Abstract A proposed action and five alternatives, including a 'no action' alternative, for a Forest Plan (Land and Resource Management Plan) for the Tahoe National Forest are described and compared. The alternatives provide different mixes of integrated management prescriptions, resulting in different levels of outputs, goods, and services at varying costs. The land area involved is 794,374 acres. The environmental consequences for the Forest Plan and alternatives are displayed.

The Forest Plan constitutes the Forest Service preferred alternative. The Tahoe National Forest Plan will guide management of the Forest for the next 10 to 15 years. Revisions and amendments can be made whenever necessary.

This Final Environmental Impact Statement responds to public comments. Copies of the Final Environmental Impact Statement have been sent to those agencies, organizations, or individuals listed in Chapter 6, and to those who specifically request a copy of the Final Environmental Impact Statement.

SUMMARY OF THE FINAL ENVIRONMENTAL IMPACT STATEMENT

BENEFITS OF FOREST PLAN

Each National Forest in the country is developing a Forest Plan which looks into the future to coordinate all its resources and activities in relation to the needs of the public. The Tahoe National Forest (TNF) Plan will benefit us all because it:

- o Involves you in deciding what issues are of special importance on the TNF
- o Provides a common planning approach for all National Forests throughout the county.
- o **Uses** the expertise of various specialists, such as wildlife biologists and soil scientists, who work with management to develop a range of choices for managing the Forest for the next 10 to 15 years.
- o Responds to major public issues, Forest Service management concerns, and resource development opportunities.
- o Enables planners to better consider economic efficiency as well as production of resources through the **use** of more detailed information.
- o Considers all resource plans within the Forest at one time, instead of considering each one separately.
- o Displays the standards and guidelines by which the Forest will be managed
- o Establishes a better system for monitoring and evaluating management actions.
- o Provides **for** review every 5 years to determine the need for revision, and will be revised at least every 15 years.

The Environmental Impact Statement for the TNF Land and Resource Management Plan describes the analysis process which led to the development of a Forest Plan. This summary condenses each chapter and highlights the major items discussed in that chapter.

ORGANIZATION OF SUMMARY

- Chapter 1 explains the background and purpose of developing the Forest Plan
- Chapter 2 tells how alternatives were developed and describes each alternative, including the outputs that would result if the alternative were implemented.
- Chapter 3 summarizes the existing environment on the TNF, including physical characteristics and resource **use**.
- Chapter 4 discloses the environmental consequences that would result if each alternative were implemented.
- Chapter 5 lists the people who assisted in the planning process
- Chapter 6 lists agencies, organizations, and people who received copies of the EIS and Forest Plan

CHAPTER I PURPOSE AND NEED FOR ACTION

HISTORICAL AND LEGISLATIVE FRAMEWORK

In 1974, Congress acted upon the need for coordinated and long-range planning of the uses and resources provided by the National Forests. Two legislative acts were passed: The Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), and the National Forest Management Act of 1976 (NFMA), amending RPA. These require that comprehensive, long-range Forest Plans replace the separate and often uncoordinated resource management plans.

Additional legislation required Forests, before developing a complete Forest Plan, to investigate and make public:

- 1 Alternative approaches which could be used in developing the plan.
- 2 The environment to be affected by the plan.
- 3 Anticipated environmental consequences of the alternatives.

This Environmental Impact Statement addresses these major subjects as required by the National Environmental Policy Act (NEPA) and the Council on Environmental Quality (CEQ) regulations.

Forest Plans form only one part of the Forest Service planning framework. Based on information from the Regions, the National RPA Recommended Program establishes direction and assigns targets to the Regions for producing goods and services. Each Region in turn provides direction and allocates its share of the national production levels to the Forests; each Forest Plan validates the levels or provides a basis for changing the production levels assigned by the Regions.

PUBLIC INVOLVEMENT

Although the broad goals and objectives are established by higher levels of Forest Service management, each Forest has a range of choices in meeting these goals. For example, a Forest can emphasize one resource, such as recreation, if that is an important issue to local people. This is why public involvement is so important throughout the planning process. When the TNF Plan was in its early stages several years ago, many individuals, organizations, and agencies helped pinpoint issues of special importance to them. These issues were incorporated into the planning process and taken into consideration when alternatives were developed.

The Forest received over 12,000 letters commenting on the Draft EIS and Draft Plan. Clearly, the public response indicated a strong interest in management of the TNF. Comments ranged from supporting alternatives that emphasize commodity production such as timber and range, to alternatives that provide for amenity values such as visuals, wildlife, soil productivity, and water quality. Two of the alternatives presented in the Final Environmental Impact Statement, CMD and NMK, were developed by representatives of the timber and environmental communities, respectively. Development of the Forest Plan was guided in part by the public comment, and through the participation of both timber industry and the environmental community.

FEIS

The Final Environmental Impact Statement (FEIS) describes a proposed action (preferred alternative) and five other alternatives for the management of the land and resources of the TNF. Each alternative addresses issues differently, provides for the use and protection of resources, and meets all legislative requirements. Every alternative generates a different mix of goods and services and maximizes benefits to the public in an environmentally sound manner.

The FEIS also describes the affected environment and discloses environmental consequences of each potential decision. It is written to meet the format and guidelines set by the National Environmental Policy

Act (NEPA). The proposed action is the alternative chosen by the Regional Forester based on advice and recommendations from the Tahoe National Forest Management Team.

ISSUES, CONCERNS, AND OPPORTUNITIES

The Tahoe National Forest Land and Resource Management Plan is formulated to address public issues and management concerns related to the Forest. These issues and concerns (referred to as issues in this EIS) and the associated questions were identified by the Interdisciplinary Team and indicate the scope and nature of the analysis needed for the **EIS**. The **issues** represent important reasons for *considering* changes in the current management direction and are instrumental in formulating alternatives and understanding the consequences of implementing any one of the alternatives.

The Pacific Southwest Regional Forester notified the public and other agencies of intentions to prepare a Land and Resource Management Plan for the TNF in the Federal Register, August 18, 1979. In November 1979, and again in November 1983, the Forest Supervisor published notices in local newspapers and in the Tahoe Planner newsletter that meetings would be held to accept public comment. Eight meetings to receive public comment were held in the TNF area of influence.

The meeting held in 1983 was to receive comments on seven additional roadless areas added to the planning process as the result of the October 30, 1982, revised NFMA regulations.

The Interdisciplinary Team identified and evaluated public issues, management concerns, and resource **use** and development opportunities, including those identified through public participation activities and coordination with other Federal agencies and State and local governments throughout the planning process. Nine major issues were identified. These issues were approved by the Regional Forester and addressed in the planning process. Enacting the California Wilderness Act of 1984 resolved ~~in~~ terms of wilderness designation the inventoried roadless area issue (**Issue #4**) for this round of Forest planning.

In addition, the Pacific Southwest Regional Guide deferred 11 Regional **issues**, concerns, and opportunities to be answered during the Forest planning process. These have been incorporated into the list of Forest issues. These issues were addressed in at least one alternative in the DEIS. More detailed information on the scoping process and each of the issues can be found in FEIS Appendix A.

Following release of the DEIS and Draft Forest Plan and a five-month comment period, a list of 12 major issues was developed. This list **was** the result of analysis of the comments contained in approximately 12,000 letters of input and oral testimony from two formal public hearings on the DEIS and Draft Plan. Some of these 12 issues are the same as those contained in the initial issue list, others are a variation of those initial issues, and *others* are new. The Forest Service response to the public comment can be found in FEIS Appendix A.

Following are.

A listing of initial issues.

A listing of the 12 major issues resulting from the Draft document review.

A listing and analysis of the relationship between the initial and the new major issues.

Initial Issues

#1. Ownership Patterns and Land Uses

In what ways and to what extent can the Forest Service lessen or resolve conflicts in **use** between National Forest, private, and other public ownerships within the Tahoe National Forest boundary? Some of these conflicts result from the conflicting desires and needs of different owners and the public in their resource management objectives.

#2. Minerals

What emphasis by the Forest Service should be placed on the surface management of mineralized areas within the Tahoe National Forest? This includes both locatable and leasable mineral resources.

#3. Energy

How should management of the Tahoe National Forest contribute to conserving energy and meeting future energy needs?

#4. Inventoried Roadless Areas

How should all inventoried roadless areas be managed on the Tahoe National Forest?

This issue was resolved in terms of wilderness designation by enactment of the California Wilderness Act of 1984, which designated the 18,705 acre Granite Chief Wilderness and released the 10 remaining roadless areas to other multiple uses for this round of planning. (See FEIS Appendix A)

#5. Facilities

How can the Tahoe National Forest management, operation, and development of its facilities (roads, trails, administrative facilities) be optimized with respect to user interests, resource management and human resource needs, private landowner concerns, and economic efficiency?

#6. Forage, Wood, and Soils

How much area of the Tahoe National Forest should be managed for renewable commodity outputs (forage and wood)? How intensively should vegetation be managed to optimize commodity outputs? What Forest Service emphasis should be placed on the soil resource to maintain or enhance productivity?

#7. Water

How should the management of Tahoe National Forest resources respond to the demands and allocations for water quality, quantity, storage, and transmission?

#8. Recreation

To what extent should Tahoe National Forest land be allocated for recreation and scenic purposes? What should be the mix of recreation uses on Tahoe National Forest land?

#9. Fish and Wildlife Habitat

What Forest Service emphasis should be placed on wildlife habitat to maintain or enhance productivity, quality, and diversity?

Major Issues resulting from the Draft document review:

~~##~~ **1. Spotted Owls**

How many spotted owl habitat areas (SOHA's) should be established on the Tahoe National Forest and how should they be managed?

#2. Viable Populations/Diversity

How shall the Tahoe National Forest comply with National and Regional direction to maintain diversity and viable populations of animals?

#3. Budget

What effect will reduced budgets have on the implementation of the proposed Forest Plan?

#4. Roadless Areas

How should existing roadless areas be managed?

#5. Herbicide Use

Should herbicides be used on the Tahoe National Forest?

#6. Mt. Lola

How should the Lola Management Area be managed?

#7. Urban/Rural Wildland Interface

How should the Forest Service manage National Forest System lands that are adjacent to or affected by private lands, particularly those private lands developed or developing within this planning period for recreation, rural, residential, urban, or commercial uses.

#8. Soil Erosion/Long-Term Soil Productivity

With what practices can intensive timber management be conducted on Forest lands while maintaining soil productivity?

#9. Riparian/Streamside Management Zones

What level of management is acceptable in riparian areas/streamside management zones that still protects riparian-dependent resources?

#10. Visual Quality

How should the visual resource be managed on the Tahoe National Forest?

#11. Clearcutting

What should be the role of clearcutting in meeting the vegetative management objectives of the Tahoe National Forest?

#12. Timber Supply

What should be the amount of timber supplied by the Tahoe National Forest?

Relationship between the **Initial** and new major issues:

This will be shown by comparing the new issues to the initial issues

#1 Spotted Owls - a new issue.

#2 Viable Populations/Diversity - within parameters of #9. Fish and Wildlife Habitat

#3. Budget - a new issue.

#4. Roadless Areas - within parameters of #4. Inventoried Roadless Areas and #8 Recreation

#5. Herbicide Use - within parameters of #6 Forage, Wood, and Soils.

- #6. Mt Lola - a new issue
- #7 Urban/Rural Wildland Interface - within parameters of #1 Ownership Patterns.
- #8 Soil Erosion/Long-Term Soil Productivity - within parameters of #6. Forage, Wood, and Soils.
- #9. Riparian/Streamside Management Zones - within parameters of #7 Water.
- #10 Visual Quality -within parameters of #8 Recreation
- #11. Clearcutting - within parameters of #6 Forage, Wood, and Soils.
- #12. Timber Supply - within parameters of #6. Forage, Wood, and Soils.

CHAPTER 2 ALTERNATIVES INCLUDING THE PROPOSED ACTION

FORMULATING ALTERNATIVES

Six different approaches to resolving conflicting issues and reducing adverse environmental effects are described by alternative. They were formulated within given criteria of laws, regulations, directions, public issues, TNF management concerns, and the physical capabilities of the Forest to produce goods. Each would provide the public with a diverse mix of goods and services, and develop resources to varying degrees. Many other alternatives were considered and rejected from detailed study. Reasons included a significant departure from the multiple-use concept, not adequately addressing **issues**, or inefficiency. The six alternatives that were selected to be analyzed in detail are described next.

ALTERNATIVES CONSIDERED IN DETAIL

Alternative	Name
PRF	Preferred
CUR	Current Management
RPA	1980 RPA
CMD	Commodity
NMK	Nonmarket
UNE	Uneven-aged

Resource outputs, costs, and benefits are estimated for five time periods of ten years each (50 years). The alternatives also consider those resources that cannot be qualified in terms of dollars or other units, such as scenic beauty or maintenance of threatened and endangered species habitat.

ALTERNATIVE DESCRIPTIONS

The themes, emphases, and issues for the six alternatives considered in detail and displayed in the FEIS are described as follows:

Preferred Alternative (PRF)

The Preferred Alternative in the Draft was modified as a result of public comments and additional analysis to become the Preferred (PRF) Alternative in the FEIS. This alternative will increase the level of environmental protection while maintaining timber and grazing outputs near existing levels. The alternative establishes a high level of protection for wildlife, riparian areas, soil productivity, water quality, and visual quality. The alternative provides for a mix of resource uses in former roadless areas. The highly productive lands are managed for timber, and those lands with high recreation values will be managed for a variety of recreation activities. Expansion of existing ski areas and development of new ski areas is provided for. The Allowable Sale Quantity (ASQ) is 142.3 MMBF through five decades.

Current Management (No Action) Alternative (CUR)

The no action alternative remains unchanged from the Draft EIS. This alternative continues the Forest's current direction, policies, and practices as of **1982**. Timber, grazing, and other goods and services are provided at existing levels. A mix of recreation opportunities is also provided. No specific resource issue or opportunity is emphasized over another. Standards implemented for the CUR Alternative provide for basic protection of soil productivity and water quality. All issues are addressed to the extent allowed by current direction and budget. All roadless areas are available for uses other than wilderness. Expansion of existing ski areas is provided. New ski area development is evaluated on a site-specific basis. The **ASQ** is **173.4** MMBF, increases to **193.7** MMBF by the second decade, and remains constant through the fifth decade.

1980 RPA Alternative (RPA)

This alternative is unchanged from the Draft. This alternative achieves the **1980** RPA program targets assigned to the Forest, by providing moderately high levels of timber and livestock production with an increase in campground facilities. All unroaded areas are available for timber management activities on productive timber lands. Expansion of existing ski areas is provided. New ski area development is evaluated on a site-specific basis. Standards implemented for the RPA Alternative provide for basic protection of soil productivity and water quality. The **ASQ** is **173.0** MMBF, increases to **186.0** MMBF in the second decade, to **198.4** MMBF in the third decade, then remains constant through the fifth decade.

Commodity Alternative (CMD)

Alternative **I** as described in the Draft is modified and emphasizes timber production, livestock grazing, and recreational camping. All unroaded areas are entered within the first decade. Standards implemented for this alternative provide for basic protection of such resources as riparian and streamside zones, viable wildlife populations, water quality, soil productivity, and visual quality. Expansion of existing ski areas is provided. New ski area development is evaluated on a site-specific basis. The **ASQ** is **180.1** MMBF in the first decade, then increases to **184.8** MMBF, **189.6** MMBF, **194.5** MMBF, and **196.9** MMBF in succeeding decades.

Nonmarket Alternative (NMK)

This alternative emphasizes protection of the natural environment and recommends that all inventoried roadless areas plus the Lafayette Ridge area remain without roads. Recreational opportunities that protect amenity values are emphasized. These activities include hiking, cross-country skiing, and nature study. Expansion of ski areas is limited to existing developments; no new areas are developed for downhill skiing. Grazing and timber production are immediately reduced from current levels. This alternative provides for a higher level of protection over current levels for wildlife, riparian areas, soil productivity, water quality, and visual quality. The **ASQ** is **104.9** MMBF through five decades.

Uneven-aged Alternative (UNE)

This alternative provides for the same land allocations, the same direction for environmental protection, and the same grazing and recreation outputs as the Preferred Alternative. The major difference is that this alternative utilizes uneven-aged timber management to produce 50 percent of the timber volume. The **ASQ** is **110.8** MMBF, increases to **114.5** MMBF in the second and third decades, then drops to **114.4** MMBF in the fourth and fifth decades.

The following table describes Alternatives PRF through UNE in an easy-to-compare format. It shows the anticipated average annual output, cost, and benefit levels for the first ten years of implementation. (The fifth ten-year time period is also displayed for some activities.) Following are some of the terms used in the table:

M Ac-Ft: Thousands of acre-feet The amount of water that would cover one acre to a depth of one foot (43,560 cubic feet, or 325,850 gallons).

MMBF: Millions of board feet One boardfoot is the amount of wood contained in an unfinished board 1 inch thick, 12 inches long, and 12 inches wide.

M AUM: Thousands of animal unit months. An AUM is the amount of forage required to sustain one mature cow or equivalent for one month.

MM \$ Millions of 1982 dollars.

M RVD: Thousands of recreation visitor days. One visitor day equals 12 hours of recreation use in any combination of persons and hours, such as 1 person for 12 hours, 3 persons for 4 hours, etc.

M WFUD Thousands of wildlife and fish user days One user day equals 12 hours of recreation use oriented to wildlife and fish.

Cord A stack of wood measuring 4 feet high, 4 feet deep, and 8 feet long (128 cubic feet). In wood volume, 2 cords roughly equal 1,000 board feet.

VQI: Visual Quality Index. A numerical rating of scenic quality that reflects both the inherent scenic value of, and the amount of human modification to, the Forest landscape. The VQI would be 60.0 if none of the TNF had been altered, and would be 20.5 if all the Forest had been drastically disturbed.

SOHA Spotted Owl Habitat Area. An area established to provide a minimum of 1,000 acres of suitable habitat at all times for the nesting, roosting, and feeding requirements of a spotted owl pair.

CHAPTER 3 THE AFFECTED ENVIRONMENT

This chapter describes the physical setting to be affected by the alternatives. It includes the current management situation. The general Forest description is followed by discussions of the economic, social, and resource environments.

GENERAL FOREST DESCRIPTION

The Tahoe is located in the north central Sierra Nevada. Portions of Nevada, Placer, Plumas, Sierra, and Yuba counties are within the Forest boundaries. The Tahoe is bounded on the north by the Plumas National Forest, on the east by the Toiyabe National Forest and Lake Tahoe Basin Management Unit (LTBMU), and on the south by the Eldorado National Forest. Interstate Highway 80 crosses the central part of the Tahoe and provides primary access across the Sierra Nevada between Sacramento, California and Reno, Nevada.

The Tahoe encompasses 1,175,535 acres, with 381,161 acres in other ownerships in an alternate section (checkerboard) pattern. Within the past 50 years the Tahoe has been enlarged by some 32 percent (253,425 acres) with lands acquired through purchase, donation, or exchange.

Within the Tahoe are 28,833 acres which form part of the Lake Tahoe watershed. Although legally part of the Tahoe, these acres are managed by the Lake Tahoe Basin Management Unit. The LTBMU was formed in 1973 by Presidential proclamation to provide unified, more efficient management of the National Forest System lands in the Lake Tahoe watershed.

The western slope of the Tahoe contains numerous historic mining **sites**, some dating back to the 1860's, which created an early heavy demand for timber. Due to this early demand, much of the Tahoe today is characterized by young growth stands of timber 80 to 90 years old, which supply local mills in Nevada, Butte, Sierra, Plumas, Yuba, and Placer counties in California and Douglas County, Nevada.

Today, an estimated eight million residents live within a four-hour drive of the Tahoe. This large, urban population increases the demand for all types of recreational activities, utility rights-of-way, and fuelwood. Major attractions include the Placer County Grove of Sierra Redwoods, the North Fork American Wild River, Granite Chief Wilderness, numerous ski areas and reservoirs, Donner Camp, and the historic Overland Emigrant Trail from Verdi to the Sacramento Valley.

CURRENT MANAGEMENT SITUATION

The following discusses the current management situation. The TNF is managed on an integrated basis, which means that management decisions that affect all resources are designed to achieve multiple resource objectives. Management activities affect a variety of resources, and decisions are made only after considering the entire set of ramifications involved. Similarly, single management activities are actually designed to **serve** a variety of resource objectives. For example, treating lodgepole pine stands with small clearcuts to increase water yield will also provide additional wildlife habitat and a wood source for various purposes. Water developments are designed to **serve** the needs of certain wildlife species as well as domestic livestock. Roads are located to efficiently transport logs from a timber sale area to the mill, but these same roads are also designed to provide access for hunting, fuelwood gathering, and other recreation activities.

Other relationships are more separated in time. For example, greater diversity of vegetation in different stages of growth leads to a gradual increase in populations of certain animal species, which in turn increases recreation opportunities for viewing, photographing, and hunting these animals. This series of events may take several years to complete, yet it may be entirely the result of a single management activity.

Resources are part of a very complex system with numerous interactions. They are described individually only to emphasize important aspects of the current situation in some type of organized framework. These resources must be conceptually combined to understand the overall Forest situation.

SOCIOECONOMIC

An overview was prepared of the existing social and economic conditions which exist in the TNF's zone of influence. The counties of Nevada, Placer, Plumas, Sierra, and Yuba are directly and indirectly affected by Forest activities. Local counties are economically affected in three ways: direct payments to county governments, employment, and income. Payments to counties significantly contribute to all counties' revenues. Sierra County is the most dependent on revenue from the TNF; Yuba County is the least dependent.

Employment and income in the affected counties are influenced by Forest activities, primarily in the wood products manufacturing and recreation-dependent businesses.

AIR QUALITY

Air quality on the Forest is high. Smoke pollution from forest and range prescribed fire has not been identified as a problem. All areas within the Forest are Clean Air Act Class 1, including the Granite Chief Wilderness.

ADJACENT LANDS

The administrative boundary encompasses 1,175,535 acres. Of this total, 381,161 acres are in other ownerships in an alternate section (checkerboard) pattern, with parcels that vary from less than 1 acre to over 12,000 acres. This intermingled ownership pattern results from various public land and mining laws. Additional private land adjoins the TNF's exterior boundary and lies along interior exclusions (e.g., areas of private land excluded when the Forest was established). More than 2,700 miles of property boundary interface between the National Forest and private land.

Most of the private land is owned by small landowners or large industrial owners. Approximately 165,000 acres (44 percent) of the intermingled private land is zoned for timber production by the counties. The large industrial owners are interested in high-yield timber production.

Many small communities were established on public lands during the last century. The residents of most of these communities have received title to the land either through land exchanges or townsite laws.

Scattered throughout the Forest are smaller, privately-owned parcels and tracts, typically 5 to 100 acres in size. These parcels mostly result from homesteads, mineral patents, and State school land sales.

DIVERSITY

The Forest is composed of two broad, yet distinct, vegetative and geomorphic management zones: the eastern and western slopes. Together, they provide a broad array of plant and animal communities.

On the TNF the diversity issue is most strongly associated with: 1) maintenance of diverse forest seral stages over time (particularly older forests), and 2) important habitat elements such as snags, down logs, hardwoods, riparian areas, meadows and meadow edges, and wetlands. Alternate sections of land are privately owned over most of the TNF. The resulting 'checkerboard' ownership pattern seriously complicates analyses of forest diversity.

FACILITIES

TNF facilities include roads, trails, dams, and administrative sites, including utility systems and buildings. Construction and operation of facilities consider energy requirements, resource development and protection, public demand for Forest uses, and transportation needs of private landowners. Direction for construction and operation of facilities comes from Public Laws, multiple-use and land-use plans, the transportation management program, and cooperative agreements with private landowners and other government agencies.

The existing road system under Forest jurisdiction is about 2,400 miles. An additional 850 miles within the Forest boundary are under the jurisdiction of counties, the State, or private owners. Nearly 90 percent of the TNF is accessed by roads.

The existing trail system comprises 508 miles. Use by trail bikes and other off-highway vehicles is prohibited on parts of the trail system, but provided for on other parts of the trail system. About 97 miles of the Pacific Crest National Scenic Trail transects the TNF along the Sierra Nevada Crest. The Western State Trail and Tevis Cup Loop are used for a number of competitive events throughout the summer, and significant public interest has been expressed in nominating the trails for inclusion in the National Trail System. Both trails qualify for National Recreation Trail designation.

FIRE PROTECTION

The Forest has wildfire protection responsibility for about 1,237,700 acres, one third of which are privately owned. The Forest protects these private lands under a cooperative agreement with the State of California.

Fire protection has been **very** effective since 1960, when large fires burned about 100,000 acres of the Forest. Since then, about 27,000 total acres have burned. During this period, the TNF had about 148 fires per year, distributed almost equally between human-caused and lightning-caused. This history of numerous small fires with an occasional large, damaging fire is typical of central Sierra Forests. The years 1987 and 1988 have been unusual in that 1987 set records for wildfire in California where over 600,000 acres burned, and was called the 'Siege of 87'. In 1988 the 33,500-acre 49er fire in Nevada County burned on State Responsibility lands and resulted in the **loss** of 190 homes. This fire had the potential for greater **loss** if the normal westerly winds had occurred.

FUELS MANAGEMENT

Fuels management primarily treats fuels (slash) created by management activities, especially timber harvesting. An estimated 19,000 acres of older fuels are scattered throughout the Forest: these fuels are being reduced through projects such as timber sales, reforestation site preparation, and wildlife habitat improvement. About 8,000 acres of newly created fuels are treated annually on the Forest, including about 1,200 acres by prescribed broadcast burning.

FISH AND WILDLIFE

The fish and wildlife resources on the Forest are quite varied. The TNF contains approximately 366 wildlife species, including 258 bird species, 82 mammal species, 17 reptile species, 9 amphibian species, and 21 species of fish.

Federally classified threatened and endangered species on the TNF include bald eagle, peregrine falcon, and Lahontan cutthroat trout. Sensitive species include pine marten, fisher, willow flycatcher, spotted owl, great gray owl, and goshawk. Pacific Southwest Regional policy states that sensitive animal species will be treated as though they were Federally classified as threatened or endangered; this means that all necessary steps will be taken to ensure that agency actions do not jeopardize the continued existence of these species.

Fishing is a major recreational activity on the Forest. Over 1,500 miles of fishable streams exist, and 22 impoundments hold about 20,000 surface acres of water. The existing fishery is primarily cold water fishing for rainbow, brown, and brook trout. Some lakes have kokanee salmon, lake trout, and mountain whitefish. Most waters are stocked annually. One reservoir, Bullards Bar, has a warm water fishery. California has designated portions of the North Fork American River and Lavezzola Creek as wild trout streams.

FOREST PESTS

An integrated pest management (IPM) approach, which recognizes pest management as an integral part of timber and other resource management, is used to prevent and reduce unacceptable pest-related damage on the TNF. Under IPM, a full range of pest management alternatives is considered for each pest situation on a project-level, site-specific basis.

GEOLOGY

The primary geologic hazards on the TNF consist of debris slides and rockfalls. Snow avalanche hazards and small areas containing asbestos-bearing rock also occur. Seismic and volcanic activity are low potential hazards.

Geologic resources, besides locatable and leasable minerals, include groundwater, common variety mineral materials, and geologic special interest areas. Rock and soil materials sources, both public and private, are used for road surfacing, roadway fill, and streamcourse restoration projects. Many small groundwater basins and springs are used for human, livestock, and wildlife consumption. Groundwater use for domestic purposes is becoming more significant on the Forest. Two areas of geologic special interest have been identified.

HISTORICAL AND CULTURAL RESOURCES

About 25 percent of the Forest has been inventoried for archaeological sites. Over 1,500 historic and prehistoric sites have been recorded. The historic sites represent early-day logging, mining, homesteading, and ranching. They range from small camps attributed to the 49'ers to large-scale hydraulically-mined areas. Prehistoric occupation and use of the TNF is evidenced by seasonally occupied base camps, hunting and food gathering areas, petroglyph sites, and a few large year-round village sites.

HUMAN AND COMMUNITY DEVELOPMENT

Human resource programs include the Comprehensive Employment Training Act, Senior Community Service Employment Program, Youth Conservation Corps, Young Adult Conservation Corps, and the Volunteer Program. The Urban and Community Development Program involves both research and technical assistance through the State for the improvement of natural resources on private lands. One such program that the TNF helped develop and actively supports is the Resource Conservation and Development Program for the High Sierra Resource Conservation and Development Area.

HYDROELECTRIC PROJECTS

Hydroelectric development is a legitimate use of public land that is recognized by the Federal Power Act of 1920. The Forest Service objective for hydroelectric projects is to ensure that construction and operation on public land is consistent with the purposes for which the National Forests were established.

LANDS

Adjustment

The land adjustment program attempts to achieve more efficient and effective management of Forest resources by acquiring or exchanging land. Generally, National Forest System lands will be retained. Land adjustments are considered on a case-by-case basis determined by management needs and public values. Approximately 265,341 acres (34 percent of the total TNF System acreage) have been acquired through purchase, donation, or exchange within the past 50 years. The land adjustment program is guided by the TNF Master Land Ownership Adjustment Plan and specific purchase composites in critical recreation areas. These plans will be revised to reflect the direction in the Forest Plan and the California Wilderness Act. Because of the substantial amount of acquired land and intermingled ownerships on the TNF, considerable opportunities exist for survey problems, title claims, and trespass. Primary emphasis has been and will continue to be on prevention.

Special Uses

Approximately 870 permits, easements, and licenses authorize the use of National Forest System land for uses ranging from cabins, resorts, and ski areas to reservoirs, roads, and utilities, encumbering over 22,000 acres. Compatible uses are grouped by designating transportation and utility corridors, such as Interstate 80, and electronic sites. The TNF issues about 70 permits, licenses, and easements annually for authorized uses.

Transportation and Utility Corridors

There are no formally established transportation and utility corridors, although the area along Interstate 80 includes many existing facilities. This 'corridor' is up to one mile wide, contains considerable private land, and can support additional uses. An opportunity exists to expand and upgrade existing facilities to meet future demands. Other existing and proposed facilities on the Forest do not require corridor designation because they conform with management direction for the area.

Current direction excludes corridors from the Grante Chief Wilderness, the North Fork American Wild River, Onion Creek Experimental Forest, and potential Research Natural and Special Interest Areas.

LAW ENFORCEMENT

Law enforcement, which includes protection of government property, Forest users, visitors, employees, and Forest resources, is an important management concern because of the potential losses, costs, and damages to public and natural resources.

MINERALS

Four categories of minerals are located in the TNF:

1. Locatables (hardrock minerals - gold, silver, etc.)
2. Leasables (geothermal and locatable minerals on acquired land)
3. Saleables (basically common varieties - sand, gravel, etc.)
4. Outstanding Mineral Rights (land managed by the TNF where the mineral estate is reserved or outstanding)

About 94 percent of the TNF is open to locatable mineral entry under the 1872 Mining Law. Principal leasables on the Forest are geothermal, generally found on the east side of the Sierra, and metallic minerals on those acquired lands without public domain status. The saleables, or common variety form of minerals, is the only category that is 'managed' by the Forest Service.

The western side of the Forest is highly mineralized. This area includes part of the historic Northern Mines gold mining region (Downieville to Placerville). Other important minerals and common variety minerals found in the Forest include chromite, barite, silver, iron, copper, sand, and gravel. Chromite is a strategic mineral with critical significance because current supplies are primarily from foreign sources.

RANGE

The available domestic livestock forage consists of transitory and permanent range. Transitory range is created by wildland fires and by management practices, especially timber harvesting. Transitory range occurs mostly on the lower elevation western slopes, whereas the permanent range consists of high mountain meadows throughout the Sierra Nevada Crest and the eastside pine forest type.

Forty-six active grazing allotments within the TNF encompass 310,448 acres of public land and 192,194 acres of waived and cooperative private land. Cattle graze on 30 allotments, and sheep graze on 15 allotments, with one allotment grazed by both cattle and sheep. These allotments produce a total of 20,000 animal unit months (AUMs) on public land and 10,800 AUMs on private land. Currently, two allotments have no livestock. Eighty-five percent of the rangelands are currently in satisfactory condition with a stable trend. Grazing allotments with improved management systems have an upward trend.

RECREATION

Recreational **use** of the TNF has increased steadily for the past 30 years to **its** present annual level of about **5,000,000** recreation visitor days (**RVD's**) **as of 1986**.

Forest recreational **use** is projected to climb to about **5,200,00RVDs** in **1990**, **6,200,00RVDs** in **2000**, and **9,100,00RVDs** by the year **2030**. These projections assume that recreation **use** will increase at the same rate as the population growth in the neighboring counties and the extended zone of influence

Recreation facilities and **RVD use** consist of the following

- o **197** developed recreation **sites** on **1,843** acres. These sites accounted for **1,885,800 RVDs** in **1982**.
- o Four winter sports resorts operating under Forest special-use permits. They provide about **497,600RVDs** per year (**209,50RVDs** per year on public land and about **288,100RVDs** on private land).
- o **177** facilities under special-use permit (**155** recreation residences in **9** tracts, **5** summer resorts and commercial establishments, and **17** organizations and clubs).
- o Cross-country skiing, along with snowmobiling and other recreational winter sports, accounted for **36,100RVD's** in **1982**
- o Off-highway vehicle **use** of about **177,500RVD's** in **1982**

RESEARCH NATURAL AREAS

Research Natural Areas (**RNA's**) are recommended to the Chief of the Forest Service to preserve examples of all significant natural ecosystems for purposes of research and ecological study and to provide gene pools. Currently, there are no designated RNA's on the Tahoe National Forest

RIPARIAN AREAS

Riparian areas comprise the aquatic ecosystem, the riparian ecosystem, floodplains, wetlands, and streamside management zones. The riparian ecosystem/wetlands areas total about **54,200** acres within the Forest boundary, of which about **32,000** acres are public land. About **47,800** acres of identified streamside management zones lie adjacent to perennial water bodies on public lands. About **38,700** of these acres comprise 6.0 percent of the Forest's total timber producing land. Activities within streamside zones are not excluded but are closely managed. About **4,600** acres of floodplains are associated with large (Class I) streams, mostly on public land. The condition of riparian areas on the Forest is generally quite good. Water quality is generally quite high, indicating that the aquatic ecosystem is in good condition.

SENSITIVE PLANTS

One Federally endangered and **12** sensitive plant species are known or suspected to occur on the Forest or in its vicinity. No plant is listed as threatened. All necessary steps will be taken to ensure that agency actions do not jeopardize the continued existence of these species, and that viable populations of sensitive plants will be maintained.

SOILS

Forest Service direction is to maintain or enhance soil productivity. No management action will be intentionally taken that will irreversibly impair soil productivity. Soil characteristics and qualities that are indicators of soil productivity will be monitored to detect any changes caused by management activities. A third-order soil resource inventory has been completed for the Forest.

The western third of the TNF contains soils developed mainly from metasedimentary and ultrabasic bedrock; soils on the ridgetops have developed primarily from andesitic tuff breccia mudflows of the Meherten Formation. Soils around Bullards Ear Reservoir have developed mainly from granitic bedrock. The western third of the TNF has the most productive soils

Soils in the eastern third of the TNF have developed from rhyolitic and granitic bedrock and from alluvial deposits. Low precipitation is a major limitation to productivity.

Soils at higher elevations along the crest of the Sierra have developed from volcanic, metasedimentary, and granitic rocks, and from glacial-alluvial deposits. Steep slopes and shallow and rocky slopes limit productivity.

SPECIAL INTEREST AREAS

Special Interest Areas (SIAs) are established to protect special or unique geological, ecological, or cultural features. No established SIAs are presently on the TNF. The SIA Environmental Assessment and Establishment Report for the Placer County Big Tree Grove Botanical Area (346 acres) is being prepared. The Forest recognizes the need to search out other unique areas for their establishment and protection through SIA status.

TIMBER

The available wood supply from the TNF depends upon the amount of land capable of producing at least 20 cubic feet of timber per acre per year (estimated at 649,867 acres) and which is not withdrawn from timber production. Timber producing land is classified into five major forest types: mixed conifer, red fir, eastside pine, lodgepole pine, and hardwoods. There are 449,842 acres of intensively managed forest land (land capable of annually producing at least 85 cubic feet of timber per acre) on the Forest.

The current timber management direction was established in the October 16, 1978, TNF Timber Management Plan and Final Environmental Statement. The average annual programmed sale quantity is 147.6 million board feet. Most of this volume is harvested from 306,000 acres identified for intensive forest management in the Timber Management Plan, which emphasizes even-age management and regeneration harvest of understocked timber stands.

VISUAL RESOURCES

The TNF has varied and distinctive landscapes. The California Master Plan for Scenic Highways designates portions of Highways 20 and 49 that are within the boundary of the TNF as scenic highways. Highway 89, Interstate 80, and the remainder of Highways 20 and 49 are eligible for designation as scenic highways.

Public concerns and demands for natural-appearing scenic environments has led to Forest Service standards being established for quantifying the current and probable future condition of the visual resource. The intermingled private lands, however, generally do not have established scenic standards that would retain visual qualities.

WATER

The Forest produces about 3,244,000 acre-feet of water per year within its boundaries. About 2,000,000 acre-feet of this total are produced from National Forest System land. No active Forest Service effort exists to increase water production on the TNF.

About 98 percent of the runoff originating within the Forest boundary meets State and Federal water quality objectives. The remaining runoff fails to meet objectives for sediment and turbidity. Major sediment sources are abandoned hydraulic mine sites, roads, and old wildfire areas.

WILD AND SCENIC RIVERS

In November 1978, Congress designated the North Fork American River as a Wild River from a point 0.3 mile above Heath Springs downstream to a point approximately 1,000 feet upstream of the Colfax-Lowa Hill Bridge. The Wild River area totals 38.3 miles and includes the Gold Run Addition Area. The area is managed according to the North Fork American Wild River Management and Development Plan, approved October 3, 1979. The Forest Service (5,788 acres) and Bureau of Land Management currently share the responsibility for administering the North Fork American Wild River. The State of California retains management responsibility for its land (123 acres) within the designated Wild River boundary. Management of this land is coordinated through a Memorandum of Agreement.

The Heritage Conservation and Recreation Service (HCRS) (now a part of the National Park Service) Nationwide Rivers Inventory of 1981 included portions of the Middle Yuba River and South Yuba River. A USFS assessment of the eligibility of these rivers concluded that the inventoried portions of the Middle Yuba River and South Yuba River are 'outstandingly remarkable' and are eligible for inclusion in the Wild and Scenic River System.

In addition, based on public response to the Draft EIS and Plan and Forest staff review, the Middle Fork American River, North Fork of the Middle Fork American River, Laveuola Creek, and Canyon Creek were identified and evaluated for outstandingly remarkable values to determine if they were eligible for Wild, Scenic, or Recreational River status. No outstandingly remarkable values were identified for these four rivers, and they are not eligible for inclusion in the Wild and Scenic River System. The Truckee River will be studied for eligibility and suitability in the next three years in coordination with the Lake Tahoe Basin Management Unit. The upper Rubicon River from Hell Hole Reservoir and above will be studied for eligibility in coordination with the Eldorado National Forest. See Appendix E of the FEIS for more information.

WILDERNESS

The California Wilderness Act of 1984 designated about 18,705 acres of National Forest System land of the Granite Chief RARE II Area as wilderness and released the remaining roadless areas for nonwilderness uses in this round of planning.

CHAPTER 4 THE ENVIRONMENTAL CONSEQUENCES

This chapter discusses the environmental consequences (commonly referred to as impacts) of implementing the proposed action and alternatives, and forms the scientific and analytic basis for the comparisons of alternatives described in Chapter 2. The resource output levels by alternative are displayed, and the environmental consequences that result are described. The environmental consequences for all alternatives assume the implementation of Forestwide standards and guidelines. These standards and guidelines provide means to mitigate adverse impacts to ensure that the long-term productivity of the land is not impaired.

The following narrative compares the alternative approaches to resource management and the significant environmental consequences.

ECONOMIC

Output levels are discussed by resource category in the remainder of this section. Because it shows the most variation among alternatives, timber harvest explains most of the differences among alternatives in terms of income and employment. Ranking alternatives by timber harvest, income, or employment results in the same order: CMD is highest and NMK is lowest, the PRF alternative (Preferred) is fourth from the highest.

Income and Employment

All alternatives provide growth in income, employment, payments to counties, and returns to the U.S. Treasury. Alternatives NMK, UNE, and PRF would result in **less** growth, and the remaining alternatives (RPA and CMD) would result in greater growth than current management (CUR alternative).

Other economic effects of interest at the National and local levels are returns to the U.S. Treasury and payments to counties. The same relationship holds here **as** for income and employment. Timber harvest explains the first-decade variation among alternatives. Timber harvest accounts for over **95** percent of returns to the U.S. Treasury and payments to the counties.

Forest Budget

Alternative CMD would require the greatest budget for implementation, nearly **\$24.4** million per year for the first decade. The PRF alternative ranks **fifth**, with a projected budget of **\$21.2** million. Alternative CUR would have the lowest budget of **\$20.1** million. These budgets include appropriated funds and funds for brush disposal, reforestation, and timber stand improvement.

Economic Efficiency

The measure of economic efficiency used in evaluating alternatives is net public benefits. Net public benefits, conceptually, are the sum of the non-priced commodity values and the present net value.

The goal of planning is to develop a plan that obtains the highest net public benefit (36 Code of Federal Regulations **219.1(a)**). (Please refer to FEIS Appendix D for a detailed discussion of the concepts of net public benefits, present net value, and the **use** of economics in this analysis.) The PRF alternative has the highest net public benefits.

Present net value is the difference between the discounted value of all outputs to which monetary values or established prices are assigned and the total discounted costs of managing the planning area. Examples of non-priced benefits include scenic quality, wildlife habitat, and community stability. Values of some non-priced commodities are inferred from observations of indicators such as the number of participants, tolerance of congestion, and expense of participation.

All alternatives have a positive present net value (PNV) that range from **\$2,733** million for Alternative CMD to **\$2,324** million for Alternative NMK. The PRF alternative ranks fourth with a PNV of **\$2,438** million. Recreation (developed and **ski**) and timber are the largest contributors to PNV and potential first-decade income and employment in all alternatives. Short rotation timber management and protection of resources such as soil productivity, water quality, wildlife, and visual quality are the major tradeoffs between PNV and non-priced benefits among the alternatives. Changes in timber harvest levels account for most of the changes in PNV among alternatives.

Benefits associated with hydroelectric and mineral development are currently unquantified, but would be inversely related to the amount of land withdrawn for such noncompatible uses as Research Natural Areas, recreation developments, or cultural areas.

SOCIAL

The social benefits provided by each alternative cannot be measured or compared in terms of one being better, worse, higher or lower than another; however, different social groups are affected differently by each alternative. For example, the long-time resident group would generally benefit most from the CUR, RPA, and CMD alternatives and least from the NMK and UNE alternatives; the PRF alternative is relatively high in opportunities for this group. The alternative lifestyle resident group would benefit most from Alternatives NMK and UNE and least from the CUR, RPA, and CMD alternatives; the PRF alternative is low in opportunities for this group. Native Americans would benefit more from those alternatives with increased commodity production, because a majority are employed in the timber industry; however, these alternatives would also increase the risk of **loss** or damage to Native American cultural resource sites.

AIR QUALITY

The effects on air quality would be similar among alternatives. Short-term impacts of dust from road use and smoke from prescribed fire would occur. Air quality, however, would still meet State Air Resource Board standards. At this time, no significant long-term impacts are identified.

DIVERSITY

The alternatives that provide large amounts of regeneration harvest (PRF, CUR, RPA, and CMD) would yield large increases in grass and forbs or early successional vegetative stages. Alternatives NMK and UNE, with less acres of regeneration harvest, would produce **less** acres of early successional stages.

Alternative NMK would maintain the current inventory of late successional stages or older forests. Alternatives CUR and UNE would retain about 50 percent of the current inventory of late successional vegetative stages at the end of 50 years. Alternatives PRF, RPA, and CMD would retain about **40** percent of the inventory at the end of **50** years.

Overall, most alternatives would improve diversity as timber age classes become balanced. The distribution of diversity elements is guided by the Forestwide standards and guidelines.

FACILITIES

Alternatives CUR and CMD would develop the most access within the Forest during the next 30 years by reconstructing existing and constructing new arterial, collector, and local roads. Alternatives NMK and UNE would develop the least access. Alternatives RPA and PRF would access a moderate amount of area to provide for commodities and the recreational program.

Under all alternatives, miles of road open or closed to use would remain about the same. Seasonally, restricted road miles would vary by alternative. The location of roads open, closed, or seasonally restricted would vary by each alternative emphasis.

FIRE AND FUELS

Net resource losses from wildfire would increase over time under the CUR alternative, in which detection, prevention, and suppression would be limited by constrained fire management programs and budgets. Under all other alternatives, the net wildfire losses would remain relatively unchanged.

Decade by decade, the CUR alternative would have more acres burned annually by wildfire than any other alternative. In all other alternatives, the fire management program emphasis would shift from a mix of large and small engines to all small engines and hand crews, and budgets would increase by 20 percent.

FISH AND WILDLIFE

All alternatives would focus management programs on fish and wildlife indicator species and groups. Each would fulfill Forest Service responsibility to protect and enhance habitat for threatened and endangered species. Alternatives PRF, CUR, RPA, and CMD offer the greatest opportunities to increase populations of deer, bear, blue grouse, mountain quail, gray squirrel, and other associated species needing early successional stages. Alternatives NMK and UNE would provide the largest populations of spotted owls, pileated woodpeckers, and other species associated with mature forest habitats. Fish habitat is not expected to vary significantly among alternatives. Fish numbers would vary in relation to stocking and harvest levels.

FOREST PESTS

Because of the differing intensities of integrated pest management implemented under the different alternatives, Alternatives CUR, RPA, and CMD should have the lowest level of pest-related damage. Moderate damage levels would likely occur under the PRF alternative, and the greatest potential damage would most likely occur under the NMK and UNE alternatives, which provide the fewest opportunities to manage vegetation and implement pest-prevention practices.

GEOLOGY

Risk for geologic instability was estimated by the amount of timber harvested on slopes greater than 30 percent, and by the amount of protection given the unstable inner gorges within the streamside zone. Using these criteria, Alternatives NMK, PRF, and UNE would provide the lowest geologic instability risk. Alternative RPA would cause the **most** instability risk. Alternatives CUR and CMD would have a moderate risk. When the standards and guidelines are implemented, the risk is minimal for all alternatives.

HISTORICAL AND CULTURAL RESOURCES

All alternatives would meet minimum legal requirements. Interpretation and enhancement of cultural resources are emphasized in Alternatives PRF, NMK, and UNE. All alternatives require additional non-project related inventories to meet the RPA goal of a complete Forest inventory by the year 1995.

While cultural resources are afforded protection by law, the likelihood of disturbance by management activities by increasing access or by increasing visitor **use** of the Forest would vary among the alternatives. The RPA and CMD alternatives, which emphasize timber management and roading, would create an overall high threat to cultural resources. The PRF alternative would create a moderate threat to cultural resources. While recreation **use** would increase under the NMK and UNE alternatives, because these alternatives do not emphasize timber management activities, the overall threat to cultural resources would be low.

HYDROELECTRIC PROJECTS

Future hydroelectric projects would be prohibited in the Granite Chief Wilderness, the North Fork American Wild River, and Special Interest and Research Natural Areas. On all other lands, the Forest Service would respond to proposals on a project-by-project basis.

LANDS

Adjustment

The acreage in the land adjustment program would not vary much by alternative. The emphasis of the land adjustment program would be dictated generally by the objectives of the alternative.

Property boundaries need to be established because of the timber sale program. About two-thirds of the land line location would follow the scheduled timber outputs for the first two decades. Therefore, alternatives stressing timber production (Alternatives CUR, RPA, and CMD) would have the greatest number of land line miles to post and mark per year in the first decade. All alternatives would complete the land line program by 2020.

Special Uses

Special-use applications would not vary much among alternatives. Alternatives with more proposed semi-primitive nonmotorized recreation areas, Research Natural Areas, and Special Interest Areas would tend to discourage applications in those particular areas, but the overall number of special-use applications would not change significantly.

MINERALS

The NMK alternative proposes the greatest number of acres of high mineral potential for withdrawal from mineral entry and leasing. Overall, the total acres of mineral withdrawal would correspond to the acres recommended for scenic highways, concentrated public **use**, Research Natural Areas, and Special Interest Areas. The Placer County Big Tree Grove Special Interest Area is already withdrawn. Alternatives NMK, RPA, UNE, CMD, PRF, and CUR (in descending order) would have the largest amount recommended for withdrawal. Alternatives with more acres withdrawn would reduce opportunities to explore and develop the mineral resource.

RANGE

The RPA alternative has the greatest AUM production, while the CMD alternative would provide slightly fewer AUMs. The PRF and UNE alternatives would provide for a small increase over the existing level of 20,000 AUM's. The NMK alternative would immediately reduce the current level of grazing to 9,000 AUM's and continue to reduce grazing until it levels out at 1,000 AUMs by the fifth decade.

About 95 percent of the suitable range would be in satisfactory ecological condition by the year 2030 in Alternatives PRF, RPA, CMD, and UNE. The trend of those acres in satisfactory condition would be upward. Alternative CUR would have 85 percent of the suitable range in satisfactory ecological condition by the year 2030 with no change in trend. Since only 1,000 AUMs remain in the NMK alternative by the year 2030, the vegetation would develop mostly through natural succession. The ecological range condition cannot be evaluated for Alternative NMK.

RECREATION

Developed Recreation

All alternatives would meet projected demand (measured by RVDs) for developed recreation through the first decade. Alternatives PRF, CMD, NMK, and UNE would meet demand over the entire planning period through expansion of existing sites and construction of new ones. The RPA alternative would meet demand for three decades. The CUR alternative would meet demand only for the first decade and would not construct any new developed recreation facilities, by the fifth decade, only 65 percent of developed recreation demand would be met.

Ski Areas

Alternatives PRF, UNE, and CUR would both expand existing and develop new downhill ski areas to meet projected demand over 5 decades. These alternatives would provide the most opportunity for downhill ski recreation. Alternatives RPA and CMD would meet demand through the fourth decade and meet 77 and 88 percent of demand, respectively, in the fifth decade. Alternative NMK would *not* develop new ski areas, and only 31 percent of ski demand would be met in the fifth decade.

Dispersed Recreation

All alternatives would meet overall dispersed recreation demand because of the Forest's large capacity for dispersed recreation activities. Opportunities for some types of dispersed recreation may be limited in some alternatives, however, in all alternatives, except NMK, semi-primitive nonmotorized recreation opportunities would diminish because road access would increase throughout much of the Forest and because vegetation management activities would expand into areas currently natural-appearing,

Similarly, in all alternatives, opportunities for motorized recreation that require primitive roads and near-natural settings would be reduced from the current situation. In all alternatives, opportunities would increase for activities that benefit from improved road access (such as hunting, fishing, driving for pleasure, and auto camping) and that are not affected by the appearance of human-caused landscape modifications.

RESEARCH NATURAL AREAS

Candidate areas for RNA designation are listed by alternative.

	PRF	CUR	RPA	CMD	NMK	UNE
Babbitt Peak (1,061 acres)	X	X	X	X	X	X
Sugar Pine Point (625 acres)	X			X	X	X
Basin Peak (60 acres)					X	
Lyon Peak/Needle Lake (700 acres)	X				X	X
Mt Lola (498 acres)					X	

The PRF, NMK, and UNE alternatives would provide representation of the Washoe pine, mountain hemlock, and mixed conifer types in the RNA system. Alternative CMD includes Washoe pine and muted conifer, while the CUR and RPA alternatives would provide representation of the Washoe pine

RIPARIAN AREAS

Alternative RPA would result in the greatest potential to damage streamside management zones (SMZ's) and the aquatic ecosystem: potential impacts are very high compared to 1982 levels. Alternative CMD would result in high to very high potential impacts compared to 1982 levels. Alternative CUR would result in high potential impacts compared to 1982 levels. Alternative UNE would result in low potential to damage SMZ's and the aquatic ecosystem: this alternative slightly changes 1982 conditions. Alternatives PRF and NMK would result in moderate potential to damage SMZ's and the aquatic ecosystem: their potential impacts are somewhat greater than 1982 conditions.

SENSITIVE PLANTS

To maintain the present populations of sensitive plant species, the TNF developed sensitive plant program standards and guidelines. They ensure that sensitive plant species are considered in all Forest projects. Sites not identified (obscured by heavy vegetation, poor flowering year, etc.) during project inventory, however, could be adversely affected.

Ground-disturbing activities, such as road building and timber harvesting, provide a good measure to judge the effects of various alternatives. The risk to sensitive plants and their habitats was determined by the number of acres proposed for ground-disturbing activities. High risk represents an increased chance of disturbance, and low risk represents a decreased chance of disturbance.

Alternatives PRF, CUR, RPA, CMD, and UNE would have the greatest potential to disturb or destroy sensitive plant species and their habitats. Alternative NMK would have the lowest risk of disturbance.

SPECIAL INTEREST AREAS

Placer County Big Tree Grove Botanical Area (346 acres) is proposed as a Special Interest Area (SIA) under all alternatives. Alternative NMK (17 areas, 36,333 acres) would provide the greatest number of SIA's and therefore would provide the most protection of special values and the most opportunities for public appreciation. Alternatives PRF, CMD, and UNE (7 areas, 886 acres) would provide moderate protection of special values and moderate opportunities for public appreciation. Alternatives CUR and RPA (1 area, 346 acres) provide only the Placer County Big Tree Grove Botanical Area and would provide the least protection of special values and only limited opportunities for public appreciation.

SOILS

Alternatives RPA, CMD, and CUR would result in the greatest potential to reduce soil productivity because of the greater emphasis on regeneration harvest and, to a lesser extent, the level of livestock grazing. Alternative NMK would have the lowest potential to reduce soil productivity, followed by UNE and PRF, basically due to the size of the timber program, associated road construction, and the amount of logging on steep ground. All alternatives would maintain soil productivity and would be within watershed thresholds. The risk of not maintaining soil productivity and water quality would increase when the timber program increases.

TIMBER

Alternatives CUR, RPA, and CMD are similar in overall environmental consequences. These three alternatives would have the largest suitable landbases, the largest percent of intensively managed forest land in the timber landbase, and the highest productivity index. In other words, these alternatives combine large, high quality timber landbases with high intensity management. Timber would be generally emphasized on capable, prime lands.

Alternatives NMK and UNE would be at the opposite end of the range of landbase and management intensity. Alternative NMK would have the smallest timber suitable landbase and the lowest productivity level and essentially would operate on the existing roaded landbase. Alternative UNE would have the lowest amount of land allocated to short rotation even-age management, but a total timber suitable landbase similar to the PRF alternative. Alternative NMK would have the lowest productivity index, with UNE the second lowest.

The PRF alternative lies between the CUR/RPA/CMD alternative group and the NMK/UNE alternative group in terms of suitable landbase, amount of land in the highest yield category, and overall timber productivity.

Alternatives that have the highest allowable sale quantity also have the highest potential wood energy available. This potential wood energy would also be available for lumber, wood chips, fuelwood, and other uses.

VISUAL RESOURCES

The NMK alternative would provide the highest visual quality of all the alternatives, with the UNE alternative providing similar emphasis. The NMK alternative maintains the most areas of any alternative as natural appearing while the UNE alternative, with its uneven-age approach to timber management, provides almost the same level of protection to existing visual quality. The PRF alternative would significantly improve visual quality compared to the CUR alternative because visually important middleground areas, including the middlegrounds as viewed from State scenic highways and major scenic vistas, would remain mostly natural appearing. The CUR, RPA, and CMD alternatives would protect the visual quality in the foreground along the State scenic highways, while most middleground views would be dominated by obvious landscape alterations.

WATER

Although all alternatives are expected to be within watershed thresholds, none of them are free of the potential for effects. Alternative RPA would result in the highest potential to incur cumulative watershed effects with long-term equivalent road acre (ERA) values 60 percent greater than current levels. Alternative NMK would result in the lowest potential to incur cumulative watershed effects with ERA values 14 percent greater than current levels. Overall, Alternatives RPA, CMD, and CUR would result in moderate potential for cumulative watershed effects in small watersheds. Alternatives NMK, UNE, and PRF would result in low potential for cumulative watershed effects in small watersheds. Another important factor in determining effects is the amount of private land in the watershed and the activities on that private land. The determination of cumulative watershed effects at the project level will consider activities on both public and private lands.

Alternatives RPA and NMK would restore about 2,500 acres of watershed (the maximum treatable acreage) over the next fifty years. Alternatives PRF and UNE would treat about 1,900 acres, while Alternatives CUR

and CMD would treat about 500 acres. Alternatives RPA and NMK would result in the largest acreage of soil and water improvement and would provide the greatest emphasis in improving water quality and degraded riparian areas. Alternatives CUR and CMD would result in the fewest acres of planned treatment due to historic management emphasis on other resources, such as timber and recreation, this would result in the lowest improvement in water quality and currently degraded riparian areas. Alternatives PRF and UNE would treat the highest priority areas that are contributing to degradation of riparian areas and water quality; a large improvement in water quality and currently degraded riparian areas would occur.

Turbidity and sedimentation would occur under all alternatives, but would be slightly lower than the current level in Alternatives PRF, NMK, and UNE, and slightly higher in Alternatives CUR, RPA, and CMD. The turbidity and sediment levels produced would be local, short-term, and would not harm beneficial uses.

WILDERNESS

The Granite Chief Wilderness (18,705 acres) would be managed for its wilderness values under all alternatives.

WILD AND SCENIC RIVERS

The North Fork American River, as designated by Congress, will be managed as a wild river. The Plan does conclude that the Middle Yuba River and South Yuba River are outstandingly remarkable and eligible for inclusion in the Wild and Scenic River system, and provides for study of the Truckee River and upper Rubicon River. Under all alternatives no activities would occur within the wild river corridor unless the activities are consistent with the North Fork American River Wild River Management Plan. Outside the wild river corridor the PRF and UNE alternatives could slightly affect the recreation experience. The CUR alternative would have some effects and recreation experience would reduce moderately. The RPA alternative could moderately reduce the recreation experience. The CMD alternative has the greatest likelihood of creating vegetation changes that would be visible from the wild river and recreation experience levels would be reduced the most. The NMK alternative provides the greatest emphasis on dispersed recreation while maintaining a near-natural forest environment. Therefore, this alternative would provide the highest quality recreation experience levels for the wild river.

CHAPTER 5 LIST OF PREPARERS

The Interdisciplinary Team of Forest Service specialists coordinated and conducted the planning activities for development of the Forest Plan. They integrated all resource disciplines according to multiple-use principles. These people were selected because of their expertise and ability to respond to the major issues being analyzed during the planning process. This team used other specialists inside and outside the Forest Service to assist as needed.

The Forest Management Team guided, reviewed, modified as appropriate, and recommended for approval the work of the Interdisciplinary Team.

CHAPTER 6 LIST OF AGENCIES, ORGANIZATIONS, AND PERSONS TO WHOM COPIES OF THE STATEMENT WERE SENT

The FEIS and Forest Plan have been sent, or copies made available, to the various agencies and individuals who commented on the Draft EIS and Draft Plan. For additional information, contact the Supervisor's Office, Tahoe National Forest, Highway 49 and Coyote Street, Nevada City, California 95959, or call (916) 265-4531.

AMENDMENTS AND REVISIONS

The Plan will be revised at least every 15 years under requirements of the National Forest Management Act. The Plan may be revised sooner whenever the Forest Supervisor determines that conditions or demands in the area covered by the Plan have changed significantly, or when changes in national policies, goals, or objectives **would** have a significant effect on programs of the TNF.

The Regional Forester will approve any significant amendments to this Plan. The determination of significance or nonsignificance will be documented in a decision notice. Determination of significance or nonsignificance are appealable under 36 CFR 217.

Forest Supervisor Richard L. P. Bigelow at Banner Mountain Lookout, 1912

CHAPTER 1

PURPOSE AND NEED

A. Introduction	1.1
B. Purpose and Nature of the Action	1.1
C. Planning Process	1.2
D. Vicinity of the Forest	1.4
E. Scope of Issues to be Addressed	1.4

CHAPTER 1 PURPOSE AND NEED

A. INTRODUCTION

Described in Chapter 1 of this Final Environmental Impact Statement (FEIS) are (B) the purpose and nature of the planning action, (C) the planning process, (D) the vicinity of the Tahoe National Forest (TNF), and (E) the scope of the issues addressed. Described in Chapter 2 are the alternative development process, alternatives considered but eliminated from detailed study, and alternatives considered in detail. Described in Chapter 3 is the environment in which the proposed action and alternatives will take place. Displayed in Chapter 4 are the environmental consequences of implementing the proposed action (preferred alternative) and other alternatives. Listed in Chapter 5 are the names, together with their qualifications, of the persons who are primarily responsible for preparing the FEIS and significant background papers. Listed in Chapter 6 are the agencies, organizations, and persons to whom copies of the FEIS are sent.

B. PURPOSE AND NATURE OF THE ACTION

Historical and Legislative Framework.

In 1974 Congress acted upon the need for coordinated and long-range planning of the uses and resources provided by the National Forests. Two pieces of legislation were passed: the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) and the National Forest Management Act of 1976 (NFMA), amending RPA. These require that comprehensive, long-range Forest Plans replace the separate and often uncoordinated resource management plans.

Additional legislation required Forests, before developing a complete Forest Plan, to investigate and make public:

1. Alternative approaches which could be used in developing the Plan
2. The environment to be affected by the Plan
3. Anticipated environmental consequences of the alternatives.

This Environmental Impact Statement addresses these major subjects as required by the National Environmental Policy Act (NEPA) and the Council on Environmental Quality (CEQ) regulations.

The TNF Plan is the preferred alternative chosen from the alternatives described in this FEIS. Published separately from this FEIS as a companion document, the Forest Plan accomplishes the following:

- o Guides management of the Forest for the next 10 to 15 years.
- o Allocates land to the combination of management activities for which it is most suited.
- o Includes 50-year long-range objectives.
- o Provides for multiple use and sustained yield of goods and services to maximize long-term net public benefits in a cost-efficient and environmentally sound manner (see Appendix D).
- o Responds to major issues, management concerns, and resource opportunities.

The Forest Plan will be revised at **least** every 15 years or whenever conditions or demands significantly change. It will be reviewed every 5 years to determine the need for more frequent revision.

All existing resource plans were examined by the Forest's interdisciplinary planning team during this planning process. The plans identified in Appendix A of the Plan will be incorporated, superseded, or will be developed as indicated.

C. PLANNING PROCESS

Forest Plans form only one part of the Forest Service planning framework. Based on information from the Regions, the National RPA Recommended Program establishes direction and assigns targets to the Regions for producing goods and services. Each Region in turn provides direction and allocates its share of the National production levels to its Forests; each Forest Plan validates the levels or provides a basis for changing the production levels assigned by the Region.

At the local level, activities and projects carry out the direction developed in the Forest Plan. These local projects can use all the data, evaluations, and other information in the Plan and the EIS as a basis for local project environmental analyses. This process of 'tiering to' the broader documents and incorporating the Plan and EIS by reference permits concentration on issues specific to subsequent smaller projects. Similarly, the Forest Plan is tiered to the Pacific Southwest Regional Guide (previously called the Regional Plan), which is tiered to the National RPA Program. (Figure 1.1 shows the planning process.)

The Forest planning process, as specified in the NFMA regulations (36 CFR 219), is an interdisciplinary approach, which, with public participation, fully considers economic, environmental, and social impacts. The process includes the following steps:

1. Identification of issues, concerns, and opportunities (ICO's).
2. Development of planning criteria
3. Data inventory and information collection.
4. Analysis of the management situation (AMS)
5. Formulation of alternatives.
6. Estimating effects of alternatives.
7. Evaluation of alternatives (and identification of a preferred alternative).
8. Selection of the preferred alternative (or 'proposed action').
9. Plan implementation
10. Monitoring and evaluation.

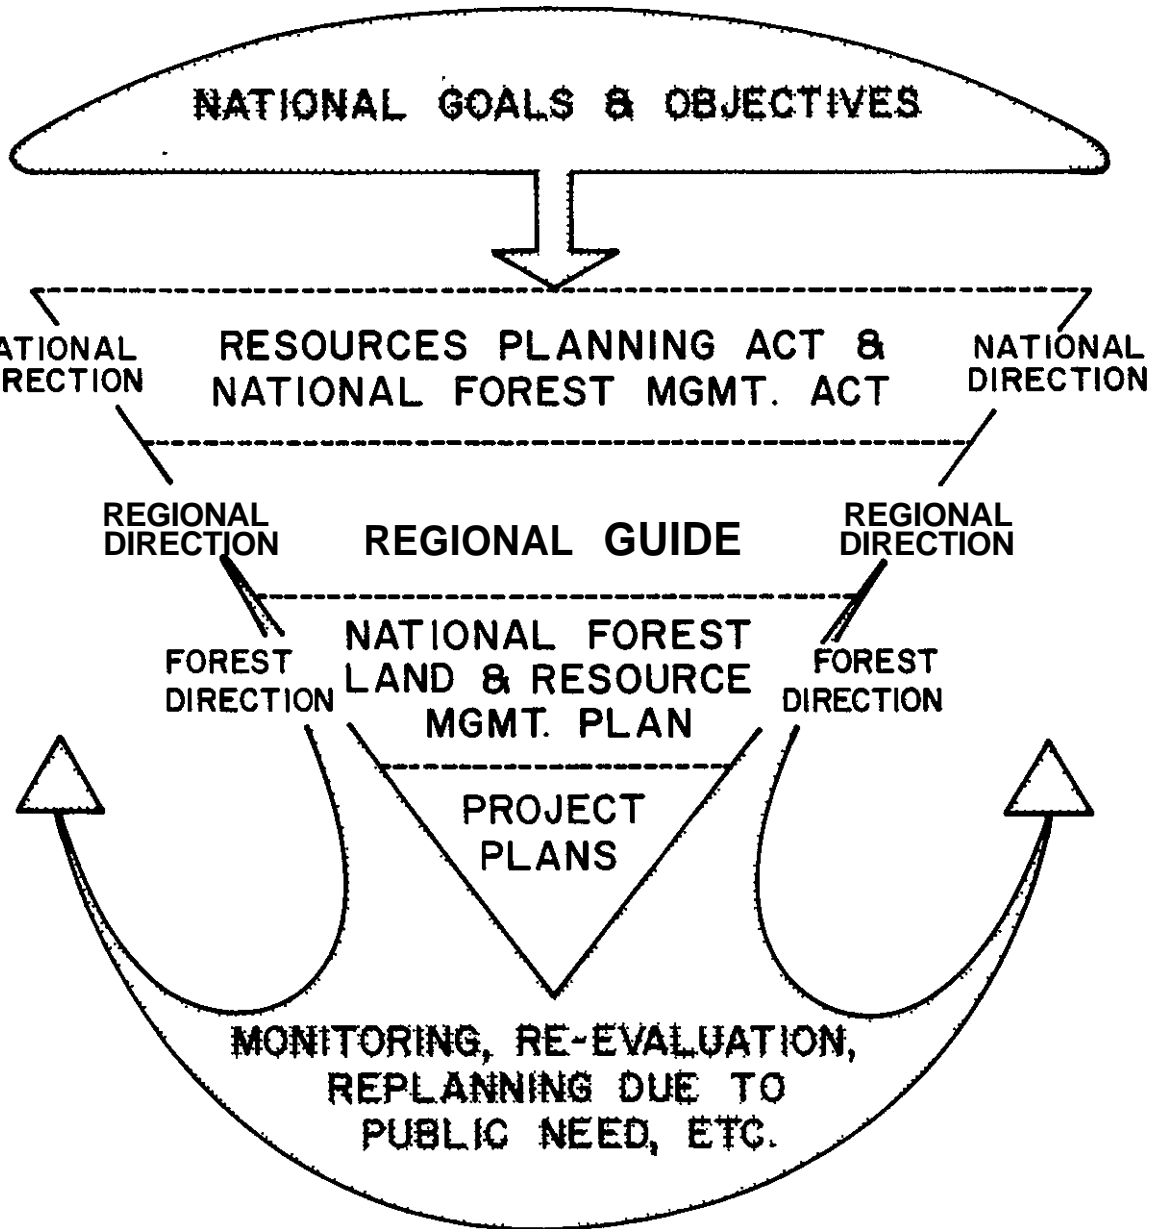

This FEIS presents the results of planning actions 1 through 7 and identifies the preferred alternative (proposed action) that forms the basis for the proposed Forest Plan. Public comments on the draft Plan and the DEIS were used to develop the Final Environmental Impact Statement and selected Forest Plan. The final Forest Plan will be selected by the Regional Forester and documented in a Record of Decision that will be provided to the public.

All of the documents and planning records that chronicle the Forest planning process are available for inspection at the Forest Supervisor's Office, Tahoe National Forest, Highway 49 and Coyote Street, Nevada City, CA 95959, during regular business hours. These planning records contain the detailed information and processes in developing the Forest Plan as required in 36 CFR 219.12. They are incorporated by reference at appropriate points in the text of this FEIS and the Forest Plan.

Figure 1.1

TAHOE N.F.

HIERARCHY OF LAND MGMT. PLANNING IN THE NATIONAL FOREST SYSTEM

4/82

A glossary is located in the Plan to aid readers with abbreviations and unfamiliar terms

D. VICINITY OF THE FOREST

The Tahoe National Forest is in the north-central Sierra Nevada (Figure 1 2) Portions of Nevada, Placer, Plumas, Sierra, and Yuba Counties are within the Forest boundaries. The TNF is bounded on the north by the Plumas National Forest, on the east by the Toiyabe National Forest and the Lake Tahoe Basin Management Unit, and on the south by the Eldorado National Forest The TNF boundary encompasses 1,175,533 acres Of this total, 381,161 acres are privately owned.

The TNF is within one hour's drive from Sacramento, a half-hour's drive from Reno, and a three-hour's drive from most San Francisco Bay Area cities Several communities are within the Forest boundaries

Analyzed in the FEIS and Forest Plan are 794,374 acres of the TNF. Excluded from this analysis is that portion of the TNF that is in the Lake Tahoe Basin Management Unit (28,833 acres). Land within the Lake Tahoe Basin was declared a separate management unit by Presidential Proclamation in 1973

E. SCOPE OF ISSUES TO BE ADDRESSED

The Tahoe National Forest Land and Resource Management Plan is formulated to address public issues and management concerns related to the Forest These issues and concerns (referred to as issues in this EIS) and the associated questions were identified by the Interdisciplinary Team and indicate the scope and nature of the analysis needed for the EIS (40 CFR 1501.7) The issues represent important reasons for considering changes in the current management direction and are instrumental in formulating alternatives and understanding the consequences of implementing any one of the alternatives

The Pacific Southwest Regional Forester notified the public and other agencies of intentions to prepare a Land and Resource Management Plan for the TNF in the Federal Register, August 18, 1979. In November 1979, and again in November 1983, the Forest Supervisor published notices in local newspapers and in the Tahoe Planner newsletter that meetings would be held to accept public comment. Eight meetings to receive public comment were held in the TNF area of influence (refer to TNF planning records, specifically, 192216a(2)).

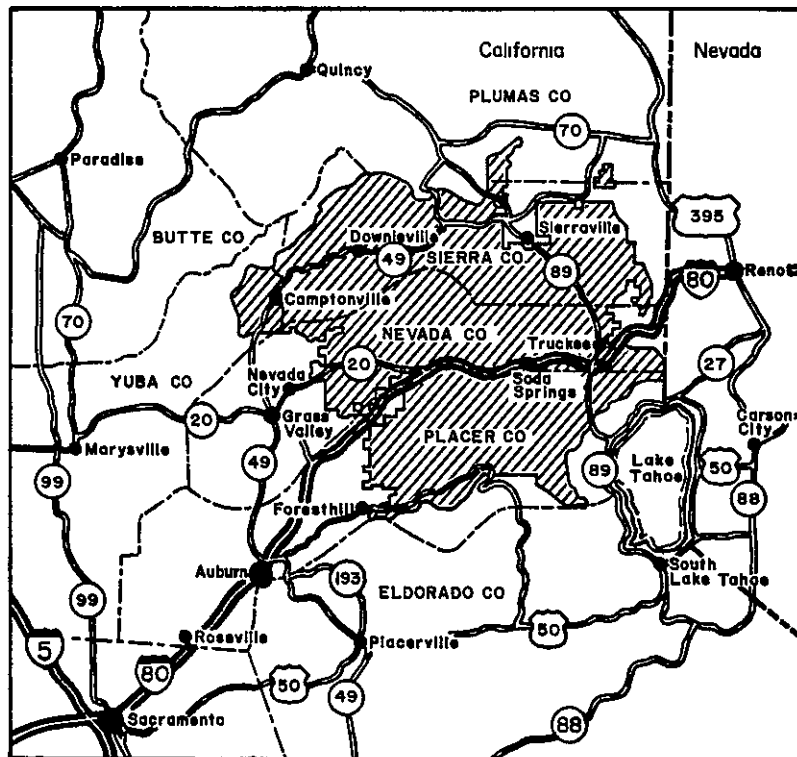

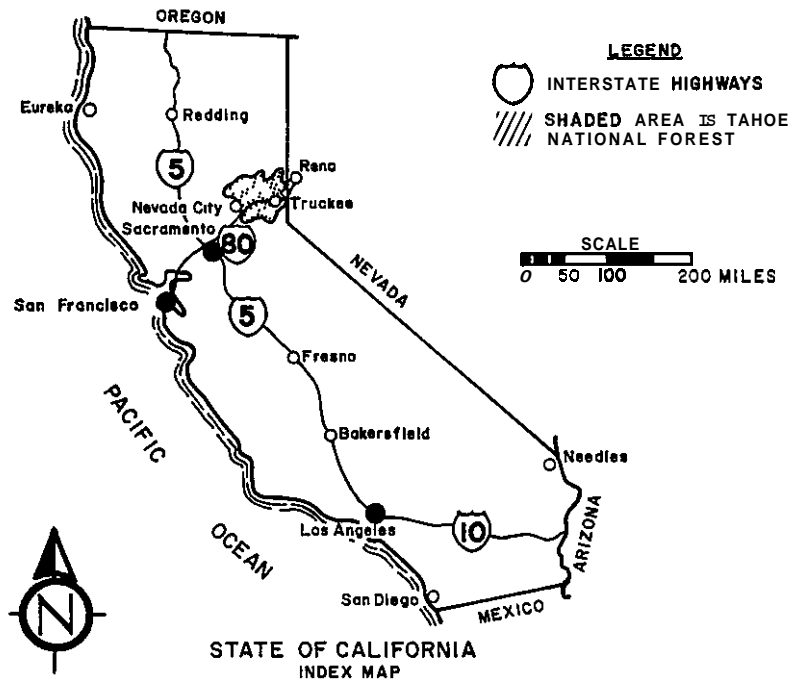

The meeting held in 1983 was to receive comments on seven additional roadless areas added to the planning process as the result of the October 30, 1982, revised NFMA regulations.

The Interdisciplinary Team identified and evaluated public issues, management concerns, and resource use and development opportunities, including those identified through public participation activities and coordination with other Federal agencies and State and local governments throughout the planning process Nine major issues were identified. These issues were approved by the Regional Forester and addressed in the planning process. Enacting the California Wilderness Act of 1984 resolved in terms of wilderness designation the inventoried roadless area issue (Issue #4) for this round of Forest planning.

In addition, the Pacific Southwest Regional Guide deferred 11 Regional issues, concerns, and opportunities to be answered during the Forest planning process. These have been incorporated into the list of Forest issues. These issues were addressed in at least one alternative in the DEIS. More detailed information on the scoping process and each of the issues can be found in Appendix A

Figure 1.2

Vicinity Map

Following release of the DEIS and Draft Forest Plan and a five-month comment period, a list of **12** major issues was developed. This list was the result of analysis of the comments contained in approximately **13,000** letters of input and oral testimony from two formal public hearings on the DEIS and Draft Plan. Some of these **12** issues are the same as those contained in the initial issue list, others are a variation of those initial issues, and others are new. The Forest Service response to the public comment can be found in Appendix A.

Following are:

A listing of initial issues.

A listing of the **12** major issues resulting from the Draft document review

A listing and analysis of the relationship between the initial and the new major issues.

Initial Issues

#1. Ownership Patterns and Land Uses

In what ways and to what **extent** can the Forest Service lessen or resolve conflicts in use between National Forest, private, and other public ownerships within the Tahoe National Forest boundary? Some of these conflicts result from the conflicting desires and needs of different owners and the public in their resource management objectives.

#2. Minerals

What emphasis by the Forest Service should be placed on the surface management of mineralized areas within the Tahoe National Forest? This includes both locatable and leasable mineral resources.

#3. Energy

How should management of the Tahoe National Forest contribute to conserving energy and meeting future energy needs?

#4. Inventoried Roadless Areas

How should all inventoried roadless areas be managed on the Tahoe National Forest?

This issue was resolved in terms of wilderness designation by enactment of the California Wilderness Act of **1984**, which designated the **18,705** acre Granite Chief Wilderness and released the **10** remaining roadless areas to other multiple uses for this round of planning (See Appendix A)

#5. Facilities

How can the Tahoe National Forest management, operation, and development of its facilities (roads, trails, administrative facilities) be optimized with respect to user interests, resource management and human resource needs, private landowner concerns, and economic efficiency?

#6. Forage, Wood, and Soils

How much area of the Tahoe National Forest should be managed for renewable commodity outputs (forage and wood)? How intensively should vegetation be managed to optimize commodity outputs? What Forest Service emphasis should be placed on the soil resource to maintain or enhance productivity?

#7. Water

How should the management of Tahoe National Forest resources respond to the demands and allocations for water quality, quantity, storage, and transmission?

#8. Recreation

To what extent should Tahoe National Forest land be allocated for recreation and scenic purposes? What should be the mix of recreation uses on Tahoe National Forest land?

#9. **Fish** and Wildlife Habitat

What Forest Service emphasis should be placed on wildlife habitat to maintain or enhance productivity, quality, and diversity?

Major Issues resulting from the **Draft** document review:

~~#1.~~ Spotted Owls

How many spotted owl habitat areas (SOHA's) should be established on the Tahoe National Forest and how should they be managed?

#2. Viable **Populations/Diversity**

How shall the Tahoe National Forest comply with National and Regional direction to maintain diversity and viable populations of animals?

#3. Budget

What effect will reduced budgets have on the implementation of the proposed Forest Plan?

#4. Roadless Areas

How should existing roadless areas be managed?

#5. Herbicide Use

Should herbicides be used on the Tahoe National Forest?

#6. Mt. Lola

How should the Lola Management Area be managed?

#7. **Urban/Rural** Wildland Interface

How should the Forest Service manage National Forest System lands that are adjacent to or affected by private lands, particularly those private lands developed or developing within this planning period for recreation, rural, residential, urban, or commercial uses.

#8. Soil **Erosion/Long-Term** Soil Productivity

With what practices can intensive timber management be conducted on Forest lands while maintaining soil productivity?

#9. **Riparian/Streamside** Management Zones

What level of management is acceptable in riparian areas/streamside management zones (SMZ's) that still protects riparian-dependent resources?

#10. Visual Quality

How should the visual resource be managed on the Tahoe National Forest?

#11. Clearcutting

What should be the role of clearcutting in meeting the vegetative management objectives of the Tahoe National Forest?

#12. Timber Supply

What should be the amount of timber supplied by the Tahoe National Forest?

Relationship between the initial and new major **Issues**:

This will be shown by comparing the new issues to the initial issues

#1 Spotted Owls - a new issue

#2 Viable Populations/Diversity - within parameters of **#9**. Fish and Wildlife Habitat

#3 Budget - a new issue.

#4. Roadless Areas - within parameters of **#4**. Inventoried Roadless Areas and **#8** Recreation.

#5. Herbicide Use - within parameters of **#6**. Forage, Wood, and Soils.

#6. Mt Lola - a new issue.

#7 Urban/Rural Wildland Interface- within parameters of **#1** Ownership Patterns

#8 Soil Erosion/Long-Term Soil Productivity - within parameters of **#6**. Forage, Wood, and Soils.

#9. Riparian/Streamside Management Zones - within parameters of **#7**. Water.

#10 Visual Quality -within parameters of **#8**. Recreation.

#11. Clearcutting- within parameters of **#6**. Forage, Wood, and Soils.

#12 Timber Supply - within parameters of **#6**. Forage, Wood, and Soils.

The role of Issues In the planning process.

It is important to note that these issues which you have just reviewed have significantly shaped the following sections of this document. That is because planning is an issue-driven process.

The Forest issues were identified when the planning effort was in its infancy, and again from public response to the Draft Plan and DEIS. These issues were used to focus the entire planning effort. First, they were used to identify what was important to address during planning. In the second step of the planning process, this knowledge was utilized to define what information would be gathered and analyzed. The highlights of the information so identified are presented in the Affected Environment (Chapter 3, FEIS)

The issues influenced the formulation of alternative plans, which are presented in Chapter 2, FEIS, (any of which could be selected for implementation). Finally, the issues were used during the comparison and evaluation of the various alternatives in Chapter 2, FEIS, (Alternatives Including the Proposed Action) and Chapter 4, FEIS, (Environmental Consequences)

CHAPTER 2 ALTERNATIVES INCLUDING THE PROPOSED ACTION

A. INTRODUCTION

This chapter contains six sections, each dealing with a different aspect of alternative development. Section B presents the process used to develop alternatives. Section C contains a discussion of benchmarks and compares them in a display. Alternatives considered, but eliminated from detailed study, are summarized in Section D. Section E presents management direction and requirements that are common to all alternatives, and those alternatives that were considered in detail. Section F contains a detailed comparison of alternatives, displayed by outputs, costs, timing, and resolution of issues.

B. ALTERNATIVE DEVELOPMENT PROCESS

This section defines alternatives, describes the process used to develop alternatives (including benchmark analyses), and discusses limitations to the range of alternatives.

DEFINITION OF AN ALTERNATIVE

In the Forest planning process, an alternative is a unique combination of resource uses and a mix of management prescriptions that achieve a desired management direction, output, goal, or emphasis. These uses and prescriptions are formulated in many ways to produce a reasonable range of alternatives for evaluation.

The following laws, regulations, and directions are relevant to the concept of alternatives and how they are formulated:

1. The Forest and Rangeland Renewable Resources Planning Act (RPA), as amended by the National Forest Management Act (NFMA), which requires the preparation of a National Forest Land and Resource Management Plan.
2. The procedures (36 CFR 219) for implementing RPA, as amended.
3. The National Environmental Policy Act (NEPA), which requires disclosing the consequences of implementing the proposed action and alternatives.
4. The Council on Environmental Quality NEPA regulations (40 CFR 1500), which provide procedures for implementing NEPA.
5. The Pacific Southwest Regional Guide, which provides guidance and direction for National and Regional issues.
6. The Tahoe National Forest Forestwide standards and guidelines, which are specific management requirements designed to meet resource management goals, objectives, and development techniques that apply to all alternatives.

The requirements of the NEPA and NFMA establish guidelines for the development of alternatives. NEPA regulations (40 CFR 1502.14) require rigorous exploration and objective evaluation of all reasonable alternatives to the proposed plan, including a "no action" (no change) alternative, as well as alternatives not within the jurisdiction of the agency. The NEPA regulations also require identification and discussion of alternatives eliminated from detailed study.

NFMA regulations (36 CFR 219.12(f)) establish the following criteria for guiding the development of alternatives:

- o Each alternative will be capable of being achieved
- o A *no action. alternative (continuation of present management into the future) will be formulated that represents the most likely condition expected to exist in the future if current management direction were to continue unchanged
- o One or more alternatives will meet the RPA program specified in the Regional Guide.
- o Each alternative will provide for the orderly elimination of backlogs of needed treatment to restore renewable resources necessary to achieve the multiple use objectives of that alternative
- o Each identified major public issue and management concern will be addressed in one or more alternatives.
- o Each alternative will represent to the extent practicable the most cost-efficient combination of the management practices examined that can meet the objectives established in the alternative.

The NFMA regulations also require that each alternative state the following:

- o Purposes of the management direction proposed.
- o Resource management standards and guidelines
- o The goods and services to be produced, and the timing and flow of these resource outputs.
- o Conditions and uses resulting from the long-term application of the alternative

Under the NFMA regulations, the development of alternatives is based on management prescriptions, each of which is a strategy for managing the lands and resources of a given area. Each management prescription responds to issues or concerns and is composed of compatible practices that would attain desired resource management objectives on a specific management area.

The alternatives considered represent different combinations of management prescriptions in different locations to provide varying levels of outputs, goods, and services. The total possible set of management prescriptions is the same for all alternatives. Each alternative, however, has a particular combination of management prescriptions and area allocations that, in aggregate, meet the desired goals and objectives of the alternative. The mix of acres related to each prescription is different by alternative (see Table 2.11). A full description of each management prescription is found in the Management Prescriptions and Management Areas discussion of this chapter.

DESCRIPTION OF THE PROCESS USED TO DEVELOP ALTERNATIVES

The formulation of alternatives (Planning Action 5) is the culmination of Planning Actions 1 through 4 of the NFMA planning process (refer to Chapter 1 for all 10 planning actions). The following summarizes how Planning Actions 1 through 7 were accomplished on the TNF:

1. Major public issues were identified through public involvement. Forest Service management concerns were also identified and combined with the public issues to form an integrated list of issues and concerns.
2. Based on an analysis of the issues from the public scoping meetings, Forest Service management concerns, and resource development and use opportunities, the Interdisciplinary (ID) and Management Teams identified the nine major issues to be addressed in the Forest Plan. The issues were then applied to each subsequent step described below. (Appendix A contains a more detailed discussion of the scoping and screening process.)

3. The public issues, management concerns, and opportunities (ICO's) were consolidated into a set of planning questions (issues) to be answered. These issues and their subsets, called components and indicators, were used to develop planning criteria
4. Planning criteria were developed by the ID Team, recommended by the Management Team, and approved by the Regional Forester on May 12, 1981. The document titled **Planning Criteria** is available for review (planning records 1922.16a.7b). These criteria detail what information needed to be collected, methods of collection, accuracies, responsibilities, time schedules, and how the information would be presented.
5. Based on the planning criteria, the ID Team collected Forest resource data. These data are documented in the TNF planning records (1922.16a.7c), and are important in determining the TNFs capabilities for producing goods and services. For Forest planning purposes, these data were collected for specific land units called capability areas. Capability areas are units of land that are relatively homogeneous in their physical attributes, resource production potential, and potential environmental effects. Over 26,000 capability areas were identified on the TNF.
6. The capability areas were then aggregated into analysis areas according to common characteristics (physical, biological, and political). These analysis areas were used to analyze the resources of the TNF for *capability*, *availability*, and *suitability* for resource management. The *physical* capability and legal (or administrative) availability did not change in the analysis process. Suitability varied depending on the emphasis of each management alternative.
7. The ID Team developed resource coefficients (yield tables) for the analysis process from conclusions determined in the Analysis of the Management Situation (AMS). (Refer to the AMS and planning records (1922.16a.7b).)
8. All suitable prescriptions for a unit of land were defined prior to FORPLAN analysis. The suitability determination is documented in the TNF identification of Land Tentatively Capable, Available, and Suitable for Resource Management.
9. The TNF ID and Management Teams developed a comprehensive list of management standards and guidelines that could be applied to TNF land. This list is documented in the Reference Book of Management Practices. These practices allow for the achievement of the entire range of resource opportunities described in the AMS.
10. The development and analysis of the benchmarks included tests of the effects and sensitivities of prescriptions, management intensities, and land allocations. To facilitate analysis of the benchmarks and, later, the alternatives, a linear programming model, FORPLAN (Johnson, K.N., et al., 1980) was used. FORPLAN was used to allocate and schedule management activities while maximizing economic efficiency (present net value) or minimizing deviation from goals established under previously specified resource objectives. FORPLAN simultaneously applies management prescriptions to specific land areas and schedules activities to achieve the specified management objectives for the individual alternative. The model analyzes and selects the most economical output mix and schedule to accomplish the resource objectives. Based on this analysis, FORPLAN projects resource outputs and values over the planning period.
11. The outputs considered by prescription in the model include acres of vegetation treated, timber, range, water, cost plus loss from wildfire, dispersed recreation, developed recreation, and fish and wildlife.
12. The FORPLAN analysis process began with the following three types of analyses: base, constraint opportunity costs, and single-resource emphasis. Base and single-resource emphasis analyses are addressed as 'Benchmarks.'
13. The Forest analyzed four base scenarios to provide knowledge of the decision space, the cost of the minimum management requirements, and the sensitivity of nonmarket commodity outputs to assigned prices.

14. Constraint cost analyses were conducted to estimate the opportunity cost of protecting such resources as threatened and endangered animal species, soil and water productivity, vegetative habitat diversity, and vertebrate species viability. Three timber policies--nondeclining yield, culmination of mean annual increment, and dispersion of created openings--were tested to determine the opportunity cost of each policy constraint.
15. To analyze a broad range of reasonable resource management alternatives, as required by NEPA and NFMA, the ID Team identified upper and lower limits for a feasible range of resource outputs. These limits were identified through separate, single-resource emphasis analyses. These analyses identified maximum feasible and legal output levels for timber, forage, water, and wilderness. These analyses provided knowledge of resource production potentials and interactions among resource production processes. This knowledge was used to help formulate Forest alternatives. (See Section C later in this chapter and Appendix B for the benchmark descriptions.)
16. The ID Team developed management prescriptions and delineated management areas to spatially allocate FORPLAN alternative solutions. Each management prescription is a set of compatible directions, including standards and guidelines necessary to attain multiple-use goals and objectives, while applying the FORPLAN prescriptions. The management prescription provides a particular emphasis and contains all the compatible practices and activities that would occur on a management area in addition to the practices allocated by FORPLAN. Each management prescription applies to one kind of management area, within which all lands would be managed for one emphasis.
17. The Forest Supervisor, Deputy Forest Supervisor, Forest Staff, and the five District Rangers made up the Management Team. They were responsible for developing the final alternatives considered in detail in the DEIS. Three ad hoc groups were formed from the Management and ID Teams. These groups responded to the issues grouped by three categories: market (commodities), amenities, and developed recreation. Each group had the responsibility to develop as many alternatives as necessary to address the issues assigned to their group. The alternatives were formulated within given criteria. These criteria are laws, regulations, directions, public issues, TNF management concerns, and resource use and development opportunities (ICO's) and the physical capabilities of the TNF to produce goods. These alternatives were presented to the Management and ID Teams. The results of this process are described later in this chapter. The ID Team prepared the preliminary proposals using the mapped data and outputs from computer analyses (refer to planning records, specifically 192216a).
18. The Draft EIS and Draft Forest Plan were issued in January, 1986. Over 12,000 letters were received in response, which demonstrated the public's interest in management of the Forest. These comments were analyzed by the Forest Interdisciplinary and Management Teams. The Draft EIS alternatives were reviewed and several were modified to more clearly address the public issues and internal management concerns. The TNF worked closely with representatives of the timber and environmental communities to modify two of the DEIS alternatives, I and E, respectively, into Alternatives CMD and NMK. The Forest evaluated 19 plan alternatives during this review. Thus, the public review of the DEIS and Draft Plan helped focus on the major issues. The Preferred alternative in the Draft was modified as a result of public comments and additional analysis to become the Preferred (PRF) alternative, which is displayed in this document and more clearly defined in the Forest Plan.

LIMITATIONS TO THE RANGE OF ALTERNATIVES

Physical characteristics, statutory or judicial requirements, and contractual obligations limit the possible range of alternatives for the TNF. Specifically, these present significant limitations on the kinds and amounts of goods and services, the management options, and, thus, the range of viable alternatives that can be considered as part of this planning process. These are summarized below. (Refer to Chapter 3 for a detailed explanation of these characteristics.)

Alternate (Checkerboard) Ownership Pattern. About **381,161** acres (**32** percent) of the land within the TNF administrative boundary are owned by others. This consideration affects the potential use and development (or nondevelopment) of TNF lands

Classified Areas. The classification of the North Fork American Wild River (**5,788** acres), the Onion Creek Experimental Forest (**2,846** acres), and the Granite Chief Wilderness (**18,705** acres) would not change as a result of this planning.

Special Uses. There are **870** permits on about 22,000 acres that authorize the use of TNF lands. These range from cabins and resorts to ski areas, roads, utilities, and established water uses in and along reservoirs. Except for possible change when renewal is required, these permits would not change as a result of this planning

Withdrawals About **68,100** acres of existing and previously proposed withdrawals from mineral entry would not change

Accessible Terrain About **78** percent of the TNF is accessed by about **2,400** miles of road About **850** of the 2,400 miles are under the jurisdiction of the counties or the State, or are controlled by private landowners Approximately 15 percent of the remaining TNF system roads are cooperatively managed with other landowners. These authorities would not change.

wildfire. Wildfire cannot be avoided, mitigated, or eliminated regardless of the fire management policies or organization available

C. BENCHMARKS

Eight benchmark analyses were made using FORPLAN to establish an analytical base for developing alternatives and to provide a reference point to compare alternatives.

The benchmarks display physical, biological, and technical capabilities of the Forest. Benchmarks are not reasonable management alternatives because they provide for few multiple-use opportunities and are not limited by Forest Service policy, budget, discretionary constraints, spatial feasibility, or program or staffing requirements. They are physically and technically possible, but are not operationally feasible.

The benchmarks were formulated to display the TNF's minimum level of outputs and effects and to determine the maximum potential to produce individual resources such as timber, water, livestock forage, and wilderness. They determine the possibility for change and identify the boundaries of the decision space in which change can or must occur.

A complete technical description of and the modeling specifications for each benchmark developed in the TNF planning process is located in Appendix B and in the TNF Analysis of the Management Situation. The following discussion describes what was learned from each benchmark during the analysis process. After the discussion, Table 2.1 displays the outputs, cost, and present net value (PNV) of each benchmark. Finally, the conclusions reached through the benchmark analyses are summarized.

- 1 MLV - Minimum Level of Management. This benchmark shows the outputs and fixed costs of public ownership of the Forest. The management objective is to minimize cost. Activities are only those needed to protect life, health, and safety, prevent environmental damage, and manage unavoidable land uses. No outputs of timber, developed recreation, livestock forage production, or wildlife habitat improvement would occur. Incidental outputs of dispersed recreation use and water yield would occur.
- 2 FLW - Unconstrained Maximum Present Net Value (with limited timber harvest fluctuation and long-term sustained yield constraints). This benchmark provides the most economically efficient level of market outputs. The management objective is to maximize PNV. This benchmark is the

basis for evaluating the effects of adding minimum management requirements in future analyses. This benchmark's outputs are at the highest achievable levels for most priced resources.

3. **MMA** - Maximum Present Net Value, **with** Minimum Management Requirements (and nondeclining sustained yield and culmination of mean annual increment). As compared to the FLW benchmark above, this benchmark displays the cost of the minimum management requirements considered collectively. It forms the basis for evaluating requirements beyond the minimum management requirements. The management objective is to maximize PNV. All modeled outputs with either assigned or market values are analyzed.
4. **MKV** - Maximum Present Net Value, Market Values Only (with the same constraints as MMR). This benchmark maximizes the present net value of only those outputs that have established market values (timber, livestock forage, and developed recreation).
5. **TBR** - Maximum Timber Production for One Decade (with the same constraints as MMR). This benchmark defines the maximum possible timber output for the first decade given minimum management requirements and nondeclining sustained yield. With this timber volume goal for the first decade, resources are managed for maximum economic efficiency.

The opportunity cost of managing for maximum timber is an \$86 million decline in PNV compared to the MMR benchmark. The allowable sale quantity increased 18 MMBF compared to the MMR benchmark. Clearcut acres were 1,300 acres per year higher in the first decade but did not display a consistent relationship the following four decades. Timber suitable acres were 23,000 acres more than MMR because potential recreation sites were managed for timber production. Because potential developed sites and ski areas were managed for timber production, developed sites did not meet demand beyond the first decade, and downhill ski demand was never met.

6. **WLN** - Maximum Present *Net* Value with Maximum Wilderness (with the same constraints as MMR). In this benchmark all roadless areas not designated wilderness under the California Wilderness Act of 1984 are allocated to wilderness on the Forest. The management objective is to maximize economic efficiency.

The opportunity cost of managing for maximum wilderness was a decline in PNV of 2 percent from the MMR benchmark because of the allocation of 125,000 additional acres to wilderness. The allowable sale quantity declined 5 percent or 11.1 MMBF per year, although timber suitable acres declined 13 percent or 77,000 acres. The reduction in timber suitable acres reduces WFUDs and water yield generated indirectly by timber management activities.

