - ft²/sec

The results are true regime values only if Q is the channel forming discharge. However, a width, depth and slope will be calculated for any discharge by these equations.

Blench suggests that the following values be used for the side factor:

F_S = 0.10 for friable banks

F_S = 0.20 for silty, clay, loam banks

F_S = 0.30 for tough clay banks

In order to calculate the Blench regime dimensions, the side factor, bed-material sediment concentration, and the bed-material gradation should be input.

SAM.hyd sets default values for the Blench variables if none are specified: F_S = 0.20, C = 0.0, and d₅₀ = 0.25 mm.

Sample input

The following example is data set 2A with a Blench record, a BL record, added. This record is not currently available in SAMwin and must be put in the input file manually. The side factor is all that has been specified in this example. The BL record can be added to the following calculations: normal depth, bottom width, hydraulic roughness, flow distribution, and the riprap calculations given discharge and depth. Since the Blench equation requires a discharge and a slope, the BL record added to a data set which will calculate discharge, slope, or riprap given velocity and depth will be ignored, usually with a message printed to the output file saying the Blench regime calculations could not be made.

Sample Output

Adding a BL record to a data set only triggers additional output, "Table 3. Blench Regime-Channel Dimensions." It does not change the calculated results for that data set. Shown below is a selection of output from above input file, including Table 3, Table 5-1 and Table 5-4. Tables 5-1 and 5-4 can be compared to the output shown in the bottom width calculations section earlier to see that there is no change in the calculated output specified by the input file without the BL record.

Stable Channel Dimensions Calculations: Input and Output

These calculations are accessed through the Edit-Hydraulic Function Input-Stable Channel Dimensions (Copeland Method) dropdown menu, as shown in Figure 6.14.

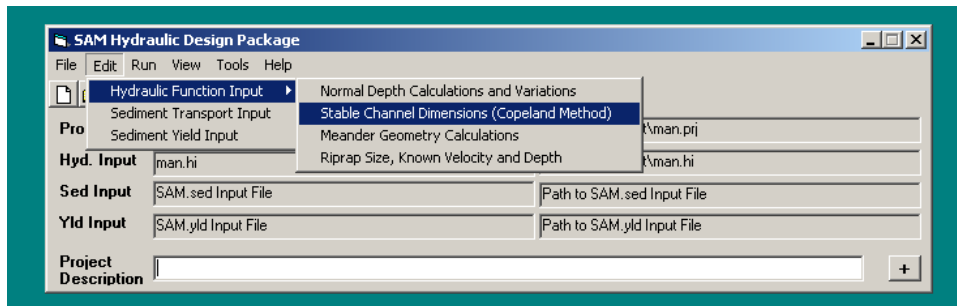

Figure 6.14. Accessing the Stable Channel Method input screens.

General Input Requirements

The input data required, sediment inflow concentration, base width, side slope, bank roughness coefficient, bed material d_{50} , bed material gradation coefficient, valley slope and water discharge, are shown in Figure 6.15.

Figure 6.15. Main data input screen for the Stable Channel Dimensions Method.

If sediment inflow is to be calculated, which is the recommended procedure, additional data are required for the supply reach. This screen is accessed by clicking the “Define Supply Reach” button on the lower right, Figure 6.15. The additional input screen, asking for base width, side slope, bank roughness coefficient, bed-material median grain size geometric gradation coefficient, average slope, and discharge, is shown in Figure 6.16.

Supply Reach		Left Bank	Right Bank
Water Discharge			
Bottom Width	140	Side Slope (Horiz. to 1)	2
Bank Height	15	Roughness Equation	Manning
Energy Slope	.0017	Roughness Value	

Figure 6.16. Input screen for the Supply Reach for Stable Channel Design Method Calculations.

For both these sub-data sets, it is important that the base width is representative of the total movable-bed width of the channel. The bank roughness should serve as a composite of all additional roughness factors, i.e., channel irregularities, variations of channel cross-section shape, relative effect of obstructions, vegetation, and sinuosity. Only flow that is vertical above the bed is considered capable of transporting the bed material sediment load.

Specific Input Requirements

Water Discharge The design discharge is critical in determining appropriate dimensions for the channel. Investigators have proposed different methods for estimating that design discharge. The 2-year frequency flood is sometimes used for perennial streams. For ephemeral streams the 10-year frequency is sometimes used. The “bankfull” discharge is sometimes suggested. Others prefer using the “effective” discharge. Currently, there is no generally accepted method for determining the channel-forming discharge. It is recommended that a range of discharges be used in the analysis to test sensitivity of the solution. However, currently SAMwin will calculate for only one discharge at a time.

Inflowing Sediment Discharge This is the concentration of the inflowing bed material load. It is best if SAM.hyd is allowed to calculate the sediment concentration based on hydraulic conditions in the sediment supply reach. The bed-material composition is defined by the median grain size and the gradation coefficient.

Valley Slope Valley slope is the maximum possible slope for the channel invert. This value is used in the test for sediment deposition. If the required slope exceeds the prescribed valley slope, the following message is printed:

>>>>MINIMUM SLOPE IS GREATER THAN VALLEY SLOPE - THIS IS A SEDIMENT TRAP <<<<

Bank Slopes and Roughness The analytical method assumes all bed material transport occurs over the bed of the cross section and that none occurs above the side slopes. Therefore, the portion of water conveyed above the side slopes expends energy but does not transport sediment, making "Flow Distribution" an extremely important calculation. The input parameters for flow distribution are bank angle and bank roughness. The recommended procedure to use for this is that discussed in Chapter 5 of EM 1110-2-1601 (USACE 1991, 1994). Any roughness input for the bed will be disregarded by the calculations as bed roughness is calculated using the Brownlie equations. Also, only the Manning and Strickler equations are available for roughness calculations in this option. For maximum transport of sediment, use the steepest bank angle allowed by bank stability requirements

Bottom Width Again, it is important that the base width is representative of the total movable-bed width of the channel.

Figure 6.17. Cowan Multipliers input turned on – Stable Channel Methods screen.

Gravel Bed River Option

In this option SAM uses the Limerinos (1970) equation to calculate grain roughness on the bed, the Manning equation to calculate roughness on the channel side slope, and the Meyer-Peter and Muller (1948) equation to calculate sediment transport.

To access this option the “Gravel Bed River” box in the Options area must be checked. No extra input is required; the checkbox simply sends flag to the program to make the gravel bed calculations.

Cowan Multiplier Option

This option is currently available **only** for gravel bed streams. To access this option, the “Specify Cowan Multipliers” box in Options area of the Stable Channel Design screen must be checked see Figure 6.17. It allows the user to provide additional bed roughness that may be added to the grain bed roughness using the Cowan (1956) method. The additional roughness may be added to account for factors such as surface irregularities, variability in channel shape, obstructions, vegetation and meandering.

$$n_{total} = m(n_{base} + n_{additional})$$

where

$$\begin{aligned} n_{base} &= \text{the base } n\text{-value, input for the bed and channel side} \\ &\quad \text{slopes (input elsewhere on the screens)} \\ n_{additional} &= \text{the addition for surface irregularities} + \\ &\quad \text{the addition for variation in channel cross section} + \\ &\quad \text{the addition for obstructions} + \\ &\quad \text{the addition for vegetation.} \end{aligned}$$

Suggested values for these additions can be found in Cowan (1956) and Chow (1959).

Meandering is accounted for with a meandering coefficient, m ; for a straight channel the meandering coefficient is 1.0. Appropriate values for the meandering coefficient and additions to the grain roughness n -value can be found in Cowan (1956) and Chow (1959).

The n -value additions and the meandering coefficient can be input for the design reach and/or the supply reach. See Appendix C, GB record.

Example input data

Test 8A is a data set that provides the parameters for calculating the stable channel dimension, i.e., the GC and PF records, and asks SAM.hyd to calculate

the inflowing sediment concentration by providing information about the supply reach, i.e., the CT record. Note that when field 2 of the GC record is either blank, a zero or a -1, the program will calculate the design sediment concentration for the design water discharge; that is, all concentrations will be calculated from the supply reach parameters. However, if a negative value other than 1 is coded, it is interpreted as the water discharge to use for calculating the design sediment concentration, i.e., the water discharge for the approach reach. (See Appendix C, GC record.) Also note that the channel geometry, (CT record), channel slope (ES record) and bed sediment gradation (PF record) must be supplied for the approach channel when concentrations are to be calculated.

Test 8B contains two GC records which will allow SAM.hyd to calculate two sets of stable channel dimensions with the only difference between the two being the water discharge. This means of running is not currently available in SAMwin, but may be accomplished by manually editing the input file. Test 8C provides the sediment inflow concentration on the GC record, so is complete without any supply reach information records.

Output description

The general output tables are the same as those generated in the normal depth calculations and are described in that section. The following output is from Test 8A. The calculations being made are stated, and then the results of the inflowing sediment concentration calculations are listed. The rest of the parameters used for the stable channel dimension calculations are listed. Table 4-1 provides the results of these calculations. Note that included in this output, at the end of the file, is a key to the regime abbreviations in the right-most column. Also notice that the line starting "Table 4-1" also lists the discharge, concentration and d_{50} . If gravel bed calculations had been made, as for Test 8D, the statement

USING MEYER-PETER-MULLER & LIMERINOS EQUATIONS

would have appeared on the line after

CALCULATE STABLE CHANNEL DIMENSIONS.

That statement in the output is the only one that flags that output file as having used the gravel bed calculations.

...END OF JOB...

Table 4-1 contains the family of widths, depths, and slopes which satisfies the sediment transport and resistance equations for the given conditions. It is important to consider river morphology when interpreting these calculated values. That is, each line in the table satisfies the governing equations, but natural rivers tend toward a regime width. Consequently, the calculations start with the regime width as determined by the following equation:

$$B = 2.0 Q^{0.5}$$

For the water discharge in this example, the equation gives a regime width of 120 feet. This regime width is then divided by 10 to provide a starting value for the table, 12 ft in this case. The rest of the table is produced by adding the 12 ft increment to each successive width and repeating the depth, slope, n-value calculations. Note the last column in the table, "Flow Regime." Four conditions are possible:

- LO** = Lower regime
(i.e. ripples and dunes)
- TL** = Transition zone, Lower regime selected
(bed forms tend towards ripples and dunes.)
- TU** = Transition zone, Upper regime selected
(Bed forms tend toward plain bed.)
- UP** = Upper regime selected
(Plain bed and antidunes)

Channel dimensions corresponding to minimum stream power, $Q \cdot S$, (which also corresponds to minimum slope), are presented at the bottom of the table. In this example the energy slope reaches a minimum value at about the regime width. However, that is not always the case. Much depends on the bank roughness.

These calculations will provide the information to plot the stable channel dimension curve,

Range of Solutions

Stable channel dimensions are calculated for a range of widths. For each combination of slope and base width, a unique value of depth is calculated. This can be used to evaluate stability in an existing channel or in a proposed design channel. It is important to consider river morphology when interpreting these calculated values. It is important to be consistent in the selection of channel dimensions. That is, once a width is selected, the depth and slope are fixed. This allows the designer to select specific project constraints, such as right-of-way, bank height or minimum bed slope, and then arrive at a consistent set of channel dimensions.

If the calculations indicate that the slope of the project channel needs to be less than the natural terrain, the slopes in the table can be used to aid in spacing drop structures or introducing sinuosity into the project alignment.

An example of a family of slope-width solutions that satisfy the resistance and sediment transport equations for the design discharge is illustrated by Figure 6.18. Any combination of slope and base width from this curve will be stable for the prescribed channel design discharge.

NOTE: Combinations of width and slope that plot above the stability curve will result in degradation, and combinations below the curve will result in aggradation. The greater the distance from the curve, the more severe the instability.

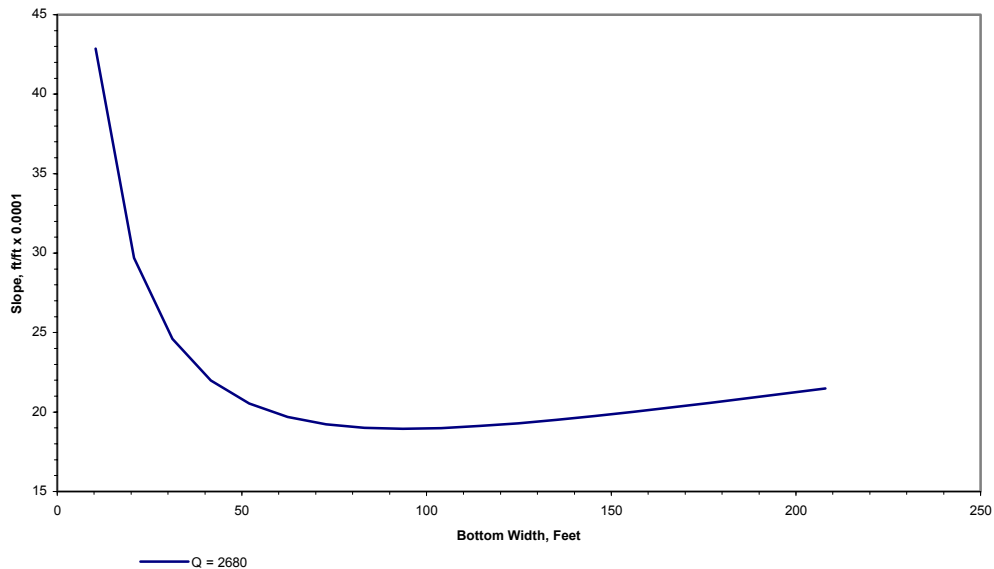

Figure 6.18. Example slope-width graph from the stable channel dimensions calculations.