7. **RGN** - Maximum Range Grazing for Five Decades (with the same constraints as MMR). This benchmark estimates the maximum capability of the Forest to provide commercial livestock grazing over the RPA planning horizon (five decades) subject only to minimum management requirements. The management objective is to maximize livestock forage production. Production of outputs that do not reduce grazing capacity are provided at economically efficient levels. Given these forage production goals, resources are managed to maximize economic efficiency.

The opportunity cost of managing for maximum range is a \$291 million decline in PNV compared to the MMR benchmark. The allowable sale quantity declined 12 percent. Timber suitable acres increased 4 percent because of the allocation of potential ski and developed recreation sites to timber production. Potential AUM's increased 163 percent in the first decade from the MMR benchmark to 55,000 AUM's per year. The demand for developed recreation was met through the third decade. Demand for downhill skiing was met through the second decade. Potential ski areas and developed sites were allocated to timber to obtain the associated transitory range AUM's.

8. **H2O** - Maximum Water Yield for Five Decades (with the same constraints as MMR). This benchmark estimates the capability of the Forest to provide maximum water yields over the RPA planning horizon (five decades) subject only to minimum management requirements. With these goals for water production, other outputs are produced at economically efficient levels.

The opportunity cost of managing for maximum water is a 4 percent decline in PNV compared to the MMR benchmark. The developed sites and downhill ski areas met demand through the second decade. Potential developed sites and downhill ski areas were managed for timber production to capture water yield. Water yield increased from the MMR benchmark less than 1 percent per year or 0.01 million acre feet.

CONCLUSIONS

The following conclusions were reached as a result of the benchmark analyses. These were carried forward to the formulation of alternatives. The benchmarks suggest that a potential exists for increasing all resource outputs through more intensive resource management.

Economic. The conclusions from not pricing nonmarket outputs (MKV) in the allocation results in no production of dispersed recreation above the background levels. Because of the link between timber and water, not pricing water in the allocation reduces timber outputs.

Timber. The TBR benchmark indicates that the TNF would be capable of producing timber nearly 25 percent above the current level if only the minimum management requirements were applied. Maximizing timber would have the most significant impact on developed recreation because potential developed sites would be managed for timber and developed recreation would be restricted to current capacity. Downhill skiing use only increases slightly from current capacity.

Timber production varied less than 20 percent among the single resource emphasis benchmarks. This variation reflects the linkages between the production of timber and other commodity outputs.

Range. The maximum range benchmark, RGN, indicates that the TNF could produce forage at over twice the current level. Higher forage production is due primarily to conversion of less palatable species to grass.

Water. Water production does not vary significantly between the unconstrained (FLW) and minimum level (MLV) benchmark analyses because the background amount accounts for the majority (89 percent) of all production. Converting existing vegetation to grass is the most productive practice to increase water yield.

Developed Recreation. When the management objective is to maximize PNV, potential recreation sites would be reserved for developed recreation to meet demand for four decades. Thirty-two percent of the existing potential developed recreation sites and 97 percent of the existing potential downhill ski site acreages are needed to meet projected demand. Downhill skiing is the most cost-effective land use.

When the objective is to maximize PNV, developed recreation (campground) sites are always rehabilitated to capture the full standard value. Sites are never shut down.

Dispersed Recreation. Dispersed recreation always meets demand unless it is constrained as in the minimum level (MLV) or is not valued as in the market (MKV) benchmarks. Dispersed recreation is always managed at standard when the objective is to maximize PNV.

Facilities. Facilities are always managed at the least cost level (building investment level) to provide minimum health and safety (maintenance) to existing facilities unless another level is required.

Fish and Wildlife. All nonstructural habitat improvements are implemented when WFUD's are valued, and the objective is to maximize PNV. Structural habitat improvements named LOGS, DEBRIS, BOULDR, and GZZLER are implemented in all benchmarks.

Fire Management The model selects the same fire program organization in all benchmarks.

The expected acres burned by fire programs among benchmarks (except the minimum level MLV) were similar in mature timber and differ only in relationship to plantation acres. The fire program organizations that have the least acres burned are Attack/Prevention, followed by As Attack and Current. The budget level is inversely related to expected acres burned (more funding, fewer acres burned). The program with the fewest acres burned would not be necessarily the most cost effective.

Wilderness. Roadless areas are never managed as wilderness when economics are the sole consideration. The maximum wilderness benchmark, WLN, shows that maximum wilderness and market outputs near current levels are feasible.

1/ See the Glossary in the Plan for definition of terms

2/ The expected low-high range over decades 1-5 is based on the amount of capable-suitable habitat adjusted to reflect the biological factors

D. ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

The 13 alternatives in this category, in conjunction with the 6 alternatives considered in detail, represent a full range of alternatives for the Tahoe National Forest. Together, the 19 alternatives represent a wide range of emphases and outputs on the Forest and address all the issues and concerns. Furthermore, the alternatives provide a range of production for each Forest resource output as appropriate to respond to the issues and concerns

TABLE 22 - DISPOSITION OF ALTERNATIVES FORMULATED

No.	Alpha Code and Name	Disposition
1	CEE (Constrained Economic Efficiency)	incorporated in all alternatives
2	CEF (CEE with Forest Constraint)	Incorporated in all alternatives
3	MKT (Market Opportunities Emphasis)	Forest constraints applied to form Alternative CMD
4	AMN (Amenities or Nonmarket Emphasis)	Forest constraints applied to form Alternative NMK
5	PRO (High Productivity)	Considered but eliminated
6	LBU (25% Budget Reduction from Current)	Incorporated in Alternative NMK
7	WLI (SPNM and Output Investments)	Forest constraints applied to form Alternative JJJ
8	DDD (Wildlife)	Considered but eliminated
9	FFF (Motorized Recreation)	Considered but eliminated
10	GGG (Nonmotorized Recreation)	Considered but eliminated
11	HHH (Range/Timber)	Considered but eliminated
12	JJJ (Amenity/Commodity)	Considered but eliminated
13	KKK (Preferred with Departure)	Considered but eliminated
14	PRF (Preferred)	Considered in detail
15	CUR (Current Management)	Considered in detail
16	RPA (1980 RPA)	Considered in detail
17	CMD (Commodity)	Considered in detail
18	NMK (Nonmarket)	Considered in detail
19	UNE (Uneven-age)	Considered in detail

All 13 alternatives not described in detail were fully developed, narratively described, and analyzed through FORPLAN prior to their elimination. These alternatives were considered by the IDT and Management Team, along with the six alternatives that are presented in detail, before making the decision that they were not needed as implementable alternatives. The primary reasons were that they were similar to other alternatives, displayed nothing unique, or provided limited resolution of or responsiveness to public issues and concerns. Table 2.3 summarizes the outputs for these alternatives. In most instances the goals of the eliminated alternatives are embodied in one or more of the final alternatives, which have less adverse impact or more beneficial output. The following alternatives were eliminated

1. CEE - Constrained Economic Efficiency

This alternative displayed the most economically efficient allocation and schedule for meeting minimum management and minimum implementation requirements. It measured the opportunity cost of adding the scenic highway constraint when compared to the MMR benchmark. Disposition: CEE provides the foundation for all Forest alternatives. It does not respond to the full range of issues raised during scoping. As such, it is incorporated into all alternatives considered in detail.

2. CEF - Forest Constraint

This alternative added the Carman Valley Watershed protection constraint to those of CEE. This is the only constraint common to all the Forest alternatives considered in detail. CEF provided a measure of the opportunity cost of protecting the Carman Valley Watershed. All alternatives considered in detail are compared to CEF to display the degree of change in costs, benefits, and PNV. Disposition: CEF is expanded with different emphasis in all alternatives considered in detail

3. MKT - Market Opportunities Emphasis

This alternative emphasized high output levels of market resources (timber, range, minerals, etc) with nonmarket outputs at economically efficient levels. Opportunities to increase receipts from activities that contribute income

to the US Treasury are expanded. MKT responds to two Forest issues (#6) forage, wood and soils and (#8) recreation. Timber targets are constrained to meet or exceed 170 MMBF in 1990 and 210 MMBF by 2030. Disposition: The MKT theme is developed in Forest Alternative CMD, which is considered in detail and emphasizes high output levels of market resources.

4. AMN - Amenities or Nonmarket Emphasis

This alternative emphasized high output levels of nonmarket resources (fish and wildlife, recreation, wilderness, etc.) with market outputs at economically efficient levels. AMN responded to four Forest issues' (#4) inventoried roadless areas, (#7) water, (#8) recreation, and (#9) fish and wildlife habitat. AMN reflects assumptions of high levels of demand for amenity resources. Disposition: The AMN theme is developed in Forest Alternative NMK, which is analyzed in detail and emphasizes high output levels of amenity resources.

5. PRO - High Productivity

This alternative determined the effects of meeting timber targets of 230 MMBF by the year 2000 and at least 215 MMBF by the year 2030. Nonmarket goods and services are produced at economically efficient levels. Disposition: The timber targets are met or exceeded in Alternatives DDD and CMD, the latter which is presented in detail. For this reason, and because PRO resulted in fluctuating timber outputs, this alternative was eliminated from detailed study.

6. LBU - 25% Budget Reduction from Current

This alternative estimates the expected outputs and services that could be provided in the future if the current budget was reduced by 25 percent. Disposition: This limited-budget alternative is incorporated in Forest Alternative NMK, which is discussed and analyzed in detail.

7. WLI - SPNM and Output Investment

This alternative displays the potential to maintain or increase commodity outputs while designating quality roadless areas to semi-primitive nonmotorized recreation use. Disposition: The WLI theme is developed in Alternative JJJ and NMK, the latter which is considered in detail and emphasizes semi-primitive nonmotorized recreation and high commodity outputs.

8. DDD - Wildlife

This alternative emphasized the achievement of high outputs of fish and wildlife commodity and amenity benefits by improving and developing their structures and habitats. It would manipulate vegetation to benefit the rarest species using range, timber, and other functional activities along with direct habitat improvements. This alternative responded to two forest issues: (#6) forage, wood, and soils and (#9) fish and wildlife habitat.

The results of this alternative were similar to the CMD and RPA alternatives, which are both considered in detail. After developing and analyzing the results of this alternative, the IDT recommended and the Management Team determined that it provided limited resolution to the public issues and directed that it was not needed as an implementable alternative.

9. FFF - Motorized Recreation

This alternative emphasizes the achievement of high output levels of motorized recreation commodity and amenity benefits by emphasizing motorized recreation, development of downhill ski areas, and development of recreation sites for a variety of motor vehicle uses. Included are opportunities for four-wheel drive vehicles, motorcycles, snowmobiles, motorboats, motorhomes, and general highway driving. Resolved in favor of motorized recreation are any conflicts with nonmotorized recreation. This alternative responded to Forest issue (#8) recreation.

The results of this alternative were similar to the CMD and RPA alternatives for the miles and acres available for OHV use, and similar to the UNE alternative for visual and roaded recreation emphasis. After developing and analyzing the results of this alternative, the IDT recommended and the Management Team determined that it

displayed nothing unique and provided limited responsiveness to the public issues and directed that it was not needed as an implementable alternative.

10. GGG - Nonmotorized Recreation

This alternative emphasizes the achievement of high output levels of nonmotorized recreation amenity benefits with commodity outputs at economically efficient levels by emphasizing nonmotorized recreation activities, such as Nordic skiing, hiking, and dispersed camping. Resolved in favor of nonmotorized recreation are any conflicts with motorized recreation.

The results of this alternative were similar to the NMK alternative for the levels of timber management intensity, the objectives for visual quality, and the allocation of SPNM acres. After developing and analyzing the results of this alternative, the IDT recommended and the Management Team determined that it displayed nothing unique and provided limited resolution to the public issues and directed that it was not needed as an implementable alternative.

11. HHH - Range/Timber

This alternative emphasizes the achievement of high range and timber commodity outputs while providing amenity benefits at economically efficient levels. It emphasizes intensive management of the forage resource on permanent range and nonprime forest land while maximizing timber opportunities on prime forest land. (Prime forest land is capable of growing 85 or more cubic feet of timber per acre per year.) It resolves in favor of range and timber commodity resources any conflicts with the amenity resources. This alternative responded to Forest issue (#6) forage, wood, and soils.

The results of this alternative were similar to the RPA alternative for timber, and greatly exceeded the RPA grazing targets. After developing and analyzing the results of this alternative, the IDT recommended and the Management Team determined that it provided limited responsiveness to the public issues, would create unacceptable conflicts among the grazing, riparian, and water resources and unacceptable environmental degradation, and directed that it was not needed as an implementable alternative.

12. JJJ - Amenity/Commodity

This alternative emphasizes the achievement of quality recreation, amenity benefits, and high commodity outputs. It emphasizes semi-primitive, nonmotorized recreation for quality roadless areas. On all other lands it emphasizes capital investment commodity production to mitigate losses for lands managed for semi-primitive, nonmotorized recreation. This alternative responded to Forest issues (#2) minerals, (#6) forage, wood, and soils, and (#8) recreation.

The results of this alternative were similar to the RPA alternative. The passage of the California Wilderness Act created the Granite Chief Wilderness, eliminated all the wilderness candidate areas on the TNF, and made this alternative unnecessary. Thus, after developing and analyzing the results of this alternative, the IDT recommended and the Management Team determined that it provided limited resolution to the public issues and directed that it was not needed as an implementable alternative.

13. KKK - Preferred with Departure

In the draft EIS, departure opportunities were evaluated to determine if allowing a departure from the principle of nondeclining flow of timber would better meet the multiple-use objectives of the proposed Forest Plan. The departure alternative is not studied in detail because the overall objectives of multiple use management are not enhanced

1/ See the Glossary of the Plan for an explanation of terms

2/ Potential yield from standard, special, and marginal components

3/ The expected low-high range over decades 1 to 5 is based on the amount of capable-suitable habitat adjusted to reflect the biological factors

4/ The entries are total pounds of fish produced during the 5th decade Comparison with the base level (1982) will show the overall loss or gain during the 5 decades

5/ Refer to Appendix B for an explanation of fire programs

E. ALTERNATIVES CONSIDERED IN DETAIL

INTRODUCTION

This section describes the six alternatives considered in detail. The management direction common to all alternatives is summarized. The concept of management prescriptions and how they relate to management areas is explained. Finally, each alternative is presented including the theme, resource program direction, expected future condition, and tabular displays of outputs and costs. Section F of this chapter compares the alternatives and explains the differences between them.

In addition to the descriptions presented in this **EIS**, each of the alternatives is shown on 1/4-inch-per-mile maps in the Maps packet accompanying this document.

MANAGEMENT DIRECTION COMMON TO ALL ALTERNATIVES

In the process of developing alternatives, some direction common to all alternatives was necessary to meet legal requirements or to ensure that all alternatives would be implementable.

Six types of direction are common to all alternatives. (1) technological constraints, (2) minimum management requirements (MMR's), (3) timber policy requirements, (4) minimum implementation requirements (MIR's). (5) Forest constraints, and (6) summary of Forestwide policy, standards, and guidelines.

A complete discussion of the use of constraints in FORPLAN, and their effects, is found in Appendix B.

Technological Constraints. Outputs of each benchmark and alternative are estimated by simulating the behavior of the production processes on the TNF in a mathematical model, FORPLAN. To ensure that the simulation results are realistic and implementable on the ground, several relationships, termed 'technological constraints,' are built into the model.

The model limits certain management activities to certain types of land. For example, timber is not managed in campgrounds except to remove hazardous trees. Timber is not clearcut on some harsh south-facing slopes because of regeneration difficulties. Only those lands having the proper characteristics for ski areas (**slope**, snow, access, land not otherwise encumbered) are considered for ski area expansion or development as a management option. Technological constraints ensure that some commodities, such as campgrounds, are not built before needed as measured by campground demand, and they also ensure that an appropriate level of timber in each age class exists by the end of the planning horizon.

Minimum Management Requirements (MMR's) Minimum management requirements were developed from the forest planning regulations, 36 CFR 219.27, and comply with statutes and regulations. They are legal requirements outside of Forest Service authority to change. The following MMR's were applied to both benchmarks (except the unconstrained FLW benchmark) and alternatives:

- 1 Capable, Available, and Suitable (CAS) Lands Consider lands capable, available, and suitable for regulated timber production under the following conditions,
 - a The land is forested and is currently producing, or is capable of producing, crops of industrial wood (at least 20 cubic feet or more per acre per year)
 - b The land has not been withdrawn from timber production by Congress, the Secretary of Agriculture, or the Chief of the Forest Service. On the TNF withdrawn areas include the Granite Chief Wilderness, the North Fork American Wild River, and Onion Creek Experimental Forest
 - c Technology and knowledge exist, and are available, to ensure timber production without irreversible damage to soils, productivity, or watershed conditions.

- d. Existing technology and knowledge provide reasonable assurance that adequate restocking can be attained within five years after final harvest
 - e. Adequate information is available to predict responses to timber management practices.
2. **Threatened and Endangered (T&E) Species** Identify habitat critical to T&E species, and prescribe measures to prevent the destruction or adverse modification of this habitat. Provide habitat management in accordance with recovery or species management plans. On the TNF, bald eagles, peregrine falcons, and Lahontan cutthroat trout are the only identified T&E species
 3. **Viable Populations for Wildlife.** Maintain sufficient habitat to support, at a minimum, estimated numbers and distribution of reproductive individuals of all native vertebrates to ensure their continued existence.
 4. **Goshawk** Maintain sufficient suitable habitat to support at least 75 pairs.
 5. **Spotted Owls** Maintain sufficient suitable habitat to ensure continued existence of an adequate number and distribution of spotted owl pairs. Establish a network of spotted owl habitat areas (SOHA's) that conform to the spacing and distribution standards on pages 4-18 and 4-19 of the Regional Guide. Within each SOHA, provide at least 1,000 acres of suitable owl habitat in all time periods. On the TNF, the minimum SOHA network needed to comply with the Regional Planning Guide direction is 33
 6. **Diversity** Manage plant and animal communities so that diversity is similar to that currently on the Forest. Localized reductions in diversity will be allowed only when necessary to meet overall multiple use objectives. On the TNF maintain at least five percent of each major vegetation type in one of seven seral stages.
 7. **Riparian Area Protection** Emphasize protection of riparian area-dependent resources over commodity production. Where conflict exists between the two, resolve in favor of the most limiting riparian area-dependent resource.
 - a. Apply no practices or prescriptions to these areas that cause detrimental changes to water quality, aquatic flora and fauna, hydrophytic vegetation, or riparian-dependent wildlife.
 - b. Permit timber harvesting, grazing, developed recreation, and OHV's only if these uses are compatible with needs of riparian-dependent resources. Preferential consideration will be given to riparian-dependent resources when conflicts occur among land-use activities

Riparian areas are defined, as a minimum, as follows (1) areas within a 100-foot horizontal distance from the edge of standing bodies of water, (2) areas within a 100-foot horizontal distance on each side of perennial stream channels, and (3) all wetlands.
 8. **Soil and Water Productivity** Conserve soil and water resources and do not significantly or permanently impair land productivity. Limit disturbance on lands characterized by over-steepened slopes, very high erosion potential, or high instability to no more than 5 percent per decade to avoid soil loss, activation of mass failures, and degradation of water quality.

Timber Policy Requirements The following timber policy requirements are needed to ensure that timber harvest meets sustained yield, that harvest is generally at culmination of mean annual increment (CMAI), and that harvest areas are sufficiently dispersed.

1. Ensure that all even-aged stands scheduled for final harvest will have generally reached CMAI of growth
2. Provide a range of rotation ages
3. Ensure that long-term sustained yield, as defined for each alternative, is perpetuated through the end of the planning horizon

- 4 Prevent regeneration units that are still considered 'openings' from having more than 15 percent of their boundaries in common with other openings. Disperse units to leave logical harvest units between openings

Minimum Implementation Requirements (**MIR's**). Minimum implementation requirements ensure that alternatives are minimally acceptable and implementable. They embody Regional Forest Service policies beyond legal requirements. The MIR's are applied only to the alternatives and not to the benchmarks

1. Manage sensitive plant species to ensure that they do not become threatened or endangered because of Forest Service activities.
2. Employ the 'partial retention' visual quality objective in foregrounds and middlegrounds as viewed from Highways 20, 49, 80, and 89 (officially designated as, or candidates for, California State and County Scenic Highways).

Forest constraints common to all alternatives can be established to further ensure implementability at the local level. They are based on Forest (rather than Regional) conditions in addition to the MMR's. These constraints are not applied to benchmarks, but are applied to all alternatives except the Constrained Economic Efficiency (CEE) alternative. Forest constraints unique to an alternative are discussed under the alternative descriptions. The only Tahoe National Forest requirement common to all alternatives relates to Carman Valley Watershed, which has excessive channel cutting and loss of adjacent wetlands. In this watershed timber harvest is limited to unregulated harvesting in riparian areas; on all other suitable timber lands in this watershed, harvesting will be done under long rotations. These requirements are needed to reduce watershed disturbance in this area.

Summary of Forestwide Policy, Standards, and Guidelines. In addition to the above, the TNF has developed Forestwide policies, standards, and guidelines common to all alternatives (1) to ensure the efficient management of Forest resources, (2) to establish baseline conditions that must be maintained, (3) to guide implementation of any project on the Forest, and (4) to facilitate an integrated approach to resource management. (See Chapter V of the accompanying Forest Plan for the complete set of Forestwide policies, standards, and guidelines common to all alternatives and those practices unique to the preferred alternative.) Those standards that vary by alternative are discussed in each alternative description later in this chapter. The following summarizes those that apply to all alternatives.

1. Economics. Achieve economic efficiency as directed by NFMA.
2. Social. Continue with the Human Resource Programs and with Occupational Safety and Health Administration. Continue to coordinate such programs with other Federal, State, and local agencies and maintain special coordination for urban and community programs, such as coordinated resources management planning and resource conservation and development area projects.
3. Air Quality. Adjust burning programs and other Forest activities as needed so that Federal, State, and local air pollutant standards are not violated.
4. Energy. Ensure energy-efficient land management practices on the TNF, to the degree practicable.
5. Facilities. Continue to maintain National Forest System administrative (including radio installation) and residential facilities for use by National Forest personnel, as required by Forest Service policy. Level I - Health and Safety, and Level II - Protect Government Investment. Ongoing feasibility and organizational studies could identify additional investments (minimum and maximum building investment levels) for new facilities.

Manage the TNF trail system to protect the resources and the health and safety of users while maintaining and developing the system to meet demand for dispersed recreation uses.

Provide roads necessary to meet adopted management goals.

Eliminate and obliterate unneeded routes

Restrict road, trail, and off-highway use as necessary to protect threatened, endangered, and sensitive plants or animals, essential wildlife functions, cultural resources, and riparian areas and wetlands.

- 6 Fire and Fuels Stress fast, energetic, thorough, and safe attack on wildland fires in combination with an aggressive, efficient fuels management program. This emphasis is clarified further by the following fire management objectives.
 - a. Provide a balanced fire management program that is cost efficient and commensurate with threats to life and property, public safety, hazards, risks, and resource values and objectives.
 - b. Use prescribed fire to protect, maintain, enhance, and attain the production and quality of TNF resources.
 - c. Provide data, information, and coordination for full integration of fire use and protection in the analysis, formulation, and evaluation of alternative land management prescriptions, goals, and objectives.
 - d. Work with State and local cooperators to achieve these objectives.
- 7 Fish and Wildlife. Provide habitat leading to viable populations of threatened and endangered species. Manage for three pairs of peregrine falcon into areas having suitable nesting habitat. Construct nesting platforms and manipulate vegetation to enhance bald eagle nesting habitat in suitable areas.
- 8 Forest Pests. The principles of integrated pest management (IPM) described by Forest Service policy direct pest management programs. This Forestwide IPM program is to protect forest, recreation, and range resources against unacceptable losses from destructive forest pests by using no methods that will damage the quality of the environment. Forestwide, emphasize IPM using a full range of pest management activities. The Forestwide policy of IPM does not require or exclude a specific method, such as pesticide use.

The IPM direction was discussed in detail in the February 1989 Pacific Southwest Region Final Environmental Impact Statement. Vegetation Management for Reforestation. This FEIS included detailed discussions and analyses of a preferred alternative, alternatives to the preferred (including no vegetation management, no application of herbicides, and no aerial application of herbicides), and the consequences of these alternatives on the environment. Based on the selected alternative in the Vegetation Management FEIS, all alternatives, except the Nonmarket Alternative (NMK), in this Forest Plan EIS are predicated on the use of the full range of alternative treatment methods including mechanical, prescribed fire, biological, and chemical methods (with limitations).

The Regional Vegetation Management for Reforestation FEIS is hereby incorporated by reference. The FEIS was approved February 27, 1989. The proposed Forest Plan (Chapter V) directs that the selection of any particular treatment method will be made at the project level based on a site-specific analysis of the relative effectiveness, environmental effects, and costs of the feasible alternatives, and that herbicides will be selected only if (a) their use is essential to meet management objectives and (b) monitoring and enforcement plans to implement specific measures will be developed for site-specific projects and described in the environmental analyses for these projects.

The effects of not allowing the use of herbicides by LMP alternative are summarized in Table 2.4. The NMK alternative is not displayed because herbicides would not be used under this alternative. These changes are projected from data from the Region's computer model of vegetation management costs and yields adapted to this Forest's specific situation and to the Forest Plan alternatives presented in this EIS. See the planning records for detailed information about the changes from the Regional model, and Appendix M, Effect of Herbicide Constraints on Timber Management.

TABLE 2.4 - THE EFFECT OF VARIOUS HERBICIDE USE POLICIES ON LMP ALTERNATIVES - INTENSIVELY MANAGED LANDS ONLY 1/

EFFECT	HERBICIDE POLICY 2/	PRF	CUR	RPA	CMD	UNE	EFFECT DIFFERENCE BY HERBICIDE POLICY

	No herbicide, unlimited \$	300	369	370	365		
	No herbicide, limited \$	252	310	311	307		-32%
	No aerial herbicide	333	410	411	406		-11%
Annual cost 5/ (MM\$)	Recommended alternative	2 96	334	3 47	3 82	2 59	--
	No herbicide, unlimited \$	3 60	4 07	4 22	4 65	3 15	+21%
	No herbicide, limited \$	286	3 24	335	369	2 50	--
	No aerial herbicide	290	329	3 41	3 75	254	-1%
Average cost per MBF (\$) 6/	Recommended alternative	23	23	23	23	23	--
	No herbicide, unlimited \$	35	35	35	35	35	+52%
	No herbicide, limited \$	31	31	31	31	31	+35%
	No aerial herbicide	25	25	25	25	25	+9%

1/ Alternatives are R-5 "Vegetative" Alternative (PRF).

2/ Alternatives that assume herbicide use. See Appendix M for a discussion of the Nonmarket (NMK) alternative.

3/ Long-term sustainable yield for indicated landbase. Volume from nonintensively managed lands (TM-marginal) not included.

4/ Intensively managed lands only. Regulation Class I (TM-FULL) and Regulation Class II (TM-REDUCED).

5/ Includes all reforestation and timber stand improvement costs, except animal damage control.

6/ Average cost of reforestation and TSI per thousand board feet of timber produced on a sustained, long-term basis.

9 Geology. Complete the Forest Geologic Resources (and hazards) Inventory and use it to make preliminary assessments of impacts and needed mitigations on land-disturbing activities and to identify and analyze potential geologic resources. Conduct project-specific geologic and/or geotechnical investigations on projects that have the potential to initiate or accelerate slope movements, be adversely affected by fault zones, or impact groundwater quality or quantity.

10. Historical and Cultural Resources Identify cultural resources as a part of the environmental analysis of specific Forest projects. Identify and evaluate cultural resources for significance. Monitor cultural resource protection measures designed for specific projects.

Manage those cultural resources on, or eligible for inclusion on, the National Register of Historic Places and those which have not been evaluated to preserve their historic, scientific, or social values. When planning for public interpretation of cultural resources, emphasize those resources that are on the National Register of Historic Places, those that are located near recreation developments, and those that best represent significant historical events, processes, and places.

Coordinate cultural resource activities with the State Historic Preservation Officer, the Advisory Council on Historic Preservation, and interested public groups.

11 Land Adjustments Acquire private land in areas existing or recommended for Wilderness, Wild and Scenic Rivers, Research Natural Areas, and Special Interest Areas as necessary to protect the area for the specific purpose for which it was designated

12 Land Line Surveys. Eliminate the 2,450 mile land line (TNF property boundaries) backlog by the year 2020 as described in the 1980 RPA Program.

Locate and establish TNF property boundaries as necessary to protect resources and minimize conflict with adjacent owners.

13. Special Uses. Manage Ward, Boreal Ridge, Cisco Butte, Galloway, Harding, Ruby, Squaw Peak, Pass, and Idaas electronic sites Generally, do not issue special-use permits for electronic uses without preparing an environmental analysis (Exceptions include base station communication radios for special-use permit holders) Continue under special-use permit the Sagehen Station, Martis, and Hirschdale areas.

Designate, in all action alternatives, the Donner Pass area as an existing corridor.

Consider new special uses or easements only when suitable private land is not available and such use does not conflict with management objectives. Consolidate uses as much as possible

Acquire road and trail rights-of-way for facilities needed for the Forest transportation system

14. Withdrawal from Mineral Entry and Leasing To protect areas for specific management objectives, propose withdrawing from mineral entry and leasing the Babbitt Peak Research Natural Area Propose mineral withdrawal of those portions of Elliot Ranch, the Foresthill Seed Orchard, existing developed recreation sites, and Onion Creek Experimental Forest not already withdrawn The 68,100 acres of existing and previously proposed withdrawals will be reduced by about 2,000 acres if the BLM approves our recommendations in the current withdrawal review process. The Granite Chief Wilderness is withdrawn from all forms of mineral entry and leasing.

15. Law Enforcement. Comply with laws and regulations: protect the public and its property; protect Forest Service employees; and protect the Forest resources and property

The visitor, whenever possible, should have an enjoyable experience. Therefore, prevention of criminal violations will be given first priority Aggressive action also will be taken to discover and investigate violations of laws.

The TNF will continue cooperative law enforcement agreements with State and local authorities. Forest officers also will cooperate with and aid State, local, and Federal agencies to execute their agency responsibilities

All employees are responsible for initiating appropriate action when they become aware of violations. Appropriate action is dependent on the level of law enforcement training completed by the individual employee. Law enforcement activity under all alternatives will require additional numbers of employees qualified as criminal investigators, law enforcement officers, or Level IV Forest officers

16 Minerals. Process notices of intent, plans of operation, and responses to requests for prospecting permits and mineral leases with special emphasis for requests involving energy minerals.

Impose reasonable conditions in mineral extraction plans of operation to protect surface resources and to reclaim disturbed areas consistent with the statutory rights of claimants, leaseholders, and permittees.

- 17 Range Protect, use, and improve both permanent and transitory range for livestock grazing.
- Continue the Federal cooperative predator control program to protect livestock
- Allocate forage to wildlife to satisfy wildlife policies.
- Improve ranges and implement grazing systems to protect riparian areas.
- In the Granite Chief Wilderness, implement only extensive grazing systems to maintain forage production while maintaining the wilderness attributes.
- 18 Recreation. Continue to manage existing **sites** for developed recreation. Charge fees where allowed by law.
- Favor OHV trail development over indiscriminate cross-country use
- 19 Research. Continue to manage Onion Creek Experimental Forest, Foresthill Tree Improvement Center, and Elliott Ranch as research areas.
20. Cooperative Studies. Manage the Sagehen Basin to provide for cooperative studies that emphasize wildlife, timber management, and other multiple use relationships between the University of California at Berkeley and the TNF.
21. Riparian. Maintain the riparian habitat and an effective filtration strip adjacent to streamcourses and lakes
- Maintain perennial stream temperatures by limiting removal of shade-casting vegetation.
- Off-highway use will be eliminated except on designated routes and stream crossings.
22. Sensitive Plants. Plan vegetation management practices to protect or enhance sensitive plant species.
23. **Silvicultural** Systems. The PSW Regional Guide established five criteria for selection of silvicultural systems to meet long-term resource management objectives. Appendix I compares even-age and uneven-age management on the TNF with criteria described in the Regional Guide.
24. **Soils** As determined through project analysis, improve soil productivity on forest land currently significantly altered
25. Timber. Progress toward a regulated Forest condition by emphasizing regeneration of stands using clearcutting and shelterwood cutting
- Schedule regeneration harvests when stands have generally reached culmination of mean annual increment, and disperse harvest openings.
- Consider use of all logging systems, and base selection on silvicultural needs, resource protection, feasibility, and costs
- Continue to implement the TNF's genetic tree improvement program following the PSW Regional Tree Improvement Master Plan
- Eliminate all existing reforestation needs within 5 years as funding becomes available
- Reforest all newly created openings within 5 years of final regeneration cutting.
- Eliminate timber stand improvement (release, thinning, or both) needs for identified young conifer stands within the first decade.

26. Water. Maintain water quality where it meets or exceeds State objectives. Strive to improve water quality where it is below State objectives

Protect established snow courses and related hydrometeorological data sites from disturbances that will affect snow accumulation or measurement.

Implement Best Management Practices (BMPs) to meet water quality objectives and to maintain and improve the quality of surface water on the Forest. Methods and techniques for applying the BMPs will be identified during project-level environmental analyses and incorporated into the associated project plan and implementation documents. (See Plan Appendix E.)

Reduce sediment from treatable but deteriorating lands

Limn intensive management on about **11,500** acres identified in a declining hydrologic condition. Allow this land to recover naturally.

In all alternatives, protect and restore the deteriorating Carman Valley Watershed

27. Wild, Scenic, and Recreation **Rivers**. Continue to manage the **5,788** acre North Fork American Wild River as designated by Congress. These acres have been withdrawn from timber production and mineral appropriation.

28. Wilderness Manage the Granne Chief area as wilderness.

MANAGEMENT PRESCRIPTIONS AND MANAGEMENT AREAS

A management prescription is a grouping of similar and compatible practices, all of which have the same management emphasis. Fifteen management prescriptions (emphases) are used on the Tahoe National Forest. Within one management emphasis, a range of management intensities is possible. For example, all the water-oriented recreation activities are grouped under management prescription 4. Similarly, the emphasis of management prescription 15 is 'to manage for a predominantly natural-appearing landscape and late successional wildlife habitat'; within this emphasis, however, a full range of timber management practices (intensities) is allowed.

A management area is a geographically distinct area managed under one management prescription (emphasis). Several areas on the Forest may be assigned the same management prescription, but if they are physically separate units, they are different management areas. Likewise, though several management areas may have the same prescription, the intensity of the practices may vary between the areas. The number of management areas will vary by alternative (depending on the prescriptions assigned). Under the preferred alternative, there are **106** management areas (see the Forest Plan, Chapter V, for examples of management area direction)

The alternatives in this **EIS** vary by theme and management emphasis to attain certain multiple use, or other, goals and objectives. Only one management prescription was assigned to a management area in each alternative; some management prescriptions may not apply in a particular alternative.

In addition to the descriptions contained in the next subsection of this EIS, each of the alternatives is shown on a map contained in the Maps packet that accompanies this document. The maps show the spatial distribution of the management prescriptions selected for each alternative. The acres by management prescription assignment are summarized by alternative in Table 2.11 later in this chapter.

Management prescriptions apply only to existing National Forest System land. Land acquired after January 31, 1984, will be managed in accordance with the management prescriptions for the area within which they occur.

Each management prescription's theme and objectives is summarized below

- 1 Theme The theme is to manage the designated Granite Chief area as wilderness. Manage for dispersed recreation. Manage grazing under extensive use This land is unsuited for timber production.
- Objective Recreation and scenic values will be emphasized. Road access to trailheads for this area will be provided, transportation within this area will be restricted to nonmotorized travel. Some of the specific objectives include the following.
- a. Primitive recreation opportunities will be abundant.
 - b. **No** recreation facilities will be available.
 - c. Trails will be constructed throughout the area and no motorized travel will be permitted.
 - d. The VQO will be to maintain a pristine environment.
 - e. **No** direct fish and wildlife habitat improvement will occur, but there will be indirect management for the maintenance of existing species.
 - f. Range will be extensively managed for grazing of domestic livestock.
 - g. Timber will not be harvested or managed.
 - h. The area will be withdrawn from entry under the mining laws; however, operations on existing valid claims can continue
- 2 Theme. The theme is to retain a near-natural appearing forest environment while also producing some forage and water. Manage for dispersed nonmotorized recreation. Grazing is permitted. Low standard roads may be developed for hawesting, but are closed to public vehicle use Land is unsuited for regulated timber production
- Objective Scenic and recreation values will be emphasized. A limited transportation system may be developed. Forest resources will be managed to achieve a range of multiple use objectives and outputs. **Some** of the specific objectives include the following
- a. Modification of vegetation and landforms will not be visually evident.
 - b. Recreation opportunities will be provided in a near-natural environment.
 - c. No motorized recreation use will be permitted
 - d. Wildlife habitat will be managed to emphasize species that require late successional stages.
 - e. Fish habitat will be maintained.
 - f. Timber will be managed on an unregulated basis with **some** salvage and sanitation harvesting.
 - g. Range will be extensively managed for domestic livestock.
 - h. Mineral exploration will generally be permitted.

- 3 Theme. The theme is to produce a moderate level of commodities while enhancing or emphasizing other selected resources. Manage for dispersed motorized recreation.

Allow regulated timber harvesting, subject to visual and recreation constraints and maintenance of stand production. Range will be extensively managed. Roads are developed to serve timber harvesting.

Objective. Limited quantities of timber, forage, and water will be produced, recreation and scenic values will be emphasized. A good transportation system will be developed for these areas, including both roads and trails. Forest resources will be managed to achieve a range of multiple use objectives and outputs. Some of the specific objectives include the following:

- a. Recreation opportunities will be provided where there is some modification to the natural environment.
- b. Off-highway vehicles will be permitted on designated routes only.
- c. Modification of the vegetation and landform will be visually subordinate to the landscape.
- d. Wildlife habitat will be managed to emphasize species requiring early and midsuccessional vegetative stages.
- e. Direct improvements to enhance fishery habitat will be used to increase fish numbers.
- f. Timber will be managed to achieve a low level of production using special cutting practices, salvage, and some sanitation harvesting.
- g. Range will be extensively managed for livestock.
- h. Mineral exploration will generally be permitted.

- 4 Theme. The theme is to provide water-oriented recreational opportunities. Manage for developed recreation use around reservoirs and lakes. Maintain and upgrade developed facilities. Maintain visual quality background for the recreation users. Allow vegetative management, including regulated timber harvest, only when compatible with recreation and visual objectives and maintenance of stand vigor. Provide interpretive services and facilities where appropriate.

Objective. Developed sites with many facilities, including water, toilets, tables, fire rings, boat ramps, etc., will be provided within these areas. Good road access will be provided. Forest resources will be managed for developed recreation objectives and outputs. Some of the specific objectives include the following:

- a. Developed recreation facilities will be provided
- b. Off-highway vehicles will be restricted to designated routes.
- c. Modification of the vegetation and landform for recreation facilities will be visually evident, but vegetation disturbance will be minimized.
- d. Some wildlife will occupy these areas (i.e., squirrel, quail, deer, etc.), but habitat effectiveness will be limited because of human disturbance.
- e. Direct improvements to enhance fishery habitats will be used to increase fish numbers.
- f. Timber will be harvested on a regulated basis using special cutting practices such as the salvage of dead, diseased, or hazardous trees.

- g Range will be extensively managed for domestic **livestock**.
- h A large portion of these areas has been withdrawn from mineral entry to protect the reservoirs and recreation developments. Continued protection of these facilities during the FLPMA review process will be considered.

5 Theme. The theme is to establish representative vegetation and geologic areas for scientific and educational research. Manage for research and special interest purposes. Also establish SIA's to protect special or unique geologic, ecologic, or cultural features. Other uses permitted when not in conflict with research or protection objectives. Timber harvest would be unregulated

RNA Objective. Some of these areas will be components of the Research Natural Area system. These are to be located in the **best** representative vegetation type and will be maintained in a natural state, allowing natural vegetation succession to occur. Modification of the environment will be very limited

- a. There will **be** few roads or trails.
- b. Recreation opportunities will be consistent with research natural area objectives. Recreational use will be discouraged.
- c. **The** area is unsuited for regulated timber harvest. Domestic livestock grazing will be permitted when needed to perpetuate the desired vegetation in the RNA.
- d. Motorized vehicle use will be **prohibited**.
- e. These areas will be proposed for mineral withdrawal

SIA Objective. Some of the areas will be special interest areas where special or unique geologic, ecologic, or cultural features are located and will be managed for their special values and public appreciation. Modification of the environment will be limited.

- a. There will be few roads. Trails will **be** developed appropriate for public enjoyment of special features.
- b. Recreation opportunities will be consistent with special interest area purposes. Recreation use will be encouraged as long as use is consistent with special interest values.
- c. Timber harvesting and domestic livestock grazing will be permitted if SIA objectives can be met.
- d. Motorized vehicle use will be **prohibited or** limited, depending on resource needs.
- e. These areas will be proposed for mineral withdrawal.

6 Theme. The theme is to manage as a classified Wild River, in accordance with the North Fork American Wild River Management Plan and as stated in Section 10(a) of the Wild and Scenic River Act of 1968. The fisheries will be managed as stated in the Cooperative Habitat Management Plan for the river. These lands are unavailable for forage and timber production and have been withdrawn from mineral appropriation since 1975.

Objective. Section 10(a) of the Act states as follows

'Each component of the National Wild and Scenic Rivers system shall be administered in such a manner **as** to protect and enhance the values which caused it to be included in said system without, insofar as is consistent therewith, limiting other uses that do not substantially interfere with public use and enjoyment of these values. In such administration primary emphasis shall be given to protecting its aesthetic, scenic, historic, archaeological, and scientific features. Management plans for any such

component may establish varying degrees of intensity for its protection and development, based on the special attributes of the Area."

- 7 Theme. The theme is to improve fish and wildlife harvest species habitat while producing other commodities. Allow grazing if not conflicting with wildlife. Restrict transportation use to meet wildlife objectives. Harvest timber on a regulated basis.

Objective. Waterfowl and deer habitat values will be emphasized. Limited quantities of timber and forage will be produced. A limited transportation system will be developed for these areas. Forest resources will be managed to achieve a range of multiple use objectives and outputs. Some of the specific objectives include the following:

- a. Wildlife-oriented recreation opportunities will be enhanced.
- b. Wildlife habitat will be managed so that improvement for deer and waterfowl will be emphasized and other species, including fish, will be maintained.
- c. Off-highway vehicles will be restricted, including both roads and trails
- d. Timber will be managed for a moderate level of production using a wide range of silvicultural methods
- e. Range will be extensively managed for domestic livestock subordinate to wildlife objectives
- f. Mineral exploration will generally be permitted

- 8 Theme. The theme is to retain a natural-appearing forest environment while also producing some timber, forage, and water. Manage for visual attractiveness as viewed from major travel routes. Allow uses compatible with adopted visual quality objectives. Provide interpretive services and facilities where appropriate. Allow regulated timber harvest.

Objective. Scenic and recreation values will be emphasized. A transportation system will be developed, including both roads and trails. Forest resources will be managed to achieve a range of multiple use objectives and outputs. Some of the specific objectives include the following:

- a. Modification to the vegetation and landform will not be visually apparent.
- b. Recreation opportunities will be provided in a natural environment
- c. Off-highway vehicles will be restricted.
- d. Wildlife habitat will be managed to emphasize the indicator species associated with late successional vegetation
- e. Fishery habitat will be maintained.
- f. Timber will be managed at a low level of production through application of some regeneration, salvage, and sanitation harvesting
- g. Range will be extensively managed for domestic livestock.
- h. A portion of the area is withdrawn from mineral entry
- i. Additional withdrawals will be proposed to protect valuable improvements or resources

- 9 Theme. The theme is to maintain watershed integrity. Manage for watershed protection and improvement. Allow other resource uses when compatible with water quality objectives. Provide no

new developed recreation facilities. Stabilize those roads which contribute to watershed degradation. Restrict off-highway vehicle uses. Allow regulated timber harvest.

Objective. Streamside management zones (SMZ's) are unsuited for timber production. Other lands will be managed for a moderate level of timber production. Some of the specific objectives include the following:

- a. Forage will be intensively managed for livestock production
- b. Waterfowl and deer habitat will be enhanced
- c. Watershed restoration will be emphasized
- d. Mineral exploration will generally be permitted.

10 Theme. The theme is to maintain land and resource values necessary to retain a high value for exchange. The land is unsuited for regulated timber production.

Objective. Forest resources will be managed to achieve limited multiple use objectives and outputs. These lands are available for exchange. Some of the specific objectives include the following:

- a. Dispersed recreation opportunities and off-highway vehicle use will be permitted.
- b. Fish and wildlife habitat will be managed for species presently occupying the sites, but no direct improvements will be done
- c. Modifications of the vegetation and landform will not be visually evident.
- d. Extensive range management for domestic livestock will be practiced
- e. Timber may be harvested on an unregulated basis for salvage or sanitation of dead, diseased, or hazardous trees.
- f. Cultural resource inventory evaluation and mitigation will be high priority.

11 Theme The theme is to provide winter recreation opportunities. Manage for Nordic and alpine ski potential with other compatible uses. Timber harvest would be unregulated on most areas.

Objective. Facilities, including water, toilets, ski lodges, ski runs, parking areas, etc., may be provided within most of these areas. Year-round road access to the developed sites will be available. Forest resources will be managed for developed alpine and Nordic ski recreation objectives. Some of the specific objectives include the following:

- a. Developed ski facilities will be provided.
- b. Facilities and vegetative disturbance will usually be visually evident.
- c. Some wildlife will occupy these areas, but wildlife habitat management will not be emphasized.
- d. Fishery habitats will be maintained.
- e. Timber may be harvested in the unregulated areas (alpine) for salvage and sanitation of dead, diseased, or hazardous trees: on the Nordic areas, timber harvesting will include a wide range of practices.
- f. Grazing will be permitted under extensive management.
- g. Mineral exploration will generally be permitted.

- 12 Theme. The theme is to emphasize land uses for facilities such as pipelines, transmission lines, and administrative sites. Manage for primary use as allowed under special-use permit and administrative uses. Other compatible uses allowed. Timber harvest would be unregulated.

Objective. Some specific objectives of these developed sites, which have many facilities, include the following:

- a. Ensure the safe maintenance of pipelines, powerlines, buildings, fences, electronic transmission equipment (antennas, generators, etc.), roads, and other transportation facilities
- b. Modification of the vegetation will usually be evident
- c. Some wildlife will be present, however, they will be limited because of human disturbance.
- d. All areas will have road access.
- e. Recreation use will not be encouraged
- f. Timber harvesting, livestock grazing, and off-highway vehicle use will be restricted.
- g. Mineral exploration may be permitted.

- 13 Theme. The theme is to intensively manage timber and forage resources. Emphasize regulated timber production utilizing even-age or uneven-age silvicultural systems on available, capable, and suitable lands. Grazing would be managed under both intensive and extensive systems.

Objective. Timber, forage, and water will be intensively managed. A transportation network will be developed for these areas, specifically, roads for timber and range management access. Some of the specific objectives include the following:

- a. Timber will be managed for maximum economically efficient production using a full range of silvicultural methods.
- b. Perennial range will be intensively managed for forage production; transitional range will be extensively managed.
- c. Recreation opportunities requiring a roaded, natural-appearing environment will be enhanced, and off-highway vehicle use will be permitted
- d. Geothermal and mineral exploration will be permitted.
- e. Wildlife habitat will be managed to emphasize maintenance or improvement for species requiring early or mid-successional stages.
- f. Direct improvements to enhance fishery habitat will be used to manage fish numbers.
- g. Modification of vegetation and landform will be apparent.

- 14 Theme. The theme is to provide areas for cooperative studies emphasizing wildlife and timber resource management relationships. Manage for fish and wildlife cooperative research and a regulated flow of timber products. Maintain the existing water quality and flow needs for aquatic ecosystem research

Objective A moderate level of timber and forage will be produced Recreation in a near-natural environment will be enhanced because of the vegetation variety, scenic quality, and natural features. Generally, adjacent areas have good road access to these management areas, and many have trail access through them. Some of the specific objectives include the following.

- a. Habitat will be managed for a variety of wildlife and fish species selected for the cooperative research objectives.
- b. Off-highway vehicle use will generally be restricted.
- c. Ranges will be intensively and extensively managed for domestic livestock and grazing
- d. The areas will be open to geothermal leasing and mineral entry.

- 15 Theme The theme is to manage for a predominantly natural-appearing landscape and late successional wildlife habitat, using a full range of timber management practices

Objective Moderate quantities of timber, forage, and water will be produced; recreation and scenic values will be emphasized A moderate transportation system will be developed. Forest resources will be managed to achieve a range of multiple use Objectives. Some of the specific objectives include the following:

- a. Timber will be intensively managed to achieve a predominantly natural-appearing landscape and late successional wildlife habitat.
- b. Long rotation even-age management using a full range of silvicultural methods will be implemented
- c. Modification of the vegetation and landform will remain visually subordinate or unnoticed by major travel route observers.
- d. Perennial range will be intensively managed for forage production. Transitory range will be extensively managed.
- e. Recreation opportunities requiring a roaded, natural-appearing environment will be enhanced.
- f. Off-highway vehicle use will be permitted
- g. An intensive trail system will be developed to enhance dispersed recreation.
- h. Wildlife habitat will be managed to emphasize maintenance or improvement for species requiring late successional vegetation
- i. Fishery habitat will be maintained
- j. Geothermal and mineral exploration will be permitted

INDIVIDUAL ALTERNATIVE DESCRIPTIONS

Six of the alternatives formulated were selected for detailed analysis to address the specific issues or concerns and the requirements of laws, regulations, or policies. The alternatives differ from each other in their themes, the amount of commodity and activity production targets, the environmental effects resulting from implementation (Chapter 4), and in the total acres and land allocated to a management prescription (see Table 2.11 - Acres by Management Prescription by Alternative, and the alternative maps in the map packet). More detailed information on the alternatives, such as resource outputs, costs, environmental effects, and acres allocated to specific management areas and prescriptions, is displayed in the next Section F, Comparison of Alternatives.

For each alternative described in this section, the following information is presented

Theme

This describes what would be achieved through management of the Forest. Included is the philosophy or management emphasis distinguishing it from other alternatives. Specific issues, concerns, and opportunities that are emphasized are also displayed. The theme guided the development of the FORPLAN assumptions. (See Table 2.21 - Comparison of Alternatives by Major TNF Issues, Concerns, and Opportunities - for specific discussions of the issues.)

Resource Program Direction

This describes the resource program emphasis that would be implemented and any direction unique to the alternative.

The Environment to be Created

This describes what the Forest would look like in the year 2030 if the alternative were implemented totally.

Average Annual Outputs by Decade

Average annual resource outputs for each alternative are displayed for the next 5 decades. Each alternative described in detail has a schedule of resource outputs for 16 decades (planning horizon) which is documented in the planning records. Timber harvest was examined for another 11 decades beyond the fifth to ensure the nondeclining yield of wood fiber production as required by NFMA regulations.

ALTERNATIVE PRF (Preferred)

1. Theme

Achieve a broad range of commodity and amenity benefits that meet short-term needs while retaining long-range management options.

Emphasize a mixture of commodity production and amenity benefits that maximizes net public benefits while responding to the planning issues.

Specific issues emphasized are (#6) forage, wood, and soils; (#8) recreation, and (#9) fish and wildlife habitat

2. Resource Program Direction

- a. Recreation. Provide a program of developed (including downhill skiing) and dispersed recreation which would meet projected demand by expanding existing facilities before developing new facilities. Expand visitor information service and interpretive facilities and programs.

Manage land surrounding major reservoirs for water-oriented recreation. Manage Grouse Lakes as a motor vehicle closure area.

Expand opportunities for the private sector to operate campgrounds under special-use permit. Develop and manage at full standard the following potential recreation sites: Boca, Prosser, Stampede, French Meadows, Jackson Meadow, Sugar Pine, and Bullards Bar Reservoirs; Truckee and North Yuba Rivers areas, Sierra Buttes; and Interstate Highway 80 area. All other potential recreation sites would be available for other multiple uses during the first decade.

Provide 67,500 acres of SPM and 74,000 acres of SPNM ROS-class recreation opportunities.

Develop trail systems to accommodate motorized and nonmotorized recreation use, including use by the disabled. Provide designated routes for off-highway vehicle use in dispersed recreation areas.

Provide for cultural resource interpretation when planning for recreation facilities.

Manage for visual quality objectives (VQO's) of retention and partial retention along most major recreation roads and trails and around major recreation areas. Outside of the more visually sensitive areas, establish visual quality direction which would be compatible with the use of the timber resource. Emphasize visual qualities along major access roads, the North Fork American Wild River, the Granite Chief Wilderness, and in concentrated recreation use areas.

- b. Research Natural Areas. Recommend to the Chief the establishment of Babbitt Peak (1,061 acres), Lyon Peak/Needle Lake (700 acres), and Sugar Pine Point (625 acres) as RNA's.
- c. Special Interest Areas. The following SIA's are established: Placer County Big Tree Grove (346 acres), Devils Postpile (69 acres), Glacier Meadow (84 acres), Grouse Falls (220 acres), Sagehen Headwaters (79 acres), Meadow Lake (58 acres), and Mason Fen (30 acres). These areas would be designated by the Regional Forester.
- d. Wilderness. Manage Granite Chief as wilderness (18,705 acres).
- e. Fish and Wildlife. Use the species recovery and management plans as guides for managing Federal threatened and endangered species. Manage a network of 33 spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Give

additional attention to Forest Service sensitive species, State-listed threatened and endangered species, harvest species, State 'Species of Special Concern', and species groups associated with important wildlife habitats

- f. **Forest Pests.** Implement a high level of integrated pest management over a moderate forested acreage suitable for timber production
- g. **Range.** On about 75 percent of the capable, available, and suitable permanent range, implement range improvement practices such as seeding, fencing, and water developments to facilitate improved grazing systems such as deferred grazing and rest rotation. On the transitory range, implement vegetative management practices in harmony with other resource objectives and needs on the existing and potential forage created by timber management practices, both inside and outside of existing allotments, by developing new and improved grazing systems and techniques. Study range management practices on low-site eastside pine lands that would improve vegetation condition and maintain site productivity in a dual-use management setting.
- h. **Timber.** Apply intensive timber management practices to forest lands scheduled for high timber yields. On all lands capable, available, and suitable for timber production, obtain timber yields while maintaining other resource values. Timber yield calculations are based upon the nondeclining even-flow timber policy. The even-age silvicultural system would be the principal method for regulating lands suitable for timber production. Apply uneven-age management in five selected compartments to obtain information on the operational needs of a large-scale uneven-age management program.
- i. **Water and Soil.** Maintain water quality at existing levels. Restore water quality on 1,900 acres of stream channels, meadows, roads, old wildfire areas, and priority hydraulic diggings
- j. **Minerals.** The Granite Chief Wilderness is withdrawn from all forms of mineral entry and leasing. Propose withdrawing from mineral entry the RNA's and SIA's, areas of concentrated public use (including potential recreation sites), areas along portions of designated or eligible State scenic highways not previously withdrawn (200 feet from the centerline along Highways 20, and 89 and approximately 400 feet on each side of Interstate 80), and areas 200 feet from the centerline of the Gold Lake Highway
- k. **Land Ownership and Special Uses.** Acquire private land within the Granite Chief Wilderness. Use selected National Forest System lands to acquire other lands which would enhance Tahoe National Forest management

Designate and manage the Donner Pass area as a utility corridor and designate the Galloway site as an electronic site. The Granite Chief Wilderness, North Fork American Wild River, Special Interest and Research Natural Areas are excluded from consideration for utility corridors.
- l. **Facilities.** Construct and maintain roads to access areas suitable for resource management. Maintain facilities at building investment level III; provide for improvement and replacement of existing facilities.
- m. **Fire Management.** Emphasize all small engines and hand crews. Continue fuel treatment at present or greater levels using both engine and hand crews. The specific program organization would consist of the following:
 - o Prevention and detection (40 percent)
 - o Suppression, including fuels management (60 percent).
- n. **Riparian/SMZ.** Apply the Forest requirement (S&G's 46 and 47 and Appendix F) for riparian areas/SMZ's. Timber harvest scheduled from variable width SMZ's (minimum of 100 feet) along perennial streams would be minimal. Scheduled timber yields are also reduced within

variable width **SMZ's** adjacent to intermittent streams where needed to protect channels and water quality.

- o.** Diversity. Provide a minimum of **15** snags per acre in each eastside planning **compartment**. Establish a goal of **20** snags/acre for westside compartments. Also provide a minimum of **30 sq. ft** basal area per acre in hardwood/conifer mix (**3X** and **4X**) and **5 sq. ft** per acre in mixed-conifer stands.

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, range practices, and wildlife habitat improvement would produce a forest of greater diversity than currently exists.

The major change in vegetation by the year **2030** would be the replacement of a portion of the existing timber stands by even-age young growth conifer stands. This alternative would have about **186,940** acres, or **27** percent of the existing forested land, of new timber stands less than **50** years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About **233,200** acres would be managed for timber on a short rotation (**50-120** years). This timber management approach would result in a mosaic of similar sized, even-aged timber stands that differ by 10-year age classes. The larger trees would be 18 to 27 inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management to create and maintain a regulated forest.

Long rotation (**150+** years) even-aged timber management would be applied to about **126,900** acres. Long rotations are necessary to meet the partial retention **VQO's**. This timber management approach would result in a mosaic of even-aged timber stands. The larger trees would be **30** to 40 inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats and scenic quality. This forested pattern would also be intermixed with areas of short-rotation harvest.

About **9,300** acres of timber stands on gentle slopes in five compartments would be managed by group and single tree selection methods. A mixture of tree sizes and ages would occur within these stands. Tree species would tend toward shade-tolerants such as white fir and incense cedar.

The future condition of special management areas, such as streamside management zones, scenic areas, unroaded areas, and noncommercial conifer stands, would most likely be very similar to the existing irregular uneven-aged timber stand structure. Approximately **159,000** acres would reflect this forested condition.

There are **18,705** acres of wilderness, **2,386** acres would be managed as Research Natural Areas and **886** acres would be managed as Special Interest Areas.

The arterial and collector transportation system would be completed.

Existing downhill skiing facilities would be expanded to their maximum capacity. New downhill skiing facilities and key potential developed recreation sites would be developed in response to demand (see Resource Program Direction).

Human-caused changes in natural vegetative patterns would be more evident in the landscape than they are currently. While most highly sensitive areas adjacent to major recreation roads, trails, and use areas would remain natural or predominantly natural in appearance, less conspicuous portions of the Forest would be visually dominated by evidence of human practices.

Semi-primitive nonmotorized and semi-primitive motorized acres would be reduced.

Wildlife species composition would shift slightly from species requiring late successional vegetation to species adapted to early and mid-successional vegetation.

Riparian areas and **SMZ's** would receive a high level of protection. Water quality would remain similar to current conditions.

Range management would provide a vegetative management program that is geared to focus attention on sustained yield of range vegetation to protect the soil and water and provide ecological diversity. On the east side of the Sierra Nevada, 75 percent of the permanent range would be intensively managed, providing forage for 15,800 cattle and sheep. Transitory range among the early successional timber stands (plantations) would increase on the west side of the Sierra. Domestic livestock would be used to reduce competition to the tree seedlings while maintaining particular seral stages for specific wildlife habitat enhancement, providing forage for 5,200 head of cattle and sheep.

TABLE 2.5 - ALTERNATIVE PRF: AVERAGE ANNUAL OUTPUTS BY DECADE

RESOURCE ELEMENT	BASE YEAR		1980 RPA GOALS FOR			DECADES 1/			5
	1982	1990	2030						
RECREATION									
Developed Public (MRVD)	1,388	1,850	2,800	1,976	2,393	2,784	3,129	3,318

ALTERNATIVE CUR (Current Management)

1. Theme

Maintain the current range of commodity and amenity benefits necessary to meet existing individual resource plans.

Continue current management emphasis by maintaining wood-fiber and forage production while providing a mixed program of developed and dispersed recreation opportunities

No special issue is emphasized over another. All issues are addressed to the extent allowed by current direction and budget.

2 Resource Program Direction

- a. Recreation. Develop new and improve existing facilities for dispersed recreation in response to demand. Maintain existing developed recreation sites

Expand existing downhill ski areas within their present boundaries to their maximum capacity. Continue facilities operated by the private sector under special-use permit

Manage land surrounding major reservoirs for water-oriented recreation

Provide about 46,000 acres of SPM and 53,000 acres of SPNM ROS-class recreation opportunities.

Administer off-highway vehicle use and management according to the Off-Highway Vehicle Travel and the Transportation Management Plans

Follow visual quality direction in the Truckee-Little Truckee Rivers and Mohawk Land Use Unit Plans. Determine visual quality objectives (VQO's) on a project basis for the remainder of the Forest using Multiple-Use Management Plan visual zones as guidelines.

- b. Research Natural Areas. Recommend to the Chief the establishment of Babbitt Peak (1,061 acres) as an RNA
- c. Special Interest Areas. The following SIA is established. Placer County Big Tree Grove (346 acres).
- d. Wilderness. Manage Granite Chief as wilderness (18,705 acres).
- e. Fish and Wildlife. Use the recovery and management plans as guides for managing Federal threatened and endangered species. Provide a network of 33 spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Give additional attention to Forest Service sensitive and harvest species.
- f. Forest Pests. Implement a high level of integrated pest management over a large forested acreage suitable for timber production.
- g. Range. On about 25 percent of the permanent rangelands in the eastside pine stands, implement range improvement practices, such as seeding, fencing, and water developments, to facilitate improved grazing systems such as deferred and rest-rotation grazing. On the transitory range, use the existing and potential forage created by timber management practices in harmony with other resource needs and objectives, implement extensive grazing management practices, such as fencing and water.

- h. **Timber.** Manage timber to meet the volume objectives in the Tahoe Timber Management Plan of 1978. All roadless area lands released by the California Wilderness Act of 1984 that are suitable for timber production are available for timber management. Manage timber stands at the intensity and emphasis for each capability area described in the District Multiple-Use and other Unit Plans. Establish harvest priorities and outputs using the even-aged silvicultural system. Timber yield calculations are based upon the nondeclining even-flow timber policy.
- i. **Water and Soil.** Maintain water quality standards. Restore water quality on 500 acres of stream channels, meadows, roads, and old wildfire areas.
- j. **Minerals.** The management direction for minerals that is common to all alternatives applies.
- k. **Landownership and Special Uses.** Respond to opportunities for land exchange or land acquisition in accordance with the current landownership adjustment plans. Continue to evaluate requests for nonrecreation special-uses on a case-by-case basis.
- l. **Facilities.** Emphasize road construction and maintenance to support the timber program. Reconstruct roads with high recreational use. Maintain facilities at building investment level III; provide for improvement and replacement of existing facilities.
- m. **Fire Management.** Maintain a combination of suppression (initial attack), prevention, and detection programs. **Fuels** management would primarily treat fuels created by other resource activities.

No significant changes in the kinds and amount of equipment, people or dollars would be expected. The fire program organization (1982 level) would be as follows:

 - o Prevention and detection (32 percent)
 - o Suppression (51 percent)
 - o Fuel management (17 percent)
- n. **Riparian/SMZ.** Apply the Regional MMR for riparian/SMZ's. This schedules timber harvest at a lower level within the first 100-foot horizontal distance on either side of perennial streams. Streamside zones adjacent to intermittent and ephemeral streams would be managed under the same intensity as their encompassing strata.
- o. **Diversity.** Provide a minimum of 1.5 snags/acre in all planning compartments. Also provide at least 5 sq. ft. basal area in hardwoods in mixed-conifer and hardwood-conifer mixed stands.

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, range practices, and wildlife habitat improvement would produce a forest of greater diversity than currently exists.

The major change in vegetation by the year 2030 would be the replacement of a portion of the existing timber stands by even-age, young growth conifer stands. This alternative would have about 202,500 acres, or 30 percent of the existing forested land, of new timber stands less than 50 years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About 337,200 acres would be managed for timber on a short rotation (50-120 years). This timber management approach would result in a mosaic of similar sized, even-aged timber stands that differ by 10-year age classes. The larger trees would be 18 to 27 inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management to create and maintain a regulated forest.

Long rotation (**150+** years) even-aged timber management would be applied to about **121,200** acres. This timber management approach would result in a mosaic of even-aged timber stands. The larger trees would be 30 to **40** inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats or scenic quality (distant view zones or areas with partial retention **VQOs**), and would be intermixed with areas of short-rotation harvest.

The future condition of special management areas, such as streamside management zones, scenic areas, unroaded areas, and noncommercial conifer stands, would most likely be very similar to the existing irregular uneven-aged timber stand structure. Approximately **146,400** acres would reflect this forested condition.

There are **18,705** acres of wilderness; **1,061** acres would be managed as a Research Natural Area and **346** acres as a Special Interest Area.

The arterial and collector road system would be completed to accommodate timber and recreation activities.

Existing downhill ski facilities would be expanded to their maximum capacity within their present boundaries.

The Forest landscape would have a higher level of unnatural changes in vegetative patterns than it does under existing conditions. Most visually sensitive areas adjacent to major roads or recreation sites would remain natural or predominantly natural, but evidence of human practices would visually dominate most of the Forest.

Habitats produced by this alternative would favor wildlife species adapted to early and mid-successional vegetation.

Riparian areas and **SMZ's** receive the minimum level of protection allowed by Regional planning direction. The percentage of water yield meeting standards would slightly decline from current conditions.

On the east side of the Sierra Nevada, 25 percent of the permanent range would be intensively managed, providing forage for **12,000** cattle and sheep. Transitory range among the early successional timber stands (plantations) would increase on the west side of the Sierra. Domestic livestock would be used to reduce competition to the tree seedlings while maintaining particular seral stages for specific wildlife habitat enhancement, providing forage for **6,000** cattle and sheep.

ALTERNATIVE RPA (1980 RPA)

1. Theme

Achieve the TNF's share of the **1980** RPA Program as defined in the Pacific Southwest Regional Guide. These Program targets are discussed in each resource element below.

Emphasize a mixture of commodities and amenities that meets the assigned targets.

Specific issues emphasized are **(#5)** facilities; **(#6)** forage, wood, and soils, **(#8)** recreation; and **(#9)** fish and wildlife habitat

2. Resource Program Direction

- a. Recreation. Meet the **1980** RPA targets for developed and dispersed recreation by the year **1990**. The developed recreation target is **1,930,000 RVDs**, the dispersed recreation target is **2,610,000 RVD's**. Develop support facilities for both winter and summer dispersed recreation activities. Maintain trail systems to meet dispersed recreation targets.

Continue recreation facilities operated by the private sector under special-use permits. Expand facilities, including developed campgrounds and ski areas, to meet the RPA targets through the year 2030.

Provide about **17,000** acres of SPM and **77,000** acres of SPNM ROS-class recreation opportunities

Manage land surrounding major reservoirs for water-oriented recreation.

Off-highway vehicle use and management would remain basically the same as present, with necessary changes for resource protection

Where possible, meet the visual quality objective targets are based on the initial **VQO's** stated in the Pacific Southwest Regional Guide and Planning Direction. Retention and partial retention would be the VQO targets for most visually sensitive areas along major roads and trails and around recreation facilities

Accelerate cultural resource inventory to achieve a complete Forest inventory by **1995**

Meet the RPA targets of **14** to **16** miles per year for trail construction and reconstruction in the first decade.

- b. Research Natural Areas. Recommend to the Chief the establishment of Babbitt Peak (**1,061** acres) as an RNA
- c. Special Interest Areas. The following SIA is established: Placer County Big Tree Grove (**346** acres).
- d. Wilderness. Manage Granite Chief as wilderness (**18,705** acres).
- e. Fish and Wildlife. Use the species recovery and management plans as guides for managing bald eagles, peregrine falcons, and Lahontan cutthroat trout. Manage a network of **34** spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Give additional attention to Forest Service sensitive species, harvest species, and cavity nesting species.
- f. Forest Pests. Implement a high level of integrated pest management over a large forested acreage suitable for timber production
- g. Range. Implement range improvement practices, such as seeding, fencing, water developments, and other range improvements, on about 80 percent of all capable, available, and suitable permanent

range to achieve an AUM production level 46 percent above the 1981 level as allocated in the Regional Forester's letter of June 1982. The 1980 RPA target is to produce 18,500 AUMs by the year 1990 and 30,400 AUMs by the year 2030. Fully use the transitory range created through timber management practices in harmony with other resource objectives and needs by developing new and improved grazing systems and techniques.

- h. Timber. Apply intensive timber management practices to land available, capable, and suitable for timber production with the objective of attaining the 1980 RPA harvest schedule. The even-age silvicultural system would be the principal method of regulating lands suitable for timber production. Timber yield calculations are based upon the nondeclining even-flow timber policy. The allowable sale quantity of timber is designed to produce at least the following average annual sale quantity levels.

1981-1990 - 164.5 MMBF
1991-2000 - 186.0 MMBF
2001-2030 - 198.4 MMBF

- i. Water and Soil. Rehabilitate 2,500 acres of declining watershed through the application of manual and structural practices. The 2,500 acres is a more accurate estimate of maximum treatable acres than the 1980 RPA target.
- j. Minerals. The Granite Chief Wilderness is withdrawn from all forms of mineral entry and leasing. Propose withdrawing from mineral entry the RNAs and SIA's, areas of concentrated public use, and areas along portions of designated or eligible State scenic highways not previously withdrawn (200 feet from centerline along Highways 20, 49, and 89 and approximately 400 feet on each side of Interstate 80).
- k. Landownership and Special Uses. Meet long-range goals of RPA which are to (1) mark and post 2,700 miles of Forest boundary by the year 2020 to complete the RPA backlog and (2) resolve existing occupancy trespass by the year 2000. Acquire all private land within the Granite Chief Wilderness.

The 1980 RPA Program targets for land purchase and acquisition on the TNF ranged from 2,300 to 3,000 acres per year for the first decade. The RPA targets were based on an active land acquisition program in the North Fork American Wild River. Recent, very restrictive county zoning and a reduced Land and Water Conservation Fund has lessened both the need for and the expectation of funding for major purchases in this area. The targets under this alternative call for land purchase and acquisition of about 250 acres per year in the first decade.

- l. Facilities. Construct and maintain roads to access areas for resource management to meet RPA goals. Maintain facilities at building investment level III. Provide for improvement and replacement of existing facilities.
- m. Fire Management. Emphasize all small engines and hand crews. Continue fuel treatment at present or greater levels using both engine and hand crews. The specific program organization would consist of the following:
 - o Prevention and detection (40 percent).
 - o Suppression, including fuel management (60 percent).
- n. Riparian/SMZ. Apply the Regional MMR for riparian areas/SMZ's. This schedules timber harvest at a lower level within the first 100-foot horizontal distance on either side of perennial streams. Streamside zones adjacent to intermittent and ephemeral streams would be managed under the same intensity as their encompassing strata.
- o. Diversity. Provide a minimum of 1.5 snags/acre in all eastside planning compartments. Establish a goal of 2.0 snags/acre for all westside compartments. Also provide at least 5 sq. ft. basal area of hardwoods per acre in mixed-conifer and hardwood-conifer mix stands.

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, range practices, and wildlife habitat improvement would produce a forest of greater diversity than currently exists.

The major change in vegetation by the year **2030** would be the replacement of a portion of the existing timber stands by even-age young growth conifer stands. This alternative would have about **225,400** acres, or **33** percent of the existing forested land, of new timber stands less than 50 years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About **378,200** acres would be managed for timber on a short rotation (**50-120** years). This timber management approach would result in a mosaic of similar sized, even-aged timber stands that differ by 10-year age classes. The larger trees would be **18** to **27** inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management practices to create and maintain a regulated forest.

Long rotation (**150+** years) even-aged timber management would be applied to about 80,800 acres. This timber management approach would result in a mosaic of even-aged timber stands. The larger trees would be **30** to **40** inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats and scenic quality goals (partial retention VQO's) and would be intermixed with areas of short-rotation harvest.

The future condition of special management areas, such as streamside management zones, scenic areas, unroaded areas, and noncommercial conifer stands would most likely be very similar to the existing irregular uneven-aged timber stand structure. Approximately **121,700** acres would reflect this forested condition.

There are **18,705** acres of wilderness; 1,061 acres would be managed as a Research Natural Area and 346 acres as a Special Interest Area.

The arterial and collector transportation system would be completed. Local roads would be managed for dispersed recreation use.

Existing downhill skiing facilities and developed campgrounds would be expanded to meet RPA targets. Dispersed recreation and support facilities also would be developed to meet RPA targets.

Human-caused changes in vegetative patterns would be more evident in the landscape than they are currently. **Most** lands seen from major roads, trails, and recreation facilities would appear natural or predominantly natural, but most other areas would be visually dominated by the effects of human practices.

Wildlife species composition would shift from species requiring late successional vegetation to species adapted to early and midsuccessional vegetation.

Riparian areas and **SMZ's** would receive the minimum level of protection allowed by Regional planning direction. The percentage of water yield meeting standards would slightly decline from current levels.

Range management would provide a vegetative management program that is geared to focus attention on sustained yield of range vegetation to protect the soil and water and provide ecological diversity. On the east side of the Sierra Nevada, 80 percent of the permanent range would be intensively managed, providing forage for **22,900** head of cattle and sheep. Transitory range among the early successional timber stands (plantations) would increase on the west side of the Sierra. Domestic livestock would be used to reduce competition to the tree seedlings while maintaining particular seral stages for specific wildlife habitat enhancement, providing forage for **5,400** head of cattle and sheep.

ALTERNATIVE CMD (Commodity)

1. Theme

Achieve high timber commodity outputs while providing amenity benefits at economically efficient levels

Emphasize intensive management of the timber resource on forest lands capable of producing at least 20 cubic feet of timber per acre per year. Resolve in favor of the timber resource any conflicts with other commodity or amenity resources.

The specific issue emphasized is (#6) forage, wood, and soils and (#8) recreation.

2. Resource Program Direction

- a. Recreation. Do not expand existing or develop new recreation sites, including ski areas, on capable forest land. Continue existing special-use permits for facilities operated by the private sector.

Restrict OHV travel to avoid conflicts with timber management or damage to capable forest land.

Provide around 45,000 acres of SPM and 52,000 acres of SPNM dispersed recreation opportunities.

Establish visual quality direction which would be compatible with the use of the timber resource. The predominant visual quality objective throughout the Forest would be modification.

- b. Research Natural Areas. Recommend to the Chief the establishment of Babbitt Peak (1,061 acres) and Sugar Pine Point (625 acres) as RNAs.
- c. Special Interest Areas. The following **SIA's** are established: Placer County Big Tree Grove (346 acres), Sagehen Headwaters (79 acres), Devils Postpile Geologic Area (69 acres), Glacier Meadow Geologic Area (84 acres), Grouse Falls Scenic Area (220 acres), Meadow Lake Cultural Area (58 acres), and Mason Fen (30 acres).
- d. Wilderness. Manage Granite Chief as wilderness (18,705 acres).
- e. Fish and Wildlife. Use the recovery and management plans as guides for managing Federal threatened and endangered species. Provide a network of 33 spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Give additional attention to Forest Service sensitive and harvest species.
- f. Forest Pests. Implement a high level of integrated pest management over a large forested acreage suitable for timber production.
- g. Range. On about 75 percent of the capable, available, and suitable permanent range, implement range improvement practices, such as seeding, fencing, and water developments, to facilitate improved grazing systems such as deferred grazing and rest rotation. On the transitory range, fully use in harmony with other resource objectives and needs the existing and potential forage created by timber management practices, both inside and outside of existing allotments, by developing new and improved grazing systems and techniques. Study range management practices on low-site eastside pine lands that would increase forage production and maintain site productivity.
- h. Timber. Practice intensive timber management on capable, available, and suitable forest land. Timber yield calculations are based upon the nondeclining even-flow timber policy. Place emphasis on site-specific silvicultural prescriptions utilizing all treatments where appropriate. Clearcutting will be limited to 2,300 acres per year and uneven-age management group selection will be used on about 39,000 acres (about 250 acres per year).

- i. **Water and Soil.** Restore water quality on 500 acres of forest lands where productivity is declining, for example, on old wildfire sites
- j. **Minerals.** Allow no saleable mineral development on land available, capable, and suitable for timber harvesting. Do not recommend developing leaseable prime forest land. Propose withdrawing from mineral entry the Research Natural and Special Interest Areas
- k. **Lands.** Direct land adjustment activities to acquire capable forest land and recreation and Special Interest Areas

Evaluate nonrecreation special-uses on a case-by-case basis to minimize conflicts with timber management objectives
- l. **Facilities.** Expand the transportation system into unroaded capable forest land. Maintain the local road system for multiple reentries to aid intensive timber management.

Maintain facilities at building investment level IV; provide for minimum construction of new facilities.
- m. **Fire Management.** Emphasize all small engines and hand crews. Continue fuel treatment at present or greater levels using both engine and hand crews. The specific program organization would consist of the following:
 - o Prevention and detection (40 percent).
 - o Suppression, including fuel management (60 percent).
- n. **Riparian/SMZ.** Apply the Regional MMR for riparian areas/SMZ's. This schedules timber harvest at a lower level within the first 100-foot horizontal distance on either side of perennial streams. Streamside zones adjacent to intermittent and ephemeral streams would be managed under the same intensity as their encompassing strata
- o. **Diversity.** Provide a minimum of 1.5 snags per acre in all planning compartments. Retain at least 5 sq. ft. per acre basal area in hardwoods in hardwood-conifer mixed stands.

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, range practices, and wildlife habitat improvement would produce a forest of greater diversity than currently exists.

The major change in vegetation by the year 2030 would be the replacement of a portion of the existing timber stands by even-age young growth conifer stands. This alternative would have about 235,160 acres, or 34 percent of the existing forested land, of new timber stands less than 50 years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About 269,200 acres would be managed for timber on a short rotation (50-120 years). This timber management approach would result in a mosaic of similar sized, even-aged timber stands that differ by 10-year age classes. The larger trees would be 18 to 27 inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management to create and maintain a regulated forest.

Long rotation (150+ years) even-aged timber management would be applied to about 150,400 acres. This timber management approach would result in a mosaic of even-aged timber stands. The larger trees would be 30 to 40 inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats and scenic quality and would be intermixed with areas of short rotation harvest.

Uneven-age management by group selection would be applied to 39,700 acres. Stands would have trees of a variety of ages and sizes in small groups. Tree species composition would tend toward shade-intolerant species such as white fir and incense-cedar.

The future condition of special management areas, such as streamside management zones, unroaded areas, and noncommercial conifer stands, would most likely be very similar to the existing irregular uneven-aged timber stand structure. Approximately 132,600 acres would reflect this forested condition.

There are 18,705 acres of wilderness, 1,686 acres would be managed as Research Natural Areas and 886 acres as Special Interest Areas

The arterial and collector transportation system would be completed.

Downhill skiing facilities would be expanded to their maximum capacity concentrating on expanding existing areas first then new sites that would not have high timber values

The Forest vegetation would appear more greatly changed than it does at present. The landscape would reflect more managed vegetative alterations with even-aged timber stands. Modifications caused by human practices would dominate almost all of the Forest, except along the scenic highways.

Wildlife species composition would shift from species requiring late successional forest habitat to species adapted to early and midsuccessional vegetation.

Riparian areas and SMZs would receive the minimum level of protection allowed by Regional planning direction. The percentage of water yield meeting standards would slightly decrease from current levels

Range management would provide a vegetative management program that is geared to focus attention on sustained yield of range vegetation to protect the soil and water and provide ecological diversity. On the east side of the Sierra Nevada, 75 percent of the permanent range would be intensively managed, providing forage for 19,200 head of cattle and sheep. Transitory range among the early successional timber stands (plantations) would increase on the west side of the Sierra. Domestic livestock would be used to reduce competition to the tree seedlings while maintaining particular seral stages for specific wildlife habitat enhancement, providing forage for 5,200 head of cattle and sheep.

ALTERNATIVE NMK (Nonmarket)

1. Theme

Achieve high output levels of amenity (nonmarket) resources with commodity (market) outputs at a production level that will not result in environmental degradation.

Emphasize amenity resources, such as fish and wildlife, water quality, and recreation. Resolve in favor of the amenity resources any conflicts with market resources

Specific issues emphasized are (#7) water, (#8) recreation, and (#9) fish and wildlife habitat

2. Resource Program Direction

- a. Recreation. Maintain existing public recreation and interpretive facilities and programs. Provide additional developed and dispersed facilities for Special Interest Areas and other amenity resources.

Continue existing private recreation facilities operated under special-use permit. Expand or issue new permits when consistent with amenity values. Continue existing downhill ski facilities under special-use permit. Expand or develop new ski and recreation facilities to meet demand where other amenity values are not reduced. For example, avoid existing late successional vegetation and visually sensitive areas.

Maintain existing trail system. Expand system to distribute dispersed recreation visitors and to access wilderness, semi-primitive nonmotorized (SPNM) areas, and Special Interest Areas.

Manage land surrounding major reservoirs for water-oriented recreation

Maintain or increase semi-primitive nonmotorized acres of the Recreation Opportunity Spectrum. Manage the following roadless areas released by the California Wilderness Act for dispersed SPNM recreation: North Fork American River, East Yuba, West Yuba, Duncan Canyon, Castle Peak, Grouse Lakes, North Fork Middle Fork American River, Lakes, Middle Yuba, North Lafayette, and Bald Mountain, for a total of about 151,000 acres. Provide about 1,300 acres of SPM dispersed recreation opportunities

Emphasize interpretation of significant cultural resources and encourage their scientific study.

Permit OHV use when amenity resource values are not reduced.

Use small clearcut openings no larger than three acres to result in more acres meeting retention and partial retention **VQOs** than any other alternative.

On sensitivity level 1 roads, allow harvest units right up to the road. Because of the small size of openings, **VQOs** would range from modification to retention. On scenic highways, the **VQO** would range from partial retention to retention in the middleground. Improve existing visual conditions on mountain top electronic **sites** by screening or other methods.

- b. Research Natural Area. Recommend to the Chief the establishment of Babbitt Peak (1,061 acres), Sugar Pine Point (625 acres), Basin Peak (60 acres), Mt. Lola (498 acres), and Lyon Peak/Needle Lake (700 acres) as RNA's.

- c. Special Interest Areas. The following **SIA's** are established: Placer County Big Tree Grove (346 acres), Devils Postpile (69 acres), Glacier Meadow (84 acres), Grouse Falls (220 acres), Hawley Lake (5,323 acres), Meadow Lake (58 acres), Boca (1,976 acres), Kyburz (1,097 acres), Sagehen Headwaters (79 acres), Sierra Buttes (1,827 acres), Little Truckee River Terrace (468 acres), Sagehen Creek Basin (8,373 acres), Independence Lake (81 acres), Headwaters Basin of the North Fork American River (9,381 acres), San Juan Ridge (6,541 acres), Macklin Creek (380 acres), and Mason Fen (30 acres)

- d. Wilderness. Manage Granite Chief as wilderness (18,705 acres).
- e. Fish and Wildlife. Use the recovery and management plans as guides for managing bald eagles, peregrine falcons, and Lahontan cutthroat trout. Provide a network of 40 spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Provide additional attention to Forest Service sensitive species, State-listed threatened and endangered species, harvest species, State 'Species of Special Concern', and species groups associated with important wildlife habitats.
- f. Forest Pests. Implement a moderate level of integrated pest management over a small forested acreage suitable for timber production. Pesticides will be utilized only after all other methods have been tried and have failed and then only in the direst of emergencies. The use of conventional pesticides of unknown toxicity is prohibited. The use of the only more recently developed behavioral chemicals such as pheromones, attractants, repellants, confusants, and inhibitors is allowed.
- g. Range. Manage range resources consistent with late successional vegetation. Implement extensive range management practices on the remaining permanent range acres. Reduce the grazing program over five decades to about 1,000 AUM's.
- h. Timber. Limit opening size to three acres to maintain growth and maximize edge effect. Rotations will be at least 70 years. Timber yield calculations are based upon the nondeclining even-flow timber policy. At least 50 percent of the volume harvested would result from group selection management.
- i. Water and **Soil**. Maximize water quality improvement. Rehabilitate all treatable sediment producing areas (treat 2,500 acres).
- j. Minerals. Propose withdrawing areas from mineral entry and leasing where mining activities would conflict with amenity protection and improvement. In particular, propose withdrawing areas within 400 feet of designated or eligible State scenic highways, RNA's and **SIA's**, and areas of concentrated public use. Permit mineral development on acquired land only if this use would not conflict with protection of amenity values.
- k. Landownership and Special Uses. Emphasize acquisition of private land within the Granite Chief Wilderness, SPNM areas, and RNAs and SIA's where it would enhance amenity values. No SPNM land would be available for exchange.

Continue existing activities operated under special-use permits, and expand or issue new permits when compatible with amenity values. Work with special-use permittees as opportunities arise to mitigate possible conflicts between special uses and amenity values.
- l. Facilities. Develop, construct, and maintain access to facilities where roads and trails would be compatible with the overall amenity objectives. Close existing roads and trails conflicting with amenity objectives. Permit new road and trail construction and reconstruction where access would be needed to use the amenity resources or to achieve other objectives of this alternative. Maintain or improve trailheads and other features to facilitate use of the Granite Chief Wilderness, the North Fork American Wild River, SPNM areas, SIA's, etc.

Maintain facilities at building investment level II; protect Government investment of existing facilities.
- m. Fire Management. Emphasize all small engines and hand crews. Continue fuel treatment at present or greater levels using both engine and hand crews. The specific program organization would consist of the following:
 - o Prevention and detection (40 percent).
 - o Suppression (60 percent).

- n. **Riparian/SMZ.** Apply the Forest requirement (S&G's 46 and 47 and Appendix F) for riparian areas/SMZ's. Timber harvest scheduled from variable width SMZ's (minimum of 100 feet) along perennial streams would be minimal. Scheduled timber yields are also reduced within variable width SMZ's adjacent to intermittent streams where needed to protect channels and water quality.
- o. **Diversity.** Provide a minimum of 15 snags per acre in all eastside timber compartments. Establish a goal of 20 snags per acre for westside compartments. Maintain at least 30 sq ft basal area in hardwoods per acre in hardwood-conifer mixed stands. Retain at least 5 sq. ft. basal area in mixed-conifer stands. Retain all existing late seral stage stands

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, and range practices would produce a forest of greater diversity than currently exists.

The major change in vegetation by the year 2030 would be the replacement of a portion of existing timber stands by even-age young growth conifer stands. This alternative would have about 156,080 acres, or 23 percent of the existing forested land, of new timber stands less than 50 years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About 151,400 acres would be managed for timber on a short rotation (50-120 years). This timber management approach would result in a mosaic of very small, even-aged timber stands that differ by 10-year age classes. The larger trees would be 18 to 27 inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management to create and maintain a regulated forest.

Long rotation (150+ years) even-aged timber management would be applied to about 121,600 acres. This timber management approach would result in a mosaic of very small even-aged timber stands. The larger trees would be 30 to 40 inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats and scenic quality (partial retention initial **VQO's**) and would be intermixed with areas of short-rotation harvest. The future condition of special management areas, such as streamside management zones, scenic areas, unroaded areas, and noncommercial conifer stands, would most likely be very similar to the existing irregular uneven-aged timber stand structure. About 177,300 acres would reflect this forested condition.

There are 18,705 acres of wilderness; 2,944 acres would be managed as RNA's and 36,333 acres managed as **SIA's**.

The arterial and collector transportation system would remain unchanged. Local roads would access timber stands outside unroaded areas. The trail system would be in place to facilitate management of wilderness, SPNM areas, and Special Interest Areas. Existing downhill ski facilities would be expanded, and new ski facilities developed to meet demand where amenity values would be maintained. No expansion or development would be permitted in areas of late successional vegetation or Mt. Lola. Additional developed and dispersed recreation facilities would be provided in **SIA's** or where compatible with amenity values.

The visual quality of the Forest would reflect an older stand condition with less visual landscape modification than is currently evident. Almost all areas commonly seen by Forest visitors would be natural or mostly natural in appearance. Most major modifications in visible locations would be rehabilitated to at least a somewhat natural state.

Wildlife species composition would shift from species adapted to early and mid-successional vegetation to species requiring older, mature forest habitat. Riparian areas and SMZ's would receive a high level of protection. Water quality would remain similar to current conditions.

Forage for 900 head of cattle and sheep would be provided with extensive management of the permanent range acres.

ALTERNATIVE UNE (Uneven-aged)

1. Theme

Achieve a broad range of commodity and amenity benefits that meet short-term needs while retaining long-range management options; apply uneven-age management as the principal method for regulating lands suitable for timber production

Emphasize a mixture of commodity production and amenity benefits that maximizes net public benefits while responding to the planning issues

Specific issues emphasized are (#6) forage, wood and soils; (#8) recreation; and (#9) fish and wildlife habitat.

2 Resource Program Direction

- a. Recreation. Provide a program of developed (including downhill skiing) and dispersed recreation which would meet projected demand by expanding existing facilities before developing new facilities. Expand visitor information service and interpretive facilities and programs.

Manage land surrounding major reservoirs for water-oriented recreation. Manage Grouse Lakes as a motor vehicle closure area. Provide 74,000 acres of SPNM and 71,000 acres of SPM dispersed recreation opportunities.

Expand opportunities for the private sector to operate campgrounds under special-use permit. Develop and manage at full standard the following potential recreation sites: Boca, Prosser, Stampede, French Meadows, Jackson Meadow, Sugar Pine, and Bullards Bar Reservoirs; Truckee and North Yuba Rivers areas: Sierra Buttes; and Interstate Highway 80 area. All other potential recreation sites would be available for other multiple uses during the first decade.

Develop trail systems to accommodate motorized and nonmotorized recreation use, including use by the disabled. Provide designated routes for off-highway vehicle use in dispersed recreation areas.

Provide for cultural resource interpretation when planning for recreation facilities.

Manage for visual quality objectives (VQOs) of retention and partial retention along most major recreation roads and trails and around major recreation areas. Outside of the more visually sensitive areas, establish visual quality direction which would be compatible with the use of the timber resource. Emphasize visual qualities along major access roads, the North Fork American Wild River, the Granite Chief Wilderness, SPM and SPNM areas, and in concentrated recreation use areas.

- b. Research Natural Areas. Recommend to the Chief the establishment of Babbitt Peak (1,061 acres), Sugar Pine Point (625 acres), and Lyon Peak/Needle Lake (700 acres) as RNA's.
- c. Special interest Areas. The following SIA's are established Placer County Big Tree Grove (346 acres), Devils Postpile (69 acres), Glacier Meadow (84 acres), Grouse Falls (220 acres), Sagehen Headwaters (79 acres), Meadow Lake (58 acres), and Mason Fen (30 acres)
- d. Wilderness. Manage Granite Chief as wilderness (18,705 acres).
- e. Fish and Wildlife. Use the species recovery and management plans as guides for managing Federal threatened and endangered species. Manage a network of 33 spotted owl habitat management areas. Maintain viable populations of all local fish and wildlife species. Give additional attention to Forest Service sensitive species, State-listed threatened and endangered species, harvest species, State 'Species of Special Concern', and species groups associated with important wildlife habitats

- f. Forest Pests. Implement a high level of integrated pest management over a moderate forested acreage suitable for timber production
- g. Range. On about **75** percent of the capable, available, and suitable permanent range, implement range improvement practices such as seeding, fencing, and water developments to facilitate improved grazing systems such as deferred grazing and rest rotation. On the transitory range, implement vegetative management practices in harmony with other resource objectives and needs on the existing and potential forage created by timber management practices, both inside and outside of existing allotments, by developing new and improved grazing systems and techniques. Study range management practices on low-slope eastside pine lands that would improve vegetation condition and maintain **site** productivity in a dual-use management setting
- h. Timber. Apply intensive timber management practices to forest lands scheduled for high timber yields. On all land capable, available, and suitable for timber production, obtain timber yields while maintaining other resource values. Timber yield calculations are based upon the nondeclining even-flow timber policy. The uneven-age silvicultural system would be the principal method for regulating lands suitable for timber production. Apply even-age management (shelterwood) where uneven-age management is not feasible, such as cable ground
- i. Water and **Soil**. Maintain water quality at existing levels. Restore water quality on **1,900** acres of stream channels, meadows, roads, old wildfire areas, and priority hydraulic diggings
- j. Minerals. The Granite Chief Wilderness is withdrawn from all forms of mineral entry and leasing. Propose withdrawing from mineral entry the RNA's and **SIA's**, areas of concentrated public use (including potential recreation sites), areas along portions of designated or eligible State scenic highways not previously withdrawn (200 feet from centerline along Highways 20, **49**, and **89** and approximately 400 feet on each side of Interstate 80), and areas 200 feet from centerline of the Gold Lake Highway.
- k. Land Ownership and Special Uses. Acquire private land within the Granite Chief Wilderness. Use selected National Forest System lands to acquire other lands which would enhance Tahoe National Forest management

Designate and manage the Donner Pass area as a utility corridor, and designate the Galloway site as an electronic site. The Granite Chief Wilderness, North Fork American Wild River, Special Interest and Research Natural Areas are excluded from consideration for utility corridors.

- l. Facilities. Construct and maintain roads to access areas suitable for resource management. Maintain facilities at building investment level III; provide for improvement and replacement of existing facilities.
- m. Fire Management. Emphasize all small engines and hand crews. Continue **fuel** treatment at present or greater levels using both engine and hand crews. Specific program organization would consist of:
 - o Prevention and detection (**40** percent).
 - o Suppression, including fuel management (60 percent)
- n. **Riparian/SMZ**. Apply the Forest requirement (**S&G's 46** and **47** and Appendix F) for riparian areas/SMZ's. Timber harvest scheduled from variable width SMZ's (minimum of **100** feet) along perennial streams would be minimal. Scheduled timber yields are also reduced within variable width SMZ's adjacent to intermittent streams where needed to protect channels and water quality.
- o. **Diversity**. Provide a minimum of **1.5** snags per acre in all planning compartments. Maintain hardwoods with at least 30 sq. ft. per acre basal area in hardwood-conifer mixed stands. Also maintain at least **5** sq. ft. per acre in mixed-conifer stands

3. The Environment to be Created

Timber harvesting, reforestation, timber stand improvement, range practices, and wildlife habitat improvement would produce a forest of greater diversity than currently exists

The major change in vegetation by the year 2030 would be the replacement of a portion of the existing timber stands by even-age young growth conifer stands. This alternative would have about 98,340 acres, or 14 percent of the existing forest land, of new timber stands less than 50 years old. The understory vegetation in these plantations would feature a combination of light densities of brush intermingled with small amounts of slash and natural fuels.

About 127,200 acres would be managed for timber on a short rotation (50-120 years). This timber management approach would result in a mosaic of similar sized, even-aged timber stands that differ by 10-year age classes. The larger trees would be 18 to 27 inches in diameter. The ground fuels would be scattered brush and light slash. This forested pattern would exist in areas of intensive timber management to create and maintain a regulated forest.

Long rotation (150+ years) even-aged timber management would be applied to about 96,800 acres. Long rotations are necessary to meet the partial retention **VQOs**. This timber management approach would result in a mosaic of even-aged timber stands. The larger trees would be 30 to 40 inches in diameter. The ground fuels would be an accumulation of moderate slash and natural fuels with patches of mature brush. This forested pattern would exist in areas emphasizing late successional wildlife habitats and scenic quality. This forested pattern would also be intermixed with areas of short-rotation harvest.

Uneven-age timber management would be applied to about 95,700 acres of tractor-loggable land. This would result in a mixture of tree ages and sizes within these stands. Tree species would tend to be shade tolerants such as white fir and incense-cedar.

The future condition of special management areas, such as streamside management zones, scenic areas, unroaded areas, and noncommercial conifer stands, would most likely be very similar to the existing irregular uneven-aged timber stand structure. Approximately 208,800 acres would reflect this forested condition.

There are 18,705 acres of wilderness; 2,386 acres would be managed as Research Natural Areas and 886 acres managed as Special Interest Areas.

The arterial and collector transportation system would be completed.

Existing downhill skiing facilities would be expanded to their maximum capacity. New downhill skiing facilities and key potential developed recreation **sites** would be developed in response to demand (see Resource Program Direction).

Human-caused changes in natural vegetative patterns would be more evident in the landscape than they are currently. While most highly sensitive areas adjacent to major recreation roads, trails, and use areas would remain natural or predominantly natural in appearance, less conspicuous portions of the Forest would be visually dominated by evidence of human practices.

Semi-primitive nonmotorized acres and semi-primitive motorized acres would be reduced.

Wildlife species composition would shift slightly from species requiring late successional vegetation to species adapted to early and mid-successional vegetation.

Riparian areas and **SMZ's** would receive a high level of protection. Water quality would remain similar to current conditions.