Constraints on this wide range of solutions may result from a maximum possible slope, or a width constraint due to right-of-way. Maximum allowable

depth could also be a constraint. Depth is not plotted in Figure 6.18, but it is calculated for each slope and width combination determined. With constraints, the range of solutions is reduced, see Figure 6.19.

Different water and sediment discharges will produce different stability curves. First, the stable channel solution is obtained for the channel-forming discharge. Then, stability curves are calculated for a range of discharges to determine how sensitive the channel dimensions are to variations in water and sediment inflow events.

The stable channel dimensions are calculated for a range of widths on either side of a prescribed median value. (A median value can be prescribed, manually, on the GC record, but not in SAMwin.) If no median value is prescribed, the program assigns a value based on the following hydraulic geometry equation, proposed in EM 1110-2-1418 (USACE 1994).

$$B = 2.0 Q^{0.5}$$

Figure 6.19. Slope-width graph showing the effect of constraints on the range of solutions.

The SAM program assigns 20 base widths for the calculation, each with an increment of $0.1B$. Calculations for these conditions are displayed as output. Stability curves can then be plotted from these data.

A solution for minimum stream power is also calculated by the model. This solution represents the minimum slope that will transport the incoming sediment load. Solution for minimum slope is obtained by using a second-order Lagrangian interpolation scheme. Opinions are divided regarding the use of

minimum stream power to uniquely define channel stability. An optional use of the analytical method is to assign a value for slope, thereby obtaining unique solutions for width and depth. Typically there will be two solutions for each slope.

Meander Geometry

Input

The purpose of the meander calculations is to provide both curvilinear and Cartesian coordinates for a meander planform based on the sine-generated curve. The sine-generated curve has been shown to effectively replicate meander patterns in a wide variety of natural rivers. (Langbein and Leopold, 1966)

Required input are the meander arc length and the meander wavelength, as shown in Figure 6.20. Title records are optional. The Meander arc length is the actual length of the channel, whereas the wavelength is the length, along the valley, of one full meander.

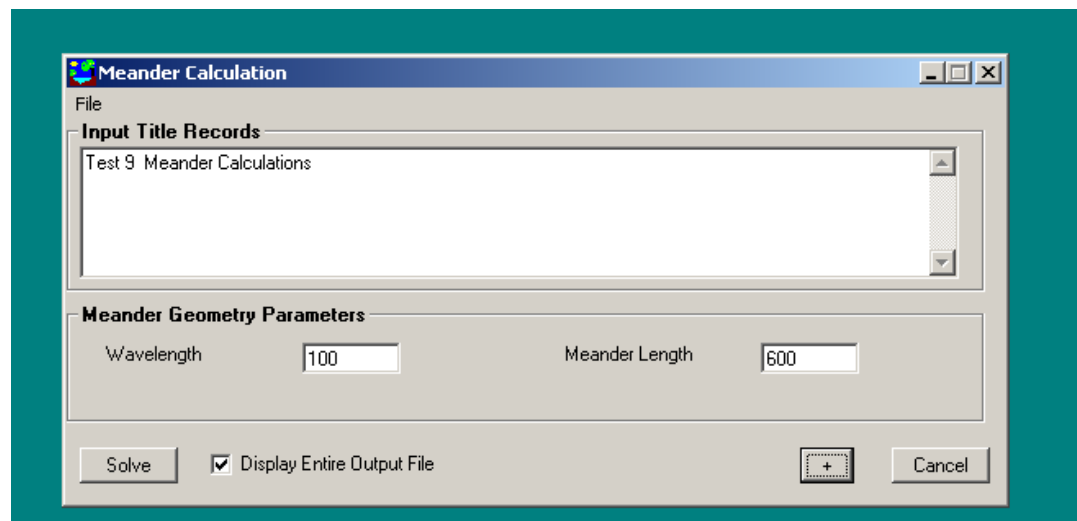

Figure 6.20. The Meander Calculation screen, with input.

Output

The output file first displays the SAM.hyd banner and echoes the input. An internal banner stresses that these calculations are appropriate for sand-be streams. The input wavelength and meander length are then printed along with the sinuosity, maximum deflection angle (in degrees), and the amplitude. Then a table of "Coordinates along one meander wavelength" is printed, giving the distance along the channel, deflection angle in degrees, the Y perpendicular to the valley slope, and the X along the valley slope.

This calculation has no plotting capability, but the table of coordinates could be copied into a spreadsheet for plotting.

7 Input Requirements and Program Output for SAM.sed

Purpose

SAM.sed calculates sediment discharge rating curves for the bed material load using sediment transport functions. The input and output vary only insofar as different functions are selected. This chapter will address the input data requirements and discuss the associated output. Be aware that there is an option, SAM.aid (under Tools on the SAMwin main menu) that can provide guidance in the selection of sediment transport functions.

General

The SAM.sed module expects an input file designated as *xxxxxxx.si*, where *x* can be any DOS acceptable character, including a space (but no embedded spaces), i.e., acceptable file names could be *say.si* or *ITSNEVER.SI*. SAM.sed will write a corresponding file *xxxxxxx.so*, which is the sediment transport calculation's output file; and a *xxxxxxx.yi* file which may be used as an input file to SAM.yld.

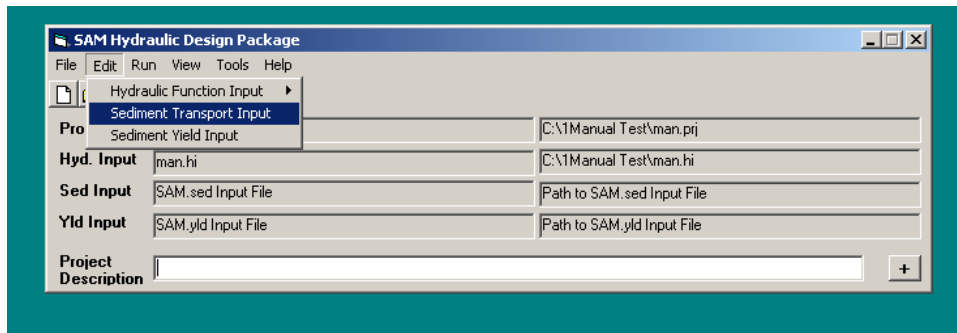

Figure 7.1. Accessing the Sediment Transport Input screens.

SAM.hyd generally creates a “.si” file. The “.si” file can be created or edited in SAMwin as shown in Figure 7.1. A sediment transport input file can also be created or edited using a system editor, or, in a DOS window only, by using SAM.m95 in combination with a TAPE95 from an HEC-2 execution (see

Appendix H). In some cases, modifications to the SAM.hyd-created “.si” file may be necessary before sediment transport calculations can be made.

The sample data sets used in the input and output discussions are those provided with the SAM package in the SEDPC.LIB files.

Program execution

The sediment transport calculations are made in SAMwin from the “Solve” button on the input screen, Figure 7.2, or from the “Run” dropdown menu on the opening screen, Figure 7.1. This second option is useful if a ready-to-run data set exists.

Selected output will scroll to the screen. The output coming to this window cannot be selected by the user. All output will be saved in the default output filename.

Solve ☐ Display Entire Output File + Enter Bed Material Data

Figure 7.2. Sediment transport calculations input screen.

Title Records.

This area allows the user to input descriptive strings, up to 78 characters long, for use in identifying data sets. This input is optional.

Transport Functions. All sediment transport functions available in SAM.sed are listed here. The user can select functions to be calculated. The Laursen-Madden (1985) function is simply the one function that is on by default when the input file has been created by SAM.hyd.

Flow Characteristics. Generally, these fields would be filled with the calculated data from a SAM.hyd-generated input file. However, the user can input this information if so desired. A “column” of numbers is considered together for calculation purposes. The maximum is 10 columns.

Bed Material Gradation. This input is necessary for these calculations, Figure 8.3. DMAX is a required input whereas the specific gravity of sediment is optional (the value shown is the default value). The program will accept up to 18 points on the bed material gradation, and they **must** be input from largest grain size to smallest. However, a grain size for 100% finer and for 0% finer is not required.

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18

Figure 7.3. Bed Material Gradation data input screen.

“+ “ **Box.** This button toggles, opens/closes, a small window which will receive selected output. The output coming to this window cannot be selected by the user.

Display Entire Output File. When this box is checked the output file will open in its own window (using Notepad) after calculations are complete. If this button is not checked, some input will echo to the screen in the area mentioned above. The entire output file can also be viewed by checking the View menu of the SAM main window and selecting “Sediment Transport Results.”

Solve. This button causes SAM.sed to execute.

Sample Input Data

In addition to the SAMwin option to create or edit a sediment transport input file, the input data file can be prepared with a system editor, or by the hydraulics calculations in SAM.hyd. (SAM.m95, which reads the HEC-2 output to create a SAM.sed input file, is not available in SAMwin). Of these, however, only

SAM.hyd provides the "effective" value for sediment transport variables. If channel and overbanks are specified in the SAM.hyd file, only the channel variables are transferred to the ".si" file. The discharge is the total discharge and is used only as an identifier and not used in the calculations.

The following example shows input data as created by running TEST 1C in SAM.hyd. Notice that only the Laursen (Madden) function shows "YES." Other transport functions can be "turned on" for computation with an editor or the SAMwin data entry windows.. The SAM.hyd input file from which this file was developed contained a PF-record so this required record is already in the file. If the record were not in the SAM.sed input file, it would also have to be added.

Sample Output Data

Selected results are printed to the screen as the program executes. The entire output is saved in the default output file. Also, the sediment transport rating curve needed for the sediment yield calculations is written to the default SAM.yld file.

Output Data Sets

The following output description refers to the output of Test 1C listed above. The Ackers-White,D50, and the Van Rijn functions have been selected in order to point out certain associated output.

Output Data Description

Table 1 echoes the input data file. An un-numbered table lists the “Bed Sediment Fractions Calculated From PF-Data.” The properties of water, Table 3, are calculated from the water temperature at sea-level. The hydraulic parameters from input data are listed in Table 2.1. Effective discharge is the product of the width, depth, and velocity and represents channel discharge. Table 4.1 presents detailed results of the sediment transport calculations by discharge, in rows by sediment size class and in columns as labeled. Notice the discharges are the total discharges from the QW-record. Concentration is calculated using total discharge, not channel discharge. There will also be a separate Table 4.1 for each sediment transport function selected in the input file. Only two discharges’ output for each function are shown here.

The Van Rijn function provides additional printout – for each water discharge, the sediment concentration profile by size class is calculated in mg/l. Table 5 is a summary of the calculated total bed-material sediment discharge, in rows according to water discharge and in columns by sediment transport function.

Sample of Data Written to SAM.yld Input File

SAM.sed writes the sediment concentration rating curve calculated for each sediment transport function selected to the SAM.yld input file, as shown below.

```

$$END

```

A separate sediment concentration rating curve is written for each sediment transport function selected in SAM.sed. If there is only one discharge in the SAM.sed input file, no SAM.yld input file is written, as no curve had been calculated. A warning message to that effect is written to the end of the output file and is echoed to the printout area on the input window.

8 Input Requirements and Program Output for SAM.yld

Purpose

SAM.yld provides hydraulic design engineers a systematic method for rapidly calculating bed-material sediment yield. This chapter will address the input data requirements and discuss the associated output.

SAM.yld calculates sediment yield passing a cross-section during a specified period of time. The time period considered can be a single flood event or an entire year. In SAM.yld the flow can be specified by either a hydrograph or a flow duration curve. The sediment rating curve can be specified either as sediment discharge versus water discharge or as sediment concentration versus water discharge. Calculations are based on the flow-duration sediment-discharge rating curve method (EM 1110-2-4000 USACE 1989).

General

The SAM.yld module expects an input file designated as *xxxxxxx.yi*, where *x* can be any DOS acceptable character, including a space (but no embedded spaces), i.e., acceptable file names could be *say.yi* or *ITSNEVER.YI*. SAM.yld will write a corresponding file *xxxxxxx.yo*, which is the output file. There is no plot output. SAM.yld input screens are accessed as shown in Figure 8.1.

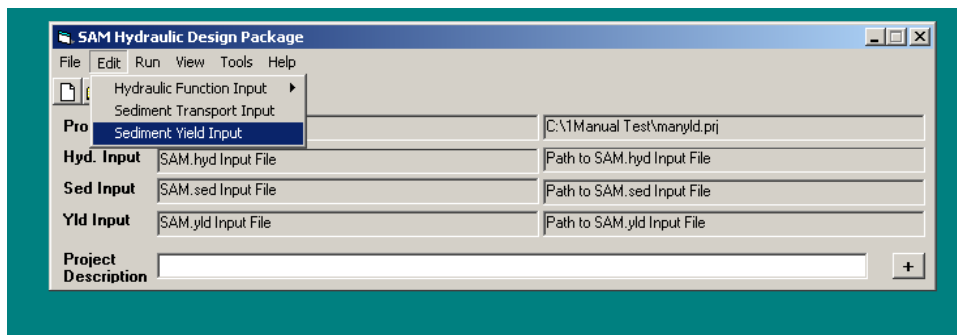

Figure 8.1. Accessing the Sediment Yield Input Screen

On the SAMwin main menu, clicking Edit/Sediment Yield Input brings up the screen in Figure 8-2. If there is an appropriate input file, a *.yi file, in the project directory, it's data will appear on the screen.

SAM.yld is designed to most easily run the data set made by SAM.sed, the *.yi file. SAM.sed writes the sediment concentration rating curve to a SAM.yld input file. If more than one sediment transport function was selected in SAM.sed, the SAM.yld input file will contain all sediment concentration rating curves, separated by a \$JOB record. The flow duration curve or hydrograph, whichever is used, is not written into the *.yi file. This information can be added to a SAM.yld data set on the SAMwin Sediment Yield Input screen shown, Figure 8-2. Both the *.yi input file and the flow data file can be prepared with a system editor and read into the screen in Figure 8-2 using the File dropdown menu. The flow data file **MUST** be named CDFFIL and reside in the project directory.