Range management would provide a vegetative management program that is geared to focus attention on sustained yield of range vegetation to protect the soil and water and provide ecological diversity. On the east side of the Sierra Nevada, 75 percent of the permanent range would be intensively managed, providing forage for 15,800 head of cattle and sheep. Transitory range among the early successional timber stands (plantations) would increase on the west side of the Sierra. Domestic livestock would be used to reduce competition to the tree seedlings while maintaining particular seral stages for specific wildlife habitat enhancement, providing forage for 5,200 head of cattle and sheep.

F. COMPARISON OF ALTERNATIVES

OVERVIEW

This section compares and highlights major differences among alternatives regarding outputs, costs, responses to issues, and environmental effects. These factors are summarized here from detailed discussions in Chapters 3 and 4. These comparisons present relevant, specific, and detailed information previously expressed in more general terms in the alternative descriptions. Included are the following:

- o A narrative comparison of major differences among alternatives
- o A comparison of acres assigned to each management prescription (Table 2.11)
- o A comparison of average annual outputs for first and fifth decades (Tables 2.12 and 2.13).
- o A comparison of Research Natural Areas and Special Interest Areas (Table 2.14).
- o A comparison of land classified for timber management (Table 2.15a)
- o A comparison of acres by silviculture practice (Table 2.15b).
- o A summary comparison of economic effects (Table 2.16).
- o A comparison of present net value and tradeoffs (Tables 2.17, 2.18, 2.19, and 2.20, and Figure 2.21)
- o A comparison of issue resolution by alternative (Table 2.21)

MAJOR DIFFERENCES AMONG ALTERNATIVES

The following discussion highlights the major differences between the alternatives considered in detail. Refer to Table 2.11 for comparative acreage allocated by management prescription, and Tables 2.12 and 2.13 for comparisons of the average annual outputs by alternative for the first and fifth decades.

Social

The social benefits provided by each alternative cannot be measured or compared in terms of one being better, worse, higher, or lower than another because different social groups are affected differently by each alternative. For example, the long-time resident group generally benefit most from Alternative CMD and least from Alternative NMK, Alternative PRF is relatively high in opportunities for this group. The alternative lifestyle resident group would benefit most from Alternative NMK and least from Alternative CMD, Alternative PRF is low in opportunities for this group. Native Americans would benefit more from those alternatives with increased commodity production because a majority are employed in the timber industry; however, these alternatives would also increase the risk of loss or damage to Native American cultural resource sites.

Economic

Alternatives CMD and RPA would have the highest present net value with CMD returning slightly more to the Federal treasury (including payments to local governments) in the first decade. Alternative PRF would have the fourth highest present net value and return to the Federal treasury. Alternative NMK would have the lowest present net value and return to the Federal treasury. (See Figure 2.1)

Alternative CMD would provide the greatest employment opportunities. with Alternative PRF the fourth highest. The number of Forest Service employees (full-time equivalents) required for TNF administration in the first decade ranks highest for Alternative RPA, fifth highest for Alternative PRF, and lowest for Alternative CUR.

Alternatives CMD and RPA would require the greatest budgets for implementation, about **\$24.4** and **\$24.3** million per year, respectively, for the first decade. Alternative PRF ranks fourth, with a projected budget of **\$21.2** million. Alternative CUR, which has a constrained budget, would have the lowest budget of \$20.1 million. These budgets include appropriated funds and funds for brush disposal, reforestation, and timber stand improvement.

Diversity

The alternatives differ considerably in overall seral stage diversity and management of important diversity elements

Several alternatives (PRF, CUR, RPA, and CMD) provide extensive use of even-age silvicultural systems. These alternatives would produce shifts in overall seral stage diversity and the abundance of early stages (1X, 2X, 3A, 3B/C) would increase substantially over current conditions. These alternatives would produce 50 to 60 percent reductions in mature and overmature forest stands by the fifth decade. The UNE alternative would produce about a 35-percent reduction in the current inventory of mature and overmature seral stages. The NMK alternative would maintain the current acreage of mature and overmature forest, it would yield fewer early seral stage stands than the other alternatives.

The PRF, NMK, and UNE alternatives provide the most extensive programs for managing important diversity elements such as hardwoods, meadow edges, riparian areas, and snags. The CUR and RPA alternatives would offer moderate programs of management and the CMD alternative would yield the least protection.

Facilities

Alternatives CUR and CMD would develop the most access within the TNF during the planning period by reconstructing existing and constructing new arterial, collector, and local transportation systems. Alternatives NMK and PRF would develop the least access. Alternatives UNE and RPA would access a moderate amount of area to provide for the commodity and recreational program.

Under all alternatives miles of road open or closed to use would remain about the same. Seasonally restricted road miles would vary by alternative. The location of roads open, closed, or seasonally restricted would vary by each alternative's emphasis. Common to all alternatives is the assumption that there will always be a need to construct some new roads. This would be true even after the second and third decades, when the Forest transportation system would be essentially completed. However, the number of miles constructed would be very low. Also, in the long term, there would probably be a net decrease in the total miles in the Forest transportation system. This is due to closing existing roads, and the roads that would be constructed would be of a lower standard and would be closed after use.

Alternatives PRF, RPA, CMD, NMK, and UNE would build the most miles (approximately 700 miles) of trail for dispersed recreation. The CUR alternative would construct and reconstruct the least trail miles (approximately 550 miles). The estimated miles are based on the end of the fifth decade projected information.

Fire and Fuels

Net resource losses from wildfire would increase over time under Alternative CUR, in which detection, prevention, and suppression would be limited by constrained fire management programs and budgets. Under all other alternatives the net wildfire losses would remain relatively unchanged.

Decade by decade, Alternative CUR would have more acres burned annually by wildfire than any other alternative. In all alternatives, except CUR, the fire management program emphasis would shift from a mix of large and small engines to all small engines and hand crews, and budgets would increase by **20** percent in the third, fourth, and fifth decades.

Fish and Wildlife

Each alternative would provide a habitat management program for fish and wildlife. However, the focus of the programs would vary among alternatives.

All fish and wildlife programs would employ recovery and management plans as direction for managing Federal threatened and endangered species. Each program would also meet the 'Minimum Management Requirements' for diversity and viable population management as prescribed in the Regional Planning Guide.

The PRF, NMK, and UNE alternatives would provide a fish and wildlife program that emphasizes Forest Service sensitive species, State-listed threatened and endangered species, harvest species, and species groups associated with important wildlife habitats. The PRF and NMK alternatives would also include the State 'Species of Special Concern' in the fish and wildlife program. The CUR, RPA, and CMD alternatives would provide a fish and wildlife program that focused on threatened and endangered, Forest Service sensitive, and harvest species. The RPA program would also include cavity nesting animals.

The fish and wildlife habitat program in the PRF, NMK, and UNE alternatives would emphasize protection of important habitat diversity elements including snags, riparian areas, meadows, hardwoods, and down woody material. In addition, the NMK alternative would not allow harvest of existing candidate old-growth forest stands over time. The CUR, RPA, and CMD alternatives would provide considerably less protection to snags, riparian areas, hardwoods, down woody material, and old-growth forest than the PRF, NMK, and UNE. Accordingly, the CUR, RPA, and CMD alternatives would provide poorer conditions for fish and wildlife associated with important habitat diversity elements.

Historical and Cultural Resources

All alternatives would meet minimum legal requirements. Interpretation and enhancement of cultural resources are emphasized in Alternatives PRF and UNE. The NMK alternative emphasizes conservation of cultural resources. All alternatives require additional non-project related inventories to meet the RPA goal of a complete Forest inventory by 1995.

While cultural resources are afforded protection by law, the likelihood of disturbance by management activities by increasing access or by increasing visitor use of the Forest would vary among the alternatives. The CMD alternative, which emphasizes timber management activities and roading, would create an overall high threat to cultural resources. The PRF, CUR, RPA, NMK, and UNE alternatives would create a moderate threat to cultural resources.

Lands and Urban/Rural/Wildland Interface

The acreage in the land acquisition program would not vary much by alternative. The emphasis on the type of property acquired would be dictated generally by the objectives of the alternative. Alternatives NMK, PRF, and UNE, which recommend more semi-primitive nonmotorized recreation areas, motor vehicle closure areas, and Special Interest Areas containing private land, would require the most direct acquisition.

Property boundaries need to be established because of the timber sale program. About two-thirds of the landline location would follow the scheduled timber outputs for the first two decades. Therefore, alternatives stressing timber production (Alternatives CMD, RPA, and PRF) would have the greatest number of landline miles to post and mark per year in the first decade. All alternatives would complete the landline program by 2020.

Special-use applications would not vary much among alternatives. Alternatives with more proposed semi-primitive nonmotorized recreation areas, Research Natural Areas, and Special Interest Areas would tend to discourage applications in those particular areas, but the overall number of special-use applications would not change significantly.

The Forest's ability to respond to public concerns relevant to urban/rural wildland interface situations varies by alternative. The CMD, RPA, and CUR alternatives are the least responsive because the higher levels of timber harvesting would create larger openings more often in interface situations, and there would be less flexibility in rearranging units once proposed. The PRF, UNE, and NMK alternatives would respond moderately, fairly responsive, and most responsive, respectively. These three alternatives have from moderate to high opportunities to manage timber in interface situations with small and less apparent openings that could respond to many of the public concerns.

Minerals

Alternative NMK proposes the greatest number of acres of high mineral potential proposed for withdrawal from mineral entry and leasing. Overall, the total acres of mineral withdrawal would correspond to the acres recommended for scenic highways, concentrated public use, Research Natural Areas, and Special Interest Areas. The Placer County Big Tree Grove SIA is already withdrawn. Alternatives NMK, UNE, RPA, and PRF (in descending order) would have the largest amount recommended for withdrawal, while Alternatives CMD and CUR would have the fewest acres recommended.

Alternatives with more acres withdrawn would reduce opportunities to explore and develop the mineral resource.

Range

The average annual permitted AUM outputs for Alternatives PRF and UNE would be **less** than 1 percent above the current level's average over the five decades. The average annual permitted AUM outputs for Alternative CMD would be about 6 percent above the current level's average over the five decades. These increases would be achieved through intensively managing 75 percent of the permanent range (compared to 25 percent under the current level) and intensively managing 12,556 acres of scattered eastside pine stands.

The average annual permitted AUM output for Alternative RPA would be 52 percent above the current level's average over the five decades. This increase would be achieved through intensively managing 80 percent of the permanent range and converting 26,709 acres of low-site brush to intensive management.

The average annual permitted AUM outputs for Alternative NMK would be about 77 percent below the current level's average over the five decades. Range would be extensively managed in this alternative.

Alternative RPA would exceed the Regional Forester's allocated 2030 RPA goal of 30,400 AUM's. Alternatives PRF and UNE would achieve 33 percent of the 2030 goal. Alternative CMD would achieve 77 percent of the 2030 goal. The remaining alternatives did not attempt to meet the 2030 goal.

Recreation

- a. **Developed Recreation.** All alternatives would meet projected demand for developed recreation through the first decade. The PRF, CMD, NMK, and UNE alternatives would meet demand over the entire planning period through expansion of existing sites and construction of new ones at key locations along major travel routes, reservoirs, and rivers. The RPA alternative would meet about 90 percent of demand after the first decade. The CUR alternative would not construct any new developed recreation facilities: by the fifth decade only 65 percent of developed recreation demand would be met.
- b. **Developed Recreation Ski Areas.** The PRF, CUR, and UNE alternatives would both expand existing and develop new downhill ski areas to meet projected demand over the planning period. The CMD alternative would encourage the expansion of existing ski areas to their maximum capacity first, and would allow enough new site expansion to meet demand in the fifth decade: those sites with high timber values would be avoided. These alternatives would provide the most opportunity for downhill ski recreation. The NMK alternative would restrict ski area expansion to areas outside of late successional, mature forest types, and Mt. Lola, and would meet 88 percent of the projected demand for downhill ski recreation in the fifth decade. Alternative RPA would meet demand through the fourth decade and meet 88 percent of demand in the fifth decade.
- c. **Dispersed Recreation.** All alternatives would meet overall dispersed recreation demand because of the TNF's large capacity for dispersed recreation activities. Each alternative, however, emphasizes certain management activities differently than others. Opportunities for some types of dispersed recreation may be limited in some alternatives. In all alternatives except the NMK alternative, semi-primitive nonmotorized recreation opportunities would diminish because road access would increase throughout much of the Forest and because vegetation management activities would expand into areas currently natural-appearing.

In all alternatives, sufficient acres to meet projected dispersed recreation demand for activities requiring unroaded, near-natural settings would not be available

Similarly, in all alternatives opportunities for motorized recreation that require primitive roads and near-natural settings would be reduced from the current situation. The PRF and UNE alternatives would provide a little less than ~~two~~ thirds of the acres available for SPM recreation. The CUR and CMD alternatives would provide about **40** percent of the acres, and the NMK and RPA alternatives would provide less than **15** percent of the acres available for SPM recreation opportunities. In all alternatives, opportunities would increase for activities that benefit from improved road access (such as hunting, fishing, driving for pleasure, and auto camping) and that are not affected by the appearance of human-caused landscape modifications.

Research Natural Areas

Babbitt Peak Washoe Pine (**1,061** acres) is proposed under all alternatives. Sugar Pine Point (**625** acres) is proposed under Alternatives PRF, CMD, NMK, and UNE. Lyon Peak/Needle Lake (700 acres) is proposed under Alternatives PRF, UNE, and NMK. Mt. Lola (498 acres) and Basin Peak (**60** acres) are proposed under Alternative NMK.

Riparian Areas

The RPA alternative would result in the greatest potential to damage riparian areas/SMZ's and the aquatic ecosystem. The CUR and CMD alternatives would also result in high potential to adversely impact these areas. All three exhibit significant risks because of the dramatic increase in timber regeneration harvests and associated activities on steep ground.

The UNE alternative would result in the lowest potential to damage riparian areas/SMZ's and the aquatic ecosystem. The NMK and PRF alternatives would result in slightly greater risks. These three alternatives either envision smaller increases than the other alternatives in hawest-related activities on steep ground, or in the case of the NMK alternative, would result in minor disturbance associated with site preparation.

Special Interest Areas (SIA's)

Placer County Big Tree Grove Botanical Area (**346** acres) is proposed under all alternatives. Alternative NMK (17 areas, **36,333** acres) would provide the greatest number of **SIA's**, followed by Alternatives PRF, CMD, and UNE (7 areas, **886** acres. Alternatives CUR and RPA would provide no additional **SIA's**. (See Table **2.14** for the specific areas proposed.)

Soils

Alternatives CMD and RPA would have the greatest potential to reduce long-term soil productivity. The overall risk to the soil resource under these alternatives would be moderate.

The overall risk to the soil resource under Alternative CUR would be low.

Alternatives UNE and PRF would have a lower potential to reduce long-term soil productivity because they would have a lower risk of soil erosion. Under Alternative UNE steep slopes would be in shelterwood systems; under Alternative PRF fewer acres of steep slopes would be allocated to timber management. The overall risk to the soil resource under these alternatives would be low to very low.

Alternative NMK would have the lowest potential to reduce long-term soil productivity because of its special emphasis on protection of the soil resource. The overall risk to the soil resource under these alternatives would be very low.

Timber

Alternatives CUR, CMD, and RPA would provide the greatest opportunities for intensive timber management on suitable land. These alternatives would have the largest available landbases and the most intensive

management. They also would have the highest allowable sale quantities and long-term sustained yield capacities. None of the alternatives would meet the RPA goal of 194.2 MMBF in the first decade. Alternative RPA would exceed the goal in the third decade and Alternative CMD would exceed **194.2** MMBF in the fourth decade. Alternatives RPA and CUR would be the most efficient in silvicultural methods and use of the timber inventory over time. Alternatives RPA, CMD, and CUR would have the highest potential wood energy (biomass) available.

Alternatives PRF and UNE would provide lesser opportunities for timber production and biomass. They would have similar landbases for regulated timber management, but Alternative PRF would have a higher level of management intensity than Alternative UNE. Alternative UNE would have the lowest management intensity of all alternatives. Alternative PRF would have relatively efficient silvicultural methods, while Alternative UNE would be more difficult to implement because it would necessitate very small openings, multiple entries, and complicated record-keeping.

Alternative NMK would provide the least opportunities for timber production. This alternative has the smallest landbase, the second lowest management intensity, and the least efficient silvicultural methods. Similar to Alternative UNE, Alternative NMK would require small openings and cumbersome record-keeping and, thus, would be difficult to implement. Both Alternatives UNE and NMK would have high costs to achieve their timber yield.

Visual Resources

Under the CMD alternative, visual resources would be emphasized only to the extent required by the State scenic highway minimum implementation requirement, Granite Chief Wilderness, and major reservoirs. Visual quality in Alternatives PRF, CUR, RPA, CMD, NMK, and UNE would be reduced to varying degrees to allow emphasis of other resource management objectives. The CUR, RPA, and CMD alternatives would significantly reduce visual quality from the current level, with the CMD alternative having the greatest decline. This reduction would restrict the quality and quantity of recreational opportunities available in the TNF. The PRF alternative would also reduce visual quality, but to about half the extent that the previous alternatives would. The UNE alternative is about halfway between the PRF and NMK alternatives for the level of visual quality provided. The NMK alternative would reduce visual quality the least of all alternatives from current conditions. The NMK alternative would afford the greatest opportunities to maintain and enhance visual quality and would result in almost three times as many acres for the retention visual quality objective as would alternative PRF.

Water

The RPA and NMK alternatives would provide for about **2,500** acres of watershed restoration (the maximum treatable acreage) over the planning period. The PRF and UNE alternatives would provide for 1,900 acres of treatment. The CUR and CMD alternatives would treat about **500** acres.

All alternatives would result in slightly increased water yields compared with current levels because of increased regeneration cutting.

When accounting for watershed restoration and intensity of timber management and related activities, minor differences would be expected in water yield meeting water quality standards. The PRF alternative would result in a similar percent of water yield meeting standards. The RPA, CMD, and CUR alternatives would likely result in a slightly smaller percentage of water yield meeting standards. The NMK and UNE alternatives would result in a similar or slightly greater percentage of water yield meeting standards relative to the current situation.

Wilderness

- The Granite Chief Wilderness (18,705 acres) would be managed for its wilderness values under all alternatives.

ACRES IN MANAGEMENT PRESCRIPTIONS

Alternatives vary by the number of acres proposed by management prescription and by the different management prescriptions used. Not all prescriptions apply to every alternative. A management prescription represents combinations of compatible management practices, and the combination of management prescriptions for a particular alternative reveals its overall management emphasis. (See the previous discussion of management prescriptions earlier in this chapter. Also refer to the alternative maps in the packet accompanying this EIS for the spatial distribution of the management prescriptions by alternative. The relationship of management prescriptions to FORPLAN prescriptions is discussed in Appendix B.)

Table 211 displays the acres allocated to each management prescription under each alternative. The amount of each prescription applied under an alternative determines how much of a given resource output would be produced. The outputs produced reflect the emphasis of the alternative

NUMBER & THEME	PRF	CUR	RPA	CMD	NMK	UNE
1 Manage to retain the wilderness qualities	18,705	18,705	18,705	18,705	18,705	18,705
2 Retain a near-natural appearing forest environment while also producing some forage and water, manage for dispersed nonmotorized recreation	45,817	0	50,361	0	123,481	45,817
3 Produce a moderate level of commodities while enhancing or emphasizing other selected resources, manage for dispersed motonzed recreation	66,452	62,281	0	0	39,053	66,452
4 Provide water oriented recreational oppoltuntlies with visual quality backgrounds	30,530	26,279	30,530	30,530	27,362	30,530
5 Establish representative vegetation and geologic areas for scientrfic and educational research and establish special areas with unique geologic. ecologic. or cultural features	6,582	4,777	4,777	5,418	39,157	6,642
6 Manage as a designated Wild River	5,788	5,788	5,788		5,788	5,788
7 Improve fish and wildlife harvest species habitat while producing other commodities	18,574	23,974 1/	18,574	18,574	17,888	18,574
8 Retain a natural-appearing forest environment while also producing some timber, forage, and water	46,846	42,154	44,994	0	46,025	46,846
	12,164 2/					
10 Maintain all land and resource values necessary to retain a high value for exchange	5,559	5,559	5,719	5,559	5,559	5,559
11 Provide winter recreation oppourtunities	13,288	11,296	3,645	6,862	6,708	13,288
12 Emphasize land uses for facillities such as pipelines, transmission lines, and administrative sites	2,153	555	2,153	2,153	2,153	2,153
13 Intensively manage timber and forage resources	354,850	408,238	487,644	567,849	140,134	353,790
14 Provide areas for studies emphasizing wildlife and timber resource management relationships	6,818	6,818	13,493	0	361	6,818
15 Manage for predominantly-natural appearing landscape and late successional wildlife habitat using intensive timber management	160,148	158,810	95,827	120,772	309,836	160,148
TOTAL FOREST ACRES	794,374	794,374	794.374	794,374	794,374	794,374

1/Acreages also include those areas managed for protection of T&E species that are not individually identified on all other alternative maps because they are Minimum Management Requirements (MMR's) The habltat on these acres is required for T&E species protected by law

2/Carman Valley Watershed

3/Primarily Water Influence Zones in existing Ranger District Multiple Use and Land Use Plans, also includes 9,118 acres of land with current management direction emphasizing watershed management

Potential Energy Made Available (Billions of BTUs)	1	595	773	771	769	507	561	---

¹ All values associated with a given decade are average annual values for the period 1982 levels are goals or potentials to be comparable with project values

^{2/} OHV Prescription categories

^{3/} The chance of disturbing or destroying cultural resources. 'High' represents an increased risk of disturbance, 'Moderate' represents no change in the risk of disturbance, and 'Low' represents a decreased risk

PROPOSED RESEARCH NATURAL AND SPECIAL INTEREST AREAS

The ID Team identified twenty-two areas in the TNF as having potential for Research Natural Areas or Special Interest Areas Table 2.14 displays the areas by alternative. Those areas assigned in an alternative have a "yes" in the alternative column, a "no" means the area was not assigned. Appendix C contains a detailed description of each area and the analysis process

TABLE 2.14 - COMPARISON OF ALTERNATIVES BY PROPOSED RESEARCH NATURAL AREAS AND SPECIAL INTEREST AREAS

AREA	INVENTORIED ACRES	PRF	CUR	RPA	CMD	NMK	UNE
RESEARCH NATURAL AREAS

GRAND TOTAL	39,277	3,272	1,407	1,407	2,572	39,277	3,272

Note: Wild Plum was considered for R designation but eliminated because of current and past logging of the area

LAND CLASSIFICATION FOR TIMBER

Table 21 5a summarizes the land classification for timber management by alternative. Appendix K contains a detailed description of the process used to identify land available, capable, and tentatively suited for timber production. Selection of the suitable timber base (item 9 of Table 2 15a) depends on the theme of each alternative, prescriptions compatible with the alternative program direction, costs and benefits, management intensity, constraints applied, and the FORPLAN linear program modeling procedure (see Appendix B).

Alternatives emphasizing timber production, such as Alternatives CUR, RPA, and CMD, would have the largest land base suited for timber production. Conversely, alternatives emphasizing amenity values and semi-primitive nonmotorized recreation, such as Alternative NMK, would have a low suitable land base.

TABLE 2.15a LAND CLASSIFICATION FOR TIMBER BY ALTERNATIVE

TIMBER CLASSIFICATION	PRF	CUR	RPA	CMD	NMK	UNE
1 NON-FORESTED LAND	112,775	112,775	112,775	112,775	112,775	112,775
2 FORESTED LAND	681,599	681,599	681,599	681,599	681,599	681,599
3 WITHDRAWN FROM TIMBER PRODUCTION	20,849	20,849	20,849	20,849	20,849	20,849
4 NOT CAPABLE OF PRODUCING INDUSTRIAL WOOD	31,732	31,732	31,732	31,732	31,732	31,732
5 PHYSICALLY UNSUITED	0	0	0	0	0	0
a Irreversible damage to soils, watersheds or productivity	0	0	0	0	0	0
b Unregenerable within 5 years of final harvest	0	0	0	0	0	0
6 INADEQUATE INFORMATION TO PROJECT RESPONSES	0	0	0	0	0	0
7 NOT SUITABLE FOR TIMBER UNDER THE ALTERNATIVE	100,544	24,183	48,254	37,074	178,691	100,482

Acres in group selection (i.e., clearcuts in less than 3-acre units) or single tree selection	1,620	0	0	2,500	0	16,050

1/ Candidate acres. Actual acres harvested will depend on market conditions.

ECONOMIC EFFECTS

The purpose of this section is to compare economic values and significant tradeoffs. The following six sections include tables and accompanying narratives that display and describe various economic aspects of the alternatives considered (See Appendix D for a discussion of the conceptual relationships between net public benefits and economic variables, and Appendix B for a discussion of models and assumptions used in the analysis.)

- (1) Table 2.16 summarizes economic effects of the alternatives. Benefits and costs are displayed by major categories over decades 1 through 5. Estimated effects on local income and employment are presented for each alternative
- (2) Table 2.17 develops cash flow relationships from data contained in the previous table.
- (3) Table 2.18 and the accompanying discussion identifies tradeoffs in terms of present net value and affected resources of the minimum management requirements (MMR's), minimum implementation requirements (MIR's), and the common Forest constraint.
- (4) Table 2.19 displays PNV and major components of discounted costs and benefits for each alternative. Figure 2.1 displays the contribution to PNV by timber and recreation.
- (5) Table 2.20 displays indicators of each alternative's response to major local issues and National concerns.
- (6) The final section identifies the reasons for changes in PNV among the alternatives in terms of affected resources and recipient social groups.

Table 2.16 summarizes the economic effects of each alternative. The increase in total benefits over time is primarily the result of recreation expansion and projected timber price increases. Total benefits are disaggregated to returns to the U.S Treasury and noncash benefits. Returns to the Treasury represent potential revenues generated from the resource prescriptions proposed by each alternative. Over 95 percent of the returns to the Treasury are generated by timber sales

Because National policy calls for providing forest outputs such as water, recreation, and range for free or at a nominal charge, total benefits are substantially higher than returns to the Treasury. (See Appendix B for more detail on benefit and cash receipt values used in the analyses.) The difference between total benefits and return to the Treasury is displayed as noncash benefits. Noncash benefits account for 75 percent of total benefits the CUR, RPA, and CMD alternatives and 81, 82, and 83 percent of total benefits in the PRF, UNE, and NMK alternatives, respectively.

Costs are displayed in seven categories. Included in total costs are operations and maintenance costs, capital investment costs, and wildfire suppression. The last category is not included in the annual budget. Road construction and reforestation account for most capital investment on the TNF. Capital investment, therefore, relates primarily to the amount of timber harvest in each alternative, Timber harvest also accounts for most of the differences in operations and maintenance costs among alternatives. Fixed costs on the TNF account for about 3 million dollars (See Appendix B for more detail on costs used in the analyses.)

Effects on State and local economies in terms of potential 25 percent receipt shares and State yield tax revenues are also displayed. Differences in income and employment are also related to differences in timber harvest between alternatives. The recreation-generated component of total income and employment is larger than that for timber in all alternatives. The recreation-generated component, however, shows no variation among all alternatives in the first decade because developed and dispersed recreation RVD production is limited by demand Each of the 18 entries in Table 2.16 is accompanied by an explanatory footnote.

TABLE 2.16 - SUMMARY COMPARISON OF ECONOMIC EFFECTS BY ALTERNATIVE (Millions of 1982 \$/Yr.)

16 Discounted Costs *		527	446	542	635	476	502	
17 Present Net Value *		2,438	2,584	2,671	2,733	2,324	2,346	
18 Benefit/Cost Ratio *		5.6	6.8	5.9	5.3	5.9	5.7	

- 1 Total benefits include both cash returns to the US Treasury and noncash benefits. Total benefits are the estimated total amount that consumers would be willing to pay for Forest outputs, whether or not this amount is actually collected by the US Government. See Appendix B for an explanation of benefits and costs.
- 2 Returns to the US Treasury are the estimated potential payments by consumers of Forest outputs collected by the Federal Government.
- 3 Noncash benefits are the difference between the total estimated amount that consumers would be willing to pay for Forest outputs and actual collections by the Federal Government. At present it is national policy to provide most Forest outputs either at no charge to consumers or at a charge less than the total willingness-to-pay value.
- 4 Total costs include the Federal costs needed to produce Forest outputs, appropriated roads, FFF, and nonfederal costs. Nonfederal costs equal about \$0.7 million (see Appendix I).
- 5 Total budget is equal to Federal cost less the cost of fighting forest fires (FFF).
- 6 Operation and maintenance costs include the cost of administration, management, and protection of existing resources and capital assets. Operation and maintenance cost equals Total Cost less Capital Investment Cost.
- 7 Capital investment costs are the costs of creating or enhancing capital assets. Costs of treatments or activities that generate outputs or benefits over more than one period are capital investment costs.
- 8 Purchaser road credit is the cost of roads built by timber purchasers. These roads are accepted as in-kind payments in lieu of cost from timber purchasers.
- 9 Appropriated roads is the cost of roads built by the Forest Service rather than by timber purchasers. Total road cost less purchaser road credit equals appropriated road cost.
- 10 Other capital investment is all investment cost other than purchaser road credits and appropriated roads. This includes site preparation, cultural treatment, recreation development, etc.
- 11 Twenty-five percent of potential returns to the US Treasury would be distributed back to the counties in proportion to the Tahoe National Forest's acreage in each county.
- 12 Under California law, a yield tax currently equal to 2.9 percent of timber harvest value is levied on timber operators.
- 13 Total personal income including wages, salaries, proprietor's income, and rents was estimated for the Forest's zone of influence. See Appendix B, Section IV, and Chapter 4, Section B for a description of the input-output model used to make estimates.
- 14 Employment generated by the Forest in the zone of Influence was estimated with an input-output model. See Appendix B, Section IV, and Chapter 4, Section B. FTE's are full-time equivalents of part-time and full-time Forest Service employees.
- 15 Discounted benefits over the planning period.
- 16 Discounted costs over the planning period.
- 17 Discounted benefits less total discounted costs.
- 18 Discounted benefits divided by total discounted costs.

*Induced by management activities (net of MLV)

Table 2.17 displays average annual cash flows and noncash benefits for the first and fifth decades by alternative. Cash flow is the difference between cash receipts and total Federal costs. The following discusses the relationships displayed in the table for the first and fifth decades.

Ranking the alternatives by PNV and cash flow yields the same general pattern because both are dependent on the amount of timber produced. The RPA, CMD, and CUR alternatives maintain the top three positions whether ordered by PNV or fifth-decade cash flow. Likewise, the PRF, UNE, and NMK alternatives are always at the bottom of the list.

Total Federal cost also relates to timber volumes. The CUR, CMD, and RPA alternatives are the top three in total Federal costs and timber volume. The UNE alternative is fourth in total costs. It is more than the PRF alternative, mainly because of increased timber costs and roads per unit of timber output. The NMK alternative has the lowest timber yields and total costs.

The return to Treasury pattern follows the amount of timber harvest. In decade five, returns to the Treasury (and timber costs) are higher than in the first decade, primarily because of anticipated timber price (and timber cost) increases.

TABLE 2.17 - AVERAGE ANNUAL CASH FLOWS AND NONCASH BENEFITS

ALTERNATIVE	NET CASH FLOW		TIMBER ASQ		TOTAL FEDERAL COSTS		RETURN TO TREASURY		NONCASH BENEFITS	
	1 \$MM	5 \$MM	1 MMBF	5 MMBF	1 \$MM	5 \$MM	1 \$MM	5 \$MM	1 \$MM	5 \$MM
CUR	17.1	43.5	173.4	193.7	20.7	30.0	37.8	73.5	111.5	141.1
CMD	13.7	42.4	180.1	196.9	25.2	42.7	38.9	85.1	120.1	160.7

1/ Costs are limited to agency expenditures. Payments to counties and cooperators' expenditures are not included.

CONSTRAINT ANALYSIS

Marginal Cost of Constraints Table 2 18 displays the opportunity cost in terms of the PNV of the MMR's, the MIR's, and the common Forest constraint. (See the Management Direction Common to All Alternatives in Section E of this chapter for a discussion of the purpose of these requirements.) These constraints also provide non-priced amenity benefits. The primary recipients of these amenity benefits are the former urban residents, regional recreationists, alternative lifestyle, and Native American social groups. (See Chapter 3, THE SOCIAL ENVIRONMENT, for a discussion of the characteristics of each social grouping represented on the TNF.) The opportunity costs and amenity benefits are discussed below.

As a group, the MMR's reduce PNV in the first decade \$454 million and timber harvest volume 223 MMBF. In the first decade, the MMR's individually account for 82 percent of the decline in PNV and 39 percent of the decline in timber harvest volume. The remaining decline in PNV and timber volume is because of individual MMR interaction or overlap, i.e., where restrictions help meet more than one MMR. In terms of priced benefits and costs, the MMR's significantly affect only timber and related water and range benefits and timber and related road costs.

1. Viable Populations for Spotted Owl (**VPD**). The minimum management requirement for spotted owl maintains 1,000 acres of suitable habitat for each of the 32 non-wilderness pairs needed to maintain a viable population on the TNF. This requirement limits the silvicultural practices, and their timing, on affected acres to maintain spotted owl habitat. Allowable harvest is reduced 25 MMBF per year for the first 8 decades. PNV is reduced \$150 million. Water production declines slightly because fewer acres are harvested. Recreation outputs are not affected.

Because the spotted owl constraint results in lengthened timber harvest rotations, visual and recreation quality is also enhanced. Other wildlife species (besides spotted owls) also benefit from the spotted owl habitat.

2. Sensitive Watershed Lands (**WSD**). The minimum management requirement for sensitive watershed lands limits the amount of vegetative disturbance on erosive and overly-steepened slopes. This requirement is fulfilled by practicing selective timber harvest on 48,000 acres of sensitive watershed lands. Allowable harvest is reduced 16 MMBF for the first 8 decades. PNV is reduced \$88 million. Water and range outputs are reduced when fewer productive acres are harvested. The quantity of recreation outputs is unaffected.

The selective harvesting used to protect sensitive watershed lands also enhances visual and recreation quality.

3. Riparian Areas (RIP). The minimum management requirement for riparian areas prevents adverse riparian area changes. This requirement is fulfilled by practicing selective timber harvest on 34,000 acres adjacent to perennial streams. Allowable harvest is reduced about 9 MMBF per year for the first 8 decades. PNV is reduced \$71 million. Water and range outputs are slightly reduced because fewer acres are harvested. The quantity of recreation outputs is unaffected, but recreation and visual quality is enhanced.
4. Nondeclining Yield (NDY). The nondeclining yield requirement helps reduce fluctuations in the local wood products manufacturing industry and enhances multiple-use management. This requirement ensures that planned sale levels for future decades are equal to or greater than the sale quantity of the previous decade. Allowable timber harvest is reduced about 29 MMBF per year for the first decade and PNV is reduced \$41 million. In periods when the nondeclining yield requirement results in fewer acres harvested, or shifts the harvest to less productive vegetation types, range and water outputs are also reduced.
5. Dispersion (DSP). The requirement to disperse regeneration units maintains logical harvest units of at least 5 acres between openings. Allowable timber harvest is reduced 3 MMBF per year for the first 8 decades and PNV is reduced \$13 million. Water and range outputs are reduced.

when fewer productive acres are harvested. The quantity of recreation outputs is unaffected.

The primary benefit of the dispersion constraint is enhanced visual quality. Dispersion also increases habitat diversity and reduces adverse impacts to water and air quality. The quality of the recreation experience is also enhanced through increased scenic diversity.

6. **Threatened and Endangered Species (TES).** The T&E minimum management requirement protects T&E species habitat. This requirement is fulfilled by practicing selective timber harvest in bald eagle and Lahontan cutthroat trout habitat. Peregrine falcon recovery projects are also implemented. PNV declines \$7 million because of the 2.5 MMBF per year decline in allowable harvest that occurs in the first 8 decades and because of the added costs for the falcon recovery projects. Water, range, and recreation outputs are not significantly affected. The selective timber harvesting used to protect T&E species habitat generates other non-priced benefits. These include enhanced visual and recreation quality.

7. **Culmination of Mean Annual Increment (CMI).** The requirement to grow trees to an age that produces 95 percent of the maximum average growth reduces timber benefits by extending minimum rotation lengths of plantations. Allowable harvest is reduced 1.5 MMBF per year for the first 8 decades and PNV is reduced \$2.5 million. Water, recreation, and range outputs are not significantly affected.

Because the CMAI constraint only applies to plantations, few non-priced benefits occur. The effect of extending harvest rotation lengths might provide a minor benefit to the visual quality of the plantations.

8. **Minimum Implementation Requirements (CEE).** The minimum implementation requirement for scenic highways maintains an attractive roadside along existing and planned State scenic highways. Timber is managed along scenic highway corridors on long rotations. A second operational requirement to restrict the total acreage of regeneration cutting to 18 percent of the timber suitable acres was always met because of the restrictions previously placed on regeneration cutting by the MMR's and the timber policy requirements. This operational requirement thus had no effect on PNV or timber harvests.

The scenic highway requirement reduces allowable harvest 0.4 MMBF per year for the first 8 decades and 9 MMBF per year for the following 8 decades. PNV is reduced \$9 million. Water, recreation, and range outputs are not significantly affected.

9. **Carman Valley Watershed (CEF).** This management requirement, common to all alternatives considered in detail, limits timber management in a watershed that is declining. The SMZ's are removed from regulated timber management and the remainder of the watershed is managed on a long rotation. Allowable harvest is reduced 0.09 MMBF per year for the first 8 decades. PNV is reduced \$0.4 million. Water, range and recreation outputs are not significantly affected.

Table 2.19 displays the alternatives ranked by decreasing PNV. The table also displays major components of discounted costs and benefits for each alternative. The constrained economic efficiency (CEE) benchmark, which represents the MMR's, MIR's, and common Forest constraint, and the minlevel benchmark (MLV), which represents fixed costs and background outputs, are also displayed for comparison.

In MLV, fire loss is displayed as a negative benefit, but because MLV benefits and costs are subtracted from the alternatives, reduced fire losses are displayed as loss reductions (a benefit) in the alternatives. Timber and recreation account for most benefits and costs. Water benefits and road costs are closely related to timber benefits and costs. Changes in timber output primarily determines the rankings of alternatives by PNV.

2/ All changes measured from CEF - Constrained Economic Efficiency alternative with common Forest Constraint

31 Direct comparison of benefits and costs by individual resource provides general indicators of specific relationships, but may be misleading because many costs are inseparable under multiple use management

4/ WFUDs and facilities

Table 2.20 highlights major differences and similarities among alternatives in terms of tradeoffs among priced and non-priced benefits and responses to national concerns and local issues

In Table 2.20 the alternatives are ranked by decreasing PNV (in millions of dollars) in relation to selected quantitative indicators of responsiveness to issues. Also displayed are first and fifth decade average net cash flows and potential local income and employment induced by the proposed alternatives. PNV and net cash flow are indicators of concern to the Federal taxpayer and measure responsiveness to the national issues of economy in government and deficit reduction. Timber production is both a national and a local issue. The other columns display acres regenerated or converted to range, acres meeting preservation, retention, and partial retention visual quality objectives in the fifth decade, and the 5-decade trend in potential spotted owl habitat; these indicators respond to major local issues. The general pattern is that a tradeoff exists between responding to these local issues and the regional and national issues represented by PNV, cash flow, and timber production. Only indicators of local issues that involve major tradeoffs with the national issues are shown in Table 2.20. A more complete display of how the alternatives respond to the planning issues is in Table 2.21.

2/ Visual Quality Objectives

Summary of Reasons for Change In PNV. The major components of each alternative that cause a tradeoff with PNV are discussed below. (See Appendix D for a full discussion of economic values and net public benefits)

Most of the total variation in PNV, costs, and benefits is attributed to timber and recreation. With few exceptions, the changes in benefits and costs in water, range, roads, and fire are due to a link with recreation or timber (Table 2.19).

Alternative **CEF-Constrained** Economic Efficiency With Common Forest Constraint

PNV = \$2,911 Million

Change in PNV = 0

First Decade Net Cash Flow = \$22.9 Million

CEF represents the least constrained alternative that meets minimum management and implementation requirements. When measured by PNV, the most economically efficient mix and schedule of resource outputs is represented by CEF. Short rotation even-aged timber management would be practiced on most suitable forest land. As explained in Appendix D, PNV is an imperfect measure of economic efficiency because it does not account for non-priced benefits. While it is a feasible alternative, CEF does not respond to the demand for non-priced outputs implied by the public issues. To respond to this demand, additional requirements are imposed on CEF to form the other alternatives and to provide a range of priced and non-priced benefits. Each alternative thus represents a different perception of the demand for priced and non-priced benefits. Because all alternatives share the CEF constraint-set in common, CEF provides a logical basis for comparison. The change in PNV from CEF, therefore, represents an implied minimum dollar value of the additional non-priced benefits provided by each alternative.

Alternative CMD - Commodity

PNV = \$2,733 Million

Change in PNV = -\$178 Million

First Decade Net Cash Flow = \$137 Million

Alternative CMD addresses the public concern for increased intensity of vegetation management for timber outputs. This alternative would decrease timber outputs below the CEF level [Throughout this section the primary reason for restricting timber management practices are given. Acres are approximate. There is rarely a single resource benefit from reduced timber management intensity. The benefit given reflects the thrust of the alternative theme.] However, this alternative would produce more timber than any other alternative to respond to the timber issue and benefit the local timber industry. Direct recipients of these benefits would primarily be those employed in the timber industry, the long-time residents and Native Americans social groups.

Developed recreation expands existing facilities and develops new **sites** to meet demand above CEF level, this increases PNV. All potential developed recreation and downhill ski **sites** would be managed so that no negative impacts on timber production would occur. Wildlife is a major emphasis on 8,000 acres. Harvests are planned in all 32 spotted owl habitat areas on CAS lands (one is in wilderness). Range benefits would remain about the same as in the CEF alternative. Water benefits would be decreased because of their linkage to timber harvest. However, water benefits under this alternative would be higher than under any other alternative over the first 5 decades except Alternative RPA. Range and water yields are most beneficial to the long-time residents' social group.

Alternative RPA - 1980 RPA

PNV = \$2,671 Million

Change in PNV = -\$240 Million

First Decade Net Cash Flow = \$12.3 Million

Alternative RPA addresses public concerns for the level of commodity outputs, recreation, and selected harvest species habitat. PNV is reduced from CEF because output levels for recreation, range, water quality, and wildlife are emphasized to meet RPA targets. Timber management prescriptions would be restricted to be compatible with dispersed recreation objectives on about 42 thousand more acres than CEF. Timber management prescriptions would also emphasize harvest species habitat on about 17 thousand more acres than CEF. Harvests are scheduled in all 32 nonwilderness spotted owl habitat areas (one is in wilderness)

Short rotation even-aged timber management would be practiced on about 70 thousand fewer acres than CEF. Primary recipients of the benefits to recreation and wildlife would be the regional recreationists

Meeting the RPA range target by converting brushland to permanent range would also reduce PNV from CEF, but would benefit the local ranching community.

Water production and its benefit would be reduced from CEF because timber harvest is reduced as described above, although water quality would be enhanced as compared to CEF

Alternative CUR - Current Management

PNV = \$2,584 Million

Change in PNV = -\$327 Million

First Decade Net Cash Flow = \$17.1 Million

Alternative CUR maintains current mixes of commodity and amenity outputs. PNV is reduced from CEF because of reductions in timber management below the CEF level to provide non-priced benefits.

Compared to CEF, timber management practices would be restricted on an additional 51 thousand acres to enhance dispersed recreation, and about 50 thousand acres to enhance visual quality. The primary recipient of these benefits would be the regional recreationists social group. Short rotation even-aged timber management would be practiced on about 111 thousand fewer acres than CEF. Harvests are scheduled in all 32 nonwilderness spotted owl habitat areas (one is in wilderness).

PNV is also reduced from CEF because campgrounds are restricted to existing capacity, which is below the CEF level. The Forest budget is maintained at the current level in this alternative, which restricts opportunities to generate additional benefits.

Alternative PRF - Preferred

PNV = \$2,438 Million

Change in PNV = -\$473 Million

First Decade Net Cash Flow = \$5.7 Million

Alternative PRF addresses public concerns for commodities, recreation, and fish and wildlife habitat. Livestock forage would be higher than the CEF level, which also reduces PNV; this benefits the local livestock ranching community and responds to the range issue.

The recreation portion of PNV is greater for this alternative relative to the CEF alternative because this alternative would expand existing facilities and develop new sites. PNV is reduced from CEF because timber practices would be limited on additional acres to enhance visual quality and dispersed recreation opportunities. Wildlife is an emphasis on 76,000 acres compared to none in CEF. This alternative would also provide additional basal area in mixed hardwood stands compared to CEF. Harvests are not scheduled in 22 of the 32 nonwilderness spotted owl habitat areas (one is in wilderness). The primary recipients of these benefits would be regional recreationist and second-home owners. The primary recipients of the expanded range outputs, the local ranchers, are among the longtime residents social group. Short rotation even-aged timber management would be practiced on about 215 thousand fewer acres than CEF.

Perennial streamside management zones (SMZ's) are considered as varying in width. Perennial and intermittent SMZ's are assigned marginal yields, thus reducing timber yields and PNV.

Alternative UNE - Uneven-Aged

PNV = \$2,346 Million

Change in PNV = \$565 Million

First Decade Net Cash Flow = \$32 Million

Alternative UNE responds to the public concern for the amount of clearcutting and even-age management being practiced on the Forest. PNV is reduced from CEF because of reductions in timber harvest and increased costs associated with uneven-age practices. Short rotation even-age timber management would be practiced on about 321 thousand fewer acres than CEF.

Group selection uneven-age management would be practiced on about 96,000 acres, compared to 0 in CEF. This practice is associated with decreased yields and increased costs, both of which reduce PNV.

Wildlife is emphasized on 76 thousand acres. This alternative would also provide additional basal area in mixed hardwood stands compared to CEF. Harvests are not scheduled in 22 of the 32 nonwilderness spotted owl habitat areas (one is in wilderness).

The primary recipients of the expanded range outputs, the local ranchers, are among the long-time residents social group.

Perennial SMZ's are defined as varying in width. Both perennial and intermittent SMZ's are assigned marginal yields, thus reducing timber yields and PNV.

Alternative NMK • Nonmarket

PNV = \$2,324 Million

Change in PNV = -\$587 Million

First Decade Net Cash Flow = \$0.9 Million

Alternative NMK responds to public concerns for SPNM recreation, water quality, dispersed recreation, and fish and wildlife habitat. This alternative has the next to lowest PNV of the alternatives studied in detail. Amenity values would dominate Forest management in this alternative. Timber harvesting practices would be restricted, compared to CEF, to provide amenities such as visual quality and recreation. Short rotation even-aged timber management would be practiced on about 297 thousand fewer acres than CEF. The maximum amount of land is assigned to **SIA's**, RNA's, and roadless areas. Additional acres are also withheld from timber production due to sensitive watershed lands.

Range production would decrease to nominal outputs by decade 5. PNV is also reduced from CEF because of the reduction in water production that would accompany reduced timber harvest. This alternative would provide the most old-growth and spotted owl habitat. No harvests are scheduled in 29 of 40 nonwilderness spotted owl habitat areas (one is in wilderness). Additional basal area in mixed hardwood stands is also provided. Recreation benefits are higher than CEF because the restrictions on timber management would make campgrounds relatively more economical.

Clearcuts would be limited to approximately 3 acres, and no herbicides would be used. Both of these practices would reduce timber yields and increase costs, thus lowering PNV.

Perennial SMZ's are considered as varying in width. Perennial and intermittent SMZ's are assigned marginal yields, thus reducing timber yields and PNV.

The amenity benefits would be enjoyed by all social groups. The long-time residents social group and others with a commodities interest might be adversely affected by the reduction in timber harvest and forage production.

ISSUES, CONCERNS, AND OPPORTUNITIES

Table 221 summarizes each alternative's response to the TNF issues, concerns, and opportunities (see Chapter 1) in expected outputs and management objectives.

TABLE 2.21 -COMPARISON OF ALTERNATIVES BY MAJOR TNF ISSUES, CONCERNS, AND OPPORTUNITIES

PLANNING ISSUES 1/	OUTPUT OR EFFECT TO BE MEASURED	PRF	CUR	RPA	CMD	NMK	UNE
1 OWNERSHIP & LAND USES In what ways and to what extent can the Forest Service lessen or resolve conflicts between uses on the National Forest private, and other public ownerships within the TNF boundary?	Acres proposed for acquisition first decade	5,000	2,480	2,500	8,000	20,000	5,000

- 1/ These are the major Tahoe National Forest issues, concerns, and opportunities. For a complete discussion of these issues, refer to Chapter 1 and Appendix A of the EIS the Planning Records (1922 16a.7b), and Chapter IV of the Forest Plan
- 2/ The Regional Guide and the Forestwide Management Standards and Guidelines provide Forest direction for fire protection (structural and wildland) for intermingled private lands
- 3/ All alternatives would emphasize intergovernmental coordination of land use planning with the State of California and Nevada, Placer, Sierra, Plumas, and Yuba Counties
- 4/ There are no known significant energy-mineral resources that could contribute to meeting the Nation's future energy needs
- 5/ Forestwide S&G's for all alternatives would allow for hydroelectric development. Proposals would be evaluated on a project-by-project basis. Energy potential shall be considered a National Forest resource in these evaluations.
- 6/ MMBF = Million board feet
- 7/ Average annual Animal Unit Months (AUM's) produced at the end of the fifth decade
- 8/ Percent of total permanent range on the TNF that is intensively managed.
- 9/ Acres treated with soil-imparting activities divided by acres under Alternative CUR. Average for decades 1 through 5
- 10/ Forestwide Standards and Guidelines to maintain long-term soil productivity would be applied to all alternatives
- 11/ MRVD = Thousand recreation visitor days
- 12/ The North Fork of the American River was designated a Wild River by Congress. Other proposals have been evaluated for Wild, Scenic, or Recreation classification, however, none meet the eligibility criteria for further evaluation (see Appendix E)
- 13/ PAOT = Persons-At-One-Time Capacity

CHAPTER 3 THE AFFECTED ENVIRONMENT

A. INTRODUCTION

The Affected Environment chapter describes the physical setting to be affected by the alternatives. It includes the current management situation. The general Forest description is followed by discussions of the economic, social, and resource environments.

B. GENERAL DESCRIPTION OF THE FOREST

VICINITY

The Tahoe National Forest (TNF) is located in the north central Sierra Nevada mountains in California. The TNF is bounded on the north by the Plumas National Forest, on the east by the Toiyabe National Forest and Lake Tahoe Basin Management Unit, and on the south by the Eldorado National Forest.

Interstate Highway 80 crosses the central part of the TNF and provides primary access across the Sierra Nevada between Sacramento, California and Reno, Nevada.

The TNF includes land in the Counties of Nevada (169,116 acres), Placer (241,229 acres), Plumas (11,313 acres), Sierra (352,222 acres), and Yuba (20,494 acres). The administrative boundary encompasses 1,175,535 acres. Of this total, 381,161 acres are in other ownerships in an alternate section (checkerboard) pattern. Approximately 253,425 acres (32 percent) of the remaining 794,374 acres of National Forest System lands have been acquired through purchase, donation, or exchange within the past 50 years.

The TNF is divided into five administrative units called Ranger Districts: Downieville (212,479 acres), Foresthill (155,975 acres), Nevada City (140,928 acres), Sierraville (164,049 acres), and Truckee (120,782 acres).

The Lake Tahoe Basin Management Unit (LTBMU) was formed in 1973 by Presidential proclamation to provide special protection for the unique features of Lake Tahoe and its watershed. A portion of the TNF (28,833 acres), along with portions of the Toiyabe and Eldorado National Forests, comprise the LTBMU. The LTBMU is not covered by this Forest Plan, although it is still legally part of the TNF. Further mention of the TNF will not include those lands in the LTBMU.

LANDFORM

The elevation of the TNF ranges from about 1,200 feet above sea level in the west to over 9,000 feet along the crest of the Sierra Nevada. Many of the higher slopes and peaks have been glaciated, exposing the hard underlying rock materials with glacial moraines formed along the adjacent slopes and valleys. These landforms are observed in the Sierra Buttes-Gold Lakes area and around Donner Summit. The western two-thirds of the TNF tilt to the west, exhibiting nearly uniform flat ridges which have been dissected by westerly flowing streams.

CLIMATE

The TNF experiences a typical Mediterranean-type climate: warm, dry summers alternate with cool, wet winters. Overall precipitation on the TNF is moderate. Average annual precipitation varies from about 50 inches near the TNF's western boundary to 80 inches at the 6,000-foot level. East of the Sierra Nevada crest, precipitation decreases dramatically to approximately 35 inches per year near Truckee and 20 inches per year near the California/Nevada State line. Most precipitation occurs between November and May in the form of snow on the east side of the Sierra Nevada crest and above 5,000 feet elevation on the west side. Thunderstorms are common during the summer on the east side of the crest and at higher elevations on the west. The west side has extended drought periods at lower elevations.

HISTORIC INTEREST

The western slope of the TNF contains an old and important mining district, commonly referred to as The Northern Mines. This area has numerous historic mining **sites**

The development of these mines and construction of townsites created a demand for sawtimber. In **1869**, timber harvesting increased with access provided by the Central Pacific Railroad. This early demand *for* sawtimber resulted in a large portion of the TNF being harvested. Because of this harvesting, much of the TNF is in young growth stands of timber approximately **80 to 90** years old.

RECREATION

Recreation use is high on the TNF because many areas of high scenic beauty and recreational appeal are located within a short travel distance of the metropolitan areas of Reno, Sacramento, and San Francisco. An estimated eight million residents live within a four-hour drive from the TNF. Some features of special interest that attract visitors to the TNF include: Placer County Grove of Sierra Redwoods, North Fork American Wild River, Granite Chief Wilderness, Donner Camp, the historic emigrant route from Verdi to the Sacramento Valley, and numerous ski areas and reservoirs. Demand for these and other areas creates conflicts in the TNF for camping, picnicking, swimming, off-highway vehicle use, hiking, winter sports, hunting, and fishing.

The proximity to the large, spreading urban populations also increases the use of National Forest System lands for rights-of-way for power, phone, and water lines, fuelwood, access roads, and timber harvesting.

C. THE ECONOMIC ENVIRONMENT

The TNF and surrounding area has a complex social and economic environment. Recognizing this fact, the TNF contracted with David M. Dornbusch and Company to prepare a socioeconomic overview as part of the Analysis of the Management Situation. This overview consists of two documents: The *Socio-Economic Overview for the TNF*, and the Socio-Economic Interrelationship Study, *Central Sierra Forests and the Lake Tahoe Basin Management Unit*. These two technical documents serve as a baseline overview of the existing social and economic conditions which exist in the TNF's zone of influence. These documents detail the socioeconomic structure and relationship of the TNF with local communities. Following is a brief summary of the documents and implications of the study.

The counties of Nevada, Placer, Sierra, Yuba, and Plumas are directly and indirectly affected by TNF activities. In turn, they affect management of the TNF because the population of these counties creates much of the demand for TNF goods and services.

EMPLOYMENT

The major employment sectors in the impacted counties (Table 3.1) are government, manufacturing, retail trade, and services. The retail trade and service industries include employment both from tourism and recreation and from serving the growing *resident* populations. Construction and manufacturing employment are also significant. The portion of retail trade and services employment that results from tourism and recreation is highly seasonal.

TABLE 3.1 • 1979 EMPLOYMENT PERCENTAGE BY INDUSTRY

County	TNF Acres	Govt.	Mfg.	Retail	Services	Other
Nevada	169,116	21.3	13.3	22.1	22.8	20.5

SOURCE. Socio-Economic Overview for the TNF

Table 3.2 summarizes employment in the impacted counties for the wood products industry. Wood products employment constitutes a major share of all manufacturing employment in all impacted counties; it occupies a substantial share of all employment only in Plumas and Sierra Counties. The industry is important because it is a 'basic' or export industry, which brings money into the counties. Nonbasic industries generally support the local populations, but do not bring income into the local economy. Unfortunately, wood products is a highly cyclical industry. The actual logging operations are seasonal, and most of the sector is sensitive to the demand for lumber, which varies with interest rates and construction cycles. One noncyclical aspect is the wood chip market, which satisfies demand for wood pulp. Pulp demand has been steadily increasing at 5 percent per year. Companies with large and efficient chip conversion operations can more easily weather slumps in the lumber market. Given the cycles observed in the impacted counties, this noncyclical operation is not substantial enough to smooth variations in activity for the solid-wood products sector.

Nevada County. In 1979, three industries contained two-thirds of all employment in the County: retail trade, services, and government. Each comprised an approximately equal share of total employment, and was somewhat higher than State averages. Manufacturing employment was well below the State average in 1979, with lumber and wood products accounting for one-third of the manufacturing total.

The retail trade and services sectors are related to the importance of recreation to Nevada County. Several ski areas along the heavily traveled Interstate 80 provide winter recreation. Tourism in the historic Gold Country is increasing. Employment in winter recreation helps balance seasonal unemployment in other industries, and because employment in hotels and lodging is higher in winter than in summer, total employment in winter tourist-related services is higher than that for summer. [Labor Market Newsletter (Planning Edition) Nevada County, 1980-81, California Employment Development Department, May 1980.] Because of tourism and the growing population, services and retail trade are the largest industries.

TABLE 3.2 - EMPLOYMENT IN THE WOOD PRODUCTS INDUSTRY, PERCENT OF COUNTY MANUFACTURING EMPLOYMENT, AND PERCENT OF TOTAL COUNTY EMPLOYMENT, SELECTED YEARS

County	Year	Wood Products- Number of Persons Employed	Wood Products- Percent of Manufacturing Employment	Wood Products- Percent of Total County Employment
Nevada	1960	400	73	17

	1975	700	58	11
	1980	800	66	10

SOURCE. U.S. Department of Commerce

Employment in the wood products manufacturing industry is important in the western part of Nevada County, where lumber and sawmill operations are located. Since 1974, the County's share of all wood products employment has varied from about 8 percent to 4 percent, largely because of the cyclical nature of the industry. Indirect employment generated by the timber industry in other sectors includes employment in logging services suppliers, mechanics, truckers, and consulting foresters.

Employment in construction and mining increased substantially between 1974 and 1979, and constituted 8.4 percent of total employment in 1979. The construction component of this industry is sensitive to changes in the National, State, and local economies. High interest rates have detrimentally affected construction and wood products employment; the primary reason that construction employment has not declined more has been the high growth (and new building) rate in the County.

Manufacturing employment in other than wood products grew to 9 percent of 1979 employment. Jobs in the electronics and computer industries have contributed significantly to the local economy, and may grow in the future. A sizeable increase in finance, insurance, and real estate employment was reported between 1978 and 1979, which can be attributed primarily to increased real estate activity accompanying the high rate of recent population growth in the County.

Placer County. Retail trade, government, and services also dominate employment in Placer County, with retail trade and services accounting for a somewhat larger share than the State average. Transportation and public utilities comprise 10 percent of the County's employment, nearly twice the State average. Employment in wholesale trade is almost half the State average.

Construction employment is higher than the State average at **7.7 percent in 1979**, which is a reflection of steady building activity in support of population growth. Because employment in this sector apparently was not affected by high interest rates, demand for housing in the communities in the western part of the County near Sacramento was strong enough to overcome adverse economic conditions. This demand may be due to homebuying by Sacramento commuters, with a smaller share of all construction being second homes. Also, construction of proposed dams, pipelines, and electronics manufacturing facilities may prevent future slumps.

Generally, employment in the wood products sector has been subject to the same cycles exhibited in Nevada County, except that a smaller share of all employment is devoted to wood products in Placer County. Apparently, stable construction activity in the County has not offset the cyclical nature of the wood products industry.

Agriculture and mining retained the same numbers of employees between **1974** and **1979**, but these figures represent a declining share of total employment. Finance, insurance, and real estate, in addition to services, maintained approximately the same share of all employment by steady growth over the period. Government employment peaked in **1977**, with a **27 percent** share that has since declined in response to State and Federal policies. Service employment has slowly increased since **1974**, while retail trade only increased significantly in **1978** and **1979**. The presence of Lake Tahoe's north and west shores in Placer County, along with the **1-80** corridor, ensure that recreation-related employment will continue to be important. Summer and winter recreation are important to Placer County. Lake Tahoe attracts skiers in the winter and water sport enthusiasts in the summer.

Plumas County. The present economy of the County is geared to the wood products industry and to recreation. Three-fourths of the County is public land. Both manufacturing and retail trade have experienced a gradual rise in total percentage of employment.

The manufacturing sector consists primarily of wood products manufacturing, and the cycles of that industry reflect the declines during **1975** and **1976**. In **1979**, manufacturing added **100** new jobs, primarily in the wood products sector.

The gradual increase in the retail trade and services industries can be attributed to both summer recreation and the County's expanding population. These sectors should be a major source of new jobs as they continue to expand.

The government sector reflects the State in general and has shown a slight decline since Proposition 13 was passed. It still accounts for nearly a third of all employment.

In other areas, agricultural employment declined from **100** employees in **1974** to only **50** in **1979**. Construction appears to be on the rise in both number of employees and percentage of the total market. It has risen from **1.2 percent** in **1974** to **4.6 percent** in **1979**. High interest rates could cause future problems in the industry, which might ultimately affect the lumber industry.

Sierra County. Total wage and salary employment in this County increased 20 percent between **1974** and **1979**. Its major industry in **1979** was government, which represented 50 percent of the total wage and salary employment. The only other industry that provided a substantial percentage of employment was manufacturing, with **20.2 percent** of the total employment. Manufacturing employment in Sierra County is especially heavy in wood products, and yearly totals reflect the cycles of this industry. Other County employment includes Christmas tree farming, cattle ranching, and farming.

Statistics suggest that mining is not presently a significant source of employment, although some officials believe mining employment is important. Recreational mining has become an important activity.

Yuba County. The major industry of Yuba County is government, constituting nearly half of all employment. Half of the government total is military employment related to Beale Air Force Base.

Other important industries are retail trade, services, manufacturing, and agriculture. Agricultural employment is significant because some of the County is in the Central Valley. Agricultural employment declined between

County Finances. Under the National Forest Management Act, 25 percent of the revenues collected by the TNF from timber, grazing, recreation, mineral, and other resource uses of the Forest are returned to the counties in which the TNF is located. Each county receives a portion of these revenues based on total TNF acreage within the county. Law provides that these revenues be split evenly between public schools and roads. These payments are commonly referred to as Receipt Act payments. The Receipt Act program includes the Knudsen-Vandenberg Fund and Purchaser Road Credits. Twenty-five percent of the collections from these two categories are included in the base income for the Receipt Act payments to the counties.

Collections from timber accounted for over 90 percent of the Forest's total revenues in 1987. Table 3 4 displays collections in each category between 1983 and 1987

The second Governmental program through which the impacted counties receive revenues because of the Forest is the Payment in Lieu of Taxes Act, administered by the U.S. Bureau of Land Management (BLM). Under this Act, payment is made to counties containing Federally owned land. Payments received under the Act may be used by the recipients for any Governmental purpose. Each of the impacted counties receives payment from the BLM under this Act in proportion to the acreage of Federal lands within each impacted county.

The third program is a State program, the Timber Yield Tax, which is administered by the State Controller. This tax is paid when the trees are harvested and includes the harvest on both public and private lands.

	1983	1984	1985	1986	1987
Timber 2/	\$10,780,758	\$13,993,233	\$8,633,041	\$9,517,032	\$15,846,209

the TNF, accounting for 19 percent of total County school revenues. The TNF's Receipt Act payments are very important in terms of the County's ability to provide educational services. In the other four impacted counties, the TNF Receipt Act payment provided less than 2 percent of total county school revenues.

ECONOMIC EFFICIENCY

Economically efficient Forest management has not been explicitly required until recent years. The National Forest Management Act of 1976 (NFMA) set forth explicit requirements for economic efficiency analysis of Forest management proposals. While economic efficiency must be analyzed and considered, it is not the sole decision criterion. Although the Forest Service has generally tried to achieve cost-efficient management (lowest possible input cost per unit of output), systematic evaluation of all costs and benefits from practices and activities has been undertaken only in recent years

The measure of economic efficiency applied in formulating and evaluating alternatives is Net Public Benefits (NPB), as mandated in 36 CFR 219.1(a) and 219.12(f). NPB are the sum of Present Net Value (PNV) and nonpriced commodity values. PNV is the difference between the discounted value of all outputs to which monetary values or established prices are assigned and the total discounted costs of managing the planning area. Examples of nonpriced benefits include scenic quality, wildlife habitat, and community stability. Values of some nonpriced commodities are inferred from observations of indicators such as the number of participants, tolerance of congestion, and expense of participation. (Appendix D contains additional discussion of economic efficiency analysis.)

The dominant nonpriced commodities for the TNF are embodied in the planning issues. One function of the public involvement process, which produced the planning issues, was the inference of nonpriced commodity values.

To account for the ultimate subjectivity of the inferred demand for nonpriced commodities, a range of production of priced and nonpriced commodities is provided by the alternatives considered. Within each alternative priced and nonpriced commodities are produced in the most cost-efficient method by maximizing PNV. The major components of PNV on the TNF are timber, recreation, water, and range. Recent trends in these components are discussed below.

Timber. Timber management and production costs have increased in the past decade as less accessible areas of the TNF have come under management. Timber production costs are sensitive to changes in energy, labor, and capital costs, all of which have experienced increases in the past decade. Costs of management and production have also increased as the costs of environmental protection are internalized in the planning, logging, and manufacturing processes. A significant factor in the cost of regeneration is the availability of herbicides for plantation release.

To achieve the goal of stable timber outputs, an even flow of timber is offered for sale. Actual sale volume ranged from 85 to 179 million board feet in the past decade. Harvest ranged from 60 to 160 MMBF as timber operators responded to changing market conditions. Timber values displayed a general increase in recent years, with the exception of the 1979-82 recession. Bid prices in this period still averaged 2-1/2 times appraised values.

Recreation. The costs of developing and maintaining developed recreation sites rose at greater rates than the general trend of the economy over the past decade. The cost increases stemmed from rapidly rising construction and material costs, and higher standard sites designed in response to the demand for more full-service developed recreation facilities. Those increases slowed in the early 1980's, however, because of depressed economic conditions in the construction trade. Also, because of reduced development and maintenance costs, the TNF has emphasized standardized facility designs, high durability and longevity of facilities, and moderation of the high-design standards. The recent recreation management emphasis has also shifted more toward dispersed recreation. This shift includes significant new trail construction, such as the Pacific Crest Trail. Because of the new construction, and upgraded trail maintenance, the quality of the trails and the trail users' recreation experience on the TNF has improved over the past decade.

Conversely, the recreational experience of visitors in developed sites has, in many cases, declined because of the deterioration and overcrowding of facilities (caused by deferring costly new development and maintenance).

Recreation use on the Forest increased from 4 062 MMRVD's (Million Recreation Visitor Days) use in 1972 to 41 92 MMRVDs in 1982 and over 5 MMRVDs in 1986. Population growth in the Reno, Sacramento, and Nevada County areas has contributed heavily to this growth. Also, per capita recreation use rates of these populations in activities such as camping, alpine skiing, and sightseeing have increased. Daily user fees charged in full-service campgrounds increased from \$1.00 in 1972 to \$5.00 in 1987.

Water. Water production on the TNF has not changed significantly over the past decade. During that period, expenditures to maintain water quality have been largely for protection of fisheries, meadow and aquatic ecosystems, and scenic quality. While the TNF does not charge for the use of water from National Forest System lands, its value has increased. This increase has resulted from expanding demand for water for domestic uses, agriculture, industry, and energy production.

Range. The cost of range management is linked more closely to budget than to production levels. Structural and habitat improvements and allotment administration costs have declined on a per-AUM (animal unit month) basis in the past decade as budgets were reduced. AUM production on the Tahoe has risen from 14,500 in 1975 to approximately 20,000 in 1982.

Grazing fees are set to reflect the cost of alternative feed sources and livestock prices. Fees per AUM increased from \$1.17 in 1975 to \$2.58 in 1980, declined to \$1.86 in 1982 and \$1.54 in 1988.

D. THE SOCIAL ENVIRONMENT

ZONE OF INFLUENCE

The management and activities of the TNF influence people living both in the local area and in an extended zone of influence. Nevada, Placer, Sierra, Yuba, and Plumas Counties are directly affected by TNF activities. They are characterized by recent, rapid population growth, a relatively rural living environment, cyclical employment trends, and some dependency on the Forest for revenue and jobs. The extended zone of influence for the TNF is the San Francisco Bay Area, the Central Valley metropolitan areas, and Reno. These market areas have demographic characteristics closer to the State of California than the impacted counties: urban, younger, more minorities. Steady population growth is also expected to occur in the extended zone, but at rates lower than in the impacted counties. Table 3.5 compares the recent population growth of these five counties and projections for the future.

A comprehensive review of the complex TNF social and economic environment is contained in two documents prepared by David M. Dornbusch and Company: The Socio-Economic Overview for the TNF and the Socio-Economic Interrelationship Study, Central Sierra Forests and the Lake Tahoe Basin Management Unit. These two technical documents serve as a baseline overview of the social and economic conditions which exist in the TNF's zone of influence. They present detailed information on the socioeconomic structure and the relationship of the TNF with local communities.

SOCIAL ROLE OF THE FOREST

The Forest has two social roles, provider and protector, and is frequently faced with incompatible role demands. Forest planning attempts to find solutions that are feasible, economically efficient, and which will result in the greatest benefit to the public at large.

As a provider, the TNF supports local communities through land-use permits, easements for utility corridors, electronic sites and roads, and water runoff. The Forest provides economic support through grazing, logging, and recreational concessions. Additionally, the TNF provides a variety of recreational opportunities and open space for an increasingly urban population.

TABLE 3.5 - IMPACTED COUNTY POPULATION PROJECTIONS 1980-2000

Area	1980	1985	1990	1995	2000
California	23,063,700	24,893,900	26,661,400	28,287,700	29,702,100
Nevada County	51,000	65,100	74,300	83,000	91,300
Placer County	119,200	145,200	168,900	192,200	214,700
Plumas County	17,700	20,800	22,800	24,700	26,400
Sierra County	3,300	3,700	4,000	4,400	4,700
Yuba County	49,900	54,900	59,600	64,000	68,300
Impacted County Total	241,100	289,700	329,800	368,300	405,400

Former urban residents are families who have moved from the urban areas to find a quieter, more rural atmosphere. They tend to use roads and recreation developments. In general they favor amenity uses over commodity.

Alternative lifestyle residents are residents from urban areas who generally have a liberal philosophy and feel strongly about environmental protection of natural and human resources. Some are highly effective at mobilizing local and outside resources for specific local environmental issues.

Second-home owners permanently reside in predominantly urban areas, but live in this area part time. Many of these families live on land adjacent to or within National Forest boundaries. Their demands are for permits authorizing special uses of TNF land and for dispersed and developed recreation. Second-home owners want to retain the natural setting of the Forest. Many are relatively affluent, and family income is not closely tied to Forest commodities. 'Natural' values encouraged them to purchase second homes in the area. Commodity uses, such as timber harvesting near their homes, often conflict with their interests.

Regional recreationists are mostly people who live in the Reno, San Francisco Bay, and Central Valley metropolitan areas and recreate in the TNF. Regional recreationists use the high quality recreation facilities on the Forest for a wide variety of activities. These users are very interested in the amenity values of the TNF, more so than commodity production. They desire, however, facilities for both dispersed and developed recreation.

Native Americans comprise two groups, the Washoe and Maidu, who traditionally lived in and used the TNF. Today the Washoe are primarily a Nevada-based group with recognized tribal status. The Maidu are scattered throughout the foothill region and do not have recognized tribal status. The Maidu, however, are organized into local Native American cultural organizations. For the most part, traditional Native American sociocultural activities do not occur on TNF lands. Modern use of the TNF by Native Americans is generally confined to recreational activities. As with individuals from other social or ethnic groups, Native Americans employed in the timber industry are economically dependent upon TNF natural resources to varying degrees.

Both Native American groups are interested in the management of cultural resources in the TNF. Forest projects which involve land disturbance have the potential to damage or destroy cultural resources related to Native American heritage. In addition, the alternate ownership (checkerboard) pattern, specifically activities on private land, influence what some of these groups may or may not be able to do. These alternate private lands may or may not meet the demands of this social group. (Refer to the ADJACENT OWNERSHIPS section for further discussion.)

In summary, over the past years the social group composition has shifted from long-time residents, many with strong economic ties to the Forest, to retirees, former urban residents, alternative lifestyle residents, second-home owners, and regional recreationists. This means the demands for TNF products have shifted from commodity towards amenity uses.

SOCIAL VARIABLES

The impacts of the Forest Plan's alternatives on social groups are measured and analyzed by their effect on the social groups. The indicators used to measure social effects are discussed below.

Lifestyles. This variable includes the ways people live: patterns of work and leisure, customs and traditions, and relationships with family and friends. Forest outputs generate a portion of the jobs and income in the TNF area of influence. By law, 25 percent of Forest receipts go to the counties containing Forest Service land for schools and roads. For many alternatives, the Forest's economic effects will increase county employment and 25 percent receipt shares over the first decade, with the same amount or more in later decades. The local economy, however, is growing from a variety of new employers, and the proportionate share of natural resources dollars is decreasing considerably.

Additionally, aesthetic amenities (e.g., open space, scenery, quiet) and recreation opportunities on public lands are affected by Forest Service decisions.

Attitudes, beliefs, and values. This variable refers to the feelings, preferences, and expectations people have for the TNF and the management and use of particular areas. It may include the social group's sense of freedom or self-sufficiency and their feeling of certainty or uncertainty about the future. The former includes changes in perceived control by outside interests, perceived capability of local government to meet their needs, and the group's sense of whether they can meet their sustenance needs for food, fuel, and shelter from the Forest. Feelings about the future may be affected by rates of change caused by Forest Service management and the predictability of consequences of the change.

Community **stability** and **cohesion** (social organization). Community stability refers to the rate of change with which people can cope without exceeding their capacity to deal with that change. The TNF area of influence is growing rapidly regardless of Forest Service influence. Thus, it is expected that Forest outputs will generate a smaller portion of the total jobs and income, and will have a decreasing effect on community stability.

Community cohesion refers to the unity and cooperation shown by various social groups in the community. A lessening of community cohesion can occur with an influx of people from diverse backgrounds. **Issues** which the Forest must face, such as roadless area uses, can polarize communities into opposing factions, thus decreasing community cohesiveness.

Population growth. Forest Service policy can affect population characteristics, distribution, growth rate, and density. In the TNF area of influence, Forest Service effects on population are minor, although there are concerns that increasing population may exceed capacities of community services and the ecological carrying capacity of the land, resulting in pollution and land-ownership changes.

Community services. The TNF and its users require (1) law enforcement, (2) solid waste disposal, (3) sewage, (4) transportation facilities, and (5) drinking water services from local government. These items are briefly discussed in the following sections as to their specific impacts on the counties. Other social and economic impacts are detailed in the two documents previously referenced on page 3.9.

1. Law enforcement. The beauty and recreational opportunities of the TNF draw many visitors. Campgrounds, ski areas, reservoirs, and the general forested environment attract all types of people. These people also visit the TNF to collect fuelwood under permit and, although illegal, to attempt to cut Christmas trees. The appropriate Sheriff's Department and the California Highway Patrol are responsible, as well as TNF officers, for enforcing the **Minor Forest Transportation Permit** for hauling fuelwood, and the Christmas **Tree Transportation Permit** for Christmas trees and greenery.

Other commodities available on the TNF are fish, game, and mineral resources. The California Department of Fish and Game is responsible for enforcing the fish and game laws and suction dredging permits. (For additional information on this subject, see the discussion under LAW ENFORCEMENT in this chapter.)

2. Solid waste. Visitors to the TNF leave behind considerable solid waste, generally at developed sites. The waste must be hauled to a county-operated landfill. The cost of operating these landfills and the lack of suitable **sites** on private lands create an economic burden to the counties.
3. Sewage. Effluent from developed recreation **sites**, special-use permit sites, and TNF administrative **sites** is all treated by the counties' sewage treatment plants. The method of sewage disposal varies between the east and west sides of the TNF. On the east side of the TNF, sewage from facilities, including ski resorts, along the Truckee River is transported directly to treatment plants by the waterborne system; whereas, in remote recreation areas on the east side and on the west side, vault pumpouts are transported to the treatment plants by truck. In both cases, surplus treatment capacity of the local treatment plants is reduced; however, all the treatment costs are paid by the TNF.
4. Transportation facilities. Funds for construction of roads necessary for management of the TNF's resources are obtained from appropriations and purchaser credits from the appraised rate of timber. The TNF roads generally terminate at a county road or State highway. Recreationists often use these county roads to access the TNF during inclement weather. Their use often causes damage to

the roadbeds, creating an unusually high county road maintenance cost. Although 25 percent of the revenues collected from the sale of resources are returned to the counties for roads and schools, these funds are often insufficient to repair all the damage to county roads accessing National Forest System land. The Forest Service and the counties are identifying issue areas and are negotiating their resolution during transportation planning at the project level.

Use of the Truckee area for winter sports has caused overcrowding of county and State transportation facilities.

- 5. Drinking water.** All developed sites and special-use permits are required to have a periodic testing and monitoring of their water systems. These tests are conducted by Forest Service personnel and county sanitarians. County costs are reimbursed by the TNF or permittee.

E. THE RESOURCE ENVIRONMENT

The following discussion states the current management situation. The TNF is managed on an integrated basis, which means that management decisions affect all resources and are designed to achieve multiple resource objectives.

Management activities affect a variety of resources, and decisions are made only after considering the entire set of ramifications involved. Similarly, single management activities are actually designed to serve a variety of resource objectives. For example, treating lodgepole pine stands with small clearcuts to increase water yield will provide additional wildlife habitat and a wood source for various purposes. Water developments are designed to serve the needs of certain wildlife species as well as domestic livestock. Roads are located to efficiently transport logs from a timber sale area to the mill, but these same roads are also designed to provide access for hunting, firewood gathering, and other recreation activities.

Other relationships are more separated in time. For example, greater diversity of vegetation in different stages of growth leads to a gradual increase in populations of certain animal species, which in turn increases recreation opportunities for viewing, photographing, and hunting these animals. This series of events may take several years to complete, yet it may be entirely the result of a single management activity.

Resources are part of a very complex system with numerous interactions. They are described individually only to emphasize important aspects of the current situation in some type of organized framework. These elements must be conceptually combined to understand the overall current situation on the Forest

AIR QUALITY

Air quality within the TNF is high, and pollution has not been a problem, probably because of the Forest's remoteness, elevation, and the prevailing westerly and southwesterly winds. Short-term effects on air quality within the TNF result from forest and range prescribed fires, usually associated with timber management practices. Slash disposal by prescribed fire is often the least expensive and most energy efficient treatment method. Smoke from these prescribed fires has not been identified as harmful to the environment.

The characteristics of wood smoke as an air pollutant are well documented in the 'Environmental Statement - Forest Reestablishment on National Forests in California' (R-5, USDA Forest Service, 1974). Briefly, the visible cloud of smoke from a prescribed fire consists of water condensed on particulate matter and partly burned carbon. The sulphur content of forest fuel (slash) is negligible, so that essentially no sulphur dioxide is created. The temperatures reached in burning slash are usually too low for nitric oxide to form: thus, the amount of nitrogen oxides produced is very low and cannot be considered important in the production of 'photochemical smog' common to urban areas.

The Forest Service (Pacific Southwest Region) has established an Air Resource Management System (FSM 5153), which is under Regional direction. Under these guidelines, the Forest Service manages all

burning operations to prevent or minimize the penetration of smoke into urban or smoke-sensitive areas. Most of the Forest is located within the Mountain Counties Air Basin, with a small portion of Yuba County within the Sacramento Valley Air Basin. Within these air basins, agricultural burning regulations are implemented by the County Air Pollution Control Officer. All Forest burning projects follow these regulations and Forest Service Manual guidelines. One Clean Air Act Class I area is adjacent to the TNF: the Desolation Wilderness to the south of the TNF boundary. All areas within the TNF are classified as Class II, including the Granite Chief Wilderness.

ADJACENT OWNERSHIPS AND URBAN/RURAL/WILDLAND INTERFACE

Adjacent National Forest System Land

The amount of contrast in management between adjacent National Forests is an important issue. Planning for coordination with and management of adjacent National Forest System land is required by NFMA (16 USC 1604) and by the Forest Planning Regulations (36 CFR 219.7). This coordination is also necessary when deciding land allocation. The degree of difference between the management objectives (management prescriptions) will determine the amount of contrast in the management of adjacent National Forests. Currently, management objectives along contiguous National Forest boundaries are coordinated through the existing Ranger District Multiple-Use Plans, unit management plans, and the subsequent special management plans and decisions.

The TNF adjoins three other National Forests: Plumas, Eldorado, and Toiyabe, as well as the Lake Tahoe Basin Management Unit (LTBMU). Shared administrative duties often occur along Forest boundaries. The TNF, for example, currently administers a small portion of the Plumas National Forest northeast of Bullards Bar Reservoir. Also, the TNF administers grazing allotments for a small part of the Lake Tahoe Basin Management Unit. This shared administration is intended primarily to facilitate efficient, economical management of National Forest System land. The LTBMU and the TNF share the Granite Chief Wilderness. Opportunities for the coordinated management of these lands are extensive.

Adjacent National Forests currently have coordinated management plans, special plans, and project plans. Coordination should continue to ensure that the amount of contrast between respective National Forests is minimized.

Adjacent Lands of Other Ownership

Compatibility between the management of National Forests and the management of adjacent private land is important in reducing conflicts and minimizing contrast in appearances.

The Forest Planning Regulations state that Forest planning activities 'should be coordinated to the extent practicable' with the owners of the 'lands intermingled with, or dependent for access upon, National Forest System lands' (36 CFR 219.6). Existing landownership patterns create an interdependence between the respective owners. The public and private use and development of intermingled private land has frequently predetermined the particular use of adjacent National Forest System land. Examples include public utility lines for electrical power and telephone, gas lines, public and private access roads, water supply systems, fences and pastures, and public service facilities (e.g., solid waste disposal sites and community parks).

Within the established boundaries of the TNF are approximately 381,161 acres of privately owned land, with parcels varying in size from about 5 acres to over 12,000 acres. Additional private land adjoins the TNF's exterior boundary and along interior exclusions (i.e., areas of private land excluded when the TNF was established). More than 2,700 miles of property boundary interface between the National Forest and private land.

The checkerboard pattern of ownership in this area results from the railroad land grants of the 1860's, which were intended to encourage the construction of railroads and schools by granting alternate sections of land to the railroads and the States. The majority of this land is owned currently by timberland managing companies, resulting in about 2,000 miles of property boundary between them and the TNF. Many

cooperative agreements for such things as road construction and boundary surveys have been entered into with adjacent landowners.

Scattered throughout the TNF are smaller parcels and tracts of privately owned land. These parcels are mostly the result of homesteads, Native American allotments, mineral patents, and State school land sales. These small parcels are typically 5 to 100 acres with irregular shapes.

Different landownerships, by themselves, do not create conflict. Different land use objectives often do, even on lands in the same ownership. Opportunities to coordinate with intermingled and adjacent landowners will continue, underlining the importance of developing compatible management objectives between private and National Forest System land.

Recently, more encroachment and trespassing have occurred along the National Forest/private property boundaries, resulting in an active boundary marking and posting program.

Urban/Rural/Wildland Interface

Urban/rural/wildland interface Situations may occur when National Forest System lands are adjacent to private lands that have been, or may be, developed within this planning period for recreation, rural, residential, urban, or commercial uses. When National Forest management objectives differ from our neighbors, the potential for mutual impacts exist. Generally these **urban/rural/wildland** interface situations arise adjacent to private lands described above as small parcels (5 to 100 acres) where the residents have conflicting management objectives and different perceptions about how NFS lands adjacent or near their property should be managed. Typically these lands range from small communities, towns, and subdivisions to scattered rural residences. Some of these residents are concerned that the effects of Forest Service management activities will reduce the value of their property. Residents are also concerned that Forest management activities will have negative effects on water quality, visual quality, and wildlife habitat. As a result of these concerns, often residents are opposed to the following kinds of Forest management activities: timber cutting (particularly clear cutting), prescribed fire, herbicide use, recreation development, OHV use, mining, trespassing by NF recreationists, grazing, and road maintenance. Many people feel the Forest should provide buffers on NFS land. To add to this complexity landowners may have conflicting needs and attitudes about forest land management activities next to them. One landowner may be completely supportive of an adjoining fuel reduction activity while another resident may be totally opposed due to aesthetic concerns or smoke drifting onto their property.

Visual quality objectives have been designated for all lands in the **urban/rural/wildland** interface and the objectives range from modification to retention. Meeting or exceeding adopted visual quality objectives will be helpful in meeting some public expectations by identifying specific visual mitigation measures and techniques that can reduce the visual impact of proposed management activities. While visual impacts are not the only concern in interface situations, most people develop their perceptions as to the positive or negative impact of a management activity based on their initial visual impressions.

Residential and community development of private lands adjacent to National Forest boundaries is expanding. The Sierra Nevada foothill counties are the fastest growing in the State. It is predicted that, through the subdivision of private lands, the number of landowners within and adjacent to National Forest boundaries will significantly increase. The number of land owners with different management objectives and perceptions about how NFS lands should be managed will also increase dramatically. This change will make it increasingly challenging to manage NFS land for multiple use purposes and will result in increasing **urban/rural** wildland interface situations.

The Forest can expect higher mitigation costs and the potential for reduced outputs from management activities, such as timber cutting. On the other hand, the Forest is mandated to manage Forest lands for multiple use outputs and services. Because some of the interface lands are high site and capable of the highest levels of wood production, timber management will continue to be given consideration of future land management decisions. Creating buffers and 'no touch areas' will not meet Forest goals and objectives. Because of the complex range of adjacent landowner desires as well as many Forest goals and objectives, it is expected that most issues will be resolved on a case-by-case basis developed through project environmental analysis and extensive public scoping and involvement. The Forest will need to communicate

a 'good neighbor policy to the landowners on these adjacent lands, while developing innovative ways of accomplishing Forest objectives. It will also be important for the Forest to educate the public about some of the important benefits Forest management activities can provide to adjacent private land. Examples are fuel reduction, fire protection, and timber harvest for insect and disease control. In addition, opportunities exist for the Forest to work with local, county, and State governments in joint planning efforts to resolve many of these potential conflicts. The Forest should also consider developing working relationships with other local entities such as boards of realtors, homeowner groups, and land developers.

Adjacent Public Land - Other Federal, State, **and** Local

The contrast between the management of National Forest System land and that of adjacent Federal, State, and local lands is important. Other Federal, State, and local agencies are being consulted and coordinated with during the current planning and management activities as required by NFMA (16 USC 1604), the Forest Planning Regulations (36CFR 219.7), and numerous other laws and directives. Coordinated land management objectives for the interfaced areas of National Forest and adjacent public land will foster common, more efficient resource management use and protection. Many cooperative agreements exist with other public land managing agencies through joint timber sales, road access management, boundary surveys, fire protection, and, most recently, an emphasis on range management.

Public land administered by several other Federal agencies, the State of California, and local governments, lie within or adjacent to the TNF. The Bureau of Land Management (BLM) administers a small amount of land immediately adjacent to the TNF. In addition, county, city, and special district governments own or control even more diverse types of land dedicated to various uses. Portions of these lands adjoin National Forest System land.

The compatibility (or incompatibility) of management objectives between the TNF and the agency administering the adjoining public lands determines the amount of contrasting management. The BLM, State Land Commission, and Bureau of Reclamation have land management objectives for forest and range land similar to those of the Forest Service. Exceptions exist, however, in which the management of specific parcels of land by these agencies may be in strong contrast with that of the National Forest at certain places along a common boundary.

Opportunities to coordinate management of land along boundaries shared with other Federal, State, and local agencies are considerable. For example, the BLM has a joint management plan with the TNF for the North Fork American Wild River. Coordination of land management objectives and coordination during project development is important to minimize contrasts between Federal, State, and local land. Cooperation between all ownerships and agencies is essential to control and minimize the adverse impacts of forest pest problems.

Coordinated Resource Management Planning (CRMP) is an approach used in California since the late 1970's for land and resource management where individual agency and political boundaries are not limiting, and resource problems are solved based on resource boundaries. The basic CRMP concept is that integrating and coordinating resource uses will result in improved land and resource management with the least conflict among users, landowners, and public agencies. Coordinated Resource Management and Planning is designed to achieve the following.

1. Compatibility between natural resources, energy and mineral resources, livestock production, watershed, wildlife habitat, wood products, and recreation.
2. Improvement of the resources and their perpetuation in a high quality condition.

In summary, the underlying theme of CRMP is 'improved land management through cooperation.' This approach uses the best efforts of the local people involved, private landowners, interested Federal, local, and State agencies, and other specialists. Currently, the TNF is developing CRMP's; however, none are completed.

DIVERSITY

Overview

The Forest uses the term "diversity" to reference the variety of species, habitats and seral stages, and special habitat components. Habitat diversity is usually measured on vertical and horizontal scales. The aggregate of vertical and horizontal habitat diversity is believed to strongly influence wildlife species diversity. Accordingly, management programs that change the landscape (e.g., timber management) can affect Forestwide habitat and wildlife diversity. Habitat diversity is addressed in this section. Wildlife diversity is described in the WILDLIFE section of this chapter.

On the TNF, the diversity issue is most strongly associated with: 1) maintenance of diverse forest seral stages over time, and 2) protection of important habitat elements such as snags, down logs, hardwoods, riparian habitats, meadows and meadow edges, and wetlands. For much of the public, the need to maintain diverse seral stages appears to be focused on the preservation of large tracts of undisturbed land. The principal focus for these "biological reserves" is overmature forests and riparian areas.

Management Direction

The NFMA (Sec 6 (g)(2)(A)) directs Forests to 'provide for diversity of plant and animal communities based on the capability and suitability of the specific land area in order to meet overall multiple use objectives...'. The NFMA regulations (36 CFR 219.3) define diversity as 'the distribution of different plant and animal communities and species within the area covered by a land and resource management plan'. Section 219.27 directs that overall Forest diversity should approximate that which would be expected in a natural forest, and tree species diversity should be similar to the existing Forestwide condition. However, this section also provides that reductions in diversity can occur when needed to meet overall multiple use objectives.

Direction for maintenance of diverse seral stages over time is included in the Regional Planning Guide (pages 4-22 to 4-27). The Regional Guide directs that Forests will maintain at least 5 percent of every major vegetation type in each of 5 to 7 seral stages over time (Sec. 4.F.2.a). When seral stages do not presently meet this condition, Forests are to manage to achieve prescribed levels as soon as practical (Sec. 4.F.2.c). These diversity standards are to be applied at the Forest level. Individual management areas will provide distributions of various vegetation types in proportion to their current availability unless standards and guidelines are developed to assure adequate distribution of seral stages (Sec. 4.F.2.e).

The Regional Planning Guide (page 4-14) directs that, to the extent possible, each planning compartment should be managed to provide an average of 1.5 snags per acre. The standards also specify that 80 percent of the density must be comprised of snags measuring 15 to 24 inches DBH and greater than 20 feet tall. The remaining 20 percent must exceed 24 inches DBH and 20 feet in height.

Hardwood stands are subject to the same direction for seral stage management described above. Hardwood basal area or canopy closure direction is currently lacking.

Direction for management of meadows and down logs is currently lacking. The direction and other information relating to riparian area and wetland management are described in the RIPARIAN AREAS section of this chapter.

Current Situation

The current status of riparian areas and wetlands is described in the RIPARIAN AREAS section of this chapter. The current conditions for the remaining important components of Forest diversity are summarized below:

Overall Forest Habitat Diversity. The Forest has the potential for providing a broad range of diversity conditions. For example, reducing timber harvest and increasing the fire suppression program would yield a Forestwide shift towards mature vegetation stands. Conversely, increasing timber harvest and

prescribed fire programs while reducing fire suppression efforts would result in a shift towards younger seral stages.

The current vegetation pattern on the Forest is clumped and very diverse. Patches of early succession vegetation tend to be concentrated in areas that are easily accessed for timber harvest, and sizeable areas of uninterrupted late succession vegetation usually exist in less accessible areas.

Seral Stages. Seral stages associated with wildlife habitats on the west slope of the Sierra Nevada are important to many individual wildlife species and have been described by Verner and Boss (1980). These descriptions can also be applied to eastside habitats and are summarized below.

- 1** = Grass/forb stage, consisting of annual and perennial grasses and forbs, with or without scattered shrubs and seedlings.
- 2** = Shrub/seedling/sapling stage, consisting of mixed or pure stands to **20** feet in height.
- 3A** = Pole/medium tree stage, including larger trees in the size range **20** to 50 feet in height. Total tree canopy cover is from 0 to **39** percent. Stands commonly support a substantial shrub layer.
- 3B&C** = Pole/medium tree stage, including larger trees in the size range **20** to 50 feet in height. Total tree canopy cover is 40 percent or greater. Shrub layer is variable.
- 4A** = Large tree stage, corresponding roughly to a mature and overmature classification. Trees generally exceed 50 feet in height, except some of the oak types at lower elevations. Total tree canopy cover is from 0 to **39** percent. Stands commonly support a substantial shrub layer.
- 4B&C** = Large tree stage, corresponding roughly to a mature and overmature classification. Trees generally exceed 50 feet in height, except perhaps some of the oak types at lower elevations. Total tree canopy cover is 40 percent or greater. Shrub layer is variable.

Figure 3.1 displays the current variety and amounts of the important habitats in forested land of the TNF. Approximately 21 percent of the forested land is in early successional stages, 38 percent is in mid-succession, and about 32 percent is in the mature stage. About 4 percent of the Forest is composed of hardwoods, primarily black oaks, and about 4 percent is wetland. Much of the wetland habitat contains mature aquatic vegetation.

Snags. An accurate snag inventory is currently lacking for most areas of the Forest. There are currently 11 local wildlife species that excavate cavities in snags and 33 species that are secondary users of excavated cavities. Current snag densities and distribution are considered adequate to maintain dependent species well above viability thresholds on the west slope of the Forest. Most forested planning compartments on the west slope are believed to meet or exceed prevailing Regional snag retention standards. Most planning compartments in eastside habitats are thought to be below Regional snag standards and may be approaching critically low levels. The Forest is currently evaluating methods for efficiently inventorying snag densities so that prevailing assumptions can be tested.

Down Logs. Inventory information for down log densities is almost completely lacking for the Forest. In unmanaged stands, natural-occurring densities of large down logs (over 20 inches in diameter) probably range from 5 to 20 or more per acre. In regenerated timber stands, down log densities are typically much smaller. Down, woody material is thought to be a critical habitat component for some plant and animal species. However, plant and animal relationships with down logs are poorly understood.

Figure 3.1: Quantitative Relationship of Habitat Types for Tahoe National Forest

Hardwoods The Forest currently has hardwood species on three types of lands. Pure hardwood stands (where conifers comprise less than 10 percent of the crown closure) occupy about 32,400 acres. Hardwood/conifer stands (where hardwoods comprise 51 to 90 percent of the crown closure) are found on about 37,400 acres. Many commercial stands of mixed conifer also have a hardwood component measuring 1 to 50 percent of the crown closure. Data that identify the mixed conifer stands that have a hardwood component are currently lacking.

Black oak and live oak are the predominant hardwood species on the Forest and these species are widespread. Important species that are less common and more localized include tan oak, madrone, aspen, and Brewer oak. Forest hardwood stands are important to a broad array of wildlife. Black oak, live oak, and madrone *are* also important sources of fuelwood and livestock forage. The level of hardwood retention in regenerated timber stands is often a concern during timber sale planning because increasing the amount of residual hardwoods reduces the yield for commercial species

Hardwoods are an important habitat for about 180 wildlife species. Seventy-one of these species are strongly dependent on hardwoods. Mule and black-tailed deer, gray squirrels, band-tailed pigeons, mountain quail, turkey, and black bear are important local game species that are strongly associated with hardwood mast production.

Meadows. The TNF has about 7,100 acres of meadows. On the west slope, meadows are typically small (1 to 5 acres) and are randomly scattered in locations that provide moist, flat terrain. On the east slope, meadows are often very large (20 to 100 acres) and are commonly found on flat sites adjacent to major drainages. On both slopes of the Forest, scattered dry meadows occur randomly where site conditions do not permit establishment of brush and tree species.

Meadows of the TNF are generally in satisfactory condition. They are extremely important to a broad array of fish and wildlife species and provide a significant amount of livestock forage and opportunity for recreation. Localized meadow degradation from past management practices and natural events offers opportunities for enhancement projects in some areas.