Solve ☐ Display Entire Output File

Figure 8-2. The Sediment Yield Input screen.

Title Records. This area allows the user to input descriptive strings, up to 78 characters long, for use in identifying data sets. These title records are written to the flow data file so should be used to describe the flow data, but the input is optional.

Discharge Data. The flow data may be input as a flow duration curve, the option shown in Figure 8.3, or as a flow hydrograph, Figure 8.4. Both options require the time interval to be input. Both the right hand side of the screen and the “Optional Data” area of the screen will request different data depending on the option selected here.

The screenshot shows the 'Sediment Yield Input' window. It has a 'File' menu and a 'Title Records' section with a text box containing 'Sam Yld Example'. Below this is the 'Discharge Data' section with two radio buttons: 'Specify Flow Duration Curve' (selected) and 'Specify Flow Hydrograph'. A text box for 'Flow Duration Time Interval (days)' contains the value '365'. The 'Optional Data' section has three text boxes: 'Number of Output Class Intervals' (20), 'Specific Weight of Sediment (lbs/cu-ft)' (93), and 'Number of Integration Steps' (365). At the bottom are 'Solve' and 'Display Entire Output File' checkboxes, and a '+' button.

Figure 8.3. Example flow duration data input.

Flow Duration. This area allows the user to input the flow duration data. Data can be input in either increasing or decreasing percentage. **NOTE:** Do not use zero as the first or last discharge – use a very small number instead of zero, i.e., 0.0001. EM 1110-2-1415 (USACE) describes the procedure for calculating the flow duration curve. The time interval is input in days, and the default is 365. In the “Optional Data” section the “Number of Output Class Intervals” affects the Table 3.2 in the output file, a table useful for determining the effective discharge. The default for this value is 20. The “Specific Weight of Sediment (lbs/cu ft)” defaults to 93. The “Number of Integration Steps” refers to calculations internal to SAM.yld. The default is 365.

Flow Hydrograph. This area allows the user to input the flow hydrograph ordinate data. This hydrograph must have a uniform time-step. Zero can be used as a flow. The time interval is input in hours, and the default is 24. In the “Optional Data” section the “Number of Output Class Intervals” affects the Table 3.2 in the output file, a table useful for determining the effective discharge. The default for this value is 20. The “Specific Weight of Sediment (lbs/cu ft)” defaults to 93.

“+” **Box.** This button opens a small area below this window which will receive selected output. The output coming to this window cannot be selected by the user.

Solve ☒ Display Entire Output File

Figure 8.4. Example flow hydrograph data input.

Display Entire Output File. When this box is checked the output file will open in its own window (using Notepad) after calculations are complete. If this button is not checked, some input will echo to the screen in the area mentioned above. The entire output file can also be viewed by checking the View menu of the SAM main window and selecting “Sediment Yield Results.”

Solve. This button causes SAM.yld to execute.

Program execution

The sediment yield calculations are made in SAMwin from the “Solve” button on the input screen, Figure 8.3 and 9.4, or from the “Run” dropdown menu. This second option is useful if a ready-to-run data set exists. This ready-to-run data set must contain the flow data, as described in the SAM Manual, or the flow data can be in a separate file that **MUST** be named “CDFFIL,” no extension.

NOTE: If SAM.yld is run from the Run dropdown menu and it seems as though nothing happened, and there is no output file -- check to see if there is water data for the *.yi file being used, i.e., that there is a CDFFIL file in the directory.

Input Data Descriptions

The following example shows input data as created by running TEST 1C in SAM.sed. Notice that there is a separate input data set for each sediment transport function chosen in SAM.sed, with each data set ending with a \$JOB, and a \$\$END record at the end. Also notice that no data set contains any flow-duration or hydrograph data.

```

$$END

```

In order to execute, the above data sets require flow information. This data is input through the “Sediment Yield Input” screen and automatically written to the *CDFFIL* file.

The flow information can also be in the “.yi” file, input using a system editor. Note that the information must be put in **each** “stacked” job, i.e., in each data set defined by a \$JOB record. This format may be used to describe a flow-duration curve using discharge and percent of time exceeded, or a hydrograph, using QH records. See the Appendix E of this manual. The following examples show data sets containing the water data – the JP record, the QQ-QD record sets, and the QH records.

```

Sample Output Data

Selected results are printed to a window which opens below the input area as the program executes. The output coming to this window cannot be selected by the user. The complete output is saved in the appropriate default output file.

Output Data Sets

The following output files are from TEST 1C. The first output file shows that a flow duration curve data was input on the Sediment Yield Input screen. Note that the data set originally contained only the sediment discharge rating curves as output from SAM.sed and read the water data from the *CDFFIL* file. The output from only one sediment transport function is given here. The output from all sediment transport functions in the *.yi file are written to one file, the corresponding *.yo file.

...END OF JOB... Printout is in FILE [C:\Hold\hydtests.yo]

Output Data Description

Since the SAM.yld input file contained a `$$JOB` record, the use here of the term “output data set” refers to output from program banner to the “END OF JOB” tag. As in SAM.hyd and SAM.sed, Table 1 in every output data set is an echo of the input data set. However, in SAM.yld this table echoes the input from both the *.yi file and the *CDFFIL* water data file. Table 2.1 is the “Sediment Discharge Table” and shows the input sediment discharge rating curve in tons per day. The next several table numbers and the information displayed differ depending on whether the calculations were based on a flow duration curve or a hydrograph. If the input data included flow-duration information, the output includes tables 2.2 and 2.3. Table 2.2 simply echoes the input flow-duration curve. Table 2.3, “Integration Parameters for Flow-Duration Option,” includes the number of integration steps, an input item on the Sediment Yield Input screen, and the integration interval in cfs. If the input data included QH records, the output includes tables 2.4, 2.5, and 2.6. Table 2.4 echoes the QH records and lists the time between points. Table 2.5 shows the hydrograph converted to a flow-duration table. Table 2.6 corresponds the Table 2.3, above, but is the “Integration Parameters for Hydrograph Option.” The number of integration steps, echoed on this table, is an input parameter.

At this point the output table names and information specified become the same. Table 2.7 gives the density of the sediment deposit, another possible input variable. Table 3.1, “Calculated Yields,” echoes to the screen in the drop down area of the Sediment Yield Input screen as well as printing to the output file. This table provides the “answers” for the SAM.yld option, giving the sediment yield in both tons and cubic yards, and echoing the time period, in days, as input on Figure 8.3 or 9.4. It also lists the sediment transport function used for that data set.

Table 3.2 is the “Distribution of Yield by Water Discharge Class Interval.” The first column, “Class,” is ‘20’ in the example problems, because in the “Optional Data” area on the “Sediment Yield Input” screen, the “Number of Output Class Intervals” was left at the default of 20. The number of intervals into which the range of flows is divided can be changed with this input parameter. When a flow duration curve has been input, Table 3.2 can be used to determine the effective discharge – the discharge that moves the most sediment. The effective discharge can be determined by looking for the class that has the largest “increment of sediment.” Copeland et al. (2001) has a discussion of effective discharge in chapter 3.

The end of the output for this data set is marked with “...END OF JOB...” and a note with the output filename. If the input file has stacked jobs, the next data set will begin with a new program banner.

If some discharges in the flow-duration or hydrograph information fall outside the range of discharges in the sediment discharge rating curve, the program will inform the user. These messages will print out in connection with the “Integration Parameters” table. The program will then assign a sediment discharge in tons per day to the water discharge value that is out of range, based on the existing sediment discharge table, Table 2.1. This is the “YOUT” value listed in the “INDEPENDENT VARIABLE XIN OUT OF TABLE BOUNDS” message if it appears.

Plotting

SAM.yld has no plotting capabilities at this time.

Appendix B: List of Variables

- \bar{n} = the composite n-value for the total where:
- \bar{V} = average velocity
- \bar{R} = the composite hydraulic radius
- γ = unit weight of water
- γ_s = unit weight of riprap
- γ_w = unit weight of water
- Θ = Shield's parameter
- ν = kinematic viscosity of water - ft²/sec
- ρ_f = density of fluid
- ρ_s = density of sediment particles
- σ = the geometric standard deviation of the sediment mixture, where
- τ = bed shear stress
- τ_c = critical shear stress
- A = area
- A_i = cross-sectional area of panel i, $\Delta X D_i$
- B = effective width of flow (width of portion of cross section which is transporting sediment)
- C = Chezy coefficient; also bed-material sediment concentration - in parts per million
- C_B = bend correction for average velocity (V_{SS}/V_{AVE})
- CH = channel
- C_i = the panel Chezy roughness coefficient
- C_S = Coefficient of incipient failure
- C_T = coefficient for riprap thickness
- C_V = vertical velocity coefficient
- D = depth, ft; or local water depth; or effective depth of flow; or water depth
- d_{30CR} = Critical d_{30} (i.e. minimum d_{30}) size for stable riprap
- d_{50} = median grain size of bed material, mm, or the particle size for which 50% of the sediment mixture is finer.
- d_{84} = the particle size, ft, for which 84% of the sediment mixture is finer (Data ...
- d_e = effective particle size for the mixture
- D_i = average depth in the panel i, $\frac{1}{2} (A+B)$
- d_s = geometric mean of particles in size class i
- EFD = Effective Depth of the cross section
- EFW = Effective Width of the cross section
- $f(X_1)$ = is the difference between the calculated depth for X_1 and the true depth, or between Q_{true} and the calculated Q for X_1

$f(X_2)$ = is the difference between the calculated depth for X_2 and the true depth,
 or between Q_{true} and calculated Q for X_2
 F_B = bed factor
 F_g = grain Froude number.
 F_s = side factor
 g = acceleration of gravity - ft/sec²
 G_{sf} = grain shape factor
 G_{s_i} = transport rate for size class i
 i = panel number
 i_b = fraction of size class i in bed
 k = number of panels
 K = conveyance
 K_1 = Correction for side slope steepness
 LCB = left channel bank
 LOB = Left overbank
 n = Manning's n value
 n_i = n -value in wet panel i
 P_i = Wetted perimeter in wet panel i
 Q = water discharge, cfs
 R = hydraulic radius of the bed portion of the cross section, ft
 RCB = right channel bank section
 $R_i = A_i / P_i$
 R_n = Reynolds number, $4RV/\nu$
 ROB = right overbank
 S = slope; bed slope or energy slope
 S_e = energy slope
 S_f = Safety factor
 s_s = specific gravity of sediment particles.
 T = temperature of fluid
 U_* = boundary shear velocity, \sqrt{gRS}
 V = average flow velocity
 V_{AVE} = average channel velocity
 W = channel width, ft; or bottom width
 X_1 = is the first trial value of Q , or of k_s
 X_2 = is the second trial value of Q , or of k_s
 X_3 = is the next trial value of Q , or of k_s
 z = side slopes of the channel

GENERAL NOTES

The following are conventions used in the record descriptions in this appendix.

- | | |
|-------|--|
| a1.@! | These characters in the "value" column means that any alpha or numeric characters can go in that field; generally it is a comment field. |
| b | This character in the "value" column indicates a blank field. |

Records that are not available in SAMwin are still useable -- use an editor to insert the record into a data file and execute the program from the "RUN" dropdown menu of the SAMwin main menu.

T1 RECORDS

Up to 10 title records are permitted. These records are for the user's information only and are therefore optional. TI is also an acceptable record identification for title records.

Example:

```
T1    Use these title cards to define the job, the date, the Investigator, the
T1    model #, the data source, the purpose for this run, and changes from
T1    previous runs.
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		T1 or TI	Record Identification in columns 1 and 2. TI is preferred.

F# RECORDS

Marks each data field by column numbers, each field being 8 columns wide. There can be only 1 F# record. This record is for the user's information only and is therefore optional. This record is not always printed to the output file.

Example:

```
T1      Title cards
T1      Title cards
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		F#	<u>Record</u> Identification in columns 1 and 2.

TR RECORD

SAMwin – only fields 1 and 2 of the first TR record are used.

The TR record controls the printout and selects the Compositing Method. There can be up to 2 TR records.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
TRKSW(1) KSW(2) KSW(3) KSW(..)
```

```
TR          1
```

Note: The equal velocity method is suggested for cross sections with rough vertical walls or steep side slopes. See Chapter 2. Also see Chapter 2, “Compositing compound channels and overbanks,” for further guidance on choosing a compositing method.

Field	Variable	Value	Description
0		TR	Record Identification = TRace printout.
		TR	Record Identification for continuation record.
1	KSW(1)		Method for Compositing Hydraulic Radius and n-values:
		b,1	Composite by Alpha Method.
		2	Composite by equal velocity method.
		3	Composite by total force method.
		4	Composite by conveyance method.
2	KSW(2)	1	Print out flow distribution in each panel.
3	KSW(3)		Trace... Normal depth calculations.
4	KSW(4)		Trace... Fixed-bed bottom width calculation.
5	KSW(5)	1	Trace... CI-Option (Subroutine gmsex.for)
6	KSW(6)	1	Trace... Alpha Method for Compositing Hydraulic Radius and n-values
7	KSW(7)	1	Trace... Brownlie Method
8	KSW(8)	1	Trace... Trapezoidal Integration, (Subroutine tzin.for).
9	KSW(9)	1,2	Trace... Copeland's analytical method for width, depth and slope.
10	KSW(10)		Trace... Riprap Design Computations
11	KSW(11)		Trace... Water Discharge Calculations.
12	KSW(12)		Trace... n-Value Calculations.
13	KSW(13)		Trace... Slope Calculations.
14	KSW(14)		Trace... Reading Input

CT RECORD

The CT Record is an option for prescribing simple rectangular, triangular or trapezoidal, channel cross sections. Invert elevation is always 0.0. A gage zero (GZ) record can be used to convert output to actual elevations. Up to 3 CT records can be stacked to form a complex geometry. For Bottom Width calculations, the number of discharges coded on the QW record must equal the number of CT records in the data file.

If riprap design is desired, include RR and RT records. Be sure to also include the PF record. Riprap is calculated only if the bed is not stable, and the program uses D50 in Shield's curve to test for stability.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678

Field	Variable	Value	Description
0		CT	<u>Record</u> Identification = Channel Template.
1	BW	0,+ b	Bottom <u>width</u> , ft. Program calculates bottom width for the prescribed hydraulic parameters.
2	CD	-,0,+	Bank height, ft.
3	SSL	+ b	Side <u>Slope</u> , Left side of channel facing downstream, 1V:[_]H. <u>Default</u> = 0.
4	SSR	0,+ b	<u>Side</u> Slope, Right side of channel facing downstream, 1V:[_]H. <u>Default</u> = 0.
5	NEQBED	0,+ b,0	<u>Equation</u> Number for the n-value calculation on the channel bed. <u>value</u> coded in KSBED(CT-6) is n-value.
		1	Keulegan <u>Equation</u> . Program expects Ks value for bed (CT-6).
		2	Strickler n- <u>value</u> equation. Program expects Ks value for bed (CT-6).
		3	Limerinos n- <u>value</u> equation. Program expects a D84, either on a BR record (not available in SAMwin) or calculated from a PF record.
		4	Brownlie <u>bed</u> roughness equations. Program expects a D84, either on a BR record or will be calculated from a PF record.
		5	SCS Grass lining, type E.
		6	SCS <u>grass</u> , type D.

CT RECORD, continued

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
		7	SCS grass, type C.
		8	SCS grass, type B.
		9	SCS grass, type A.
6	KSBD	+	<p>If NEQBED =0, Code the Manning n-value here.</p> <p>If NEQBED =1 or 2, Code the surface roughness for the bed, ft, here.</p> <p>If NEQBED =3 or 4, This field can be blank, but program expects BR or PF record to prescribe the bed surface gradation. The BR record is not available in SAMwin.</p> <p>If NEQBED =5 thru 9, This field can be blank.</p>
7	NEQBKL	0,+	Equation Number for the n-value calculation on LEFT bank. Same rules apply as described for NEQBED.
		b	Manning n-value is coded in field 8.
8	KSBKL	+	Hydraulic roughness for the LEFT bank. Same rules apply as described for KSBD.
9	NEQBKR	0,+	Equation Number for the n-value calculation on RIGHT bank. Same rules apply as described above for NEQBED.
		b	Manning n-value is coded in field 10.
10	KSBKR	0,+	Hydraulic roughness for the RIGHT bank. Same rules apply as described above for KSBD.

CI RECORD

Not available in SAMwin.

The CI Record provides input for the channel improvement option. This option simulates the modification of cross section data, GR records, by a trapezoidal excavation. Up to 3 CI records are allowed. The channel improvements are performed in the order that the records are specified.

Note: HEC-2 allows the natural channel to be filled prior to excavation if desired, see variable BW. Low areas of the natural cross section may be filled by the sediment option in HEC-2. But neither of these options are available in SAM at this time.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
CI CLSTA CELCH XLCH.CN XLSS RSS BW
CI 50 -15 2 2 20
```

Field	Variable	Value	Description
0		CI	Record Identification = Channel Improvement.
1	CLSTA	+	Station of centerline of trapezoidal channel excavation expressed in terms of the stations used in the natural cross section descriptions, on the GR records.
		-1	Program determines CLSTA to be halfway between bank stations.
2	CELCH	+ or -	Elevation of channel invert, but not -1.
		-1	Elevation of channel invert is equal to minimum elevataion in cross section
	.1>=CELCH>=.00001		Elevation of channel invert is based on CELCH (slope) and XLCH.CN (channel reach length). This is an HEC-2 option and is <u>NOT NEEDED IN SAM</u> .
3	XLCH.CN	0 or +	New channel reach length and n-value for HEC-2. (<u>NOT NEEDED IN SAM</u>)
4	XLSS	0	Left side slope will be vertical.
		+	Left side slope of excavation, 1V:[_]H.
5	RSS	0 or +	Right side slope of excavation, 1V:[_]H, same as for left side.
6-10	BW	+	Bottom width of channel.
			Same as + but the old channel will be filled up to an elevation equal to the minnum bank elevation. This HEC-2 option NOT YET working in SAM.
		.01	Signals the program to stop modifications.
			This HEC-2 option <u>NOT NEEDED IN SAM</u> .

X1 RECORD

This record is used to prescribe the cross section location and the program options which are applicable to that cross section. Since SAMwin looks at only one cross section, there may be only 1 X1 record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
X1  ASN      NXY    STCHL    STCHR
X1  22.5      9      337      387
```

Field	Variable	Value	Description
0	ICG,IDT	X1	Identification characters = X-Section.
1	RMILE	-,0,+	River Mile, for identification only, not for measuring distance.
2	NXY	+	Total number of coordinate points on the following GR record set.
3	STCHL	-,+	The station of the left bank of the channel. Use top bank so the bank roughness will be included in the composite n-values for the channel. The value <u>MUST</u> equal one of the station values on GR record.
4	STCHR	+	Station of the right bank of the channel. Same rules as for STCHL above.

GR RECORD

This record is used when coding cross sections by coordinate point (Elevation, Station). Code stations in increasing order. Negative values are permitted, in which case "increasing order" means "the positive direction of the x-axis." A maximum of 20 GR records is allowed.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
GR EL(1) STA(1) EL(2) STA(2) EL(3) STA(3) EL(..) STA(..)

GR4496.0      0 4494.5      52 4495.3      146 4493.9      266 4492.2      337
GR4490.3      348 4490.3      360 4489.7      367 4495      387
```

Field	Variable	Value	Description
0	ICG,IDT	GR GR	Record Identification = GRound co-ordinates Record Identification for continuation records, also.
1	EL(1)	-,0,+	Elevation of first coordinate, in ft.
2	STA(1)	-,0,+	Station corresponding to EL(1), in ft.
3	EL(2)	-,0,+	Elevation of second coordinate.
4	STA(2)	-,0,+	Station corresponding to EL(2).
.			
.			
.			
10	STA(10)	-,0,+	Station corresponding to EL(9).

Continue for up to 100 points. Each continuation record is identified with GR, and the format is identical for all records.

GL RECORD

Not available in SAMwin.

This Record is used to prescribe reach lengths, if necessary. There can be up to 10 GL records.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
GLTZL(1) TZL(2) TZL(3) TZL(...)
```

```
GL 500 1000 1500
```

Field	Variable	Value	Description
0	ICG, IDT	GL GL	Record Identification = Reach Length. Record Identification on continuation records also.
1	TZL(1)	+ b(1)	Reach length for panel 1 in the cross section. There is no default for panel 1.
2	TZL(2)	+	Reach length for panel 2.
3	TZL(3)	+	Reach length for panel 3.
4	TZL(...)	+	Code as necessary.

If the cross section contains more than 10 panels, continue coding lengths using field 1 on each continuation GL record. The number of values needed by the program is NXY-1. However, the program will supply missing values by linear interpolation between values which are coded.

NE RECORD

This record is used with the HEC-2 format (i.e. X1-GR records) to prescribe the n-value (i.e. hydraulic roughness) equation to use in each “panel” across the section. There must be NXY-1 values. Code the number from the following list of n-value equations. See Table 4, Characteristics of Grass Cover, Chapter 2, for details on the grass equations.

- 0 = Manning n-values are coded.
- 1 = Keulegan equations
- 2 = Strickler Equation
- 3 = Limerinos Equation
- 4 = Brownlie Bed Roughness Predictor
- 5 = Grass lining, Type E
- 6 = Grass lining, Type D
- 7 = Grass lining, Type C
- 8 = Grass lining, Type B
- 9 = Grass lining, Type A

Do not mix KN and KS records at this time.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
NE EQNV1 EQNV2 EQNV3 EQNV( . . )

NE      5      5      2      2      2      3      3      1
```

Field	Variable	Value	Description
0	ICG,IDT	NE NE	Record Identification = N-value Equations Record Identification on continuation records also.
1	EQNV		Roughness equation for panel 1.
		0	Manning's n-value will be coded for panel 1 on a KN record. (Note: It will be read and converted to Strickler's Ks. Equation 2, from the above list, will then be used in the computations.)
		1	Keulegan Equations. Program expects Ks value for panel 1 (KS record).
		2	Strickler n-value equation. Program expects Ks value for panel 1 (KS record).
		3	Limerinos n-value equation. Program expects Bed Gradation Data (PF records)
		4	Brownlie bed roughness equations. Program expects Bed Gradation Data. (PF records)

SCS Grass lining, type E. See Text for details.

NE RECORD, continued

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
		6	SCS grass lining, type D. etc...
		7	SCS grass lining, type C.
		8	SCS grass lining, type B.
		9	SCS grass lining, type A.
2	EQNV	+	Roughness equation for panel 2.
		b,0	If Manning's n-values are being used, the default is 0. However, if Manning n-values are not being used, the program considers blank and 0 as missing data and will supply the equation number from the n-1 panel.
3	EQNV	+	Continue coding RTYPE values until there is one for each panel in the cross section. Begin in Field 1 of each record.

KS RECORD

This record is used to prescribe the effective roughness height when calculating n-values from the Keulegan or Strickler equations, when coding cross sections in HEC-2 format, (i.e. X1-GR records). A roughness value is needed in each panel across the section, i.e. between each pair of coordinate points on the GR record. There can be up to 10 KS records.

NOTE: Limerinos, Brownlie and the Grass equations are not to be used with negative roughness values because there is nothing to calculate — the roughness is implicitly determined by the bed gradation or the grass.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
KS KS(1) KS(2) KS(3) KS(...)
KS .4 10 .007
```

Field	Variable	Value	Description
0	ICG,IDT	KS KS	Record Identification = Effective Roughness. Code on continuation records, also.
1	KS(1)	+	Effective roughness height-ft in panel 1.
		b,0	There is no default for panel 1.
		-	The negative is a flag for the program, telling it to make the hydraulic roughness calculations. The absolute value of the number in the field tells the program the ratios of roughness in that element to the composite roughness.
2	KS(2)	+	Effective Roughness height, ft, in panel 2.
		b	The value for KS(1) is used.
		-	See description for field 1.
3	KS(3)	+	Continue coding Ks values until there is one for each panel in the cross section. There will be up to NXY-1 values. The program will supply missing values using the rule: KS(N) = KS(N-1). However,

NOTE: Currently the above does not work, and
data for all fields should be supplied by the user.

Continue in field 1 on continuation records.

KN RECORD

This record is used to prescribe the Manning's n-value, n-value equation number 0, when coding cross sections with X1-GR records. An n-value is needed in each panel across the section, i.e. between each pair of coordinate points on the GR record. There may be up to 10 KN records per cross section.

NOTE: If the NE record has equation number 0 and others on it, KS record values can be put on a KN record.

NOTE: Limerinos, Brownlie and the Grass equations are not to be used with negative roughness values because there is nothing to calculate — the roughness is implicitly determined by the bed gradation or the grass.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
KN KN(1) KN(2) KN(3) KN(4) KN(5) KN(6) KN(7) KN(8) KN(9) KN(10)
KN .05 .04 .04 .04 .04 .04 .04 .04 .04 .04
KN .018
```

Field	Variable	Value	Description
0		KN	Record Identification = Roughness, Manning's n-values.
		KN	Record Identification on continuation records also.
1	KN(1)	+	Manning's n-value in panel 1.
		b(1)	There is no default for panel 1.
2	KN(2)	+	Manning's n-value in the panel 2.
		b	The value for KN(1) is used.
3	KN(3)	+	Continue coding n-values until there is one for each panel in the cross section. There will be up to NXY-1 values. The program will supply missing values using the rule: KN(N) = KN(N-1).

NOTE: Currently the above does not work, and
data for all fields should be supplied by the user.

Continue in field 1 on continuation records.

PF RECORD

This record prescribes the gradation of the bed sediment reservoir at a cross section. Code Continuation records as **PFC** records. It is not necessary that a PF coordinate correspond to a class interval boundary although it can. Otherwise, semilog interpolation is used to calculate the percent finer at each class interval boundary. These are then subtracted to calculate the fraction of sediment in each size class. The program assigns a percent finer = 100 to correspond with DMAX. There can be up to 18 data points, i.e., 1 PF and 3 PFC records.

The data **MUST** be coded in decreasing order; i.e., the largest grain size (after DMAX) and corresponding percent are to be coded in fields 5 and 6, respectively.

Example:

F#	45678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678
PF	cmt	ASN	SAE	DMAX	DAXIS	PFXIS	DAXIS	PFXIS	DAXIS	..etc
PF		308.0	1.0	18.29	9.14	95.0	1.0	94.2	.5	78.0
PFC	.25	46.7	.125	14.3	.0625	9.9	.004	4.9		

Field	Variable	Value	Description
0	ICG, IDT	PF PFC	Record Identification = Percent Finer Record Identification = Continuation record
1	ISI	1234	Comment field for PF record-use numeric characters only.
	DAXIS	+	For PFC (continuation) records, code the particle diameter, mm.
2	RMILE	-,0,+,b	Identifier of this Cross Section (ie, River Mile); this field is optional.
	PFXIS	+	For PFC records, code the percent finer.
3	SAE	b	SAE is not needed for this code, but it is provided for compatibility with HEC-6.
	DAXIS	+	For PFC records, code the particle diameter, mm.
4	DMAX	+, b	The diameter of the maximum particle size, in mm. Not allowed -- ALWAYS code a value.
	PFXIS	+	For PFC records, code the percent finer.
5	DAXIS(2)	+	On the PF record, this is the first coordinate point down the percent finer curve from DMAX. If this particle size is larger than 64 MM, choose a point that will approximate the PF curve with 2 straight line segments from DMAX to 64mm.
6	PFXIS(2)	0,+	The percent finer corresponding to DAXIS(2). Code as a percent.
7	DAXIS(3)	0,+	Continue to code points from the percent finer curve, with the DAXIS in the odd-numbered fields and the PFXIS in the even-numbered fields. Up to 16 points, including the DMAX point, are permitted. Use a continuation record when coding more than 4 points.

BR RECORD

Not available in SAMwin.

This Record is used to prescribe the D50 and the Geometric Standard Deviation of the bed sediment. Only 1 BR record is permitted.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
BR d84 d50 d16 DQDT SPGS

BR 2.0 .35 .125
```

Field	Variable	Value	Description
0	ICG, IDT	BR	Record Identification = BRownlie parameters.
1	D84	+	D84 of the bed surface in mm.
2	D50	+	D50 of the bed surface in mm.
3	D16	+	D16 of the bed surface in mm.
4	DQDT		Rate of change of the water discharge hydrograph. i.e. rising side or falling side. (The Discharge at which the bed regime will transition from lower to upper and back, is different on the rising side and the falling side of the hydrograph.)
		-1	Use the upper regime equation to define this point in the transition zone.
		0	The default. Use the equation which is closest to the current point in the transition zone.
		+1	Use the lower regime equation to define this point in the transition zone.
5	SPGS	+	Specific Gravity of sediment particles.
		b	Default = 2.65

RC RECORD

Not available in SAMwin.