Mature and Overmature Forests - The Forest currently contains *about* 600,000 acres of timber-producing lands. Most of these lands were once mature and overmature forest. Many groups and individuals refer to overmature forests as 'old growth'. Although a 'Generic Definition and Description of Old-Growth Forest' has been developed by the Washington Office, specific forest type old-growth definitions have not yet been developed for the Tahoe.

Current timber inventories indicate that approximately 126,200 acres of late successional (4g and 6g strata; see Plan Appendix H) seral stages exist on the Forest. Not all of these acres are expected to meet the definition of *old growth*. As indicated above, there is no current inventory of old growth.

Old-growth forests have many values including providing biodiversity, wildlife and fisheries habitat, recreation, aesthetics, soil productivity, water quality, and industrial raw material. For example, about 72 wildlife species are associated with the old-growth eastside pine forest; about 50 of these species strongly depend on these older habitats. On the westside, about 125 and 75 wildlife species are associated with the old-growth mixed conifer and red fir forests, respectively. About 40 of these species strongly depend on the older mixed conifer habitats and 30 strongly depend on the older red fir habitats.

Existing and Projected Demand

The current and future demands for Forest diversity are very difficult to assess because a consensus definition of diversity is lacking. The NFMA regulations define diversity as 'the distribution and abundance of different plant and animal communities and species'. However, the diversity issue on the TNF is most strongly associated with important habitat elements such as snags, down logs, hardwoods, riparian habitats, meadows and meadow edges, wetlands, and old-growth forests.

It is clear that diversity is an emerging issue in Forest management. Yet, prevailing information is insufficient to allow an accurate assessment of the current and future demands.

FACILITIES

TNF facilities include roads, trails, dams, and *administrative sites*, including utility systems and buildings. The objective of TNF facilities management is to provide support for TNF management activities such as timber production, fire protection, and recreation. Construction and operation of facilities considers energy requirements, economic efficiency, resource development and protection, public demand for Forest uses, and transportation needs of private landowners. Direction for construction and operation of facilities comes from Public Laws, multiple-use and land-use plans, the Code of Federal Regulations, the Transportation Management Program, and cooperative agreements with other government agencies and private landowners.

Roads

The existing maintained road system under TNF jurisdiction is about 2,400 miles. An additional 850 miles within the TNF boundary are under the jurisdiction of counties, the State, or are controlled by private landowners. About 15 percent of the road system serving private timbered land (Sierra Pacific Industries, Fibreboard, and Erickson Lumber Company) was developed cooperatively and is jointly maintained.

Development and operation of the TNF road system are currently directed by ~~two~~ plans: the TNF Arterial/Collector Transportation Plan, approved by the Regional Engineer October 1978, and the Transportation Management Program approved in June 1980. Table 3.6 presents current (1988) road mileages in the TNF by road classification.

TABLE 3.6 - ROAD MILEAGE BY CLASSIFICATION

Classification*	Miles
Arterial	122
Collector	416
Local	1,934

Based on data contained in the TNF Planning File, 90 percent of the total TNF is accessed by roads (accessed is defined as being within 1/4 mile of a road). The arterial and collector system is about 95 percent complete. Part of the remaining development is contingent upon land management decisions within the roadless areas released by the California Wilderness Act of 1984. Timber sale project planning will dictate the road system development, with completion expected in 10 to 30 years. Reconstruction would be a continuing need because of low maintenance funding levels

The transportation system increases by 15 to 25 miles per year. This increase is primarily because of the timber management program, which constructs roads at approximately 0.35 mile per million board feet of timber harvested. Each mile of road constructed removes about four acres of land from resource production.

Average existing density of road access is 0.006 mile per acre, or 3.8 acres of road right-of-way per square mile. The density varies, with higher densities being located in intensive timber harvesting areas and lower densities in nontimbered areas or virgin timberland. The highest density of the existing road system is 6 miles per square mile.

Roads could be constructed throughout the TNF. Appropriateness of construction is an economic, rather than a technical question. Existing roads occur on all slope classes and geological formations. The economic feasibility of constructing and maintaining the roads depends upon the benefits derived.

Trails

The existing trail system comprises 508 miles, according to the TNF's 1982 Transportation System Inventory. A portion of the trail system (26 trails) is regulated by TNF Supervisor's Order 17-79-39 of May 11, 1979, which prohibits use by trail bikes and other off-highway vehicles. This order is incorporated into the 1980 TNF Off-Road Vehicle Management Plan.

The Pacific Crest National Scenic Trail (PCNST) was mandated by Congress in 1968 and is managed according to the Chief's Pacific Crest Trail Management Plan. The trail transects the TNF along the Sierra Nevada Crest for 97.4 miles and was completed in 1983. Off-highway vehicles and mountain bikes are not allowed on the PCNST.

The existing trail system consists of old access trails from the gold mining era, recreation trails, and a few interpretive nature trails. The trails receive many uses, including hiking, equestrian, motorcycle, ATV, and four-wheel drive. The volume of use depends on proximity to population centers or developed recreation areas and the attraction of the destination. User conflicts exist, and current management direction resolves those conflicts where safety or resource damage occurs. The Western States and Tevis Cup Trails are used extensively for a competitive long distance horse race, and for foot races. There is significant public interest in designating these trails under the National Trails System. The trails qualify for National Recreation Trails designation.

Management of the trail system is guided by the Transportation Management Program Environmental Assessment and is implemented through Order 17-79-39. A high-use trail system has been identified. Improvement would be made to meet user demand. Trail planning and operation for special interests, such as off-highway vehicle, skiing, and equestrian uses, would be based on a comprehensive land allocation plan. A separate analysis will be made correlating land capacity, user needs, and user/landowner conflicts on a Forestwide basis for all dispersed recreation travelways.

Dams and Diversions

There are 112 dams within the boundaries of the TNF. The ownership of these dams is as follows:

- 19 Forest Service
- 38 Private or municipal on National Forest System lands licensed for power generation by Federal Energy Regulatory Commission
- 4 Bureau of Reclamation
- 1 Corps of Engineers
- 10 Privately owned on National Forest System lands under special-use permits
- 45 Privately owned and on private lands

The classification for the 19 dams under TNF jurisdiction is as follows:

Class A	Higher than 100 feet, impounds 50,000 acre-feet or more of water.	none
Class B	Between 40 and 100 feet in height or impounds between 1,000 and 5,000 acre-feet of water.	4 dams
Class C	Between 25 and 40 feet in height or impounds between 50 and 1,000 acre-feet of water	6 dams
Class D	Less than 25 feet high or impounds less than 50 acre-feet of water	9 dams

The dams are inspected and maintained periodically depending on the hazard rating. The primary uses are recreation, irrigation, domestic water supply, and power generation. The State of California inspects all non-Federal dams over 25 feet high that impound more than 50 acre-feet of water. The Upper Sardine Dam (Class B) was the only dam owned by the Forest Service considered unsafe. This dam was breached in the fall of 1983.

Administrative Facilities

Currently, 23 administrative sites are on the TNF. Administrative buildings and sites are developed and operated based on resource program needs and their strategic locations. Existing sites and buildings were located to provide housing and office facilities for personnel involved in resource development, recreation, and fire protection. Site location was influenced by access roads and travel times, the need for interaction with local government, visibility to the public, and availability of community support services.

During the next 20 years, substantial investment must be made to provide seasonal and permanent residential facilities for employees. This investment is an integral part of building investment levels I through V, which include mandated maintenance (custodial) dollars and programmed facility improvement and

construction. Deterioration of existing facilities, increasing costs for private housing, geographic shift of work, and travel costs or constraints will continue to increase the need for new facilities. Ongoing feasibility and organizational studies will identify investment and developmental requirements.

Currently, 125 Government-owned buildings are on the TNF, with a total of 165,000 square feet. The existing buildings, particularly residences and those at remote administrative sites, were constructed in the following three periods:

1. Civilian Conservation Corps days, pre-World War II. These buildings account for approximately 43 percent of the current inventory. Many are scheduled for removal or are not presently in use. Building maintenance is disproportionately high because of age and lack of funding for a routine preventive maintenance program.
2. Post-World War II from 1947 to 1965. These buildings were either constructed during this period or were acquired as surplus from military base facilities and moved to the TNF. These are low-standard and, in most instances, are approaching replacement.
3. 1966 to the present. Nine buildings were constructed in recent years. They are generally in an economically maintainable condition and represent our most modern facilities.

FIRE AND FUELS

The fire management policy on National Forest System lands is 'to provide well planned and executed fire protection and fire use programs that are cost efficient and responsive to land and resource management goals and objectives', (FSM 5103).

Although fire protection was not identified as a major issue, it relates to most of the major issues and is an underlying premise to successful land and resource management. The first step to managing a forest is to protect it from catastrophic losses, including fire.

The TNF has wildfire protection responsibility for about 1,237,700 acres, of which approximately 774,700 acres are National Forest System lands, 9,000 acres are public domain lands administered by the Bureau of Land Management (BLM), and about 454,000 acres are State Responsibility Area (SRA) lands.

The TNF protects the SRA lands under a Statewide contract (cooperative agreement) with the California Department of Forestry and Fire Protection (CDF). Under this cooperative agreement, the Forest Service agrees to protect the SRA lands at a level equivalent to that which the CDF would provide if they were protecting them directly. These SRA lands are for the most part intermingled with National Forest System lands and quite often include developments such as homes that make the wildland protection job much more difficult than if it were all National Forest without development.

Conversely, the CDF protects about 19,700 acres of TNF lands that are outside the TNF protection boundary but are covered by the Forest Plan. These lands are located along the western edge of the Forest.

Fire protection has been very effective since 1960, when about 100,000 acres burned on the TNF. In two years (1959-60), almost 10 percent of the TNF protection area (about 120,000 acres) burned over.

Since 1960, about 27,000 acres have burned. The high was 1987, when 12,367 acres burned during what was coined 'The Siege of 1987'. During the 'Siege of 1987' over 600,000 acres burned in Northern California when a widespread lightning storm started over 2,500 fires in about a 48-hour period.

Activity	Number of Fires	Percent	Acres Burned	Percent
Human-Caused	665	48	673	5
Lightning	707	52	13,139	95
TOTAL	1,372	100	13,812	100

This reduction in burned acreage is primarily attributable to an improved fire protection program because the weather during over half of the years during this period was worse than normal throughout the western United States.

In 1988 the TNF experienced a total of 282 fires (81 human-caused and 201 lightning-caused) and a loss of only 536 acres burned. In early September the 49'er Fire started just outside of the western boundary of the Forest on SRA lands and burned to the west and south under a strong, dry northeastern wind. This fire consumed 33,500 acres of wildlands and destroyed about 190 homes and hundreds of out buildings. This same fire, if started farther to the east, would have resulted in added losses to the Forest in addition to what burned on SRA lands.

The current organization is a combination of suppression (initial attack), prevention, and detection resources located at various stations on the TNF. These resources include:

- 10 fire engines with either 3- or 5-person crews.

- 15 fire prevention units having 1 person per unit.

- 4 budgeted lookout towers (four additional towers are operated only during lightning activity or high fire danger days).

- A 20-person Interregional Hotshot Crew

- Four (4) 10-person hand crews.

- An air attack base jointly run by the CDF and the Forest Service at the Nevada County Air Park that includes two S-2 air tankers, an air attack aircraft (Cessna 337), a fire cache, and a fire camp.

Additional resources, including fire engines, hand crews, fixed-wing aircraft (including air tankers), and helicopters, are available from adjacent agencies, such as the CDF, Bureau of Land Management, Nevada Division of Forestry, local Fire Protection Districts, and other National Forests.

Based on the past fire history and the current fire management organization, the expected future average annual burned acres and number of fires by fire intensity levels are displayed in Table 3.8

TABLE 3.8 - EXPECTED ANNUAL BURNED ACRES BY INTENSITY LEVEL

Fire Intensity Level	Average Annual Acres Burned	Average Annual Number of Fires
1	20	92.0
2	73	37.0
3	94	15.0
4	219	3.0
5	404	0.6
6	228	0.3
TOTAL	1,038	147.9

The manipulation and reduction of fuel beds to create a more favorable fire control environment is a key to effective, efficient fire protection of the TNF. The fuels management program on the Forest is primarily working with activity fuels created by management activities (especially timber harvesting). The objective of fuel management is to modify or maintain the resultant fuel levels in a cost-efficient method to meet land and resource management goals and objectives.

Whenever a management activity creates a fuel hazard greater than would exist without the activity, an analysis is required to determine the level of treatment appropriate to meet land and resource objectives. Where practical, the fuels management program, especially all prescribed fires, will be closely coordinated with the CDF vegetation management program. This coordination is particularly important given the intermingled private lands within and adjacent to the TNF.

Vegetative cover types are referred to in fire management as fuel models. The representative fuel models are grouped into the four broad categories of timber, plantations, brush/grass, and barren (no vegetation). The acres of these groupings are shown in Table 3.9

TABLE 3.9 - ACRES BY FUEL MODEL GROUPS

Fuel Model Group	Acres
Timber	604,700
Plantations	35,300
Brush/Grass	113,100
Barren	41,300
TOTAL	794,400

Within the timber fuel model group, an estimated 19,000 acres of fuels generated from management activities before 1975, which do not meet current objectives (backlog fuels), are scattered throughout the TNF. These backlog activity fuels are being treated when possible primarily through other activities such as timber sales, reforestation site preparation, and wildlife habitat improvement projects.

Approximately 8,000 acres of activity fuels are treated annually on the TNF. This treatment includes about 1,200 acres of broadcast burning.

Within the Granite Chief Wilderness and the North Fork American Wild River, prescribed fire by planned ignition in accordance with Forest Service wilderness and fire management policies may be used where necessary to meet resource and management objectives. Prescribed fire by unplanned ignition will not be used until the proper studies have been conducted and management plans developed and approved prescribing and authorizing this activity.

FISH

Fishing is a major recreational activity on the TNF. Eleven major watersheds contain over 1,500 miles of fishable streams, and 22 impoundments hold about 20,000 surface acres of water. Portions of the North Fork American River are designated as a Federal Wild River, and the State of California has designated it as a wild trout stream.

A management plan for wild trout in the North Fork American River was prepared by the California Department of Fish and Game (CDF&G). A habitat plan for the North Fork has been developed by the Forest Service in conjunction with the State's plan for wild trout. These plans form the basis for trout management in this river.

Lavezzola Creek has been designated as a wild trout stream by the CDF&G.

Twenty-one fish species are known to use waters of the TNF. A complete species list and summary of habitat relationships are included in the TNF planning records (192216a.7c). The Lahontan cutthroat trout (LCT) is Federally listed as a threatened species and is a management indicator species for the TNF. A management plan for LCT in California has been prepared jointly and signed by the Forest Service, CDF&G, and the U. S. Fish and Wildlife Service. This management plan is a component of the draft federal recovery plan for the Lahontan cutthroat trout. Action items in the management plan will form the guidelines for overall LCT recovery. Consultation with the U. S. Fish and Wildlife Service on management activities involving or potentially affecting LCT habitat has and will continue to occur. The TNF will be managed to achieve recovery levels for the Lahontan cutthroat trout according to management strategies contained in the final recovery plan.

The existing fishery is primarily cold water fishing, but two reservoirs, Bullards Bar and Sugar Pine, contain largemouth and smallmouth bass, crappie, and catfish. Anadromous fish do not occur in the waters of the Forest because of downstream dams constructed on west side rivers. The major harvest species are rainbow trout, brown trout, and brook trout. Most of the lakes and streams are stocked annually with a variety of the harvest species.

The Forestwide emphasis species for fisheries are rainbow, brown, and brook trout. Kokanee salmon, smallmouth bass, and largemouth bass are site-specific emphasis species because of their limited occurrence on the TNF. Forestwide emphasis species are used to guide and monitor Forestwide management. Site-specific emphasis species are used for project coordination in localized areas where opportunities exist to improve their habitats.

About 90 percent of the TNF's existing waters have been inventoried to assess their fisheries potential. Table 3-10 summarizes the quantity and quality of fish habitat. At present, about 73 percent of the impounded waters and about 49 percent of all flowing waters have good quality fish habitat. The total production of trout within all TNF waters is about 256,000 pounds. The breakdown for the emphasis species is 120,000 pounds for rainbow trout, 64,000 pounds for brown trout, and 72,000 pounds for brook trout.

TABLE 3.10a - SUMMARY OF EXISTING FISH HABITAT FOR THE TNF - LAKES, RESERVOIRS, AND PONDS

TYPE (Surface Acres)	NUMBER OF WATERS	TOTAL SURFACE ACRES	Habtat Quality* Good	Habltat Quality* Fair	Habltat Quality* Poor	Habitat Quality* Unknown
Large Lake (501-2000)	3	2,462	2,462	0	0	0
Medium Lake (51-500)	6	862	440	0	0	422
Small Lake (6-50)	67	885	298	118	116	353
Major Reservoir (2000+)	2	8,254	8,254	0	0	0

TOTAL	363	1,438	3,556	699	1,727	613	1,571	126	258

NOTE Includes both public and private rivers and streams within the Forest boundary.

* Habitat quality is defined as follows

Good - Lacking induced (erosion, siltation) or natural (barriers) problems, and having high fish productivity as indicated by stream survey results.

Fair - Good channel stability and moderate induced impact, **but** having low flows or isolated areas of low productivity.

Poor - Having combinations of factors that will lower fish productivity (erosion, cattle use, low flows, heavy fishing pressures).

Table 3 11 summarizes the quantity, quality, and habitat improvement potential for the trout emphasis species. Rainbow trout are the most prevalent species Forestwide and are probably the most sought-after by fishermen.

TABLE 3.11a • FISHERIES QUANTITY, QUALITY, AND HABITAT IMPROVEMENT POTENTIAL FOR THE TNF - LAKES, RESERVOIRS, AND PONDS (in Surface Acres)

Species	Quantity	Quality 1/ Good	Quality Fair	Quality Poor	HIP High 2/	HIP Medium	HIP Low

TABLE 3.11b • FISHERIES QUANTITY, QUALITY, AND HABITAT IMPROVEMENT POTENTIAL FOR THE TNF - RIVERS AND STREAMS [In Miles (MI) and Surface Acres (SA)]

Species	Quantity		Quality Good 1/		Quality Fair		Quality Poor		HIP 2/ High		HIP Medium		HIP Low	
	MI	SA	MI	SA	MI	SA	MI	SA	MI	SA	MI	SA	MI	SA
RAIN- BOW	528	1,298	309	747	192	1,517	27	34	88	168	175	461	265	669
BROWN	112	288	81	203	31	85	0	0	15	40	20	70	77	178
BROOK	169	374	92	257	77	117	0	0	18	29	72	155	79	190
LCT 3/	6.3	8.9	6.0	8.6	0.3	0.3	0	0	4.3	4.0	2.0	4.8	0	0

- 1/ Fish habitat quality for lakes, reservoirs, and ponds is defined as follows:
- Good - Nutrient levels are not limited for fish populations, pollution is not a detectable concern
 - Fair - Fish populations limited by some factor (food, oxygen, winter freeze), some pollution detectable
 - Poor - Eutrophic, marginal habitat, fish survival would require constant stocking, pollution contributing to degradation

Fish habitat quality for rivers and streams is defined as follows.

- Good - Lacking induced (erosion, siltation) or natural (barriers) problems and having high fish productivity as indicated by stream survey results.
- Fair - Good channel stability and moderate induced impact, but having low flows or isolated areas of low productivity.
- Poor - Having combinations of factors that will lower fish productivity (erosion, cattle use, low flows, heavy fishing pressures).

- 2/ Habitual improvement potential (HIP) is defined as follows:
- High - Critical habitat deficiencies that need to be corrected through improvement projects.
 - Medium - Habitat deficiencies are present but are not in critical need of correction.
 - Low - Very few habitat deficiencies are present and those that do occur are minor

- 3/ LCT - Lahontan cutthroat trout

Table 3 12 indicates that about 70 percent of all impounded waters and 50 percent of stream habitat can be improved to some degree for rainbow trout (in lakes, rivers, and streams with high and medium habitat improvement potential). Approximately 60 percent of the lakes and 30 percent of the stream habitat can be improved for brown trout. For brook trout, about 80 percent of the lakes and 50 percent of the stream habitat can be improved. The potential for the other fish species is presently unknown.

TABLE 3.12a - HABITAT IMPROVEMENT POTENTIAL FOR FISH SPECIES (Expressed as a percentage of the total known quantity) - LAKES, RESERVOIRS, AND PONDS

Habitat Improvement Potential * (Surface Acres)

Indicator Species	High	Medium	Low
Rainbow	9%	59%	32%
Brown	6%	56%	38%
Brook	12%	70%	18%
Lahontan cutthroat trout	49%	51%	0%

Indicator Species	High	Medium	LOW
Rainbow	17%	33%	50%
Brown	13%	18%	69%
Brook	11%	42%	47%
Lahontan cutthroat trout	68%	32%	0%

- * Habitat improvement potential is defined as follows
- High** - Critical habitat deficiencies that need to be corrected through improvement projects
 - Medium** - Habitat deficiencies are present but are not in critical need of correction
 - Low** - Very few habitat deficiencies are present and those that do occur are minor

If implemented, these improvements would result in the following approximate increases:

Lakes	Streams
Rainbow - 28,000pounds	Rainbow - 24,000pounds
Brown - 17,000pounds	Brown - 4,200pounds
Brook - 24,000pounds	Brook - 7,000pounds

Thus, a vigorous habitat improvement program for all lakes, rivers, and streams could increase rainbow, brown, and brook trout by 104,200 pounds

The TNF has an adequate inventory of fish habitat on the Forest, but current, accurate information regarding population estimates and trends is extremely limited. We suspect that the trends for harvest species are relatively stable because of the annual stocking effort.

Table 3.13 indicates the extent of our knowledge regarding fish supply and the TNF's ability to meet demand. The data that is available is better than 50 percent reliable, but is not statistically valid.

TABLE 3.13 SUPPLY AND DEMAND FOR THE FISHERIES EMPHASIS SPECIES ON THE TNF

SPECIES	CATEGORY	CURRENT PRODUCTION POTENTIAL	CURRENT POPULATION TREND	ABILITY TO MEET DEMAND
Rainbow trout	Harvest	120,000 lbs.	Stable	Unknown
Brook trout	Harvest	72,000 lbs.	Stable	Unknown
Brown trout	Harvest	64,000 lbs.	Stable	Unknown

The demand for trout should increase approximately 22 percent during the next decade. The RPA objective for the Forest is to increase the resident trout habitat capability 20 percent. If the TNF were to be totally dedicated to fish production and each acre was producing to the maximum, the demand for both consumptive and nonconsumptive use could be met during the planning period. Under current management levels, a portion of the demand would be met during the planning period, but how much is not known. Indications based on past demand suggest stressing the management of consumptive species. The management level needed to meet most of the demand and address RPA targets is somewhere between current fish management intensity and maximum production.

Fish management, under multiple use, can act as a constraint to other Forest management activities not directly related to fisheries, and can itself be constrained by other activities. For example, the transportation system can impact fisheries by roads that cross or parallel rivers and streams that have a viable fishery. The roads could increase sedimentation in the fishing stream. Expansion of roads into wetlands or through riparian areas can lead to a loss of these environments. In short, any activity that takes place on the Forest may positively or negatively affect the fish resource, although some impacts are more serious than others.

The following major fishery concerns relate to the basic issue of fish habitat productivity, quality, and diversity:

- o Continuing protection and possible expansion of the Lahontan cutthroat trout habitat.
- o **Reservoir** construction that eliminates wetland, riparian, and other key habitats.
- o Water diversions that reduce stream flows below the level needed to support fish production.
- o Water temperatures that increase beyond the limits of cold water fish tolerances.
- o Siltation of spawning areas.

These concerns occur in specific situations on the TNF. In some cases, fish production is being limited as a result (e.g., stream barriers, competition by nongame species). The greatest potential opportunities to increase fishery production include mitigation of water diversions, improvement of instream fish habitat, and enhancement of riparian areas to provide shade, canopy cover, and long-term woody debris sources where none now exists.

FOREST PESTS

Pest Damage

Insects, diseases, plants, and animals damage trees and other forms of vegetation. Damage includes mortality, reduced growth, reduced tree quality, top killing, degradation, and reduced quantity and quality of seed production. If the damage affects the attainment of land and resource management goals and objectives, the destructive agents are considered pests. In addition to plants, humans can also be affected by pests, such as poison oak or plague-infected rodents in recreation areas.

Pest damage can vary by year and by place within the Forest. Damage is frequently the result of several pests and environmental factors acting together, rather than the result of a single pest. Common insect and disease complexes on the Forest include root disease-bark beetle and dwarf mistletoe-bark beetle. Damage from these pests is often accentuated during severe environmental conditions, such as drought, and by certain stand conditions, such as overstocking. In general, these pests, along with their natural enemies (parasites and predators), are a part of the environment and have adapted to exploit certain ecological niches or conditions during a forest's development. In addition, pocket gophers cause damage to about 10 percent of the reforestation acres. (See the TIMBER section of this chapter for a discussion of competing vegetation as part of the Forest pest complex.)

In recent years, the average annual pest-related mortality on Northern California National Forests has ranged from a low of .06 tree per acre (4.7 cubic feet per acre) to a high of 1.37 trees per acre (285.0 cubic feet per acre). On the TNF, salvage sales annually remove approximately 8 to 10 MMBF, and sanitation and thinning, conducted in part to reduce the potential for pest-related damage, could remove another 5 to 20 MMBF depending on existing market conditions for forest products. Estimates of losses because of growth reduction and decay are difficult to obtain and are currently unknown.

Integrated Pest Management

Under the Integrated Pest Management (IPM) approach, the level or intensity of pest management practiced would vary to meet the needs (resource management emphasis and targeted outputs) of each alternative. For example, alternatives that involve high levels of vegetation management and high resource outputs would both require and provide the opportunity for implementing high levels of IPM. High levels of IPM would involve frequent surveillance, detection, and reporting; a high level of pest management training for Forest personnel directly involved in resource management, an increased number of site-specific biological evaluations, and an increased likelihood, directly related to the high resource output targets, of directly controlling pests. In addition, the timely use of new methodologies and close coordination with pest management research would be very important. A high level of IPM would also mean increased opportunities to integrate pest management considerations into resource management decision making and to implement preventive actions, including vegetation management, which should, through time, reduce the need for future direct control projects. Alternatives with lower resource outputs and less vegetation management would require **less** frequent pest management activities and would also provide fewer opportunities to implement preventive strategies.

An IPM approach is used to prevent and reduce pest-related problems on the TNF. Under this approach, pest management is an integral part of resource management, and insects, diseases, plants, and animals are recognized as established elements of forest and range ecosystems. They are considered pests only when they cause unacceptable damage by interfering with the attainment of management goals and objectives or when they endanger public health. For each specific pest situation, on a case-by-case, site-specific basis, a full range of pest management alternatives, including a 'no action' alternative, would be considered in accordance with NEPA requirements. The preferred course of action is selected on the basis of biological effectiveness, cost efficiency, and human health and environmental safety.

In Forest planning, the IPM approach is implemented in all alternatives at levels necessary to minimize unacceptable damage. Integrated Pest Management activities include prevention, detection, evaluation, suppression, and post-action evaluation. Prevention and suppression activities consider a full range of techniques, including chemical, biological, mechanical, manual, silvicultural and prescribed fire for each pest situation. The goals and objectives, management intensity, and resource emphases of each alternative

determine the intensity or level at which IPM should be implemented to minimize unacceptable damage. Additionally, when appropriate, commitments will be made to participate in TNF pest management and IPM demonstrations, pilot projects, and field experiments.

The protection goals of TNF pest management are to establish and maintain an effective dynamic surveillance system within the concept of the detection component. The TNF also will be aggressive in implementing sound, safe, and effective preventive measures to keep potential pest problems to a minimum commensurate with resource goals and objectives. These objectives will be achieved by implementing IPM, which will provide protection of forest resources with the least hazard to people, their possessions, wildlife, fish, and the environment. These objectives include the following:

- o Managing the TNF's resources in a way that discourages pest problem development and persistence.
- o Prudent timing of treatments.
- o Demonstrating effective and workable IPM practices and strategies and encouraging their acceptance.

GEOLOGY

Geologic Hazards

Potential geologic hazards within the TNF include landslides, earthquakes, and ash fall from distant volcanic eruptions. Of those three types, landslides are the most common and most frequently affect Forest management. Shallow debris slides are the most common and most destructive type of landslide found on the TNF, but deeper mass movements, road cut failures, stream channel instability, and rockfalls also occur. These various types of slope movement, whether human caused or naturally occurring, can affect water quality, fish habitat, land productivity, visual quality, human safety, structures, utilities, and roads.

Land instability is not extensive on the Forest. Most instability features are found in the steep canyons and inner gorges in the lower elevations of the western part of the Forest. Preliminary landslide hazard work shows a higher rate of occurrence of landsliding in various contact zones beneath the Meherten Formation (volcanic mudflows), more often on north facing slopes where springs occur. Much more work is needed to verify this hypothesis and identify the zones with the highest risk of failure. The Forest is currently working on a Forestwide Geologic Hazards and Resources Inventory (GRI), which will identify landslide and seismic hazards, and discuss volcanic hazards. Geologic resources will also be identified. In lieu of a completed GRI, hazards and resources have been identified, analyzed, and where appropriate mitigated or developed whenever recognized as issues on a given project.

The potential for reactivation of dormant features under natural conditions is considered to be greatest within the inner gorge, and to a lesser extent along the steep canyon slopes where streams actively erode the toe of dormant landslides. Under natural conditions, dormant landslides are most likely to be reactivated by stream undercutting and/or during periods of heavy rainfall. The potential for reactivation is dependent on site-specific conditions such as groundwater, slope inclination, and the nature of the underlying materials.

Under 'altered' conditions such as vegetation manipulation, road excavation, mining operations, or hydroelectric developments, existing landslides are sometimes reactivated or new landslides are triggered. The more land-disturbing activity in soil and rock types sensitive to land instability, the higher the likelihood of altering the equilibrium of the slopes and thereby causing landslides.

The concern, therefore, is to prevent mass earth movement or soil loss associated with performing management practices on lands with geologic hazards.

In the past, timber harvesting and road building on the TNF have avoided much of the steepest and most unstable ground. Increasing demand for timber, minerals, and hydroelectric development requires

access to the more remote, steeper, and often more unstable ground. Consequently, the need for land stability inventory and analysis will increase.

Although considerable volcanic activity has occurred on the TNF through geologic time, no active or dormant volcanoes now exist, nor are there indications of future volcanism. Signs of possible volcanic activity occurred recently in the Mono Basin-Long Valley region to the south, and to the north. Lassen Peak erupted as recently as 1921. Should future eruptions occur in these areas, the TNF could be covered by air-fall ash; however, because of prevailing wind directions, the probability of any significant ash deposits is low and is not considered a management concern.

Geologic Resources

Potential geologic resources include rock and soil materials for construction purposes, geologic Special Interest Areas, and groundwater.

Rock and earth construction materials are used in the construction of the Forest transportation system's roads, recreational facilities, and in various watershed restoration and wildlife projects. Road construction design methods call for balanced quantities (cuts and fills) and some surfacing materials (native soils, rock aggregates, or paved surfaces) to protect the environment or road investment.

The Forest has prepared an inventory of potential rock and soil materials sources which are considered for use on a project basis. Historically, most aggregate needs have been filled by commercial sources within or near the Forest boundaries. Each year the Forest has constructed approximately 4 to 9 miles of surfaced roadways requiring nearly 1,800 tons of rock materials per mile. Sufficient sources of rock and soil materials exist on the TNF and from commercial sources to meet needs for many decades.

Two potential geologic Special Interest Areas (SIA's) are proposed under some alternatives: Glacier Meadow geologic area and Devils Postpile geologic area. Other areas exhibiting unique or noteworthy geologic features may be identified in the future. Geologic SIA's are discussed in more detail along with other SIA's in the SPECIAL INTEREST AREAS section.

Groundwater is available on the TNF primarily in small isolated basins, in alluvial and landslide deposits, and in deep bedrock fracture zones or porous layers. Wells and springs are needed to serve campgrounds, administrative sites, and watering ponds or troughs. Forest lands serve as recharge areas for downstream underground reservoirs called aquifers. Geologic or geotechnical studies can aid in locating the most likely sources for development. Further discussion of the groundwater resource can be found under the WATER section.

HISTORICAL AND CULTURAL RESOURCES

The management of cultural resources was not identified as a major issue to be considered in the TNF Plan. The TNF is, however, charged with managing cultural resources as a nonrenewable resource to maintain their scientific, historical, and social integrity.

Current Direction

A number of laws, Executive Orders, and regulations provide direction for the TNF cultural resource management program. These have been codified in FSM 2361 as objectives, policies, and responsibilities. Briefly, the TNF is charged with conducting an inventory of resources located within the Forest, evaluating resources for their eligibility for the National Register of Historic Places, and managing those resources with historical, scientific, or social significance. Protecting cultural resources on the TNF has not, to date, measurably affected the management of other resources.

The TNF fosters and maintains relationships with the California Office of Historic Preservation, the President's Advisory Council on Historic Preservation, local universities and colleges, Native American tribes and organizations, historical societies, and other parties interested in the cultural resources of the TNF. The relationship with the California Office of Historic Preservation and the President's Advisory Council on

Historic Preservation is formal and involves regular consultation as specified by 36 CFR 800. TNF cultural resource activities are also coordinated with the California State History Plan and the Statewide Archaeological Site Survey.

Consultation with Native American tribes and organizations occurs whenever Forest management decisions may affect cultural resources of interest or concern to Native Americans. Such resources may be religious areas, archaeological sites or artifacts, or areas traditionally used for specific purposes by California Native Americans. The TNF is directed by the American Indian Religious Freedom Act to ensure that its policies and procedures do not infringe upon Indian religious freedom.

Inventory

The inventory of locations containing evidence of historic and prehistoric use of the TNF has been the primary objective of the cultural resources program. Inventory work is accomplished in conjunction with other Forest projects such as timber sales and recreational developments. Resources identified during inventory are evaluated for their eligibility for the National Register of Historic Places. Those which meet the eligibility criteria are protected from disturbance by activities and developments, and are managed to maintain their historic, scientific, or social values.

The inventory of the cultural resources located within the TNF began in 1972. Approximately 25 percent of the Forest (218,000 acres) has been examined. This inventory work has succeeded in locating over 1,550 cultural resource sites. Of these, over 900 represent historic sites characteristic of early day mining, logging, homesteading, and ranching activities. Prehistoric sites total over 650 and represent use and occupancy of the Forest by California Native Americans and their ancestors. The following cultural resource sites are presently listed in the National Register of Historic Places:

Hawley Lake Petroglyph Site
Kyburz Flat Archaeological Site
Meadow Lake Petroglyph Site
Sardine Valley Archaeological Site
Stampede Archaeological Site
Oregon Creek Covered Bridge Historic Site

In addition, over 330 sites have been found to meet the National Register of Historic Places eligibility criteria. These criteria are the principal ones used to evaluate the significance of cultural resource sites on the TNF.

A synthesis of Forest history and prehistory has been prepared that details the nearly 10,000 years of human occupation of the TNF. This synthesis is based on data gathered from published historical sources, unpublished manuscripts, diaries, records, oral histories, and the results of archaeological surveys and excavations.

The gathering and analysis of these data were guided by principles that reflect a belief that human culture and human history represent complex and dynamic systems. The history of human use of the TNF is viewed as a dynamic, evolving phenomenon. The economic, political, social, technological, and ideological aspects of cultural systems are of principal interest. Through the study of the dynamics and evolution of these systems, we come to learn about past societies and how modern cultures change, evolve, and survive.

Human History

Knowledge of the time preceding the coming of the first white settlers stems primarily from archaeological studies of ancient villages, seasonal camps, and other locations inhabited prehistorically. These studies indicate that native people began to live in the TNF soon after the last glacial age, nearly 10,000 years ago. These people were skilled and specialized hunters who found the area rich in game and other resources. Over a period of time, the economics of these prehistoric peoples diversified, and by 2,000 B.C. the TNF was home for a large human population whose culture was specialized, complex, and elaborate.

When the first settlers arrived in the 1840's the TNF area was occupied by two tribes, the Washoe and Nisenan (Maidu). The Gold Rush of 1849 brought about dramatic changes in the native cultures, as it did elsewhere in California

Gold mining was the principal industry in the TNF through the 1880s. Many of the area's modern communities began as early gold camps. With the completion of the transcontinental railroad in 1869, an extensive lumber industry developed. Much of the TNF's forested land was cut over between 1880 and the mid-1930's. The Truckee region, which experiences exceptionally cold winters, was the location of one of California's largest natural ice production industries in the late 19th and early 20th centuries.

Management Opportunities

Cultural resources are especially vulnerable to disturbance because, once disturbed or damaged, the information lost is irreplaceable. Vandalism of cultural resources is a major concern. The large amount of private land within the TNF boundary and the ease of access to most areas of the Forest have contributed to an ever-increasing vandalism problem. Bottle and relic collectors have systematically disturbed historical sites. Disturbance stems from the use of metal detectors and shovels to obtain artifacts, and in some cases heavy equipment is used. A comprehensive program of public education, site enhancement, 'antiquities' signing, frequent patrolling, and site monitoring will be necessary to reduce vandalism.

A major objective of the cultural resources program has been the identification and protection of cultural resources threatened by Forest projects. This represents a base-level management strategy. Higher levels of management in the future may include developing specific cultural resources into interpretive displays for public education and enjoyment, and intensifying efforts to obtain scientific information through archaeological studies. The initiation of cultural resource inventories, separate from Forest project impetus, would increase the rate at which cultural resources are identified and protected. These inventories would also help correct a bias in the cultural resource data base wherein forested lands have received a disproportionate share of inventory work.

HUMAN AND COMMUNITY DEVELOPMENT

Human and community development was not identified as a major issue to be considered in the TNF Forest Plan. To address NFMA regulations and Pacific Southwest Regional concerns, it is briefly discussed.

The mission of the human resource programs on the TNF is to improve the welfare of underprivileged members of society, enhance the quality of life in the TNF's area of influence by benefiting both the human and natural resources, and expand public understanding of environmental conservation. Human resource programs include the Comprehensive Employment and Training Act, Senior Community Service Employment Program, Youth Conservation Corps, Young Adult Conservation Corps, and the Volunteer Program. During fiscal year 1980, these programs accomplished \$1.6 million worth of resource improvement related work on the TNF. The TNF hosts these programs by providing employment opportunities and supervision. Enrollees in these programs are subsidized by funds Congress has allocated for operation of each specific program. The TNF will use whatever human resource programs are authorized and funded to achieve objectives of the TNF and the programs.

The Urban and Community Development Program involves both research and technical assistance through the State for the improvement of natural resources on private lands. One such program, which the TNF was instrumental in developing and actively supports, is the Resource Conservation and Development Program for an area called the High Sierra Resource Conservation and Development Area.

The High Sierra Resource Conservation and Development Area is one of three approved by the Secretary of Agriculture within California (the others are the Cal-Neva and Central Coast Areas). The Secretary has directed the Forest Service to assist the Resource Conservation and Development Areas to the extent of available funds. The Soil Conservation Service is the agency responsible for administering activities relating to these areas.

The Counties of Sierra, Nevada, El Dorado, and Placer lie within the High Sierra Resource Conservation and Development Area. Within the Resource Conservation and Development Area there are five Soil Conservation Service Resource Conservation Districts. The governing council for the High Sierra Resource Conservation District is composed of the following members.

One President

Five Representatives, one from each Soil Conservation Service Resource Conservation District

Four Representatives, one from each county government

One Representative from the Sierra Planning Organization

The council establishes policy direction and provides necessary administrative guidance to ensure an action plan. The action plan is developed by the council to use local people interested in and familiar with specific resources. These citizens are aided by resource specialists from local, State, and Federal agencies, including the TNF. The council has established these citizen committees to evaluate resources and to respond to the council with suggested necessary improvements.

Human Health and Safety

The principal activities associated with the proposed Forest Plan are timber harvest, transportation, manufacturing, reforestation, timber stand improvement, recreation, mining, and grazing.

The logging and mining industries have a high incidence of accidents per work-hour. Accidents occur in spite of elaborate safety programs. Worker safety is regulated by Federal and State agencies. The Occupational Safety and Health Administration (OSHA) and the Mine Safety and Health Administration of the Department of Labor are responsible for program activities, including safety and health standards, enforcement, training, education, and State programs. The California OSHA State Plan for enforcement of State standards places the responsibility of enforcing standards and orders with the Division of Industrial Safety. Specific reference to timber harvest and manufacturing of forest products is found in the Logging and Sawmill Safety Orders. Safety of nonindustrial workers and National Forest visitors in a timber sale area is covered by timber sale contract provisions. Public safety is also considered in the design of TNF roads built to harvest and manage timber stands.

HYDROELECTRIC PROJECTS

Hydroelectric development is a legitimate use of public land, recognized by the Federal Power Act of 1920. That Act granted authority to license hydroelectric developments to the Federal Energy Regulatory Commission. This Commission is responsible for completing environmental analyses for proposed projects, but the Forest Service, as the land management agency, participates in the evaluation as a cooperating agency. The Forest Service objective for hydroelectric projects is to ensure that construction and operation on National Forest System lands are consistent with the purposes for which the National Forests were established, while considering the energy generating potential of the project.

The TNF comprises a large portion of several major watersheds which feed hydroelectric production facilities operated by Pacific Gas and Electric Company, Sierra Pacific Power Company, and a number of local water agencies. Approximately 60 percent of the hydroelectric power in the Pacific Gas and Electric system is derived from National Forest System watersheds. In excess of 60 billion kilowatt hours of electrical production can be attributed to the TNF's watersheds. About three dozen applications were received in the early 1980's for small hydroelectric projects, with as many as three applicants for the same site. About ten proposals are currently being analyzed. Some existing dams and other facilities are being examined to see if it would be cost effective to increase their power production capabilities. The potential generating capacity from existing hydroelectric facilities within and adjacent to the TNF is 29,000 kilowatts per year.

In the early 1900's, the US Geological Survey inventoried, classified, and withdrew from mineral entry hundreds of potential power production sites throughout the TNF. This inventory was concerned only with physical dam site possibilities and did not deal with other important considerations such as water rights, economics, and distance to markets.

LANDS

Approximately 1,175,535 acres of land lie within the TNF boundary, of which 32 percent (381,161 acres) is land of other ownership. The intermingled landownership pattern found within the TNF boundary is a result of various public land and mining laws. A large portion of the Forest has a checkerboard ownership pattern which was a result of railroad and school grants.

This checkerboard ownership pattern is an important consideration when planning for the use and development (or nondevelopment) of TNF land. Intermingled landownerships can increase the costs for such things as boundary surveys and rights-of-way acquisition. It also can create more challenges for timber harvest and fire management programs. On the other hand, it contributes access to fish and wildlife which might not otherwise be available and encourage a positive land-use ethic.

Right-of-way Acquisition

The TNF acquires about 15 rights-of-way per year. Rights-of-way have been obtained for most of the arterial and collector roads. Occasionally, widening or realignment of these roads requires additional rights-of-way. The current program is focused on providing access via local roads to isolated blocks of National Forest System lands. The rights-of-way for the Pacific Crest National Scenic Trail have been obtained and work has begun for those needed for the Western States Trail. The TNF completes about three cost-share supplements to master road rights-of-way construction and use agreements with major landowners each year, mostly for local roads and reconstruction of arterials and collectors.

Property Boundary Surveys and Trespass

Because of the substantial amount of acquired land and intermingled ownerships on the TNF, considerable opportunities exist for survey problems, title claims, and trespass. Primary emphasis has been and will continue to be on prevention. There are 2,796 miles of property line on the TNF, of which 507 miles have been surveyed to date. Approximately 120 miles of boundary are being marked and posted each year. Six applications for relief under Small Tracts Act authority are being processed. Several important cases are being litigated in Federal Court. More encroachments will be discovered as the survey program continues, but the marking and posting phase of the program should help reduce incidents in the future.

Adjustments

The goal of the land adjustment program is to achieve more efficient and effective management of TNF resources by acquiring or disposing of land. Forest Service policy is to consolidate scattered parcels and to acquire identified key parcels. The land adjustment program is guided by the Master Forest Land Ownership Adjustment Plan (planning records 1922.16a.7c) for the TNF and specific purchase composites in certain critical recreation areas. Subsequent composite and adjustment program updates will be based on the direction established in the Forest Plan. To implement land adjustments, the Forest Service uses exchange, purchase, or donation; exchange is the most common.

The trend to lot split and develop subdivisions on the intermingled private lands, which was prevalent during the last two decades, has come to an end. Fewer lot splits are approved because of much stronger county zoning and land use controls and a less vigorous economy.

TNF landownership adjustments are coordinated with the plans and programs of other Federal agencies and State and local governments. The President's August 2, 1979, Environmental Program directed the Forest Service and the Bureau of Land Management to study possible boundary adjustments between the two agencies. A current National study will determine what adjustments should take place. Such action would require an Act of Congress, following full public involvement. If major transfers should take place, the Forest Plan will be amended or revised accordingly.

Special Uses

The TNF land is generally available to occupancy if it is in the public interest, except where special uses are specifically prohibited through legislation, local zoning, or administrative decision. Occupancy is

authorized by special-use permits. The TNF's proximity to population centers is increasing the demand for such use of public land to satisfy individual and public needs. Approximately 870 permits, easements, and licenses authorize the use of National Forest System land for uses ranging from cabins, resorts, and ski areas to reservoirs, roads, and utilities, encumbering over 22,000 acres. There is an effort to group compatible uses by designating transportation and utility corridors, such as Interstate 80, and electronic sites. An average of 70 permits, licenses, and easements are issued for authorized uses, while an average of 90 requests for use of National Forest System land are received each year. The TNF discourages special uses which would lower the value of parcels that are identified for exchange.

Withdrawal

All withdrawals of public lands from mineral entry are subject to the requirements of the Federal Land and Policy Management Act (FLPMA) of 1976. The Bureau of Land Management determines policy and procedures for withdrawals of public lands. That policy states that Withdrawals are to be allowed only where there is a definite showing of need and where analysis has shown that no alternative approach would meet this need. Among the factors to be considered are the uniqueness of resource values and the ability of the site to tolerate surface disturbances. The Forest Service requires that, where feasible, all mining operations be conducted to minimize adverse impacts on surface resources (36CFR 228.8).

In compliance with Section 204 of FLPMA (Public Law 94-579), each withdrawal will be reviewed by the Secretary of the Interior to determine whether the withdrawal should continue and for how long. This review is to be completed by October 21, 1991. The Forest has recommended about 2,000 acres of withdrawal be terminated and opened to mineral entry.

Withdrawals protect administration, recreation, and natural history sites, experimental areas, and scenic values from impacts which might be caused by mineral entry and development. For more information concerning existing withdrawals, see the TNF Status Records. Approximately 68,100 acres of the TNF are withdrawn from mineral development to provide this protection. Most of this acreage is within the North Fork American Wild River and the Granite Chief Wilderness. About one-tenth of the acreage in withdrawals is considered to have a high mineral potential.

Withdrawals by other agencies for active power and reclamation projects prohibit mineral entry on land immediately surrounding various reservoirs and hydroelectric facilities. These withdrawals do not affect areas of high mineral potential.

Transportation and Utility Corridors

One major existing transportation and utility location on the TNF will be designated as a corridor under all action alternatives and in the Forest Plan.

The Donner Pass corridor includes the following facilities:

- o Four-lane transcontinental (Interstate 80) highway.
- o Southern Pacific transcontinental railroad.
- o Transcontinental and local telephone lines.
- o Southern Pacific high-pressure petroleum pipeline.
- o Variety of parallel electrical transmission lines.

This corridor is up to one mile wide, contains considerable private land, and can support additional uses. An opportunity exists to expand and upgrade existing facilities to meet future demands. (Also see the discussion under VISUAL RESOURCES - Distance Zones, in this chapter.)

Other existing and proposed facilities on the TNF do not require corridor designation as they conform with management direction for the area.

Current direction excludes corridors from the Granite Chief Wilderness, the North Fork American Wild River, Onion Creek Experimental Forest, and potential Research Natural and Special Interest Areas

LAW ENFORCEMENT

The TNF administers its responsibilities of regulating and protecting National Forest System lands under Title 36 of the Code of Federal Regulations, Part 261, and appropriate sections of Title 18 of the United States Code

The U.S. Constitution reserves to the States the general police power, the authority and responsibility to protect citizens and their property. Except in specific areas, the States have delegated their general police powers to city police departments or local county sheriffs (which is the case in the TNF area), and the Forest Service does not assume the sheriffs' responsibilities in such matters. Consequently, State, local, Forest Service, and other Federal law enforcement authorities exist simultaneously on National Forest System lands.

The time-tested, successful philosophy that all Forest Service employees have law enforcement responsibilities will continue and will be strengthened. Although only a very small percentage of visitors and users on the TNF commit a violation requiring law enforcement action, the number of incidents requiring law enforcement action is increasing steadily because of an increase in the following:

- o Visitors and users.
- o Conflicts between users.
- o Enclaves of lawlessness on National Forest System and adjacent lands.
- o Users involved in illegal activities.
- o The trend toward increased criminal activity by many segments of society.

The increase in volume and seriousness of law violations and the complexity and diversity of law enforcement situations occurring on the Forest today require professional law enforcement support. This support requires additional employees trained and equipped to function in a full law enforcement capacity.

The TNF currently has cooperative law enforcement agreements with Nevada, Placer, Sierra, and Yuba Counties. The services provided by the Sheriff protect recreation users and their property. These services are reimbursable under the Jurisdiction Act of August 10, 1971 (P.L. 92-82), from National Forest appropriations. The Forest has good working relationships with all four county law enforcement agencies.

TNF personnel also cooperate routinely with other State and Federal agencies such as the California Department of Fish and Game, California Highway Patrol, Federal Bureau of Investigation, U.S. Marshall's Office, and various drug enforcement agencies.

Local law enforcement agencies are small and have suffered budget reductions in the past four years. For example, Sierra County has only eight deputy sheriffs and is unable to handle all situations that occur within its area of responsibility on the Forest. Incidents and crimes normally associated with urban areas, such as robberies, assaults, burglaries, narcotics trafficking and cannabis cultivation, are increasing on the Forest. Increased criminal activity leads to delayed responses by responsible agencies, which in turn can expose Forest officers and visitors to potential personal risk.

MINERALS

Interest in mineral and energy mineral sources and production has increased significantly over the last decade. The identification, exploration, and development of potential mineral and energy mineral sources are important. Potential energy sources on the Forest include geothermal, wood byproducts, and

hydroelectric. Land uses that restrict or prohibit mineral prospecting and mining are also of concern, and the potential environmental impacts of mining make minerals an important public issue. (Mineral withdrawals are discussed in the LANDS section of this chapter.)

Four categories of minerals are located in the TNF

- o Locatables (hardrock minerals - gold, silver, etc.)
- o Leasables (geothermal and locatable minerals on acquired land)
- o Saleables (basically common varieties - sand, gravel, etc.)
- o Outstanding Mineral Rights (land managed by the TNF where the mineral estate is reserved or outstanding; there are 460 acres on the TNF and development is unlikely)

The TNF has analyzed mineralization, based on available nonproprietary information and professional expertise (Mineral Potential Map, planning records, 1920.16a.7d). This analysis includes an estimate of potential conflicts between minerals and other resources (refer to Chapter 4). Maps of the reserved mineral rights are too voluminous to be included in the EIS (planning records, 1920.16a.7d).

The majority of the TNF is open to mineral entry under the 1872 Mining Law for locatables. Principal leasables on the TNF are geothermal, generally found on the east side of the Sierra, and metallic minerals, found on those acquired lands without public domain status. The saleables, or common variety form of minerals, are the only minerals 'managed' by the Forest Service.

The western side of the TNF is highly mineralized. This area includes the historic Northern Mines gold mining region (Downieville to Placerville). Other important minerals and common variety minerals found in the TNF include chromite, barite, silver, iron, copper, sand, and gravel. Chromite is considered to be a strategic mineral of critical significance because current supplies are obtained primarily from foreign sources. No deposits of fissionable materials are known on the TNF.

Over 10,000 mining claims have been filed on the TNF, along with about 200 notices of intent to operate and 150 plans of operations. Very little mineral production information is available, particularly for gold. Use of National Forest System land for purposes other than mineral resource development and extraction, under the assertion of rights provided by the 1872 Mining Law, is a continuing problem.

Gold production has declined since World War II. The last large mine in the Northern Mines shut down in 1956. The mines at Alleghany, the last active quartz mining district, shut down in 1965. The increase in the price of gold during the past few years has created a second gold rush of both mining for recreation and speculation in gold mining properties.

The need to provide plans of operations for mining activities has increased by about 100 per year until 1986 and then leveled off. Management of minerals, except saleables, on the TNF is mainly in response to demand. All land open to mineral entry has the potential to be explored and developed. Market conditions are the driving force for exploration and development.

The National demand for minerals is increasing; as a result, greater emphasis will be placed on exploring for and developing minerals on public land. New exploration, production, and development technologies, the depletion of current reserves, and a National desire to reduce dependence on foreign supplies are other factors that can stimulate mineral exploration and development on National Forest System land. The demand for aggregate is local, and it is expected that transportation costs and depletion of existing sources will accelerate the future demand for this resource.

Access for mineral exploration and development is generally unrestricted subject to the mitigation of impacts on surface resources. Exceptions are the Granite Chief Wilderness, special area allocation (i.e., the North Fork American Wild River, research natural areas, etc.), and other appropriated land.

Access to wilderness, special areas, and other appropriated land is subject to valid existing rights. It is restricted to the extent that the integrity of the area involved must be maintained. The specific restrictions for the areas of concern are contained in the prescriptions

As the scale of mining activities increases from prospecting and exploration to development, considerably more time and effort will be required to administer the operations because of greater potential for serious impacts. Suction dredging activities have increased in the major river drainages on the west side of the TNF during the past few years.

A potential geothermal energy source has been identified on the east side of the TNF; its potential appears to be minor. The TNF has no geothermal leases or lease applications. Applications for development of energy minerals (including oil, gas, and geothermal) are handled on a project basis

The prospecting, locating, and development of mineral resources within National Forests is authorized by the Organic Act of June 4, **1897**. The Act also allows the Secretary of Agriculture to establish rules and regulations in connection with operations authorized by mining law. These regulations, which minimize impacts on the resources or define procedures, can be found in **36 CFR 228** (locatable minerals and disposal of saleable mineral materials) and **293.14** (mineral leases and permits in wilderness).

Generally, the authority to manage locatable and leasable mineral resources is retained by the Secretary of the Interior. Agreements, embodied in memorandums of understanding between the Secretaries of Agriculture and the Interior which share various work processes, are found in **FSM 1500**, External Relations. The authority for the management and disposal of mineral materials (including but not limited to common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay) is with the Forest Service.

The detailed authorities and direction for locatable minerals, mineral leasing, and mineral sales are in **FSM 2800**, Minerals and Geology.

RANGE

The ranges on the TNF are used by domestic livestock and wildlife. Range management is important because of the large number of domestic livestock, primarily cattle and sheep, that graze these ranges. Important issues are to maintain forage condition in satisfactory ecological condition or improve those ranges in less than satisfactory ecological condition; the amount of land available for grazing domestic livestock, the amount of forage produced; the number of permitted animals; and the competition between livestock and wildlife for available forage.

Current Situation

The available domestic livestock forage that exists on the TNF is in transitory and permanent range. Transitory range is created by wildland fires and by management practices, especially timber harvesting. Transitory range occurs primarily on the lower elevation western slopes. Permanent range consists of high mountain meadows throughout the Sierra Crest and the eastside pine forest type.

As displayed in Table 3.14, 46 active grazing allotments within the TNF encompass 310,448 acres of National Forest System land and 192,194 acres of waived and cooperative private land. Cattle graze on 30 allotments and sheep graze on 15 allotments, with 1 allotment grazed by both cattle and sheep. These allotments produce a total of 20,000 animal unit months (AUMs) on National Forest System land and 10,800 AUMs on private land. Currently, two allotments have no livestock.

Three management strategies employed on the TNF, as defined in the Nation's Range Resources, Forest Resource Report No. 19, December 1972, are (1) intensive management of the environment and livestock, (2) extensive management of the environment and livestock, and (3) environmental management with livestock. Table 3.15 summarizes the current range allotments and strategies. About 85 percent of the suitable range currently is in satisfactory ecological condition.

Thirty-four ranches and about 44 families depend on TNF grazing allotments. About 13 of the 44 families live in the Sierra Valley area. The rest of the ranchers who use grazing allotments are based in the Nevada City, Auburn, and Sacramento Valley areas. Five large sheep operations use the TNF.

Supply and Demand

The TNF identified all land capable, available, and suitable for range production using District Range Atlases, allotment management plans, and analysis data contained in the allotment files. These land classifications were transferred to 1:24,000 scale base maps in the form of range types (permanent and transitory), allotment boundaries and names, and average condition and trend for each range type. The range maps are found in the planning records.

TNF land was identified by three major categories to determine land capable of range production: (1) land capable of producing permanent range, (2) land capable of producing transitory range, and (3) land that is not capable of producing forage.

The North Fork American Wild River's designation precludes grazing by domestic livestock. The remaining National Forest System land considered capable of range production is available.

1/ Mount Haskell Allotment is located on the Plumas National Forest but is administered by the TNF

Portions of the Sierra Crest Sheep Allotment and the Chipmunk Cattle Allotment are located within the Granite Chief Wilderness. The majority of the area is used by sheep through an extensive management system, starting at the lower elevations on July 15 and ending the season on September 30. Cattle use the northwestern portion from late August until the end of September. Management systems were developed for both allotments to permit the livestock to use the forage in harmony with the high recreation use of the area

Suitable range is capable and available land currently (or potentially) accessible to livestock that can be grazed on a sustained yield basis. Slopes greater than 50 percent are unsuited for livestock use. Table 3.16 displays the maximum acres of capable, available, and tentatively suitable range on the TNF.

MANAGEMENT STRATEGY	NO. OF ACTIVE ALLOTMENTS	NFS ACRES	PRIVATE ACRES	% OF TOTAL ALLOT.ACRES
Intensive	7	132,120	31,635	33
Extensive	33	162,574	160,509	64
Other (with livestock)	6	15,754	60	3
TOTAL	46	310,448	192,194	100

TABLE 3.16 • MAXIMUM ACRES OF CAPABLE, AVAILABLE, AND TENTATIVELY SUITABLE LAND FOR RANGE PRODUCTION ON THE TNF

Land Type	Acres*
Permanent Range-Forest Land (capable)	105,844
Transitory Range-Forest Land (potentially capable)	647,264
Noncapable Forest Land	41,266
Land determined as not available	6,074
Land unsuitable due to other uses or >50% slope	189,621
Land determined as capable, available, and tentatively suitable	577,131

* Acreages do not include private land within the TNF boundary.

Demand to use all capable, available, and suitable range resources on the TNF will keep increasing. This increase is primarily because of the loss of private grazing land to other uses, such as crops and urbanization. Permittees will need to use the TNF range resource to sustain their breeding stock of cattle and sheep. Some demand, such as from the Sierra Valley, may not only be to produce meat, but to sustain family ranches. A limited potential exists to increase forage capacity by implementing intensive grazing systems on existing allotments, fully using transitory range opportunities in harmony with other resource needs and objectives, and returning vacant allotments back to AUM production during the first decade. Under current management direction this increase would only partially meet demand.

Research studies are also needed to evaluate the site potential of the eastside pine forest type for dual use (timber and forage).

* MRVD Use - Thousands of Recreation Visitor Days

Note: Projections are based on 1982 figures.

Developed Recreation

Presently, 197 developed recreation sites are on 1,843 acres. They have a combined capacity of 30,104 persons-at-one-time (PAOT). These sites accounted for 1,885,800 RVDs in 1982 (Table 3.18).

TABLE 3.1a DEVELOPED RECREATION SUMMARY

TOTALS	197	1,843	30,104	1,885,800

Developed Campgrounds. Most developed campgrounds are filled to capacity on weekends, with vacancies during weekdays. At higher elevations, seasonal use is June through September, with a few sites at lower elevations being used throughout the year. The TNF's average use of developed campgrounds is about 24 percent of its theoretical capacity. Experience throughout the Pacific Southwest Region indicates that optimum campground use is about 35 to 40 percent of theoretical capacity. This indicates that the overall existing campground capacity should be adequate for the next 5 to 10 years. Many of the more popular campgrounds often exceed the optimum level while the less popular sites may be used at only 12 to 15 percent of theoretical capacity. This means that the demand for certain sites and locations may exceed capacity and the Forest may have to provide additional capacity in the next 5 to 10 years. Other types of developed facilities in the public sector appear adequate to meet the anticipated 1990 demands.

A number of potential recreation sites have been inventoried within each Recreation Opportunity Spectrum (ROS) class. These sites were originally inventoried for the Outdoor Recreation Resources Review Commission (ORRRC) studies based on the criteria of water availability, existing vegetation, and gentle slopes. Existing access was not emphasized because that factor could change over time. Desired characteristics for dispersed use vary so widely that no inventory could display the desired areas for all dispersed recreation use opportunities. The ROS classes inventory addresses the broader desired recreation experiences for both developed and dispersed recreation. The identified potential developed recreation sites should be adequate to meet the developed recreation demand for the next several decades. By the year 2030, however, developed recreation site capacity would probably need to be increased by 52 percent to accommodate dispersed recreationists. If recreation use patterns shift because of high fuel costs and scarcity, those sites nearest metropolitan areas would receive increased use.

Recreationists on National Forest System lands sometimes trespass onto adjacent private land, often resulting in conflicts between recreationists and private landowners.

Facilities Under Special-Use Permit. The TNF has a variety of recreation facilities under special-use permit. These include 155 recreation residences in 9 tracts, 5 summer resorts and commercial establishments, 17 organizations and clubs, and 4 winter sports resorts. These facilities receive active use and provide an important service. Future use determinations have been made on all recreation residences. These decisions are incorporated in the Forest Plan.

Dispersed Recreation

Dispersed recreation is forest and rangeland outdoor recreational use that occurs outside of developed areas. Examples of dispersed recreation on the TNF include cross-country skiing, off-highway vehicle use, horseback riding, hiking, and fishing.

Winter Sports

Cross-country Skiing. Cross-country (Nordic) skiing is currently the fastest growing dispersed recreation activity on the TNF. This activity was about 36,100 RVDs in 1982, and practically nonexistent in 1970. Cross-country skiing, along with snowmobiling and other recreational winter sports, including snowplay, creates an increased need for support facilities, e.g., snow removal, adequate parking, sanitation, trails, and provisions for search and rescue. A primary cause of conflict between cross-country skiing and snowmobiling is their use of the same trail system.

The opportunity to provide parking, marked trails, and other support facilities is available from the private sector, either through the use of National Forest System land under special-use permit or through the use of private land.

Downhill Skiing. Four existing winter sports resorts are operated under special-use permits. They provide about 209,500 RVDs per year on National Forest System land and about 288,100 RVDs on private land, for a total of about 497,600 RVDs per year. Five other winter sports resorts are located entirely on private land within the TNF boundary and several others are on private land adjacent to the TNF boundary. Existing downhill ski resorts are approaching full use of their existing facilities. By 1990, a developed capacity of 19,320 PAOT increase over the 1982 existing capacity is expected through expansion of existing facilities onto 1,270 acres of National Forest System land. Four potential winter sports areas have been identified

either wholly or partially on TNF land Existing facilities are overcrowded on peak weekends and holidays, which diminishes the recreation experience. This overcrowded situation also adds pressure to an already overcrowded transportation system and overextended local public services. The periodically proposed 'Ski Circus' concept would interconnect several existing and proposed ski areas along the Sierra Crest. The proposal is still being discussed. No commitments have been made. Expansion of existing facilities and construction of new facilities depends upon the availability of local support facilities, transportation, and market considerations.

Off-Highway Vehicle Use

Recreational off-highway vehicle (OHV) use was about **177,500** RVDs in **1982**. Off-highway vehicle use is administered through the direction in the **TNF Off-Road Vehicle Travel Plan** and **Transportation Management Plan**.

At the same time, demand for nonmotorized access into undeveloped areas is increasing. Hikers and horseback riders seeking this experience are often in conflict with OHV use, especially with mountain bikes and motorized trail bikes on narrow trails. Presently, Grouse Lakes, Granite Chief Wilderness, and Castle Peak motor vehicle closure areas provide recreational opportunities for hikers and equestrians without this conflict.

Snowmobile use is permitted in most of the TNF. Critical winter deer ranges and key cross-country ski areas are exceptions. An assessment correlating land capacity, user needs, and user/landowner conflicts will be made on a Forestwide basis for all dispersed recreation travelways. Particular attention will be paid to opportunities for the disabled.

A draft Statewide Off-Highway Motor Vehicle Recreational Trails Plan has been developed for the State of California Department of Parks and Recreation. This plan presents the concept of a Statewide OHV trail system that connects use areas to provide opportunities for long-distance trail touring. Although the State plan identifies specific route locations, it recognizes that actual route locations may vary. Existing Forest OHV trails and low standard roads can serve as part of the Statewide system and provide long-distance touring opportunities. New connector trails may be needed to supplement existing routes and to complete the system.

Recreation Opportunity Spectrum Class Allocations

Recreation Opportunity Spectrum (ROS) is a system that stratifies the TNF into recreational opportunity categories based on the size, distance from roads, and degree of development of any given recreational area. ROS is used to allocate a variety of existing and potential recreation activities and opportunities to National Forest System land. The ROS classes are urban (U), rural (R), roaded natural (RN), semi-primitive motorized (SPM), semi-primitive nonmotorized (SPNM), and primitive (P) (see Chapter VIII of the Plan - Glossary). Current recreation use, in recreation visitor days (RVDs), and recreation capacity, in persons-at-one-time (PAOT), on the TNF are shown in Tables **3.19** and **3.20** for each ROS class. The classes are separated into two categories: developed recreation and dispersed recreation. In dispersed recreation the eleven roadless areas discussed under the **WILDERNESS AND ROADLESS AREAS** section contribute the majority of the acres available for SPNM and SPM recreation opportunities.

4/ MRVD - Thousand Recreation Visitor Days

5/ Primitive ROS class: Zero acres exist on the TNF but the Granite Chief Wilderness is managed for Primitive ROS class direction to be consistent with Wilderness values.

RESEARCH NATURAL AREAS

Research Natural Area (RNA) candidates are recommended to the Chief of the Forest Service to preserve examples of all significant natural ecosystems for purposes of research and ecological study, and to provide gene pools. The Pacific Southwest (PSW) Regional Guide displays the target Research Natural Area system for the California Region. Presently no established RNA's are on the TNF.

Proposed RNA's include Babbm Peak, representing Washoe pine (*Pinus washoensis*). Other areas which have been identified as candidates to meet the PSW Regional target Research Natural Area system are Basin Peak because of its mountain hemlock (*Tsuga mertensiana*), Sugar Pine Point with its muted conifer, the Mt. Lola mountain hemlock area near Independence Lake, and a mountain hemlock area located near Needle Lake and Lyon Peak.

A detailed evaluation of all the RNA's is contained in Appendix C. This evaluation presents for each area: (1) a description of the physical setting, (2) an analysis of the environmental consequences of designating the area to specific uses, and (3) findings as to the suitability, availability, manageability, and boundaries as an RNA. A map of RNA locations is found in the 'Maps' packet. Additional maps, documents, working papers, and other information relating to the RNA planning process are available for public review at the Forest Supervisor's Office, TNF, Nevada City, California.

Following is a brief description of each potential RNA.

Babbitt Peak Research Natural Area. This area, located on the Sierraville Ranger District near the Tahoe/Toiyabe National Forest boundary, is characterized by an unusual vegetative community which includes Washoe pine and mature stands of mountain mahogany.

Sugar Pine Point Research Natural Area. This area, located on the Nevada City Ranger District, is representative of mid-elevation mixed conifer forest with a large old-growth sugar pine component.

Basin Peak Research Natural Area. Located northeast of Basin Peak on the Truckee Ranger District, this area is characterized by distinctive vegetation including mountain hemlock and western white pine. This area is located adjacent to private land.

Mt. Lola Research Natural Area. This area, located northwest of Independence Lake in the headwaters of Cold Stream on the Sierraville Ranger District, is characterized by a nearly pure stand of mountain hemlock 200-300 acres in size. Stands of this size rarely are larger than 40-50 acres in the TNF. The stand is immediately adjacent to and includes private land.

Lyon Peak/Needle Lake Research Natural Area. This area, located immediately north of the northern boundary of Granite Chief Wilderness on the Truckee Ranger District, is representative of mountain hemlock stands. This area contains a number of unique plant communities.

RIPARIAN AREAS

Riparian areas consist of the aquatic ecosystem, the riparian ecosystem, floodplains, wetlands, and the first 100 feet of streamside management zones (SMZ's) on either side of perennial streams. Because there is an overlap of riparian areas and SMZ's, and because the purpose of SMZ's is ultimately to protect riparian area values, they are discussed together in this section.

Existing Condition

The aquatic ecosystem consists of about 1,500 miles of perennial streams, totaling nearly 4,000 acres of surface water, and about 20,000 surface acres of lakes and reservoirs within the Forest boundary. About 70 percent of the streams (1,050 miles or 2,800 acres) and about 10,300 of the lake surface acres are under National Forest System management.

The riparian ecosystem/wetlands areas total about **54,200** acres within the Forest boundary. Approximately **32,000** acres of these are National Forest System lands. These vary in size from less than one acre to hundreds of acres of open, wet meadows. They occur mostly on the east side of the Sierra Crest, and above 5,000 feet elevation on the west side.

Floodplains associated with large rivers (Class I streams as defined in FSH **2509.22** Chapter 30) total about **4,600** acres, most of which are on National Forest System land. These floodplains are adjacent to the main stems of the North, Middle, and South Yuba Rivers, the North and Middle Forks of the American River, and the Truckee and **Little** Truckee Rivers.

Streamside management zones comprise about **47,800** acres adjacent to perennial streams on National Forest System lands. About **38,700** acres of these are part of the TNF's capable forest land, representing 60 percent of the productive forest land base. **Eighty-six** percent of these SMZ acres constitute the riparian areas as defined in Regional direction; these constitute the first 100 feet horizontal distance on both sides of perennial streams. The remaining acreage represents the SMZ area outside the riparian area. Because drainage density is greater west of the Sierra Crest, the SMZ protection acreage is also greater here. The amount of SMZ acreage needed adjacent to intermittent and ephemeral streams is undetermined. SMZ widths are routinely identified during project-level planning in response to specific proposals.

Figure 3.2 displays the relationship between riparian areas and SMZ's (perennial streams). Figure 3.3 displays the relationship of riparian ecosystems and SMZ's for Class I and II intermittents.

When accounting for acreage overlap, there are about **85,000** acres of riparian area on the TNF. This represents 11 percent of the Forest area.

The condition of riparian areas on the TNF is generally very good. Water quality is generally high, indicating that the aquatic ecosystem is in good condition. The exceptions are some sedimentation problems relating to abandoned hydraulic diggings, some roads, recent fires, and logging on sensitive sites (refer to the WATER section for a more detailed discussion of this subject). Floodplains, the riparian ecosystem, and wetlands are generally in good condition with some exceptions, such as Carman Creek and isolated problems of streambank compaction and erosion caused by grazing.

Because of only recent emphasis on regeneration harvesting with attendant intensive site preparation activities, such as broadcast burning, there has been to date relatively **little** cumulative impacts on SMZ's. First indications are that it will be possible to protect SMZ's adjacent to perennial streams and adjacent to intermittent and ephemeral streams on flatter (tractor-loggable) ground, assuming the diligent implementation of BMP's including SMZ protective measures. There have been several recent problems where **SMZ's** and/or water quality were adversely impacted because of lack of proper implementation of SMZ protective measures; examples of this include Rock Creek, Blackwolf Creek, Deer Creek (Pride Sale), and Holden Spring Creek. A higher risk exists in protecting SMZ's adjacent to intermittent and ephemeral streams on steeper (cable-loggable) ground, mainly due to post-harvest activities, notably broadcast burning. Monitoring should emphasize these areas to determine the extent of this risk; as necessary, activities on these slopes would then be adjusted to reflect the soil and water resource needs.

Riparian Area-Dependent Resources and Use by Other Resources

Many important resources, including about 20 species of fish, many wildlife, and certain vegetation communities, are totally dependent on riparian areas for their existence. Approximately 70 percent of the **387** vertebrate species occurring on the TNF either live exclusively in riparian areas or are frequently found there.

FIGURE 3: 2 RELATIONSHIP OF RIPARIAN AREAS AND SMZS
Perennial Streams

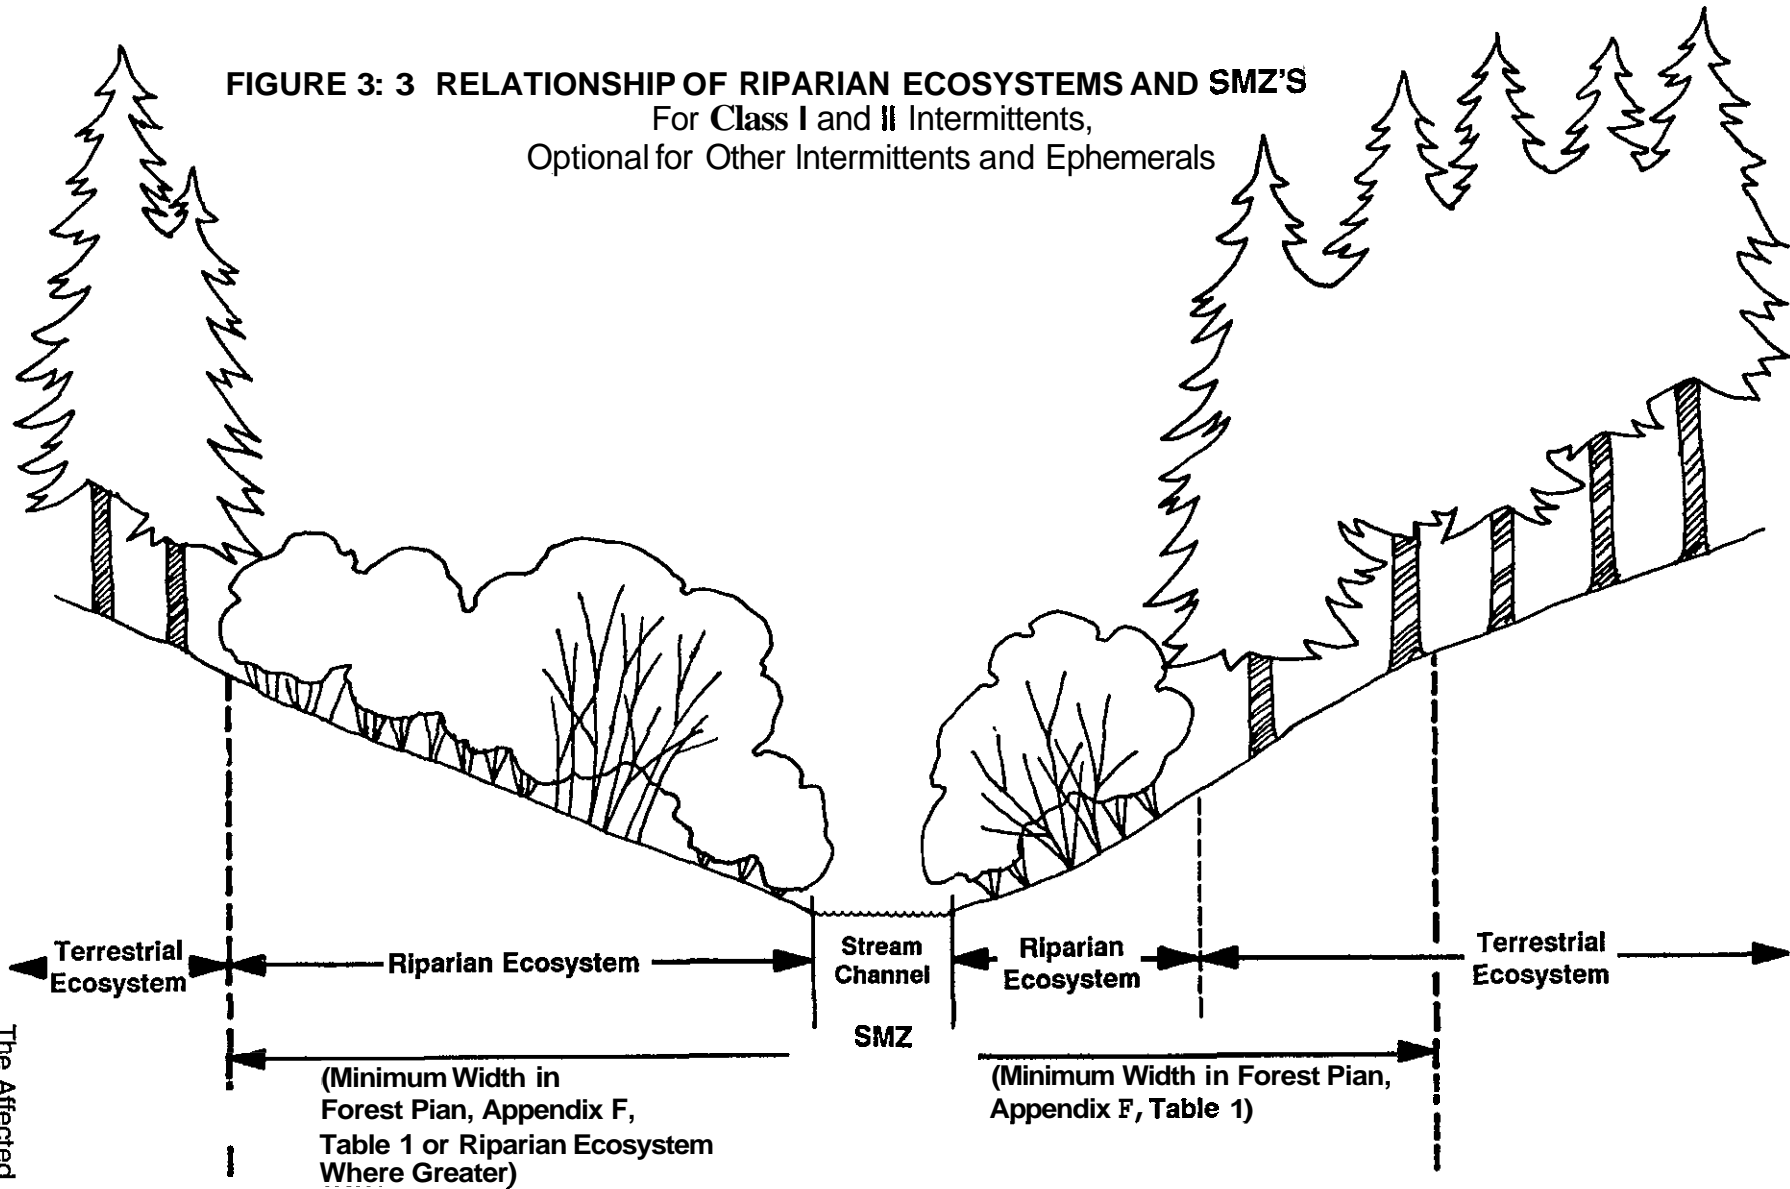

FIGURE 3: 3 RELATIONSHIP OF RIPARIAN ECOSYSTEMS AND SMZ'S
 For Class I and II Intermittents,
 Optional for Other Intermittents and Ephemerals

Other important resources and values associated with riparian areas on the Forest include groundwater recharge, moderation of peak floods, forage production, cultural resources, timber, and recreational enjoyment. Timber production in SMZ's is planned at a very low yield in deference to riparian area-dependent resource dictations. An undetermined amount of the Forest's 20,000 AUM range capacity is in the riparian zone. Recreation within riparian areas includes 238,000 RVDs of fishermen's use per year, 90,000 RVDs of swimming use, 84,000 RVDs of use involving various watercraft from rafts to powerboats, and nearly 2,000 RVDs of waterfowl hunting

Conflicts **Associated** with Riparian Areas

Current management policy allows timber harvest in SMZ's adjacent to perennial streams only where hydrologic, fishery, wildlife, and recreational values dictate. Protecting riparian vegetation adjacent to intermittent and ephemeral streams in clearcuts is difficult, particularly when treating slash on cable-logged areas.

Livestock grazing is permitted on 40 percent of the Forest. Most of this is at higher elevations and on the east side of the Forest where riparian ecosystem/wetlands acreage predominates. Riparian areas provide primary range and receive more grazing use than drier hillside or upland areas. The riparian ecosystem and wetland acreage amount to 4 percent of the Forest land base, but account for a greater but undetermined percentage of the Forest grazing use.

Other isolated concerns involve OHV use in riparian areas, and ski area development.

Current Direction and Management

Riparian areas are protected through direction contained in various Forest Service manuals, handbooks, and timber sale contracts as summarized in Best Management Practices (**BMP's**), documented in the PSW Region's publication. Water Quality Management for National Forest System Lands in California: See Plan Appendix E. General policy is to avoid or minimize any activities that could result in adverse impacts on water quality and riparian areas. Where riparian area impacts are unavoidable, such as where roads cross stream courses, mitigation measures are adopted that minimize the impacts to acceptable levels.

Designating SMZ's is an example of BMP application (BMP 1.8). This BMP is implemented to retain the tree canopy for stream shade, protect riparian vegetation along channels, maintain a sediment filter zone, protect channels and streambanks, maintain recreation values, and provide cover for certain riparian-dependent wildlife. Other examples of BMP's include those for watershed restoration, wetlands protection, and floodplain planning.

Management **Opportunities** and Potential to Resolve Conflicts

Regional riparian area management policy is currently being implemented. Riparian areas are protected so that habitat for riparian-dependent wildlife and fish is maintained, and aesthetically pleasing areas for fishing and other recreation are provided. The SMZ policy designed to protect hydrologic values will remain in effect and complements riparian area management

Timber management will be allowed only under special guidelines and is subject to riparian area-dependent resource needs. Grazing will be continued provided watershed, fishery, and wildlife values can be maintained. Some streams will be fenced, but generally the emphasis will be to control grazing impacts through permit administration and improved range management

New campgrounds will be excluded from riparian areas. Undeveloped camping will be moved or improved to mitigate vehicle and camping impacts. At heavily impacted recreation sites and range sites in the Granite Chief Wilderness, riparian ecosystems will be rehabilitated as funds and opportunities arise.

The Forest will improve the condition of riparian areas by better coordination with other resource activities: an example would be to take advantage of opportunities to do direct habitat improvement in riparian areas by planting new species where diversity can be enhanced

SENSITIVE PLANTS

The sensitive plant list for the Pacific Southwest Region was originally developed by combining the Smithsonian and the California Native Plant Society lists. The TNF was then provided with a list of plants known or suspected to occur in the TNF or its vicinity. Changes in the PSW Regional list are made as new information becomes available, resulting in occasional changes to the TNF list

Currently, the TNF has one Federally endangered and twelve listed sensitive plant species known or suspected to occur in the TNF or its vicinity; no plant is listed as threatened. All necessary steps will be taken to ensure that agency actions do not jeopardize the continued existence of these species, and that viable populations of sensitive plants will be maintained. Table 3.21 lists these plant species.

TABLE 3.21 ABBREVIATION CODES, ENDANGERED AND SENSITIVE PLANT SPECIES LIST

Endangered		
1.	MASO	<i>Mahonia sonneri</i> (Truckee Barberry)
Sensitive		
1.	ARCO	<i>Arabis constancei</i> (Constance's rock-cress)
2.	CAPA-4	<i>Carex pauciflorus</i> (Few fruited sedge)
3.	ERUMT	<i>Eriogonum umbellatum</i> var. <i>torreyanum</i> (Torrey's Buckwheat)
4.	IVAP-1	<i>Ivesia aperta</i> (Sierra Valley Ivesia)
5.	IVSE-1	<i>Ivesia sericoleuca</i> (Plumas Ivesia)
6.	IVWE	<i>Ivesia webberi</i> (Webber's Ivesia)
7.	LECAN-1	<i>Lewisia cantelowii</i> (Wet cliff Lewisia)
8.	LEPYL	<i>Lewisia pygmaea</i> ssp. <i>longipetala</i> (Large flowered pygmy Lewisia)
9.	LESE	<i>Lewisia serrata</i> (Sawtoothed Lewisia)
10.	PHST-2	<i>Phacelia stebbinsi</i> (Stebbins' Phacelia)
11.	SIIN	<i>Silene invisus</i> (Hidden petal champion)
12.	VACO-1	<i>Vaccinium coccinium</i> (Scarlet huckleberry)

SOILS

The western third of the TNF contains deep canyons separated by nearly level to sloping, broad ridgetops. Soils on the steep canyon sideslopes have developed mainly from metasedimentary and ultrabasic bedrock; soils on the ridgetops have developed primarily from andesitic tuff breccia mudflows of the Meherthen Formation. Soils in the vicinity of Bullards Bar Reservoir have developed mainly from granitic bedrock. The western third of the Forest contains the most productive soils.

Soils in the eastern third of the Forest occur on gentle to steep slopes and in broad valleys. These soils have developed from rhyolitic and granitic bedrock and from alluvial deposits. Low precipitation is a major limitation to productivity.

Soils at higher elevations (5,500 to 9,500 feet) along the crest of the Sierra have developed from volcanic, metasedimentary, and granitic rocks, and from glacial-alluvial deposits. Steep slopes and shallow, rocky soils limit productivity in much of this central third of the Forest.

Forest Service direction concerning soil productivity and conservation is to maintain or enhance soil productivity. No management action will be intentionally taken that will irreversibly impair soil productivity. Soil characteristics and qualities that are indicators of soil productivity will be monitored to detect changes caused by management activities.

Because soil characteristics affect timber growth rates, forage quantity and quality, ease of road and campsite construction, and other Forest resource production or use, they are a major consideration in management activities.

Soil productivity is the inherent capacity of a soil to support the growth of specified plants, plant communities, or a sequence of plant communities. One estimate of soil productivity is timber site class, a measure of potential timber growth. Site class 1 is the most productive, site class 6 the least. Table 3.22, the 1980 TNF timber inventory, updated to reflect the current land base, lists the following acres in each TNF Forest Survey site class.

TABLE 3.22 - THE 1980 TNF TIMBER INVENTORY

Site Class	Acres	Percent of TNF
1	0	0
2	3,918	0.5
3	250,097	31.5
4	195,899	24.7
5	168,441	21.2
6	28,919	3.6
Not Capable	147,110	18.5
TOTAL	794,374	100.0

cycling is lost by removal of biomass, displacement into tractor piles, or by burning the forest duff and litter.

The implementation of Forestwide standards and guidelines for these soil qualities would minimize the risk of reducing soil productivity. The effectiveness of Forestwide standards and guidelines in maintaining soil productivity will be monitored.

Soils on about **23,000** acres of capable forest land have been inventoried as eroded or altered. About 5,000 acres of this total are classified as eroded or severely eroded, and 18,000 acres as altered by terracing (contour furrowing) or by displacing the surface soil into windrows or piles. Disturbance on these soils has reduced their productivity by one or more site classes. Soil productivity on many of these sites could be increased through soil improvement practices such as fertilizing and respreading topsoil now in windrows or piles.

A third-order soil resource inventory (SRI) has been completed for the TNF. Soil maps have been printed at a scale of 1:24,000. Soil descriptions, maps, and management interpretations are in the planning records. The soil maps delineate different soils in sufficient detail for timber compartment planning and for some project planning. The soil maps may not have the detail necessary for site-specific project planning or design.

SPECIAL INTEREST AREAS

Special Interest Areas (SIAs) are established to protect special or unique geologic, ecologic, or cultural features. The TNF has no established SIAs.

The Special Interest Area Establishment Report for the Placer County Big Tree Grove Botanical Area is being prepared. Potential SIAs on the TNF include the Devils Postpile and Glacier Meadow Geologic Areas, the Grouse Falls Scenic Area, the Hawley Lake, Meadow Lake, Boca, and Kyburz Cultural Areas, the Macklin Creek Lahontan Cutthroat Trout Habitat Area, the Independence Lake Cutthroat Trout Habitat and Geologic Area, and the Sierra Buttes, Little Truckee River Terrace, Sagehen Basin, Mason Fen, Sagehen Headwaters, San Juan Ridge, and the Headwaters Basin of the North Fork of the American River Ecosystem Study Areas.

A detailed evaluation of all the SIAs is contained in Appendix C. This evaluation presents for each area: (1) a description of the physical setting, (2) an analysis of the environmental consequences of designating the area to specific uses, and (3) findings as to the suitability, availability, manageability, and boundaries as an SIA. A map of SIA locations is found in the 'Maps' packet. Additional maps, documents, working papers, and other information relating to the SIA planning process are available for public review at the Forest Supervisor's Office, TNF, Nevada City, California.

Following is a brief description of each potential Special Interest Area. Cultural sites not selected for SIA designation will be managed to maintain their important values in accordance with FSM 2361.

Hawley Lake Cultural Area (5,323 acres). This area is located in the upper reaches of the Pauley Creek drainage on the Downieville Ranger District. Numerous historic and prehistoric cultural resource sites occur in the area, including one which is in the National Register of Historic Places.

Kyburz Cultural Area (1,097 acres). This area is located on the Sierraville Ranger District in the Little Truckee River drainage. The area is one of the principal waterfowl nesting areas on the TNF. Prehistoric archaeological evidence indicates that the area has been a prime wildlife area for thousands of years. One of the major routes to the Comstock silver mines in Nevada passed through Kyburz Flat.

Boca Cultural Area (1,976 acres). Located on the Truckee Ranger District, this area shows substantial evidence of prehistoric and historic use. The former town of Boca figured prominently in the development of industries such as logging, mining, and ice manufacturing in the nineteenth century. The area provided wood products (lumber, charcoal, etc.) and ice to the Comstock mines in Nevada and was a major stopping point on the transcontinental railroad from the 1860's to the early 1900's.

Meadow Lake Cultural Area (58 acres). This area on the Sierraville Ranger District includes the remnants of the former town of Summit City. When gold was discovered there in 1863, a city sprang up overnight. Because of the inability to extract the gold from the ore found in the area, the town died within two years. The area includes Meadow Lake reservoir, constructed in the nineteenth century for mining, and also includes extensive evidence of prehistoric use such as petroglyphs and other cultural resource sites.

Glacier Meadow Geologic Area (84 acres). This area is located on the Truckee Ranger District on the western slope of the Sierra Nevada. This distinctive and unusual glaciated landscape of scoured and polished granite is overlain by large boulders left when the glaciers retreated over 10,000 years ago.

Devils Postpile Geologic Area (69 acres). This prominent feature on the Downieville Ranger District is located near the Plumas and TNF boundary. The geologic feature is a large vertical pillar of basalt rock that rises above the surrounding landscape.

Placer County Big Tree Grove Botanical Area (346 acres). Located on the Foresthill Ranger District, this area contains a unique grove of giant sequoias (*Sequoiadendron giganteum*). The grove represents the northernmost natural occurrence of these giant trees in the Sierra Nevada. Because they represent an isolated stand (the closest occurrence of giant sequoias is many miles to the south in Calaveras County), they are of great interest to botanists. They have been a popular tourist attraction since the 1800's and each tree bears the name of a prominent American, such as Theodore Roosevelt and General Pershing.

Grouse Falls Scenic Area (220 acres). Grouse Falls is one of the highest cascading falls in California. It is located in the steep, rugged Last Chance area of the Foresthill Ranger District. The falls are on Grouse Creek and can be reached only by a primitive trail.

Sierra Buttes (1,827 acres). Located on the east side of the Buttes on the Downieville Ranger District is the southernmost occurrence of green spleenwort (*Asplenium viride*). Mountain hemlock (*Tsuga mertensiana*) is also found in the Sierra Buttes.

Headwaters Basin of the North Fork of the American River (9,381 acres). This area includes the Onion Creek Experimental Forest and is located on the Truckee Ranger District. The basin provides numerous opportunities for study and research of all aspects of plant, animal, and aquatic ecology.

Independence Lake (81 acres). Independence Lake, located on the Truckee Ranger District, supports a genetically pure strain of Lahontan cutthroat trout. Surrounding the lake are Quaternary glacial deposits that represent the northernmost extent of Sierra Nevada "classical" glacial sequences.

Sagehen Basin (8,373 acres). This area is located on the Truckee Ranger District and is recognized for the diversity and variety of its springs and spring habitats, including the minerotrophic peatlands (fens). The largest of the fens is the Mason Fen.

Mason Fen (30 acres). This fen is the largest fen in the Sagehen Creek Basin and has been the subject of research since 1957. The Mason Fen area is about 30 acres as compared to over 8,000 acres for the above Sagehen Basin.

Little Truckee River Terrace (468 acres). Located on the Truckee Ranger District, this area is on the geologic terrace formed by glacial dam-burst floods from Lake Tahoe. The soils are scientific standard reference soils used to calibrate degrees of soil development over time.

San Juan Ridge (6,541 acres). This area, located on the Nevada City Ranger District, is recognized for its epoch geology and historic hydraulic mining activity.

Macklin Creek (380 acres). This creek is located on the Nevada City Ranger District and contains the only existing remnant of the Pyramid Lake population of the Lahontan cutthroat trout.

Sagehen Headwaters (79 acres). The headwaters of Sagehen Creek are located in a glacial cirque basin on the Truckee Ranger District. The area is noted for its rich diversity of plant and aquatic species and 'avalanche' forest of virgin red fir (*Abies magnifica*), mountain hemlock, and mountain mahogany.

(*Cercocarpus betuloides*). Significant opportunity exists for botanical research and ecological study in this area

TIMBER

The available wood supply from the TNF is based upon the amount of land which is capable of producing at least 20 cubic feet of timber per acre per year (estimated at 649,867 acres) and which is not withdrawn from timber production. Timber-producing land is classified into five major forest types. (1) mixed conifer, (2) red fir, (3) eastside pine, (4) lodgepole pine, and (5) hardwoods. There are 449,842 acres of prime forest land (land capable of producing 85 cubic feet of timber per acre per year or more) on the TNF

Figure 3.4: TNF Current Age Class Distribution

The large number of acres of 90- to 110-year old stands is a result of timber harvesting associated with gold mining and railroad logging. The stands older than 130 years represent the natural stands that occurred before settlement began in the 1850's. Many of these older stands have been harvested by a variety of partial cuts. The large forest fires such as Mountain House, Donner, and Volcano and subsequent reforestation efforts represent the stands in the zero to twenty-year age class. The lack of stands in the 30- to 50-year age class results from early fire protection efforts and very little regeneration cutting after the establishment of the TNF.

Current Timber Sale Program

The current timber management direction was established in the October 16, 1978, TNF Timber Management Plan and Final Environmental Statement. The timber management program includes commercial timber harvesting, salvage of dead and dying timber, reforestation, tree improvement, timber stand improvement, and fuelwood production. The Timber Management Plan provides for a schedule of harvest and regeneration

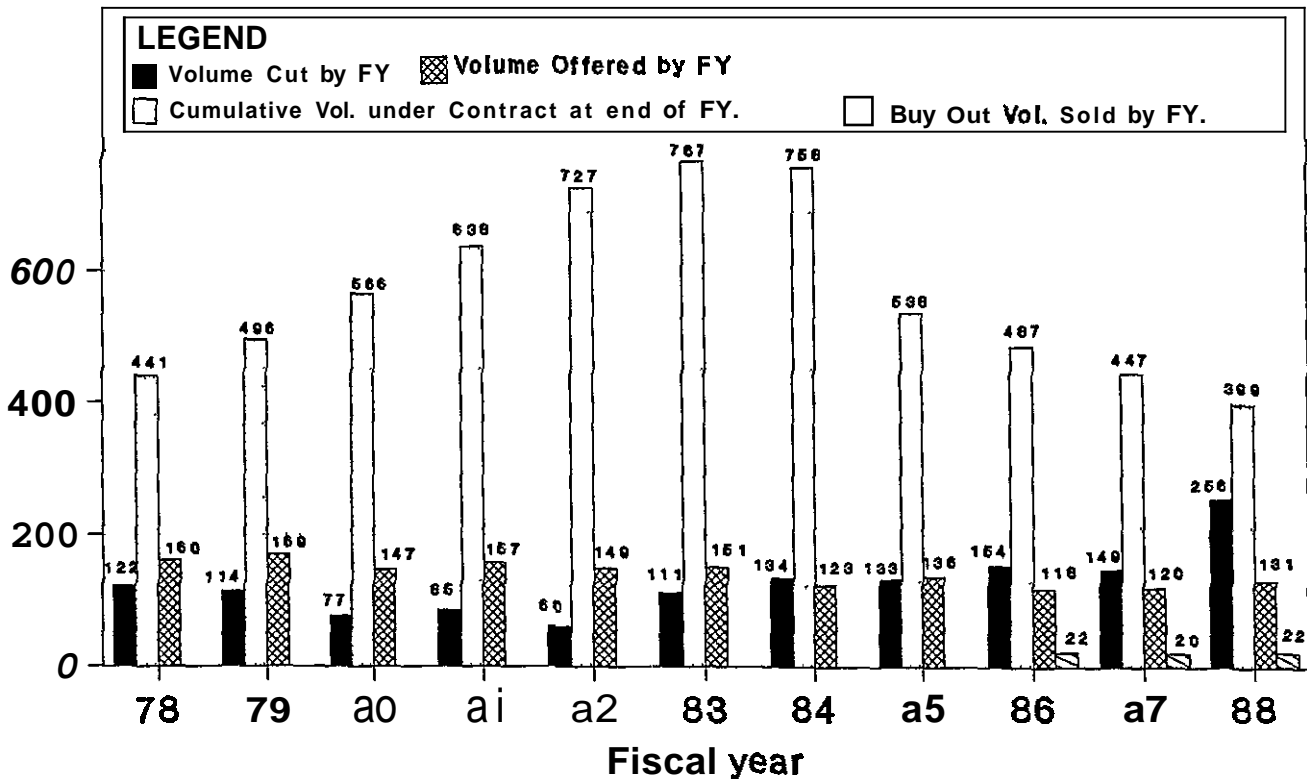

based on sustained yield, **with** a guide for coordination of timber production with other National Forest resource **uses**. Land most suited to timber production is being intensively managed for timber commodity uses. Timber management **objectives** depend mainly on the use of even-aged silvicultural systems to reach the goal of sustained yield.