This Record is used to prescribe the cost-in-place per ton of each riprap size in the Standard Gradation Table. See Chapter 2 for more details. The program expects 13 values. For quarry run stone, code on the RQ record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
RC RC(1) RC(2) RC(3) ... max is RC(13)

RC .5 1 1.5 2.0 2.5 3 4 5 6 7
RC 8 9 10
```

Field	Variable	Value	Description
0	ICG,IDT	RC	Record Identification = Riprap Cost
1	RC(1)	+	Riprap cost for the first size of riprap in the Standard Gradation table.
2	RC(2)	+	Riprap cost for the second riprap size.
.			
.			
.			
n	RC(3)	+	Program expects up to 13 values -- one for each riprap size in the Standard Gradation Table.

RQ RECORD

Not available in SAMwin.

This Record is used to describe quarry run riprap gradation. There can be up to 5 RQ records. The gradations should be entered one size per record starting with the smallest and ending with the largest size. When this information is present, riprap size computations use the quarry run stone. When quarry run stone is prescribed, those stone sizes are used in lieu of the gradation tables encoded in SAM.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
RQDMAXRR D90RR D50RR D30RR PORRAP RRCPT
RQ 24.0 17.7 14.4 7.9 38
```

Field	Variable	Value	Description
0	ICG,IDT	RQ	Record Identification = Riprap - Quarry run.
1	DMAXRR	+	Dmax for the quarry run riprap, in inches.
2	D90RR	+	D90 for the quarry run riprap, in inches.
3	D50RR	+	D50 for the quarry run riprap, in inches.
4	D30RR	+	D30 for the quarry run riprap, in inches.
5	PORRAP	b	Porosity, volume of voids divided by total volume expressed as percent. Default = 38.
6	RRCPT		Unit cost for the quarry run stone in place, \$/ton.

RR RECORD

This record is used to prescribe the general design parameters needed in sizing the riprap. There can be only 1 RR record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
RR SGRR BENDR BENDA NTRAP SAFEF CIFRRS

RR 2.48      600                1
```

Field	Variable	Value	Description
0	ICG, IDT	RR	Record Identification = RipRap properties
1	SGRR	+ b,0	Specific gravity of the riprap Default = 2.65.
2	BENDR	+ b,0	Bend radius in feet. Default = Straight channel.
3	BENDA	+	LEAVE BLANK
4	NTRAP	1 b,0	Trapezoidal Cross Section in a bend - not a natural river bend. Default = Cross section is a natural river bend.
5	SAFEF	b,0 +	Safety factor above failure. Default is recommended. Default = 1.1, the EM value. Enter your own safety factor.
6	CIFRRS	b,0 +	Multiplier to calculate the stability coefficient of incipient failure ratio for rounded rock from the stability coefficient of incipient failure for angular rock (Coefficient of incipient failure ratio for rounded stone). Default = 1.25, the EM value. Enter your own value.

When making riprap calculations in the cross-section-shape option, it is important that the side slope protection be defined as a single panel in the geometry input. SAM will use 0.8 times the maximum depth in the panel for the local flow depth in the riprap equation. When a bend radius is specified, SAM uses the average velocity in the cross section in the riprap equation. When a bend radius is not specified, SAM uses the calculated panel velocity in the riprap equation. Careful study of the recommendations and guidelines described in EM 1110-2-1601 should be considered essential. Also see Chapter 2, "Riprap Size for a Given Discharge and Cross Section Shape."

NOTE: In each panel designated as having riprap, the hydraulic roughness equation is automatically changed to the Strickler equation with the Strickler coefficient set equal to 0.034. Normal depth is calculated for the resulting n-values. The alpha method is used to calculate normal depth and flow is distributed across the section. The riprap size equation is solved for each panel. When the resulting size is stable in each panel, riprap computations are finished. Otherwise, computations move to the next larger riprap size and the procedure is repeated. After the stable stone size is determined, a stage discharge curve is calculated for the riprapped channel. The Strickler coefficient, which was 0.034 when determining stone size, is increased to 0.038 in this calculation for flow capacity. This calculation determines the rating curve with the selected riprap in place.

RS RECORD

This record is used to prescribe the general design parameters needed to calculate the size of riprap when velocity and depth are known. There can be only 1 RS record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
RS  VAVG      WS      SSL  SUMWWS      RSEC
RS  6.48      12      2      600      1
```

Field	Variable	Value	Description
0	ICG, IDT	RS	Record Identification = Riprap Size.
1	VAVG	+	Water velocity, fps, over toe.
2	WS	+	Water depth over toe.
3	SSL	+ b	Side Slope (Bank slope) of revetment (1V:[Z]H). Default = 1.5
4	SUMWWS	+ b	Water Surface Width. Required if in a bend. Default = D*Z
5	RSEC	+ b -	Ratio of riprap layer thickness to DMAX. Default = 1.*Dmax A flag for the program to use rounded stone.

RT RECORD

This record is used to prescribe the riprap thickness across each panel in the cross section. Only those panels having a positive RT value will get riprap. There can be up to 10 RT records.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
RT RT(1)  RT(2)  RT(3) RT(...)
RT      1      0      1
```

Field	Variable	Value	Description
0	ICG,IDT	RT RT	Record Identification = Riprap Thickness Record Identification for continuation records, also.
1	RT(1)	+ b,0 -	Riprap thickness in panel 1 expressed as the ratio times Dmax, i.e. [RT]*DMAX. Values usually range from 1 to 1.5. Default = no riprap. Indicates cobbles, i.e., rounded stone.
2	RT(2)	+ b,0 -	Thickness of riprap in panel 2. Default = no riprap. Indicates cobbles, i.e., rounded stone.
3	RT(3)	+, -, b	Continue coding RT values as above until there is one for each panel in the cross section. The program will accept NXY-1 values.
.			
.			
.			
11	RT(11)	+, -, b	There are only 10 fields on a record. For panel 11, code in field 1 of the second RT record.

BL RECORD

Not available in SAMwin.

This Record is used to request the BLENCH REGIME values for width, depth and slope using equations shown on pp 127-128 of ASCE Manual 54, "Sedimentation Engineering." There can be only 1 BL record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
BL      FS

BL      .2
```

Field	Variable	Value	Description
0	ICG, IDT	BL	Record Identification = BLench Regime parameters.
1	FS		"Side Factor" which measures the tendency of the bank to resist erosion.
		.1	Sand banks, very little resistance to erosion.
		.2	Silty clay-loam banks, moderate resistance to erosion.
		.3	Tough Clay banks, high resistance to erosion.
			Default = 0.2
2	REGCON	+	Bed-material sediment concentration.
			Default = 0.0

NOTE: The bed factor needed for the Blench equation, the variable FB, defaults to 0.95, which corresponds to a d_{50} of 0.25mm. This variable will be calculated if there is a PF record in the data set.

QW RECORD

This record is used to prescribe water discharge(s). **Caution:** They must be coded from the smallest to the largest to plot rating curves. Only 1 QW record is permitted.

NOTE: For the Bottom Width calculations only, the number of discharges prescribed must equal the number of CT records in the data file.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QW Q(1)    Q(2)    Q(3)    Q(...)
QW   10     100    1000    10000    20000    23750
```

Field	Variable	Value	Description
0		QW	Record identification = Water Discharge
1	Q(1)	+	Enter water discharge in cfs.
2-10	Q(2)-Q(10)	+	Up to 10 discharges may be entered.

WS RECORD

This record prescribes the water surface elevations. Same rules apply as for discharges coded on the QW record. There can be only 1 WS record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
WS WS(1)   WS(2)   WS(3) WS(...)
WS   402     405    410.3
```

Field	Variable	Value	Description
0		WS	Record identification = Water Surface elevation.
1	WS(1)	+	Enter the value that goes with Q(1) when a water surface elevation is needed; enter the value in feet
2	WS(2)-WS(10)	+	Enter the water surface elevation for Q(2)-Q(10).

GZ RECORD

Not available in SAMwin.

The GZ Record is an option which allows a gage zero elevation to be input and subtracted from all water surface elevations to provide water depth. This is sometimes useful when working with CT records. There can only be 1 GZ record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
GZ  GZRO

GZ 129.7
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		GZ	Record Identification = Gage Zero
1	GZRO	+	Gage zero reading.

ES RECORD

This record prescribes the energy slope, in ft/ft, corresponding to each discharge on the QW record. A slope is needed for each Q(i) on the QW record, but the program will fill in missing values, so it is only necessary to code those which change. There can be only 1 ES record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
ES S(1) S(2) S(3) S(...)
```

```
ES284E-6 .000174 .000170
```

Field	Variable	Value	Description
0		ES	Record identification = Energy Slope
1	SLOA(1)	+	Energy slope corresponding with Q(1). If field width does not permit sufficient accuracy, code in scientific notation as shown above. If 3 significant digits do not provide sufficient accuracy, code a dummy Q in the first field and begin the real problem in field 2.
2-10	SLOA(2)-SLOA(10)	+	The slope can change with each Q on the QW record. However, the program will fill in missing values using the rule, ES(I)=ES(I-1) so only those which change must be coded.

WT RECORD

This record is used to prescribe the water temperature, degrees Fahrenheit. There can be only 1 WT record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
WT WT(1)   WT(2)   WT(3) WT(...)
WT    55      60      75
```

Field	Variable	Value	Description
0		WT	Record identification = Water Temperature.
1	WT(1)	+ b	Water temperature for Q(1). Default = 60.
2-10	WT(2)-WT(10)	+	A water temperature is needed for each water discharge, but only those values which change must be coded. The program will supply missing values using the rule: WT(I) = WT(I-1).

GC RECORD

The GC Record initiates Copeland's Analytical stable channel dimensions computations. In SAMwin, only one GC record is allowed per data set. If the input file is edited and run outside SAMwin, up to 10 GC records may be stacked in one job.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
GC      Q  CONPPM      SLOV      SSLAM      SSRAM      NEQLAM      BANKKL      NEQRAM      BANKKR      FTXBAM

GC  3680          .00162          3          3          2          .7          2          .7
GC  4850          .00162          3          3          0          .050          0          .050
```

Field	Variable	Value	Description
0		GC	Record Identification = Geometry by Copeland's method
1	Q	+	Water discharge in cfs.
2	CONPPM	+	Design sediment concentration in PPM.
		-1,b,0	Program will calculate the DESIGN SEDIMENT CONCENTRATION for the DESIGN WATER DISCHARGE, Q(GC-1); i.e., all concentrations will be calculated from the supply reach parameters.
		-Q	When a negative value other than 1 is coded, it is interpreted as the water discharge to use for calculating the DESIGN SEDIMENT CONCENTRATION, i.e., the water discharge for the approach reach.
			NOTE: Channel geometry and gradation of bed sediment, CT and PF records, must be supplied for the approach channel when concentrations are to be calculated.
3	SLOV	0,+	Valley slope, used as the maximum feasible slope, in ft/ft.
4	SSLAM	0,+	Side Slope, left side of channel facing downstream, 1V:[_]H.
5	SSRAM	0,+	Side Slope, right side of channel facing downstream, 1V:[_]H.
6	NEQLAM		Code the equation number for the n-value calculation, left bank of project channel. Note that only the Manning and Strickler equations are available for bank roughness calculations in this option.
		b,0	value coded in BANKKL(GC-7) is n-value.
		2	value coded in BANKKL(GC-7) is K_s for Strickler n-value equation. For riprap, k_s should be set equal to the minimum design d90.
7	BANKKL	0,+	Hydraulic roughness value, left bank If NEQLAM = 0 Code as Manning n-value. If NEQLAM = 2 Code the surface roughness, K_s -ft. For riprap, k_s should be set equal to the minimum design d90.

GC RECORD, continued

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
8	NEQRAM		Code the equation number for the n-value calculation, right bank of project channel, same rules as for field 6.
		b,0	value coded in BANKKR(GC-9) is n-value.
		2	value coded in BANKKR(GC-9) is "Ks" for Strickler n-value equation.
9	BANKKR	0,+	Hydraulic roughness, right bank.
			If NEQRAM = 0 Code as Manning n-value.
			If NEQRAM = 2 Code the surface roughness, Ks-ft.
10	FIXBAM	+	Option to prescribe width for median position in Table of Stable Channel Dimensions. FIXBAM/10 = incremental width used in same table.

GB RECORD

The GB record provides options when using Copeland's Analytical stable channel dimensions computations. Only one record is allowed. The user can make these calculations using a sand bed or a gravel bed equation, and can apply the Cowan multipliers to either. If sandbed calculations are to be made, and the defaults for the Cowan method to increase channel roughness are used, no GB record is necessary. This record is optional.

Note the defaults.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
GB MTC COWM COWXN COWMAX COWXNAX

GB 10 1.2 1.1
```

Field	Variable	Value	Description
0	GB		Record Identification = Gravel Bed option parameters
1	MTC		Sets the equations to be used:
		0	Sandbed calculations using the Brownlie equation No DEFAULT
		10	Gravelbed calculations using the Meyer-Peter Muller equation
2	COWM	+	Cowan meander multiplier, for the study reach. DEFAULT = 1.0
3	COWXN	0,+	Increase in n-value for surface irregularities, variation in channel cross section and obstructions, for the study reach. DEFAULT = 0.0.
4	COWMAX	+	Cowan meander multiplier, for the supply reach. DEFAULT = 1.0
5	COWXNAX	0,+	Increase in n-value for surface irregularities, variation in channel cross section and obstructions, for the supply reach. DEFAULT = 0.0

MG RECORD

The MG record sets parameters for the meander calculations. Only one record is allowed.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
MGXLAMDA      XML
MG      10      1.2
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0	MG		Record Identification = Meander Geometry Calculations
1	XLAMDA	+	Wavelength – the length of one full meander, along the valley. Must be shorter than the meander length.
2	XML	+	Meander Length – the actual length of the channel.