The average annual programmed sale quantity is 1476 million board feet (MMBF). The majority of this volume is derived from the 306,000 acres established for intensive forest management in the Timber Management Plan. This Plan emphasizes even-age management and regeneration harvesting of under-stocked stands. Table 3.23 summarizes the major cutting practices scheduled by the current Timber Management Plan for the period 1979-1988.

TABLE 3.23 MAJOR CUTTING PRACTICE SCHEDULE OF 1978 TIMBER MANAGEMENT PLAN

Cutting Method	Volume MMBF	Acres
Clearcutting		
1. Mixed Conifer	656	30,000
2. Eastside Pine	3	1,500
3. Total	659	31,500
Shelterwood		
1. Mixed Conifer	256	21,000
2. Eastside Pine	85	4,000
3. Total	341	25,000
Regeneration Total	1,000	56,500
Intermediate & Salvage	290	
Standard Component Total	1,290	
Special Component	EO	
Marginal Component	100	

Figure 3.5: Comparison of Tahoe National Forest Timber Sold and Harvested

In summary, the TNF's multi-year extension plans for all purchasers are as follows

Number of Purchasers	4
Number of Sales	17
Volume of Timber	126 MMBF

The Federal Timber Contract Payment **Modification** Act (Public Law 98-478) was enacted October 16, 1984. This law and the subsequent implementation regulations allowed purchasers of Federal timber to return to the Forest Service, upon payment of a buy-out fee, a maximum of 200 million board feet per company. Approximately 222 MMBF, with a total value of \$55.8 million, was returned to the Tahoe NF under this program.

Volume sold and harvested in the eastside pine type (most forested lands east of State Highway 89) has averaged 3 MMBF annually. Some timber sales have been offered, but not sold, due to poor market conditions. Although the terrain is flat and well roaded, the wild second-growth trees are small, probably a result of early excessive stocking following logging at the turn of the century. Many of these stands are stagnated, with little net growth. Managed plantations such as the Donner burn, in contrast, are showing excellent growth for their sites with no sign of stagnation. Early stocking and competing-vegetation control are especially important on lower sites and the difference in growth between plantations and wild stands

shows the positive effects of management. If the productive potential of eastside sites are to be realized, stagnated wild stands will need to be replaced by new plantations with improved genetic stock

In early 1989 there were indications that the market for small logs on the eastside of the Forest would be improving, although it may take several years to establish a clear trend

The 1975 reforestation backlog identified through aerial photo surveys 16,939 acres needing reforestation. This backlog has been eliminated through (1) planting (7,498 acres), (2) stand examinations reporting adequate existing stocking (7,552 acres), and (3) rejection for reforestation because of other multiple-use needs (1,889 acres).

A total of 21,280 acres were reported on the 1988 Reforestation Needs Report. Most of these acres are a result of timber harvesting, but thousands of acres were added by the large wildfires of 1987. Most of the acreage will be reforested by 1991, but the actual schedule will depend on funding and the availability of silvicultural tools including herbicides.

Timber stands needing precommercial thinning and release are the two types of projects in the timber stand improvement (TSI) needs report. As of October 1, 1988, 10,600 acres have been tentatively identified as needing precommercial thinning and 26,490 acres as needing release. Competing vegetation is the major forest pest in management of young timber stands. The 26,490 acres needing release consist of young seedling and sapling conifers competing for light, moisture, and nutrients with a wide variety of grass, forb, brush, and hardwood plants. Elimination of the current needs will require a wide variety of techniques. The threat of large, damaging fires in extensive plantations and precommercial thinning areas will require proper fire hazard reductions to ensure adequate protection.

Plantation release projects have been accomplished on about 1,000 acres per year during the last ten years. Mechanical and manual control techniques accounted for about 16 percent of the acres per year and herbicide application about 84 percent of the acres per year until 1984. In the spring of 1984, a moratorium on the use of herbicides resulted in subsequent accomplishment of all release by manual or mechanical methods. The unavailability of herbicides as a vegetation management tool has resulted in greatly increased costs for control of competing vegetation. Funding has not always kept pace with vegetation management needs. Livestock grazing for vegetation control has increased in recent years. An estimated 800 to 1,000 acres of plantations are grazed per year to control competing vegetation.

Herbicide use prior to the 1984 moratorium resulted in public concern specifically centered around the use of phenoxy herbicides such as 2,4-D. This concern resulted in several administrative appeals and legal challenges on the use of herbicides in the early 1980's throughout the PSW Region, including the TNF. Other pesticides were also subject to similar public concerns, although not to the degree expressed over the use of phenoxy herbicides. From 1976 to 1984, pesticides were applied to about 1,119 acres of TNF lands per year by contractors, permittees, and the Forest Service. Application of herbicides accounted for 1,051 acres, insecticides for 36 acres, rodenticides for 26 acres, and fungicides for 6 acres of the total annual pesticide use. In recent years pesticide use has been limited to gopher control, occasional treatment of cut stumps with borax for root disease control, and minor use at the Foresthill Seed Orchard.

On February 27, 1989, the Regional Forester issued a decision on the Final Environmental Impact Statement (FEIS), Vegetation Management for Reforestation. The selected alternative allows for the full range of methods for controlling competing vegetation to be considered, including the limited use of herbicides. As of May, 1989, the moratorium on herbicide use had not been lifted by the Chief of the Forest Service and remains in effect.

Additional discussion on the current situation and environmental effects of forest chemicals is contained in the Environmental Statement for Forest Reestablishment on National Forests in California (1), (2), (3), and (4), and other Forest Service sponsored studies (5), (6), (7), and (8).

The National Forest Management Act regulation 36 CFR 219 14, Timber Resource Land Suitability, describes the process for identification of lands capable, available, and suitable for timber production. Details and the results of this process for the TNF are described in Appendix K.

The minimum biological growth potential is defined as all land capable of producing at least 20 cubic feet of timber per acre per year for fully stocked natural stands. The land capable of timber production on the TNF is 649,867 acres. There are 31,732 acres of noncapable forested land and 112,775 acres of nonforest land.

Lands administratively withdrawn from timber production by the Chief of the Forest Service or higher authority are the North Fork American Wild River, the Granite Chief Wilderness, and the Onion Creek Experimental Forest. This land is not available for timber production. This removes a total of 20,849 acres of capable land from timber production for all alternatives, leaving 629,018 acres of land considered as tentatively suited. The disaggregation by forest type is shown in Table 3 24.

TABLE 3.24 ACRES OF TENTATIVELY SUITED LAND FOR TIMBER PRODUCTION

Forest Type	Acres	Percent
Mixed Conifer	361,797	57.5
Red Fir	100,818	16.0
Eastside Pine	104,281	16.6
Lodgepole Pine	9,041	1.5
Hardwood-Conifer	36,660	5.8
Other	16,256	2.6
TOTAL	629,018	100.0

Timber Demand

Timber demand cannot be projected from historical sale trends on the TNF. Most timber offered in viable sale packages in the past decade was sold therefore, past sale trends only reflect the amount of timber that the Forest was able to offer for sale rather than the amount demanded. Almost all of the timber is

sold to eleven companies operating twelve sawmills within 50 miles of the Forest. Over the short run (0 to 5 years), mill capacity in the local area could limit the amount of timber that can be sold. Over longer periods, however, both the number and size of mills operating in the local areas historically have adjusted to fit the supply of available private and National Forest timber.

The demand for timber on the TNF is determined by trends in Regional and National markets for wood products. These markets are primarily influenced by population and income levels, interest rates, the number of housing starts, and the level of imports and exports in wood products. The size of Regional and National markets is very large in comparison to the productive capacity of the TNF, and the Forest by itself is unable to significantly affect market prices. Over the long term, timber price trends have moved upward, reflecting the increasing scarcity of timber. This pattern is expected to continue in the future. (See Appendix B for the timber prices and trends used in the modeling and analysis process. For a comprehensive analysis of timber markets, see *An Analysis of the Timber Situation in the United States 1952-2030*, USDA--Forest Service, Forest Resource Report No. 23, December 1982)

The demand for wood as home fuel has increased greatly and then fell sharply within the last decade. The increase was most rapid after the large increases in energy prices that occurred in the late 1970's. In 1979, the number of cords cut on the Forest was approximately 26,000. By 1983 the number of cords cut had increased to 35,000. In 1987 the number had fallen to less than 18,000 cords. The most recent trend can be attributed to lower home heating costs and less interest in fuelwood gathering since the energy crisis. Higher air quality standards are also becoming a factor in fuelwood demand, particularly in the Reno area.

Predicting Potential Harvest Volumes

Both management intensity levels and the quantity of land allocated to timber management practices affect the harvest level. A given level of timber production can be achieved by manipulating these factors. Thus, RPA timber goals could be achieved by practicing low intensity management on a large acreage or by practicing high intensity management on a smaller acreage.

The NFMA regulations require the use of the most cost-efficient combination of management practices examined that can meet planning objectives. The regulations also specify that cost-efficiency analyses use discounted costs and benefits. Any harvest schedule formulated for the Forest will be affected by these requirements.

In developing harvest schedules, the objectives most often used are 1) to maximize the volume of sustainable harvest and 2) to maximize the present net value (PNV) of the Forest. The objective of maximizing PNV is **most** comprehensive. It evaluates the financial attractiveness of all possible management prescriptions.

A harvest objective (level) is often determined by maximizing timber volume for the first decade, subject to timber policy constraints such as non-declining yield or ending inventory, and subject to objectives for other resources. A cost-efficient harvest schedule is then developed which achieves that timber harvest objective along with objectives for other resources.

The NFMA regulations define long-term sustained yield (LTSY) capacity as the highest uniform yield that may be sustained under a specific management intensity on lands being managed for timber production, consistent with multiple use objectives. In relation to a wide range of possible LTSY's, the existing forest inventory is deficient in both volume and growth. If harvests were scheduled at LTSY capacity, the standing timber on suitable lands plus its growth would be harvested in less than one rotation period. To meet the nondeclining yield policy, the Forest's timber inventory must be meted out until new stands of rotation age are available. Under this concept harvests would have to be below the LTSY capacity until the forest is fully regulated.

Essentially, a fully regulated forest is one in which age and size classes are represented in such proportions and growing at such rates that approximately equal annual or periodic yields of products of desired size and quality may be obtained. To meet LTSY capacity, age and size classes would range from seedling to an age where growth is at culmination of mean annual increment (CMAI). Stands produce at the highest rates if harvested at culmination of mean annual increment. CMAI is normally not applied to unmanaged

(wild) stands because stand history, especially mortality, is unknown. In regenerated stands (managed plantations), CMAI is influenced by stocking control (thinning). In any discussion of CMAI, it is important to know if commercial thinning yield was included and what measure was used, i.e., cubic feet.

Silvicultural Systems

Three major forest types occur on the commercial forest land of the Tahoe National Forest: Sierra Nevada Muted Conifers (Muted Conifer*), Society of American Foresters (SAF) cover type 243; Red Fir, SAF cover type 207; and Northwestern Ponderosa Pine ('Eastside Pine'), SAF cover type 237. Table 3.24 displays the number of acres of land tentatively suited for timber production by forest type.

Each of the major types are described in detail and analyzed for biologically feasible silvicultural systems in Agriculture Handbook No 445, 'Silvicultural Systems for the Major Forest Types of the United States.' Information from that publication is summarized for each major forest type on the Tahoe National Forest, supplemented by local information. Additional information on Silvicultural systems is in Appendix L.

On the Tahoe, the mixed conifer belt occurs from about 3,500 to 6,000 feet on the west slope of the Sierra Nevada mountains. Some mixed conifer occurs on the eastside below the red fir belt. At the lower elevations and on south slopes, stands are dominated by ponderosa pine. At higher elevations, white fir becomes the major component of stands. Douglas-fir can be locally important, especially on north slopes, but usually occurs in a mixture, as does sugar pine. White fir and incense-cedar are very shade tolerant and commonly found in the understory at mid and lower elevations. California black oak is the most important hardwood species in the mixed conifer type. Pacific madrone and tan oak occur as minor species. Jeffrey pine is found on ultramafic (serpentine) sites and at higher elevations. The northernmost natural grove of giant sequoia, the Placer Grove, is part of a mixed conifer stand at 5,200 feet in the southern part of the Tahoe.

Decades of partial cutting and fire suppression have changed the composition of many stands from relatively shade intolerant species such as ponderosa pine, sugar pine, and Douglas-fir to tolerant species (white fir and incense-cedar). Natural regeneration of shade intolerant species, especially where there is not bare mineral soil and sunlight, is spotty and unpredictable. Competing vegetation is the primary reason for failure and competition for available moisture is the most limiting factor in stand establishment and growth. Incense-cedar and white fir are more successful in natural regeneration. Various insect and disease problems have accompanied the species shift, including dwarf mistletoes and Douglas-fir tussock moth infestations (tussock moths feed on white fir in the Sierra). Plantations dating from the 1950's and 1960's are almost entirely comprised of ponderosa pine, for that species was only available then from nurseries. These older plantations for the most part originated from wildfires. More recently established plantations are commonly dominated by ponderosa pine, but also contain Douglas-fir, sugar pine, and white fir. Incense-cedar will usually become established naturally under planted trees and brush. Giant sequoia, considered intermediate in shade tolerance, is occasionally planted as a minor species, particularly on the Foresthill Divide.

There are several decades of experience and research in the application of even-aged silvicultural systems in the mixed conifer type. The less shade tolerant conifer species (ponderosa pine, Douglas-fir, sugar pine) respond well to even-aged systems because these systems provide the full sunlight conditions under which these species become established naturally (e.g., from events such as wildfire or blowdown). If competing vegetation and stocking levels are controlled, plantations can be expected to significantly exceed the growth and yield of wild stands.

The trend in clearcutting on the Tahoe has been toward leaving groups of healthy advanced reproduction up to 16' dbh, hardwoods, down logs, and snags to meet objectives for wildlife diversity, visual quality, and soil productivity. These stands are interplanted with genetically improved stock following logging and site preparation. To the public these stands appear to be managed under an uneven-age system. While still labeled as "clearcuts," they vary significantly in appearance and environmental qualities from openings that are completely cleared. Where silviculturally sound, this type of cutting is being routinely implemented.

Most experience in uneven-aged systems is derived indirectly from partial cutting and the application of the Unit Area Control method in the 1960's. There was no long-term forest regulation scheme associated with this method, but the growth response of trees and stands is indicative of that expected with uneven-aged

silvicultural systems Intolerant species were found to require at least a 1/4-acre opening to become established. Long-term effects on tree growth in these small openings are not known, but it is generally accepted that shade intolerant conifers would not be perpetuated under a single-tree selection system. Openings of 1 to 2 acres are regarded as a necessary minimum size to maintain ponderosa pine as a species component in stands.

White fir and incense-cedar will regenerate under a single-tree selection system, but volume growth diminishes as stand density increases. Brush competition remains a limiting factor in all but the densest stands, so vegetation control would be necessary under both even- and uneven-aged systems

In addition to the considerations of maintaining an acceptable level of stand growth and mixture of tree species, the single-tree selection system has some other disadvantages when applied to the mixed conifer type. These include: '...inability to control dwarf mistletoes, diseconomy of scale for cultural treatments (including site preparation), and the immense cost of inventorying and maintaining required age-class distribution' (from Ag. Handbook No. 445).

The red fir type extends above the mixed conifer type at elevations of about 6,000 to **7,500** feet. White fir occurs in nearly pure stands (SAF cover type **207**) situated in a narrow elevational band between the mixed conifer and red fir types. For purposes of planning and inventory, pure white fir stands are included in the acreage for the mixed conifer type. However, from the standpoint of silvics and stand management, white fir stands are best associated with the red fir type Along a gradient of increasing elevation, pure white fir stands give way to stands containing increasing amounts of red fir Pure red fir stands occur at higher elevations; on wet sites lodgepole pine is a common associate. Lodgepole pine may act as a "nurse crop" for red fir establishment in some situations. Jeffrey pine and western hemlock are occasional minor stand components at higher elevations. Commercial hardwoods do not generally occur on upland, mesic sites.

Both red and white fir are moderately shade-tolerant. They are both able to regenerate naturally under partial shade and light fuels, but control of competing vegetation (grass, forbs, brush) and rodents is necessary for successful stand establishment and growth. Pocket gopher control is a critical factor in the establishment of true fir stands Red and white fir will respond to release after moderate understory or brush suppression. Both typically grow in dense, even-aged stands with high standing volume at maturity.

Dwarf mistletoes infect about 30 to 40 percent of natural red and white fir stands Mistletoe causes growth losses, but also weakens trees and makes them vulnerable to other pathogens and insects. Large numbers of true fir were killed in 1989 as a result of drought and a pest complex involving fir engravers, cytospora canker, and dwarf mistletoe interactions. Small understory trees are susceptible to mistletoe infection from overstory trees.

Both red and white fir can be regenerated by planting Seedling survival is not as high as the pines and Douglas-fir, but planting is a common practice for reforestation. Red fir artificial regeneration costs are the highest of the major conifer species in the Sierra.

Until recently, low demand for red and white fir stumpage existed on the Tahoe National Forest. This has influenced timber management activities in the true fir type In the last decade, increased demand has resulted in an increase in harvest activity in this type. For the most part, even-aged silvicultural systems have been applied. Shelterwood and small strip clearcutting methods have been favored. Modified clearcutting practices, including leaving groups of healthy advanced reproduction, snags, and down logs, are being implemented in areas prescribed for clearcutting. Removal of shelterwood overstory trees at an early stage of stand development has been found to be essential for stands infected with dwarf mistletoe. Control of competing vegetation is also critical, particularly grasses and forbs, because they contribute to pocket gopher problems. Where these conditions have been met, regeneration is dense and grows rapidly.

Uneven-aged management is possible in stands that have not been infected with dwarf mistletoe. Single-tree selection would be very difficult because openings are needed for regeneration and reasonable growth. True fir is susceptible to rot from mechanical damage. The frequent stand entries necessitated by single-tree selection systems elevates the risk of losses to decay and rot organisms in the residual growing stock.

Group selection is feasible, however control of competing vegetation and gophers would be essential to successfully apply this method

Eastside pine mainly occurs east of State Highway 89. Jeffrey and ponderosa pine are the only conifers present in many stands in this type. This type extends into the mixed conifer type where white fir becomes an understory component. Minor amounts of lodgepole pine, incense-cedar, and sugar pine occur in some eastside pine stands. Sites are dry and tree size is smaller than on the westside. Grass, forbs, snowbrush ceanothus, and greenleaf manzanita are common understory components.

Jeffrey and ponderosa pine are usually regenerated by planting, although natural regeneration will occur if seedbeds are adequately prepared, competing vegetation controlled, and overstory trees are widely spaced. Stagnation and bark beetle attacks are problems of dense stands. Stocking control is essential. Eastside pine will release after prolonged suppression if thinned heavily and the remaining crop trees still possess acceptable live crowns and leader growth. Dwarf mistletoe is a major problem in some stands. Annosus root disease in pine is a serious pathogen and appears to be increasing in areas with repeated entries for partial cutting. Damage from porcupines is a local problem in plantations.

Even-aged management has been practiced successfully for decades. Large wildfires such as the Donner Burn (1960) are now pine plantations with good growth rates and relatively few pest problems. Survival rates for planted seedlings is usually excellent where competing vegetation has been controlled. Modified clearcutting practices described in the mixed conifer type section are also used in the eastside pine type

Uneven-aged management, while essentially untried, is feasible. Single-tree selection at wide spacing and low stocking density, in mistletoe-free stands, could be successful. Stocking control of the reproduction would be necessary to avoid stagnation. Small group selection would be more applicable in stands with light mistletoe infections. In heavy mistletoe areas, uneven-age management would be impractical until mistletoe was eliminated from the stand.

VEGETATIVE TYPES (CHAPARRAL)

Two-thirds of the chaparral lands on the TNF occur in scattered parcels of less than 100 acres (Table 3.25) that are too small for cost-effective management units. About 8 percent are in brushland capable of reforestation and another 11 percent are on slopes greater than 50 percent. The steep slopes and shallow soils of these lands severely limit management. Of the 10,673 acres that could be managed as chaparral, over 60 percent is east side rangeland. Thus, only 4,066 acres of shrublands are in parcels of over 100 acres and with slopes less than 50 percent that could be managed for chaparral. Most of these lands are now managed for wildlife habitat through prescribed fire. The current management of these lands for forage and wildlife habitat represents the best opportunities available for management.

Chaparral lands do occur adjacent to the TNF on the west boundary at lower elevations. Management of these private lands through coordinated resource planning benefits adjacent TNF lands. This coordinated planning occurs when requested by adjacent landowners or affected State agencies, such as the California Departments of Fish and Game or Forestry.

TABLE 3.25 - CHAPARRAL VEGETATION

Vegetative Type	Number Of Capability Areas	Acres
Reforestation brushland	210	6,439
Areas less than 100 acres	1,758	53,748
Areas larger than 100 acres with slopes over 50 percent	43	8,453
(BS)* Basin Sage, Bitterbrush, Mountain Mahogany with Perennial Grass, and Wyethia	40	6,607
(CH) Huckleberry Oak, Wyethia, Forbs, Perennial Grass	15	2,397
(CW) Whiteleaf Manzanita, Deerbrush, Bear Clover	7	1,141
(CG) Tobacco Brush, Whitethorn, Greenleaf Manzanita, Huckleberry Oak, Wyethia	3	392
(HG) Whiteleaf Manzanita, Annual Grass, Forbs	1	136
TOTAL	2,077	79,313

* Letters in parentheses () are CalVeg types.

VISUAL RESOURCES

The TNF exhibits diverse and distinctive landscape qualities highly suited to scenic appreciation. One indication of these scenic qualities is the inclusion by California of all four major roads that traverse the TNF - Highways 20, 49, and 89, and Interstate 80 - in the Master Plan of State Highways Eligible for Official Scenic Highway Designation.

While no specific statistical analysis of the demand for visual quality is available, the presence of strong demand can be inferred from a variety of sources. One of these sources is the number of laws and policies that have cited visual quality or scenery as their primary or secondary purpose. The establishment of the State Scenic Highway Master Plan is one indication that the State legislature perceives this demand. In 1965, Regional Forester Charles Connaughton also acknowledged this demand by coordinating Regional Forest Service policy with the Master Plan. He stated that National Forest System lands would be managed to retain natural appearing conditions for public enjoyment by restricting or modifying the cutting of timber in the immediate vicinity of and in the view from eligible highways.

These findings indicate a need for scenic routes and highways, turnouts, and vista points. The State of California has already officially designated the portion of Highway 20 from near White Cloud to Bear Valley, and Highway 49 in Sierra County from the Yuba County boundary to Yuba Summit, as State Scenic Highways.

Another measure of the demand for visual quality is the level of recreation use in activities associated with the enjoyment of scenery. The California State Comprehensive Outdoor Recreation Plan, 1975, projects that the demand in the categories of driving for pleasure, walking for pleasure, and sightseeing will increase 31 percent by 1990.

The California Recreation Patterns Study of 1982 also projected increased participation in activities associated with visual qualities on National Forests in the northern non-metro counties. Visiting scenic areas was projected to increase 31 percent, and nature appreciation was predicted to increase 24 percent between 1980 and 2000. Per capita participation rates will increase about 5 percent during this period, indicating total participation will grow even faster than the population. As the population continues to gain in affluence and education, people will expect a high-quality scenic environment for their leisure-time activities.

Because of this public concern and demand for natural scenic environments, standards have been established for measuring the current and future condition of the visual resource. Inventories of the present state of visual resource values are used to derive two baselines against which the effects of each alternative can be evaluated. The two baselines are the initial visual quality objectives (IVQO's) and existing visual condition (EVC). Visual quality objectives (VQOs) are goals of how the landscape should appear in the future. (See Visual Quality Objectives in Agriculture Handbooks 461 and 462 of the Visual Management System.) The initial VQOs set those goals based on predictions of the amounts of landscape alteration that would be acceptable to the public without consideration of other competing resource values.

The IVQO mapping system is developed by combining indices for the public's concern for scenic quality (sensitivity level); the diversity of natural features (variety class); and the three distance zones of foreground, middleground, and background.

The initial visual quality objectives that have been mapped for the TNF closely follow the Forest Service direction provided by Agriculture Handbook #434 and #462, Superintendent of Documents, Washington, D.C.

Sensitivity Levels

Sensitivity levels are a measure of people's concern for the scenic quality of the National Forests. These people are generally either traveling through the National Forest or permanently or temporarily occupying a use area. Travelways can be roads, trails, or waterways. Use areas can be campgrounds, recreation day-use facilities, or visitor centers. The sensitivity level classification, based on how many people see the area and how concerned they are with aesthetics, is divided into three levels, which apply to all travel routes, use areas, and water bodies:

- Level 1: High sensitivity
- Level 2: Moderate sensitivity
- Level 3: Low sensitivity

The distribution of lands on the TNF between these sensitivity levels by seen area is shown in Table 3.26

TABLE 3.26 - ACRES AND PERCENT OF TNF BY VISUAL SENSITIVITY LEVELS

	1	2	3
Acres	617,119	133,047	44,208
Percent	78%	17%	5%

	A	B	C
Acres	311,728	400,282	82,364
Percent	39%	51%	10%

Distance Zones

A visitor's perception or the sensitivity of a seen area can vary according to how close the viewer is to the seen object. True distance can be a factor of how important a viewed scene is. Detail change can be perceived from where a person is to about one-quarter to one-half mile away. This is called a **foreground** distance zone. The next distance zone is called **middleground**, which is from one-quarter to one-half mile away up to a maximum of 3 to 5 miles. In this distance zone, perception of detail is reduced to being able to still distinguish individual tree forms. The last distance zone is **background**. This zone extends from middleground to infinity.

Foreground, middleground, and background distance zones are evaluated with variety class and sensitivity levels and these are combined for initial VQO mapping.

The initial VQO inventory allocates the land of the TNF to four of five different objectives and is shown in Table 3.28.

	PRESERVATION	RETENTION	PARTIAL RETEN- TION	MODIFICA- TION	MAXIMUM MODIFICATION
Total Acres	0	348,359	342,699	89,414	13,902
Percent	0	44%	43%	11%	2%

	I	II	III	IV	V	VI
Total Acres	30,674	557,830	142,523	55,152	7,413	782
Percent	4%	70%	18%	7%	1%	>0%

One of the indicators used to compare the effects of the alternatives on the visual resource is the visual quality index (VQI). The VQI is a means of quantifying the overall visual quality of the Forest. It reflects both the inherent scenic value of the Forest landscape and the amount of human modification to the landscape. The index is correlated to public preference ratings of these two characteristics, which give higher values to landscapes of higher variety and more natural appearance. A VQI can be calculated for the existing visual condition as well as for the future visual condition (FVC) that **would** result from implementing each alternative. The VQI for the existing visual condition is **52.0**. The VQI for the initial VQO is 51.0. If none of the TNF had been altered by man, the VQI would be 60.0, and if all the TNF had been drastically disturbed, the VQI would be **20.5**.

Over the last 40 years, the VQI has declined steadily. The visual condition of the Forest has been reduced **13.3** percent from **its** original natural condition.

WATER

Water **Production** and Quality

The TNF produces about **3,244,000** acre-feet of water per year within **its** boundaries. Of this total, about **2,000,000** acre-feet are produced from National Forest System land. Gross water yield by watershed is shown in Table **3.30**

About **98** percent of the runoff originating within the TNF boundary meets State and Federal water quality objectives. The remaining runoff fails to meet sediment and turbidity objectives. The main beneficial uses affected by sedimentation are instream needs, particularly fisheries. Major sediment sources are abandoned hydraulic mine **sites**, unmaintained roads, recent wildfires, and logging on sensitive **sites**; some of these have resulted in long-term water quality impacts. Short-term (normally two to four years) sedimentation may be associated with timber-related activities, assuming the inadequate application of BMP's. Sheet and gully erosion are particular problems on certain granitic soils in the Bullards Bar area. Natural instability occurs in the Oregon Creek watershed. The Forest maintains a preliminary Watershed Improvement Needs (WIN) inventory of major suspected sediment sources.

Water quality standards applicable to the Tahoe NF are detailed in 'Water Quality Control Plan Reports' for the North Lahontan and Central Valley Regional Water Quality Control Boards. The Truckee and Little Truckee Rivers and Upper Long Valley watersheds are within the North Lahontan Basin and this part of the Forest must comply with the Lahontan Basin Plan. The remainder of the Forest falls under jurisdiction of the Central Valley Basin Plan. Objectives are very similar for both plans. All public and private entities, including the Forest Service, must comply with the requirements and provisions of the North Lahontan and Central Valley Regional Plans; this includes meeting terms of the State non-degradation policy. In cases where a TNF project results in a water quality problem or violation, the State and Regional Boards retain the authority to intervene under provisions of the Basin Plans.

Water quality is currently maintained and improved through the application of state certified and EPA-approved Best Management Practices (BMP's) for controlling non-point sources of pollution to surface waters. In a 1981 Management Agency Agreement between the State Water Resources Control Board and the Forest Service, it was agreed that reasonable implementation of BMP's would constitute compliance with water quality standards; it is expected that compliance would also result in successful attainment of the State non-degradation policy. Methods and techniques for applying appropriate BMP's are identified during site investigation of Forest projects that have the potential to degrade surface water quality. A more detailed discussion of BMP's and the implementation process is presented in Appendix E of the Forest Plan.

Water Yield Increase

The Forest Service is not actively trying to increase water production on the TNF. Weather modification (i.e., cloud seeding) efforts are occasionally made by various water service and utility districts in the northern portion of the Sierra Nevada. An intensive weather modification study was recently conducted by the U.S. Bureau of Reclamation in the American River drainage. Water yield fluctuations (not caused by climatic

NFS WATERSHED NAME	NFS WATERSHED NO.	EST. GROSS AVG. ANN. RUNOFF (ACRE-FEET) 1/
Sierra Valley (Tahoe NF portion of Mid Fork Feather)	18 02 01 23 02	80,000
North Yuba	1802012501	850,000
Middle Yuba	1802012502	322,000
South Yuba	18 02 01 25 03	653,000
Deer Creek	18 02 01 25 04	15,000
Bear River	18 02 01 26 01	38,000
North Fork American	18 02 01 28 01	454,000
Middle Fork American	1802012802	342,000
Rubicon	18 02 01 28 03	138,000
Upper Long Valley	18 08 00 03 01	2/
Truckee 3/	16 05 01 02 01	241,000
Little Truckee	16 05 01 02 02	111,000 3,244,000 (Public and Private Lands) (2,000,000 from Public Lands only)

The main potential for a permanent water yield increase is to convert deep-soil commercial timber sites to grass. Conversion would directly conflict with the current emphasis to intensively manage timber on the same sites. Intensive timber management has increased water yields compared to yields of the recent past, though less than the maximum potential. The main potential to improve timing of yield (i.e., by delaying snow melt) is to specially design clearcut units in the snow zone above 5,000 feet: this would sometimes result in conflicts with silvicultural priorities in vegetation manipulation.

Assuming management for maximum water yield, the increased yield over current production would be about 8 percent of the net TNF yield of about two million acre-feet per year. Off-Forest demands for water would likely far surpass any increases resulting from vegetation manipulation.

Water Uses and Needs

Current TNF water uses and foreseeable needs, both consumptive and nonconsumptive (except for minimum instream flow needs for fisheries, riparian areas, and recreation uses), have been inventoried and are included in the TNF planning records. Consumptive uses include uses associated with administrative sites, recreation developments, ski areas, organization camps, summer home tracts, livestock, and irrigation needs. Nonconsumptive uses include impoundments and free-flowing waters for recreation, fisheries, and wildlife. As documented in the Analysis of the Management Situation, the TNF currently uses about 800 acre-feet of water annually for consumptive uses and 6,800 acre-feet for nonconsumptive uses. Future needs (by the year 2030) include an estimated additional 1,800 acre-feet for consumptive uses and about 400 acre-feet for nonconsumptive uses. Groundwater sources are needed to provide safe and relatively constant water supplies for campgrounds and for livestock and domestic use. Groundwater avoids problems of contamination and intermittency that are common with surface sources. Demands are slowly increasing. Total demands are relatively small.

Approximately 90 percent of the current and foreseeable TNF consumptive needs occur from May through October during the heavy recreation and range use season, and for TNF administration and protection purposes.

Existing and future water needs for State and private uses within the TNF boundary are undetermined. The anticipated sum of Forest, State, and private consumptive uses of water within the TNF boundary, however, is minor in proportion to the total annual TNF production.

In spite of low water needs within the TNF boundary, there may be future availability problems. The extent of these needs is undetermined because of uncertain socioeconomic factors. Already, water availability is limited in Sierra Valley (adjudicated), Deer Creek (fully allocated), and the Truckee-Little Truckee watershed (possible adjudication). New appropriative uses of water in these watersheds are difficult to acquire, although it is possible to exercise riparian rights. The amount of existing shortages in the Sierra Valley, Deer Creek, and Truckee River watersheds is unknown. Anticipated shortages in these and other National Forest System watersheds are also unknown.

The exact off-Forest demand for TNF water in the Sacramento River system is difficult to trace because water from the TNF combines with water from private land and public land, including five other National Forests, Bureau of Land Management, and State land, in the watershed. About 85 percent of off-Forest consumption is used in agriculture. As noted, the off-Forest demand for the Truckee River water already exceeds the current production: the greatest needs are for irrigation in Nevada, maintenance of Pyramid Lake, and municipal and industrial use in the Reno and Sparks area.

Sensitive Watershed Lands

Over 105,000 acres of sensitive watershed lands are characterized primarily by oversteepened slopes and very high erosion potential. The amount of sensitive watershed lands that are actively unstable is not extensive on the Forest, and is restricted to a few highly visible locations, such as the Oregon Creek slides in the Gales Orchard area. The 105,000 acres of sensitive watershed lands include the following:

- o 44,000 acres of land with **slopes** over 70 percent.
- o 15,000 acres of soils **with** 50 percent or more rock outcrops on slopes of 50 to 70 percent.
- o 43,000 acres of lithic and shallow soils on slopes of 50 to 70 percent.
- o 1,000 acres of glacial soils on slopes of 50 to 70 percent.
- o 2,500 acres of granitic soils on slopes of 30 to 70 percent.

About 48,000 acres of these **sensitive** watershed lands are capable of producing commercial timber.

Cumulative Watershed Effects

The current Forestwide disturbance value as calculated by 'equivalent road area' (ERA) is currently about 2.2 percent of the Forest. This was determined using the Regional methodology described in draft Chapter 20 of FSH 2509 22, titled 'Cumulative Off-Site Watershed Effects Analysis.' Cumulative impacts for specific watersheds are presently being analyzed during project-level planning.

Several major National Forest System watersheds contain substantial acreages of private land in an alternate ownership pattern which greatly influences the Forest Service's ability to meet multiresource objectives while meeting water quality maintenance objectives. These watersheds include the Middle Yuba (44 percent private), South Yuba (51 percent private), North Fork of the American (35 percent private), Rubicon (37 percent private), and Truckee River (61 percent private) Portions of all the other National Forest System watersheds have an intermingled ownership pattern with similar problems in meeting water quality objectives.

Declining Watershed Conditions

The TNF has **about** 14,000 acres of land in a declining watershed **condition**. About 2,000 to 3,000 acres of this total can probably be physically restored by artificial revegetation and mechanical restoration measures. Current RPA direction is to restore an average of 270 acres per year of deteriorated watersheds by 1990, and an average of 310 acres per year by 2030. These acreage targets are impractical and unattainable because they reflect a total watershed restoration program over time that would far exceed the backlog of physically treatable and restorable acres on the TNF. Of the 2,000 to 3,000 treatable acres, about 700 acres are abandoned hydraulic diggings. These are located mainly below 5,000 feet in elevation along the **west** side of the Forest. An additional 400 acres of treatable lands include roads, which are a local erosion problem on all parts of the Forest, and channel and meadow erosion that mostly occurs in the Sierra Crest zone and on the east side of the Forest. The remaining acreage of treatable land are located in the Indian and Cap Fire areas on the Downieville District. Treatment on the remaining 11,000 to 12,000 acres in a declining condition is limited because of excessive cost, poor access, a lack of technology, or the acreage is judged to best recover by **just** limning intensive resource management practices. This may involve **restricting** or severely limiting timber harvesting and livestock grazing from certain areas.

A priority listing of the **TNF's** ten major problem areas includes:

- | | |
|-------------------------|--|
| 1. Indian and Cap Burns | 6. Woolsey Flat Diggings |
| 2. meadow erosion | 7. Eureka Diggings |
| 3. roads | 8. Indian Hill Diggings |
| 4. Oregon Creek slides | 9. Sailor Flat Diggings |
| 5. Moores Flat Diggings | 10. LMIe Truckee River-Sierra Valley Diversion |

The expected watershed restoration cost for the 2,000 to 3,000 treatable acres is unknown but would probably approach several million dollars.

The 12,000-acre Carman Valley Watershed, located on the northern edge of the Forest near Sierra Valley, is currently in poor condition. Historic logging and overgrazing and recent fires have resulted in excessive channel cutting and **loss** of adjacent wetlands. This area is a continuing high priority for treatment.

Groundwater

Two significant groundwater basins lie within or adjacent to the Forest boundary: Sierra Valley and Martis Valley. Usable storage capacity for the Martis Valley basin has been estimated at 50,000 acre-feet. The usable storage capacity for Sierra Valley is unknown. The groundwater aquifers in these basins almost entirely underlie private land. Some of the groundwater recharge zone and much of the surrounding upland areas are National Forest System land. Most groundwater used on the TNF comes from wells or springs that tap small isolated underground reservoirs in fractured bedrock or porous rock and soil units. Groundwater supply varies depending on local geological characteristics. Little can be done to alter the quantity in most basins. Geologic or geotechnical studies aid in locating the most likely sources for development. The TNF Geologic Resource Inventory (in progress) will specifically address where groundwater basins are located and make recommendations for potential future management of the groundwater resource.

Water Developments

Numerous impoundments exist on the Forest, ranging in capacity from under 100 to hundreds of thousands of acre-feet. These occur throughout the TNF. Some of the larger ones include Bullards Bar Reservoir, at the west side of the Forest; Stampede and Boca Reservoirs on the east side; French Meadows Reservoir on the south border; and Jackson Meadow, Bowman Lake, Lake Spaulding, and Fordyce Lake in the north-central part of the Forest. These were built primarily for downstream irrigation and municipal needs, with power development also an important use. Many of the older, smaller impoundments were originally built for mining purposes, but are now serving other uses. Since the operation of these impoundments is mainly for downstream uses, there are occasional conflicts with National Forest System needs. These conflicts usually negatively affect downstream fisheries, such as in the lower South Yuba River and in the Little Truckee River between Stampede and Boca Reservoirs. Also, lakes are occasionally below desired levels during the summer high recreation use period; this has affected recreation use at Stampede Reservoir.

Recently there have been many Federal Energy Regulatory Commission and associated State water right applications for small hydroelectric developments on TNF lands. These applications have occurred primarily in the Yuba and American River drainages. The primary instream beneficial use, fishery needs, may be already impacted because most applications routinely request more water than naturally flows during the proposed periods of use. Current Forest policy is to protest water rights applications until instream flow needs are determined and agreed to. This is normally done in conjunction with similar California Department of Fish and Game (CDF&G) actions. The TNF and CDF&G routinely require small hydro proponents to conduct the Instream Flow Group Incremental Methodology, or similar studies, to establish instream flow requirements for affected streams.

As with small hydro proposals, the TNF responds to proposed water storage developments on a case-by-case basis. Mitigation measures are incorporated into proposals to protect National Forest interests, including instream fishery needs, wildlife, and recreation uses. During relicensing procedures, the Forest may require changes in release schedules if previous agreements proved inadequate.

WILD AND SCENIC RIVERS

In November 1978, Congress designated the North Fork of the American River as a Wild River from a point 0.3 mile above Heath Springs downstream to a point approximately 1,000 feet upstream of the Colfax-Iowa Hill Bndge, including the Gold Run Addition Area, a total of 38.3 miles. Subsequently, the North Fork American Wild River Management and Development Plan, October 3, 1979, was prepared for guiding its management and development.

The Forest Service and BLM presently share the responsibility for administering the North Fork American Wild River. The State of California retains management responsibility for its land (123 acres) within the designated Wild River boundary. Management of this land is coordinated through a Memorandum of Agreement.

In **1972**, the State of California designated the North Fork of the American River as a component in its Wild and Scenic Rivers Systems. This designation is far broader than the current Federal classification. It more or less extends to the top of the canyon, rather than one-quarter mile on either side of the river. The management objective for the State is generally compatible with the National Forest management objective, which is to maintain the river's natural, freeflowing condition. The plan has not been approved by California as of May, 1989.

Portions of the Middle Yuba River and South Yuba River were included in the Heritage Conservation and Recreation Service (now a part of the National Park Service) Nationwide Rivers Inventory completed in 1981. An assessment of the eligibility of these rivers was completed during the Forest planning process. This eligibility assessment concluded that scenic and recreational values in the inventoried portions of the Middle Yuba River and the South Yuba River are 'outstandingly remarkable'; therefore, they are eligible for inclusion in the Wild and Scenic River System. (Refer to Appendix E.) These river segments are not included in any of the alternatives considered in detail because suitability was not analyzed.

The Truckee River will be studied for eligibility and suitability in coordination with the Lake Tahoe Basin Management Unit in the next three years. The Truckee River is not included in any alternatives. The upper Rubicon River above Hell Hole Reservoir will be studied for eligibility in coordination with the Eldorado National Forest.

Based on public response to the Draft EIS and Draft Plan, the Middle Fork American River, North Fork of the Middle Fork American River, Lavezzola Creek, and Canyon Creek were identified and evaluated for outstandingly remarkable values to determine if they were eligible for Wild and Scenic River status. No outstandingly remarkable values were identified for these four rivers; therefore they are not eligible for inclusion in the Wild and Scenic River System and are not included in any of the alternative considered in detail. Refer to Appendix E for more detail.

WILDERNESS AND ROADLESS AREAS

The following eleven roadless areas were identified in the roadless area reviews: Granite Chief, East Yuba, West Yuba, North Fork American River, Middle Yuba, Castle Peak, Bald Mountain, North Fork of Middle Fork American River, Duncan Canyon, Grouse Lakes, and Lakes Basin (the majority of which is on the Plumas National Forest). The first four areas were identified for further study in Rare II and were managed to protect their wilderness character; the remaining areas were managed for various objectives according to existing multiple use and land use planning direction.

The California Wilderness Act of **1984** designated **18,705** acres of the Granite Chief RARE II Area as Wilderness and allowed release of the remaining roadless areas for nonwilderness uses in this round of planning. Nonwilderness use includes a wide range of management options from roading and logging an area to maintaining the area in a semi-primitive nonmotorized management condition.

The Granite Chief Wilderness has a varied, highly scenic landscape of forest, meadows, and glacially exposed granite rock. The Wilderness is located adjacent to the western watershed boundary of Lake Tahoe and includes Five Lakes Creek and the headwaters of the North Fork and Middle Fork of the American River. The major attractions of this area are its high, rugged granite cliffs and broad, glaciated valleys. Portions of a State game refuge extend into the area, and the abundance of game and nongame animals attracts large numbers of visitors. A Granite Chief Wilderness implementation plan will be prepared within two years after approval of the TNF Final EIS.

Granite Chief Wilderness is the only wilderness area on the TNF. The closest wilderness area is Desolation Wilderness on the Eldorado National Forest, approximately six air miles due south. To the north, Bucks Lake Wilderness on the Plumas National Forest is the closest wilderness. Wilderness supply is very limited on the TNF as evidenced by the ROS inventory that indicates that there are no acres available that can provide a primitive recreation experience as defined by ROS criteria. Recreation supply and demand for wilderness and primitive recreation experiences are discussed under Recreation ROS classes in Chapters 3 and 4. In a broader sense the demand for wilderness has been and is continuing to be expressed by Congress as Wilderness Bills are passed, such as the California Wilderness Act of **1984**.

WILDLIFE

Current Management Direction

The National Forest Management Act. The principal source of National direction for management of wildlife resources on National Forest System lands is NFMA (Public Law 94-588, 1976) and its associated regulations (36 CFR 219.19). The NFMA directs the Forest Service to include coordination of wildlife resources when developing comprehensive multiple use plans for National Forests (Sec. 6 (e)(1)). The Act also directs that diversity of plants and animals will be provided as consistent with land capability and multiple use objectives (Sec.6 (g)(3)(B)).

The NFMA regulations direct Forests to 'maintain viable populations of existing native and desired non-native vertebrates in the planning area' (Sec 219 19) Section 219.19 also defines a viable population as 'one which has the estimated numbers and distribution of reproductive individuals to insure its continued existence.' The Section also directs that Forest Plans and alternatives will identify 'Management Indicator Species' (MIS), and fish and wildlife resource planning will include the following elements.

1. MIS will be used to evaluate the effects of management on fish and wildlife resources, and species selected shall include where appropriate:
 - a. Endangered and threatened plant and animal species identified on State and Federal lists.
 - b. Forest Service sensitive species.
 - c. Species with special habitat needs that may be influenced significantly by planned management programs.
 - d. Species that are commonly hunted, fished or trapped
 - e. Non-game species of special interest.
2. Biologists from State fish and wildlife agencies as well as other Federal agencies shall be consulted to coordinate planning for fish and wildlife.
3. Population trends of the MIS will be monitored and relationships to habitat changes determined. The monitoring will be done in cooperation with State fish and wildlife agencies to the extent practical.
4. Critical habitats for threatened and endangered species shall be identified and protected.

Section 219.27 of the NFMA regulations identifies management requirements which include maintenance of viable populations of native vertebrates and appropriate habitat for MIS (a)(4); protection of critical habitats for threatened and endangered species (a)(8); revegetation of non-system roads within 10 years (a)(11); designing timber harvest strategies that are consistent with the protection of fish and wildlife habitats and other resources (c)(6); protection of riparian areas (e); and preservation and enhancement of plant and animal diversity (g).

Regional Guide Direction. The Pacific Southwest Region of the Forest Service has complimented National direction for preparation of Forest land management plans by issuing the Regional Planning Guide (LMP Direction, 1984). This document specifies protection of critical habitats and management for sensitive, threatened, and endangered species. It also specifies standards for the management of viable populations. The standards relating to specific wildlife species are discussed in the following sections.

Present Resource Status

The wildlife resources on the TNF reflect the diversity of local habitats and life zones. The Forest is comprised of two distinct management zones, the eastern and western slopes. Each slope has distinct combinations of vegetation types and animal assemblages.

The Forest is *inhabited* by an estimated **366 wildlife** species, including **258 birds**, 82 mammals, **17 reptiles**, and **9 amphibians**. The Wildlife Habitat Relationship (WHR) database indicates that most Forest species are widespread and do not require individual management attention. However, some individual species have been given special status as described below.

Management indicator Species

As directed by **36 CFR 219.19 (1)**, the Forest has identified an array of management indicator species to evaluate the effects of various management alternatives. The MIS list and a status summary for each is presented in Table 3.31.

TABLE 3.31 - SUPPLY AND DEMAND FOR THE WILDLIFE MANAGEMENT INDICATOR SPECIES ON

SPECIES	SPECIES STATUS.	POPULATION STATUS	POPULATION TREND	INTEREST/ DEMAND	CAPABILITY TO MEET DEMAND
Bald Eagle	FE	20-25	unknown	high	good
Peregrine Falcon	FE	unknown	unknown	high	fair
Spotted Owl	FSS	110 pairs	unknown	high	good
Great Gray Owl	FSS	unknown	unknown	mod	poor
Goshawk	FSS	unknown	unknown	mod/high	good
Willow Flycatcher	FSS	unknown	unknown	mod/high	fair
Pine Marten	FSS	unknown	unknown	mod	fair
Pacific Fisher	FSS	unknown	declining	mod	unknown
Sierra Nev Red Fox	FSS	unknown	unknown	mod/low	unknown
Deer	HA	10-15,000	declining	high	good
Black Bear	HA	200-250	stable	mod	good
Gray Squirrel	HA	unknown	unknown	mod.	good
Mountain Quail	HA	unknown	unknown	mod	good
Wild Turkey	HA	unknown	unknown	mod/low	unknown
Band-tailed Pigeon	HA	unknown	unknown	low	good
Blue Grouse	HA	unknown	unknown	low	good

- * FE - Federally Endangered
- HA - Harvest
- FSS - Forest Service Sensitive

Federal Threatened and Endangered Species. Federally-listed threatened and endangered (T&E) species receive special management attention on the Forest as prescribed by the Endangered Species Act (1973, as amended). The **peregrine falcon** and **bald eagle** are endangered species that have been observed on the Forest. No threatened wildlife species are known to occur locally. The Forest has consulted with the U. S. Fish and Wildlife Service regarding this Forest Plan. The Service prefers not to consult in detail on forest plans but consultation regularly occurs when projects that could affect peregrine falcons or bald eagles are planned.

To compliment the recovery plan for the peregrine falcon, the Regional Planning Guide establishes a target of three pairs for the TNF. The Forest completed peregrine cross-fostering projects in **1986, 1987, and 1988**. Cross-fostering projects yielded fledgling falcons each year. The present status of fledgling falcons is uncertain.

The Forest has a wintering population of bald eagles that is believed to be between **15 and 25** individuals. In addbon, a breeding pair was documented adjacent to Stampede Reservoir in **1986**. The species recovery plan specifies a target of five breeding pairs for the Forest. Accordingly, the Forest has implemented habitat improvement projects at Stampede, Boca, and Bullards Bar reservoirs to improve breeding habitat conditions for bald eagles.

Forest Service Sensitive Species. Sensitive species also receive special management attention on the Forest as prescribed by the Forest Service Manual (Section 2670). The goal of habitat management for sensitive species is to prevent these animals from becoming candidates for threatened or endangered status.

Sensitive species that occur on the Forest are the spotted owl, great gray owl, willow flycatcher, goshawk, pacific fisher, pine marten, and Sierra Nevada red fox.

Spotted owls are distributed throughout forested areas on the western slope of the Forest. The Forest believes that about **110** pairs of spotted owls exist in westside habitats. An adequate survey has not been completed in eastside habitats. However, eastside siting records are few and the species is not believed to be present in large numbers there. The Regional Planning Guide establishes habitat management requirements for spotted owls. The document offers direction for organizing spotted owl habitat areas (SOHA's) and minimum specifications for distributing the SOHA's across the species range. The minimum spacing requirements yields a network of **33** SOHA's for the TNF. The Regional Guide also directs that at least 1,000 acres of suitable owl habitat will be provided in each SOHA over time. Additional direction for defining and organizing suitable habitat is given on pages **4-15** through **4-19** in the Regional Guide.

Comprehensive surveys for great gray owls have not been conducted on the Forest. Accordingly, little is known about the local status of this species. Siting records suggest that great gray owls inhabit several areas on the eastside and at least one area on the westside of the Forest. At least two additional locations offer suitable habitat conditions.

A statewide survey was recently conducted by the California Department of Fish and Game to locate important breeding habitat for the willow flycatcher (Sanders and Flett, **1988**). Eastside riparian areas of the TNF contain **39** of the **72** singing males or pairs of willow flycatchers located during the survey. Willow flycatchers prefer relatively large wet meadows adjacent to large streams. Most nest sites contain tall clumps of willows separated by openings. This species typically nests in the lower **1/3** of willow assemblages where heavy livestock grazing often occurs. The effects of grazing on willow flycatcher reproduction are not completely understood. However, adverse impacts have been suggested for other locations in the Sierra Nevada (Serena **1982**, and Valentine, in preparation).

The goshawk prefers mature forest stands and is believed to be common and widespread on the east and west sides of the Forest. A comprehensive survey for this species has not been completed, but sightings have been recorded for many areas of the Forest. The Regional Guide specifies that Forests will manage for at least two breeding territories per township. Each territory must have at least 50 acres of suitable (closed canopy) forest habitat.

California Department of Fish and Game and Forest Service sighting records indicate that the pacific fisher populations appear to be small and declining in the Sierra Nevada. The present population size on the TNF is unknown. No research has been conducted on the species in the Sierra Nevada, and habitat relationships data for the Forest are presently lacking. In northern California, the home ranges of fisher reproductive units (one male and two females) average about **9,000** acres (Slader Buck, personal communication). Slightly larger home range sizes have been reported for several other North American study areas. Home range size can be highly variable in response to habitat quality, season, and other factors.

On the TNF, suitable and optimum fisher habitat is regarded as conifer and hardwood-conifer forests with dense canopy closure and multi-storied structure. Suitable and optimum habitats provide relatively high densities of snags and down logs for feeding, denning, and resting. Preferred habitats include meadows or riparian corridors and may extend well into upland areas. The animals use saddles with at least 50 percent crown closure as travelways between drainages with suitable habitat.

Pine marten populations appear to be higher and more stable than fishers in the Sierra Nevada. However, current population estimates are not available. Four pine marten research projects have been completed in the central Sierra Nevada (Simon **1980**, Spencer **1981**, Hargis **1982**, and Barrett and Martin **1987**). These researchers conclude that pine marten reproductive unit home ranges average about **2,000** acres. Habitat use is affected by the sex of the animal, season, habitat quality, prey availability, and other factors.

Suitable and optimum pine marten habitat is similar to the conditions preferred by fishers. Martens prefer multi-storied conifer forests with moderate to dense canopy closure. Suitable and optimum habitats provide **2** to **3** large snags or stumps and **10** to **20** large logs per acre. Preferred habitats are adjacent to meadows or riparian corridors and may extend **1/4** to **1/2** mile into upland areas. Suitable marten habitats may provide

scattered openings that measure 2 acres or smaller. Pine martens also need travelways comprised of closed canopy forests to move between areas with preferred habitat conditions.

The Forest database indicates that there are currently 111,212 acres of suitable and optimum fisher and pine marten habitat in seral stages 4B and 4C. A smaller but undetermined number of suitable acres also exists in other strata. The actual acreage of potentially suitable habitat in other strata is not known because of insufficient information in the existing database. The 'checkerboard' land ownership pattern and high degree of fragmented habitats are believed to have significantly reduced the amount of occupied habitat on the Forest. The amount of occupied habitat is presently unknown, but a preliminary assessment indicates that 20 to 40 percent and 40 to 60 percent of the suitable acreage may be occupied by fishers and pine martens respectively.

The **Sierra Nevada red fox** is rare and appears to be declining in the Sierra Nevada (Shempf and White 1977). The present population on the TNF is unknown and no research has been conducted on this species in the Sierra Nevada. The animals prefer mature coniferous forest habitats near meadows (Verner and Boss 1980). Forest Service and California Department of Fish and Game biologists believe that habitat managed for pine marten and fisher provide suitable conditions for the Sierra Nevada red fox.

Harvest Species. Harvest species are those animals traditionally hunted or trapped. Commonly hunted species that inhabit the TNF include: deer, bear, gray squirrel, mountain quail, blue grouse, turkeys, band-tailed pigeons, and waterfowl. Other furbearing mammals are trapped and include mink, raccoon, bobcat, beaver, coyote, muskrat, badger, and gray fox.

Deer are the most commonly hunted mammal on the Forest. They prefer a mix of forest succession stages. Like many other areas in the west, deer herds on the westside of the Forest have declined during the past 15 to 20 years. Low fawn survival is suspected as a major reason for the decline, but the actual cause has not been determined. Several possibilities such as changes in plant succession, reduced forage quality, livestock competition, road construction, and predation have been postulated. Deer are believed to be increasing on the eastside of the forest and may be approaching the target numbers identified in the management plan for the Loyalton-Truckee herd.

Historically, the TNF has provided approximately 2 to 3 percent of the Statewide deer harvest according to State harvest records. Deer on the Forest have been organized into the Downieville, Nevada City, Blue Canyon, and Loyalton-Truckee herds. The TNF and the California Department of Fish and Game have cooperated in the preparation and implementation of management plans for each herd.

Deer range on the Forest is divided into two seasonally important segments: summer range and winter range. The former is mostly above 5,000 feet and is primarily associated with moist meadows, brushfields, seeps and springs, and riparian areas. Winter range is located primarily below 5,000 feet and is probably limiting the eastside and westside herds. Limiting factors on winter ranges are thought to be localized reductions in forage quality and habitat loss from development of private lands. There are an estimated 94,085 acres of deer winter range on the Forest. Of this total 33,780 acres are believed to be key winter range. Other important areas include migration corridors between winter range and summer use areas and the holding areas along the migration corridors. Winter range, fawning areas, holding areas, and migration corridors are shown on the fish and wildlife map in the planning files. Many areas of the forest offer opportunities for improving deer habitat conditions through careful planning of timber management projects, road closures, and other measures.

Black bear occur throughout the Forest. They prefer mature forests with brushfields and meadows. Uprooted trees, windfalls, and hollow logs are used for den sites. The best habitat is on the western slope. Local populations are well distributed and are believed to be stable or increasing. The highest bear densities are in the northwestern portion of the Forest. Historically, bear kills on the TNF have made up 2 to 3 percent of the State harvest according to State harvest records.

Gray squirrels are widespread over the lower hardwood and mixed conifer-hardwood portions of the Forest. Hunting appears to be relatively light, but harvest levels have not been quantified by the California Department of Fish and Game. Squirrel numbers are strongly influenced by the amount and distribution of mast-bearing hardwoods.

Upland game birds are a source of recreation on the Forest, but hunting is relatively light. Habitat on the TNF is excellent for mountain quail and blue grouse. Mountain quail prefer timber stands with extensive shrub cover and low canopy closure. Blue grouse prefer open canopied stands of mixed conifer and fir with interspersed brush-covered openings. Both species tend to use wet meadows and riparian zones extensively.

The Forest has a few wild turkeys, but not enough to accommodate intensive hunting. The Forest does provide areas with suitable turkey habitat. The species prefers wooded areas with a hardwood component and scattered grassy openings in rugged terrain. Turkey populations could be expanded on the Forest through a stocking program in cooperation with the California Department of Fish and Game.

Band-tailed pigeons occur on the Forest but little is known about current population levels. They prefer open canopied, mature mixed conifer-hardwood forests. Hunting pressure is generally light, but there are some areas of concentrated hunting use and some opportunities for habitat improvement.

Waterfowl use most local lakes and large streams for resting and feeding during migration. Ducks are more widespread than geese and tend to use small wet meadows and lakes for nesting. Geese use the large wet meadows and lakes, particularly on the Truckee and Sierraville Ranger Districts, for nesting. Projects to improve waterfowl habitat have been initiated on the Sierraville District. Additional opportunities for habitat improvement exist at several locations on the Sierraville and Truckee Ranger Districts.

Emphasis Species

For the draft Forest Plan, 15 management indicator species were selected to compare the effects of plan alternatives on wildlife. These species were also used as the focus for wildlife habitat management.

The TNF received comments on the draft Forest Plan from the California Department of Fish and Game, the U.S. Fish and Wildlife Service, and many others. The comments included recommendations to broaden the list of animals used for habitat management. The Forest has added several species and species groups in response to these recommendations. The effects of Forest Plan alternatives are thought to be adequately described with the original 15 MIS. Therefore, the new species were included as 'emphasis species' to avoid an unnecessarily lengthy wildlife analysis and discussion in this EIS. The emphasis species are described in Appendix D of the Forest Plan.

Species With Special Status The Forest recognizes two additional groups of species as having special status. These groups are: 1) State-listed threatened and endangered species, and 2) animals listed as 'Species of Special Concern' by the California Department of Fish and Game. Some species in these groups are also identified on Federal T&E or Forest Service sensitive species lists. These animals are addressed in the preceding sections.

State Threatened and Endangered Species. Two species that are identified on the the State T&E species list are not recognized on Federal lists. The species are the wolverine and the Swainson's hawk.

Wolverines are believed to be rare on the TNF. They prefer forests having large trees with medium to dense canopy cover adjacent to alpine meadows and rocky areas with caves. Wolverines seek areas with low human activity and need logs or snags for den sites. Sightings may be increasing and may reflect an increase in wolverines in the Sierra Nevada. However, reliable census information is presently lacking.

Swainson's hawks were once common breeding birds along the eastern slope of the Sierra Nevada and the Sacramento/San Joaquin Valleys. Although reasons for the decline are presently unclear, conversion of grassland habitats for farming and other uses are believed to be a major factor. Present opportunities for increasing Forestwide populations of Swainson's hawk are thought to be very limited. Accordingly, the draft Forest Plan did not identify desired habitat management practices for Swainson's hawks.

State Species of Special Concern State species of special concern that could inhabit the TNF include the osprey, sharp-shinned hawk, Sierra Nevada snowshoe hare, long-eared owl, merlin, purple martin, yellow warbler, yellow-breasted chat, prairie falcon, and golden eagle.

Ospreys prefer large reservoirs and nest in snags. Little is known about the number of ospreys on the Forest, but numerous sightings have been reported. One nest has been discovered on the Forest and several platforms have been constructed near local reservoirs to encourage nesting activity. There is local interest to continue providing nest platforms and habitat for osprey

The current status of the sharp-shinned hawk is unknown for the TNF. The species prefers forest stands with high tree densities, closed canopies, and sub-mature age classes. Accordingly, close coordination between timber and wildlife management will be needed to maintain suitable habitat for sharp-shinned hawks.

The present status of the Sierra Nevada snowshoe hare is uncertain. This species inhabits boreal regions of the Sierra. Reliable population projections are lacking for the TNF or elsewhere. Local interest in this species is extremely low.

Little is known about Forest populations of long-eared owls, merlins, purple martins, yellow warblers, yellow-breasted chats, prairiefalcons, and golden eagles. Prairiefalcons and golden eagles are presently regarded as low priorities for habitat management because public interest is small and opportunities for management are few. The remaining State species of special concern do not currently receive management attention because each is believed to be very rare or absent from the TNF and opportunities for increasing populations are limited.

Species Associated With Special Habitats. Management of the TNF has the potential for substantially changing several important *wildlife* habitats over time. These habitats *are*: riparian, hardwoods, old-growth, meadows, and wetlands. Continued harvesting of timber would reduce the amount of old-growth forest and could degrade the quality of hardwood and riparian habitats for associated species. Livestock grazing, road management, and recreation activity have the potential for substantially changing habitat conditions in riparian and meadow habitats. *In addition*, an *opportunity* exists to enhance habitat quality for waterfowl and other wetland species through direct habitat improvement projects. Wildlife managers are concerned about the future trend in species that are closely associated with habitats that could change substantially over time.

CHAPTER 4 THE ENVIRONMENTAL CONSEQUENCES

A. INTRODUCTION

This chapter discusses the environmental consequences (commonly referred to as impacts) of implementing the proposed action and alternatives, and forms the scientific and analytic basis for the comparisons of alternatives described in Chapter 2. The resource output levels by alternative are displayed and the environmental consequences that result are described. The environmental consequences for all alternatives assume the implementation of Forestwide standards and guidelines (Chapter V of the Forest Plan). These standards and guidelines provide means to mitigate adverse impacts to ensure that the long-term productivity of the land is not impaired.

This chapter is divided into the following seven sections:

- (B) Direct, Indirect, and Cumulative Environmental Consequences.
- (C) Means to Mitigate Adverse Impacts.
- (D) Adverse Environmental Effects Which Cannot be Avoided.
- (E) Relationship Between Short-Term Uses and Long-Term Productivity.
- (F) Irreversible and Irretrevable Commitments of Resources.
- (G) Possible Conflicts with Federal, Regional, State, and Local Land Use Plans
- (H) Energy Requirements and Conselvation Potential.

The information in Section B is grouped by the same resource headings used in Chapter 3 - The Affected Environment. Chapter 3 describes the TNF as it now exists; this current condition provides the basis for understanding the environmental consequences. In Sections D, E, F, and G, the consequences discussed in Section B are summarized according to the type of impact. For example, adverse environmental effects that cannot be avoided with the implementation of any alternative are discussed in Section D. Because of the many specific effects upon many resources, 'indicators' are used to represent and display the overall effect of implementing an alternative on a resource.

Environmental consequences are described for the preferred and other alternatives as they relate to the existing situation. Analyses and detail on the method of estimating the effects of each alternative are included in the planning records.

B. DIRECT, INDIRECT, AND CUMULATIVE ENVIRONMENTAL CONSEQUENCES

ECONOMIC CONSEQUENCES

All dollar figures shown are constant 1982 dollars.

Present Net Value (PNV)

The effect of each alternative's management direction on PNV is described in Chapter 2, Section F, COMPARISON OF ALTERNATIVES - Constraint Analysis.

Income and Employment

Income and employment in the local economy is described in Chapter 3, Section C, THE ECONOMIC ENVIRONMENT.

The production of goods and services from the Tahoe National Forest affects the economy of the impact area by generating income and employment. Income represents the sum of wages, salaries, other labor income, and proprietors income in the local economy. These effects are measured by multipliers. An income multiplier, for example, means that the spending generated by each MBF of timber sold by the Tahoe National Forest creates \$204 of income in the local economy. This \$204 is not to be confused with the 'benefit' of timber used in present net value or benefit/cost calculations. These are **two** separate measures. Multipliers are not precise but are useful for displaying the relative differences between alternatives.

An input/output model for the TNF's zone of influence was used to develop the income and employment multipliers (see Tables 4.1 and 4.2, and Figures 4.1 and 4.2). Measurement is by dollars and worker years.

Income Multipliers

\$ 7.58 per recreation visitor day
\$ 7.66 per animal unit month of livestock grazing
\$204.00 per thousand board feet of timber
\$ 0.45 per dollar spent by TNF in administration

Timber. Most of the variation in income is because alternatives differ in their timber yields, this yield variation is compounded by timber's relatively higher income multiplier. Timber shows the largest range of variation of the outputs contributing to income. Ranking alternatives by total income or timber yield results in the same order: the CMD alternative is highest and the NMK alternative is lowest.

Recreation. In the first decade, income generated by developed recreation on the TNF would be the same for all alternatives because RVD production is limited by demand.

Range. Income generated by livestock grazing is the smallest contributor to total income. Range income is **less** than 1 percent of total income generated by all alternatives. Range income would be highest in the RPA alternative, which generates the highest range output in the first decade, because of the range conversion needed to meet the RPA range target. The CUR alternative also provides for a high range output.

TNF Administration. Forest administration generates income by procuring goods and services. This income would vary directly with the Forest budget. Ranking alternatives by this income element results in the same order (*i.e.*, the CMD alternative is highest and the NMK alternative is lowest) as the ranking by timber-related income because timber is the largest budget item.

When generating employment and income figures using multipliers, a straight proportionality exists between income, employment, and outputs and budget. In other words, the explanation of changes in income among alternatives discussed above also would account for variations in employment.

Employment Multipliers

.505 worker year per thousand recreation visitor days
.511 worker year per thousand animal unit months
.014 worker year per thousand board feet
.030 worker year per thousand dollars spent by TNF

Another type of employment is the number of employees or full-time equivalents (**FTEs**) needed by the TNF for administration. FTEs are not to be confused with the employment due to Forest administration determined by the multiplier. FTEs are government employees. Employment due to TNF administration is nongovernment employment.

Other measures of income include payments to counties from the 25-percent payments, return to the Department of the Treasury, timber-yield taxes, and Forest budget.

Twenty-five percent of the return to the Treasury is distributed to the five counties to finance roads and school budgets. The following components comprise the majority of receipts used to formulate the return to the Treasury and the '25-percent fund'

- o Value of timber harvested
- o Land use permits
- o Grazing fees
- o Recreation permits and user fees

Tables 4.3 and 4.4 and Figures 4.3 and 4.4 compare the alternatives considered in terms of yield tax and return to the Treasury that would be generated in the first decade

SOCIAL CONSEQUENCES

Social and economic effects are closely related (Income and employment effects are discussed under ECONOMIC CONSEQUENCES in this chapter) Social effects are expressed through the evaluation of the following social variables (discussed in Chapter 3, Section D, THE SOCIAL ENVIRONMENT): lifestyles; attitudes, beliefs, and values; community stability and cohesion; population growth, and community services. The affected social groups include long-time residents, retirees, former urban residents, alternative lifestyle residents, second-home owners, regional recreationists, and Native Americans. Minority groups, per se, are not affected differently as special groups than they would be as a part of one of these social groups. The Tahoe National Forest is committed to equal treatment of all individuals and social groups. None of the alternatives considered for the Forest is expected to have discriminating effects.

These groups also include minorities, women, the disabled, the elderly, those for whom English is a second language, and those of different ethnic origins.

Social groups that may be more preservation-oriented include alternate lifestyle, former urban residents, second-home owners, and regional recreationists

The effect of a given alternative may be both beneficial and negative to Native Americans. For example, increased commodity production would benefit those Native Americans working in the timber industry; but, at the same time, it would increase the risk of loss or damage to Native American cultural resource sites.

Implementing the alternatives would have social consequences. When two or more groups within the Forest sphere of influence differ significantly in their expectations for Forest resource use and when the alternatives have different effects on the social groups, potential conflict exists. Generally, the smaller the range of alternative choices, the less conflict between social groups.

For example, alternatives which emphasize timber harvest, forage production and use, and developed recreation are most beneficial to certain long-time residents, although there are a large number of long-time residents who are equally concerned about environmental protection. On the other hand, alternatives which emphasize dispersed recreation and a natural environment are most acceptable to most new arrivals and most second-home owners. Regional recreationists are most likely to derive benefit from alternatives that protect natural values yet provide ample dispersed and developed recreation opportunities. Many regional recreationists, however, would prefer one class of recreation to another; e.g., expanded ski areas, on the one hand, or expanded semi-primitive nonmotorized recreation areas on the other. Conflicts can usually be resolved or reduced if adequate social information is available.

Source data for social and economic effects were obtained by literature review and personal interviews and are summarized in the **Socio-Economic** Overview for the Tahoe National Forest (see TNF planning records 1922.16a.7c). The data were collected for the impact area, i.e., the five counties within the boundary of the TNF: Nevada, Placer, Plumas, Sierra, and Yuba.

The Social groups are the focus of the discussion that follows. Summary tables of selected variables by social groups assess how each alternative is evaluated for the variables and groups. Following Tables 4.5, 4.6, 4.7, and 4.8 specific social consequences by alternative are evaluated. The growth variable is not displayed by social group because it is tied closely to community stability (refer to the footnote in Table 4.6).

Alternative PRF. This alternative retains a level of market outputs beneficial to the lifestyle, community stability, attitudes, beliefs, and values of people associated economically to natural resources such as longtime residents and Native Americans. The Granite Chief Wilderness, slight increases in fish and wildlife populations, and increases in various recreation opportunities, specifically developed recreation sites and expansion of ski areas, should generally meet the needs and expectations of retirees, former urban residents, alternative lifestyle residents, second-home owners, and regional recreationists for more recreation, open space, unmodified scenery, and solitude.

Community stability and cohesion in the Truckee area would be reduced by new sources of Forest economic growth (primarily the result of ski-area expansion), and some community services could be strained. In the other communities, there would be increased requirements from local government for law enforcement, solid waste disposal, sewage, roads, and drinking water services.

This alternative would not induce population growth, and limited changes in land use from timber to nontimber uses would occur.

Alternative CUR. No change from the existing situation, which is described in the Socio-Economic Overview and the AMS, would occur.

Current policy is generally supported by the lifestyles of most social groups because it provides the same level of timber production, fuelwood supplies, grazing, fire protection, and recreation opportunities as in the past decade.

Timber-related employment opportunities would be the same, but recreation lifestyles would be negatively affected because more people would use the same number of Forest Service recreation sites.

TABLE 4.5 - SUMMARY OF ALTERNATIVE EFFECTS ON SOCIAL GROUPS FOR THE LIFESTYLE VARIABLE

SOCIAL GROUP	PRF	CUR	RPA	CMD	NMK	UNE
Long-time Residents	GS	GS	GS	SS	LS	LS
Retirees	GS	GS	GS	GS	GS	GS
Former Urban Residents	GS	LS	LS	LS	GS	GS
Alternative Lifestyle Residents	GS	LS	LS	LS	SS	SS
Second-home Owners	GS	GS	GS	LS	GS	GS
Regional Recreationists	GS	GS	GS	GS	LS	GS
Native Americans	GS	GS	GS	GS	GS	GS

SOCIAL GROUP	PRF	CUR	RPA	CMD	NMK	UNE
Long-time Residents	LS	S	S	S	LS	LS
Retirees	S	S	S	S	LS	S
Former Urban Residents	S	LS	LS	LS	S	S
Alternative Lifestyle Residents	S	LS	LS	LS	S	S
Second-home Owners	S	LS	LS	LS	S	S
Regional Recreationists	N/A	N/A	N/A	N/A	N/A	N/A
Native Americans	S	S	S	S	S	S

Legend

LS - Alternative would be Less Stable and lessen the community's cohesiveness, i.e., polarization w/d the group

S - Alternative would create Stability and cohesiveness between the group and the community

N/A - Not Applicable to the group since it is not part of the community

Footnotes

1/ Communities are the most stable and cohesive w/d alternatives that produce little social impact change since generally the Forest Service outputs are not growth inducing. There would be considerable new economic growth, but it would be from sources other than the Forest Service with the exception of new ski area development. The alternatives which are more growth inducing would offer less community stability and cohesion.

TABLE 4.7 - SUMMARY OF ALTERNATIVE EFFECTS ON SOCIAL GROUPS FOR THE ATTITUDES, BELIEFS, AND VALUES VARIABLE

SOCIAL GROUP	PRF	CUR	RPA	CMD	NMK	UNE
Long-time Residents	GC	GC	GC	SC	LC	LC
Retirees	GC	LC	LC	LC	GC	GC
Former Urban Residents	LC	LC	LC	LC	SC	SC
Alternative Lifestyle Residents	LC	LC	GC	LC	SC	GC
Second-home Owners	GC	LC	GC	LC	SC	SC
Regional Recreationists	SC	GC	GC	GC	GC	SC
Native Americans	GC	GC	GC	LC	GC	GC

TABLE 4.8 - SUMMARY OF ALTERNATIVE EFFECTS ON SOCIAL GROUPS FOR THE COMMUNITY SERVICES VARIABLE

SOCIAL GROUP	PRF	CUR	RPA	CMD	NMK	UNE
Long-time Residents	S	F	F	F	N	N
Retirees	S	F	F	S	N	F
Former Urban Residents	S	N	N	N	S	F
Alternative Lifestyle Residents	S	N	N	N	F	F
Second-home Owners	F	S	N	N	F	F
Regional Recreationists	N	N	N	N	N	N
Native Americans	N	N	N	N	N	N

Expectations of long-time residents and others linked economically to natural resources would be met because of the stable harvest levels of Forest commodities. Expectations of social groups who use the Forest primarily for recreation (former urban residents, retirees, regional recreationists, and second-home owners) would not be met because limited recreation opportunities result in crowded facilities. Preservation groups, such as alternative lifestyle, former urban residents, second-home owners, and regional recreationists, would not be content with no semi-primitive nonmotorized recreation area designation. The same quantity of fuelwood would not adequately supplement residents' primary energy needs because the population of the five counties is expected to increase.

All social groups would benefit from community stability and cohesion because the Forest Service outputs would not induce growth. Considerable new economic growth would occur, but it would be from sources other than the Forest Service.

Alternative RPA. This alternative would benefit the lifestyle of those groups economically linked to the Forest (primarily long-time residents) slightly more than would Alternative CUR because of slightly higher market outputs of timber, livestock grazing, and developed recreation. This alternative would also benefit recreation-user groups' lifestyles, primarily regional recreationists, new arrivals, and second-home residents, by providing more recreation opportunities than currently exists.

The preservationist groups would benefit with the existing Granite Chief Wilderness designation. Expectations for use of the National Forest would be met to a certain extent for all social groups except the alternative lifestyle groups, and the former urban residents who desire the amenity resources.

This alternative would induce slight growth. Limited changes in land use would occur, from timber to nontimber uses. No loss of community stability and cohesion from the slight increase in growth of National Forest outputs would occur. Economic growth would occur, but from development in the private sector.

Alternative CMD. Except for a moderate increase in livestock grazing, this alternative would produce high market outputs very beneficial for the lifestyle stability of people linked economically to natural resources, such as long-time residents and specifically those related to the timber industry, and would add to their sense of self-sufficiency and feelings of certainty about the future. The slightly higher fish and wildlife outputs than currently exist would be somewhat beneficial to the lifestyles of regional recreationists and second-home owners.

Regional recreationists would have additional developed recreation opportunities, however, second-home owners, former urban residents, and some retirees may be dissatisfied with the environmental impacts associated with increased market outputs. Preservationists would be dissatisfied with this alternative because no semi-primitive nonmotorized areas are provided. Native Americans would be dissatisfied with the high risk to cultural resources associated with this alternative.

The outputs of this alternative would induce slight growth over the current situation, but no loss of community stability would be expected. Economic growth would occur, but would be primarily in the private sector as described in Alternative PRF.

Alternative NMK. Lower market outputs would be unacceptable to the lifestyle of the long-time resident group and other groups economically linked to the outputs. Higher dispersed recreation and certain fish and wildlife outputs would be beneficial to the lifestyles of the alternative lifestyle group and second-home owners. Consequently, this alternative might not meet the expectations of the long-time residents but would meet the expectation of many others. Preservationists and most second-home owners, however, would have their desires satisfied for more open space and solitude because this alternative would provide the most semi-primitive nonmotorized recreation areas. Less fuelwood would be available to meet self-sufficiency needs. Native Americans would benefit by the low risk to cultural resources associated with this alternative, but those working in the timber industry could be affected by the loss of jobs. Those groups that enjoy motorized recreation activities would not be favored by this alternative.

This alternative would not induce any growth, and there may be limited changes in land use from timber to nontimber uses. Limited loss of community stability and cohesion may occur from outmigration of timber workers, but most unemployment problems would be alleviated by other new local sources of economic growth such as tourism.

Alternative UNE. The effects of this alternative would be similar to that for Alternative NMK. The major difference is that this alternative would benefit the regional recreationists and the retirees more than the former urban residents, the second-home owners, and the alternate lifestyle groups. The lower market outputs would be unacceptable to the lifestyle of the long-time resident group and other groups economically linked to the outputs. Higher developed and motorized recreation opportunities than presented in Alternative NMK, and certain fish and wildlife outputs, would be beneficial to the lifestyles of regional recreationists and second-home owners. Consequently, this alternative might not meet the expectations of the long-time residents but would meet the expectation of many others. Native Americans would benefit by the low risk to cultural resources, but those working in the timber industry could be adversely affected by the reduction in timber supply.

As in Alternative NMK, this approach would induce no growth, but may result in some limited changes in land use from timber to nontimber uses. Limited loss of community stability and cohesion may occur from outmigration of timber workers, but most unemployment problems would be alleviated by other new local sources of economic growth such as tourism.

RESOURCE CONSEQUENCES

AIR QUALITY

None of the alternatives would result in long-term air quality effects. The short-term effects of dust from road use and smoke from prescribed fire would occur in all alternatives, with a direct relationship between the average annual tons of particulate matter created from prescribed fire and the amount of timber harvested; however, air quality would still meet State Air Resource Board standards.

Table 4.9 displays the short-term consequences of the average annual tons of particulate matter from prescribed fire (based on data published by the U.S. Environmental Protection Agency, "Impact of Forestry Burning Upon Air Quality-1978"). This publication states that burning of slash generates from 17 to 67 pounds of particulate matter per ton of slash and the average estimated slash burned per acre is 36 tons. The median of 32 pounds of particulate matter and the 36 tons per acre burned are used for the calculation of particulate matter.

TABLE 4.9 - AIR QUALITY BY ALTERNATIVE AVERAGE ANNUAL TONS OF PARTICULATE MATTER FROM PRESCRIBED BURNING FIRE *

DECADE	PRF	CUR	RPA	CMD	NMK	UNE
1	1,800	3,700	6,300	3,300	1,200	1,200
2	1,600	4,900	5,900	2,100	1,800	1,200
3	2,300	4,900	5,800	2,600	1,400	1,800
4	1,900	4,000	4,200	2,400	1,200	600
5	2,000	4,300	4,200	2,500	900	800

Alternatives CUR, RPA, and CMD would generate increases in particulate matter; however, these increases would be short-term and would not significantly reduce air quality within the established air basins.

ADJACENT OWNERSHIPS

Restrictive types of land-use allocations, such as wilderness, wild and scenic rivers, Special Interest Areas and Research Natural Areas usually are incompatible with most private land management objectives. Those alternatives (PRF, NMK, and UNE) that dedicate considerable acreages to these types of uses, therefore, would create pressures to acquire private lands within and adjacent to the area.

Alternatives CUR, RPA, and CMD, which propose a high timber program, would require correspondingly higher levels of land line location and right-of-way acquisition through adjacent private land

DIVERSITY

Introduction

Alternate sections of land are privately owned over most of the TNF. The resulting 'checkerboard' ownership pattern seriously complicates analyses of forest diversity. Because the long-term management strategies for private lands are unknown to the TNF, the following discussions are limited to the effects of management on public lands.

On the TNF, the diversity issue is most strongly associated with maintenance of diverse forest seral stages over time (particularly mature and overmature forests), and important habitat elements such as snags, down logs, hardwoods, riparian habitats, meadows and meadow edges, and wetlands. Each alternative provides a unique strategy for managing the Forest and would result in distinct assemblages of forest seral stages, important habitat elements, and diversity of animal communities. Some vegetation types and their associated animal communities (e.g., lodgepole pine and pure hardwood stands) would not change substantially because little management occurs in these types in any alternative. Other types would change considerably in response to management.

The effects of the alternatives on riparian areas, meadows, and wetlands are discussed in the RIPARIAN section of this chapter. The effects on wildlife diversity are addressed in the WILDLIFE section. A comparison of other elements of forest diversity is presented below.

Overall Forest Diversity

The structure of forest vegetation is dynamic and changes in response to natural and induced disturbances. Most resource management programs on the TNF can induce changes in overall forest structure. However, the timber management program and wildfires have the largest effect on landscape diversity over time. Together, they have a profound effect on the species composition and structure of the forest vegetation. As the forest vegetation changes, animal communities adjust to the prevailing mix of habitat components.

While the characteristics of wildfires cannot be predicted, vegetation trends resulting from timber management can be estimated. Noteworthy seral stage changes that would occur from timber harvest are shown for the alternatives in Figures 4.5 through 4.9.

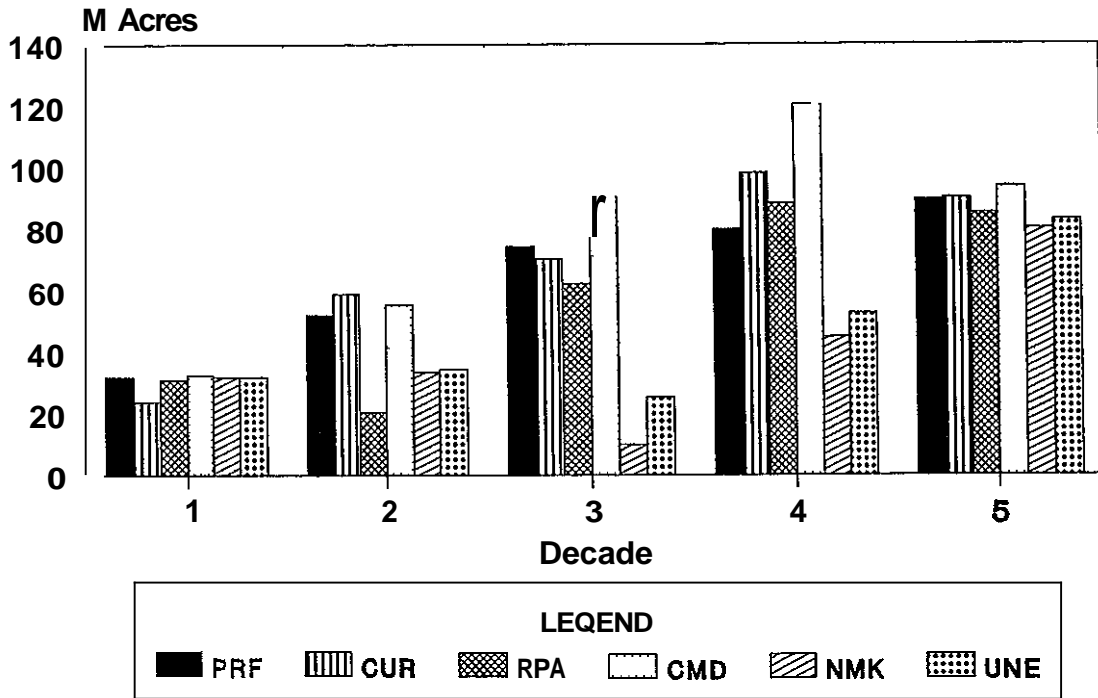

Figure 4.5 demonstrates the trends in early succession seral stages in commercial forest stands. The alternatives that provide large amounts of regeneration harvest (PRF, CUR, RPA, and CMD) would yield large increases in grasses and forbs (seral stage 1X). Alternatives that produce less regeneration harvest (NMK and UNE) would produce fewer acres of early succession stages. Seral stage 2X (brush and sapling trees) acreages follow similar trends to those shown for stage 1X in Figure 4.5. The minimum Regional standard for five percent of the forest seral stages in the 1X and 2X stands would be maintained in all alternatives.

Trends in open stands of pole and small sawlogs (seral stage 3A) are shown in Figure 4.6. Figure 4.6 indicates that all alternatives would maintain about the current acreages of seral stage 3A for the first two decades. NMK would reduce the seral stage by about 35 percent in decades 4 and 5. The PRF, CMD, NMK, and UNE alternatives would reduce the acreage of seral stage 3A by about 30 percent through the fifth decade. The CUR and RPA alternatives would reduce seral stage 3A by about 65 percent in the fifth decade. All alternatives would greatly exceed the minimum Regional standard of five percent of the forest in the 3A seral stage.

The abundance of closed stands of poles and small sawlogs (stages 3B and 3C) are displayed in Figure 4.7. All alternatives would maintain about the current acreage of seral stage 3B/C over the first three decades. The CUR and RPA alternatives would produce increases of 50 percent and 30 percent by the fifth decade, respectively. The PRF and CMD alternatives would yield increases in seral stage 3B/C of about 10 percent by the fifth decade, and the NMK and UNE alternatives would provide increases of about 25 percent. All alternatives would greatly exceed the minimum Regional standard of five percent of the forest in the 3B and 3C seral stages.

Trends in seral stage 4A are shown in Figure 4.8. The PRF, NMK, and UNE alternatives maintain stage 4A at about the current acreages for the first three decades. These alternatives would yield reductions of about 20 percent, 50 percent, and 30 percent, respectively, in the fifth decade. The CUR, RPA, and CMD alternatives would produce similar trends that would maintain reductions in seral stage 4A of 15 to 35 percent after the first two decades. All alternatives would greatly exceed the minimum Regional standard of 5 percent of the forest lands in the 4A seral stage.

Figure 4.8: Trend in Wildlife Habitat 4 A (Large Tree-Open Canopy)

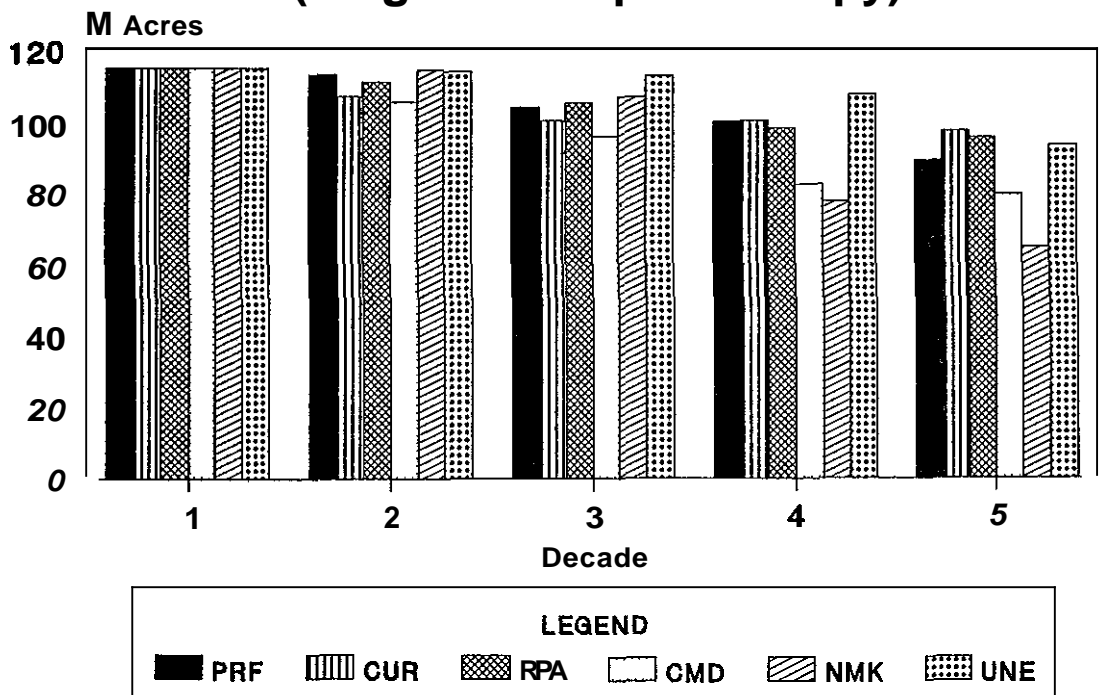

Figure 4.9: Trend in Wildlife Habitat 4B&C (Large Tree-Closed Canopy)

Mature and Overmature Forests

The availability of mature and overmature forest (200+ years old) is shown in Figure 4.9. The amount of seral stage 4B and 4C forest would be maintained at the current inventory (126,200 acres) in the NMK alternative. The NMK alternative would provide the **most** habitat for the wildlife **MIS** groups associated with seral stage 4B and 4C forests. Alternatives PRF, CUR, and RPA would reduce mature and overmature forest to about 50 percent of the current acreage by the fifth decade. Alternative CMD would yield about 60 percent less mature and overmature forest than exists today and would yield the least amount of habitat for the wildlife MIS group associated with seral stage 4B and 4C forests. The UNE alternative would reduce current inventories of seral stage 4B and 4C by about 35 percent in the fifth decade. All alternatives would meet the minimum Regional standard of 5 percent of the seral stages in the 4B/C stage. As described in the DIVERSITY section of Chapter 3, the amount of mature and overmature forest represented by the 4B/C seral stage cannot be determined with existing vegetation data.

Snags

The absence of suitable nesting and foraging sites has been suggested as a limiting factor for snag-dependent animals (Davis et al. 1983). The effects of the alternatives on snags is displayed in Tables 4.10 and 4.11. Table 4.10 compares the snag standards associated with each alternative. Table 4.11 estimates the potential population levels for representative primary cavity nesters. The estimates were made from data in Thomas et al. (1979). Secondary cavity nesters are assumed to follow similar trends to those shown for primary users.

TABLE 4.10. MINIMUM SNAG STANDARDS IN THE ALTERNATIVES (TREES/ACRE)

	PRF	CUR	RPA	CMD	NMK	UNE
Eastside Pine	1.5	1.5	15	15	15	15
All Other Habitats	1.5	1.5	2.0	15	20	15

Species	Eastside Pine All Alternatives	Other Habitat PRF, RPA, NMK	Other Habitat CUR, CMD, UNE
Common Flicker	100	100	100
White-headed Woodpecker	60	90	60
Hairy Woodpecker	80	100	80

Table 4.11 demonstrates that all alternatives would provide sufficient snags for maximum Forestwide densities of common flickers if other important habitat elements are present. The CUR, CMD, and UNE alternatives would reduce the forestwide carrying capacity for white-headed woodpeckers and hairy woodpeckers to about 60 percent and 80 percent of the maximum potential, respectively

The PRF, RPA, and NMK alternatives would also reduce the carrying capacity for white-headed woodpeckers and hairy woodpeckers in eastside pine habitats to 60 percent and 80 percent of the maximum potential. However, these alternatives would provide sufficient snags to permit nearly maximum populations of cavity nesters in other habitats. These estimates approximate the relationships between primary cavity nesters and snag densities observed on the TNF by Raphael and White (1984).

Down Logs

All alternatives would provide the same standard for maintenance of down logs and large woody debris (see discussion on maintenance of long-term soil productivity in the SOILS section of this chapter). The standards are thought to be sufficient to maintain viable populations of dependent wildlife species. However, empirical relationships for down logs and dependent wildlife are lacking.

Hardwoods

All of the alternatives would manage pure hardwoods (stands where less than 10 percent of the crown closure is conifers) for hardwood dependent resources. Accordingly, none of the alternatives would yield significant changes in pure hardwood stands over time.

Each alternative would allow hardwood reductions in other forest types. The reductions would occur in hardwood/conifer stands (where hardwoods comprise 51 to 90 percent of the crown closure) and commercial stands of mixed conifer that have a hardwood component. A comparison of the hardwood standards for the hardwood/conifer and mixed conifer stands is given in Table 4.12.

TABLE 4.12. HARDWOOD STANDARDS IN THE ALTERNATIVES (SQ. FT./ACRE)

	PRF	CUR	RPA	CMD	NMK	UNE
Hardwood/Conifer	30	5	5	5	30	30
Mixed Conifer	5	5	5	0	5	5

Table 4.12 indicates that the PRF, NMK, and UNE alternatives would provide the largest hardwood basal areas. These alternatives would yield the best conditions for the wildlife management indicator species group associated with hardwoods. Alternative CMD would provide the smallest hardwood basal areas, would yield the worst condition for wildlife associated with hardwood stands, and would present a risk for maintaining viable populations of associated wildlife in later decades. Alternatives CUR and RPA would yield intermediate hardwood basal areas and conditions for associated species.

FACILITIES

Road and Trails

The environmental consequences of each alternative on facilities are assessed by the following indicators: (1) miles of arterial, collector, and local road construction and reconstruction (Table 4.13), and (2) miles of trail construction and reconstruction (Table 4.14).

Traffic Characteristics and resource access requirements determine whether a road will be arterial, collector, or local. The Forest arterial and collector transportation system is 95 percent complete. All alternatives would build the 19 miles needed outside of roadless areas. However, the number of miles that would be constructed varies slightly with each alternative. Alternative NMK would require the fewest new miles, 19 miles of arterial and collector construction, because it does not access any unroaded areas. Alternatives PRF, RPA, and UNE would enter both the East and West Yuba roadless areas and would require an additional 11 miles (total of 30 miles) of arterial or collector road construction. Alternatives CMD and CUR would require an additional 18 miles (total of 37 miles) of arterial and collector roads because they enter all unroaded areas.

The Forest has 90 percent of the local road transportation system built. The number of miles of local road construction varies slightly by alternative based on the acres of capable, available, and suitable (CAS) lands being accessed. Alternative PRF would complete the transportation system in three decades. Alternatives CUR, RPA, CMD, NMK, and UNE would complete the transportation system in two decades due to increased harvest levels or silvicultural system needs. Alternative NMK requires the fewest miles of local road construction, 233 miles, because it does not access any unroaded areas. Alternative CUR requires the most miles of local road construction, 311 miles. Alternative CMD requires 304 miles of local road construction and completes all local road construction in the unroaded areas by the end of the first decade. The remaining alternatives require local road construction as follows: RPA (298 miles), PRF (275 miles), and UNE (263 miles).

Alternatives NMK and UNE require fewer total miles of local road construction because of the lesser amount of CAS lands accessed. However, some roads constructed as temporaries and later obliterated in the other alternatives would now become lower standard permanent roads under these alternatives. This is because silvicultural prescriptions for these alternatives requires multiple reentries to the same land base and therefore permanent access must be provided.

For all alternatives the amount of annual road maintenance would not vary substantially and would increase gradually as more roads are constructed.

Because each alternative has a different resource emphasis, the resulting traffic volumes also are varied and could affect road standards, such as width or alignment. However, all roads must be constructed to a standard that provides safe, cost-effective access consistent with the management strategy for each road. Specific road standards and road management objectives (such as closure) would be addressed during project-level environmental analysis.

The Forest Service only recommends road jurisdiction changes. The counties must agree to accept or convey all jurisdictional changes. It would be improbable that such changes would result from this plan because the counties' gas tax revenues for jurisdiction mileages are often less than the counties' maintenance expenditures for the same mileages.

Most roads would be built to achieve specific project objectives under each alternative's emphasis. Few roads would be built for administrative needs or under cooperative agreements. Reconstruction of roads is proportional to new construction and remains relatively constant.

Administrative Facilities

Currently, 23 Federally owned and 5 leased administrative sites are on the TNF. Under all alternatives, by the first decade the number of sites would be reduced to 20 government and 3 leased. Different consequences among the alternatives would result from the intensity of building development, i.e., size and number of buildings per administrative site, and not only to the number of sites. Further studies could identify additional reductions in leased facilities or reorganization of existing government sites for greater cost efficiency.

TABLE 4.13 - AVERAGE ANNUAL MILES OF ARTERIAL, COLLECTOR, AND LOCAL ROAD CONSTRUCTION/RECONSTRUCTION*

	DEC	PRF	PRF	CUR	CUR	RPA	RPA	CMD	CMD	NMK	NMK	UNE	UNE

Trails

The total projected miles of trail construction and reconstruction under Alternatives PRF, CMD, NMK, and UNE would be the same over five decades. Alternative CUR would have the least amount of trail miles while Alternative RPA would have the greatest amount over the first five decades. The trail construction and reconstruction program would be essentially completed by the end of the fourth decade. Table 4-14 displays the average annual trail miles by alternative by decade.

TABLE 4.14 AVERAGE ANNUAL MILES OF TRAIL CONSTRUCTION/RECONSTRUCTION *

* Miles of trail construction and reconstruction; 1982 was 30.0

FIRE AND FUELS

The environmental consequences of implementing each alternative on fire and fuels are evaluated by the following indicators

Average Annual Acres Burned by Wildfire. (See Table 4.15)

Average acres burned annually would increase the most in the CUR alternative, as fire management budgets are constrained to the current level, whereas all other alternatives would have a 20 percent increase in budget. Under all other alternatives, the net wildfire losses would remain similar to the 1970-1979 average level.

Under the CUR alternative the fire suppression emphasis would be a mixture of large and small engines, while under all other alternatives the emphasis would shift to a mix of small engines and hand crews and the fire suppression budget would increase by 20 percent.

Acres of Young Timber Plantations.

Increases in acres of new plantations would increase the overall difficulty of fire protection on the Forest, and without increases in the fire management budget the losses from wildfire would increase.

How flammable a plantation is and how long it remains flammable varies by timber type. For example, the lower-elevation, mixed conifer plantations are highly flammable until about age 30, while the higher-elevation, red fir plantations remain so until age 60. Losses would be proportional to the acres of plantations, i.e., alternatives with more acres of plantations would have greater wildfire losses, and alternatives with fewer acres, fewer losses.

Another key factor affecting flammability and the difficulty to protect plantations from fire losses is the residual fuel loading. Any plantations with Northern Forest Fire Laboratory (NFFL) Fuel Models 12 (medium slash) and 13 (heavy slash) would be very difficult to protect over the entire rotation age of the plantation. Plantations on steep terrain (>35 percent) will have residual fuels and brush that would meet the NFFL Fuel Models 12 or 13 about 75 percent of the time, while on flatter terrain (<35 percent) it could be reduced to Fuel Model 11 (light slash) relatively easily in most cases.

Average Annual Acres of Prescribed Fire by Broadcast Burning.

Increases in acres burned by broadcast fire would increase the risk of fires escaping and damaging other resources (Table 4.16).

Acres to be broadcast burned are directly proportional to the amount of timber regeneration harvest under each alternative. Annual broadcast burn acres vary from a low of 700 in the 4th decade under Alternative

UNE to a high of 4,100 in the first decade under Alternative RPA. Although this is a rather large range, the risk would be within acceptable limits in all alternatives. Also, the amount of broadcast burning would most likely be reduced in the future as alternative methods to broadcast burning become more widely used to reduce residual fuels and prepare sites for planting.

TABLE 4.15 - EXPECTED AVERAGE ANNUAL ACRES BURNED BY WILDFIRE BY ALTERNATIVE BY DECADE*

DECADE	PRF	CUR	RPA	CMD	NMK	UNE
1	739	1,817	736	736	713	715

4	1,631	2,782	1,675	1,689	1,552	1,542
5	1,790	3,105	1,986	2,058	1,708	1,901

* The 1970 to 1979 average annual acres burned by wildfire was 1,038 acres.

TABLE 4.16 - PROPOSED AVERAGE ANNUAL BROADCAST BURNING BY ALTERNATIVE BY DECADE (ACRES)*

DECADE	PRF	CUR	RPA	CMD	NMK	UNE
1	1,800	1,900	4,100	2,400	1,700	1,100
2	1,600	1,700	1,900	1,400	2,600	1,100
3	1,300	2,200	2,100	2,000	1,800	2,000
4	1,100	1,800	1,900	1,600	1,200	700
5	1,200	1,700	1,200	2,000	1,100	900

* 1,200 acres were broadcast burned in 1982

FISH

Fish are a riparian area-dependent resource. Impacts to, and the management of, riparian areas and streamside management zones (SMZ's) adjacent to fish-bearing streams directly affects the condition of the aquatic ecosystem, instream fisheries habitat, and fish populations. Impacts to non-fish-bearing, or ephemeral, streams can also directly affect downstream fish habitat and the fisheries resource. Indirect effects to the fishery resource may be incurred from management of lands adjacent to riparian areas and SMZ's (e.g., cumulative watershed effects).

Best Management Practices (BMP's) for water quality and riparian areas would be implemented under all alternatives. Additional, more specific riparian area protection measures have been established through development of Forestwide standards and guidelines and **SMZ** guides for all Forest watercourses. The **SMZ** standards and guidelines, and BMP's, should prevent any serious, long-term impact to fisheries from other resource activities (Forest Plan, Chapter V). Short-term impacts would be minimized through mitigation measures and habitat improvements to ensure retention of adequate habitat to support viable populations of the fish indicator species.

The potential of the alternatives to affect the fisheries resource are in line with those described in the Environmental Consequences for RIPARIAN AREAS. They vary with the amount of harvest activities scheduled under each alternative, especially those on steeper ground (greater than 30 percent slope). They would be also greater in those alternatives with higher forage and road construction activities (which may produce more sediment). Finally, they would vary with the degree of protection accorded to the riparian area through SMZ designation and management.

The risk of impact to aquatic habitat and the fisheries resource would increase directly with the amount of activity scheduled to occur near and within the SMZ's for each alternative. The impacts could include acceleration of erosion and mass movement processes, introduction and removal of large woody debris, and removal of streamside vegetation. The greater the disturbance and removal of groundcover and streamside vegetation, including both deciduous trees and conifers, the greater the risk of detrimental impact to the fisheries resource.

Fish habitat improvements scheduled under each alternative would also affect aquatic habitat and fish production. The number of improvements are not significantly different for each alternative, but the effect of the improvements would be negated with increased riparian area/SMZ impacts. Not all habitat improvements could be accomplished under any given alternative. Each alternative provides the amount of improvement that realistically could be accomplished given the alternative's emphasis.

Under no alternative would the demand for fishing be met without continuation of the State's fish stocking program.

In all alternatives, habitat for the threatened species, Lahontan cutthroat trout, would be maintained or improved. Negative effects on the habitat would be minimized and mitigated. Existing populations would be protected and an additional population would be established.

PRF Alternative: This alternative schedules an overall large amount of activities on steep ground. The alternative also incorporates the Tahoe riparian area/SMZ standards and guidelines for protection and management of Forest streams and watercourses (see Appendix F of the Forest Plan). The potential for detrimental effects to the fisheries resource would be moderate.

CUR Alternative: This alternative schedules a large amount of steep ground harvest activities and does not incorporate the Tahoe riparian area/SMZ standards and guidelines. The potential for detrimental effects to the fisheries resource would be high.

RPA Alternative: This alternative schedules a very large amount of steep ground harvest activities. It does not incorporate the Tahoe riparian area/SMZ standards and guidelines. The potential for detrimental effects to the fisheries resource would be very high.

CMD Alternative This alternative, like the CUR alternative, schedules a large amount of steep ground harvest activities and does not incorporate the Tahoe riparian area/SMZ standards and guidelines. The potential for detrimental effects to the fisheries resource would be high to very high

NMK Alternative: This alternative schedules a moderate to high amount of steep ground activity and incorporates the Tahoe riparian area/SMZ standards and guidelines. The potential for detrimental effects to the fisheries resource would be moderate because this alternative requires much greater retention of ground cover than the other alternatives

UNE Alternative: This alternative schedules an overall low amount of steep ground activity and incorporates the Tahoe riparian area/SMZ standards and guidelines. The potential for detrimental effects to the fisheries resource would be low

FOREST PESTS

Different levels of integrated pest management (IPM) would be practiced under each alternative (see Chapter 2). These different IPM levels of management would result in different amounts of pest-related damage (depending to a certain degree on the intensity of vegetation management practiced). Indicators of pest-related damage include tree mortality, reduced growth, top killing, degradation, reduced tree quality, and reduced quantity and quality of seed production. Such damage could result in understocking, failure and delay of regeneration, reduced site productivity, degradation of recreation sites, more hazardous trees, and undesirable vegetation changes. Depending on management goals and objectives, pest-related damage could have unacceptable quantitative and qualitative effects on outputs and services

Adverse impacts of pests on resources would be mitigated or prevented by following Forestwide standards and guidelines (Forest Plan, Chapter V). If damage to a resource increases to an unacceptable level, a full range of options to reduce this damage would be evaluated on a site-specific basis and the selected option would be integrated into project activities. Biological effectiveness, environmental safety, and compatibility with other resource concerns would be considered when selecting a pest management option.

Insect and Disease Control

Vegetation management would provide the best opportunity to prevent and reduce the amount and impact of pest-related damage, although direct actions against pests could be necessary in specific situations. The level of pest damage by alternative could not be quantitatively predicted because of the lack of adequate methodologies. To compare alternatives, the intensity of vegetation management was used to reflect the opportunity to prevent and reduce damage. With greater opportunity to manage vegetation, less damage would be anticipated because pest considerations would be integrated into the vegetation management plan. Each prescription was analyzed to determine the intensity of vegetation management which would be expected. The prescriptions were categorized as having "limited", 'moderate', or 'best' opportunity to prevent and reduce pest-related damage. For example, management areas managed intensively for timber or that support developed recreation sites have the greatest opportunity and need to reduce and prevent pest losses. The Granite Chief Wilderness, on the other hand, has limited opportunities because pest management needs only occur when pests threaten resources on surrounding lands or when exotic pests threaten to cause unnatural loss to the wilderness resource. Figure 4.10 displays the relative opportunities to reduce the long-term potential for insect and disease problems for all alternatives.

Figure 4.10: Opportunity to Prevent Forest Pest-related Damage

The following narrative provides more details on the types and magnitude of anticipated losses for each alternative.

Alternatives **CUR**, **RPA**, and **CMD**. These alternatives should have the least amount of tree mortality and growth loss because they offer the greatest opportunity to manage vegetation and implement pest prevention practices. Where intensive management would occur (timber-full and timber-reduced prescriptions), pest-caused mortality and growth loss should decline from current levels. During stress periods, such as drought, the chance of large-scale, pest-caused losses should be reduced. In those areas receiving moderate levels of pest management (timber-special prescriptions), pest-caused losses should remain at current levels. Vegetation management in developed recreation areas should result in improved vegetation health, decreased tree mortality, and fewer hazardous trees. Vegetation management would help reduce degradation of recreation sites. Areas with low levels of vegetation management and pest prevention practices (timber-unsuited prescriptions) should experience tree mortality and growth loss at or above current levels with an increased chance of catastrophic losses. The lower elevation, over-stocked, low-site areas generally should experience high levels of tree mortality, while the higher elevation, moderately-to-sparsely-stocked sites should continue to experience moderate damage and low tree mortality.

Alternatives PRF and UNE. In these alternatives, tree mortality and growth loss could be greater than current levels because of a reduced level of pest management. Vegetation management in developed recreation areas should result in improved health of the vegetation, decreased tree mortality, and fewer hazardous trees. In those areas intensively managed (timber-full and timber-reduced prescriptions), pest-caused mortality and growth loss should decline, and the occurrence and magnitude of large-scale losses should be reduced. In those areas receiving moderate levels of pest management (timber-special prescription), pest-caused losses should remain at current levels, although large-scale losses should decline. Areas receiving low levels of vegetation management and pest prevention activities (timber-unsurtd prescription) could experience tree mortality and growth loss at or above current levels with an increased magnitude of large-scale losses. Generally, the lower elevation, over-stocked, low-site areas should experience high levels of tree mortality, while the higher elevation, moderately-to-sparsely-stocked sites should continue to experience moderate damage and low tree mortality

Alternative NMK This alternative could result in the greatest pest-caused losses of any of the alternatives. The lower amount of intensive vegetation management (timber-full and timber-reduced prescriptions) and pest prevention practices on forested land should result in more tree mortality and growth loss than current levels, and more frequent and higher levels of large-scale loss during stress periods. Vegetation management in developed recreation areas should result in improved health of the vegetation, decreased tree mortality, and fewer hazardous trees. The acres of forest land in SPNM areas that provide limited opportunities for pest prevention practices should experience varying damage depending upon the site and stand conditions, but, in general, increased losses could be expected

Because of the differing intensities of forest management implemented under each alternative, Alternatives CUR, RPA, and CMD should have the lowest level of pest-related damage, with Alternatives PRF and UNE somewhat higher. Moderate damage levels would likely occur under Alternative NMK, which provides the fewest opportunities to manage vegetation and implement pest prevention practices.

Vegetation and Animal Control

The indicators used to display the potential need to control weeds and animals are the acres requiring reforestation

TABLE 4.17 - ESTIMATED REFORESTATION ACRES BY ALTERNATIVE FOR FIVE DECADES

ALTERNATIVE	ESTIMATED REFORESTATION ACRES FOR FIVE DECADES
PRF	186,940
CUR	233,695
RPA	283,641
CMD	235,160
NMK	156,080
UNE	180,450

GEOLOGY

Landslides of various types occur naturally as a result of slopes seeking to reach equilibrium with their environment. When land management activities alter that equilibrium sufficiently, a slope movement will result.

Any one or a combination of factors can cause landsliding: oversteepened slopes, high water content, low soil/rock strength, and earthquakes. These conditions are sometimes encountered or created when roads are constructed or reconstructed, timber is harvested, mines are developed, or timber regeneration activities occur. Timber harvesting activities can damage soil structure, decrease the effect of root systems in providing soil retention, and change groundwater flows. These effects occasionally cause landslides within or adjacent to harvest units. Excavation of road cuts or road cut maintenance often remove the support for the slopes above and thereby cause slope failure. Fire, especially wildfire, but also prescribed fire, destroys vegetative cover and can thereby alter surface and ground water flows sufficiently to trigger slides. Mining can induce slides due to timber removal or road construction, or by direct removal of supporting material. Many other activities such as hydroelectric development, range use, powerline installation, quarrying, and facility construction can alter slope equilibrium and induce landslides of varying size.

On most lands, except the granitic areas where surface erosion predominates, landslides are the most important cause of sedimentation into streams and lakes. They can be hazardous to humans and wildlife.

The risks of impacts from landslides can be mitigated by:

- a. avoiding activity in unstable terrain.
- b. designing activities and structures to minimize the risk of triggering landslides
- c. designing activities and structures to account for the increased risk of sliding or damage due to earthquakes.
- d. maintaining structures/facilities so they do not degrade and become hazard-prone.

Under all alternatives, human activities will increase the risk of landslide occurrence and some landslides would occur. On a case-by-case basis, the magnitude of risk can best be predicted by studying the area, the proposed activities, and the **TNF's** Geologic Resources Inventory (in progress). As timber harvest, road building, forest regeneration, mining, and other activities access steeper terrain, the risk of human-caused landslides may have disproportionate increases.

Landslides can affect the suitability of lands for timber production. Until completion of the Geologic Resources (and Hazards) Inventory, no estimate is available of the amount of TNF land highly susceptible to landsliding, and no land has been withdrawn from the timber base as unsuitable due solely to risk of landsliding or other geologic hazards.

Consequences for geology management are approximated by analyzing the acreage involved in reforestation activities on steep slopes, miles of new road constructed on steep slopes, and acreage managed for Streamside Management Zones (SMZ). These factors can be used as indicators of the potential to affect land stability.

Assumptions important to this discussion are.

- Steep slopes can be used to indicate areas of higher geological landslide hazard.
- Timber harvest and reforestation may create adverse conditions leading to the reactivation of dormant landslides, or the initiation of new landsliding.
- Application of Best Management Practices (BMPs) would reduce impacts associated with landslides.
- The 50-year recurrence interval or greater climatic event can initiate landsliding in spite of project mitigation measures.
- Inner gorge areas have a high landslide hazard, are mainly associated with major stream drainages, and are included within the SMZ's.

Indicators of risk for slope stability are:

- Reforestation acreage on slopes > 30 percent
- SMZ guideline and acreage

Reforestation (slopes > 30 percent) Reforestation acreage represents all lands on which clearcutting and shelterwood cutting methods would occur. These lands are also the acres where artificial stand reestablishment and activity fuel reduction practices would occur. Cable and skyline harvest systems would be used for harvest methods and prescribed fire would be used for site preparation and fuels reduction. The implication of this indicator is that the higher the acres of reforestation under these circumstances, the higher would be the potential to encounter landslides and/or activate them.

Streamside Management Zone Guidelines. SMZ's relate to high landslide hazard because much of the very unstable inner gorge acreages are contained within SMZ's. The Tahoe FEIS alternatives offer different amounts and kinds of protection to these areas. As shown below, 'less restrictive' indicates that the minimum standards (MMR's) and acreage are included in the SMZ guidelines, while 'most restrictive' indicates that the more restrictive guidelines have been chosen and the intermittent stream SMZ's on over 30-percent slopes have been added for protection. The implication of this indicator is that the more restrictive the standards, and the greater the acreage in SMZ protection, the lower the potential of activating landslides from management activities.

ALTERNATIVE	SMZ GUIDES	5-DECADE AVERAGE REGENERATION ON SLOPES >30 PERCENT M/AC/DECADE	GEOLOGIC INSTABILITY RISK
PRF	most restrictive	21.9	lowest risk
CUR	less restrictive	24.3	moderate risk
RPA	less restrictive	28.3	most risk
CMD	less restrictive	23.7	moderate risk
NMK	most restrictive	20.4	lowest risk
UNE	most restrictive	20.3	lowest risk

HISTORICAL AND CULTURAL RESOURCES

Assessing the consequences of the alternatives on cultural resource sites is difficult. While precise, quantifiable measurements are not possible, effects may be evaluated in terms of degrees of risk, i.e., an alternative could raise or lower the risk of disturbing or destroying cultural resources.

To evaluate the degree of risk of each alternative, the following indicators were used.

1. Number of acres which would be disturbed by project activities.
2. Whether access would be increased or decreased
3. Whether visitor use would increase or decrease

Many ground-disturbing activities could destroy or damage cultural resources. For the purpose of displaying the effects of each alternative on cultural resources, only ground-disturbing timber management practices, including road construction, were assessed because such practices constitute a large percentage of Forest management activities. The second indicator acknowledges that the chance of cultural resource destruction would increase as sites become more accessible to the public. The third indicator assumes that the risk of site destruction would increase as recreation visitor use increases.

These indicators are not absolute, nor do they represent direct correlations. For example, many sites are not evident to the casual observer and may only be recognized by a trained archaeologist. Visitor use or access to sites could increase without adverse effects occurring. Also, planned ground-disturbing practices would be preceded by an on-the-ground cultural resource inventory that would identify and protect new sites. Only those sites which, for some reason, were not identified (obscured by heavy duff layers, dense vegetation, etc.) during the inventory could be harmed; others would be protected.

Impacts could also be beneficial. Cultural resource inventories, which can yield valuable information, are required before ground-disturbing practices occur. Once sites are inventoried they can be studied and managed.

About **75** percent of the Forest has not been inventoried for cultural resources. Based on past inventories, cultural resource sites would be found at a rate of one per 245 acres.

Adverse effects on cultural resources, which cannot be avoided through project design, would require mitigation. Past experience has shown that one site in 100 would require mitigation.

The following narrative discusses each alternative's effect on cultural resources by the three indicators.

Alternative PRF. The amount of TNF land disturbed annually by timber harvest activities in this alternative would be about 14 percent greater than the current amount. Cultural resource inventories would increase, causing more cultural resource sites to be identified. Increased road building and recreation use would raise the likelihood of damage to sites. When all indicators are considered under this alternative, the risk to cultural resources would be moderate and would be similar to the current situation.

Alternative CUR. This alternative would continue current management. The risk to cultural resources would be moderate over the next **50** years because of increased access, recreation use, and timber harvest activities.

Alternative RPA. Under this alternative, acres disturbed annually from timber harvest would increase 20 percent over the current acreage. Yearly road construction would be less than the current amount, but would continue to improve access to cultural resources. Recreation use would increase substantially. Risk to cultural resources would be moderate.

Alternative CMD. Risk to cultural resources would be high under this alternative. Over **70** percent more acres would be disturbed annually from timber harvesting compared to the current acreage. Annual road construction would be about the same as currently, but would continue to increase access to cultural resources. Recreation use would increase and raise the likelihood of cultural resource disturbance.

Alternative NMK Under this alternative, risk to cultural resources would be high on those acres intensively managed for timber production. Acres disturbed by timber harvest would increase 17 percent compared to the current acreage. Road construction would be less than the current amount. Access to Cultural resource sites would increase slightly and recreation use would increase. Overall risk to cultural resources under this alternative would be moderate.

Alternative UNE. This alternative would result in a moderate risk to cultural resources. Acres disturbed by timber harvesting annually would increase by 22 per percent over the current amount. Road construction would be reduced compared to the current situation, but would still increase access to cultural resource sites. The increased frequency of timber harvest entries on those acres managed under the uneven aged management system would increase risk to cultural resources on those acres. Recreation use would increase under this alternative.

TABLE 4.19 - EFFECTS ON CULTURAL RESOURCES BY ALTERNATIVE

EFFECT	PRF	CUR	RPA	CMD	NMK	UNE
M Acres Disturbed by Timber Harvest Activities Over 50-Year Period.	232	203	245	351	238	247
M Acres Requiring Cultural Resource inventory Over 50-Year Period	174	152	183	263	178	186

Cultural Resources Accessed by New Roads	298	338	322	330	245	293
Percent RVD Increase Over 50-Year Period	185	167	203	185	185	185
Risk to Cultural Resources*	M	M	M	H	M	M

* H = 'High' chance of disturbance
M = 'Moderate' chance of disturbance

HYDROELECTRIC PROJECTS

Future hydroelectric projects would be prohibited in the Grante Chief Wilderness, the North Fork American Wild River, and Special Interest and Research Natural Areas. Alternative NMK, which proposes the largest acreages for these uses, would result in proportionately fewer hydroelectric proposals. On all other lands, the Forest Service would respond to proposals on a project-by-project basis.

LANDS AND URBAN/RURAL WILDLAND INTERFACE

The type of land considered for acquisition would vary by alternative and would reflect the particular alternative's theme.

Many factors affecting land use would not vary by alternative, such as special uses and hydroelectric projects.

All alternatives, except Alternative CUR, designate the Donner Pass area as a transportation and utility corridor. This designation provides a major trans-Sierra route. Under all alternatives new corridors would be prohibited in the Granite Chief Wilderness, the North Fork American Wild River, and classified Special Interest and Research Natural Areas. Alternative NMK, which proposes the largest acreages of SIAs and RNAs, would result in proportionately fewer options for potential corridors through the Forest. On all other lands the TNF would respond to corridor proposals on a case-by-case basis.

Decade	PRF	CUR	RPA	CMD	NMK	UNE
1	128	120	132	135	115	115
2	100	100	88	100	100	100
3	30	30	30	30	30	30
4	10	10	10	10	10	10
5	10	10	10	10	10	10

* These projections assume that for the first two decades the landline program would respond primarily to the timber harvest programs and that, eventually, all boundaries would be established.

Urban/Rural Wildland Interface. The Forest's ability to respond to public concerns relevant to urban/rural wildland interface situations varies by alternative. Those alternatives with more forest management activities, such as timber cutting, fuels management, and road building would be less responsive to urban/rural wildland interface situations. Alternative NMK would be the most responsive to urban/rural wildland interface situations because the least number of acres of timber are cut and the size of openings would be small and less noticeable to the public. Alternative UNE would be fairly responsive to urban/rural wildland interface situations because a moderate number of acres of timber would be cut and treated, and much of the Forest would be treated with uneven-aged management, which would be the least noticeable to adjacent landowners. Alternative UNE would be between the NMK and PRF alternatives in terms of response to public concerns. Alternative PRF would be moderately responsive to urban/rural wildland situations due to a moderate level of acres being cut and a moderate opportunity to keep harvest openings small or less noticeable. Alternatives RPA, CUR, and CMD would be the least responsive to urban/rural wildland interface situations because the amount and therefore the intensity of harvest would be greater, and larger openings with more management activities would be more often evident to adjacent landowners.

LAW ENFORCEMENT

Law enforcement problems and consequences would not vary by alternative. Law enforcement problems are more a function of social morality and economics than any alternative's intent or emphasis. Law enforcement has been addressed under SOCIAL CONSEQUENCES.

MINERALS

Because the Forest Service only responds to outside requests to explore and develop locatable and leasable minerals, the alternatives only affect mineral development by proposing to withdraw from mineral entry and leasing different acreages with high, moderate, and low mineral potential. Areas proposed for withdrawal include research projects, experimental forests, Special Interest and Research Natural Areas, developed recreation sites, scenic highways, and areas of concentrated public use. Other withdrawals may occur, but exact locations are not known. Valid existing claims in these areas would not be affected. Assessing the effects of mineral development is difficult without knowing where and what kind of development would take place. The TNF would respond to applications for mineral development, and evaluate their potential impacts, on a case-by-case basis.

The current level at which saleable minerals are removed from the TNF is negligible (less than \$2,000 per year), and would remain so in all alternatives.

TABLE 4.21 • TOTAL ACRES BY ALTERNATIVE PROPOSED FOR WITHDRAWAL FROM MINERAL ENTRY AND LEASING

Mineral Potential 1/	PRF	CUR	RPA	CMD	NMK	UNE
High	5,018	0	5,698	127	14,066	5,698
Moderate	697	0	350	0	4,077	697
Low	1,037	1,061	3,431	1,474	20,086	5,013
TOTAL 2/	6,752	1,061	9,479	1,601	38,229	11,408

1. Grazing Capacity. Grazing capacity is the number of AUM's of livestock grazing that an area will support while meeting basic resource needs and associated resource management goals
2. Forage Production. Forage production is the estimated weight of forage produced that could be used by domestic livestock.
3. Opportunities for Increasing AUM's. The opportunities to increase AUM's vary according to which range improvement practices would be used given the alternative's emphasis.
4. Range Ecological Condition and Trend. Range condition is the current productivity of a range relative to what that range is naturally capable of producing. Trend is the direction of change in range condition.
5. Suitable Range Acres. Tahoe National Forest range lands were evaluated against Regional and Forest objectives, conflicts with other resources, and economic and social considerations to provide the gross suitable range acres.

Table 4.22 displays for each alternative the potential permitted AUM production, the five-decade average AUM production, and the pounds of forage available. Table 4.23 displays for each alternative the annual AUM production and suitable range acres. Following the tables is a discussion of each alternative's consequences on range.

TABLE 4.22 - POTENTIAL PERMITTED ANIMAL UNIT MONTH (AUM) PRODUCTION, FIVE-DECADE AVERAGE AUM PRODUCTION, AND POUNDS OF FORAGE 1/

	PRF	CUR	RPA	CMD	NMK	UNE
Potential Permitted AUM Production	23,000	22,900	34,200	27,000	9,000	23,000
Five-Decade Average AUM Production	21,700	21,600	32,900	23,000	5,000	21,700
Potential Forage consumed (million pounds)	23.0	22.9	34.2	27.0	9.0	23.0

1/ The 1982 AUM production level was 20,000

TABLE 4.23 - AVERAGE ANNUAL ANIMAL UNIT MONTH (AUM) PRODUCTION BY THE FIRST AND FIFTH DECADES AND MAXIMUM SUITABLE RANGE ACRES BY ALTERNATIVE 1/

Decade	Range Type	PRF	CUR	RPA	CMD	NMK	UNE
1	Permanent	11,900	13,200	24,600	11,900	9,000	11,900
	Transitory	8,900	9,200	9,600	8,900		8,900
	Total	20,800	22,400	34,200	20,800	9,000	20,800
5	Permanent	16,600	13,200	24,600	20,600	1,000	16,600
	Transitory	6,400	6,800	5,800	6,400	0	6,400
	Total	23,000	20,000	30,400	27,000	1,000	23,000
Suitable Range Acres	Gross Acres Permanent Transitory (Potential)	50,789 408,730	50,789 464,653	50,789 447,188	63,343 471,990	50,789 372,812	50,789 408,728

1/ The 1982 AUM production was 20,000

Alternative PRF. The potential permitted AUM production would increase 15 percent above the 1982 level. The five-decade average AUM production would be less than 1 percent higher than currently. The maximum permitted pounds of forage for domestic livestock would be less than 1 percent above the maximum permitted under current management.

In the first two decades, AUM production on permanent range would not change. AUM production on transitory range would increase slightly in the first three decades because of additional transitory range resulting from timber harvests. After the first three decades, the existing transitory range would peak and start to decline as explained in Alternative CUR. From the third through fifth decades, AUM production on the permanent range would increase by implementing environmental range management practices such as fencing, water developments, and improved management systems (deferred grazing, rest rotation, etc.) through dual use of the sparsely stocked eastside pine stands. By the end of the fifth decade, about 75 percent of the suitable permanent range, or 38,100 acres, would be under intensive management.

About 95 percent of the suitable range would be in satisfactory ecological condition by the year 2030. The trend of these acres in satisfactory condition would be static to upward. This alternative would allow a small amount of expansion of some of the 44 permittee operations.

Alternative **CUR**. The potential permitted AUM production would increase 15 percent above the 1982 level

For the first three decades, AUM production would increase moderately because of additional transitory range resulting from timber harvests. After the first three decades, the increase in AUM production from transitory range would peak and start to decline. This decline could be attributed to two factors: loss of transitory range as stands are reforested, since less transitory range would be produced from harvested true fir stands than from mixed conifer stands. Second, the increased transitory forage produced from the first decade backlog reforestation efforts would become unavailable as tree crowns close and understory forage is shaded out. AUM production from the existing permanent range would increase slightly in the first decade because of improvement in grazing systems. By the end of the fifth decade, about 25 percent of the suitable permanent range, or 12,700 acres, would be under intensive management.

About 85 percent of the suitable range would be in satisfactory condition by the year 2030. The trend of these areas in satisfactory condition would be static. This alternative would allow little to no expansion of permittee operations.

Alternative **RPA**. The potential permitted AUM production would increase 71 percent above the 1982 level, meeting the RPA target. Average AUM production over the 50-year planning period would increase 52 percent above current amounts. The maximum permitted pounds of forage for domestic livestock would be about 49 percent higher than the maximum permitted yield of current management.

For the first decade, AUM production on permanent range would increase by converting 26,709 acres of low-site brush land to range. By the end of the fifth decade, about 80 percent of the suitable permanent range, or 40,600 acres, would be under intensive management. Transitory range resulting from timber harvests would increase moderately during the first three decades.

After the third decade, the existing transitory range would peak and start to decline as explained in Alternative **CUR**.

About 95 percent of the suitable range would be in satisfactory condition by the year 2030. The trend of these areas in satisfactory condition would be static to upward. This alternative would allow ample opportunity for expansion of some of the 44 permittee operations and bring some new permittees into the range program.

Alternative **CMD**. The potential permitted AUM production would increase 35 percent above the 1982 level. The five-decade average AUM production would be 6 percent higher than the current average AUM production. The maximum permitted pounds of forage for domestic livestock would be about 18 percent higher than current maximum permitted yield.

AUM production and the range ecological condition would be the same as displayed in Alternative **PRF**.

This alternative would allow expansion of some of the 44 permittee operations.

Alternative **NMK**. The potential permitted AUM production would decrease about 55 percent below the 1982 level. This would be 77 percent below the current average AUM production. The maximum permitted pounds of forage for domestic livestock would be about 61 percent below current maximum permitted yield.

During the first decade, AUM production would decrease greatly by eliminating grazing in riparian, roadless, wilderness, and transitory range areas. AUM production would continue to be reduced by 2,000 AUM's per decade until 1,000 AUM's remain in the fifth decade. All of the available range would be managed extensively.

Because this alternative eliminates all but 1,000 AUM's over the five decades, the vegetation will develop mostly through natural succession and the ecological range condition can not be evaluated. Livestock would not be available as a management tool to maintain these areas and the ecological range condition in early successional stages. More than 40 families that depend on the Tahoe National Forest grazing allotments would lose their grazing privileges by the year 2030. Of the 40 plus families, it is estimated that 40 percent are totally dependent upon their grazing privileges and would likely lose their ranching operations.

It is also estimated that an additional 45 percent of the 40 plus families' operations would be significantly impacted to the point that they would lose their operations as well.

Alternative UNE. The potential permitted AUM production would increase 15 percent above the 1982 level. This would be less than 1 percent higher than the current average AUM production. The maximum permitted pounds of forage for domestic livestock would be less than 1 percent higher than the current maximum permitted yield.

AUM production and the ecological range condition would be the same as Alternative PRF.

This alternative would allow for a small amount of expansion of some of the 44 permitted operations.

RECREATION

To more accurately display consequences of each alternative on recreation, this section has been divided into the following subsections: (1) Developed Recreation, (2) Dispersed Recreation, (3) Winter Sports, (4) OHV Routes, and (5) Recreation Opportunity Spectrum. Specific indicators are discussed and displayed under each subsection.

Visitor day use data displayed for the alternatives were predicted from current Recreation Information Management data and projected recreation demand.

Developed Recreation

The two indicators for developed recreation are (1) developed recreation capacity and (2) recreation visitor day (RVD) use. Developed recreation capacity measures the persons-at-onetime (PAOT) the facility is designed to serve. RVD use is estimated from Recreation Information Management data and projected recreation demand.

Depending on the theme of each alternative, potential developed recreation sites, including ski areas, may or may not be made available for development. For example, in an alternative such as CUR where timber production is emphasized, few if any potential recreation sites would be available, and no increase in recreation capacity would occur over time.

Increases in use over time are related to projected population trends; depending on the availability of future recreation facilities and each alternative's management emphasis, use levels would vary.

Figure 4.11 displays developed site recreation use in the fifth decade. Table 4.24 displays developed recreation capacity and RVD use by decade for each alternative.

Figure 4.11: Developed Recreation Use - Developed Sites by the Fifth Decade

TABLE 4.24 • DEVELOPED RECREATION CAPACITY AND RECREATION VISITOR DAY USE BY ALTERNATIVE ON NFS LANDS

Decades	PRF	CUR	RPA	CMD	NMK	UNE
Decade 1 Capacity-PAOT 1/ MRVD-Use 2/	14,234 1,976	14,234 1,976	14,234 1,976	14,234 1,976	14,234 1,976	14,234 1,976
Decade 2 Capacity-PAOT MRVD-Use	21,537 2,393	14,234 2,185	21,537 2,393	21,537 2,393	21,537 2,393	21,537 2,393
Decade 3 Capacity-PAOT MRVD Use	25,056 2,784	14,234 2,185	25,056 2,784	25,056 2,784	25,056 2,784	25,056 2,784
Decade 4 Capacity-PAOT MRVD Use	28,161 3,129	14,234 2,185	19,700 2,913	28,161 3,129	28,161 3,129	28,161 3,129
Decade 5 Capacity-PAOT MRVD-Use	29,862 3,318	14,234 2,185	19,700 2,913	29,862 3,318	29,862 3,318	29,862 3,318

Overall recreation experiences would be high, particularly for those activities not associated with motor vehicle use.

Dispersed Recreation

The indicators for dispersed recreation are (1) the acreage of land available for dispersed recreation, measured by ROS class, and (2) the anticipated recreation use, measured by the estimated RVD use. These dispersed recreation indicators are displayed in Table 4.27 in the ROS discussion.

In all alternatives dispersed recreation use would more than double by the fifth decade. The capacity of the TNF for dispersed recreation is sufficient to accommodate this level of demand. For some forms of dispersed recreation activity, the quality of the recreation experience would vary by alternative.

PRF and UNE Alternatives. Under these alternatives, expanded visitor information services would raise the quality of experience for all dispersed users. The TNF trail system would be expanded for both motorized and nonmotorized users and designated OHV routes would be established. Road system expansion would benefit dispersed motorized users and would provide access to newly designated Special Interest Areas. In roaded areas the PRF alternative would look altered in many areas because of logging activities; the UNE alternative would have less acres looking altered because in many situations uneven-aged timber management activities would be far less apparent.

CUR and RPA Alternatives. These alternatives would expand opportunities for motorized use, with road and trail system expansion somewhat higher in **Alternative RPA** than in CUR. Both alternatives would develop new dispersed recreation facilities and both would have a significant number of roaded areas where the landscape would look altered from the natural State because of logging activities.

CMD Alternative. Timber harvesting and associated road building would accelerate under this alternative. Additional roads would improve access to and within dispersed areas and benefit motorized users, but extensive landscape modifications could lower the quality of the recreation experience for those looking for near-natural settings. OHV use would be restricted to protect productive forest land. Trails would be expanded, but overall dispersed facility development would not be emphasized. Opportunities for semi-primitive nonmotorized recreation experiences would significantly diminish.

NMK Alternative. This alternative would provide the highest level of dispersed recreation experience for nonmotorized users. Trails would be built to support the nonmotorized use. The establishment of numerous Special Interest Areas would further enhance recreation experiences. Low levels of timber harvest and small openings would ensure that a near-natural forest environment is maintained, but the relatively low levels of associated road construction would limit motorized recreation opportunities. Semi-primitive motorized and OHV recreation would be the most limiting in this alternative.

Winter Sports

A component of the recreation issue is the development and operation of downhill skiing facilities. Many major ski resorts include both private and National Forest System land. Existing resorts on the Tahoe National Forest include four facilities with a combined skiers-at-one-time (SAOT) capacity of 12,100, which include 6,300 SAOT on private land and 5,800 SAOT on Forest land. Four potential winter sports areas have been identified, these areas have a total potential capacity of 13,500 SAOT and 27,000 SAOT on TNF and private lands, respectively.

The indicators and measurements for developed alpine skiing are (1) the available acres, (2) the estimated SAOT capacities, and (3) the RVD use on TNF lands. These indicators are displayed for the alternatives in Table 4.25 and Figure 4.12. As with developed recreation, variations in the amount of use and capacity projected are related to the management emphasis and land available for facility development associated with a given alternative. Thus, in an alternative where downhill skiing is emphasized, potential ski areas would be made available for development and the use and capacity figures shown in Table 4.25 reflect that.

TABLE 4.25 - DEVELOPED DOWNHILL SKIING - ACRES AVAILABLE, SKIERS-AT-ONE-TIME CAPACITIES, AND RECREATION VISITOR DAY USE ON NFS LAND 1/

1/ Additional sites would be constructed by the private sector under special-use permit. Sites would be developed only if demand is present at that time. This table does not include MRVDs and PAOT's on private land.

2/ M RVD Use - Thousands of Recreation Visitor Days

Note: The existing situation has 545 developed acres, 5,800 Skiers-at-one-Time capacity, and 210 MRVDs of use.

Figure 4.12: Developed Recreation Use - Ski Areas by the Fifth Decade

PRF, CUR, CMD, and UNE Alternatives Under these alternatives, existing downhill ski facilities would expand within their existing boundaries in the first decade or **two**. This expansion would increase the capacity of existing sites by adding ski runs, lifts, and base facilities without increasing the overall area perimeter. Beyond the first decade, new facilities would be constructed in new, currently undeveloped sites in response to demand. The undeveloped sites may be adjacent to existing ski areas or entirely new sites away from existing sites. By the fifth decade, **90** percent of all potential ski facilities would have been constructed to meet projected demand. The construction of new ski facilities would actually depend on market conditions and the capability of transportation and other support facilities to accommodate increased skiers. Existing transportation facilities would not be sufficient to meet projected ski area demand without shifting the pattern of use (weekday versus weekend) or by emphasizing mass transit. Without such changes the quality of the recreation experience would be reduced. The CMD alternative would concentrate ski area expansion to adjacent areas where timber resources would be least affected.

RPA Alternative. Under this alternative, expansion of existing downhill ski facilities and development of new ones would occur through the first four decades if market conditions, necessary support facilities, and transportation systems are available. Demand for downhill ski facilities would not be met in the fifth decade and would fall short of demand by **12** percent.

NMK Alternative The consequences would be the same as PRF, except that by the fourth decade ski area development would lessen, and by the fifth decade ski area construction would stop because this alternative would not permit ski area development in mature forest types and areas committed to SPNM ROS designation. Thus, while capacity would fulfill demand through the fourth decade, capacity would limit use in the fifth decade to **12** percent below demand.

OHV Routes

A component of the recreation issue is off-highway vehicle (OHV) use. The indicators of OHV are the acres and miles of roads and trails open, restricted, or closed to off-highway vehicle use. These are displayed in Table **4.26** for the alternatives. Below is a discussion of OHV use by alternative

Under all alternatives the final determination of designated routes will be made by the Trail Management Plan to be completed one year after the Forest Plan is approved. Until then, existing undesignated roads and trails within newly assigned Designated Routes Only areas will remain open to use except as the Forest Supervisor may determine necessary under Executive Order (E.O.) **11644**, as amended by E.O. **11989**, to protect resources against adverse effects, and under regulations to protect public safety.

The miles of roads and trails open, restricted, or closed to OHV use vary according to dispersed recreation trends. Changes in acres open, restricted, or closed reflect the theme and management prescriptions of each alternative.

PRF and UNE Alternatives. Acres open to OHV use would decrease about 70 percent during the first decade and miles of roads and trails open to OHV use would decrease about **8** percent. Acres restricted to OHV use would increase **52** percent, while areas closed would decrease 0 percent during the first decade. Miles of roads and trails with restricted OHV use would increase **88** percent, and miles closed to OHV use would decrease 89 percent. These changes in OHV categories, especially the increase in the restricted category, result from these alternatives' themes to emphasize and protect amenity benefits while still providing for dispersed OHV opportunities.

CUR Alternative. No change would occur in the current acres of OHV use classification. Miles of roads and trails open and restricted to OHV use would both increase **24** percent. Miles of roads and trails closed to OHV use would decrease **4** percent.

RPA Alternative. Acres open to OHV use would decrease 66 percent the first decade, and miles of roads and trails open to OHV use would decrease 8 percent. Acres and miles closed to OHV use would decrease **26** percent and **84** percent, respectively. Acres and miles with restricted OHV use would increase **124** percent and **86** percent each. These changes result from the alternative's direction to protect resources.

CMD Alternative. Acres open to OHV use would decrease **59** percent the first decade. Miles of roads and trails open to OHV use would increase **14** percent. Acres and miles of restricted OHV use would increase **29** percent and **81** percent, respectively. Acres closed to OHV use would decrease **54** percent, a significant change. Miles of roads and trails closed to OHV use would decrease **90** percent. This alternative would have less OHV closure and more land available for restricted OHV use. The increase in the restricted category results from the alternative's direction to avoid conflict with or damage to capable forest land.

NMK Alternative. This alternative would result in the largest decrease (**100** percent) to zero acres open to OHV use. Road and trail construction would increase by about **25** percent the miles of road open to OHV use. This alternative would increase restricted acres about **41** percent and closed acres about **51** percent. Miles of roads and trails in restricted categories would increase 60 percent while closed miles decrease **41** percent. These changes result from the amenity resource protection and SPNM area designations in this alternative.

Recreation Opportunity Spectrum

The ROS classes are urban (U), rural (R), roaded natural (RN), semi-primitive motorized (SPM), semi-primitive nonmotorized (SPNM), and primitive (P). Currently no primitive or urban ROS classes exist on the TNF and none are projected by the fifth decade. (Definitions for the ROS classes are found in the Glossary in the Plan.) Lands in certain ROS classes are appropriate or even necessary as settings for certain developed or dispersed recreation activities. The ability to meet different recreation demands depends on the ROS class. Table 4.27 displays both the acreage and use in each ROS class to illustrate this relationship.

Generally, ROS classes would change to more developed categories. ROS changes to less developed classes are less likely to occur. A given area would not likely change from rural to roaded natural, or roaded natural to semi-primitive motorized, unless management places specific emphasis and direction on such a conversion. Locations where this change in direction could occur would be in the Granite Chief Wilderness, the North Fork American Wild River, or designated SPNM or motor vehicle closure areas. In these locations management direction and action would maintain or establish semi-primitive nonmotorized environments.

In the fifth decade, capacity in the rural and roaded natural ROS classes would exceed demand in all alternatives. Because acres accessed by roads would increase for all alternatives by **12** to **22** percent, the roaded natural acres would increase accordingly. All alternatives would not meet demand for all types of facilities and environments (such as developed recreation sites and downhill ski areas) within these classes. Furthermore, the quality of the recreational settings would vary between alternatives. Some alternatives emphasize developed recreation and would therefore have newer, higher standard, more complete facilities, while other alternatives would have older, deteriorated, and crowded facilities. Roaded natural settings for dispersed recreation would also be more modified and less natural in alternatives emphasizing commodity production than in alternatives emphasizing recreation.

TABLE 4.26 - ESTIMATED MILES AND ACRES OF OFF-HIGHWAY VEHICLE (OHV) CATEGORIES FOR THE FIRST DECADE

OHV USE INDICATOR	MISTING SITUATION	PRF	CUR	RPA	CMD	NMK	UNE
CLOSED MILES ROADS & TRAILS ACRES	819 43,050	68 44,939	82 19,793	133 31,798	85 19,923	483 220,072	68 44,939

TOTAL ROADS & TRAILS SYSTEM MILES	2,910	3,302	3,294	3,317	3,372	3,182	3,302

By the fifth decade, demand in the semi-primitive motorized ROS class would not be met by any of the alternatives. While the current use (185 MRVDs) is well below the current capacity (382 MRVDs), demand in this ROS class should grow to about 430 MRVDs by the fifth decade. Conversely, capacity would be reduced in all alternatives. The trend toward declining SPM acres is inversely related to (1) the increased roading and vehicular access common to all alternatives, (2) the increasing landscape modification and loss of natural-appearing settings in all alternatives, and (3) the conversion of SPM areas to semi-primitive nonmotorized by motor vehicle closures, especially in the NMK alternative. Because SPM demand would not be met, use would transfer to other ROS settings or other forests that could provide more SPM areas.

The semi-primitive nonmotorized ROS class capacity of the TNF varies widely between alternatives. The NMK alternative designates several SPNM areas in addition to the Granite Chief Wilderness and the North Fork American Wild River. The other alternatives designate few or no areas for SPNM recreation outside of the wilderness and the wild river. In the NMK alternative, SPNM acre capacity would increase the most (69 percent). Under all alternatives except NMK, SPNM acres, like semi-primitive motorized areas, would continually diminish because of roading and commodity production. The CMD and CUR alternatives, because they emphasize commodity production, roading, and motorized recreation, would reduce SPNM capacity the most (41 percent). With demand projected to reach 378 MRVDs by the fifth decade, only the NMK alternative, which has significant amounts of designated SPNM acreage, would have SPNM capacity sufficient to meet demand. SPNM use in this alternative would exceed the 378 MRVD demand level because use would shift from other ROS settings (especially SPM) or from other forests. This shift would occur because of limited capacity in the other ROS classes and because designating areas as SPNM would attract additional use.

The projection of ROS class acreage uses the following factors and assumptions:

1. More acres of ski area development will increase rural ROS class acres.
2. More acres of other recreation development will increase rural and roaded natural ROS class acres.
3. More acres accessed by new road development will increase roaded natural ROS class acres.
4. Former roadless areas proposed for SPNM recreation or motor vehicle closure designation would be managed to achieve semi-primitive nonmotorized settings.
5. Any increase in the more developed ROS classes would decrease the less developed ROS classes, and a flow upward in the ROS development scale would occur over time.

Projections of ROS class usage assume the following:

1. The proportion in each ROS class of total Forest RVDs would remain the same unless changed by increases or decreases in the percentage of acres in an ROS class; this change would similarly change the proportion of use in that class.
2. Use could not exceed the capacity in each ROS class.
3. Use could exceed demand projections for each ROS class because of shifts in use from one class to another.

PRF and UNE Alternatives. By the fifth decade, rural ROS class acreage and capacity would increase 49 percent above current conditions as recreation sites and alpine ski areas are expanded or developed to meet demand. Because of the emphasis on additional high standard facilities, opportunities for high quality developed recreation experiences would be enhanced. Use would grow 173 percent by the fifth decade because of the increased high quality and quantity of rural ROS class facilities.

Roaded natural acreage would increase 8 percent in the PRF alternative and 7 percent in the UNE alternative by the fifth decade, primarily because of new road construction and timber harvesting. These activities would convert semi-primitive motorized and nonmotorized areas to RN.

Recreation development would both remove and create roaded natural acres because SPM and SPNM would become RN acres, and some RN areas would become rural. The TNF would be **74** percent roaded natural by the fifth decade. For the PRF alternative, besides growing in size, the RN areas would generally be more modified with **less** natural settings for dispersed recreation than current RN areas. This increased disturbance of the natural environment, caused primarily by timber management activities, would be most prevalent in the lower elevations on the western slope of the TNF. The quality of RN recreation opportunities and experiences would be reduced for recreationists concerned with a natural setting, even though the acreage would be more than sufficient to satisfy demand. The UNE alternative, although modified because of timber management and other management activities, would be far **less** modified than the PRF alternative because the acres of uneven management would appear **less** noticeable. Frfth-decade **use** would be **100** percent above the existing level for the PRF alternative and **98** percent above the existing level for the UNE alternative.

Both semi-primitive motorized and nonmotorized acres would be reduced as more of these ROS classes become roaded, altered, and converted to RN. Even though current SPM **use** (**185** MRVDs) is well below current capacity (**382** MRVD's), the shrinking SPM land base and the increasing SPM demand projections would meet and cross in the first decade. Semi-primitive motorized acres would decrease **41** percent for PRF and **38** percent for UNE by the fifth decade. Use would increase **8** percent by the fifth decade for the PRF alternative and **14** percent for UNE.

Because certain areas (the Granite Chief Wilderness, Grouse Lakes, the North Fork of the American River, and Snow Mountain) would be designated for semi-primitive nonmotorized management, SPNM acres would be converted to roaded natural acres at a lesser rate than would SPM acres. Initially, SPNM acreage would even increase **as** management converted parts of the these designated areas to SPNM from other ROS classes. But as the remaining SPNM areas (not designated as SPNM or wilderness) are roaded and converted to roaded natural, capacity would diminish until, by the second decade, projected SPNM demand would not be met. Use would continue to grow past the fifth decade until it met capacity of about 356 MRVDs, which is still below the fifth-decade projected demand.

CUR Alternative. Rural acres would remain consistent through the five decades because this alternative emphasizes maintaining developed recreation capacity at current levels. Alpine ski area capacity would expand to meet demand. Rural capacity would meet demand through five decades, but the quality of the environment would decline because many developed sites would become crowded or deteriorated. Overall rural **use** would grow **104** percent by the fifth decade.

Roaded natural acres would increase **19** percent by the fifth decade because of timber management and road construction activities. These practices would improve access, but would also modify the natural setting to a greater degree than currently is the norm for most RN areas. Thus, even more than in the PRF and UNE alternatives, RN acres would exceed demand but would be of a lower quality for recreationists desiring natural-appearing surroundings. Use would continue to increase, though, and by the fifth decade would be **130** percent above present **use**.

Semi-primitive motorized and nonmotorized acreage would decrease because of increased roading and landscape modification. Because no areas would be designated for SPNM recreation outside **of** the Granite Chief Wilderness and the North Fork American Wild River, SPNM acres would be converted to roaded natural more quickly than in the PRF alternative. SPM and SPNM acres would decrease **60** and **41** percent, respectively. This diminishing land base would be insufficient to meet SPM and SPNM demand by the second decade. By the fifth decade, SPM **use** would thus decrease **28** percent because **of** the limited available acreage. SPNM **use** would be **6** percent higher than current **use** in the fifth decade, and would increase until reaching capacity.

RPA Alternative. Frfth-decade rural ROS class acres and **use** would increase **11** percent and **121** percent, respectively, due to increased ski area and recreation site development but not to the extent as the PRF, UNE, or CMD alternatives.

Roaded natural acreage would increase **20** percent by the fifth decade because **of** roading, harvesting, and development in SPM and SPNM acres. Use would increase **141** percent but would still not approach capacity. The natural quality of the RN environment would decline from current conditions as in the CUR alternative.

TABLE 4.27 - ACRES AND THOUSANDS OF RECREATION VISITOR DAYS (MRVD) USE BY RECREATION OPPORTUNITY SPECTRUM (ROS) FOR EACH ALTERNATIVE (MRVD/Acres) 1/

1/ For developed and dispersed recreation, doesn't include ski RVD's & acres on private land

Semi-primitive motorized and nonmotorized acreages would decrease **86** and **14** percent, respectively, because acres would be converted to RN. Because the Grouse Lakes, Castle Peak, Loch Leven, and Snow Mountain areas would be managed for SPNM recreation, SPM acres would be reduced more than SPNM acres. Projected SPM demand would not be met in the first decade and thereafter, SPNM demand would be met until the fifth decade but not thereafter. The limited SPM land base would constrain use to **71** percent below current use and use would level off at this capacity. Semi-primitive nonmotorized use would increase **93** percent by the fifth decade until the diminishing SPNM land base counteracts the growing demand. Use would continue to grow until capacity limits are met.

CMD Alternative. Rural acres would increase **25** percent by the fifth decade. Downhill ski facilities and developed recreation sites would expand to accommodate demand. Use would increase **173** percent, the same as the PRF and UNE alternatives, but use would be concentrated on fewer acres.

Roaded natural acreage would increase almost as much as the CUR and RPA alternatives because of a high level of new road construction and timber harvesting. RN fifth-decade acre capacity would increase **18** percent. RN use would be between the PRF/UNE and CUR/RPA alternatives, **118** percent of current use by the fifth decade, because of the large roaded natural land base and diminished semi-primitive motorized and nonmotorized capacity. The dispersed recreation environment would be intensively modified, thereby reducing natural-setting opportunities and qualities. Vehicular access would be greatly increased over current levels.

Like the CUR alternative, the CMD alternative places little emphasis on maintaining semi-primitive settings beyond those provided by the Granite Chief Wilderness or the North Fork American Wild River. Thus, both semi-primitive motorized and nonmotorized acreages would decline significantly, by **61** and **41** percent, respectively, from current levels by the fifth decade. These decreasing acreages would be inadequate to meet SPM demand in the second decade and SPNM demand in the first decade. Fifth-decade use levels would decrease 20 percent in the SPM class and would increase **36** percent for SPNM. Use would continue to grow beyond the fifth decade for SPNM until it reached the capacity for those acres.

NMK Alternative. Fifth-decade rural acreage would increase only **3** percent. Developed recreation and ski facilities would be improved and expanded (except where conflicts occur with amenity values) to enhance the recreation experience. In addition, the forest would remain somewhat naturally appearing, thereby more consistently maintaining high quality settings than would the PRF, CUR, RPA, and CMD alternatives. Use would increase 99 percent by the fifth decade (somewhat less than the PRF and UNE alternatives' increase) because less use would be displaced to rural from less developed ROS classes.

As in all alternatives, new roading would increase roaded natural acreage. Less timber harvesting and roading would occur than under all other alternatives. The RN acres would increase only 7 percent. This RN acreage would meet demand, would remain mostly in a natural, near-natural, or somewhat natural condition, and thus would provide a higher quality environment for recreation than the more commodity-oriented alternatives. Fifth-decade use would be **98** percent above current use.

Because many areas (the North Fork of the American River, East Yuba, West Yuba, Duncan Canyon, Middle Yuba, Bald Mountain, North Lafayette, Castle Peak, Grouse Lakes, North Fork Middle Fork of the American River, and Lakes) would be designated semi-primitive nonmotorized in this alternative, most of the RN acreage increase would come from semi-primitive motorized areas. Thus, while the SPNM acreage would increase, SPM acreage would be reduced **89** percent by the fifth decade through conversion to the SPNM and RN classes. SPNM acreage would be 69 percent larger by the fifth decade than the current amount because of the designation and management of large areas as SPNM. With minimal SPM acreage, capacity would fall short of demand by the first decade and use would decline by **89** percent by the fifth decade. Much of this displaced SPM demand would be converted to SPNM use. SPNM use would increase **291** percent above current use by the fifth decade and would exceed projected demand (**378** MRVD's) by **256** MRVD's. The high quality SPNM recreation areas would be maintained in several large, viable blocks (rather than small, randomly scattered parcels such as in the CUR and CMD alternatives) and would, by their own merits and because of the shortage of useable SPM environs, attract more use than in any other alternative. Use would level off in the fifth decade at 634 MRVD's as this is about the capacity for the total SPNM acres.

RIPARIAN AREAS

Riparian areas include wetlands, floodplains, the riparian and aquatic ecosystems, and the first 100 feet of streamside management zones (SMZ's) on either side of perennial streams. Because there is an overlap between riparian areas and SMZ's, and because the purpose of SMZ's is ultimately to protect riparian area values, they are discussed together.

Impacts to the estimated 32,000 acres of wetlands and riparian ecosystems, and the **4,600** acres of floodplains associated with large (Class I) streams, would not differ significantly by alternative. These areas are identified during project-level planning. Appropriate best management practices (BMP's - see S&G 50 and Appendix E in the Forest Plan) are applied to minimize direct and indirect disturbances. For example, BMP 7.3 specifically addresses the protection of wetlands. Impacts to these components would be localized and minor.

The potential to affect riparian areas/SMZ's and related values correlates with (1) the acreage of regeneration harvest and associated activities on steep ground (slopes over 30 percent), and (2) the degree of protection provided to streamside zones.

In general, the risk that a recurrent storm event would result in adverse impacts to riparian-dependent resources increases with the amount of regeneration cutting, road building, and site preparation on steep ground. It is normally possible to protect SMZ's and the aquatic ecosystem from logging operations on flatter slopes (0 to 30 percent). Maintaining riparian areas and SMZs on steeper slopes has a much higher risk of failure largely due to post-harvest activities.

The risk to riparian-dependent resources also increases with the amount of activity scheduled within riparian areas/SMZ's. Forest S&G's 46 and 47 and Plan Appendix F are designed to maintain water quality and other riparian values by maintaining vegetation and an effective ground cover in riparian areas/SMZ's. These standards are more restrictive than the minimum management requirements (MMR's) because recent experience has demonstrated that the Forest has not always been able to protect riparian areas and SMZs when timber volumes have been scheduled from these zones. Some of the major differences in riparian/SMZ protection offered between the Forest Plan direction (S&G's 46 and 47, and Appendix F) and the MMR are: 1) the Plan provides for SMZ protection adjacent to certain intermittent and ephemeral streams as well as perennial streams while the MMR only recognizes perennials, 2) the Forest Plan allows for variable width SMZ's, which may be greater than 100 feet, whereas the MMR recognizes a fixed 100-foot zone along only perennial streams; 3) the Forest Plan schedules only incidental timber yields from perennial SMZ's for such things as cable logging corridors and road crossings, whereas the MMR schedules several million board feet per year in these areas; and, 4) the Forest Plan clearly states that riparian-dependent resources take precedence over nondependent resources such as timber in riparian areas/SMZ's, whereas the MMR, with its scheduled yield, is not restrictive. In essence, the risk involved in protecting SMZ's decreases dramatically as planned timber harvest is reduced in the SMZs. Because the MMR schedules several million more board feet of timber output than the Forest S&G's would allow in SMZ's, this built-in conflict between riparian area-dependent resource values and commodity output would likely result in continued failures.

Figure 4.17 displays the total number of acres to be regenerated in the first decade on slopes over 30 percent. The base for comparison is the **1977-87** period (**14,400** acres). Figure 4.18 displays the projected increases in regeneration acres on slopes over 30 percent as percentages, again using the **14,400** acres for **1977-87** as a base; percentage increases are shown for the first decade and for the first five decades.

In comparing alternatives and projecting the potential impacts on riparian areas and water quality, both the first-decade activity and the five-decade activity on slopes over 30 percent were considered as were riparian area/SMZ guidelines. More weight is attached to the first-decade activities since they would be scheduled immediately upon adoption of the Forest Plan. Plan updates would allow for changes in harvest levels on steep ground in later decades if warranted by monitoring; therefore the five-decade average carries less weight. The more restrictive riparian area/SMZ direction applies to the PRF, NMK, and UNE alternatives; the MMR applies to the CUR, RPA, and CMD alternatives.

Alternative **PRF**. This alternative has a first-decade regeneration harvest of **23,500** acres, which is 63 percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about **52** percent greater than the **1977-87** level. This alternative incorporates the more restrictive Forest S&G's for riparian areas/SMZ's.

The potential to damage riparian areas/SMZ's and the aquatic ecosystem would be moderate based on the overall high (first-decade)/high (five-decade) amount of activity on steep ground, and the more restrictive Tahoe NF riparian area/SMZ guides

Alternative **CUR**. This alternative has a first-decade regeneration harvest of **22,900** acres, which is **59** percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about **69** percent greater than the **1977-87** level. This alternative incorporates only the MMR for riparian areas.

The potential to damage riparian areas/SMZ's and the aquatic ecosystem would be high based on the overall high (first-decade)/high (five-decade) amount of activity on steep ground, and the less restrictive MMR for riparian areas.

Alternative **RPA**. This alternative has a first-decade regeneration harvest of **34,400** acres, which is **139** percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about **97** percent greater than the **1977-87** level. This alternative incorporates only the MMR for riparian areas.

The potential to damage riparian areas/SMZ's and the aquatic ecosystem would be very high based on the overall extreme (first-decade)/high (five-decade) amount of activity on steep ground, and the less restrictive MMR for riparian areas.

Alternative **CMD**. This alternative has a first-decade regeneration harvest of **33,700** acres, which is **134** percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about 65 percent greater than the **1977-87** level. This alternative incorporates only the MMR for riparian areas.

The potential to damage riparian areas/SMZ's and the aquatic ecosystem would be high to very high based on the overall extreme (first-decade)/high (five-decade) amount of activity on steep ground, and the less restrictive MMR for riparian areas.

Alternative **NMK**. This alternative has a first-decade regeneration harvest of **30,100** acres, which is **109** percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about 42 percent greater than the **1977-1987** level. This alternative incorporates the more restrictive Forest S&G's for riparian areas/SMZ's.

If fuels treatment were treated similarly as in the other alternatives, then under this alternative the potential to damage riparian areas/SMZ's and the aquatic ecosystem would be moderate to high based on the overall high (first-decade)/moderate (five-decade) amount of activity on steep ground, and the more restrictive Tahoe NF riparian area/SMZ guides. This alternative treats fuels differently than the other alternatives in that significantly more ground cover would be retained; when this factor is considered, this alternative would be comparable to the PRF alternative for riparian area/SMZ protection.

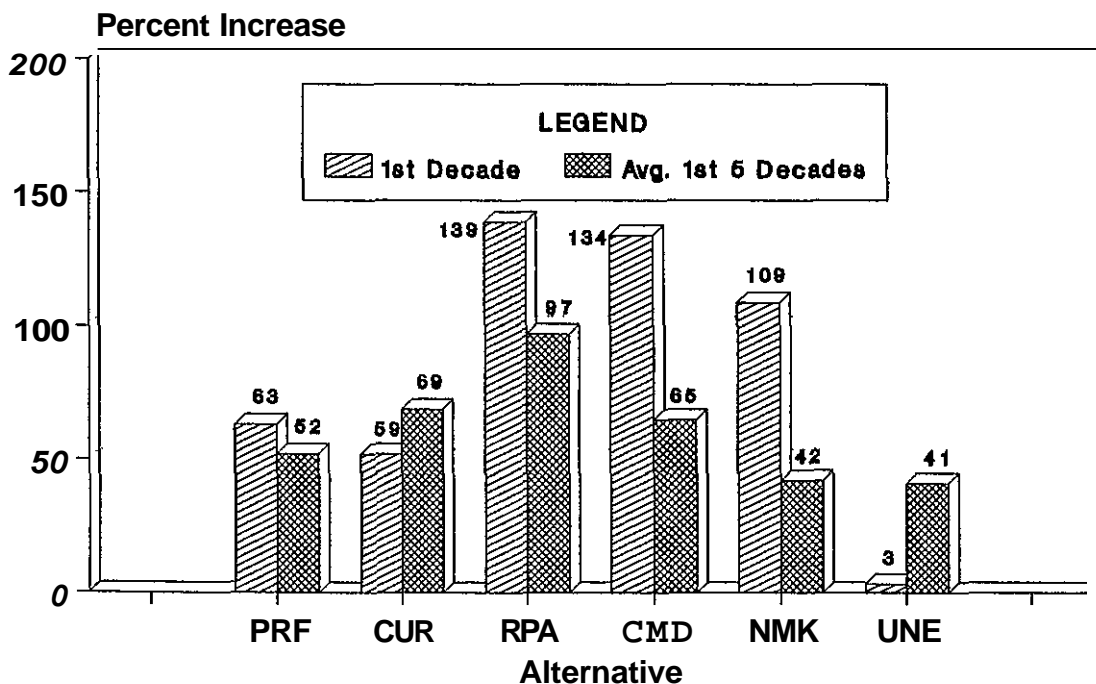

Alternative **UNE**. This alternative has a first-decade regeneration harvest of 14,800 acres, which is 3 percent greater than the **1977-1987** period; the average decade harvest for the first five decades is about 41 percent greater than the **1977-87** level. This alternative incorporates the more restrictive Forest S&G's for riparian areas/SMZ's.

The potential to damage riparian areas/SMZ's and the aquatic ecosystem would be low based on the overall low (first-decade)/moderate (five-decade) amount of activity on steep ground, and the more restrictive Tahoe NF riparian area/SMZ guides.

SENSITIVE PLANTS

To maintain the present populations of sensitive plant species, the TNF developed sensitive plant program standards and guidelines (see Forestwide S&G 23 in Chapter V of the Forest Plan). They assure that sensitive plant species are considered in all Forest projects. Sites not identified (obscured by heavy vegetation, poor flowering year, etc.) during project inventory, however, could be adversely affected.

To assess the consequences of the alternatives on sensitive plant species, effects were evaluated in terms of risk (high, moderate, and low).

Ground-disturbing activities, such as road building and timber harvesting, constitute a large percentage of forest management activities and provide a good measure to reflect and judge the effects of the various alternatives. The risk to sensitive plants and their habitats was determined by the number of acres proposed for ground-disturbing activities and the number of sensitive plant **sites** which inadvertently could be missed during preproject review. High risk represents an increased chance of disturbance, and low risk represents a decreased chance in relation to the other alternatives.

Alternatives PRF, CUR, RPA, CMD, and UNE would have the highest probable risk of disturbance. Alternative NMK would have the lowest risk of disturbance.

SOILS

Introduction

Land management activities have the potential to impact soils in several ways. Road construction is an example of a direct effect, *i.e.*, where soil is taken out of biotic or vegetative production; an intense wildfire, caused by excessive **fuel** loading, could have an indirect effect on the soil. The greatest potential to affect soil productivity, however, is the cumulative effect of many independently insignificant activities over long periods of time. This effect can be addressed by examining the effects that land management activities have on the following three soil characteristics: (1) soil depth, or thickness, (2) soil porosity, and (3) soil organic matter. Soil productivity—the inherent capacity to support the growth of specified plants, plant communities, or a sequence of plant communities—is dependent upon these basic soil characteristics.

Loss of soil depth can occur when management activities, such as broadcast burning or tractor piling to treat logging slash, leave insufficient soil cover to protect the soil from accelerated erosion. The incremental loss of soil by sheet erosion is a cumulative effect because significant soil loss over a rotation is generally too small to result in a measurable loss of tree growth. Because soil development for replacement is measured in thousands of years, soil loss is considered an irreversible effect.

Soil porosity may be reduced by operating heavy equipment when soil strength is low, causing compaction or puddling. The loss in porosity can cause a significant short-term loss in soil productivity. Although this effect can last for decades, recovery will occur over time. Tillage is an effective measure to accelerate the recovery of soil porosity.

Organic matter loss can occur through activities such as broadcast burning, tractor piling and burning logging slash, and other fuel reduction practices. The loss of organic matter can result in a short-term loss in soil productivity, although the effect may also be cumulative because most benefits of maintaining soil organic matter and large woody material accrue to future rotations. Lost organic matter can be replaced over time—if the soil can still support the growth of higher plants—but this could take several hundreds of years.

Appendix H, Soil Productivity, contains a more detailed discussion of how long-term soil productivity is related to these three soil characteristics. In the remainder of this section, the terms "soils" and "soil resource" are used interchangeably with long-term soil productivity.

Mitigation of Effects

The direct and indirect effects on soils associated with road construction, developed recreation sites, etc., are considered dedicated uses not dependent on soil productivity, and will not be mitigated. These effects, and the indirect effects of livestock grazing and wildfires, are disclosed in the comparison of alternatives that follows. The cumulative effects of management practices on long-term soil productivity will be mitigated by application of Forestwide Standard and Guideline (S&G) 55, Maintain Soil Productivity. This S&G will be applied to all alternatives and is considered essential to meet the minimum management requirement to avoid "... significant or permanent impairment of the productivity of the land ..." (36 CFR 219.27, part A). The S&G was developed to maintain long-term soil productivity by limiting incremental and cumulative losses of the three characteristics basic to soil productivity: (1) soil depth, (2) soil porosity, and (3) soil organic matter. To maintain soil depth, soil cover standards were developed to prevent soil loss by erosion from exceeding the rate of soil formation. The standard for soil porosity limits the loss of porosity to levels that would not affect forest stand growth. The guidelines for forest duff and large woody material maintain sufficient organic matter to provide essential habitat for numerous organisms important in nutrient cycling and to provide a reserve of nutrients for the future. Appendix H, Soil Productivity, contains a detailed discussion on how S&G 55 was developed and how it provides protection to the soil resource.

Unavoidable Effects

Unavoidable direct effects on soils occur when the soil is displaced or severely altered by constructing roads and trails, grading ski runs, developing campgrounds, developing mining areas, or by unrestricted off-highway vehicle traffic. There is also the unavoidable risk that the Forestwide S&G to mitigate cumulative effects on soils will not be 100-percent effective. There are several reasons for this. First, it is unlikely that the S&G would be perfectly implemented on every project; second, the S&G includes assumptions about the probability of natural events, i.e., storm intensity in relationship to soil erosion, third, measures to correct soil damage where the standards are not met are unlikely to be 100-percent effective, or for some valid reason may not be implemented; and, finally, the standard is based on current knowledge and understanding of the factors that affect soil productivity; additional knowledge and understanding may prove the standards inadequate. Monitoring the effectiveness as well as the implementation of S&G 55 will contribute to this knowledge and understanding, and will provide feedback for any necessary revisions.

Indicators of Effects

Indicators of unavoidable direct effects to the soil resource include acres developed for downhill skiing (Table 4.25), acres in developed campgrounds, miles of trails, (Table 4.14), miles of new road construction (Table 4.13), acres open to unrestricted OHV travel (Table 4.26), and acres withdrawn from mineral entry and leasing (Table 4.21). Acres withdrawn from mineral entry and leasing is an indicator of the area likely to be disturbed by mining activity; the more acres withdrawn, the lower the probability of disturbance. Indicators of indirect effects include AUM production (Table 4.22), and the risk of severe wildfire that could damage the soil. The risk of severe wildfire increases in proportion to the increase in timber harvest on slopes greater than 30 percent. This relationship is based on the assumption that more residue is likely to be left on the steep slopes, partly in response to other S&G's, and partly because fuel management is more difficult on steeper slopes.

The indicator used to analyze the risk of unavoidable adverse cumulative effects of timber management activities on soils is the Index of Relative Risk of Cumulative Effects on Long-Term Soil Productivity (Table 4.28). This index assumes that the relative risk of cumulative effects on soils is a function of the acres treated with soil-disturbing timber management activities. The index was developed for each alternative by: (1) listing all timber treatments with the potential to affect one or more of the three soil characteristics basic to soil productivity (depth, porosity, and organic matter); (2) assigning a weight for the potential impact of each treatment on each of these three soil Characteristics; (3) multiplying treated acres by the weighting factors for each treatment; and (4) dividing the total treated acres by the totals for the CUR alternative, which is considered the baseline for analysis. All treatments for a full rotation were listed, including harvest, site preparation, plantation release, and thinning. For each soil Characteristic, weight was relative to the most

severe treatment. For example, tractor piling was the reference for porosity, with a value of 1.0, thinning with a feller-buncher was assigned a weight of 0.6. Because some acres had multiple treatments, and some treatments had an impact on more than one soil characteristic, the totals resulting from this analysis were treated acre equivalents, and are useful only for comparing alternatives.

The direct, indirect, and cumulative effects on soils discussed in this section are on-site effects that apply only to National Forest System lands; they do not affect the soils of adjacent or intermingled private lands. Assuming a strong effort to implement S&G 55, Soil Productivity, and on-going monitoring of its implementation and effectiveness as described in Forest Plan Appendix K, Soil Monitoring, the risk of not maintaining long-term soil productivity under Alternative CUR should be relatively low.

Effects Common to All Alternatives

The acres developed for downhill skiing (Table 4.25) and acres in developed recreation sites are relatively small and would not differ significantly from Alternative CUR. The miles of trails open to OHV use when soil damage is likely to occur (Table 4.26) would be significantly higher than Alternative CUR in all alternatives, but differences among alternatives would not be significant. The area open to OHV traffic under all alternatives would be about half of Alternative CUR and would not differ significantly among alternatives. The effects of ski area development, developed recreation sites, and OHV use on the soil resource would be minor, largely because the acres affected would be small.

Comparison of Alternatives

Alternative CUR. New road construction would be a direct effect on the soil resource because it removes land from production. However, a transportation system is needed to manage the Forest and, relative to the amount of roads already in place, the acres of new construction would be relatively low (a little over 300 miles or 1,200 acres in the first 50 years). Although the amount of land closed to mineral entry and leasing would be low, the amount of land that would lose its biotic or vegetative production potential because of mining activity would be relatively small. Also, many land-disturbing impacts would likely occur on old diggings where the soil has already been severely altered. The livestock grazing represented by AUM production would cause some soil loss by erosion due to a loss of cover by overgrazing and bedding grounds. The areas affected, however, would be relatively small and would be monitored to develop soil cover standards and to determine if changes in current management would be needed. The risk of severe wildfire under this alternative would be moderate because of the large amount of timber management on slopes greater than 30 percent. The indices of risk in Table 4.28 serve as a reference for comparison with the other alternatives. With the implementation of Forestwide S&G 55, the risk index of 100 for this alternative would be considered a low risk of cumulative effects on long-term soil productivity.

TABLE 4.28 - INDEX OF RELATIVE RISK OF CUMULATIVE EFFECTS ON LONG-TERM SOIL PRODUCTIVITY^{1/}

	PRF	CUR	RPA	CMD	NMK	UNE
Soil Porosity	100	100	123	160	5	100
Soil Erosion	78	100	126	77	50	61
Soil Organic Matter	86	100	127	116	10	75
Overall Index	93	100	124	134	13	87

^{1/} Acres treated with soil-impacting activities (weighted for degree of impact) divided by acres treated under CUR alternative. Average for decades one through five.

Alternative PRF. Miles of new road construction, AUM production, and area closed to mineral entry and leasing in this alternative would not differ significantly from Alternative CUR. These direct and indirect effects would not differ significantly from Alternative CUR. The indirect effect of the risk of severe wildfire, however, would be significantly lower than Alternative CUR because fewer acres with slopes over 30 percent would be allocated to timber management. The risk index for cumulative effects would be the same as Alternative CUR for porosity, significantly less than Alternative CUR for organic matter, but significantly lower for soil erosion, – a reflection of fewer acres of timber management on steep slopes. The overall risk index would be slightly lower than Alternative CUR. The overall risk to the soil resource under this alternative would be low.

Alternative RPA. Miles of new road construction, AUM production, area closed to mineral entry and leasing, and risk of severe wildfire in this alternative would not differ significantly from Alternative CUR. These direct and indirect effects would not differ significantly from Alternative CUR. The risk index of cumulative effects for all three soil characteristics and for the overall index would be significantly higher for this alternative than for Alternative CUR. The overall risk to the soil resource under this alternative would be moderate.

Alternative CMD. Miles of new road construction, AUM production, and risk of severe wildfire in this alternative would not differ significantly from Alternative CUR. The area closed to mineral entry and leasing would be slightly higher than under Alternative CUR. These direct and indirect effects would not differ significantly from Alternative CUR. The overall risk index for cumulative effects, however, would be significantly higher than under Alternative CUR. The high risk index values for porosity and for organic matter, and lower risk index for erosion, reflect the large number of acres of tractor ground under timber management in this alternative. Although indices for porosity, organic matter, and the overall index would be significantly higher than under Alternative CUR, the lower index for erosion—the irreversible effect—would reduce the overall risk to the soil resource under this alternative to moderate.

Alternative NMK. Miles of new road construction would be slightly lower, and AUM production significantly lower under this alternative than under Alternative CUR. The area closed to mineral entry and leasing would be significantly higher than under Alternative CUR, which would reduce the probability of disturbance by mining activity. These direct and indirect effects on the soil resource would be significantly lower than under Alternative CUR. The risk of severe wildfire would be slightly higher, but not significantly different from Alternative CUR. This slightly higher risk would result from the relatively large area of steep slopes allocated to timber management, and from higher levels of organic residues left after harvest under this alternative. All risk indices for cumulative effects on the soil resource would be significantly lower than under Alternative CUR, which reflects the special emphasis under this alternative to leave most organic residues in place, and to restrict soil-disturbing activities such as tractor piling or broadcast burning. The risk index for erosion would not be as low as might be expected because of the relatively large allocation of steep slopes to timber management. The overall risk to the soil resource for this alternative would be very low.

Alternative UNE. Miles of new road construction and AUM production under this alternative would not differ significantly from Alternative CUR. These direct and indirect effects would not differ significantly from Alternative CUR. There would be slightly more area withdrawn from mineral entry and leasing, and the risk of severe wildfire would be significantly lower than Alternative CUR. The risk index for cumulative effects on porosity would be the same as for Alternative CUR, a reflection of the large acreage allocated to timber management on slopes less than 30 percent. The significantly lower risk index for soil erosion is because most land on slopes greater than 30 percent would be in shelterwood management systems. The overall risk index under this alternative would be slightly higher than Alternative CUR and the overall risk to the soil resource would be low.

SPECIAL INTEREST AREAS AND RESEARCH NATURAL AREAS

Table 2 14 in Chapter 2 displays the assignments by alternative of each Research Natural Area and Special Interest Area. Appendix C provides a detailed analysis of the effects of either designating or not designating each area. The information below summarizes Appendix C. Under all alternatives, Babbitt Peak is recommended for establishment as an RNA and Placer County Big Tree Grove is designated as an SIA. Decisions to designate SIAs are made in this EIS process by the Regional Forester.

Alternative PRF. Three of the five Research Natural Areas are recommended for establishment by the Chief of the Forest Service. Basin Peak area is not recommended for RNA designation because of the area's small size. Mt. Lola is not recommended and it is likely that management activities would result in a loss of the botanical values of the area. Of the 17 Special Interest Areas, seven are recommended for designation. Those not recommended would be managed for different uses, and three would likely lose their distinctive values because of management activities.

Alternatives CUR and RPA. Babbitt Peak is the only recommended RNA. Management activities in the remaining areas would likely result in a loss of RNA values. Of the SIA's, only Placer County Big Tree Grove is recommended for designation. Approximately one-fourth of the remaining SIA's would lose their distinctive qualities because of management activities.

Alternative CMD. Babbitt Peak and Sugar Pine Point are recommended for RNA establishment. The remaining areas would have their botanical values reduced by timber harvesting and other management activities. Seven of the proposed SIA's are recommended in this alternative. Of the areas not recommended, only two, LMI Truckee River Terrace and San Juan Ridge, would likely have their special characteristics reduced by timber harvesting and other management activities.

Alternative NMK. All proposed RNA's and SIA's are recommended for establishment. All candidate areas would be managed and their special values protected.

Alternative UNE. Basin Peak and Mt. Lola are not proposed for RNA establishment. The botanical values of Basin Peak would not likely be lost; however, alpine ski area development would reduce the values associated with Mt. Lola. Seven of the 17 SIA's are recommended for establishment in this alternative. Of the remaining areas, only the LMI Truckee River Terrace and San Juan Ridge area would have their special values reduced or lost.

TIMBER

The effects of each alternative on the timber resource are analyzed using the following indicators:

- Amount of suitable forest land allocated to timber management, and the intensity of management on those lands

- Mix of silvicultural systems and relative efficiency of the timber program

- Long-term harvest, growth, and inventory.

- Eastside pine harvest.

- Furbearer (pine marten, fisher, and Sierra Nevada red fox) habitat.

Landbase and Intensity of Management

Land available for timber management ultimately limits the productive capability of the Forest because an upper limit to the per acre yield always exists even at the highest intensities. The land tentatively suited for timber production was determined following a process described in Chapter 2 and in Appendix K. The landbase used for regulated timber management by alternative is listed in Tables 4.29 and 4.30.

UNE	208,775	95,706	96,863	127,192

An overall productivity index can be calculated by dividing the allowable sale quantity (ASQ) by the tentatively suitable lands (629,018 acres). This figure incorporates utilization of a potential landbase with management intensity. Alternatives with higher numbers indicate timber production closer to the potential of the Forest. Lower numbers are a result of landbase and management intensity tradeoffs for non-timber resource objectives such as wildlife habitat, recreation, visual quality, or watershed protection. Increases from the first to the fifth decade reflect increasing allowable sale quantity. Figures are expressed in board feet per acre per year. See Table 4.33.

UNE	176	182

Discussion

Alternatives CUR, RPA, and CMD are similar in overall environmental consequences. These three alternatives would have the largest suitable landbases, the largest percent of intensively managed forest land in the timber landbase, and the highest productivity index. In other words, these alternatives combine large, high quality timber landbases with high intensity management. Timber would be generally emphasized on capable, prime lands. One-half to two-thirds of the suitable land would be allocated to intensive, short rotation timber management. The highest yields would be produced by these alternatives, significantly above historical levels for the Tahoe NF. The RPA alternative would have the largest amount of acres assigned to full yields, but a smaller suitable landbase than Alternatives CUR or CMD because approximately 20,000 acres would be allocated to dispersed recreation (timber unsuitable). Alternative CMD would have the second largest total landbase, but the third largest amount of land in short rotation, even-age management, because 39,704 acres would be allocated to uneven-age management and 150,377 acres would be allocated to even-age, long rotation management. Alternative CUR would have the largest total landbase but also a relatively large amount of land in lower yield categories because it generally would match land allocations and management intensities in existing plans.

Alternatives NMK and UNE would be at the opposite end of the range of landbase and management intensity. Alternative NMK would have the smallest timber suitable landbase and the lowest productivity level. Alternative NMK essentially would operate on the existing, roaded landbase. Approximately 25 percent of the tentatively suited lands would be allocated to short rotation even-age management, but because herbicides would not be allowed reduced yields would be expected. Alternative UNE would have the lowest amount of land allocated to short rotation even-age management, but a total timber suitable landbase similar to the PRF alternative. Alternative UNE would allow the use of herbicides, but would have reduced yields because of the large amount of land under uneven-age management. Alternative NMK would have the lowest overall productivity and Alternative UNE has the second lowest. Alternatives NMK and UNE have a similar percentage of the total suitable forest land allocated to intensive timber management.

Alternative PRF lies between the CUR/RPA/CMD group and the NMK/UNE group in terms of suitable landbase, amount of land in the highest yield category, percent of intensively managed timber land, and overall timber productivity. Approximately one-half the suitable acres would be managed on a short rotation even-age basis. One-fourth of the suitable acres would produce marginal or incidental yields and the remainder of the suitable land would be managed on a long rotation or uneven-age management basis.

Mix of Silvicultural Systems and Efficiency

A comprehensive analysis of silvicultural systems is contained in Appendix L of this EIS. That analysis is the background for the present section and is suggested reading for better understanding of the summary contained here. Definitions to the technical terms can also be found in the glossary, which is in the Plan.

Efficiency in timber operations is most influenced by amount of land that must be accessed and treated for a given timber yield. Larger clearcuts (greater than 20 acres) tend to be the most efficient. Clearcuts in which a significant amount of residual understory trees, snags, and hardwoods are left are less efficient, as are shelterwood cuts (which involve two entries). Small openings scattered over a large area greatly reduce efficiency because of fixed costs associated with managing each opening, regardless of size. Uneven-age management requires large start-up investments because needed administrative systems, such as specialized inventories, are not currently in place. These needs would tend to make uneven-age management inefficient during the first decade of implementation. Uneven-aged management will be tested during the first decade to determine feasibility of implementing on a larger scale.

Table 4-34 Summarizes average annual harvest acres for the first decade by silvicultural practice for each alternative.

ALTERNATIVE	CLEARCUT	SEED STEP SHELTERWOOD	GROUP SELECTION
PRF	2,046	1,657	162
CUR	2,810	1,000	0
RPA	5,650	80	0
CMD	2,300	3,403	250
NMK	3,628*	1,263	0
UNE	257	1,481	1,605

ALTERNATIVE	ESTIMATED NUMBER OF OPENINGS/YEAR	ESTIMATED NUMBER OF OPENINGS/MMBF
PRF	300	2.9
CUR	220	1.6
RPA	330	2.3
CMD	450	2.9
NMK	1,630	22.0
UNE	900	10.0

efficient. Clearcutting would be emphasized and opening size not restricted below the Regional standard of 40 acres maximum. Implementation of such a large program increase might take several years. Areas under existing contracts would likely limit full implementation. Effects of the herbicide moratorium might cause difficulty in dispersing new openings.

Alternative CMD would also have a large program, but shelterwood cutting would be emphasized over clearcutting. There would be risk in creating large acreages of shelterwood if the market for the overwood removal step is not strong. The inability to remove overwood at the optimum time risks damage to the understory trees, increases growth loss, and delays entry into adjacent stands. Overwood removal of seed step cutting from the 1970's has recently begun. It is not clear how a large program of overstory removal will fare. A significant amount of group selection is scheduled in Alternative CMD. While some inefficiency associated with implementing the program would occur, it probably would not be necessary to restructure the standard timber management systems and organization. Group selection could occur on steep land, however, but there are major questions about the long-term success of uneven-age management on cable ground. Many of these questions are expected to be answered within the next decade as a result of new and ongoing silvicultural research.

Alternative PRF would have a higher proportion of shelterwood cutting to clearcutting than in the past decade. Depending on the market for overstory removal cutting, some risks of creating large acreages of stands needing overstory removal would exist. Clearcut openings would remain similar to present sizes, although most areas would contain patches of small residual trees, hardwoods, snags, and down logs. A small program of uneven-age management would be implemented in five timber compartments to gain information on the operational requirements of the system, possibly in preparation for a larger application in the future. Few adjustments would be needed to accommodate this level of uneven-age management.

Alternative NMK would have a relatively large clearcutting program, a large shelterwood program, and no uneven-age management. Efficiencies implied by this mix of silvicultural methods are counteracted by an opening size limit of three acres. Consequently, about six to seven times more openings per MMBF would have to be managed than under present conditions. Major administrative and organizational changes would have to occur to manage this number of openings. Funding for this intensity of management is questionable, particularly since the relatively cost-effective tool of herbicides would not be allowed. Management of such small units on steep lands would be extremely difficult and possibly infeasible in some cases. Costs are likely to be prohibitive on cable ground, particularly in the red fir and eastside pine forest types where the market has not been strong.

Alternative UNE would have a very small clearcutting program, a large shelterwood program (on steep ground), and a very large group selection program on tractor ground. There would be a four- or five-fold increase in the number of openings per MMBF from the present. Major organizational and administrative changes would have to be made to implement uneven-age management as the predominant silvicultural system on the Forest. There would be large start up costs. The shelterwood program would be very costly. The eastside pine and red fir types might not support regeneration costs for both shelterwood and group selection. Timely overstory removal would depend on market conditions, and the situation would be made more uncertain by low volumes per acre on cable ground.

Long-term Harvest, Growth, and Inventory.

Figures 4.19, 4.20, 4.21, and 4.22 show the long-term levels and trends of harvest, growth, inventory, and long-term sustained yield capacity (LTSYC), respectively, for each alternative. Growth, expressed as percent of the long-term sustained yield capacity, is shown for the fifth and last decades of the 150-year planning horizon. Alternatives at or above 90 percent of LTSYC after 15 decades have most stands growing near their potential within their yield or intensity class. Long-term harvest, growth, inventory, and LTSYC are expressed in cubic feet. Cubic feet is a uniform measure over time and is not sensitive to changes in board foot/cubic foot ratios. The current Forestwide BF/CF ratio is 6.5, but would change over time under different scenarios of conversion of older wild stands to younger managed stands.

In general, an inventory pattern that shows a sharp decrease in the first few decades, then recovery and a leveling off for the rest of the planning horizon, indicates efficient use of the inventory for timber production. Normally there would be a growth pattern of a slight drop, then rapid increase over starting growth, and then fluctuation around a high growth level that accompanies the inventory pattern just described. The reason for these patterns is that relatively slow growing wild stands are converted early in the planning horizon to rapidly growing managed plantations. The inventory is reduced initially but recovers fairly quickly. Intensive intermediate cutting and stand replacement keeps the inventory steady. Growth is reduced for a short period, but recovers rapidly to a much higher level.

In contrast, a steadily increasing inventory and growth that remains steady or slightly decreases indicates conservative use of the timber resource. The inventory of wild stands is held longer, wild stands are not converted to a more productive condition very quickly and, consequently, growth is sluggish over time. These patterns suggest underutilization of the potential timber resource.

Figure 4.19: Long-term Timber Harvest by Alternative

Figure 4.20: Long-term Timber Growth by Alternative

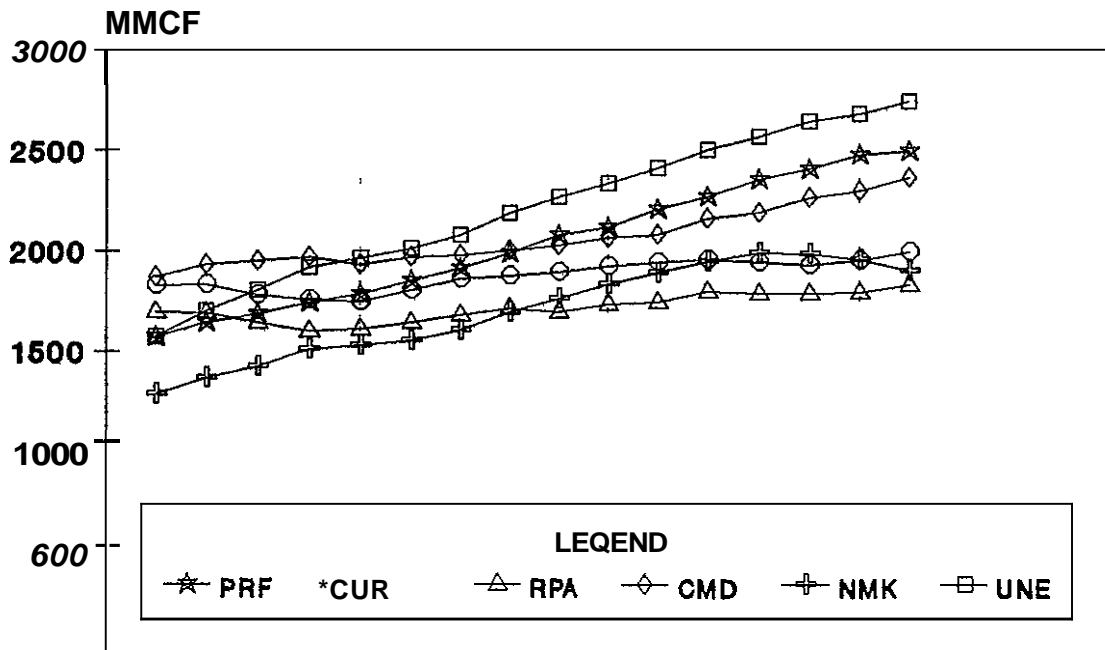

Figure 4.21: Long-term Timber Inventory by Alternative

Discussion

Alternative PRF would maintain a harvest (ASQ) of 220 MMCF (1,423 MMBF) per decade until the 15th decade, when it would increase to 249 MMCF. Growth would be about 300 MMCF in the first decade and then fluctuate between 200 and 300 MMCF for the rest of the planning horizon. Growth at the fifth decade would be 287 MMCF (106 percent of the LTSYC of 272 MMCF). At the 16th decade growth would be 237 MMCF or 87 percent of LTSYC. Inventory would start at a low of about 1,570 MMCF then steadily climb to 2,490 MMCF. These patterns suggest considerable restraint in use of the inventory and underutilization of the growth potential of the forest. It is a pattern typical of a largely young growth forest composed of wild stands with slow conversion to managed plantations.

Alternative CUR would start with a harvest of 267 MMCF (1,734 MMBF) in the first decade, climb to 298 MMCF in the second decade, and then increase to 311 MMCF for the rest of the planning horizon. Growth would start at 273 MMCF in the first decade, increase to 354 MMCF by the fifth period (95 percent of the LTSYC of 372 MMCF), and then fluctuate between 300 MMCF and 350 MMCF for the rest of the planning horizon. At the last decade growth would again be at 354 MMCF or 95 percent of the LTSYC. Inventory under Alternative CUR would begin at 1,827 MMCF, decrease to a low of 1,751 MMCF in the fifth period, then steadily rise to 1,994 MMCF at the 16th period. These patterns are indicative of relatively efficient use of the inventory and rapid conversion of wild stands to more productive managed plantations.

Alternative RPA would have a first-decade harvest of 266 MMCF (1,729 MMBF), increase to 286 MMCF in the second decade, and then increase again and level off at 305 MMCF in the third period. Growth would be at 261 MMCF initially, dip to 237 MMCF, then rise to 341 MMCF by the 5th decade. For the rest of the planning horizon growth would fluctuate between 300 and 350 MMCF. At the 16th period growth would be 341 MMCF or 95 percent of LTSYC. Inventory would begin at 1,700 MMCF, drop to almost 1,600 in the fourth period, then rise steadily to over 1,800 MMCF near the end of the planning horizon. Similar to Alternative CUR, the patterns show efficient use of the timber resource and resultant high yields.

Alternative CMD would start with a first-decade harvest of 278 MMCF (1,801 MMBF), increase over the next four decades to 303 MMCF, then level off. Growth would initially be 338 MMCF, dip to 260 MMCF in the fourth decade, then recover to 342 MMCF in the fifth period (103 percent of the LTSYC of 331 MMCF). For the rest of the planning horizon growth would be between about 310 MMCF and 380 MMCF per decade. At the end of the planning horizon, growth would be 324 MMCF or 98 percent of LTSYC. Inventory under Alternative CMD would begin at 1,873 MMCF and then steadily rise to over 2,300 MMCF by the end of the 160-year planning horizon. Harvest, growth, and inventory patterns show a combination of efficient and inefficient patterns. A large inventory is held and growth would not decrease rapidly until about the fourth period, but LTSYC and harvest would be relatively high later in the planning horizon. The reliance on uneven-age management and shelterwood cutting for a large portion of the harvest is the probable reason for the combination of patterns.