IE RECORD

Not available in SAMwin.

The IE Record allows the user to specify ineffective flow area in the overbanks. If an elevation is given in fields 1 and/or 3, all water is confined to the channel, as defined by variables STCHL and STCHR on the **X1** record, until the calculated water surface elevation exceeds the elevations given by EMIN. This record can be used only with the X1/GR-type geometry. Only 1 IE record is allowed, and may not be used with an IQ record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
IEEMIN(1) EMIN(2) EMIN(3)
IE      342              344
```

Field	Variable	Value	Description
0		IE	Record Identification = Ineffective flow area by Elevation.
1	EMIN(1)	-,0,+	Left overbank limiting elevation for ineffective flow area calculations.
2	EMIN(2)	b	Leave this field blank. The printout will show the "Ineffective Flow Elevation" for the channel, strip 2, to be -9999, the default.
3	EMIN(3)	-,0,+	Right overbank limiting elevation for ineffective flow area calculations.

IQ RECORD

Not available in SAMwin.

The IQ Record allows the user to exclude flow from the overbanks up to a specified total discharge. Once the specified total discharge is exceeded, the flow is distributed without restriction. This record can be used only with the X1/GR-type geometry. Only 1 IQ record is allowed, and may not be used with an IE record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
IQEMIN(1) EMIN(2) EMIN(3)
```

```
Iq 342 342
```

Field	Variable	Value	Description
0		IQ	Record Identification = Ineffective overbank flow area by discharge.
1	EMIN(1)	+	Left overbank limiting discharge.
2	EMIN(2)	b	Leave this field blank. The printout will show the "Ineffective Flow Discharges" for the channel, strip 2, to be 0.
3	EMIN(3)	+	Right overbank limiting discharge.

SP RECORD

The SP record allows user to prescribe the specific gravity of sediment particles. Some functions do not permit changing the specific gravity. This record can be omitted if the default value is used. There can be only one SP record.

Note that this record is not used in the SAM.hyd calculations. However, since it can be input along with the PF record in PSAM in the hydraulic calculations option, the SP record is described here with the SAM.hyd records. If input in a SAM.hyd data set, the SP record will simply be echoed to the subsequent SAM.sed input file.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
SP SPGS

SP 2.0
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		SP	Record Identification = Specific Gravity
1	SPGS	+	Specific Gravity of Inflowing Sediment
		b	Default = 2.65.

\$JOB RECORD

Not available in SAMwin.

Jobs may be stacked one after the other by substituting the \$JOB record for the \$\$END record at the end of each data set. Place the \$\$END after the last job in the stack. A stacked SAM.hyd data set will create a similarly stacked SAM.sed input data file.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678  
$JOB
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$JOB	Record identification = NEW JOB.

\$\$END RECORD

This record signifies the end of the run.

Example:

F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
\$\$END

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$\$END	Record identification = END OF RUN.

Appendix D: Data Records for Sediment Transport Functions

GENERAL NOTES	D-1
T1 RECORDS -Title Records.....	D-2
F# RECORD -Column Indicator Record	D-3
TR RECORD -Trace Printout Record	D-4
TF RECORD -Transport Function Record	D-5
ME RECORD -Metric Indicator Record	D-6
SP RECORD -Specific Gravity Record.....	D-7
VE RECORD -Velocity Record	D-8
DE RECORD -Depth Record	D-9
WI RECORD -Width Record	D-10
QW RECORD -Water Discharge Record.....	D-11
ES RECORD -Energy Slope Record	D-12
WT RECORD -Water Temperature Record	D-13
PF RECORD -Percent Finer Record.....	D-14
\$JOB RECORD -“\$JOB” Record.....	D-16
\$\$END RECORD -“\$\$END” Record.....	D-17

GENERAL NOTES

The following are conventions used in the record descriptions in this appendix.

- a1.@! These characters in the "value" column means that any alpha or numeric characters can go in that field; generally it is a comment field.
- b This character in the "value" column indicates a blank field.

Records that are not available in SAMwin are still useable -- use an editor to insert the record into a data file and execute the program from the “RUN” dropdown menu of the SAMwin main menu

T1 RECORDS

Up to 10 title records are permitted. These records are for the user's information only and are therefore optional. TI is also an acceptable record identification for title records.

Example:

```
T1    Use these title cards to define the job, the date, the investigator, the
T1    model #, the data source, the purpose for this run, and changes from
T1    previous runs.
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		T1	Record Identification in columns 1 and 2. TI is also accepted.

F# RECORDS

Marks each data field by column numbers, each field being 8 columns wide. There can be only 1 F# record. This record is for the user's information only and is therefore optional. This record is not always printed to the output file.

Example:

```
TI      Title cards
TI      Title cards
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		F#	<u>Record</u> Identification in columns 1 and 2.

TR RECORD

Not available in SAMwin.

The TR record controls the printout. There is only one TR record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
TRKSW(1) KSW(2) KSW(3) KSW(..)

TR      -1                                     2
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0	-	<u>TR</u>	Record Identification - TRace printout.
1	KSW(1)	-1	Causes only the Summary Table to be sent to the default output file.
10	KSW(14)	b,0	Normal operation -- the regular output goes to the default output file.
		1	Causes extra output from many transport functions to be printed to the default output file.
		2	Causes an extreme amount of output from all transport functions to be printed to the default output file -- used for debugging the code as most of the output is in terms of code variables.

TF RECORD

There are a series of TF records, each representing a transport function option. Each TF record in the data set has either a YES or a NO in a column after the function names. The YES signals the program to calculate the sediment transport using that function; a NO leaves that function turned off. Only those functions being used are required in the data set. "Laursen(Madden),1985" defaults to YES when the SAM.sed input file is written by SAM.hyd. There can be up to 20 TF records, as follows. Be sure that the "Y" of YES is in column 25, and that the "N" of NO is in column 26, and that the function names are spelled and punctuated exactly as given below.

Example:

F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678

TF TOFFALETI.	YES
TF YANG.	YES
TF EINSTEIN (TOTAL-LOAD)	NO
TF ACKERS-WHITE.	NO
TF COLBY	NO
TF TOFFALETI-SCHOKLITSC	NO
TF MPM (1948) .	NO
TF BROWNLIE ,D50	NO
TF TOFFALETI-MPM	NO
TF LAURSEN (MADDEN) , 1985	NO
TF LAURSEN (COPELAND)	NO
TF YANG ,D50	NO
TF ACKERS-WHITE ,D50	NO
TF MPM (1948) ,D50	NO
TF PARKER	NO
TF EINSTEIN (BED-LOAD)	NO
TF PROFITT (SUTHERLAND)	NO
TF ENGELUND-HANSEN	NO
TF SCHOKLITSCH	NO
TF VAN .RIJN	NO

Field	Variable	Value	Description
0	-	TF	Record Identification - Transport Function [This name is 21 columns long and must match one in the above example in every detail-- spelling, parentheses, dashes, periods and spaces.]
	YANG	YES	Transport function turned on
		NO	Transport function turned off

NOTES

Parker: Finer sizes, less than 2 mm, must be excluded from the specified surface size distribution; there must be a size for which 0% of the material is finer; the bed material sizes used must be representative of the coarse upper layer of the bed.

Van Rijn Recommended use is for grain sizes between 0.1 and 0.5 mm.

ME RECORD

Not available in SAMwin.

The ME record controls whether the calculations are made in English or in metric units. There is only one ME record. If this record is omitted, the calculations are made in English. All input must be in the same system of units as selected for the calculations, except that PF record data is input in percent and millimeters for both systems.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
ME METRIC
```

```
ME      1
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		ME	Record Identification - Metric or English flag.
1	METRIC	0	Calculations made in English units. This is the default.
		1	Calculations made in metric units.

SP RECORD

The SP record allows user to prescribe the specific gravity of sediment particles. Some functions do not permit changing the specific gravity. Inserting this record is optional if the default value is used. There can be only one SP record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
SP SPGS
SP 2.0
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		SP	Record Identification = Specific Gravity
1	SPGS	+	Specific Gravity of Inflowing Sediment
		b	Default = 2.65.

VE RECORD

The VE record prescribes the water velocity for up to 10 discharges. There can be only one VE record.

For the VE, DE, WI, QW, ES, and WT records, each field represents one set of test conditions. For example, the data in the first field of these 6 records contains the hydraulic input for the first discharge; the data in the 2nd field for the second discharge, etc., up to a maximum of 10 discharges. Missing data will be filled in by the program at execution time, using the rule $VELA(N) = VELA(N-1)$.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
VE VELA1  VELA2  VELA3  VELA4  VELA5  ... up to 10 ...
VE 1.19    2.89    5.17    6.55    8.42
```

Field	Variable	Value	Description
0	VE		Record Description - VELOCITY, Water
1	VELA(1)	+	Enter Water Velocity: in fps for English calculations; in cms for metric.
2-10	VELA(2) -	+	Up to 10 Velocities may be entered
.			
.			
.			
	VELA(10)		

DE RECORD

The DE record prescribes the effective depth. There can be only one DE record. The depths will be paired with data on the VE, WI, QW, ES, and WT records. Missing data will be filled in by the program at execution time using the rule, $EFDA(N) = EFDA(N-1)$.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
DE EFDA1 EFDA2 EDFA3 EDFA4 EDFA5 ... up to 10
DE .82 3.11 7.50 10.71 15.66
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		DE	Record Identification = DEpth, hydraulic
1	EFDA(1)	+	Effective depth, ft for English calculations; m for metric.
2-10	EFDA(2)	+	Up to 10 depths may be entered
.			
.			
.			
	EFDA(10)		

WI RECORD

The WI record prescribes the effective width. The width will be paired with data on the VE, DE, QW, ES, and WT records. Missing data will be filled in by the program at execution time using the rule, $EFWA(N) = EFWA(N-1)$.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
WI EFWA1  EFWA2  EFWA3  EFWA4  EFWA5  ... up to 10
WT 103.    111.    129.    143.    152.
```

Field	Variable	Value	Description
0		WI	Record Identification - top Width
1	EFWA(1)	+	Top Width, in ft for English calculations; m for metric.
2-10	EFWA(2)	+	Up to 10 Top widths may be entered
.			
.			
.			
	EFWA(10)		

QW RECORD

The QW record prescribes the discharge. There can be only one QW record. The discharges will be paired with data on the VE, WI, DE, ES and WT records. Missing data will be filled in by the program at execution time using the rule, $Q(N) = Q(N-1)$.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QW   Q1      Q2      Q3      Q4      Q5      ... up to 10
QW   100     1000    5000    10000   20000
```

Field	Variable	Value	Description
0		QW	Record Identification - Water Discharge
1	Q(1)	+	Discharge, in cfs for English calculations; cms for metric.
2-10	Q(2)	+	Up to 10 discharges may be entered
.			
.			
.			
	Q(10)		

ES RECORD

This record prescribes the energy slope. A slope is needed for each Q(i) on the QW record, but the program will fill in missing values using the rule, $S(N) = S(N-1)$. There can be only 1 ES record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
ES S(1) S(2) S(3) S(...)
ES284E-6 .000174 .000170
```

Field	Variable	Value	Description
0		ES	Record identification = Energy Slope
1	ESA(1)	+	Energy slope corresponding with Q(1), in ft/ft for English calculations; m/m for metric. NOTE: If field width does not permit sufficient accuracy, code in scientific notation as shown above. If 3 significant digits do not provide sufficient accuracy, code a dummy Q in the first field and begin the real problem in field 2.
2-10	ESA(2)-ESA(10)	+	The slope can change with each Q on the QW record. However, the program will fill in missing values using the rule, $ES(I) = ES(I-1)$, so only those which change must be coded.