Alternative NMK would have a constant harvest of about 160 MMCF (1,040 MMBF). Growth would start at 245 MMCF in the first period, rapidly drop in decades 4 through 5, recover to about 230 MMCF in decades 7 through 12, and then steadily drop to 108 MMCF by the end of the planning horizon (68 percent of LTSYC). Growth during the fifth decade would be 189 MMCF or 111 percent of the LTSYC of 170 MMCF. Inventory would be at 1,292 MMCF in the first period, increase to 1,988 MMCF in the 13th decade, then decrease to 1,901 MMCF by the 16th period. These patterns suggest severe underutilization of the timber resource potential. The dropping off of the inventory and growth in the last decades indicates significant mortality.

Alternative UNE would have a first-decade harvest of 172 MMCF (1,108 MMBF), increase to 177 MMCF in the second decade, then remain at that level. Growth would start at 301 MMCF, drop to a low of 219 MMCF in the fourth period, then fluctuate between about 280 MMCF and 230 MMCF for the rest of the planning horizon. During the fifth period growth would be 226 MMCF or 89 percent of the LTSYC of 253 MMCF. At the end of the 160-year planning horizon, growth would be 234 MMCF (93 percent of LTSYC). Inventory would initially be at 1,574 MMCF and would rise to 2,734 MMCF after 150 years. A very large inventory would be carried through the planning horizon, indicating inefficient inventory use. The growth drop and recovery during periods 4 through 6 result from large amounts of shelterwood cutting in the second and third decades.

Eastside Pine Harvest

The market for small Jeffrey and ponderosa pine on the eastside of the Forest has not been strong. Timber sales have been offered recently with no buyers. About 3 MMBF per year has been sold in the past several years but with little or no bid premium on those sales. Until small log processing or cogeneration facilities are available, the market for eastside pine is likely to remain uncertain. Listed in Table 4.36 are the scheduled outputs in million board feet per year for eastside pine by alternative.

TABLE 4.36 - SCHEDULED OUTPUTS PER YEAR FOR EASTSIDE PINE BY ALTERNATIVE (MMBF)

ALTERNATIVE	DECADE1	DECADE2	DECADE3	DECADE4	DECADE5
PRF	6	6	14	14	14
CUR	5	17	8	37	26
RPA	16	23	22	22	20
CMD	11	12	15	22	20
NMK	18	18	18	10	14
UNE	6	6	11	11	11

Discussion

Alternatives PRF, CUR, and UNE would schedule about double the recently sold volume level in the first decade. There would be some risk that a portion of the volume would not be sold. The volume above 3 MMBF per year represents 2.1 percent of the ASQ for Alternative PRF, 1.2 percent for Alternative CUR, and 2.7 percent for Alternative UNE. The volume could likely be substituted from other forest types without major disruptions in the program.

Alternatives RPA, CMD, and NMK would schedule about four to six times the recently sold volume in the first decade. There would be a major risk that this volume could not be sold. The volume above 3 MMBF per year represents 7.5 percent of the ASQ for the RPA alternative, 4.4 percent of the ASQ for the CMD alternative, and 14 percent of the ASQ for the NMK alternative. It is unlikely that in the NMK and RPA alternatives this volume could be completely substituted from other forest types.

In the second decade, Alternatives PRF and UNE would continue to schedule eastside pine volume at relatively low levels. The other alternatives schedule volume at levels well above the present sell level. The percent of the ASQ that is eastside pine volume in the second decade is shown in Table 4.37.

TABLE 4.37 - PERCENT OF ASQ THAT IS EASTSIDE PINE VOLUME (SECOND DECADE)

PRF	CUR	RPA	CMD	NMK	UNE
4%	9%	12%	6%	17%	5%

Furbearer (Pine Marten, Fisher, and Sierra Nevada Red Fox) Habitat

TABLE 4.38 - POTENTIAL ASQ REDUCTION (MMBF/YR) FOR FURBEARERS BY ALTERNATIVE

	PRF	CUR	RPA	CMD	NMK	UNE
Projected ASQ	142.3	173.4	173.0	180.1	104.9	110.8
Potential Reduction *						
A (12%)	13-14	22-23	19-20	18-19	8-9	10-11
B (5%)	25-26	40-41	36-37	33-34	17-18	19-20
C (0%)	33-34	53-54	48-49	43-44	23-24	25-26

* Assumes all needed furbearer acres are used

A -- Represents 10% yields for denning/nesting habitat and 14% yields for travel corridors: average yield is 12%

B -- Represents 5% yields for denning/nesting habitat and for travel corridors.

C -- Represents no scheduled harvest (0% yields) in either denning/nesting habitat and travel corridors.

The potential effect on timber supply, or allowable sale quantity (ASQ), of providing for furbearers is shown in Table 4.38. This potential reduction would result from the implementation of Forestwide Standard and Guideline 23 (Endangered, Threatened, and Sensitive Species Management). In order to provide for furbearer needs, it is estimated that S&G #23 would be implemented on about 19 percent of the acreage of strata M3G, 45 percent of M4G, 9 percent of M4P, 45 percent of M6G, 39 percent of R3G, 36 percent of R4G and 10 percent of R4P (See Forest Plan Appendix H for strata descriptions.) Actual timber yield projections that can be obtained from areas managed for furbearers are under development. This table represents three possible yield scenarios: 12 percent average yields, 5 percent average yields, and total dedication (no yields). The actual yield effect, which will be dependent upon the actual prescription that is developed, will be determined during project-level environmental analysis using site-specific information. The effects of the furbearer prescription on ASQ will be monitored.

VEGETATIVE TYPES (CHAPARRAL)

Because of the small and scattered acreage of manageable chaparral, only moderate opportunities for a chaparral management program exist on the TNF, and no wide range of options were analyzed by alternative theme. Therefore, chaparral acreage and make-up would not differ significantly by alternative.

VISUAL RESOURCES

To display the effects of the alternatives on the landscape, or visual resources, the following indicators are used

- 1 Initial and Recommended Visual Quality Objectives (Table 4.39)
- 2 Existing and Future Visual Condition (Table 4.40)
- 3 Visual Condition (VC) - Visual Quality Objective (VQO) (Figure 4.23)
- 4 Visual Quality Index (Figure 4.24)
- 5 Change in Visual Condition (Appendix F)
6. Visual Rehabilitation Needs (Figure 4.25)
- 7 Visual Condition Decline Index (Figure 4.26)

These indicators compare the alternatives to two baselines the initial visual quality objectives (VQO's) and the existing visual condition. The initial VQOs evolved from an inventory of the Forest's physical and social environment. They set preliminary goals on predicted acceptable amounts of landscape alteration prior to consideration of other resource values. The other baseline, the existing visual condition (EVC), measures and describes how the landscape presently looks. While the initial VQO's and the EVC of any given area are not necessarily the same (since the former sets a preliminary goal for the future and the latter displays a current condition), the six VQO levels do equate to the six visual conditions displayed in Figure 4.23. Visual quality objectives set targets on how the landscape should **look** by a particular time in the future.

- 1 Initial and Recommended Visual Quality Objectives Table 4.39 displays the number of acres that would be placed under each VQO, subdivided by variety classes and distance zones, for each alternative. The table includes initial VQO acreages for purposes of comparison. Thus, the table displays the composition of lands assigned to each VQO with respect to their visual significance (foreground lands being more significant than middleground and background, and variety class A lands being more important than variety class C lands).
2. **Existing** and Future Visual Condition (**FVC**). Table 4.40 displays the FVC, how natural or altered the land would **look**, by the fifth decade for each alternative. The table shows how altered the land would look under each alternative compared to the areas present condition, and on a relative basis, whether the areas altered or left natural would tend to **be** scenic or common.

Predictions of FVC are largely based on the acreage harvested each decade because timber harvests alter the landscape more than other management activities. The Forest landscape architect estimates that by the fifth decade the overall visual condition would have reached a steady state in all alternatives because the regrowth of old harvest units balances the effects of new harvesting.

3. Visual Quality Index (**VQI**) Figure 4.24 illustrates the VQI of each alternative for the fifth decade. The VQI is a composite rating of the visual quality of the entire Forest. Figure 4.24 compares the overall VQI of each alternative to: (1) the other alternatives, (2) the maximum visual quality possible if the entire Forest were left totally natural, (3) the minimum visual quality possible if the Forest landscape were dominated by very obvious alterations, (4) the existing visual quality, and (5) the visual quality that would result if the initial VQO's were implemented. Thus, each alternative's increase or decrease in visual quality can be determined by comparing the alternative's VQI to the existing VQI and to the maximum possible increase or decrease.
- 4 Change in Visual Condition Appendix F illustrates the changes from the existing visual condition (EVC) to the future visual condition (FVC) by alternative. The figures trace the future change in the amount of human alterations for the lands in each EVC level. Starting with the number of acres of a given visual condition, one can see how many acres would be improved to show **less** evidence of management activities, how many acres would not be changed, and how many acres would decline in visual condition. The degree of change can also be determined by comparing the EVC level that designates the current condition of a given block of acreage to the FVC to which those acres would evolve. The information from these figures is the source for the amount of area needing rehabilitation (Figure 4.25) and the visual condition decline index (Figure 4.26).

- 5 **Visual Rehabilitation Needs** Graph Figure 4.25 shows the acres of TNF land which currently would not meet each alternative's VQO. Alternatives that set higher VQOs tend to have higher rehabilitation needs.
- 6 **Visual Condition Decline** Index Figure 4.26 measures by alternative the total reduction in the scenic quality of the TNF from its current condition. This index is derived from three factors: (1) the number of acres that decline in visual condition, (2) the degree that those acres decline, and (3) the future visual condition of those acres. Thus, two acres that decline from EVC I to FVC II count twice as much in this index as does one acre that declines from EVC I to FVC II. Similarly, one acre that declines from EVC I to FVC III (two levels of decline) would count twice as much as one acre that declines only one level from EVC II to FVC III. However, one acre that declines from EVC I to FVC II counts twice as much as an acre that declines from EVC III to FVC IV because of the higher ending condition (FVC). Higher FVC's generally correlate to a greater emphasis on visual quality assigned by that alternative

All Alternatives. In many areas of the TNF, private land (primarily private timber land) is heavily interspersed with National Forest System lands. In these situations the possibility exists for cumulative visual impacts from logging and road building activities. When possible, these possible cumulative impacts are avoided by cooperation with private landowners or by using design techniques on National Forest System lands that soften, reduce, or avoid visual impacts that could be created in conjunction with private lands. Even with these efforts there are situations where management activities and timber cutting on National Forest System lands could add to the visual cumulative effect to the point that the overall visual quality of the area would be reduced. In regards to the alternatives, it is expected that in the alternatives where there would be more management activities there would be more potential for visual cumulative impacts.

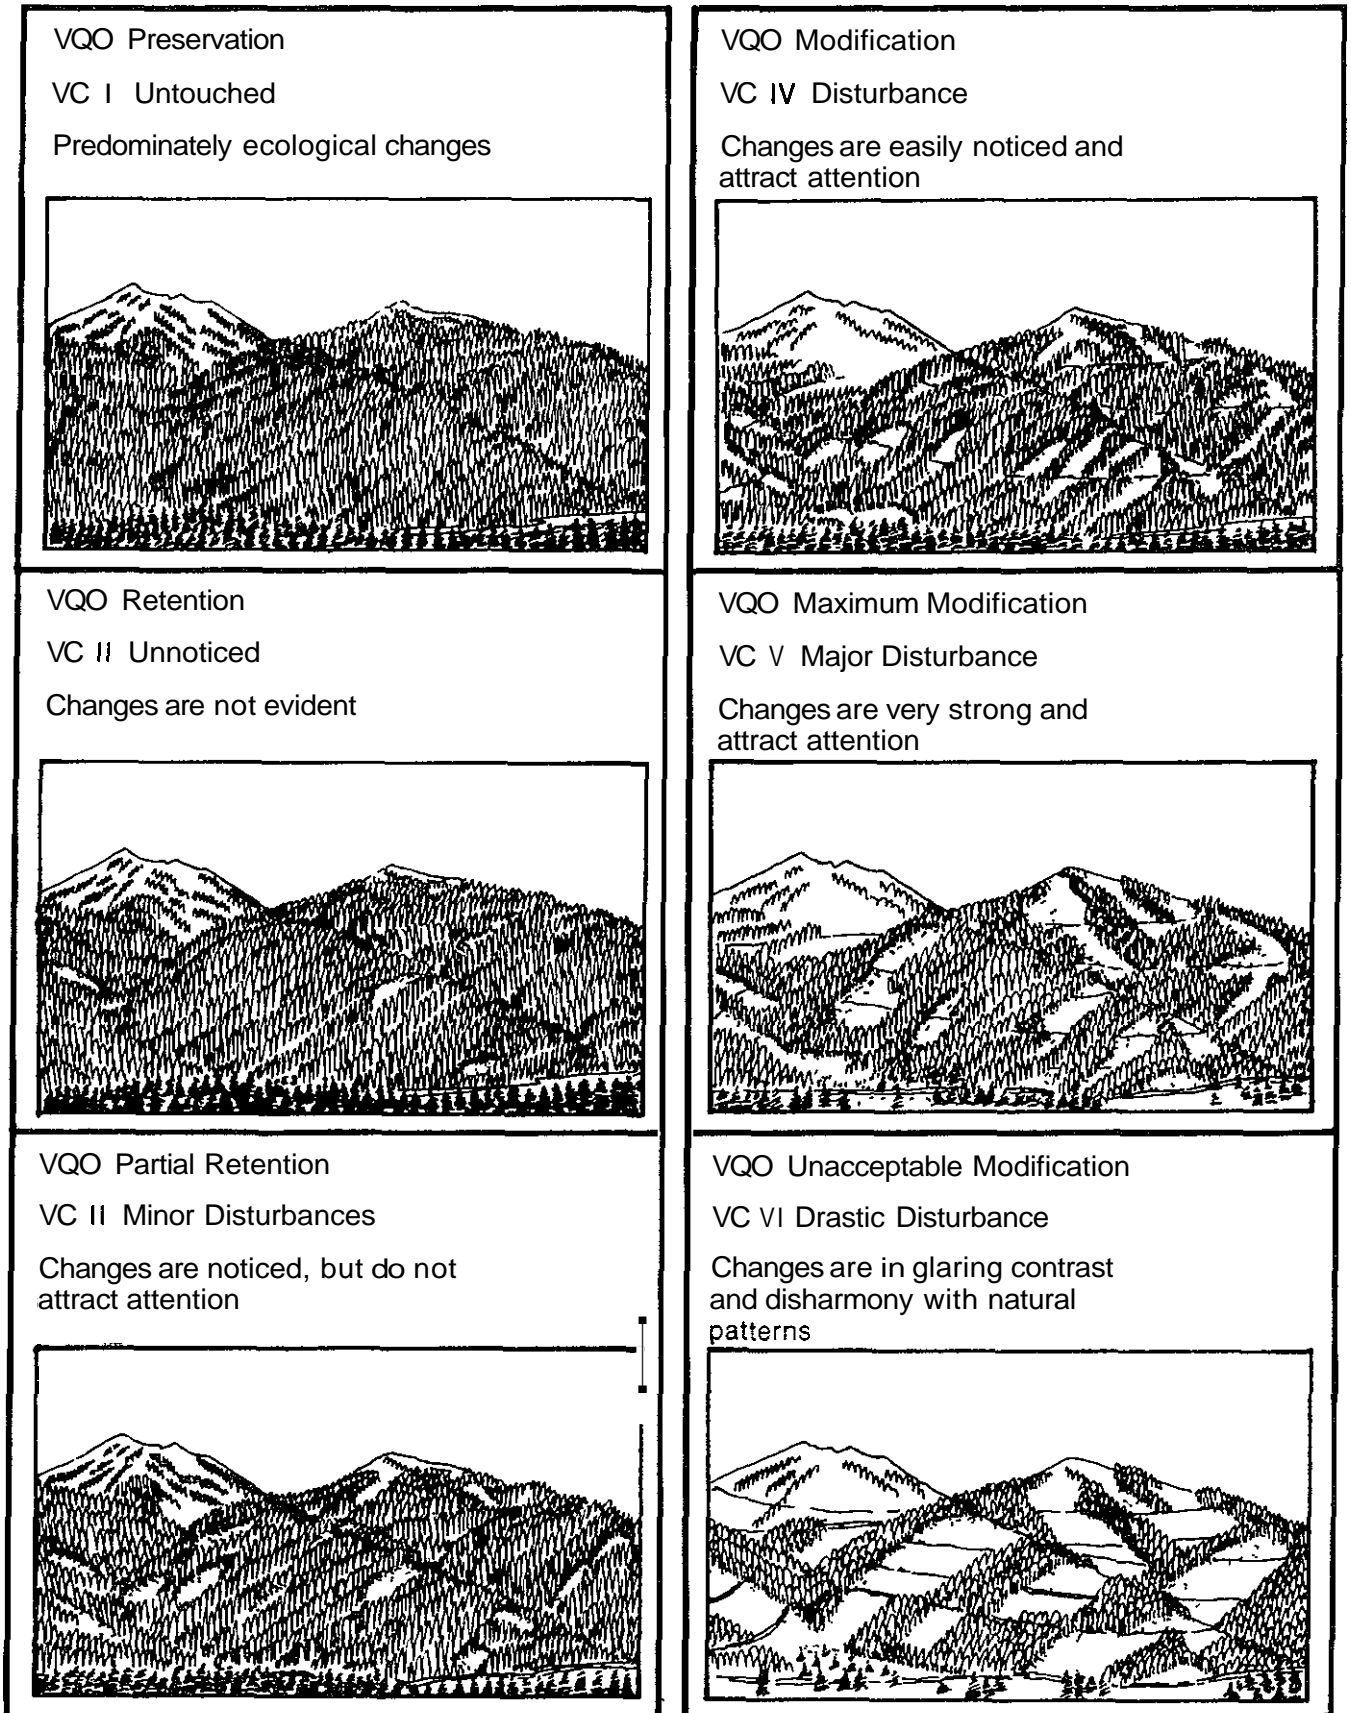

Alternative PRF. The PRF alternative would improve visual quality on 9.6 percent, maintain current visual quality levels on 25.5 percent, and reduce visual quality on 64.9 percent of the TNF. The overall visual quality of this alternative, measured by the VQI, is in the upper two thirds of all alternatives. The VQI would decrease by 5.4 from current conditions, a 10.4 percent decrease.

Five specially designated areas, the Granite Chief Wilderness, the North Fork American Wild River, and Sugar Pine Point, Lyon Peak/Needle Lake, and Babbm Peak Research Natural Areas, would be managed to appear pristine. Most foreground zones seen from major travel corridors, reservoirs, developed sites, and most major dispersed recreation areas would appear natural or almost natural with minor evidence of human changes. Most middleground views would be dominated by obvious landscape changes (chiefly, alterations in vegetative patterns caused by timber harvesting). About 5 times more acres would be in this condition than there are now. Some more visually important middleground areas, including the middlegrounds of State scenic highways, would remain largely natural in appearance with minor evidence of human activities. The major rivers crossing the Forest, the North Yuba, Middle Yuba, South Yuba, North Fork of the Middle Fork American River, and the Middle Fork American River would remain mostly natural appearing.

While most highly sensitive foreground zones would retain a natural appearance, many views that extend into the middleground and background would be dominated by the effects of timber harvests. Many moderately sensitive foreground zones would also have management activities that dominate the landscape. Timber management, however, would be generally less intensive on lands over 5,500 feet in elevation. These high country areas are the most scenic landscapes on the Forest. Consequently, while the effects of timber practices would be evident in middle and distant views in the uplands, those effects would generally be subordinate to the natural landscape.

Alternative CUR. This alternative would improve visual quality on 7.1 percent, maintain current visual quality levels on 19.0 percent, and reduce visual quality on 73.9 percent of the TNF. The overall visual quality that would result from this alternative is in the lowest quarter of all alternatives. The VQI would decrease from current conditions by 10.2, a 19.6 percent decrease.

1/ The VQO's are set for each alternative based on the management prescriptions for each area in order to be compatible with those prescriptions

2/ The three Variety Classes indicate the natural scenic quality of landscapes. Variety Class A refers to highly scenic distinctive areas, Variety Class B is associated with common or widespread landscapes, and Variety Class C corresponds to dull, monotonous landscapes

3/ Distance Zone FG - Foreground, MBG - Middle and Background.

4/ Initial VQO's are derived from an inventory system that does not generate any preservation VQO's unless the land has been, or is, awaiting classification as Wilderness, Research Natural Area, etc. The initial VQO is the result of an inventory process and sets preliminary goals on predicted acceptable amounts of landscape alteration (prior to the consideration of other resource values)

5/ NMK alternative. Initially, no VQOs were set for managed timber acres in this alternative because of the three-acre limit in opening size for timber harvest. The final VQO's set in this table are based on estimates of how many managed timber acres could meet each VQO along with the normal allocation of VQO's for other acres such as SPNM, recreation sites, etc.

6/ UNE alternative. The VQO's set for this alternative are based on the PRF alternative plus several areas with improved VQO's, and VQO's adjusted higher based on the estimated number of acres of uneven-age management that would meet partial retention and retention VQO's

Figure 4.25: Visual Rehabilitation Acres, Fifth Decade

Figure 4.26: Visual Condition Decline Index, Fifth Decade

In the CUR alternative, as in all of the alternatives, the Granite Chief Wilderness, the North Fork American Wild River, and the Babbitt Peak Research Natural Area would be managed to appear pristine. Most visually sensitive foregrounds seen from travel corridors, reservoirs, and developed sites would appear natural or almost natural with minor evidence of human changes. Relatively few acres would be managed to maintain their natural appearance for dispersed recreation. Most middleground and background views would be dominated by obvious landscape changes (chiefly alterations in vegetative patterns caused by timber harvesting). Areas dominated by human alterations would be 9 times greater than current conditions under this alternative. Thus, while most highly sensitive and some moderately sensitive foreground zones would retain a natural appearance, most middleground and background views throughout the Forest would be dominated by the effects of timber harvests.

Alternative RPA. This alternative would improve the visual quality on 7.6 percent, maintain current visual quality levels on 17.7 percent, and reduce visual quality on 74.7 percent of the TNF. The overall visual quality that would result from this alternative is in the lowest quarter of all alternatives. The VQI would decrease from current conditions by 9.6, an 18.5 percent decrease.

Three specially designated areas, the Granite Chief Wilderness, the North Fork American Wild River, and the Babbitt Peak Research Natural Area, would be managed to appear pristine. Most foreground zones seen from travel corridors, reservoirs, and developed sites would appear natural or nearly natural with minor evidence of human changes. In addition, those lands in the middleground views of State scenic highways would be managed to retain an almost natural appearance. Most other lands in background and middleground zones would be dominated by obvious landscape alterations (chiefly, alterations in vegetative patterns). Over 8 times more land would appear obviously altered by human activities than currently exists. Most sensitive foreground zones of major roads, reservoirs, and recreational trails would be maintained with an essentially natural appearance. Except for the State scenic highway corridors, which would remain predominantly natural, management activities would dominate most middleground and background areas throughout the Forest.

Alternative CMD. The CMD alternative would improve the visual quality on 5.6 percent, maintain the current visual quality levels on 8.9 percent, and reduce the visual quality on 85.5 percent of the TNF. The overall visual quality that would result from this alternative is the lowest of all the alternatives analyzed. The VQI would decrease from current conditions by 12.1, a 23.3 percent decrease.

Of all alternatives, the CMD alternative would show the most evidence of management activities. The North Fork American Wild River, Granite Chief Wilderness, and the Sugar Pine Point and the Babbitt Peak Research Natural Areas would be managed to appear untouched. Most of the rest of the Forest would appear predominantly altered. The foregrounds and middlegrounds of the State scenic highways would be managed to maintain a mostly natural appearance. Also the foregrounds of the major reservoirs on the forest would be managed to maintain a natural appearance.

Management activities would obviously alter about 10 times as much area as is presently affected. The foreground, middleground, and background of virtually all views of the TNF outside of the State scenic highway corridors and reservoir foregrounds would be dominated by human-caused changes of the landscape.

Alternative NMK. This alternative would improve the visual quality on 12 percent, maintain the current visual quality levels on 60 percent, and reduce visual quality on 28 percent of the TNF. This alternative has the highest overall visual quality of all the alternatives analyzed. The VQI would decrease from current conditions by 2.7, a 5.1 percent decrease.

The NMK alternative would manage the most areas of any alternative for natural appearance. The Babbitt Peak, Basin Peak, Mt. Lola, Lyon Peak/Needle Lake, and Sugar Pine Point Research Natural Areas, the Granite Chief Wilderness, and the North Fork American Wild River would be managed to retain a pristine appearance. The West Yuba, East Yuba, North Fork of the American River, Duncan Canyon, Castle Peak, Grouse Lakes, North Fork of the Middle Fork of the American River, Bald Mountain, Middle Yuba, North Lafayette (a new proposal in this alternative), and Lakes (Basin) roadless areas would be managed to retain a natural appearance. In general, the level of landscape alterations on the remainder of the TNF would appear mostly natural for approximately three quarters of the Forest. In this alternative there would be no effort at

setting visual priorities on timbered lands for specific roads or use areas of high public sensitivity other than the State Scenic highways. However, because of the limited size of timber harvest openings, in most cases the landscape would look natural or mostly natural. Around one quarter of the Forest acres would have some level of alterations from Forest road construction and harvest openings that would be visible and obvious to the Forest visitor. The obvious changes would tend to be seen on steeper slopes in middleground and foreground views or in immediate foreground on gentle slopes. The small size of openings would tend to moderate the visual impact of management activities so that this alternative has the least acres where there would be strong obvious alterations that would dominate the landscape. The foreground and middleground views of State scenic highways would be managed to maintain a mostly natural appearance.

Thus, the TNF landscape would have a natural or mostly natural appearance on a majority of Forest lands. Management activities would occasionally dominate the landscape to a moderate degree in areas with steeper slopes in foreground and middleground. Overall this alternative provides the most areas where the natural landscape character would dominate.

Alternative UNE. The UNE alternative would improve visual quality on 11.1 percent, maintain current visual quality levels on 29.4 percent, and reduce visual quality on 59.5 percent of the TNF. The overall visual quality of this alternative, measured by the VQI, is in the highest quarter of all alternatives. The VQI would decrease by 4.2 from current conditions, an 8 percent decrease.

Five specially designated areas, the Granite Chief Wilderness, The North Fork American Wild River, Sugar Pine Point, Lyon Peak/Needle Lake, and Babbitt Peak Research Natural Areas, would be managed to appear pristine. Most foreground zones seen from major travel corridors, reservoirs, developed sites, and most major dispersed recreation areas would appear natural or almost natural with minor evidence of human changes. Many middleground views would be dominated by obvious landscape changes (chiefly, alterations in vegetative patterns caused by timber harvesting). With uneven-aged management, fewer middleground views would look altered than in the PRF alternative because of small openings (less than two acres) and Selective logging. In the background views uneven-aged harvest activities generally would not be visible. In the foreground uneven-aged management would reduce the visual impact along secondary roads that otherwise would look substantially altered. Less than 4 times more acres would be in this condition than there are now. Some more visually important middleground areas, including the middlegrounds of State scenic highways, would remain largely natural in appearance with minor evidence of human activities. The North Yuba, Middle Yuba, South Yuba, North Fork of the Middle Fork American River, and the Middle Fork American River would appear mostly natural.

While most highly sensitive foreground zones would retain a natural appearance, many views that extend into the middleground and background would be moderately dominated by the effects of timber harvests. Some moderately sensitive foreground zones would also have management activities that dominate the landscape. Uneven-aged timber harvesting activities would reduce the overall visual impact in many of the above areas. Also, timber management would be generally less intensive on lands over 5,500 feet in elevation. These high country areas are the most scenic landscapes on the Forest. Consequently, while the effects of timber practices would be evident in middle and distant views in the uplands, those effects would be generally subordinate to the natural landscape.

WATER

Indicators used to display effects of each alternative are (1) cumulative watershed effects (CWE's), and (2) improved watershed conditions (i.e., soil and water resource improvement).

The primary management activity influencing CWEs is timber management, which includes timber harvesting, associated road construction, fuels treatment, and reforestation. Other resource management practices, such as range management, recreation development, and current mining operations, have a lesser overall influence although they are included for analysis at the project level. The soil and water resource improvement practices have a beneficial influence on water yield, water quality, and CWEs

Water developments, groundwater, water yield, and water uses and needs were not analyzed as indicators because they are not predictable or their consequences would not vary significantly by alternative.

Cumulative Watershed Effects

Table 4.41 summarizes Forestwide equivalent road acres (ERA's) and Forestwide percent changes compared to the 1977-1987 period. These values are indicative of the future potential to incur CWEs. In essence, the larger the ERA, the greater the risk that a recurrent storm event would result in unacceptable channel impacts, this is true even if individual small watersheds are within acceptable thresholds, which should lessen those impacts. The values are averages for the first five decades.

TABLE 4.41 - CUMULATIVE WATERSHED EFFECTS BY ALTERNATIVE 1/

ALTERNATIVE	EQUIVALENT ROAD ACRES 2/	PERCENT ERA CHANGE COMPARED TO 1977-1987 PERIOD
PRF	22,700	+32
CUR	24,200	+41
RPA	27,500	+60
CMD	25,800	+50
NMK	19,500	+14
UNE	21,500	+25

result in low potential for CWEs in small watersheds. None of the alternatives is expected to result in high potential for CWEs in small watersheds because the Forest would attempt to stay within thresholds in these watersheds. The difference between those alternatives rated moderate and those rated low lies in the relative differences in EPA's (and number of watersheds near threshold) relative to current levels and to each other, and the chance that a recurrent storm event would cause channel impacts even though estimated thresholds are being met

The greater the proportion of private land within a watershed, the greater the potential to limit TNF activities, primarily timber harvesting. Major watersheds where predicted outputs and planned activities might be limited by mixed ownerships because of the potential to incur cumulative watershed effects are the Middle Yuba (44 percent private), South Yuba (51 percent private), North Fork American (35 percent private), Rubicon (37 percent private), Truckee (61 percent private). Smaller portions of all other National Forest System watersheds are similarly affected.

Improved Watershed Condition (Soil and Water Resource Improvement)

The benefits of treated watershed acres have not been quantified in terms of dollars or other physical outputs. Benefits include reduced erosion and sedimentation, improved stream flows, restoration of land to timber and forage production, improved wildlife habitat, and improved visual quality.

The acres proposed for soil and water resource improvement per decade are displayed in Table 4.42 for each alternative.

TABLE 4.42 • TOTAL ACRES OF PLANNED SOIL AND WATER RESOURCE IMPROVEMENT

DECADE	PRF	CUR	RPA	CMD	NMK	UNE
1	1,000	250	1,000	250	1,000	1,000
2	900	250	900	250	900	900
3	0	0	600	0	600	0
4	0	0	0	0	0	0
5	0	0	0	0	0	0
TOTAL	1,900	500	2,500	500	2,500	1,900

There are about 2,500 acres that could be improved by vegetative and mechanical treatment. An additional estimated 11,000 to 12,000 acres of declining watershed would recover best by limiting management activities; these declining areas are treated similarly in all alternatives and thus are not analyzed here

Alternatives were assigned acreage targets for treatment based on the overall theme of each alternative. The RPA and NMK alternatives would result in the greatest acreages of planned soil and water resource improvement and treat the maximum treatable acres; water quality improvement and restoration of degraded riparian areas would be maximized. The CUR and CMD alternatives would result in the fewest acres of planned treatment due to historic management emphasis on other resources, such as timber and grazing; this would result in the lowest improvement in water quality and riparian areas in currently degraded areas. The PRF and UNE alternatives would treat the highest priority areas which are contributing to degradation of riparian areas and water quality: there would be an improvement in water quality and restoration of riparian areas in currently degraded areas, although not the maximum potential.

Investment in soil and water resource improvement on high priority abandoned hydraulic diggings may cause problems as these areas are still available for placer mining; however, soil and water resource protection measures would be incorporated into any placer mining plan of operation after preparation of a Site-Specific environmental analysis.

WILD AND SCENIC RIVERS

The North Fork American River, as designated by Congress, will be managed as a wild river. There are 5,788 acres that have been withdrawn from timber production and mineral entry.

The Heritage Conservation and Recreation Service (now a part of the National Park Service) included parts of the Middle Yuba River and South Yuba River in its Nationwide Rivers Inventory, completed in 1981. Later, an eligibility assessment by the Tahoe National Forest concluded that scenic and recreation values in the inventoried portions of the Middle Yuba River and South Yuba River are 'outstandingly remarkable;' therefore, they are eligible for inclusion in the Wild and Scenic River System (refer to Appendix E). These rivers were not included in any of the alternatives considered in detail because suitability was not analyzed.

Based on public comment on the Draft EIS and Forest staff review, Canyon Creek (along the Tahoe and Plumas National Forest boundary), the North Fork of the Middle Fork American River, Lavezzola Creek, and the Middle Fork American River were reviewed for 'outstandingly remarkable' features. No 'outstandingly remarkable' features were identified during the review process on these four rivers and therefore they are not eligible for inclusion in the Wild and Scenic River System (refer to Appendix E). These rivers were not included in any of the alternatives considered in detail.

The effects of each alternative on the North Fork American Wild River will vary according to the management emphases of the alternatives. Under all alternatives no activities would occur within the wild river corridor unless the activities are consistent with the wild river management plan. Activities undertaken outside of the wild river boundary can, however, affect the wild river. The effects of implementing each alternative are discussed below. Only those resources that may be affected by activities outside the wild river are discussed. For example, water quantity and quality would be little affected under any of the alternatives because of the small area within the watershed that would be bared because of regeneration harvests at any one time. Timber, game, and wildlife in the wild river would not be affected by activities proposed for adjacent lands.

Alternatives PRF and UNE. Activities associated with these alternatives could slightly affect the recreation experience of wild river visitors. Timber harvesting would cause some possible disturbance from noise and dust that would be more than currently produced. Visual quality would, however, remain high along trails which access the wild river and views from the wild river.

Alternative CUR. This alternative continues current management and would produce few effects on the wild river. Some timber harvest areas may be visible from within the wild river. Recreation experience levels would be reduced moderately from existing levels.

Alternative RPA. Higher timber harvest levels in this alternative would create more visual modifications than currently exist and would increase the likelihood of human activities being seen or heard from the wild river. Depending on the location and magnitude of these changes, recreational experience levels may be reduced. Visual quality along trails that access the wild river would remain high.

Alternative CMD. In this alternative the forest landscape would appear much more altered than currently. The likelihood of these alterations being visible from the wild river would be high and recreation experience levels would be reduced. The CMD alternative has the highest timber harvest levels and would have the greatest likelihood of creating vegetation changes that are visible from the wild river.

Alternative NMK. This alternative would provide the greatest emphasis on dispersed recreation and maintenance of a near-natural forest environment. Trail system improvements in the wild river and the designation of the entire North Fork American River unroaded area to semi-primitive nonmotorized would provide the highest quality recreation experience levels for the wild river.

WILDERNESS AND ROADLESS AREAS

The California Wilderness Act of 1984 designated 18,705 acres of the Granite Chief Rare II area to wilderness. Eleven areas were originally considered for wilderness evaluation.

The effects of implementing the various alternatives upon the roadless areas released for other multiple uses by the California Wilderness Act of 1984 would be of two types: These areas would either (1) be designated as semi-primitive nonmotorized (SPNM) recreation areas or would (2) be opened to varying mixes of multiple-resource management. In the former case, prevalent in the NMK alternative, the unroaded character of these areas would essentially be maintained. Consequently, the opportunity to reevaluate them as roadless areas in the future would remain. In the latter case, the areas would be roaded and modified at varying rates and to varying degrees, depending on the management themes and emphases of the alternatives. The alternatives with the greatest amounts of road construction and timber harvesting, the CMD, CUR, and RPA alternatives, would tend to reduce their SPNM character and to preclude future reevaluation. Appendix G describes each of the roadless areas, displays management prescription allocations by alternative, and describes the management prescription allocations for the preferred alternative.

The PRF, UNE, and RPA alternatives would assign some areas to SPNM recreation and most other areas to other resource management emphases, and would thereby preserve a moderate level of opportunity to reevaluate the roadless areas. The CUR and CMD alternatives would manage no former roadless areas for SPNM recreation, but the CUR alternative would tend to road them at slower rates than the CMD alternative.

The effects of implementing the various alternatives on the Granite Chief Wilderness would come from activities occurring outside of the area. Activities which produce noise, dust, or visual impacts as perceived from within the wilderness can reduce the quality of experience for wilderness users. Activities outside the wilderness that increase the risk of wildfire or insect and disease problems can cause environmental changes within the wilderness. No changes in water quality or quantity would occur due to activities outside the wilderness because the wilderness is located in the headwaters of several watersheds.

Alternatives PRF and UNE. In these alternatives vegetation modification and visual alterations would occur outside the wilderness. Noise and dust from logging and road use may be noticed by wilderness users. From the periphery of the wilderness, vegetative modification and human activities may be more evident than currently. New roads outside the wilderness may increase access and use within the wilderness. Roading and timber harvest would reduce the risk of fire and insect and disease problems spreading into the wilderness. Visual degradation could occur if ski areas expand with facilities placed on ridges in view of wilderness users.

Alternatives CUR, RPA, and CMD. These alternatives would have higher timber harvest levels that would increase the likelihood of noise and dust being noticed by wilderness users. Areas surrounding the wilderness would show greater evidence of human activities and would be visible from areas on the perimeter of Granite Chief. Roads built to facilitate timber harvests would provide greater access to Granite Chief and could increase use. New roads would also provide opportunities to build trailheads to more evenly distribute wilderness use. Vegetation management outside the wilderness would reduce the risk of insect and disease problems spreading into the wilderness. Timber harvest and fuels management in the surrounding area would reduce the risk of wildfire encroaching on the wilderness.

Alternative NMK. This alternative would preserve the area surrounding Granite Chief for dispersed nonmotorized recreation. Vegetation modification would be less evident than presently. Wilderness users would not notice outside area dust or noise except possibly from mining operations. The Granite Chief and surrounding area is not highly mineralized so few mining operations would be expected to affect the wilderness. Low levels of vegetation management and road construction would limit access to the area surrounding Granite Chief. This limited access would make treatment of insect and disease problems more difficult and could increase the risk of such problems spreading into the wilderness. Similarly, wildfire suppression would be more difficult and could increase the chance of wildfire entering the wilderness from adjacent areas.

In this alternative the Headwaters Basin of the North Fork of the American River would be designated as a Special Interest Area. This designation would further insulate wilderness users from outside influences. The emphasis on dispersed recreation in this alternative would also enhance visitor enjoyment of Granite Chief

WILDLIFE

introduction

Implementation of the management programs in any alternative would result in direct and indirect habitat changes for local wildlife species. Habitat changes would occur from direct habitat improvement projects, but would more often result from other resource management programs. On the TNF, resource management programs that could yield significant changes in wildlife habitats include timber, fire, range, hydroelectric, minerals, recreation, and engineering. These activities affect the quantity, quality, and distribution of important habitats. Collectively, they strongly influence the abundance and distribution of animals on the Forest.

Trends in selected management indicator species are displayed below to compare the relative effects of alternative Forest management strategies on wildlife. Because tools for accurately estimating changes in animal population trends are currently lacking, the evaluations are typically made by comparing trends in management programs that affect target species or their habitats.

Federal Threatened and Endangered Species

Peregrine falcons are wide-ranging and typically choose remote rock ledges for nest sites. Management activities are not expected to have serious adverse impacts on peregrine falcons in any alternative. All alternatives would comply with the recovery plan for peregrine falcons, which specifies a Forest target of three breeding pairs. Local interest in exceeding the target for three breeding pairs has not been observed.

Wintering and nesting bald eagles inhabit forested sites near reservoirs on the TNF. Recreation activities could negatively affect nest and roost sites in some locations. However, recreation use near nests and roosts has historically been regulated to protect bald eagles. Similar mitigations are assumed for all alternatives. Each alternative would comply with the recovery plan for bald eagles, which specifies a Forest target of five breeding pairs. The recovery plan target is believed to be near the maximum potential for the Forest.

Forest Service **Sensitive** Species

Spotted Owls. The current Forest population of spotted owls is believed to be about 110 pairs. Estimating the effects of management on spotted owl populations is difficult when tools for tracking the spatial arrangements of the habitat are lacking. However, the relative effects of each alternative can be evaluated by comparing management factors that could directly or indirectly affect the quantity or quality of spotted owl habitat. These factors are 1) the number of spotted owl habitat areas (SOHA's) in owl networks, 2) the strategies for their management, and 3) the number of suitable acres available on the Forest over time. Comparisons of the factors important for spotted owl habitat management are shown in Table 4.43.

Table 4.43 demonstrates that Alternatives PRF, CMD, and UNE would provide a Forest network of 33 SOHA's. The CUR and RPA alternatives would provide 34 SOHA's. The NMK alternative would provide at least seven additional SOHA's by preventing timber harvest in large tracts of mature forest that contain suitable sites for spotted owls.

Each alternative would have long-range management strategies for SOHA management (see Appendix P). Site-specific SOHA management plans would be developed by interdisciplinary teams and would be completed before any new ground-disturbing activities are planned. The RPA, CUR, and CMD alternatives would plan timber harvest in the core, nesting core, and foraging areas of each SOHA with replacement acres provided. The CMD alternative would allow this harvest in all SOHA's by the sixth decade. The PRF, NMK, and UNE alternatives use local resource information of each SOHA to determine that no scheduled harvest would occur in about 65 percent of the SOHA's.

TABLE 4.43 - EFFECTS OF THE ALTERNATIVES ON SPOTTED OWLS

	PRF	CUR	RPA	CMD	NMK	UNE
SOHA Number	33	33	34	33	40	33
SOHA Management						
No Scheduled Harvest	22	1	1	1	27	22
Harvests Planned	11	32	33	33	12	11
Suitable Acres in Decade 5 (1,000) (1988 = 176.3)	136.7	102.6	130.0	123.0	186.7	142.6

All alternatives would maintain 1,000 acres of suitable habitat in each SOHA where site conditions allow. However, the spatial arrangement of owl habitat that would result from long-term timber harvest has not been evaluated. Without an understanding of the spatial arrangement of the 1,000 acres, the PRF, NMK, and UNE alternatives offer greater assurances that prevailing direction for maintenance of several large (300-acre) tracts of spotted owl habitat would be accomplished in each SOHA over time.

The potential number of owls inhabiting areas outside network SOHA's cannot be accurately estimated from Table 4.43. However, alternatives that provide the largest number of suitable acres for spotted owls would likely yield the largest number of non-network owl pairs. Accordingly, the NMK alternative should have the largest number of non-network owls because it provides a 5 percent increase in suitable owl habitat by the fifth decade. Conversely, the CUR alternative could be expected to yield the fewest birds because it reduces suitable habitat by 30 percent over the same period. The remaining alternatives would yield conditions that are intermediate to the NMK and CUR.

Willow Flycatcher. Forestwide habitat inventories and estimates of willow flycatcher numbers are currently lacking. However, the effects of the alternatives on willow flycatchers can be evaluated by comparing management programs that could affect willow flycatcher habitat. On the TNF, those programs are 1) livestock grazing, 2) riparian area management, and 3) wildlife habitat management. Increased livestock grazing would raise the potential for adverse effects because significant cattle disturbance of nest sites and other important willow flycatcher habitat has been demonstrated in several areas in the Sierra Nevada (Serena 1982, Sanders and Flett 1988, and Valentine in prep). Conversely, extending the width of riparian protection zones and including the species in the Forest wildlife habitat management program would benefit willow flycatchers. The effects of the alternatives are compared in Table 4.44.

Table 4.44 suggests that the NMK alternative would yield the most beneficial conditions for willow flycatchers because it offers 1) the smallest potential for adverse effects from livestock grazing, 2) the widest riparian protection zones, and 3) wildlife program emphasis on willow flycatcher habitat. The RPA alternative would have the greatest potential for adverse effects because it increases livestock grazing over 60 percent in the first decade and does not emphasize protection of willow flycatcher habitat. The remaining alternatives would have an intermediate effect on willow flycatcher habitat.

TABLE 4.44. EFFECTS OF THE ALTERNATIVES ON WILLOW FLYCATCHERS

	PRF	CUR	RPA	CMD	NMK	UNE
AUM's (1,000/yr)						
Decade 1	20.8	22	34	21	9	20.8
Decade 5	23	20	30	27	1	23
Riparian Protection (Avg. Buffer Width, ft)	125	100	100	100	125	125
Species Included in Wildlife Program	yes	no	no	yes	yes	yes

Goshawks. Each alternative would provide a minimum of two goshawk nesting territories per township (total = 75) as prescribed in the Regional Planning Guide (pages 4-13 and 4-14). Nesting territories would measure at least 50 acres in all alternatives. Where overlap with visual corridors, SOHA's, RNA's, and other programs allow, nest territories will measure the desired size of 120 acres.

Additional effects of the alternatives on goshawks can be evaluated by comparing the availability of preferred and suitable habitat (Fowler 1988) Forestwide. Comparative habitat data are shown in Table 4.45.

	PRF	CUR	RPA	CMD	NMK	UNE
Suitable Habitat (Seral Stage 3B/C) (1988 = 174.2)	193.4	210.0	185.0	198.8	199.4	225.4
Preferred Habitat (Seral Stage 4B/C) (1988 = 126.2)	65.5	53.0	56.0	51.9	126.2	80.1
Total Suitable Acres (1988 = 300.4)	258.9	263.0	241.0	250.7	325.6	305.5

Although the spatial arrangement of the habitat is uncertain, Table 4.45 suggests that the NMK alternative is the most beneficial for goshawks because it would provide the largest acreage of suitable habitat and the largest number of preferred acres (4B/C). The NMK alternative would maintain seral stage 3B/C and 4B/C at about current levels. The UNE alternative would reduce preferred habitat by about 35 percent but would maintain total suitable habitat near current acreages. The PRF, CUR, RPA, and CMD alternatives would yield reductions in total suitable habitat of from 10 to 17 percent. These alternatives would reduce the availability of preferred habitat by 50 to 60 percent and yield moderate increases in other suitable stands.

Pine Marten, Fisher, and Sierra Nevada Red Fox The TNF would work closely with neighboring forests, the California Department of Fish and Game, and others to organize a habitat management program for pine marten, fisher, and Sierra Nevada red fox under all alternatives. The program would use the habitat relationships data and habitat management prescriptions developed by the Pacific Southwest Region While the program is being developed, biological evaluations would describe appropriate measures needed to conserve candidate areas for habitat management. Managed habitats would be well distributed in all alternatives. However, potential habitat configurations are presently uncertain because the locations of suitable habitats have not been completely identified and the condition of these lands have not been evaluated on the TNF Moreover, habitat relationships data and management prescriptions are still under development by the Pacific Southwest Region. All alternatives would provide direction to seek cooperative habitat management programs with private land owners where private lands are essential for achieving the Forest habitat management objectives All alternatives would also develop silvicultural practices that may be used to maintain or improve habitats.

Although programs of habitat management would be similar in all alternatives, the management strategy for meadow edges and riparian habitats vary and could affect the quality of these key habitat components. Comparisons of meadow edge and riparian area management are shown in Table 4.46.

TABLE 4.46 - EFFECTS OF THE ALTERNATIVES ON PINE MARTENS, FISHERS, AND SIERRA NEVADA RED FOX

	PRF	CUR	RPA	CMD	NMK	UNE
Meadow Edge Habitat Management Provided	yes	no	no	no	yes	yes
Riparian Area/SMZs Exceeds MMR	yes	no	no	no	yes	yes

Table 4.46 indicates that the PRF, NMK, and UNE alternatives provide additional assurances that viable populations of pine marten, fisher, and Sierra Nevada red fox would be maintained over the planning period. These alternatives would manage for wildlife habitat emphasis those areas that extend 100 feet from the edges of meadows exceeding one acre in size. The PRF, NMK, and UNE alternatives also provide less intensive commodity resource management (timber harvest) in riparian areas and streamside management zones. The CUR, RPA, and CMD alternatives would not provide wildlife habitat emphasis at meadow edges and would produce more intensive commodity resource use in riparian areas and streamside management zones.

Harvest Species

The effects of the alternatives on harvest species is dependent on the mix of important habitat features over time. Generally, alternatives that yield large quantities of early succession stages (PRF, RPA, and CMD) would produce the most favorable conditions for associated species such as mountain quail and deer. However, favorable conditions would only be provided if site preparation and other activities in managed stands maintain adequate forage and cover.

Species associated with hardwoods (e.g., gray squirrel, black bear, band-tailed pigeon, and deer) would be impacted least by the alternatives that retain relatively large hardwood components in regenerated stands (PRF, NMK, and UNE). Conversely, alternatives that considerably reduce hardwoods in regenerated stands (CUR, RPA, and CMD) would have the largest potential for adverse impacts to these species.

C. MEANS TO MITIGATE ADVERSE IMPACTS

The Forest planning process incorporates many mitigation measures to minimize adverse environmental effects under any alternative. The National Forest Management Act regulations require that the management of all resources that National Forest System lands are managed under the principles of multiple use and sustained yield. The management direction common to all alternatives provides for mitigation of major adverse impacts associated with management activities.

Management direction common to all alternatives includes:

1. Minimum management requirements (MMR's) (EIS, Chapter 2, Section E).
2. Timber policy requirements (EIS, Chapter 2, Section E).
3. Minimum implementation requirements (MIR's) (EIS, Chapter 2, Section E).
4. Forest constraint (EIS, Chapter 2, Section E).
5. Forestwide standards and guidelines (S&G's) (summarized in EIS, Chapter 2, Section E; full detail in Plan, Chapter V).
6. Management prescriptions (summarized in EIS, Chapter 2, Section E full detail in Plan, Chapter V).

Some slight differences among alternatives occur to the degree that Forestwide S&G's are incorporated, e.g., SMZ's are managed at the MMR level under Alternatives CUR, RPA, and CMD, whereas Alternatives PRF, NMK, and UNE manage the SMZ's using Forestwide S&G's 46 and 47, these differences reflect each alternative's theme, are described in each alternative writeup in Chapter 2, Section E, and the consequences are disclosed in Chapter 4.

D. ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED

Some adverse consequences cannot be avoided despite the application of mitigating measures. The magnitude of such effects varies with the emphasis of the alternative. The adverse effects identified are disturbance or destruction of cultural resources and endangered and sensitive plant species, wildlife habitat, loss of wetlands, and lowering of local water quality, visual quality, and air quality. None of the adverse environmental effects are specific to individual alternatives. The degree of risk or adverse effects varies by alternative.

Cultural Resources. Alternatives PRF, CUR, RPA, CMD, and UNE are estimated to have the greatest potential to disturb or destroy cultural resources. Alternative NMK would have the lowest potential. The likelihood of damaging cultural resources is determined by the number of acres proposed for ground-disturbing practices and the number of cultural resource sites inadvertently missed during pre-project activities (see Table 4.1 9). Sites are usually missed because of thick duff layers and dense vegetation. The disturbance or destruction of cultural resources also would be considered an irreversible loss.

Sensitive Plants. Alternatives PRF, CUR, RPA, CMD, and UNE are estimated to have the greatest potential to disturb endangered and sensitive plant species and their habitats because of project activities and increased human use. Some plant species and their habitats may not be identified (obscured by heavy vegetation, poor flowering years, etc.) during the inventory and could be destroyed. However, sensitive plants occupy relatively few acres and are scattered across the TNF. Several sensitive plants on the Forest do not occur on timbered land, and, therefore, risks are further reduced.

Wildlife. The most significant unavoidable effect on wildlife is estimated to be the development and vegetative manipulation that would occur on and adjacent to the Forest. Those alternatives with the largest timber programs and resulting road construction, along with proposed recreation development, would permanently remove wildlife habitat from production.

Wetlands Minor amounts of wetlands would be unavoidably lost because of road construction. Specific information about wetland locations is lacking until site-specific analyses are performed. The risk of loss would increase with the miles of road construction (see Table 4.13). Alternatives PRF, CUR, RPA, CMD, and UNE would have the largest amount of road construction and the greatest potential to damage wetlands, and Alternative NMK the lowest.

Watershed (Soil and Water). Any type of land disturbance (construction, vegetation manipulation) would have at least temporary and localized effects on the soil despite the application of erosion and water quality control measures and the avoidance of highly erosive soils. If bodies of water are nearby, water quality effects would also be expected. Areas maintained free of vegetation, such as roads and trails, would be constant potential sources of erosion and sediment. OHV use in open areas and alpine ski area development would reduce vegetation, increase erosion, and affect water quality regardless of preventive measures.

Visual Quality All alternatives would reduce the visual quality of the Forest to varying degrees, depending upon the extent of timber harvest, road construction, and prescribed wildlife habitat burning. Visual changes would be managed within acceptable limits of planned VQOs.

Air Quality. Alternatives CUR, RPA, and CMD would generate the most short-term reduction of air quality, due to dust, smoke, and auto emissions. Alternatives PRF, NMK, and UNE would generate progressively less short-term reductions of air quality. Airborne particulate matter under all alternatives would be below the 100 microgram per square meter for a 24-hour period allowed by the State for Class II areas.

E. RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

The relationship between the short-term uses of the human environment and the maintenance and enhancement of long-term productivity is complex. Short-term uses are generally those that occur on an annual basis, such as livestock grazing as a use of the forage resource, hunting as a use of the wildlife, or the harvesting of timber.

Long-term productivity refers to the continuing ability of the land to produce commodities and retain amenity values for the benefit of future generations. This ability depends upon management practices that do not allow for the impairment of soil productivity, the overtaxing of water resources, or the alteration of the natural landscape beyond its ability to recover. The long term is, for Forest planning purposes, defined as exceeding fifty years.

The planning alternatives have been evaluated for cumulative and long-term effects. Much of the specific direction and the Forestwide standards and guidelines are directed toward maintaining long-term productivity. Under all alternatives, unavoidable effects and irretrievable resource commitments would occur that affect long-term productivity, such as development of ski areas, construction of arterial and collector roads, and the development of mineral and energy resources. Management decisions, therefore, must ultimately be based on the capability of the land, rather than the urgency of short-term needs.

Alternatives PRF, NMK, and UNE should maintain and enhance the long-term productivity of the soils, maintain water quality, and provide for improving populations of all species on the Forest. Alternatives CUR, RPA, and CMD would maintain long-term soil productivity, water quality, and viable populations of wildlife at about existing levels.

F. IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

Each alternative commits resources to certain uses depending upon its management emphasis, which may preclude these resources from other uses. For example, committing forage to domestic livestock use makes it unavailable for wildlife. These resource commitments are expressed in the differences in outputs between alternatives (see Table 2.12). The major irretrievable resource commitments are those associated with the construction of facilities, and vegetative manipulation in current roadless areas. Approximately four acres of land productivity are irretrievably **lost** with each mile of local road construction, and seven acres with each mile of arterial or collector road construction (see Table 4.13). Differences in the effects of road construction between alternatives are slight, because most of the Forest is already fully accessed.

The extraction of minerals, gravel, and rock and the disturbance or destruction of cultural resources are irreversible resource commitments. Reliable data on the amount of extraction of mineral resources are not available. The rate of mineral extraction should not differ significantly between alternatives. The extraction of gravel and rock may vary slightly in response to the total miles of road to be constructed but would not be expected to differ greatly between alternatives over the 5-decade planning period. The withdrawal of lands from mineral entry is an irretrievable commitment (subject to valid existing rights) until management direction changes. Administrative sites and dam construction are considered irreversible because of the long-term land and resource commitments, though site-specific analysis would be required before allocating areas to these facilities.

The energy used to implement each of the alternatives is also considered an irreversible resource commitment.

The likelihood of disturbing or destroying cultural resources varies by alternative (see Table 4.19). Alternatives PRF, CUR, RPA, **NMK**, and UNE have a moderate probable likelihood of disturbance, and Alternative CMD has a high chance of disturbance.

Alternatives PRF, CUR, RPA and CMD would have the highest likelihood of disturbance or destruction to endangered and sensitive plant species and their habitat. **The** destruction of these populations would be considered an irreversible **loss**.

In terms of land alteration, the decision to allocate unroaded areas to semi-primitive recreation use and forego their timber values during the planning period is not an irreversible decision. Conversely, the decision to commit presently unused areas to resource production may be irreversible in terms of precluding some types of future recreational uses. Within the next Plan a new or continued commitment of these resources would occur, based on technology, cost of and needs for resource production, and the trends of recreation demand.

G. POSSIBLE CONFLICTS WITH FEDERAL, REGION, STATE, AND LOCAL LAND USE PLANS

No known conflicts exist between Federal, regional, State, and local planning and the Tahoe National Forest land management planning.

H. ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL

Energy is consumed in the administration and use of natural resources from National Forest System lands. For the purpose of this EIS, energy sources are gasoline, diesel fuel, liquefied petroleum, natural gas, electricity, wind, and wood. The main activities that consume energy are timber management, range management, recreation (both dispersed and developed), road construction and reconstruction, and administrative activities of the Forest Service (Table 4.47).

Energy consumed in timber harvesting is the estimated amount required for felling, bucking, skidding, loading, hauling, post sale practices, performing road maintenance commensurate with the volume hauled, and the industrial traffic associated with the logging activities.

Energy consumed in managing range vegetation is the estimated amount required for hauling domestic livestock to and from the range, for permmee range improvement practices, and for other practices such as salting and herding.

Recreation-related energy consumption is based on the estimated number of dispersed and developed recreation visitor days and estimated trip lengths.

Energy consumed in road construction and reconstruction activities is that amount used by timber purchasers or public works contractors performing road development and maintenance work.

Energy consumed by Forest Service administration includes vehicle use for all administrative activities; building lighting, heating, and air conditioning; road maintenance and construction projects performed by Forest Service personnel; and fuel used for small engines and burners.

The following factors were used to compute energy requirements for each alternative:

Forest Users The average distance traveled by recreationists, average party size, and average length of stay were determined for developed site, dispersed area, and the North Fork American Wild River users Permittee travel distance needed to manage livestock and average AUMs per permit were used to compute **BTU's** per AUM. Separate calculations were made for felling, bucking, skidding, loading, and hauling of timber. Road construction, clearing, excavation, compaction, and drainage requirements were computed separately by slope classes. Energy requirements for road maintenance by timber purchasers and cooperators were based on calculations for the Forest Service doing similar work.

Forest Service. Forest Service energy expenditures were based on actual gallons of gasoline, diesel, heating fuel, aviation fuel, liquefied petroleum gas, cubic feet of natural gas, and kilowatt hours of electricity used in fiscal year 1979. Consumption was computed for recreation, range, timber, engineering, reforestation, cultural treatments, and burning.

The TNF can produce energy from four areas: (1) water flows converted to hydroelectric power, (2) geothermal, (3) wood fiber burned for fuelwood, and (4) wind.

The potential for hydroelectric power and geothermal has been noted in Chapter 3. Proposals for their development come from outside sources to which the Forest Service responds. Because of this, the potential for development is expected to be relatively similar for all the alternatives.

No data are available for wind energy potentials.

Wood Energy and Biomass

Potential wood fiber energy data are displayed in Table 4.47 for each alternative. The data indicates cubic feet, cords, and billion BTU's based upon the 1980 timber inventory, FORPIAN harvest schedules, and conversion factors for equivalent BTU's. The potential wood fiber energy is displayed by four categories: the potential contained in (1) the merchantable bole from the regulated harvest volume; (2) cull material, unutilized bole, and the tops and limbs to three-inch diameter (referred to as unmerchantable: this volume is not merchantable as sawlogs and is part of the unregulated volume); (3) totals of 1 and 2; and (4) fuelwood available for individual firewood gatherers. The fuelwood available to firewood gatherers is based upon unmerchantable wood adjacent to roads and cull logging material decked by the timber purchasers. Approximately 77 percent of this firewood is from cull decks. The remainder is hardwoods, tops and limbs, and precommercial thinning material.

Conservation

Future technological advances could provide for efficient, economical applications for wind, solar, and geothermal energy resources. These undeveloped resources would reduce demand for more traditional energy resources such as oil, coal and shale, nuclear, and hydroelectric power. Thus, a potential exists to conserve energy locally. Specialized energy conservation systems would be applied at the project level. Facility energy surveys and conservation retrofits were accomplished in 1983 and 1984.

CHAPTER 5 LIST OF PREPARERS

The Interdisciplinary (ID) Team of Forest Service specialists developed and coordinated the planning activities for the Forest Plan beginning in **1979**. All resource disciplines were integrated according to multiple use principles. These people were selected because of their expertise and ability to respond to the major issues being analyzed during the planning process. Other specialists inside and outside the Forest Service assisted the team when special needs arose

The following were the primary duties of the ID Team:

1. Coordinate and integrate planning activities, including public participation.
2. Integrate all physical, biological, social, and economic disciplines into the planning process
3. Identify and analyze the problems and opportunities associated with providing a range of goods and services.
4. Coordinate Forest planning with the planning of local, State, other Federal agencies, and with adjacent landowners.

The Forest Interdisciplinary Team and their qualifications are as follows:

FRANK WALDO
Deputy Forest Supervisor
(1985 to present)

Frank represented the Forest Supervisor and District Rangers on the team. He received his B.S. in Forestry (1962) at New York State College of Forestry, Syracuse University. He has served on four National Forests and at the Regional Office.

RICHARD APPLE
Operations Research
Analyst/Forester
(1987 to present)

Rich provided expertise in developing and analyzing economic data. He received his B.A. in Economics from the University of Iowa (1969) and M.S. in Forestry (1983) from the University of Minnesota. He has served on two National Forests.

DONALD BEHRENS
Forest Range Conservationist
(1979 to present)

Don provided expertise in the interaction of the range science, sensitive plants, and plant ecology aspects of the Forest planning process. He received his B.S. in Range Management (1967) from Colorado State University. Don has served on three National Forests in California as both forester and range conservationist.

MIKE CHAPEL
Wildlife Biologist
(1986 to present)

Mike provided expertise in wildlife biology, including threatened and endangered animal species. He received his B.A. and M.A. in Biology in 1973 and 1977 from Fresno State University. He has served on two National Forests.

JOHN CORBETT
Lands Staff Officer
(1979 to present)

John provided expertise in lands adjustment (exchange and purchase), mineral area management and special uses. He received his B.S. in Forestry (1960) from the University of Connecticut and has completed postgraduate work in real estate. John has served on the Tahoe National Forest and is a professional forester licensed by the State of California.

PHILIP HORNING
Forest Landscape Architect
(1987 to present)

Phil provided expertise in recreation, special interest areas visual, and cultural resource management. He received a Bachelor of Landscape Architecture (1969) from the College of Forestry and Environmental Science at Syracuse, New York. He has served on four National Forests in California and a State Forest in Australia.

DENNIS KNAPP
Truckee District Engineer
(1987 to 1989)

Dennis provided expertise in civil engineering, energy conservation and transportation planning and analysis. He received a B.S. in history and has done graduate work in international affairs. He has served on two National Forests.

JANE LABOA
Forest Silviculturist
(1988 to present)

Jane provided expertise in timber management which includes silvicultural practices, timber harvest, and integrated pest management activities. She received her B.S. in Forest management (1972) from the University of California at Berkeley. She has served on three National Forests and is a registered professional forester in California.

DAVID NELSON
Fire Management Officer
(1988 to present)

Dave provided expertise in the planning process and coordinated the process. He was also responsible for fire management analysis and its integration into the planning process. He received his BS (1959) in Forestry from Iowa State University. Dave has served on three National Forests.

ROGER POFF
Soil Scientist
(1988 to present)

Roger provided expertise in soil management. He received his B.S. in Agriculture from the University of Wisconsin - River Falls (1960). He did graduate work in soil science at the University of Minnesota. He is a certified professional soil scientist and a certified erosion and sediment control specialist. Roger has served on National Forests in Montana and California, and is zone soil scientist for three National Forests.

TERRY RANDOLPH
Planning Officer
(1988 to present)

Terry coordinated the completion of the Final EIS and Plan. He received a BS in Forestry (1962) at the University of Idaho. He has served on four National Forests in California, Idaho, Utah, and Nevada.

MICHAEL ZAN
Forest Hydrologist
(1979 to 1989)

Mike provided hydrologic and soils expertise. He received his B.S. in Forestry (Watershed Management) (1966) and a M.S. in Forest Hydrology (1968), both from Utah State University. Mike has served on three National Forests in California.

PAST MEMBERS

GERI V. BERGEN

Deputy Forest Supervisor
(1979 to 1985)

Geri represented the Forest Supervisor and District Rangers on the team. Geri received her B.S. in Forestry (1962) and a M.A. in Botany (1965), both from the University of California, Berkeley. She has served in the Regional Office in San Francisco and at the Pacific Southwest Forest and Range Experiment Stations in Berkeley and Placerville. Geri is a professional forester licensed by the State of California. In January 1985, Geri was promoted to Forest Supervisor of the Tahoe National Forest.

PHILIP AUNE

Forest Silviculturist
(1980 to 1987)

Phil provided expertise in timber management which includes silvicultural practices, timber harvest, and integrated pest management activities. He received his B.S. in Forest Management (1965) from Humboldt State University, Arcata. He has served on four National Forests in California, including an assignment on a Forest Service sponsored study tour of Sweden and Finland to examine silvicultural practices. Phil is a professional forester licensed by the State of California.

GEORGE CADZOW

Team Leader,
Planning Officer
(1979 to 1987)

George provided expertise in the planning process and coordinated the planning process. He served as the liaison with the contractor providing socioeconomic data. He coordinated the RARE II Further Planning Areas. George received his B.S. in Timber Management (1959) from Utah State University and an M.A. in Environmental Planning (1979) from California State University, Chico. He was Associate Professor in fire training at Kansas State University. George has served on five National Forests in California and is a licensed professional forester in the State of California.

JAMES COIL, JR.

Public Information Officer
(1979 to 1981)

Jim was responsible for coordinating public involvement activities and integrating public concerns into the planning process. He received a B.S. in Forestry (1959) from Michigan State University. Jim served on five National Forests in Montana and California and was District Ranger on two Districts.

JOSEPH COLWELL

Land Management Planner
(1979 to 1983)

Joe was responsible for analyzing and coordinating specialists' input and documenting the planning process according to NFMA regulations. He also developed and analyzed economic data. Joe received a B.S. in Wildlife Management (1969) from the University of Idaho and a M.S. in Program and Policy Analysis (1979) from Michigan State University. He served on three National Forests in Colorado and California.

DAVID CONNELL

Wildlife Biologist
(1980)

Dave provided expertise in wildlife biology, including threatened and endangered animal species. He received a B.S. in Wildlife Management (1966) from Humboldt State University, Arcata. Dave served on two National Forests in California.

AARON GELOBTER

Fuels Management Specialist
and District Fire Management
Officer
(1984 to 1988)

Aaron was responsible for fire management analysis and its integration into the planning process. He received his B.S. in Forestry (1980) from the University of Arizona and has served on four National Forests in Arizona and California.

LAURENCE GRUVER
Transportation Planner
(1980 to 1981)

Larry provided expertise in civil engineering, energy conservation, and transportation planning and analysis. He received a B.S. in Civil Engineering (1967) and an M.S. in Transportation Planning (1972), both from U.C. Berkeley. Larry is a California registered civil engineer and also has teaching credentials in math and social sciences (1973). He served on two National Forests in California.

GARY HARTMAN
Forest Wildlife Biologist
(1980 to 1985)

Gary provided expertise in wildlife biology. He received his B.S. in Wildlife Management (1970) from Oklahoma State University. He has served on two National Forests in Texas and California. Gary also served with the U.S. Fish and Wildlife Service in Illinois.

LEE JORDAN
Transportation Planner
(1983 to 1986)

Lee provided expertise in transportation planning, energy conservation, and facilities management. He received his A.A. in Forestry (1963) from Sierra College, a B.A. (1979) and M.A. (1984) in Anthropology, a B.S. in Environmental Resources (1972), and some course work in Construction Engineering Management, all from California State University, Sacramento. Lee has served on the Tahoe National Forest.

RICHARD JUVENAL
Forest Assistant Fire
Management Officer
(1980 to 1984)

Dick was responsible for integrating fuels and fire management into the Forest Plan. He attended Cal-State University at Chico, completing course work in Range Management. Dick served on three National Forests in California.

MARY KING
Recreation Planner
(1984)

Mary provided expertise in recreation, Special Interest and Research Natural Areas, visual, and cultural resource management. She received a B.S. in Forestry (1980) from U.C. Berkeley. Mary served on the Tahoe National Forest.

RICHARD MARKLEY
Forest Archaeologist
(1982 to 1987)

Richard provided expertise in recreation, Special Interest and Research Natural Areas, visual, and cultural resource management. He received both his B.A. (1974) and M.A. (1978) in Anthropology from California State University, Chico. Richard has served on the Tahoe National Forest.

JOHN P. RILEY
Assistant Forest Engineer
(1981 to 1983)

John provided expertise in civil engineering, energy conservation, and transportation planning and analysis. He received a B.S. in Civil Engineering (1970) and has completed course work for a M.S. degree in Soil Mechanics from U.C. Davis. He served on three National Forests in California and Oregon. John is a California registered civil engineer.

JOHN ROLAND
Land Management Planner
(1984 to 1986)

John provided expertise in developing and analyzing economic data. He received his B.S. in Forest Management (1973) and a M.S. in Economics (1982), both from the University of Idaho. John has served on the Tahoe National Forest.

GEORGE TAYLOR
Recreation Planner
(1980 to 1982)

George was responsible for recreation, Special Interest and Research Natural Areas, visual, and cultural (archaeological) coordination. George received a B.S. in Forestry (1950) from U.C. Berkeley. He served on the Tahoe National Forest and is a professional forester licensed by the State of California.

MANAGEMENT TEAM

The following individuals guided, reviewed, modified as appropriate, and recommended for approval the work of the Interdisciplinary Team since the inception of the planning process in 1979.

Geri V Bergen	Forest Supervisor
Frank Waldo	Deputy Forest Supervisor
Steven Bishop	District Ranger, Sierraville District
Peter Brost	Recreation Staff Officer
John Corbett	Lands Staff Officer
Jerry Westfall	Acting District Ranger, Nevada City District
Larry Gruver	Engineering Staff Officer
Rich Johnson	District Ranger, Foresthill District
William A Kempf	Administrative Officer
William Knispek	Timber Management Officer
Jean Masquelier	Resource Staff Officer
J. Thomas Millard	District Ranger, Downieville District
David K. Nelson	Fire Management Officer
William C. Pidanick	Public Affairs Officer
Terry Randolph	Planning Staff Officer
Joanne Robique	District Ranger, Truckee District

PAST MEMBERS

Robert G Lancaster	Forest Supervisor, 1979 to 1984
Philip Aune	Acting Timber Management Officer, 1986
Jerry B. Brogan	District Ranger, Foresthill District, 1983 to 1985
George Cadzow	Resource Planning Officer, 1979 to 1987
James E. Carrier	District Ranger, Foresthill District, 1979 to 1983
James R. Coil, Jr.	Public Information Officer, 1979 to 1983
Ann Dow	District Ranger, Nevada City District, 1985 to 1989
Edwin H. Gregg, Jr.	Recreation Officer, 1979 to 1985
Harley L. Greiman	District Ranger, Downieville District, 1979 to 1984
	Resource Officer, 1984 to 1985
	Acting Recreation Officer, 1985
William L. Haire	Acting District Ranger, Foresthill District, 1985
Harlan Hamburger	District Ranger, Truckee District, 1979 to 1982
David Hammond	Engineering Staff Officer, 1979 to 1984
Robert Harris	Acting District Ranger, Nevada City, 1984 to 1985
John R. Henshaw	Lands and Recreation Officer, 1983 to 1987
John H. Holt	Resource Officer, 1979 to 1981
Rob Roy A. MacGregor	Lands Officer, 1979 to 1982
Harold D. McElroy	District Ranger, Sierraville District, 1980 to 1985
Jay D. Miller	Acting Resource Officer, 1981 to 1982
Roger J. Poff	Engineering Staff Officer, 1984 to 1987
James L. Reeves	Timber Management Officer, 1979 to 1986
Bruce E. Van Zee	District Ranger, Sierraville District, 1979 to 1980
Max Younkin	Public Affairs Specialist, 1984 to 1989
Ann Westling	

OTHER PARTICIPANTS:

Writer-editor	
William A Baker Kathy Van Zuuk Janine Benyus	B.S. in Forest Management (1965) University of California, Berkeley. Forest Environmental Assessment Coordinator and Writer-editor (1982 to present). B.S. in Biology and MA in Plant Ecology (1973 and 1978) from Northern Michigan University Writer-editor (1987 to 1989). Writer-editor (1989).
Past members Cherry J. DuLaney John Palmer Lynda Thompson Larry Best	Writer-editor (1984) Forest Environmental Assessment Coordinator (1980 to 1982) Writer-editor (1982) Shipley Associates (1985)

KURT J. WEHBRING (Principal Social Analyst, Dornbuschand Co., Inc.)
LAWRENCE W. KOZIMOR (Responsible for data gathering, interviewing, and developing the overviews Dornbuschand Co., Inc.)

A good string from Lola Montez Lake, 1936

CHAPTER 6 LIST OF AGENCIES, ORGANIZATIONS, AND PERSONS TO WHOM COPIES OF THE FEIS WERE SENT

CONSULTATION WITH OTHERS

Public participation has occurred throughout the Tahoe National Forest (TNF) planning process. Early involvement efforts focused on identification of Forestwide and area-specific issues and concerns. Extensive public involvement and public comment occurred after the Draft Environmental Impact Statement (DEIS) and Draft Forest Plan were published for review. Public concerns and suggestions were analyzed. The Final Environmental Impact Statement (FEIS) and Forest Plan (FP) were modified according to these public concerns. These concerns and Forest Service responses can be found in Appendix A.

MAILING LIST

Copies of the FEIS and FP were distributed or made available to individuals and organizations on the TNF mailing list. This list has been maintained and updated since 1979 when the planning process was initiated. All those who commented on the Draft Forest Plan have been added to this mailing list. Others have been removed via personal request, change of address/returned mail, or failure to mail back the address update cards.

Copies of the FEIS or notices of availability were sent to the following agencies, elected officials, organizations, and libraries. In addition, the documents were sent to a variety of individuals who requested copies. The complete mailing list is on file in the Planning Records located at the Forest Supervisor's Office, Nevada City, California. A list of all those who responded to the DEIS is provided in Appendix A.

ELECTED OFFICIALS

U.S. CONGRESSIONAL REPRESENTATIVES

Senator Pete Wilson
Senator Alan Cranston
Congressman Norm Shumway
Congressman Wally Herger (responded as
Assemblyman Herger)
Congressman Vic Fazio
Congressman Robert Matsui

APPENDIX B

THE MODELING AND ANALYSIS PROCESS

I. INTRODUCTION

The purpose of this appendix is to present a technical discussion of the analysis process and models used. Basic assumptions, model components and inputs, modeling rules and methods, and modeling constraints imposed along with their rationale and impacts are described in this appendix. Information presented in this appendix supplements the broader and less technical descriptions that are included in the body of the EIS. See Chapter 1, Section C, Planning Process and Chapter 2, Section B, Alternative Development Process, for a description of the overall process, including a description of analysis conducted prior to the formulation of alternatives. See Chapter 2, Section C, for the result of the benchmark analysis, and Chapter 2, Section D, Alternatives Considered in Detail, for discussion of the alternatives. Monitoring of implementation is discussed in Chapter II, Plan Implementation Process, and Chapter VI, Monitoring and Evaluation, of the Forest Plan. The plan implementation process is discussed in Chapter II of the Forest Plan, Plan Implementation Process.

FORPLAN is the primary modeling tool used to assure that land allocations and output schedules for alternatives and benchmarks are made in a way that meets all constraints in the most cost efficient manner possible. In addition to being used to formulate alternatives and benchmarks that are both feasible and cost efficient, FORPLAN is also used to perform detailed accounting work and to generate summary reports of information needed to construct the display tables in the EIS. Additional models are used to generate input data for use in FORPLAN and to interpret output data from FORPLAN. RAMPREP is the growth and harvest model used to make timber yield estimates for use in FORPLAN. The FIREPLAN system was used to estimate the fire organization, activity levels, and fire management costs required to efficiently achieve the program direction for each alternative. An income and employment model was developed, using the Regional Industrial Multiplier System in order to estimate income and employment effects from changes in Forest outputs. The Wildlife Habitat Capability Model was used to estimate effects on wildlife and fish populations because of changes in Forest Vegetation. The Effective Alteration approach employed perspective plot computer simulations to correlate levels of timber harvesting with visual quality objectives. A more detailed description of each of these models is included in this appendix.

II. THE FOREST PLANNING MODEL (FORPLAN)

(See Johnson, K. Norman, Daniel B. Jones, and Brian M. Kent: Forest Planning Model (FORPLAN) User's Guide and Operations Manual, USDA Forest Service, May 1980.)

A. Overview

Identifying the optimum resource allocation and output schedule presents a very complex problem. FORPLAN is a specialized matrix generator and report writer for a standard linear programming algorithm (FMPS). (FMPS is the acronym for Functional Mathematical Programming Subsystem, the linear programming code used on the UNIVAC 1100 Series Computer.) Linear programming is a standard mathematical technique for solving simultaneous linear equations subject to a certain set of constraints and a particular objective function.

This is expressed mathematically as.

Maximize: $z = c_1x_1 + c_2x_2 + \dots + c_nx_n$ (Objective function)

Subject to: $a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n > b_1$

$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n < b_2$ (Constraint Set)

$a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n \leq b_m$

$x_i > 0$

These mathematical expressions can also be shown in the following matrix:

	Column j=1	Column j=2	Column j=3	Column j=n	Constraint Type	Right Hand Side Constraint
Objective function	C_1X_1	C_2X_2	C_3X_3	C_NX_N		.Maximize
Row i = 1 (Timber)	$a_{11}x_1$	$a_{12}x_2$	$a_{13}x_3$	$a_{1n}x_n$	>	b_1
Row i = 2 (Land)	$a_{21}x_1$	$a_{22}x_2$	$a_{23}x_3$	$a_{2n}x_n$	<	b_2
Row i = m	$a_{m1}x_1$	$a_{m2}x_2$	$a_{m3}x_3$	$a_{mn}x_n$	\leq	b_m
				x_j	>	0

In the FORPLAN formulation, the linear equations (rows) represent resource production functions, costs, and acreage or other types of constraints (for example, row 1 might represent timber production; row 2 might represent total suitable acres; row M might represent acres burned by wildfire). The columns ($j = 1 \dots n$) represent the different activities (prescriptions) which can occur over time on specific units of land called analysis areas (represented by x_j). The a_{ij} 's in the matrix are the production, cost, or resource coefficients associated with each prescription/analysis area combination. The b_i 's are the right-hand-side constraints representing exact amounts ($=$) or upper ($<$) or lower ($>$) constraint levels that must be met. In the example above, if row 1 represents timber production, the interpretation of the constraint—

$a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \dots + a_{1n}x_n > b_1$

would be the "total amount of timber produced from all prescriptions and analysis areas must be greater than or equal to the amount b_1 ".

The FORPLAN model was built by representing the production functions, costs, values, and resource supplies for the Forest in the mathematical format described above. For the Tahoe National Forest, the resulting model contained approximately 28,000 columns and 2,500 rows. Once the model was formulated, a number of test runs were made to check the model for reasonableness and to make additional calibrations. Land allocations, activity and output schedules, costs, benefits, and present net value were developed by altering the objective function and constraint set to meet the theme of each alternative and benchmark and then running the model.

Unique constraint sets were developed to represent minimum management requirements, minimum implementation requirements, Forest discretionary constraints common to all alternatives, and specific land allocations and output schedules needed for individual alternatives. An iterative process

was used to formulate these constraint sets prior to making final FORPLAN runs for the alternatives and benchmarks.

FORPLAN was used to determine the most cost efficient mix of goods and services that could be produced from the Forest given the objectives and constraints of each alternative. The trade-offs made among alternatives were examined and the costs and benefits associated with each objective or constraint measured. This analysis provided a way of indirectly evaluating the non-priced benefits by measuring the amount of present net value (PNV) foregone. The final criterion used to evaluate alternatives was net public benefits (NPB), which is the PNV plus consideration of nonquantifiable Forest resource benefits. Economic efficiency is discussed in more depth in Appendix D and the EIS, Chapter 3, Section C, The Economic Environment, and Chapter 4, Section B, The Economic Consequences.

Management activities modeled in FORPLAN were determined by the Interdisciplinary Team and approved by the Management Team (All Interdisciplinary Team (IDT) proposals were approved by the Forest's Management Team, comprised of District Rangers and Staff. Further mention of the IDT actions also assumes approval by the Forest Management Team.). This pre-FORPLAN analysis included investigating

1. The activities that could be applied to National Forest System land.
2. Those activities that could be modeled in FORPLAN
3. The kinds of land to which each activity could be applied.
4. The costs, outputs, and benefits which would result from the application of each activity to a specific type of land
5. The compatibility of activities when applied to the same land area.

This investigation provided the basis for a matrix of all possible management activities which could be modeled and their associated costs, outputs, and benefits.

Activities which were desired but not modeled as one of the above FORPLAN inputs required the use of additional constraints

The post-FORPLAN analysis took two forms. First, activities that could not be modeled (such as watershed improvement) were analyzed and added to the prescriptions if they increased net public benefits. Second, the alternatives were ground checked to insure their implementability.

B. Land Units

Capability areas are the smallest unit of land (or water) used in forest planning. They are discrete and recognizable units classified primarily according to physical (e.g., soil, watershed), biological (e.g., vegetation), and administrative (e.g., county lines, Forest boundary, North Fork American Wild River, Granite Chief Wilderness) factors. All land within a capability area is homogeneous in its ability to produce resource outputs and in its production limitations. The Tahoe National Forest has about 26,000 capability areas.

Capability areas were developed by overlaying existing map information. The Wildland Resource Information System (WRIS) was used to calculate capability area acreages and to number each area for identification in the data base (Forest Planning File). The Forest decided what information was needed for each capability area to assess resource opportunities and public issues and then collected that information about each area. Different resource attributes were determined for each capability area. See TNF's Planning File for detailed discussion of resource data collected. This information was entered into a computerized data base system. (The TNF database is maintained in-house through DATATRIEVE and DataGeneral software.) Once entered into the system, information on capability areas could easily be retrieved, sorted, aggregated, and analyzed.

The delineation of the capability areas required several steps. First, each resource specialist on the ID Team decided which physical or biological attributes in the data base were necessary to

determine their resource yields. The selection of which resource outputs to monitor in FORPIAN was guided by the problems identified by the Forest issues, concerns, and opportunities.

Because of their large number, individual capability areas could not be used in FORPLAN. Use of such a large number of land units would be cumbersome, expensive, and would have exceeded the matrix size limits that can be utilized in FORPLAN. Analysis areas were created to handle this problem. Analysis areas are an aggregation of like capability areas with sufficiently similar physical, biological, and administrative conditions such that they would probably respond in a like manner to management activities. Each capability area was given an analysis area identifier so the database could be queried for the land information needed to build the FORPLAN model.

Next, the analysis areas were defined using each attribute proposed by the resource specialists as a level of stratification, or level identifier in FORPLAN. Because FORPLAN could accommodate only six level identifiers, the number of attributes initially selected by the resource specialist was greater than could be used. This forced the ID Team to select the most critical attributes necessary to address the planning problems and to consider the reliability of the data for making yield and cost estimates.

The criteria needed to develop analysis areas are the level identifiers in FORPLAN. The level identifiers used are shown in Table B.I.

Data reliability and the need to respond to issues related to specific geographic areas (i.e., Research Natural Areas) played a major role in the delineation of analysis areas. In many cases, the data reliability for capability areas were aggregated into individual analysis areas. The need to maintain the geographic identity of some individual capability areas limited the amount of aggregation that could occur. The Tahoe National Forest database has a total of about 60 analysis areas, based on actual National Forest System acres, and 20 analysis areas not representing real acres, such as wildlife habitat improvement projects, facilities management, fire programs, and dispersed recreation.

Management areas are contiguous capability areas with similar resource characteristics that are used to assign multiple-use prescriptions based on alternative themes. Management areas are delineated based on geopolitical factors (administrative boundaries, issue orientation, historical use patterns, access, landform, vegetation type) and are used to facilitate administration and plan implementation. All management areas are identified as a basic aggregation of capability areas from the resource data base and are delineated on Forest planning display maps shown in the Forest Plan. The TNF has 106 management areas.

C. FORPLAN Prescriptions

A prescription is the set of management practices and the schedule for their application on a specific area to achieve desired objectives. For a given analysis area, the range of prescriptions describes what could be done (i.e., the possibilities) on that analysis area. FORPLAN is used to determine the optimum choice and timing of prescriptions, given the constraints and objective function for an alternative.

Prescriptions were developed by the interdisciplinary team to represent the range of management opportunities and respond to issues. Prescriptions were developed to represent five general conditions or levels of management intensity: minimum level of management, management at greater intensity than current management, and management at the maximum intensity level that is legal and implementable. Prescriptions were formulated to use the most cost-efficient mix of practices to achieve the objectives at each level of management intensity.

Prescriptions were researched to determine the outputs, costs, and benefits that would occur when the prescription is applied to a given analysis area or land unit. This quantification process produced the output, cost, and benefit coefficients that are used in the FORPLAN yield and economic tables.

The Forest distinguishes between FORPLAN prescriptions and management prescriptions (see Section D, Management Prescriptions, which follows). FORPLAN prescriptions are sets of activities which could occur on the analysis area that can be modeled in FORPLAN. They are 'pure' activities in that they are written without imposition of the standards and guidelines needed to fit activities to site-specific conditions.

FORPLAN prescriptions were developed to allow consideration of a full range of management activities on the analysis areas. A minimum level prescription was created for each analysis area to allow a choice between selecting the possible intensive practices or selecting no active management practice. The choice of prescriptions identified for each analysis area was constrained only by technical feasibility. Limiting the number of prescriptions available to choose from in a given analysis process is a type of constraining used to formulate an alternative or benchmark. The FORPLAN prescriptions analyzed are described below. Additional information for the prescriptions and the prescription development process is included in the EIS, Chapter 2 and in the planning records. More detail on characteristics of analysis areas to which each prescription applies is in the planning records (see Identification of Lands Tentatively Capable, Available, and Suitable for Resource Management, Revised July 1985)

Prescriptions have two components, management emphasis and management intensity. These are described below

D. Management Prescriptions

Management direction for the TNF is described by 15 different management prescriptions representing 15 different bundles of management practices and the standards and guidelines (See EIS, Chapter 2, Section E, Management Prescriptions and Management Areas, and Table 2 16) Each management prescription is modeled in FORPLAN by different proportions of the FORPLAN prescriptions (emphasis/intensity combinations). The 15 management prescriptions and corresponding FORPLAN prescriptions are described as follows

#	Management Prescription	FORPLAN Prescriptions
1	The theme is to manage the designated Granite Chief area as wilderness Manage for dispersed recreation Manage grazing under extensive use. This land is unsuited for timber production	X-WLDN/X-WLDN
2.	The theme is to retain a near-natural appearing forest environment while also producing some forage and water Manage for dispersed nonmotorized recreation Grazing is permitted Low standard roads may be developed for harvesting but are closed to public vehicle use Land is unsuited for regulated timber production	NOTCAP/NOTC, TM-UNS/MINLVL RGEMGT/MAINTA
3	The theme is to produce a moderate level of commodities while enhancing or emphasizing other selected resources. Manage for dispersed motorized recreation	NOTCAP/NOTCAP TM-MRG/GR-SEL RGEMGT/MAINTA
4.	The theme is to provide water-oriented recreational opportunities Manage for developed recreation use around reservoirs and lakes. Maintain and upgrade developed facilities Maintain visual quality background for the recreation users. Allow vegetative management, including regulated timber harvest, only when compatible with recreation and visual objectives and maintenance of stand vigor. Provide interpretive services and facilities where appropriate (1/ FORPLAN will identify the most economically efficient intensity from those available See the proceeding Section C, FORPLAN Prescriptions)	NOTCAP/NOTCAP TM-UNS/MINLV TM-MRG/GR-SEL TM-RED/(INTENSITY) 1/ RGEMGT/MAINT
5	The theme is to establish representative vegetation and geologic areas for scientific and educational research Manage for research and special interest purposes. Other uses permmed when not in conflict with research objectives Timber harvest would be unregulated.	NOTCAP/NOTCAP TM-UNS/MINLVL RGEMGT/MAINTA
6	The theme is to manage as a classified wild river, in accordance with the North Fork American Wild River Management Plan and as stated in Section 10(a) of the Wild and Scenic River Act of 1968 The fisheries will be managed as stated in the Cooperative Habitat Management Plan for the river These lands are unavailable for forage and timber production and have been withdrawn from mineral appropriation since 1975.	UNAVAL/UNAVAL

FORPLAN recreation prescriptions apply to existing and potential developed recreation sites and downhill ski areas. These prescriptions are assigned based on economics or the theme of each alternative. They are compatible with the themes of management prescriptions 2, 3, 4, 8, 11, 12, 13, and 15.

FORPLAN wildlife, facilities, and fire prescriptions are associated with 'dummy' analysis areas. FORPLAN allocates the prescriptions based on economics or as constrained by the theme of each alternative. Site-specific allocation of these prescriptions would be made at the project level to meet the objectives of the management prescriptions.

E. Time Periods

To assure that the allowable sale quantity can be achieved and maintained, a 16-decade planning horizon is **used** in FORPLAN. The first decade of the planning horizon is the period 1989-1998. A total of 16 time periods, each with a duration of 10 years, is used in the modeling process. However, in order to reduce the complexity of data displayed in the EIS, 5 decades are **used** in all EIS display tables.

F. Outputs

Table B 2 displays the output environmental effects used to analyze the alternatives

Outputs are estimated using yield coefficients. For outputs modeled in FORPLAN these coefficients are built into the yield tables and are used to estimate outputs for all prescription/analysis area combinations. For outputs accounted for outside FORPLAN, yield coefficients are applied to factors that are accounted for both inside and outside the FORPLAN model. The process used by the interdisciplinary team to develop the yield coefficients for each output is summarized below. A detailed discussion of yield coefficients follows the summary.

G Coefficient Documentation

OUTPUT	SUMMARY OF PROCESS FOR ESTIMATING COEFFICIENTS
	INSIDE FORPIAN
Timber	Timber yield coefficients were developed from a Forest inventory completed in 1980 using a computer program called RAMPREP. This program predicts yields over time for each timber strata based on volume, age, and growth rate
Timber Suitable Lands	These acres are capable and suitable for timber production. See TNF's Identification of Lands Tentatively Capable, Available, and Suitable for Resource Management (7/85) and Appendix K for more information

Long-Term Sustained Yield	This is the potential long-term sustained yield capacity that is theoretically possible, based on the prescriptions allocated. Optimum capacities were predicted by FORPLAN, based on timber yield tables, and are expressed in cubic feet.
Ending Inventory of Timber	This is the merchantable volume of all the standing timber that would exist at the end of the planning period. Coefficients for predicting growth and yields are in FORPLAN and are expressed in cubic feet.
Range	These coefficients measure the potential usable AUM's (Animal Unit Months) per acre per decade for permanent and transitory range. Coefficients were also estimated for increased usable AUM's resulting from various timber management activities, prescribed burns, and type conversions. The Forest Range Conservationist developed the yield coefficients, based on vegetative types, slope, manageable range allotments, and historical use.
Recreation, Dispersed	Dispersed recreation capacity was based on the level of dispersed development, use densities for various ROS (Recreation Opportunity Spectrum) class areas of the Forest, and historical use.
Recreation, Developed	Developed recreation capacity was based on types of existing and potential developed sites and their PAOT (person-at-one-time) capacities, using data from Recreation Information Management (RIM).
Recreation, Downhill Skiing	Alpine ski area capacity was based on existing capacities, predicted potential development capacities, and historical use.
Recreation, Wilderness	Inventoried roadless area capacities were based on their predicted use densities for the ROS classes within their boundaries, and historical wilderness-compatible use. Following signing of the California Wilderness Bill on September 28, 1984, these yield coefficients were used for dispersed recreation capacity.
Wildlife and Fish User Days	WFUD's are a result of habitat improvement, resource management activities, and uninduced use based on total dispersed recreation use. Yields for various activities were based on historical use. Because WFUDs are part of the total dispersed recreation output, they contribute to the dispersed demand cutoff.
	Based on the current situation, 8 percent of the Forest's dispersed recreation is considered Wildlife and Fish User Days. Forty-five percent of this use is a background level, associated with minlevel. The other 55 percent is met by a link to timber suitable acres and fish and wildlife improvements projects (see Wildlife Improvements). Recreation Visitor Days and Wildlife and Fish User Days are the same unit of measure, and therefore are additive. Timber induced WFUDs are nonstructure habitat improvements resulting from regeneration cutting. WFUD's are also generated by structural habitat improvements projects such as guzzlers. Costs and benefits attributed to structural habitat projects are based on the local experience of the Forest Wildlife Biologist.
	The paper by Gerstung (1973) formed the basis for calculating fish production in streams. The potential maximum yield for various stream widths was the starting point. It was assumed that these values were for good quality streams. The biologist also assumed a relationship between stream quality and habitat improvement potential, i.e., streams with good quality have a low overall habitat improvement potential.

A similar method was used to calculate fish production in lakes, except that the basis for all calculations came from conversations with the Fisheries Biologist on the Eldorado NF. His work on the Eldorado NF was assumed to be applicable to the TNF. The assumption (based on his work) was that lakes having good quality would produce approximately five pounds of fish per acre per year.

The total potential increase in stream and lake production made up the maximum production that could be expected on the Forest. Finally, specific portions of the maximum production were partitioned among the alternatives. The amount of production occurring in each alternative was dependent on the theme and the amount of fisheries habitat improvement allocated to each particular alternative.

Wildlife Habitat Types

Based on the Wildlife and Fish Habitat Relationship model (WFHR), relationships were developed between the existing and future vegetation and 10 wildlife habitat types. The TNF habitat types are: Seedlings and saplings (1X); Poles (2X); Small sawtimber, <40 % crown closure (3A); Small sawtimber, >40% crown closure (3BC), Medium-Large sawtimber, <40% crown closure (4A); Medium-Large sawtimber, >40% crown closure (4BC); Hardwood/conifer mix (3X), Pure hardwoods (HD); Brush and grass (SX); and miscellaneous (00).

Spotted Owl Habitat

The habitat suitable for spotted owls was linked to the mix of vegetation that results from natural succession or forest management. Mixed conifer and red fir stands with over 70 percent crown closure that were at least 150 years old were considered suitable habitat; stands that do not meet both criteria were considered unsuitable. Each SOHA was constrained to Sustain at least 1,000 acres of suitable habitat over time.

Water Yields

The Forest Hydrologist developed coefficients to show increases in water runoff due to planned management prescriptions or fire. Coefficients for various timber management activities, prescribed burns, and type conversions were used in FORPLAN to predict yields. The water runoff coefficients varied by vegetation and elevation. Yields were predicted, based on coefficients from literature review and existing yield records.

Water yield coefficients for various broad strata were estimated based partly on water yield coefficients in a number of publications, partly on professional judgement, and by adjusting these values to agree with the total net yield derived from existing runoff records. Water yield increase coefficients were obtained from the literature including (1) EPA Publication EPA-600/8-/80-012, titled 'An Approach to Water Resources Evaluation of Non-Point Silvicultural Sources (A Procedural Handbook),' (2) USFS Publication 'The Impact of Timber Harvest on Soils and Water,' reprinted from the Report of the President's Advisory Committee on Timber and the Environment, April 1973, and (3) USFS Publication 'Water Yield Opportunities on National Forest Lands in Arizona,' by Rhey M. Solomon and Larry J. Schmidt.

A 20-year hydrologic recovery period is assumed. National Forest System lands' yield is 61.7 percent of usable reservoir capacity, or 919,000 acre-feet per year. This is 46 percent of the total water currently produced on NFS lands.

Roads

The arterial, collector, and local roads needed to access land for timber, range, and recreation for each decade were calculated for the general Forest area and for each roadless area separately. All yield coefficients were based on existing and predicted road densities.

Wildfire Loss

Burned acres, costs, and net value change for each fire program/option were based on outputs from the Initial Attack Assessment Model, version 2. These outputs and values were integrated into FORPIAN and became active outputs in the allocation and scheduling decisions. Coefficients selected were.

1) FFF Cost plus Net Value Change (NVC) excluding plantations, acres burned by wildfire within a) mature timber, brush, and grass vegetation types and b) plantations. Both cost, NVC, and acres burned are specific by fire program option by decade.