WT RECORD

This record is used to prescribe the water temperature. There can be only 1 WT record.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
WT WT(1) WT(2) WT(3) WT(...)
WT 55 60 75
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		WT	Record identification = Water Temperature.
1	WT(1)	+ b	Water temperature for Q(1), degrees Fahrenheit for English calculations, degrees centigrade for metric. Default = 60° F, English; 15.6° C, metric.
2-10	WT(2)-WT(10)	+	A water temperature is needed for each water discharge, but only those values which change must be coded. The program will supply missing values using the rule: WT(I) = WT(I-1).

PF RECORD

This record prescribes the gradation of the bed sediment reservoir at a cross section. Code “Continuation” records as PFC records. It is not necessary that a PF-coordinate correspond to a class interval boundary although it can. If it does not, semi-log interpolation is used to calculate the percent finer at each class interval boundary, and these are subtracted to calculate the fraction of sediment in each size class. The program assigns a percent finer of 100 to the given DMAX. There can be up to 18 data points, which is 1 PF and 3 PFC records.

The data **must** be coded in decreasing order; i.e., the largest grain size (after DMAX) and corresponding percent are to be coded in fields 5 and 6, respectively.

The particle diameters are input in millimeters for both the English and the metric calculation options.

Example:

F#	45678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678
PF	cmt	ASN	SAE	DMAX	DAXIS	PFXIS	DAXIS	PFXIS	DAXIS...etc	
PF		308.0	1.0	18.29	9.14	95.0	1.0	94.2	.5	78.0
PFC	.25	46.7	.125	14.3	.0625	9.9	.004	4.9		

Field	Variable	Value	Description
0	ICG,IDT	PF PFC	Record Identification = Percent Finer Record Identification = Continuation record
1	ISI	1234	Comment field for PF record-- use numeric characters only.
	DAXIS	+	For PFC (continuation) records, code the particle diameter, mm.
2	RMILE	-,0,+,b	Identifier of this Cross Section (i.e., River Mile); this field is optional.
	PFXIS	+	For PFC records, code the percent finer.
3	SAE	b	SAE is not needed for this code, but it is provided for compatibility with HEC-6.
	DAXIS	+	For PFC records, code the particle diameter, mm.
4	DMAX	+	The diameter of the maximum particle size,in mm.
		b	Not allowed -- ALWAYS code a value.
	PFXIS	+	For PFC records, code the percent finer.

PF/PFC RECORD — continued

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
5	DAXIS(2)	+	On the PF record, this is the first coordinate point down the percent finer curve from DMAX. If this particle size is larger than 64MM, choose a point that will approximate the PF curve with 2 straight line segments from DMAX to 64mm.
6	PFXIS(2)	0,+	The percent finer corresponding to DAXIS(2).Code as a percent.
7	DAXIS(3)	0,+	Continue to code points from the percent finer curve, with the DAXIS in the odd-numbered fields and the PFXIS in the even-numbered fields. Up to 18 points, including the DMAX point, are permitted. Use a continuation record when coding more than 4 points.

\$JOB RECORD

Not available in SAMwin.

Jobs may be stacked one after the other by substituting the \$JOB record for the \$\$END record at the end of each data set. Place the \$\$END after the last job in the stack. A stacked SAM.sed data set will create a stacked SAM.yld input data file.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
$JOB
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$JOB	Record identification = NEW JOB

\$\$END RECORD

This record signifies the end of the run.

Example:

F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
\$\$END

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$\$END	Record identification = END OF RUN.

Appendix E: Data Records For Sediment Yield Calculations

GENERAL NOTES	E-1
TI RECORDS -- Title Records	E-2
F# RECORD -- Field Indicator Record	E-3
ME RECORD -- Metric Indicator Record	E-4
JP RECORD -- Job Parameters Record	E-5
QQ RECORD -- Water Discharge Record.....	E-7
QD RECORD -- Discharge Duration Record	E-8
QH RECORD -- Discharge Hydrograph Record	E-9
QW RECORD -- Water Discharge Record (for Sediment Rating Curve).....	E-10
QS RECORD -- Sediment Discharge Record (in tons/day).....	E-11
SC RECORD -- Sediment Discharge Record (in mg/l)	E-12
SE RECORD -- Sediment Equation Record	E-13
\$JOB RECORD -- "\$JOB" Record	E-14
\$\$END RECORD -- "\$\$END" Record	E-15

GENERAL NOTES

The following are conventions used in the record descriptions in this appendix.

- | | |
|-------|--|
| a1.@! | These characters in the "value" column means that any alpha or numeric characters can go in that field; generally it is a comment field. |
| b | This character in the "value" column indicates a blank field. |

Records that are not available in SAMwin are still useable -- use an editor to insert the record into a data file and execute the program from the "RUN" dropdown menu of the SAMwin main menu.

T1 RECORDS

Up to 10 title records are permitted. These records are for the user's information only and are therefore optional. TI is also an acceptable record identification for title records.

Example:

```
TI    Use these title cards to define the job, the date, the Investigator, the
TI    model #, the data source, the purpose for this run, and changes from
TI    previous runs.
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		T1	Record Identification in columns 1 and 2. TI is also accepted.

F# RECORDS

Marks each data field by column numbers, each field being 8 columns wide. There can be only 1 F# record. This record is for the user's information only and is therefore optional. This record is not always printed to the output file.

Example:

```
TI      Title cards
TI      Title cards
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		F#	Record Identification in columns 1 and 2.

ME RECORD

Not available in SAMwin.

The ME record controls whether the calculations are made in English or in metric units. There is only one ME record. If this record is omitted, the calculations are made in English. All input must be in the same system of units as selected for the calculations.

Example:

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
ME METRIC
ME      0
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0	-	ME	Record Identification - Metric or English flag.
1		METRIC	1 Calculations made in English units. This is the default.
		0	Calculations made in metric units.

JP RECORD

The JP record provides data for the basic options in the yield calculations. There can be only 1 JP record.

Example:

The following example shows typical input specifying 20 intervals for output display. The time step for a hydrograph is 5 minutes, or 0.083 hours. For all other fields the defaults are accepted, as indicated by the blank fields.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
JP NCLCD IFMT NIS RWY YEAR PER UWD
JP .083
```

Field	Variable	Value	Description
0		JP	Record Identification
1	NCLPD	+ b	Number of class intervals to use for displaying results. default = 20 max = 365
2	IFMT	+ b,1	Format of input. This field is no longer used. Input described in these instructions.
3	NCLCD	+ b	Number of integration steps for Flow-Duration Option. default = 365 max = 2000.
4	RWY	+ b	Ratio to multiply times the water discharge to scale water yield value. default = 1.
5	YEAR	b,+ b	Time period represented by the flow duration curve in days. Usually the curve represents a year so the program defaults to 365 days. In some cases a curve may represent a day, a month or a single event in which case that number of days should be coded here. default = 365

[Continued on next page]

JP RECORD -- continued

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
6	PER	+	Time between hydrograph ordinates, in hours, when using the hydrograph option.
		b	default = 24.
7	UWD	+	Specific Weight of sediment in pounds/cubic foot.
		b	default = 93.

NOTE: This default is a good estimate for streams that are largely medium sand. This default is also a good estimate for sand bed streams when making BED MATERIAL LOAD calculations. Modify this parameter as appropriate for wash load or total load calculations, and for calculations of bed material load on gravel bed streams.

QQ RECORD

The QQ record is the listing of all discharges, Q, to be used for this run, in **either** increasing or decreasing order. There can be a maximum of 10 QQ records. Each Q will be paired with a duration, from the QD record.

NOTE: Do not use zero as the first or last discharge -- perhaps use 0.0001.

Example.

The following example shows typical input specifying 21 different Q's.

F#	45678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678
QQ	FLOW1	FLOW2	FLOW3	FLOW4	FLOW5	...	up to	10,000		
QQ	15	326	633	939	1244	1550	1856	2162	2469	2774
QQ	3080	3386	3692	3998	4304	4610	4916	5222	5528	5834
QQ	6140									

Field	Variable	Value	Description
0		QQ	Record Identification = Discharge list
1	FLOW(1)	+	First discharge
2-10	FLOW(2)	+	Continue coding discharges, 10 per record.
.			
.			
.			
	FLOW(10)		

QD RECORD

The QD record is the listing of the percent of time, QD, the corresponding discharge on the QQ record is equaled or exceeded. Durations do not have to be at a constant interval, and can be in increasing or decreasing order. There can be a maximum of 10 QD records.

Example.

The following example shows typical input specifying 21 different QD's.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QD DUR1    DUR2    DUR3    DUR4    DUR5    ... up to 10,000
QD 100.0   44.37    14.5    6.49    3.52    2.16    1.34    .83    0.52    0.36
QD 0.26    0.18    0.12    0.08    0.08    0.05    0.05    0.05    0.05    0.01
QD 0.0
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		QD	Record Identification = Discharge duration
1	DUR(1)	+	Duration for 1st discharge,
2-10	DUR(2)	+	Continue coding durations, 1 for each discharge, maximum of 10 per record.
.			
.			
.			
	DUR(10)		

QH RECORD

The QH record is the listing of the water discharge, in cfs, by the hydrograph ordinate. There can be a maximum of 25 QH records. Zero is an acceptable discharge on the QH record.

Example.

The following example shows typical input specifying 4 different QH's.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QH FLOH1  FLOH2  FLOH3  FLOH4  FLOH5  ... up to 10,000
QH      1      300    1300    7000
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		QH	Record Identification = Discharge -- Hydrograph.
1	FLOH(1)	+	Hydrograph ordinate for flow 1, cfs.
2-10	FLOH(2)	+	Hydrograph ordinate for each flow, maximum of 10 per record.
.			
.			
.			
	FLOH(10)		

QW RECORD

The QW record is the listing of the water discharge in cfs, and will be paired with a sediment discharge from the QS or SC record. The water discharges may be in **either** increasing or decreasing order, and there can be up to 10 values. Each QW field corresponds to exactly one QS field so the two records must be in the same order. There can be only 1 QW record.

NOTE: Do not use zero as the first or last discharge -- perhaps use 0.0001.

Example.

The following example shows typical input specifying 4 different QW's.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QW  Q1      Q2      Q3      Q4      Q5      ... up to 10
QW   1      300    1300    7000
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		QW	Record Identification = Discharge - water.
1	Q(1)	+	1st discharge, cfs.
2-10	Q(2)	+	List each water discharge, in cfs; maximum of 10 per record.
.			
.			
.			
	Q(10)		

QS RECORD

Not available in SAMwin.

The QS record is the listing of the sediment discharge in tons per day, and will be paired with a water discharge from the QW record. Each QS field corresponds to exactly one QW field so the two records must be in the same order. There can be only 1 QS record.

Example.

The following example shows typical input specifying 4 different QS's.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
QS QSR1    QSR2    QSR3    QSR4    QSR5    ... up to 10
QS      1      300    1300    7000
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		QS	Record Identification = Discharge -- sediment.
1	QSR(1)	+	First sediment discharge, in tons per day.
2-10	QSR(2)	+	Continue coding sediment discharge, 1 for each water discharge, to a maximum of 10 per record.
.			
.			
.			
	QSR(10)		

SC RECORD

The SC record is the listing of the sediment concentration in mg/l, and will be paired with a water discharge in cfs from the QW record. There can be only 1 SC record.

Example.

The following example shows typical input specifying 4 different SC's.

F#	45678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678	2345678
SC	QSR1	QSR2	QSR3	QSR4	QSR5	QSR6	QSR7	QSR8	QSR9	QSR10
SC	1	5	13	60						

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		SC	Record Identification = Sediment Concentration
1-10	QSR(1)	+	List each sediment concentration in mg/l; maximum of 10.
.			
.			
.			
	QSR(10)		

SE RECORD

Not available in SAMwin.

The SE record allows the user to specify the variables for the power equation from which to calculate the sediment discharge in tons/day. There can be only 1 SC record. The fields on the record prescribe 2 of the variables in the power equation:

$$QSR = AX (QW)^{BX}$$

Example.

```
F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
SE    AX      BX
SE 1.356 0.47529
```

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0	SE		Record Identification = Sediment power Equation
1	AX		The AX variable in the above power equation.
2	BX		The BX variable in the above power equation.

\$JOB RECORD

For stacked runs, the \$JOB record indicates the end of one job and the start of a new input data set.

Example:

F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
\$JOB

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$JOB	Record identification = NEW JOB

\$\$END RECORD

This record signifies the end of the run.

Example:

F# 45678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678 2345678
\$\$END

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0		\$\$END	Record identification = END OF RUN.

Appendix F: SAM.Aid—Guidance in Sediment Transport Function Selection

F-1. SAM.aid is on the Tools dropdown menu in SAMwin. Figure F-1 shows the opening screen for SAM.aid. There are three kinds of information on this screen: commands; input data; and output data. Only D50, Slope, Velocity, Width, and Depth can be input, but they do not have to be input manually. They can be read from a SAM.sed input file. If a SAM.sed input file is read, the 5 “input” areas, in the “Criteria Data” section of the screen, will be filled with data. The output areas are the two large, now blank, gray areas.

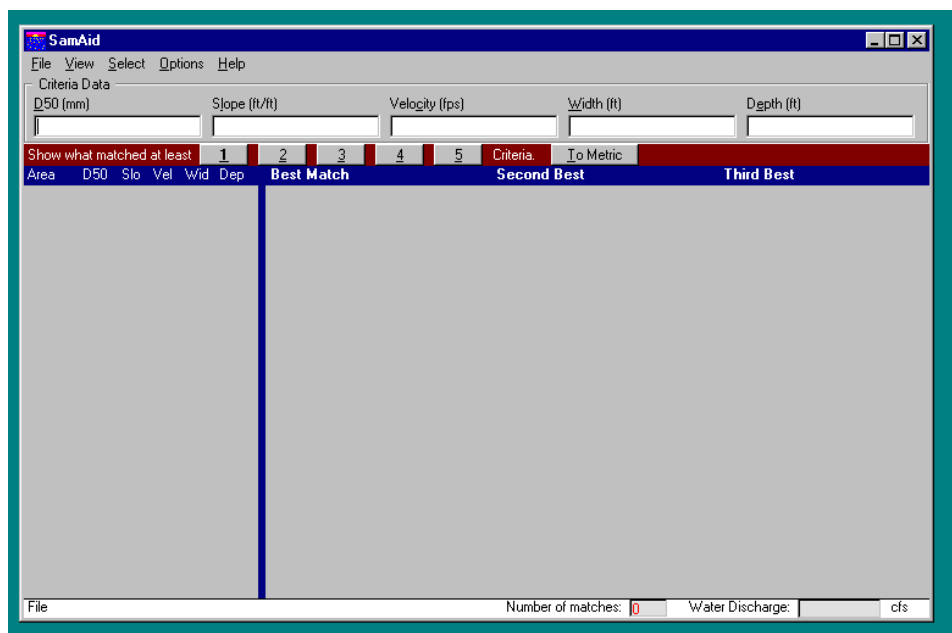

Figure F-1. SAM.aid Main Screen.

F-2. Using SAM.aid. The flow of events through SAM.aid is straightforward:

1. Read in an input file using the File dropdown menu or enter data in each of the 5 input areas.
2. If an input file has been read in, select a "data set," Figure F-2.
3. Review the listed best functions to use, checking the description of the Brice data, Figure F-6.
4. Turn on the desired functions -- Figure F-4 or Figure F-5.
5. Save the input file, exit, and run SAM.sed.

The most advantageous way to utilize SAM.aid is to go through steps 1 through 3 several times, examining several ranges of data within the input file.

F-3. The “File” dropdown menu offers standard choices. With the “View” dropdown menu the user can choose the display results or may view any of the Brice data set descriptions. With “Select,” the user can select a Data Set or a sediment transport function. The “Options” menu allows the user to choose English or metric units, and to set two configuration choices for ease in running. In the “Configure Options” the user can set a startup folder, or not, and also check whether or not to write the last used filename to the FILES.SAM file on exiting SAM.aid. The FILES.SAM file sets the input data file SAM.sed will use when run. The “Help” menu provides rudimentary information on using SAM.aid as well as information on the version, and creation, of the program.

F-4. View Menu. The user can choose how to view results – choosing to display only results that matched 1, 2, 3, 4, or all 5 parameters. This can also be accomplished by mouse clicking a number on the line above the output areas. The “Area Information” choice on this dropdown menu allows the user to view information on any Brice data set in the program, see Figure F-6.

F-5. Select Menu. The dropdown menu offers two choices, “Data Set...” or “Transport Function...” A mouse click on “Data Set...” will bring up the Select Data Set screen, Figure F-2. This screen appears automatically when a SAM.sed input file is opened, and will stay available. This dropdown menu choice is convenient if the user wishes to reopen the Select Data Screen once it has been closed.

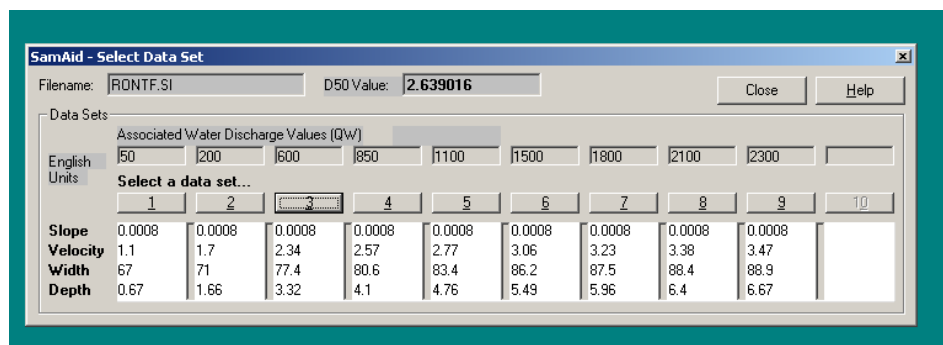

Figure F-2. Select Data Set screen showing input read from a file.

This screen echoes the data from the input file selected, arranging the information into columns of related slope, velocity, width, depth, and water discharge. The D50 value shown on the screen is calculated from the bed gradation information (the PF-records) in the input file. Data cannot be changed on this screen. Using the mouse to select a column will highlight the button for that column and cause the program to present the suggested transport functions for that one column of data, as in Figure F-3. The user selects one column of related data at a time to be used in the SAM.aid comparison. The Select Data Set screen stays visible. This is a convenient aid to comparing the results from selecting different columns. Figure F-3 shows the Select Data set screen with the results of a column selection on the main screen.

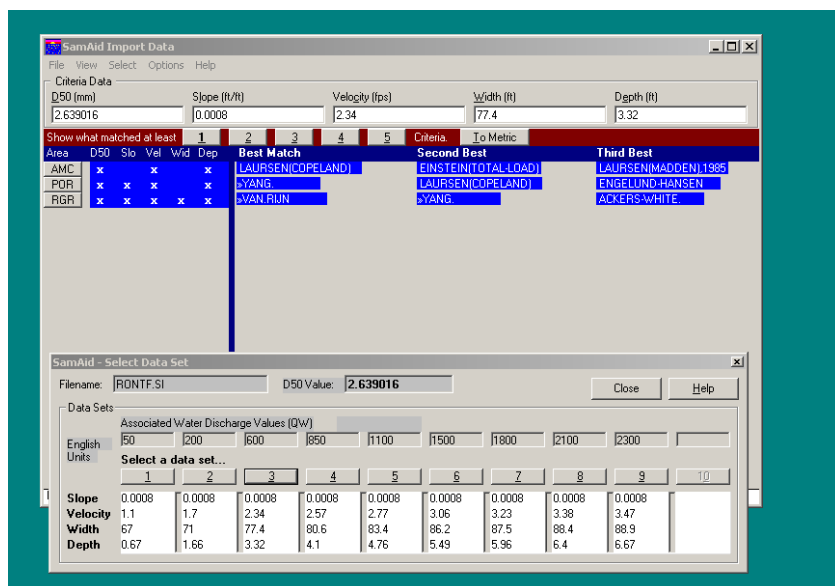

Figure F-3. Select Data screen with results.

Choosing “Transport Functions...” brings up the screen in Figure F-4. Any sediment transport function can be turned on or off in the input file by clicking on the function name.

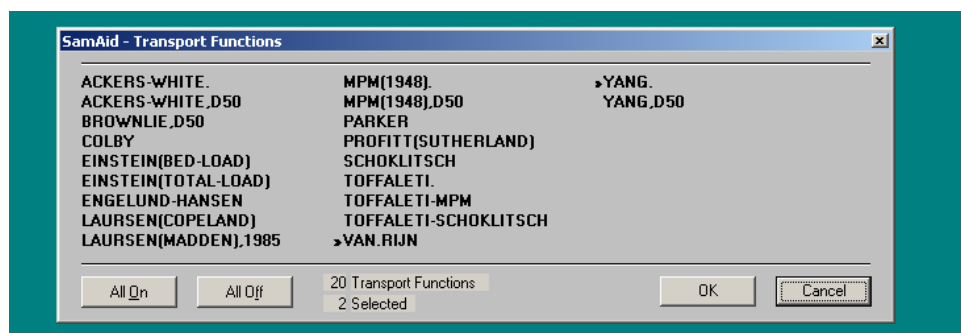

Figure F-4. Transport Functions screen, showing 2 functions selected.

If a “>” appears next to the name, as by “YANG” and “VAN.RIJN” in Figure F-4, then the function will be turned on in the input file. Mouse clicks toggle the functions on and off. The selections made on this screen are transferred to the main screen once “OK” is selected. They are transferred to the input file when the user saves the file.

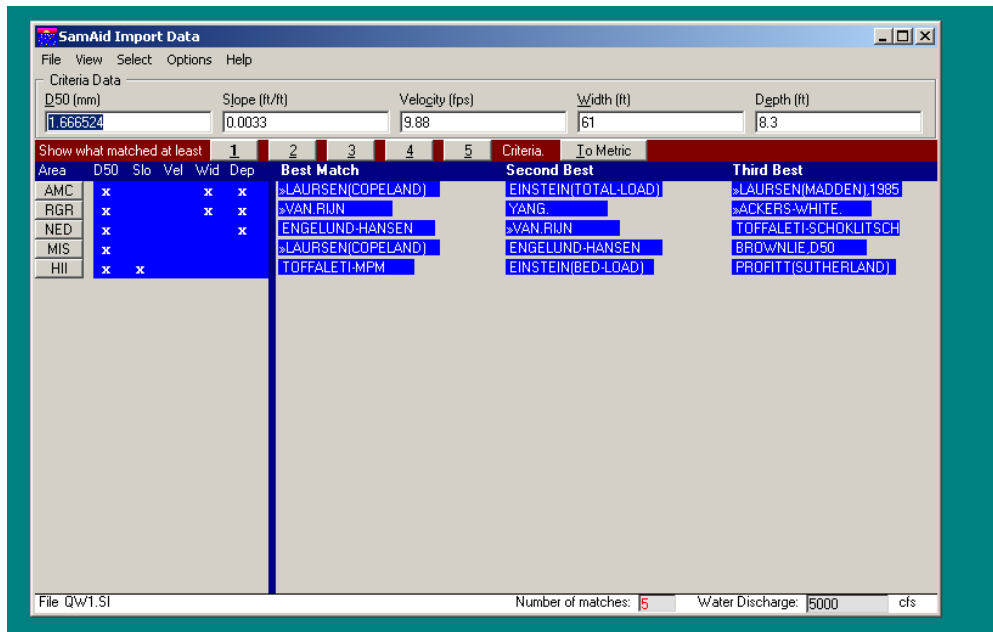

Figure F-5. SAM.aid output screen

The output screen, shown in Figure F-5, lists the various sediment transport functions that are recommended by SAM.aid. The parameters of the chosen “column” from the input file are echoed in the “Criteria Data” area. The parameters from this data that fell within the data ranges of the listed Brice data sets are checked with an “x”. The transport functions that are turned on in the input file are marked with a small “>>”. A mouse click on a function name on this screen will toggle that function on and off.

The “Area” column lists the Brice data set that matched the marked parameters with the input file chosen. Each button has a 3-letter identifier. The complete list of abbreviations and names is in the SAM.aid chapter of the “SAM User’s Manual,” or can be viewed by clicking the “View\Area Information” on the main menu. A mouse click on a button will display information on that Brice data set as well as the data ranges and the parameters on which each sediment transport function was rated, Figure F-6. The scroll arrows and bar on the side of this screen allow the user to access all information about, in this case, COL – the Colorado River Data of the U.S. Bureau of Reclamation (1958), including the ranges of the data and statistical parameters of the results of the attempt of each function in SAM.sed to reproduce this data.

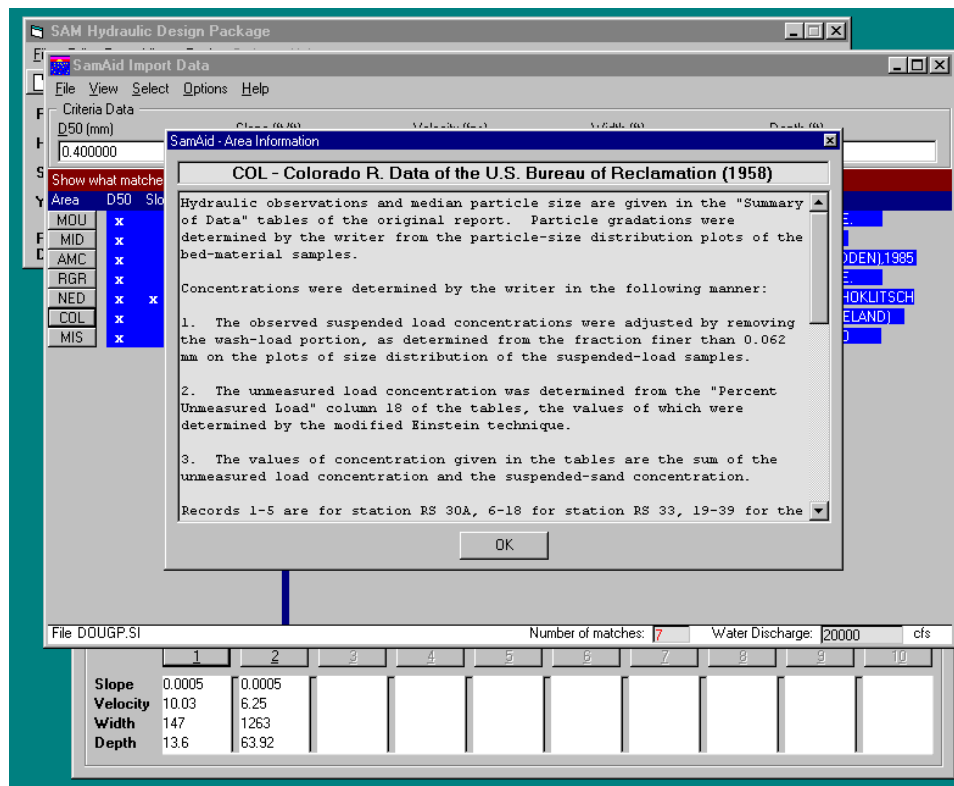

Figure F-6. Example Area Information Screen, shown as it appears over other screens.

F-6. Saving. Once the user is satisfied with the functions selected through this process, the "File" dropdown menu offers "Save," "Save as..." and "Exit" options. As discussed in F-3, the filename saved here can be written to a file that will cause this SAM.sed input file to be used when SAM.sed is run.