2) NFDRS Fuel Model associated with timber strata at present distribution and change over time. Fire Program Options. Three fire program options were developed:

a) Current Option (CUR): This program is the base fire management program and its configuration is similar to the FY 1982 Forest Fire Management Program. The emphasis is a combination of large (Model 51/60) and small (Model 40) fire engines with fuels (115) project dollars.

b) Attack/Prevention Option (AKP): This program switches emphasis from the current option (a mix of large and small engines) to all small engines. This concept will allow a greater flexibility to provide increased prevention efforts.

c) Air Attack Option (AIR): This program replaces a number of small engines from the Attack/Prevent Option with one or two medium-size (Hughes 500D) helicopters. This emphasis will provide quicker response times to some fires by initial attack forces.

Fire Program Mixes (FFP budget level). For each fire program option, five different FFP budget levels were derived from the FY 1982 budget level. In addition, a minimum budget level was estimated, displaying costs of a reduced organization (detection and initial attack only).

FFF Cost/Acre of a Plantation Fire. This is calculated from a weighted average of all fire program option FFF costs on a per-acre basis. The figure to be used is \$850/acre.

Probability Factor of Burning an Acre of Plantation (By Decade). This calculates the probability of burning an acre of plantation given the Forestwide plantation acreage.

Fuels Treatment

Based on the allocated and scheduled activities, fuel treatments over time were predicted. The categories reported were total treated acres, broadcast-burned acres, and piles burned (acres)

Fuel Model Groups

Based on the allocated and scheduled lands, acres by fuel model groups were predicted. Relationships between vegetation, seral stages, and FORPIAN prescriptions were developed as the inputs for these yields.

Effective Alteration

This output is expressed in acres effectively altered by vegetation changes. Coefficients were developed to indicate the visual impact of timber harvests and other vegetation changes. The EFFALT model is discussed in more detail in Section IV D of this appendix

OUTSIDE FORPIAN

Non-chargeable Harvest	Harvest volume per acre is based upon the average unregulated harvest for the period 1979-83, divided by the acres of unregulated as stated in the 1978 Timber Management Plan.
Fuelwood	Fuelwood yields were derived from historical data for cull material, unutilized material up to 3 inches in diameter, precommercial thinning slash, and hardwood volumes associated with timber sales. The average volume per acre available was reduced by slope classes because of access problems. On steeper slopes, only the average fuelwood volume within 50 feet of the downhill side of the road and 200 feet of the uphill side were considered available. Background data used to derive the coefficients are in the TNF planning records.
Biomass	Biomass yields were developed from timber inventory values by stratum, including the merchantable bole, tops, limbs, cull material, hardwoods, non-commercial conifers, and precommercial thinning residues. Accessibility did not enter into the calculation. Background data used to derive the coefficients are in the TNF planning records.
Visual Quality Index	Levels of visual resource outputs for each of the alternatives have been compared by applying a numerical weight to the quantity (in acres) of each Visual Quality Objective by variety class. A higher weight is given to VQOs maintaining natural qualities and higher scenic quality. A single index was developed for each alternative. The procedure is found in Forest Service Manual 2383.4 , Regional Supplement #143, 5/83 . The index for each alternative was determined from the allocated management prescriptions and their acres of VQO's by variety class. The index for the current situation is based upon review of the actual visual condition of the landscape by variety class.
Recreation Opportunity Spectrum (ROS)	Acres of ROS class over time were based on the existing physical setting, scheduled recreation development, timber harvesting, and road construction. The USDA Forest Service 'ROS User's Guide' and Forest Service Manual 2331.47 and 2353.4, R-5 Supplement #122 10/80 , were used as reference.
Watershed Improvement	There were no coefficients for this output. Acres were estimated, based on alternative theme and existing situations' potential for improvement projects.
Trails	Trail miles were calculated based on current trail system, lands allocated to nonroaded areas, and the total dispersed RVDs.
OHV	There were no coefficients for this output. Based on the total number of dispersed RVDs miles of road and trail, and the alternative theme, the ID Team developed the outputs for miles of open, closed, and seasonal OHV roads and trails.
Minerals	There were no coefficients for this output. Outputs were estimated, based on historical operating plans and available lands.

H Economics in FORPLAN

Economics is discussed in the EIS, Chapter 2, Section F, Economic Effects, and Section B, the Alternative Development Process, and displayed in various tables; in Chapter 4, Section B, The Economic Consequences Appendix D outlines how economics are used in the entire document. Demand analysis is presented in The Affected Environment, Chapter 3. Most of the economic efficiency

analysis was conducted with the use of the FORPLAN model. Economic data and assumptions incorporated into the FORPLAN/ are described below.

DISCOUNT RATE

An interest rate of 4.0 percent was used to determine the present value of future benefits and costs. This rate approximates the long-term cost of capital in the private sector as measured by the return on AAA corporate bonds after adjustment for inflation. (See Row, Clark; H. Fred Kaiser, and John Sessions, 'Discount Rate for Long-Term Forest Service Investments: Journal of *Forestry*, June 1981, for a complete discussion of the rationale for the discount rate.)

BASE YEAR FOR DOLLAR VALUES

(All dollar values are expressed in 1982 dollars. The following factors based on the implicit price deflator for gross national product were used to adjust values from other years to 1982.)

Year	Factor
1978-82	1.39
1979-82	1.28
1980-82	1.18
1981-82	1.08

REAL COST AND PRICE TRENDS

The real cost and price trends used for timber are shown below:

	Decade 1	Decade 2	Decade 3	Decade 4	Decade 5
Timber price increase, average annual percent	4.78	1.09	2.06	1.57	1.84
Timber cost increase, average annual percent	3.10	2.40	1.90	1.60	1.60

These timber price trends are projections from an econometric model of National and Regional timber markets (Haynes, Richard W., Kent P. Connaughton, and Darius M. Adams; 'Stumpage Price Projections for Selected Western Species', USDA Forest Service Research Note PNW-367, November 1980.) The timber cost trends are based on projections of per capita disposable personal income because timber management cost increases have historically been highly correlated with increases in per capita disposable income. (USDA Forest Service, An assessment of the Forest and Range Land Situation in the United States, January 1980.) Cost and prices for all other resources were held constant.

Benefits

The dollar values for outputs used to calculate PNV are the prices that consumers would be willing to pay for forest outputs, whether or not such prices are actually collected by the Federal Government. At present it is National policy to provide most forest outputs either at no charge to consumers or at a charge less than the willingness to pay price. This is shown in the following tabulations in Table B.3. All benefits which can be assigned a significant monetary value are accounted for by the model. Nonpriced benefits are accounted for outside the model in the evaluation of net public benefits.

Output above the estimated demand was not valued. A calculator with a built-in discounting routine was used to incorporate benefits valued outside of FORPLAN in the PNV analysis.

For outputs used off-site, benefits are based on the value of the outputs as they leave the land or production site. For outputs used on-site, benefits are valued when use takes place. However, in cases where it is easier to derive values after the output leaves the production site, costs incurred and profits earned after the output leaves the site were deducted from the values at later production stages.

Timber values are average stumpage prices developed from Forest sale records for the period 1979-1982.

Grazing values are the average amount that Tahoe National Forest permittees are willing to pay for grazing on the Forest as estimated from ranch livestock budgets developed by the USDA Economic Research Service.

Recreation and wildlife and fish user day values are the estimated average amount that recreationists are willing to pay at the site. These values are based on a National survey of travel cost and contingent value recreation studies conducted by the Forest Service for the 1985 Resource Planning Act (RPA) evaluation (Draft Environmental Impact Statement 1985-2030 Resources Planning Act Program, Appendix F, Forest Service, U.S. Department of Agriculture, 1/84).

Water values are based on the marginal value of water in irrigation use (the primary water used in California) determined from studies surveyed by the Forest Service for the 1985 RPA. (ibid.)

Only potentially usable water is valued; but all water, whether used or not, is tracked. Of the approximately 2,000,000 acre-feet of water yielded annually on the TNF, only 919,000 acre-feet are usable. A value of

\$59 was assigned to the usable water; a value of zero is assigned to all other water. This resulted in a weighted average of \$2711 per acre-foot.

DEMAND CUT-OFFS FOR BENEFIT VALUES

Benefit values are applied only where there is a demand for the output by Forest users. Outputs that exceed demand are given a benefit value of zero, while those that are produced at or below the quantity demanded by consumers are assigned the benefit value described in the previous section. This is handled with the use of a demand cut-off.

Most of the outputs from the Tahoe National Forest are consumed in National and Regional markets where the quantity demanded is many times larger than the productive capacity of the Tahoe National Forest (see Chapter 3 of the EIS for a resource-by-resource description of the demand situation). For this reason demand cut-offs were needed only for Recreation Visitor Days (RVD's) and Wildlife and Fish User Days (WFUD's). For these resource outputs, demand is more localized and less than the productive capacity of the Forest in early time periods. Demand cutoffs were based on projected population growth in the TNF's local market area.

TABLE 8.4 - RECREATION DEMAND CUTOFFS

Decade	1	2	3	4	5-16
Developed Cutoff (M RVD's)	1,976.0	2,393.0	2,784.0	3,129.0	3,318.0
Downhill Ski Cutoff (M RVDs)	292.0	379.0	492.0	639.0	830.0
Dispersed Cutoff (M RVDs)	2,925.0	3,436.0	3,944.0	4,452.0	4,960.0

Dispersed recreation RVDs is the sum of background WFUDs, background dispersed recreation RVDs, habitat improvement WFUDs, wilderness RVDs, WFUDs generated by timber and range prescriptions, and other dispersed RVDs.

COSTS

All costs used in the analysis are estimates based on accounting records and the experience of project managers. Costs for applying the different multiple resource prescriptions were estimated and built into the economics tables in FORPLAN. Costs for timber, recreation, range, wildlife facilities, roads and trails, fire, and fixed minimum level costs are accounted for by the model.

Fixed costs amount to \$319 million, which is 17 percent of the normalized 1982 budget of \$187 million.

Costs were checked for reasonableness by comparing the first decade costs for the current alternative developed with the use of FORPLAN against actual expenditures for FY 1982.

I Stage II Analysis

Stage II analysis is conducted prior to the Benchmark analysis. It establishes the Soil Rent Values (bare-land soil expectation values) and the Forest Rent Values (Current Value plus Soil Rent) of every proposed timber management activity, as required by 36 CFR 219.13(b) and FSM 2412.33. Soil and Forest Rent Values are calculated for every combination of analysis area, prescription,

and timing choice that will be included in the FORPLAN analysis. Both existing and regenerated prescriptions are analyzed

Forest and Soil Rent Values for every proposed timber management activity were extracted from the MATRX-RX file (columns chapter).

- Forest Rent Values varied from ~~\$-510~~ to ~~\$9,567~~.per acre
- Soil Rent Values varied from ~~\$-976~~.to ~~\$454~~. per acre

The costs and values used in the Stage-II analysis, for each proposed timber management activity, are estimated by assuming first, that no other acreage will be managed, and second, that no **Forestwide** constraints on management practices or outputs will be imposed

An important consequence of these assumptions is that the cost effectiveness of proposed timber management activities cannot be determined solely by the Forest and Soil Rent Values. For example, even if the Forest and Soil Rent Values of all the timber management activities proposed for an analysis area are negative, managing this analysis area with some of these activities may increase the PNV of a FORPLAN benchmark or alternative when forestwide management guidelines or even-flow timber harvest constraints are specified. This result has been well documented in professional forestry journals. Consequently, some timber management activities with negative Forest or Soil Rent Values are included in the FORPLAN analyses.

The Stage II analysis does ~~serve~~ to flag proposed management activities which in isolation are inefficient. This information is useful in developing management guidelines and in validating the results of the FORPLAN analysis.

It should **also** be noted that since the Tahoe matrix used the more efficient Model 2 formulation of FORPLAN, which reduces the number of redundant regeneration activities, it was not necessary to reduce the number of prescriptions as required on Forest using Model 1 formulations.

J. Socio-Economic Impact Analysis

The socio-economic environment is discussed in the **EIS**, Chapter 3, The Economic Environment and the Social Environment. The results of the socio-economic analysis of the alternatives is presented in Chapter 4, Economic Consequences and Social Consequences.

K. Constraints

Each of the resources discussed in 36 CFR 219.13 through 219.26 must be addressed by standards and guidelines, management prescriptions, or other management direction in the Forest Plan. Regional resource direction which Forests are expected to follow is in the Regional Planning Direction.

Some management requirements can be translated into modeling constraints and can be simulated or proxied in FORPLAN. Constraints are quantifiable limits placed on the linear program model to ensure that minimum or maximum acres or dollars are used or that specific minimum or maximum amounts of outputs are produced. Constraints override the objective in linear programming analysis. Thus where a predetermined level of output, minimum physical condition, or allocation is entered as a constraint, it is always achieved (or no feasible solution is found).

Output levels and other desired effects entered as constraints are assumed to contribute more to public benefits than their cost of production plus the foregone public benefits of any outputs or other effects they replace. For this reason, the interdisciplinary team tried to formulate constraints that met objectives with the lowest cost and least effect of other outputs. In most cases this required the formulation and testing of several alternative sets of constraints to determine the most cost effective set (in terms of PNV) that would meet the objectives. For Forest planning purposes constraints can be divided generally into five categories, which are discussed in the next section.

L Constraints Common to All Alternatives

1. Technological constraints. Some examples of technological constraints are
 - only those lands having the proper characteristics for ski areas (slope, snow, access, land not otherwise encumbered) are allowed to have ski area expansion or development as a management option.
 - clearcut harvest prescriptions are not available on south-facing slopes where shelterwood prescriptions are necessary to guarantee regeneration.
 - demand cutoffs limit development of developed and dispersed recreation sites
 - NFS administrative sites and electronic sites are considered suitable only for facility development.
 - Existing recreation development sites are considered suitable only for recreation
 - Timber inventory constraints by age class ensure area regulation by the end of the planning period.
 - Placer County Big Tree Grove and Babbitt Peak proposed RNA are considered suited only for Special Interest Area and Research Natural Area status, respectively.

The following discusses the modeling rules and impacts associated with minimum management requirements, timber policy constraints, minimum implementation requirements, and Forest constraints

2. Minimum Management Requirements

Constraints are needed to meet minimum management requirements or management standards. Procedures for defining the MMR's were specified by the Pacific Southwest Regional Guide. MMR's are applied to all benchmarks and alternatives but are not applied to the (FLW) unconstrained max PNV assigned with flow/LTSY constraints or the (MLV) minimum level of management FORPIAN runs. The MMR's are taken from 36 CFR 219.27 and generally represent requirements that are outside of Forest Service authority to change. They are based on statutes and regulations in contrast to manual direction or agency policy. Some examples of MMR's are: lands not available for timber prescriptions (North Fork American Wild River, Onion Creek Experimental Forest, and Granite Chief Wilderness), T&E species, viable populations, diversity, riparian areas, and soil and water productivity. MMR's are described in more detail below and in the EIS, Chapter 2, Section E, Management Direction Common To All Alternatives.

Minimum Management Requirements (MMR's) were developed for the TNF to comply with Regional Office Direction. A discussion of the modeling rules and associated impacts for each MMR follows

Capable, Available, and Suitable Land. Lands that were tentatively suitable for timber management were placed in analysis areas and were given a range of appropriate prescriptions. Lands not tentatively suitable for timber management were placed in other analysis areas where timber prescriptions were not an option. A detailed discussion of the timber suitability criteria is contained in Appendix K.

The effect of limiting the land base to only those acres that are now available, and have a reasonable chance of successful reforestation, defines the acres that are available for scheduling harvesting, reforestation, and thinning. This establishes the maximum land base available to sustained yields of timber.

Threatened and Endangered Species The bald eagle and the peregrine falcon are Federally-listed endangered species that occur on the Forest. The Lahontan cutthroat trout is a threatened species that occurs locally. The Forest will protect all species as prescribed in species recovery or management plans. Protection will be afforded by projects that do not justify constraints on other resources in FORPLAN.

Viable Populations. Goshawks Goshawks were not modeled in FORPLAN since most of the known nests were found to occur in habitat that was provided with other MMR's. Standards and guidelines provide the necessary direction to ensure habitat protection

Spotted Owls. A management scheme for each spotted owl habitat area (SOHA) was determined by alternative. The full range of FORPLAN prescriptions capable of maintaining or creating habitat for spotted owls was used in the modeling process. This range of FORPLAN prescriptions includes.

- (a) min-level prescriptions which reflect no scheduled harvest:
- (b) uneven-aged timber management prescriptions, and
- (c) even-aged timber management prescriptions.

Each SOHA was constrained to maintain 1,000 acres of suitable habitat overtime (see page 6-22).

FORPLAN was allowed to select the prescription or combination of prescriptions as well as the associated number of acres in each prescription needed to meet the habitat requirements and reflect the management scheme particular to each alternative.

Diversity. FORPLAN solutions were monitored to ensure that at least 5 percent of each vegetative seral stage combination was present for each decade

Snags On the east side of the Forest (eastside pine forest type), 7.8 to 8.4 percent of regulation classes 1 and 2 (full yields and reduced yield lands) are assigned a timber unsuitable prescription

Hardwoods. No pure hardwood stands are allowed timber management prescription choices. In the mixed hardwood/conifer stands, yield reductions are simulated to reflect hardwood standards requiring given basal areas for the hardwood component. This is done in two ways. 1) yields from every other (alternate) thinning are not counted: 2) a given percent of the stand acres regenerate to pure hardwoods.

Riparian Areas. The aquatic, riparian, and terrestrial habitat associated with riparian areas is important to a large variety of wildlife species. The riparian wildlife corridor is defined as streams and adjacent vegetative communities which are predominantly influenced by, or associated with, water. This was modeled in FORPLAN by allowing only uneven-aged timber management within 100 feet either side of perennial streams

Water Quality (or Cumulative Watershed Effects). Those Forest areas identified as sensitive watershed lands were limited to a disturbance of not more than 5 percent per decade. For modeling purposes, these areas were only allowed uneven-age timber management. A discussion of these sensitive watershed lands is in the planning records and the TNF AMS, Appendix E, 7/85

3 Timber Policy Constraints

Rotation Length. Minimum ages were established for merchantability, culmination of mean annual increment, and 95 percent of CMAI based on RAMPREP yield tables for the major forest types. These are displayed in Table B 5

TABLE 8.5 • ROTATION LENGTHS -Ages in Periods (10 years)

	Merchantable	CMAI	95% CMAI
Mixed conifer w/o thinning	4	6	5
w/ thinning	4	10	6
burned plantation	6	10	8
Red fir w/o thinning	4	10	7
w/ thinning	4	14	10
burned plantation	6	16	11
Eastside pine w/o thinning	4	9	7
w/ thinning	4	12	8
burned plantation	6	12	10
Lodgepole pine w/o thinning	4	4	4
w/ thinning	4	8	6

Sustained Yield Requirements Two constraints, inventory and growth, were used to proxy the sustained yield requirements. The inventory constraint forces an area regulation on even-age timber management in the 15th and 16th decades by requiring a proportion of the regenerated stands to be in specified age classes. The growth constraint requires that growth in the 5th and 6th decades, along with the 15th and 16th decades, is 15 percent greater than the FORPLAN-calculated long-term sustained yield.

Harvest Flow Requirements This is used only in alternatives that depart from the nondeclining, even-flow policy. In order to prevent wide fluctuations from one decade to the next, the timber output after the first decade is not allowed to change more than plus or minus 17 percent from the previous decade.

Dispersion. To proxy dispersion of clearcuts, regeneration in analysis areas totally regenerated in periods 1, 2, or 3 in the FLW unconstrained benchmark was limited by the accessibility constraint in all other benchmarks and alternatives to spread their scheduled regeneration over the first four decades. Also, FORPLAN was limited to a maximum of 15 percent regeneration cutting per decade averaged over a 20-year period.

4. **Minimum Implementation Requirements**

Constraints are needed to ensure that alternatives are minimally acceptable and implementable on the ground. Procedures for defining MIR's were specified by the Region. They are within agency control but there is little discretionary control regarding their application at the Forest level. MIR's do not apply to benchmarks but they are applied to all alternatives. Some examples of MIR's are scenic corridors for roads officially designated or eligible in the 1970 California State and County Scenic Highway System Master Plan, and maximum permitted regeneration acreage per period (18 percent). MIR's are described in more detail below and in the EIS, Chapter 2, Section E, Management Direction Common to All Alternatives.

Scenic Highways Requirements were placed on lands viewed from officially designated State and County Highways, and routes on the 1970 State Scenic Highway Master Plan, so that scenery would be managed along heavily traveled scenic highways. These include portions

of Interstate **EO** and State Highways **49, 20,** and **89**. This was achieved by assigning highway foreground and middle ground to a visual quality of partial retention. **The** area was delineated in the Forest planning file and the acres were identified by analysis area.

The partial retention constraint affects **120,772** acres of suitable land and limits the amount of regeneration cutting per decade. This has the effect of lengthening rotations which in turn reduces yields over time. Most **of** these acres are already constrained by the more restrictive minimum management requirement.

5. Forest Constraint Common to All Alternatives

Constraints are needed to ensure implementability at the local level. They are based on Forest (rather than Regional) conditions, which are in addition to **MMR's**. These constraints are not applied to all benchmarks but are applied to all alternatives except the constrained economically efficient alternative (**CEE**). Forest constraints unique to an alternative are discussed under alternative descriptions

Carman Valley Watershed For all alternatives considered in detail, limits were placed on resource activities allowed to occur in the sensitive Carman Valley Watershed. All streamside management zones within the watershed were unsuited for timber management. This affected **598** acres. The remainder of the suitable timber lands were managed under long rotations to reduce disturbance within the watershed. This resulted in **6,738** acres managed at lower yields than could have been realized with intensive even-age management.

6. Constraint Analysis

For a detailed discussion of the constraint analysis by subtraction, refer to the EIS, Chapter **2**, Section F, Constraint Analysis, and Table **2.18**.

M. Benchmarks

This section presents the required benchmarks' modeling specifications. For a complete discussion of the purpose and results of the benchmarks, refer to Chapter **2** of the EIS, Benchmarks. The analysis of constraints is presented in Chapter **2**, Section F, Constraint Analysis. The outputs and economics are displayed in Table **2.1** of the EIS.

(17MLV) - MINIMUM LEVEL OF MANAGEMENT (BACKGROUNDS)

1. Theme

The purpose of this benchmark is to determine background ("Background" in this context refers to outputs which are naturally occurring and not induced by management activities) outputs and fixed costs associated with maintaining the Forest and Federal ownership. Because this is primarily an accounting tool, the phase-in period that would be needed if minimum level were actually implemented is ignored.

2. Modeling Specifications

- a. Objective The objective is to minimize costs for 12 decades.
- b. Timber. No timber is produced. There is no background timber
- c. Range. No AUM's are produced There are no background AUM's
- d. Water. Only background water is produced because there is no timber harvest
- e. Spotted Owls and Threatened and Endangered Species The number of spotted owls is directly related to the number of acres of suitable habitat. T&E species maintenance and recovery projects would be implemented.
- f. Wildlife and Fish User Days Only background WFUDs are produced. No direct habitat improvement projects are undertaken in this benchmark.
- g. Developed Recreation All developed sites would be closed. There are no background developed site RVDs
- h. Dispersed Recreation Only background dispersed use RVD's are produced All background dispersed use RVDs receive low standard benefit values.
- i. Roads and Facilities. No Forest roads are constructed or maintained. Forest roads are assumed to be closed to the public. Facilities (office buildings, barracks, etc.) would be maintained at Level I, Health and Safety.
- j. Protection. The fire management budget is set at minlevel for this benchmark only The minlevel budget provides for detection and initial attack only

(17FLW) • UNCONSTRAINED MAXIMUM PNV ASSIGNED WITH FLOW/LTSY CONSTRAINTS.

1. Theme

This benchmark displays the maximum PNV allocation of resources, with no constraints except tentative suitability and maintenance of long-term sustained yield

2. Modeling Specifications

- a. Objective. Resources are allocated to maximize PNV.
- b. Timber. Minimum rotation is set at merchantable age The long-term sustained yield constraint provides for regulation of 90 percent of the forest by the end of the planning 160-year period (LTSY). Other timber policy constraints are removed. Harvest flow constraints limit the variability in harvest from one period to the next to provide stability to the local economy Timber costs and values are trended.
- c. Range. There are two types of range, permanent and transitory. Permanent range land is assumed to be GX and SX strata with less than 50 percent slope that are not currently in the reforestation backlog These lands are managed at one of three intensities The AUM per acre coefficient varies with intensity. FLW has the maximum land in high intensity management Transitory range is tied to timber harvest by regeneration changes, first increasing and then decreasing over time An additional source of AUM's is the reforestation backlog AUM's are derived from this source for the first three decades only since the backlog is assumed to be reforested by 1985 AUM coefficients vary with strata and cutting method Transtory range is assumed to be managed at the extensive level. Two additional intensity levels apply to permanent range These are intensive and environmental.

- d. Water. In addition to the background water, which is discussed under Minlevel, additional water is produced, in order of decreasing quantities, by regeneration, reforestation backlog, range conversion, and burned acres. There is a decay function for induced water, which reaches zero after two decades beyond the initiation of the activity

Riparian areas (SMZs) do not constrain timber management in this benchmark

- e Spotted Owls and Threatened and Endangered Species. The model is not constrained by protecting spotted owl or threatened and endangered species habitat.
- f WFUDs There are three components to WFUDs background, habitat improvement, and timber and range-induced. Timber suitable acres is the linkage which reflects KV work in habitat improvement. An implementation constraint applies to all the habitat improvement projects

There are three types of structural habitat improvement projects: those which have an infinite life span, those which are temporary, such as wood duck boxes, where the costs are incurred for periodic replacements, and those which are constructed and maintained rather than replaced, such as guzzlers.

- g Developed Recreation The model is free to choose the production of RVD's from existing and potential developed sites and ski hills at the level and amount which maximizes PNV, not to exceed demand. Downhill ski areas are always managed at full standard. Developed sites are managed at one of three levels—shutdown, low standard, or full standard.
- h Dispersed Recreation Dispersed recreation production is constrained to be less than or equal to demand. This demand cutoff represents the summation of background WFUDs, background dispersed RVDs, wilderness RVDs, timber-induced and project WFUDs, and induced dispersed RVDs

There are two management intensities for induced dispersed RVDs, low standard and full standard. Background is assumed to be managed at low standard, and the induced will be managed at full standard (including rehabilitation) to obtain the best return to PNV.

- i Roads and Facilities. Road construction and reconstruction is a by-product of timber harvest and developed recreation. Road construction, reconstruction, and maintenance associated with timber harvest is a function of acres of even-age harvest in accessed and nonaccessed land. Road construction associated with recreation is generated by constructing new developed recreation sites. Miles of new construction and reconstruction are generated based on acres of newly constructed sites. Road maintenance associated with recreation is related to acres in existing and newly constructed sites. There are no roads associated with downhill ski areas. The permittee is assumed to be responsible for road construction and maintenance.

The model is provided with five levels of facilities management, three of which are custodial, and two represent new construction. These levels of management are described in Appendix E of the AMS. Because there is no benefit attributed to facilities management, the model will always choose the health and safety level which is the least costly, unless constrained to a higher level.

- j. Protection. There are three fire management options and five budget levels which result in fifteen combinations in addition to the minlevel fire management organization. The minlevel organization is only applicable to the minlevel benchmark. The model chooses the fire management option which minimizes the cost plus net value change. Net value change is represented by the effect of fire on a timber, forage, and wildlife habitat. The effect of fire on forage and wildlife habitat is negative or positive depending upon the intensity. Acres of mature timber burned are supplied by the model and vary with the option. In addition to mature timber, it is assumed that one and one-half percent of plantation

acres will be burned each decade, and an additional amount of burned plantation acres are supplied by the model to reflect different options.

(17MMR) - MAX PNV ASSIGNED VALUES WITH MMR-NDY-CMAI

1. Theme

The theme of the MMR (Minimum Management Requirement) benchmark is to display outputs possible if management was constrained only to meet legal requirements.

The Minimum Management Requirements are specified by 36 CFR 219.27, National Forest Land Management Planning Direction.

2 Modeling Specifications

- a. Objective. The model allocates resources to maximize PNV for 12 periods, subject to constraints summarized below.
- b. Timber. Timber policy constraints CMAI, LTSY, NDY, and dispersion are applied. Timber costs and values are trended.
- c. Range. Forage lands and timber prescriptions produce AUM's. The discussion in benchmark FLW applies to MMR.
- d. Water and Soil. The discussion in the FLW benchmark pertaining to the modeling of water yield also applies to MMR.

Riparian areas (SMZ) are modeled as regulation class III. All riparian areas are assumed to be 100' wide on both sides of all perennial streams and lakes.

Sensitive watershed lands as defined in Appendix E of the AMS are modeled as Regulation Class III, which is a proxy for 200-year rotation.

- e. Spotted Owls and Threatened and Endangered Species. The model is constrained to protect 33,000 or more effective acres of spotted owl habitat. Land is assigned an effective habitat index based on vegetation type and age. The special requirements of spotted owl territories are proxied in the model by forcing 25,900 acres to be allocated from Regulation Class I, II, IV, and wilderness.
- f. WFUDs. Same as FLW.
- g. Developed Recreation. Same as FLW.
- h. Dispersed Recreation. Same as FLW except Granite Chief Wilderness acres get wilderness cost and benefits.
- i. Roads and Facilities. Same as FLW.
- j. Protection. The model selects the most cost effective budget level and mix in each period. Same as FLW.

(17MKV) MAX PNV MARKET VALUES ONLY WITH MMR-CMAI-NDY

1 Theme

This benchmark demonstrates the sensitivity of the solution to nonmarket resources' (water, WFUD's, and dispersed and wilderness recreation RVD's) price assignments. Nonmarket

outputs are valued and contribute to PNV after the solution is found and do not affect the allocation.

2. Modeling Specifications

- a. Objective. Resources are allocated to maximize PNV for 12 periods, with only timber, range and developed recreation being valued.
- b. Timber. The discussion under the MMR benchmark applies to MKV.
- c. Range. Same as FLW.
- d. Water and Soil. Same as MMR but water's value is not taken into consideration to determine the optimum allocation.
- e. Spotted Owls and Threatened and Endangered Species Same as MMR.
- f. WFUDs. Same as FLW.
- g. Developed Recreation Same as FLW.
- h. Dispersed Recreation. Same as FLW except dispersed recreation is not valued for the allocation.
- i. Roads and Facilities. Same as FLW.
- j. Protection. Same as FLW.

(17TBR) MAX TIMBER FOR ONE PERIOD WITH MMR-NDV-CMAI AND ECONOMIC ROLLOVER

1. Theme

The theme of this benchmark is to define the maximum timber output possible for the first decade under the constraints of NDV, CMAI, and MMR. After determining the maximum yield under these constraints, it is used as a constraint in a second run, which allocates resources to meet this goal and maximize PNV (economic rollover).

2. Modeling Specifications

- a. Objective. The objective function of the model is to maximize timber yield rather than PNV. The constraints are identical to MMR.
- b. Timber. Same as MMR.
- c. Range. Same as FLW.
- d. Water and Soil. Same as MMR.
- e. Spotted Owls and Threatened and Endangered Species. Same as MMR.
- f. WFUDs. Same as FLW.
- g. Developed Recreation. Same as FLW.
- h. Dispersed Recreation. Same as MMR.
- i. Roads and Facilities. Same as FLW.

j. Protection. Same as FLW.

(17WLN) MAX PNV WITH ALL ROADLESS AREAS ALLOCATED TO WILDERNESS

(No longer appropriate since signing of California Wilderness Act **9/28/84**)

1 Theme.

The theme of this benchmark is to display the opportunity cost associated with a maximum wilderness allocation.

2. Modeling Specifications.

The constraints are identical to those of the MMR run with the additional stipulation that all inventoried roadless areas are allocated to wilderness.

a. Objective. Same as MMR

b. Timber. Same as MMR

c. Range. Same as FLW.

d. Water and Soil. Same as MMR.

e. Spotted Owls and Threatened and Endangered Species. Same as MMR.

f. WFUDs Same as FLW.

g. Developed Recreation. Same as FLW.

h. Dispersed Recreation Same as FLW. In this benchmark all inventoried roadless areas are allocated to wilderness

i. Roads and Facilities. Same as FLW

j. Protection. Same as FLW.

(17RGN) MAX RANGE FOR 50 YEARS AND ECONOMIC ROLLOVER

1 Theme

The theme of this benchmark is to display the maximum capability of the Forest to provide commercial livestock grazing over five decades. The run is completed in two stages. In the first stage the resources are allocated to define maximum livestock forage potential. In the second stage, the production potential defined in the first stage is added to the model as a constraint and the model allocates resources to maximize PNV.

2 Modeling Specifications

a. Objective. The objective of the model is to maximize production of AUM's for one period.

b. Timber Same as MMR

c. Range. Same as FLW.

d. Water and Soil Same as MMR.

e. Spotted Owls and Threatened and Endangered Species. Same as MMR.

- f. WFUD's. Same as FLW.
- g. Developed Recreation Same as FLW.
- h. Dispersed Recreation Same as MMR.
- i. Roads and Facilities. Same as FLW.
- j. Protection. Same as FLW.

(17H20) MAX WATER FOR 50 YEARS AND ECONOMIC ROLLOVER

1. Theme

The theme of this benchmark is to define the maximum capability of the Forest to provide water over five decades. The run is completed in two stages. In the first stage, resources are allocated to define maximum water potential over 5 decades. In the second stage, these water production levels are added to the model as constraints, and the model allocates resources to maximize PNV. The objective of this run is to allocate resources to maximize water yield subject to the constraints of the MMR run.

2. Modeling Specifications

- a. Objective. The objective of the model is to allocate resources to maximize water production subject to the constraints of MMR benchmark.
- b. Timber Same as MMR
- c. Range. Same as FLW.
- d. Water and Soil. Same as MMR.
- e. Spotted Owls and Threatened and Endangered Species. Same as MMR.
- f. WFUDs. Same as FLW
- g. Developed Recreation Same as FLW
- h. Dispersed Recreation. Same as MMR.
- i. Roads and Facilities. Same as FLW.
- j. Protection. Same as FLW.

III. ALTERNATIVES

For definition of alternatives and a discussion of the process used to formulate alternatives, see the EIS, Chapter 2, Section B, Alternative Development Process and Section E, Alternatives Considered in Detail. For a more complete discussion of the themes and management direction of all the alternatives, refer to Chapter 2 of the EIS. (Outputs attributed to each alternative are displayed in Tables 2.5 through 2.10.) Chapter 2 discusses all constraints applied to each alternative and Chapter 4 discusses how those constraints affect the environmental consequences.

The marginal cost of constraints is displayed and discussed in the EIS, Chapter 2, Section F, Constraint Analysis. PNV is analyzed for alternatives in Chapter 2, Section F, in the tables, figure, and narrative under Economic Effects. Integration of economic analysis with alternative formulation is discussed in Chapter 2,

Section B, Alternative Development Process. Tradeoffs among alternatives are described in Chapter 2, Section F, Constraint Analysis.

Issues, concerns, and opportunities identified on the TNF are discussed in the **EIS**, Chapter 2, Section B, Alternative Development Process, and in Appendix A Resolution of IC&O's is described by alternative in **EIS** Table 2.21, Comparison of Alternatives by Major TNF Issues, Concerns, and Opportunities

The purpose, criteria, and assumptions, and relationships to IC&O's for each alternative is described in the **EIS**, Chapter 2, Section E, Alternatives Considered in Detail

Economic, social, and environmental consequences are described in Chapter 4 of the **EIS**.

TABLE B.6 - COMPARISON OF ALTERNATIVES BY DISCOUNTED COST

CUR	2584	146
PRF	2438	92
UNE	2346	22
NMK	2324	

1/ Net of MLV Costs

The major types of constraints that were modeled in FORPLAN are summarized in Table B.8 and as follows for each alternative:

A Alternative PRF - Preferred

1. Theme

Achieve a broad range of commodity and amenity benefits that meet short-term needs while retaining long-range management options. Emphasize a mixture of commodity production and amenity benefits that maximizes net public benefits while responding to the planning issues

2. Modeling Specifications

- a. Objective. 1) Maximize timber for one decade subject to the constraints summarized below: 2) maximize PNV for 12 decades to ensure economic efficiency.
- b. Timber. Timber policy constraints of CMAI, NDY, LTSY, and dispersion apply. The MMR's, MIR's, and Carman Valley Watershed constraint apply. Babbin Peak and Sugar Pine Point are allocated as RNA's, while Placer County Big Tree Grove, Devils Postpile, Glacier Meadow, Grouse Falls, Meadow Lake, Mason Fen, and Sagehen Headwaters are allocated as SIA's. Mixed conifer above 5,500 feet that is variety class A with an initial visual quality objective of retention or preservation is managed under long rotation. Long rotations are necessary primarily to meet partial retention VQO established for the higher elevation forest types. A clearcutting to shelterwood ratio, by volume, of at least 3:1 is maintained to reflect implementation concerns. Group selection is limited to tractor ground in five selected compartments (one compartment per Ranger District). Eastside pine volume harvested is limited to no more than 6 MMBF per year during decades 1 and 2 to reflect current market conditions. Implement at least 600 acres per year of shelterwood overstory removal in decade 1.
- c. Range. The eastside pine is allocated to intensive range management practices in dual use with timber management. These intensive range practices are constrained to occur in periods 3 through 5. Period 1 is to be used for studying the application of the prescription.
- d. Water and Soil. MMR's are applied. In addition, perennial streamside management zones (SMZ's) are modeled as variable widths and assigned to long rotation (Regulation Class III). Intermittent SMZ's are assigned long rotation. Sensitive watershed lands are also assigned the long rotation prescription.
- e. Spotted Owls and Threatened and Endangered Species. All owl territories are collapsed into owl analysis areas and modeled to maintain 1,000 acres of suitable habitat at all times. Territories are preassigned management choices based on the Forest biologist's knowledge of site conditions and likely management options. (See Table B.8.)
- f. WFUDs. WFUDs are modeled by the procedure described by FLW.
- g. Developed Recreation. Developed recreation RVDs are constrained to meet demand for 5 decades. Expansion of developed recreation is emphasized in the following areas: Boca, Prosser, Stampede, French Meadows, Jackson Meadow, Sugar Pine and Bullards Bar Reservoirs; Truckee and North Yuba Rivers areas: Sierra Buttes; and Interstate Highway 80 area. New ski areas and ski area expansion are allowed. All visual sensitive travel routes are managed to maintain their visual quality.
- h. Dispersed Recreation. The southern two-thirds of the former Granite Chief roadless area (MA 080) is allocated to wilderness per the California Wilderness Act of 1984. Dispersed recreation is modeled as described in FLW.
- i. Roads and Facilities. Roads are modeled as described in MMR. Facilities are managed at level III.

- j. Protection. Same as FLW.
- k. Hardwoods. No pure hardwood stands are allowed timber management prescription choices. In the mixed hardwood/conifer stands, yield reductions are simulated to reflect hardwood standards requiring given basal areas for the hardwood component. This is done in two ways: 1) yields from every other (alternate) thinning are not counted; 2) a given percent of the stand acres regenerate to pure hardwoods

B. Alternative CUR - Current Management

1 Theme

The theme of this alternative is to estimate the expected outputs and services provided if current allocations, directions, policies, and practices were to continue. Outputs will be greater than or equal to the 1982 levels. The budget is constrained to the 1982 level for the planning horizon.

2 Modeling Specifications

- a. Objective. Maximize PNV for 12 decades subject to the 1982 budget.
- b. Timber. Constraints of NDY, CMAI, LTSY, and Dispersion are applied. Land is assigned Regulation Classes I, II, III, and IV based on current multiple use unit management philosophy. Babbitt Peak is allocated as an RNA, and Placer County Big Tree Grove is allocated as an SIA.

The model is constrained to provide 1,000 acres of shelterwood harvest for four decades.
- c. Range. Same as MMR.
- d. Water and Soil. Same as MMR.
- e. Spotted Owls and Threatened and Endangered Species. Same as MMR.
- f. WFUD's. WFUDs are modeled by the procedure described by FLW.
- g. Developed Recreation. All developed sites are managed at low standard. Downhill ski areas are managed at full standard. No expansion of developed sites is permitted.
- h. Dispersed Recreation. Same as MMR.
- i. Roads and Facilities. Same as FLW benchmark. Roads and facilities are managed at level III.
- j. Protection. The base budget level and current option are specified for all periods.

C. Alternative RPA - 1980 RPA

1 Theme

This alternative will determine how the 1980 RPA program, distributed to the Forest through the PSW Regional Guide, could best be implemented.

2 Modeling Specifications

- a. Objective. Maximize PNV for 12 decades subject to the constraints summarized below.
- b. Timber Timber policy constraints of CMAI, NDY, LTSY, and dispersion apply. Timber harvest targets are displayed below. The MIR's and Carman Valley Watershed apply. Babbin Peak is allocated as an RNA, and Placer County Big Tree Grove is allocated as an SIA.

	1	2	3	4	5
MMBF/YR	173.0	186.0	198.4	198.4	198.4

- c. Range Range outputs are constrained to meet or exceed the Regional Forester's targets of 30,400 AUM's per year by 2030 AUM's are modeled as described in FLW.
- d. Water and Soil. Water production is modeled as discussed under FLW.
- e. Spotted Owls and Threatened and Endangered Species. There is no RPA target for spotted owls Spotted owl production is modeled as described in MMR.

Threatened and endangered species are modeled as described under MMR.
- f. WFUDs. Land comprising winter deer range is allocated to long rotation.
- g. Developed Recreation Developed recreation RVDs are modeled as described in FLW The model is constrained to meet or exceed the RPA target displayed below.

	1	2	3	4	5
MMRVD's	1.93	2.06	2.20	2.53	2.80

- h. Dispersed Recreation. Dispersed recreation is modeled as described in MMR. In RPA, it is constrained to meet or exceed the RPA targets displayed below.

	1	2	3	4	5
MMRVD's	2.61	2.77	2.90	3.13	3.25

- i. Facilities and Roads Facilities are managed at level III Roads are modeled as described in MMR There is no RPA target for facilities.

j. Protection. Same as FLW.

D. Alternative **CMD - Commodity**

1. Theme

Achieve high timber commodity outputs while providing amenity benefits at economically efficient levels. Emphasize intensive management of the timber resource on forest lands capable of producing at least 20 cubic feet of timber per acre per year. Resolve in favor of the timber resource any conflicts with other commodity or amenity resources.

2. Modeling Specifications

- a. Objective. 1) Maximize timber for ten decades subject to the constraints summarized below; 2) maximize PNV for 12 decades to ensure economic efficiency.
- b. Timber. Timber policy constraints apply. The MMR's, MIR's, and Caman Valley Watershed constraints apply. Babbin Peak and Sugar Pine Point are allocated as RNAs. The following are allocated as **SIA's**: Placer County Big Tree Grove, Devils Postpile, Glacier Meadows, Grouse Falls, Meadow Lake, Sagehen Headwaters, and Mason Fen. Limit group selection management to 150 to 250 acres per year and limit clearcutting to 2,300 to 3,500 acres per year.
- c. Range. Same as FLW.
- d. Water and Soil. Perennial streamside management zones are modeled as 100-foot wide and assigned Regulation Class III. Intermittent SMZ's are not restricted. Soils are modeled as in the PRF alternative.
- e. Spotted Owls and Threatened and Endangered Species. Same as MMR.
- f. WFUD's. WFUDs are modeled by the procedure described by FLW.
- g. Developed Recreation. Same as PRF alternative.
- h. Dispersed Recreation. Same as MMR.
- i. Roads and Facilities. Same as Alternative PRF.
- j. Protection. Same as FLW.

E. Alternative **NMK - Nonmarket**

1. Theme

Achieve high output levels of amenity (nonmarket) resources with commodity (market) outputs at a production level that will not result in environmental degradation. Emphasize amenity resources, such as fish and wildlife, water quality and recreation. Resolve in favor of the amenity resources any conflict with market resources.

2. Modeling Specifications

- a. Objective. 1) Maximize 4 B/C habitat type (large tree stage with canopy cover at 40 percent or greater) for wildlife associated with old-growth forests, 2) maximize timber for one decade subject to the constraints summarized below; 3) maximize PNV for 12 decades to ensure economic efficiency.

- b. Timber. Timber policy constraints of CMAI, NDY, LTSY, and dispersion apply. The MMR's, MIR's, and Carman Valley Watershed constraint apply. All proposed RNAs and SIA's are allocated. All west side regulated forest above 5,500 feet are managed under long rotation (Regulation Class II). All 6G timber stands (larger trees, two storied with canopy cover at 40 percent or greater) declared unsuitable for timber harvest.
- c. Range. Constrained to reduce the level of production to 1,000 AUM's annually by decade 5.
- d. Water and Soil. Same as PRF alternative.
- e. Spotted Owls and Threatened and Endangered Species. Same as PRF alternative, plus 7 additional territories that receive no scheduled timber harvest (*see* Table B E).
- f. WFUDs. WFUD's are modeled by the procedure described by FLW.
- g. Developed Recreation. Developed recreation RVDs are modeled as described in FLW. Both developed site and ski area development are allowed in areas not currently identified as mature forest habitat. The initial recommended visual quality objectives are met.
- h. Dispersed Recreation. All former inventoried roadless areas, are allocated to SPNM (TM-UNS). Dispersed recreation is modeled as described in FLW.
- i. Roads and Facilities. Roads are modeled as described in MMR. Facilities are managed at level II.
- j. Protection. Same as FLW.
- k. Hardwoods. No pure hardwood stands are allowed timber management prescription choices. In the mixed hardwood/conifer stands, yield reductions are simulated to reflect hardwood standards requiring given basal areas for the hardwood component. This is done in two ways: 1) yields from every other (alternate) thinning are not counted, 2) a given percent of the stand acres regenerate to pure hardwoods.

F. Alternative UNE - Uneven-aged

1. Theme

Achieve a broad range of commodity and amenity benefits that meet short-term needs while retaining long-range management options; obtain at least 50% of the harvested volume from uneven-age systems. Emphasize a mixture of commodity production and amenity benefits that optimize net public benefits while responding to the planning issues.

2. Modeling Specifications

- a. Objective. 1) Maximize timber for one decade subject to the constraints summarized below; 2) maximize PNV for 12 decades to ensure economic efficiency.
- b. Timber. Same as PRF alternative except the model is formulated to ensure that group Selection harvesting contributes at least 50 percent of the total harvest volume.
- c. Range. Same as PRF alternative.
- d. Water and Soil. Same as PRF alternative.
- e. Spotted Owls and Threatened and Endangered Species. Same as PRF alternative.

- f. WFUD's. Same as PRF alternative.
- g. Developed Recreation. Same as PRF alternative.
- h. Dispersed Recreation Same as PRF alternative.
- i. Roads and Facilities. Same as PRF alternative.
- j. Protection Same as PRF alternative.
- k. Hardwoods Same as PRF alternative

IV. OTHER MODELS

This section gives a brief description of the other models used to generate input data for use in FORPLAN and to interpret output data from FORPLAN

A. **RAMPREP**

RAMPREP is a PSW Region Timber Management model that is used to develop timber yield tables. RAMPREP timber yield tables are based on the Tahoe NF's 1980 Forest inventory data. RAMPREP summarizes the potential yields of the forest based on the 1980 inventory. For a detailed discussion of how RAMPREP calculates the potential yields, *see* The Region Five Timber Inventory Process, July 1981.

B. **Fire Management Analysis Process**

The fire management analysis process is comprised of four levels of analysis and a series of eight computer programs. (For a complete description of the fire management analysis process, *see* FSH 5109 19-National Fire Management Planning and Analysis Handbook.) Of the four levels of analysis, only **two** (described below) are used in the Forest planning process; the other two levels affect implementation and evaluation. The eight computer programs are simulators and report writers used to define the historical and current fire management situations and to evaluate candidate fire management fuels, prevention, detection, and suppression programs.

Fire Management Analysis Level I is basically an analysis of the historical and current fire management situation using fire and weather information, records of fire occurrences, and fire behavior (number of fires, acres burned by fire size and intensity). Some uses of Level I analysis are:

1. Display the general effectiveness and cost, including FFF, of the current fire management program. This program cost may be used as a basis for estimating expected future costs where the fire program is relatively stable and will not vary significantly between prescriptions on a Forestwide basis.
2. As a tool to aid the formulation and development of organizations in response to Forest Plan EIS alternatives and prescriptions. Level I analysis identifies areas which can be further analyzed in the areas of prevention, suppression, and fuels management areas.

Fire Management Analysis Level II is an analysis of various fire management program options (a suppression mix versus prevention), budget levels (costs), and their effectiveness. This analysis is based upon the simulation of representative fires using varying fuel models, differing suppression resources, historical occurrence patterns, and by changing occurrence patterns based upon prevention efficiency. Some uses of Level II analysis are:

1. Evaluate fire program options appropriate for the Forest Plan EIS alternatives analyzed by FORPLAN. This provides detailed resource output, net value change, and program cost data.

for selection of the most efficient program level where fire program cost and effectiveness will affect the choice between these alternatives

2. Evaluate the efficiency of fire program options for a number of alternative management prescriptions for the Forest Plan EIS alternatives to provide general estimates of fire program cost and consequences for FORPLAN analyses.
3. Evaluate the effectiveness of fire program options for a Forest Plan EIS alternative within a constrained budget to establish the most effective program mix where the budget level is fixed.

From Fire Management Analysis Levels I and II, inputs by alternative to FORPLAN are:

1. Probability of acres burned
2. Various program costs reflecting different fire management organizations.
3. Suppression costs reflecting the fire management organizational efficiency.

FORPLAN results by alternative are:

1. Acres burned.
2. Suppression costs.
3. Net value change for resources.
4. Optimum organization and budget level by period.

C. Regional Industrial Multiplier System (RIMS)

The U.S. Department of Commerce's Regional Industrial Multiplier System (RIMS) was used to develop impact multipliers and employment and income estimates for the alternatives analyzed in the EIS. (Industry - Specific Gross Output Multipliers for BEA Economic Areas, Regional Economic Analysis Division, Bureau of Economic Analysis, U.S. Department of Commerce, January 1977.) This system provides input-output model multipliers for 56 industrial sectors for Bureau of Economic Analysis (BEA) Economic Area 168 (Sacramento Area). Most of the economic activity associated with the Tahoe National Forest takes place within BEA Economic Area 168. BEA Economic Area 168 includes Nevada, Placer, and Yuba counties

Estimates of historical expenditures by sector associated with Forest outputs and purchases from the local economy were used with the RIMS input-output model multipliers to develop impact multipliers. These impact multipliers were used to estimate employment and income effects of the alternatives.

A number of assumptions used in the input-output modeling technique must be kept in mind when interpreting the resulting income and employment estimates:

1. Historical transaction patterns associated with Forest outputs and purchases are assumed to hold in the future.
2. Transaction patterns (production functions) for industries in the local economy are assumed to be similar to those in the national economy and are assumed to hold in the future.
3. Income and employment impacts are assumed to occur in the same time period as the underlying changes in Forest outputs and purchases (no lagged effects are assumed).

As a result of these basic assumptions, employment and income effects estimated for the alternatives have relatively low reliability in absolute terms in future time periods. However, the income and employment estimates are reasonably accurate indicators of relative changes between the alternatives in the first decade.

D Effective Alteration

The EFFALT cumulative impact thresholds are applied in FORPLAN to limit timber harvesting activities and thereby assure landscape alterations do not exceed the levels associated with desired VQO's. Perspective plot computer simulations were the primary tools used to establish these thresholds in the effective alteration approach. These simulations were developed (chiefly on HP 9845 hardware) by Northern California Forest Service Landscape Architects, including Keith Renner, formerly of the TNF. The most critical and common situations modeled were middleground landscapes with partial retention VQOs (Partial retention middleground is the primary application of EFFALT on the TNF.) Topographic and timber stand data were fed into the computer to simulate current conditions. Varying rotation lengths and harvest entry rates were then tested by modeling all units into the perspective plots. The resultant simulations of altered landscapes were then visually examined to determine maximum limits of alteration permissible under the given VQOs. Thus, the actual correlations of harvesting rates and total effective alteration to VQO's were based on the professional judgment of Forest Service landscape architects. For similar situations, these judgments were highly consistent. They were further corroborated by field inspection and aerial photos compared to EVC mapping.

The harvest entry rates found to be acceptable for the partial retention VQO assumed visual mitigation of unit shaping, distribution, and edge treatment. The rates vary with the visual absorption capability (VAC) of the model area, the VAC correlates most strongly with slope, existing vegetative patterns, distance zones, and vegetative growth and recovery rates. An average case (Medium Ste-Medium VAC) was assumed to apply to all situations on the TNF except red fir sites, which were done on middleground landscapes; the total EFFALT percentages established from this modeling have also been applied in FORPLAN to foreground and background landscapes.

TABLE 8.8 - CONSTRAINTS USED BY ALTERNATIVES

CONSTRAINTS	PRF Preferred	CUR Current	RPA 1980 RPA	CMD Commodity	NMK Nonmarket	UNE Uneven-age

- Total number of SOHA's 1/	33	33	34	33	35	33

1/ Refers to constraints in FORPLAN n that the NMK alternative is cited with 5 additional SOH/ (with no scheduled harvest) in Chap. 4 of the FEIS. This is due to the primary objective function of maximizing the 4 B/C habitat type in that alternative. See Tab 4.42, Chap. 4 and Appendix P of the FEIS.

APPENDIX C

SPECIAL AREAS

A. INTRODUCTION

Five potential Research Natural Areas (RNA) and 18 potential Special Interest Areas (SIA) have been identified on the Tahoe National Forest. These areas are also briefly described in Chapter 3 of this EIS and their locations are displayed on the map titled 'Proposed Special Interest and Research Natural Areas' that is found in the map packet.

Research Natural Areas are recommended to the Chief of the Forest Service to preserve examples of significant natural ecosystems for purposes of research and ecological study and to maintain gene pools. To accomplish these goals, management activities are directed toward the protection and preservation of the botanical elements and their ecosystems for which the RNA's are established.

The criteria used to evaluate and determine if the Tahoe National Forest proposed an area for RNA designation in the Forest Plan are as follows: The ecological attributes of the area; the theme of the alternative (what emphasis is on other attributes); land ownership; current and proposed land uses; and effects of designation on other resources.

Special Interest Areas are established to protect, and where appropriate, foster public use, study, and enjoyment of areas with scientific, scenic, historical, geological, botanical, zoological, paleontological, or other special characteristics. Management activities within SIA's are less restricted than within RNA's. For example, roads, trails, and recreation or interpretive facilities may be built within an SIA to facilitate public use. Vegetative management may occur to the extent that it is compatible with the SIA purpose and management objectives.

National Natural Landmarks (NNL) are mostly classified RNA's or SIA's which possess exceptional values or qualities that illustrate or interpret the natural heritage of the Nation. The National Park Service identified a number of themes that reflect a wide range of landforms, geology, and land and water ecosystems found in the United States. They also developed a set of criteria for determining whether sites or areas possess sufficient values to warrant registration as NNL's. If further studies indicate that some or all of the SIA's or RNA's warrant NNL registration, the areas will then be managed to preserve their significant qualities; this may constrain National Forest management activities in those areas. Only those activities which do not interfere with the purpose for which the area was designated, or alter its integrity, will be permitted.

To aid understanding, readers should familiarize themselves with the different management prescriptions (*see* the EIS, Chapter 2, Management Prescriptions and Management Areas and the Special Interest and Research Natural Areas Map contained in the map packet). Table C 1 summarizes the RNA and SIA designations by alternative.

The following narratives describe the individual TNF potential Research Natural and Special Interest Areas, discuss their significant qualities, address current and potential uses, and examine the consequences of managing each area under alternative management prescriptions.

Management restrictions due to RNA, SIA, or NNL establishment will limit commodity production and some Forest uses in the area to varying degrees. These resource trade-offs are discussed below for each area to supplement Chapter 4, The Environmental Consequences. Designation or nondesignation as an SIA or RNA has no effect on some resources because of management practices which are common to all alternatives (refer to the EIS, Chapter 2, Management Direction Common to All Alternatives). Only those resources significantly affected are discussed in the Environmental Consequences sections. Acreages are only for the TNF; private acres are not shown.

TABLE C.1 - COMPARISON OF ALTERNATIVES BY PROPOSED RESEARCH NATURAL AREAS AND SPECIAL INTEREST AREAS

AREA	INVENTORIED ACRES	PRF	CUR	RPA	CMD	NMK	UNE
RESEARCH NATURAL AREAS							
1 Babbitt Peak (Washoe Pine)	1,061	YES	YES	YES	YES	YES	YES
2 Basin Peak (Studied)	60	NO	NO	NO	NO	YES	NO
3 Sugar Pine Point	625	YES	NO	NO	YES	YES	YES
4 Mt. Lola	498	NO	NO	NO	NO	YES	NO
5 Lyon Peak/Needle Lake	77	YES	NO	NO	NO	YES	YES
SUBTOTAL ACRES	2,944	2,386	1,061	1,061	1,686	2,944	2,386
SPECIAL INTEREST AREAS							
1 Placer County Big Tree Grove Botanical Area	346	YES	YES	YES	YES	YES	YES
2 Devils Postpile Geologic Area	69	YES	NO	NO	YES	YES	YES
3 Glacier Meadow Geologic Area	84	YES	NO	NO	YES	YES	YES
4 Grouse Falls Scenic Area	220	YES	NO	NO	YES	YES	YES
5. Hawley Lake Cultural Area	5,323	NO	NO	NO	NO	YES	NO
6. Meadow Lake Cultural Area	58	YES	NO	NO	YES	YES	YES
7. Boca Cultural Area	1,976	NO	NO	NO	NO	YES	NO
8 Kyburz Cultural Area	1,097	NO	NO	NO	NO	YES	NO
9 Sagehen Headwaters	79	YES	NO	NO	YES	YES	YES
10 Sierra Buttes	1,827	NO	NO	NO	NO	YES	NO
11 L Truckee River Terrace	468	NO	NO	NO	NO	YES	NO
12. Sagehen Creek Basin	8,373	NO	NO	NO	NO	YES	NO
13. Independence Lake	81	NO	NO	NO	NO	YES	NO
14 Headwaters N F American River	9,381	NO	NO	NO	NO	YES	NO
15 San Juan Ridge	6,541	NO	NO	NO	NO	YES	NO
16 Macklin Creek	380	NO	NO	NO	NO	YES	NO
17. Mason Fen	30	YES	NO	NO	YES	YES	YES
SUBTOTAL ACRES	36,333	886	346	346	886	36,333	886
GRAND TOTAL	39,277	3,272	1,407	1,407	2,572	39,277	3,272

Note Wild Plum was considered for SIA designation but eliminated because of current and past logging of the area

B. RESEARCH NATURAL AREA NARRATIVES

1. BABBITT PEAK (1,061 acres)

Because of the distinctive and unusual occurrence of Washoe pine and mature stands of mountain mahogany, this area has significant potential for research and ecological study. It is the only such area on the TNF and it is located in Sections 5, 6, 7, 8, 17, and 18, T.20N., R.12E., MDB&M.

Within Babbitt Peak are approximately 445 acres of white fir mixed with Jeffrey, western white, and Washoe pines. This area affords excellent opportunities to study the mixture's successional relationships and the successional relationship with Washoe pine. Also located here are about 225 acres of mountain mahogany. This species is unusual because of the large size of the individual plants (15 to 25 feet tall). A rare opportunity exists to study the relationship of this species to the site and to the coniferous species in this area.

I. ENVIRONMENTAL CONSEQUENCES OF RNA DESIGNATION

Management Prescription #5 (All Alternatives)

- a. Recreation - Recreation use would be discouraged and vehicles use prohibited to protect the area's natural ecosystem for research and ecological study. One potential recreation site would not be developed. Visual quality would remain unchanged. Risk to cultural resource would be low.
- b. Range - Livestock use would be permitted when needed to perpetuate the desired vegetative type in the RNA.
- c. Timber - Approximately 816 acres of commercial forest land and a maximum annual volume of 300 MBF would be unavailable for regulated timber harvest.
- d. Minerals - The area would be proposed for withdrawal from mineral entry; however, mineral potential is low.
- e. Lands - No encumbrances permitted except those for research of the RNA.
- f. Facilities - There would be no roads, trails, or trailheads constructed in this area.
- g. Protection, Including Pest Management - The effects on fire suppression and fuels management would be similar between alternatives. There would be limits on the type of suppression equipment that would be used or the amount of fuel treatment that would occur. Lack of access would hinder fire suppression. There would be no direct or indirect insect and disease control activities unless needed to maintain the vegetation type of the RNA. Adjacent areas could become susceptible to infestations spreading from the RNA.

II. ENVIRONMENTAL CONSEQUENCES OF NONRESEARCH NATURAL AREA DESIGNATION

Management Prescription #5 (All Alternatives)

All alternatives designate this area as an RNA,

2. BASIN PEAK (60 acres)

This proposed RNA candidate is located in Section 36, T.18N., R.14E., MDB&M, it consists of a nearly pure stand of mountain hemlock sixty acres in size. Few representative mountain hemlock stands have been identified in the Sierra Nevada. It is located with the former Castle Peak roadless area and adjacent to private land. The proposed RNA is currently within the Castle Peak motor vehicles closure area that is

restricted to dispersed nonmotorized recreation and grazing. No known timber harvesting or development is planned for the adjacent private land that would detract from the RNA potential of the area.

1. ENVIRONMENTAL CONSEQUENCES OF RNA DESIGNATION

Management Prescription #5 (Alternatives PRF and NMK).

- a. Recreation - Recreation **use** would be discouraged and vehicle **use** prohibited to protect the area's natural ecosystem for research and ecological study. Visual quality would remain unchanged. Risk to cultural resources would be low.
- b. Range - Livestock use would be permitted when needed to perpetuate the desired vegetation **type** in the RNA.
- c. Timber - The area is unsuited for regulated timber harvest.
- d. Minerals - The area would be withdrawn from mineral entry; however, the mineral potential **of** the area is low.
- e. Lands - No encumbrances would be permitted, except that pertaining to research of the RNA. Adjacent private lands would not adversely affect **the** proposed RNA since there are no known planned activities by the landowner.
- f. Facilities - There would be no roads, trails, or trailheads constructed in the area.
- g. Protection, Including Pest Management - **The** effects on suppression and fuels management would be similar between alternatives. There would be limits on the type of suppression equipment and the type of fuels treatment that could occur. Lack of access could hinder fire suppression. There would be no direct or indirect insect or disease control activities unless necessary to maintain the vegetation type **of** the RNA. Adjacent areas could become more susceptible to infestation spreading from the RNA.

II. ENVIRONMENTAL CONSEQUENCES OF NONRESEARCH NATURAL AREA DESIGNATION

Management Prescriptions #'s 1, 2, 3, 8, 13 (Alternatives CUR, RPA, CMD, and UNE)

- a. Recreation - Alternatives CUR, RPA, AND UNE would continue management of this area to maintain a near-natural setting. Nonmotorized recreation would be emphasized in these alternatives as well as Alternative CMD. Alternative UNE **would** permit motorized recreation in the area, which is compatible with the alternative theme.

Visual quality would remain high under Alternatives CUR, RPA, and UND. Some reduction in visual quality would occur in Alternative CMD **if** timber harvesting occurs.

Cultural resources would receive the best protection from project related impacts in Alternatives CUR, RPA, and UNE. Impacts to cultural resources could occur from management activities or increased numbers of visitors in Alternative CMD. Because of the nature of the area, it is not likely that these impacts would occur or be substantial.

- b. Range - Grazing would occur in Alternatives CUR, RPA, and UNE under extensive management. In Alternative CMD, both extensive and intensive grazing management would be implemented.
- c. Timber - Under Alternatives CUR, RPA, and UNE, the area would be unsuited for regulated timber production. Intensive timber management could occur under Alternative CMD, but these activities are unlikely.

- d. Water, Soils, and Air - Water quality and yield would not be affected in Alternatives CUR, RPA, and UNE. Some reduction in water quality could occur in Alternative CMD if timber harvesting or road building occurs. There would be no risk of soil loss in any of the alternatives because of the nature of the area. The effects on air quality would be similar in all alternatives. Short-term impacts could occur from dust from management activities or recreational activities in Alternative CMD. State Air Resource Board regulations, however, would still be met. No long-term impacts are foreseen.
- e. Facilities - There are no existing NFS roads or trails within the proposed area. There are some old motorized travelways, however, since the area is closed to motorized vehicles use these receive only occasional foot and equestrian use.
- f. Protection, Including Pest Management - There would be no change from the current situation in Alternatives CUR, RPA, and UNE. Access could improve in Alternative CMD if road construction occurs. This would aid identification and treatment of insect and disease problems. Fuels management would be primarily associated with the treatment of activity fuels created by timber harvesting and would fluctuate with the levels of harvest.
- g. Sensitive Plants - There would be no change from the current situation in Alternatives CUR, RPA, and UNE. The possibility of increased access and activities in Alternative CMD could increase risk of damage to sensitive plants.

3. SUGAR PINE POINT (625 acres)

The Sugar Pine Point area (Section 20, T.16N., R.13E., MDB&M) is an excellent RNA candidate. (1) The area represents a discrete unit of watershed; (2) Good examples of various stages of succession in a mixed conifer forest are present; (3) The area represents a zone of overlap of ponderosa pine and Jeffrey pine; (4) The amount of mature timber is slight, and access to the area is difficult because of the steep topography, so commercial timber production potential is minimal.

Studies of succession of brush to conifer forest are relatively few. Sugar Pine Point is an excellent place to study the dynamics of this successional pattern and the role of fire ecology in the mixed conifer forest. The comparative ecology of ponderosa pine and Jeffrey pine, both important commercial conifers, could also be studied. Both pine species occur with Jeffrey in the upper portions of Section 20 and ponderosa in the lower, with zones of overlap in between. Careful work could clarify the ecological requirements of these two species.

There is a possibility of scientific study of several rare plants that occur in the general area.

I. ENVIRONMENTAL CONSEQUENCES OF RNA DESIGNATION

Management Prescription #5 (Alternatives PRF, CMD, NMK, and UNE).

- a. Recreation use would be discouraged and vehicle use prohibited to protect the area's natural ecosystem for research and ecological study. Visual quality would remain unchanged. Risk to cultural resources would be low.
- b. Range - Livestock use would be permitted when needed to perpetuate the desired vegetation type on the RNA.
- c. Timber - Approximately 435 acres of commercial forest land and a maximum annual volume of 160 MBF would be unavailable for regulated timber harvest.
- d. Minerals - The area would be withdrawn from mineral entry, however, the mineral potential of the area is low.

- e. Lands - No encumbrances would be allowed except those for research of the RNA
- f. Facilities - There would be no roads, trails, or trailheads constructed into this area
- g. Protection, Including Pest Management - The effects on fire suppression and fuels management would be similar between alternatives. There would be limits on the type of suppression equipment that could be used and the amount of fuel treatment that would occur. Lack of access would hinder fire suppression. No direct or indirect insect or disease control activities would occur unless needed to maintain the vegetation type of the RNA. Adjacent areas could become more susceptible to infestations spreading from the RNA.

II. ENVIRONMENTAL CONSEQUENCES OF NONRESEARCH NATURAL AREA DESIGNATION

Management Prescription #'s 2, 3, 13, 15 (Alternatives CUR and RPA).

- a. Recreation - Recreation opportunities would range from dispersed nonmotorized activities (hiking, camping, hunting, etc) in Alternative RPA and portions of Alternative CUR to motorized recreation on designated routes in Alternative CUR. Steep terrain would limit accessibility. No potential developed recreation sites have been inventoried

The visual quality would remain high in Alternative RPA and portions of Alternative CUR, but would be reduced by intensive timber management activities in Alternative CUR (portion).

Impacts on cultural resources would be few in Alternative RPA and inventory would be limited. Expected impacts on and inventory of cultural resources would increase with the increase in management activities in Alternative CUR

- b. RNA Potential - The consequences of not designating the area as a Research Natural Area would be loss of research potential in a natural ecosystem, including a mixed conifer succession study area, a discrete unit of watershed, and a zone of overlap of ponderosa and Jeffrey pine.
- c. Range - Grazing would be permitted in Alternatives CUR and RPA by implementing extensive management
- d. Timber - Regulated timber production would not occur in Alternative RPA. Timber would be intensively managed in Alternative CUR, but would be limited by steep terrain and accessibility.
- e. Water, Soils, and Air - Alternative RPA would maintain high water yield and quality. Alternative CUR would result in some loss of water quality, but by using Best Management Practices the loss would be acceptable. Alternative RPA would have little impact on soils. Alternative CUR would result in a slight risk of loss of soil productivity from intensive timber management. The effects on air quality would be similar between alternatives. There would be short-term effects from dust or wood smoke because of road use by recreationists, timber harvesting, and prescribed burning; however, this short-term air pollution would still meet all State Air Resource Board regulations. At this time no significant long-term impacts are identified.
- f. Facilities - Some trailhead, trail, and low-standard road construction may occur in Alternative RPA. Limited road construction would occur (because of the steep terrain) to access the small amount of commercial timber in Alternative CUR. Economics would constrain the amount, if any, of facility development
- g. Protection, Including Pest Management - The effects on protection would be similar between alternatives. Fuels management would be primarily associated with the treatment

of activity fuels created by timber harvesting and would fluctuate with the levels of harvest. There would be no change in pest management from the current situation in Alternative RPA. Some improved accessibility would occur in Alternative CUR and would allow for greater protection against insects and disease.

- h Sensitive Plants - Increased access and activities could increase the risk of damage to sensitive plants

4. MT. LOLA (498 acres)

The proposed RNA, located in Section 12, T 18N, R.14E., MDB&M, contains a distinctive stand of mountain hemlock and represents a unique botanical area because the stands occupy 200-300 acres. Similar stands on the TNF rarely are larger than 40-50 acres. The large mountain hemlock stand is adjacent to private lands that are proposed for timber harvest and winter recreation development. Impacts from these planned activities would strongly detract from the research values on TNF land

I. ENVIRONMENTAL CONSEQUENCES OF RNA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation use, including ski area development, would be discouraged and vehicles use prohibited to protect the area's natural ecosystem for research and ecological study. Visual quality would remain unchanged. Risk to cultural resources would be low.
- b. Timber - Approximately 492 acres of commercial forest land and a maximum annual volume of 280 MBF would be unavailable for regulated timber harvest.
- c. Minerals - The area would be withdrawn from mineral entry; however, the mineral potential of the area is low.
- d. Lands - No encumbrances would be allowed except those for research of the RNA
- e. Facilities - There would be no roads, trails, or trailheads constructed into this area.
- f. Protection, Including Pest Management - There would be limits on the type of suppression equipment that could be used and the amount of fuel treatment that would occur. Lack of access would hinder fire suppression. There would be no direct or indirect insect or disease control activities unless needed to maintain the vegetation type of the RNA. Adjacent areas could become more susceptible to infestations spreading from the RNA.

II. NONRESEARCH NATURAL AREA DESIGNATION CONSEQUENCES

Management Prescription #'s 2, 3, 11, and 13 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Alternatives PRF and UNE would manage the area for its downhill skiing potential. Alternative CUR would emphasize dispersed motorized recreation. Both motorized and nonmotorized recreation activities would occur in Alternatives RPA and CMD.

Visual quality would be reduced in the alternatives because of timber harvesting or if downhill ski development were to occur. Impacts to cultural resources may increase in Alternatives CMD and UNE because of greater access and project activities.
- b. RNA Potential - The consequences of nondesignation of the area as an RNA would be loss of a unique botanical area in all alternatives.

- c. Timber - Regulated timber production would occur in Alternatives CUR, RPA, and CMD. Timber production would be unregulated in Alternatives PRF and UNE
- d. Water, Soils, and Air - Water yield and quality would have some reductions in quality in the remaining Alternatives PRF, CUR, RPA, and UNE because of timber harvest or if ski development were to occur. Alternatives PRF, CUR, RPA, CMD, and UNE would result in some risk of soil loss. Short-term reductions in air quality could occur in all alternatives, however, State Air Resource Board requirements would still be met.
- e. Facilities - Road construction would occur in all alternatives
- f. Protection, Including Pest Management - Improved access would aid fire suppression and treatment of insect and disease problems. Fuels management would primarily treat activity fuels associated with timber harvest and recreation development
- g. Sensitive Plants - Increased access in all alternatives could raise the risk of damage to Sensitive plants.

5. LYON PEAWNEEDLE LAKE (700 acres)

The proposed RNA is located immediately north of the northern boundary of Granite Chief Wilderness in Sections 22, 27, 28, and 34, T.16N., R 15E., MDB&M. The area is an excellent candidate to represent the mountain hemlock target element. The elevation varies from approximately 7200 feet to 8900 feet. There is *limited* public access to this area because it is 'land-locked' to the north by **the** private lands. There is some limited access on unimproved Forest Service trails to the east and access could occur from Granite Chief, Needle Lake, and Lyon Peak along the top of the ridge

There is a possibility of scientific *study* of several rare plants that occur in the general area.

I. ENVIRONMENTAL CONSEQUENCES OF RNA DESIGNATION

Management Prescription #5 (Alternatives PRF, NMK, and UNE)

- a. Recreation - Recreation **use** would be discouraged and vehicle **use** prohibited to protect the area's natural ecosystem for research and ecological study. Visual quality would remain unchanged. Because access would be limited, risk to cultural resources would be low.
- b. Range - Livestock **use** would be permitted when needed to perpetuate the desired vegetation type in the RNA
- c. Timber - The area is unsuited for regulated timber harvest.
- d. Minerals - The area would be withdrawn from mineral entry, however, the mineral potential of this area is low.
- e. Lands - No encumbrances would be permitted, except that pertaining to research of the RNA. Adjacent private lands would not adversely affect the proposed RNA because this land has been included in the University of California's NLWRS, which is compatible with RNA status
- f. Facilities - There would be no roads, trails, or trailheads constructed in the area.
- g. Protection, Including Pest Management - The effects on suppression and fuels management would be similar between alternatives. There would be limits on the type of suppression equipment and the type of fuels treatment that could be used. Lack of access could hinder fire suppression. There would be no direct or indirect insect or

disease control activities unless necessary to maintain the vegetation type of the RNA. Adjacent areas could become more susceptible to infestation spreading from the RNA.

II. ENVIRONMENTAL CONSEQUENCES OF NONRESEARCH NATURAL AREA DESIGNATION

Management Prescription #'s 1, 2, 3, 8, or 13 (Alternatives CUR, RPA, and CMD).

- a. Recreation - Alternatives CUR and RPA would continue management of this area to maintain a near-natural setting. Nonmotorized recreation would be emphasized in these alternatives.

Visual quality would remain high under Alternatives CUR and RPA. Some reduction in visual quality would occur in Alternative CMD if timber harvesting occurs.

Cultural resources would receive the best protection from project-related impacts in Alternatives CUR and RPA. Impacts to cultural resources could occur from management activities or increased numbers of visitors in Alternative CMD. Because of the nature of the area, it is not likely that these impacts would occur or be substantial.

- b. Range - Grazing would occur in Alternatives CUR and RPA under extensive management. In Alternative CMD both extensive and intensive grazing management would be implemented.
- c. Timber - Under Alternatives CUR and RPA the area would be unsuited for regulated timber production. Intensive timber management could occur under Alternative CMD, but these activities are also unlikely.
- d. Water, Soils, and Air - Water quality and yield would not be affected in Alternatives CUR and RPA. Some reduction in water quality could occur in Alternative CMD if timber harvesting or road building occurs. There would be no risk of soil loss in any of the alternatives because of the nature of the area. The effects on air quality would be similar in all alternatives. Short-term impacts could occur from dust from management activities or recreational activities in Alternative CMD. State Air Resource Board regulations, however, would still be met. No long-term impacts are foreseen.
- e. Facilities - There are no existing NFS roads or trails within the proposed area. The only physical improvements are an unimproved trail and a packer/hunter camp. This area only receives occasional foot and equestrian use.
- f. Protection, Including Pest Management - There would be no change from the current situation in Alternatives CUR and RPA. Access could improve in Alternative CMD if road construction occurs. This would aid identification and treatment of insect and disease problems. Fuels management would be primarily associated with the treatment of activity fuels created by timber harvesting and would fluctuate with the levels of harvest.
- g. Sensitive Plants - There would be no change from the current situation in Alternative CUR and RPA. The possibility of increased access and activities in Alternative CMD could increase risk of damage to sensitive plants.

C. SPECIAL INTEREST AREA NARRATIVES

1. PLACER COUNTY BIG TREE GROVE BOTANICAL AREA (346 acres)

This locally popular and well-known attraction of the Sierra Nevada is located in all or part of Sections 18 and 19, T.14N, R.13E., MDB&M. The significance of the grove lies in its location, the northernmost grove of giant sequoia, and in its plant associations, which are considered unique. The grove has been studied

by botanists since the 19th century. Public interpretive facilities exist at the site, and there is heavy use both by individuals and institutions. Establishment of this area as an SIA has been recommended for the past 20 years.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (All Alternatives)

- a. Recreation - Current management direction would continue at the site in all alternatives. Recreation opportunities would include botanical interpretation, hiking, and picnicking. Additional facilities may be developed to foster public appreciation of the grove. Visual quality would remain high from all major viewing points. Cultural resources would be inventoried and could be interpreted as part of the overall management theme of the grove.
- b. Timber - Approximately 346 acres of commercial timber land are capable of contributing a maximum of 130 MBF per year to the allowable sale quantity. This commodity production would be forgone.
- c. Facilities - Trails and trailheads would be permitted to facilitate the public use of the area.
- d. Minerals - The area would be withdrawn from mineral entry; however, the mineral potential of the area is low.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

All alternatives designate this area as an SIA; thus, there is no discussion of the consequences of non-designation.

2. DEVILS POSTPILE GEOLOGIC AREA (69 acres)

This type of prominent geologic feature occurs in a number of locations in California. The feature found on the Downieville Ranger District (all or part of Sections 17, 20, 21, T.21N, R.10E, MDB&M) is the most outstanding example found on the TNF. Its prominence in the landscape is accentuated by its location on the edge of a rugged canyon. As a geologic phenomenon it is not unique, and its location in a remote and poorly accessed area of the Forest limits its potential as an SIA. Visitor use and enjoyment of the area is likely to remain at a low level.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, NMK, and UNE).

- a. Recreation - Both dispersed and developed recreation opportunities and interpretive facilities may be provided to facilitate public appreciation of the geologic phenomenon. Nonmotorized opportunities would be emphasized in Alternative NMK. Visual quality would be maintained except for alterations caused by trail and interpretive facility development. Cultural resources would be inventoried and protected from project impacts.
- b. Water, Soil, and Air - Water quality may be reduced slightly, and some loss of soil productivity may occur from facility development. Short-term reduction in air quality may occur but State Air Resources Board requirements would still be met.
- c. Minerals - The area would be proposed for withdrawal from mineral entry, however, the mineral potential is low.

- d. Facilities - Roads, trails, and trailheads would be permitted to facilitate public use.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 7, 13, and 15 (Alternatives CUR, RPA, and CMD)

Because of the nature of the area and its location, there would be no consequences from not designating the area as an SIA, except the area would be open to mineral entry (low mineral potential), and public interpretation would not be emphasized

3. GLACIER MEADOW GEOLOGIC AREA (84 acres)

This area near Donner Summit Rest Stop (located in Section 8, T.17N, R.15E., MDB&M) represents an excellent example of a landscape shaped by glacial action. Glaciers scoured large portions of the Sierra Nevada over 10,000 years ago. In the Donner Summit area the advancing glaciers ground down and polished the granite rocks and carried rock and debris with them as the ice advanced. When the glaciers finally melted, this rock and debris were deposited on the landscape. At Glacier Meadow this process is apparent. Large boulders left by the retreating glaciers now rest on the smoothly polished granite bedrock. Although there are similar examples scattered throughout the Sierra, Glacier Meadow is the most obvious example of this natural phenomenon on the TNF. It is also situated near heavily traveled Interstate 80, so there is potential for heavy recreation visitor use if facilities and access were provided.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, NMK, CMD, and UNE)

- a. Recreation - Both dispersed nonmotorized and motorized recreation opportunities and interpretive facilities would be permitted within the SIA to facilitate public appreciation and the study of geologic phenomenon. Nonmotorized recreation opportunities would be emphasized in Alternative NMK. Visual quality would be maintained except for alterations in the landscape caused from trail and interpretive facility development. Cultural resources would be inventoried and protected from project impacts.
- b. Timber - Commercial timber land is insignificant in this area.
- c. Minerals - This area would be proposed for withdrawal from mineral entry; however, the mineral potential is low.
- d. Water, Soil, and Air - Water quality may be reduced slightly and some loss of soil productivity may occur from road and facility development. Short-term reductions in air quality may occur, but State Air Resources Board requirements will be met.
- e. Facilities - Roads, trails, and trailheads would be permitted to facilitate public use of the area.
- f. Sensitive Plants - Encouraging public use of the area may increase risk of damage to sensitive plants.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 8 and 15 (Alternatives CUR and RPA).

- a. Recreation - Alternatives CUR and RPA would permit both dispersed nonmotorized and motorized recreation. Interpretive facilities would be compatible with the visual quality themes of these alternatives. Visual quality would be reduced slightly in this area if the maximum annual volume of 25 MBF is harvested. Cultural resources would be inventoried and protected in all non-SIA alternatives.

- b. SIA Values - Because of the nature of the area, nondesignation would not affect the SIA values; however, interpretation of the geologic phenomenon would not be emphasized.
- c. Timber - Regulated timber harvest would be permitted in all non-SIA alternatives. The area would contribute a maximum annual volume of **25** MBF to allowable harvest
- d. Minerals - The area would be open to mineral entry; however, there is low mineral potential
- e. Facilities - Same as SIA designation
- f. Water, Soil, and Air - Water quality may be reduced slightly and some **loss** of soil productivity may occur from road construction and timber harvest. Short-term impacts on air quality may also occur, but State Air Resources Board requirements would still be met

4. GROUSE FALLS SCENIC AREA (220 Acres)

Grouse Falls is one of the highest cascading falls in California. It is located in rugged country on the Foresthill Ranger District (Section 3, T.14N., R.12E., MDB&M), which enhances its scenic quality. The falls are accessed by a primitive trail. Because of the poor condition of the trail, visitor **use** is light

I ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, CMD, NMK, and UNE)

- a. Recreation - Dispersed, developed, interpretive, and motorized recreational opportunities could be available within the SIA to aid public appreciation and **use** of the Grouse Falls scenic area. Nonmotorized recreation opportunities would be emphasized in limited timber harvesting in and surrounding the SIA. Cultural resources would be inventoried and, **if** appropriate, may be included in an interpretive program
- b. Timber - Approximately 186 acres of commercial forest land are capable of contributing a maximum of **68** MBF per year to the allowable sale quantity. Visual and recreation constraints on harvesting practices within the SIA would **limit** the volume harvested.
- c. Water, Soils, and Air - Some **loss** of soil productivity and quality could result from trail and facility development. Short-term reductions in air quality may occur, but State Air Resources Board requirements would be met.
- d. Minerals - The area has a moderate potential for mineral commodity production, and it would be proposed for withdrawal from mineral entry
- e. Facilities - Trails and trailheads would be permitted to facilitate public **use** of the area.
- f. Sensitive Plants - Increased access and visitor use could increase the risk of impact on sensitive plants.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 7 and 13 (Alternatives CUR and RPA).

- a. Recreation - Alternative RPA would increase motorized recreation opportunities, permitting **but** not emphasizing dispersed nonmotorized recreation in the first decade. Visual quality would be reduced as a result of timber management in Alternative RPA. Visual quality would remain high in Alternative CUR during the first decade. Impacts on

potential cultural resources could be high, and an inventory would be conducted as a result of management activities in Alternatives CUR and RPA

- b. SIA Values - In Alternatives CUR and RPA, the area would be managed for intensive timber production, and a unique interpretive opportunity would not be developed
- c. Timber - Alternatives CUR and RPA would permit regulated timber harvest. The maximum annual volume of 68 MMBF could be removed and contributed to the allowable sale quantity
- d. Water, Soils, and Air - Some reduction in water quality and loss of soil productivity may occur due to facility and road construction, and timber harvest. Short-term reduction in air quality may occur, but State Air Resources Board requirements would still be met
- e. Minerals - The area would be open to mineral entry. A moderate mineral potential exists in the area.
- f. Facilities - Alternatives CUR and RPA would develop and maintain a transportation network necessary to facilitate timber harvest and other activities.
- g. Protection - Improved access would facilitate treatment of insect and disease problems. Fuels management would be primarily associated with the treatment of activity fuels created by timber harvest and would fluctuate with harvest levels.
- h. Sensitive Plants - Improved access could increase the risk of damage to sensitive plants.

5. HAWLEY LAKE CULTURAL AREA (5,323 acres)

This proposed SIA is located all or partially in Sections 3, 9, 10, 11, 12, 13, 14, 15, 16, 21, 22, 23, 24, 25, 26, 27, 34, and 35, T 21N, R 11E., and Section 3, T.20N., R 11E., MDB&M. It is a high elevation area which contains numerous sites representing prehistoric and historic use spanning the past several thousand years. Several of the major sites have potential for public interpretation, and others have potential for scientific study. The area is unusual in that such a high elevation area appears to have received so much prehistoric use. Available information indicates that the territories of three Indian groups (Nisenan, Northeastern Maidu, and Washoe) converged in the Hawley Lake area. One of the prehistoric sites is the most outstanding of its type found in the Sierra Nevada. The attractiveness of the area as an SIA is limited by lack of easy access and remoteness from high recreation use areas.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation - Both dispersed nonmotorized and motorized recreation opportunities and interpretive facilities may be provided with the SIA to facilitate public enjoyment and study of the cultural resources. Nonmotorized opportunities would be emphasized in Alternative NMK. Visual quality would be enhanced since development and timber harvesting would be limited. Cultural resources would be emphasized, permitting interpretation and protection of cultural resources for public enjoyment.
- b. Timber - Approximately 2,746 acres of commercial forest land are capable of contributing a maximum of 1 MMBF per year to the allowable sale quantity. Visual and recreation constraints on harvesting practices would limit this volume considerably.
- c. Water, Soils, and Air - Water quality may be reduced slightly as a result of road and facility development. The effects on air quality would be limited because these short-term impacts would meet all State Air Resource Board regulations. At this time no significant long-term impacts are identified.

- d. Minerals - This area would be proposed for withdrawal from mineral entry, which would significantly affect potential mineral commodity production. The area is highly mineralized and produced significant amounts of gold and other minerals in the late 1800's and early 1900's. There is one mine in the area that has had recent exploration work and may be operating in the future
- e. Facilities - Roads, trails, and trailheads would be permitted to facilitate public use of the area and for limited timber harvesting
- f. Protection, Including Pest Management - Improved access to the area would provide better protection from insects and disease. The effects on protection would be similar between alternatives. The fire suppression emphasis would be directly related to the land and resource management goals and objectives.
- g. Sensitive Plants - Encouraging public use of the area could increase risk of damage to sensitive plants.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 2, 3, 7, 8, 13, or 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Alternative RPA would permit only dispersed nonmotorized recreation in the area. Dispersed motorized recreation would be emphasized in Alternatives PRF and UNE. An increase in motorized recreation opportunities would be expected in Alternative CMD as a result of intensive timber management. Visual quality would remain high in Alternatives PRF, RPA, and UNE. Visual quality would be reduced in Alternatives CUR, and CMD because of their timber harvest. Impacts on and inventory of cultural resources would increase in Alternatives PRF, CUR, CMD, and UNE as a result of public use and management activities.
- b. SIA Values - The cultural values would receive protection from management activities but would have increased access in Alternatives PRF, CUR, CMD, and UNE. Nondesignation of the area would not preclude public interpretation of the cultural values
- c. Timber - Regulated timber harvest would occur subject to visual and recreation constraints in Alternatives PRF and UNE. Under intensive timber management in Alternative CMD, the maximum annual volume of 1.0 MMBF could be harvested from the area
- d. Water, Soils, and Air - Water quality would be reduced slightly in Alternatives PRF, RPA, and UNE. Water quality would be reduced further in Alternative CMD because of timber harvesting. Best Management Practices would be used to minimize reductions in water quality. Some loss of soil production may result from road and facility development and timber harvest in Alternative PRF, RPA, and UNE. Alternative CMD would result in a higher loss of soil productivity from timber harvesting. Short-term impacts of dust or wood smoke due to road use from recreationists, timber harvesting, and prescribed burning would occur, however, these short-term impacts would meet all State Air Resources Board regulations
- e. Minerals - Mineral entry would be permitted. The area is highly mineralized and has significant potential for mineral commodity production.
- f. Facilities - Same as in SIA designation for all alternatives, except Alternatives PRF, CMD, and UNE would permit development and maintenance of a transportation network necessary to facilitate timber harvest and other activities.

- g Protection, Including Pest Management - Improved access would provide better protection from insect and disease problems. Fuels management would be directly related to timber harvest and would fluctuate with harvest levels
- h. Sensitive Plants - Increased access and activities could increase the risk of damage to sensitive plants.

6. MEADOW LAKE CULTURAL AREA (58 acres)

Both historic and prehistoric sites occur within the area (located in all or part of Sections 22 and 27, T.18N, R.13E., MDB&M). The history of the area, primarily mining surrounding Meadow Lake, has the greatest potential for public interpretation, education, and enjoyment. The prehistoric resources have greater scientific than interpretive value. The area is fairly remote and access is difficult, which limits its interpretive potential and favors preservation of the scientific values.

I ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, CMD, NMK, and UNE)

- a. Recreation - Both dispersed and developed recreational opportunities and interpretive facilities may be provided to facilitate public enjoyment and study of cultural resources. Nonmotorized opportunities would be emphasized in Alternative NMK. Visual quality would be reduced slightly by interpretive development.
- b. Timber - Because of low timber productivity, little timber value would be lost due to SIA designation.
- c. Water, Soils, and Air - Water quality may be reduced slightly as a result of road and facility development. Some loss of soil productivity may also result. Short-term impacts on air quality may occur from facility development and recreation use, but State Air Resources Board requirements would be met.
- d. Minerals - Meadow Lake would be proposed for withdrawal from mineral entry. The area has historically produced minerals and is considered to have high mineral potential. Designation as an SIA would result in a loss of potential mineral commodity production in the area.
- e. Facilities - Roads, trails and trailheads would be permitted to facilitate public use and for limited timber harvest.
- f. Sensitive Plants - Encouraging public use of the area could increase risk of damage to sensitive plants

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 4, 7, 8, 13, and 15 (Alternatives CUR and RPA).

- a. Recreation - Alternative CUR would permit water-oriented recreation development. Alternative RPA would provide greater opportunities for motorized recreation because of timber harvest. Visual quality would be reduced as a result of timber harvest in Alternative RPA. Background visual quality would be maintained for recreation users in Alternative CUR. Cultural resources would be inventoried in all non-SIA alternatives.
- b. SIA Values - Alternative CUR would not emphasize cultural resource interpretation. Alternative RPA would permit cultural resource interpretation. Cultural resources would be protected from project activities in all alternatives

- c Timber - Regulated timber harvest would be permitted in all non-SIA alternatives. The area would only contribute a maximum annual volume of 18 MBF to the allowable sale quantity.
- d Water, Soils, and Air - Same as with SIA designation
- e Minerals - The area would be open to mineral entry. Meadow Lake has high mineral potential.
- f Facilities - Same as SIA designation, except Alternatives CUR, and RPA would develop a transportation network necessary to harvest timber or to facilitate water-oriented recreation.

7. BOCA CULTURAL AREA (1,976 acres)

This area coincides with an area of high recreation use located adjacent to Interstate 80 (all or part of Sections 8, 9, 10, 15, and 16, T.18N., R.17E., MDB&M). The cultural attributes have been described in Chapter 3 and represent a variety of themes that characterize the history and prehistory of this area of the Sierra Nevada. Lumbering, mining, ice production, and transcontinental railroad history may be interpreted for the public in conjunction with recreation facilities and activities. The incorporation of interpretive facilities into the master plan for recreation development of the Boca Area would be consistent with SIA designation

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a Recreation - Both dispersed and developed recreation opportunities and interpretive facilities may be provided within the SIA for public enjoyment and study of cultural resources. Nonmotorized opportunities would be emphasized in Alternative NMK. Visual quality would be reduced slightly because limited development may occur. Cultural resources would be emphasized, permitting interpretation and protection for public enjoyment.
- b Timber - Approximately 642 acres of commercial forest land are capable of contributing a maximum of 200 MBF per year to the allowable sale quantity. Since the timber potential is not significant, timber harvesting would be unregulated and recreation and visual constraints would make only salvage harvesting appropriate
- c Water, Soils, and Air - Water quality may be reduced slightly because of road and facility development. Some loss of soil productivity may also result. Short-term impacts on air quality may result from road dust and wood smoke from recreational use. State Air Resource Board regulations for air quality would be met. No long-term impacts are identified.
- d Minerals - The area would be proposed for withdrawal from mineral entry; however, it is low in mineral potential.
- e Facilities - Roads, trails, and trailheads would be permitted to facilitate public use of the area.
- f Protection, Including Pest Management - Improved access to the area would provide better protection from insects and disease. Fuels management would be primarily associated with the treatment of activity fuels created by timber harvesting and would fluctuate with levels of harvest.

- g Sensitive Plants - Encouraging public use of the area could increase risk of damage to sensitive plants.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 3, 4, 7, 13 or 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a Recreation- All alternatives would allow for water-oriented recreation development and some interpretive facilities. Alternative CUR would also emphasize motorized recreation in a portion of the SIA. Alternative CMD would provide more motorized recreation opportunities because of intensive timber management. Visual quality would be slightly reduced in Alternatives PRF, CUR, RPA, and UNE because of water-oriented recreation development and some timber management. Visual quality would be further reduced in Alternative CMD because of intensive timber management. Cultural resource inventory would increase with the increase in management activities.
- b SIA Values - In all alternatives, a non-SIA designation would not alter the interpretive use of the area significantly. Developments would emphasize water-oriented activities over interpretive cultural facilities, but some interpretive facilities would probably still be developed. Alternative CMD would allow intensive timber management, but there is little commercial timber land. Harvesting activities could be accomplished while protecting the cultural significance of the area.
- c Timber - Timber would be harvested on a regulated basis. Alternatives PRF, CUR, RPA, and UNE would constrain harvesting practices to a manner compatible with visual and recreation objectives. Under intensive timber management in Alternative CMD, the maximum annual volume of 200 MBF could be harvested.
- d Water, Soils, and Air - Water quality would be reduced in Alternatives PRF, CUR, RPA, and UNE because of water-oriented recreation development and use and some timber management. Water quality would be further reduced in Alternative CMD because of intensive timber management. **Best** Management Practices would be used to minimize reductions in water quality in all alternatives. Air quality and soils consequences would be the same as under SIA designation.
- e. Facilities- In Alternatives PRF, CUR, RPA, and UNE, roads and trails would be built to facilitate water oriented recreation. Alternative CMD would permit development and maintenance of a transportation network necessary to facilitate timber harvest and other activities.
- f. Protection- Improved access would provide better protection from insect and disease problems. Fuels management would be directly related to timber harvest and would fluctuate with harvest levels.
- g. Sensitive Plants - Increased access and activities could increase the risk of damage to sensitive plants.

8. KYBURZ CULTURAL AREA (1,097 acres)

As with the Hawley Lake area, there is a high density of historic and prehistoric sites in the area (located in all or part of Sections 1 and 12, T 19N., R. 15E., and Sections 5, 6, 7, 8, 17, and 18, T. 19N., R. 16E., MDB&M). The historic Henness Pass Road passes through the area. The large marsh within the area, which attracts large numbers of waterfowl, was the focus of prehistoric occupation. The most intensive prehistoric use occurred 2,000 to 4,000 years ago during a period of cooler, moister climate.

Establishing this area as an SIA would complement the ongoing program of wildlife habitat improvement and public interpretation of Forest Service management activities. The proximity of the area to Highway

89 and developed recreation sites would make this a potential high use area and create an excellent opportunity to provide for public use, enjoyment, and understanding of forest resources and Forest Service management.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation - Both dispersed motorized and nonmotorized recreation opportunities and interpretive facilities may be provided to facilitate public enjoyment and study of the cultural resources. Alternative NMK would emphasize nonmotorized opportunities. Visual quality would be reduced slightly because of limited development.
- b. Timber - Approximately 723 acres of commercial forest land are capable of contributing a maximum of 300 MBF per year to the allowable sale quantity. Timber harvesting would be unregulated, and recreation and visual constraints would make only sanitation and salvage harvesting appropriate.
- c. Water, Soils, and Air - Water quality may be reduced slightly because of road and facility development. Some loss of soil productivity may also occur because of such activities. The effects on air quality would be from dust or wood smoke because of road use. State Air Resource Board regulations governing air quality would still be met. There are no significant long-term impacts identified.
- d. Minerals - The area would be proposed for withdrawal from mineral entry; however, mineral potential is low.
- e. Facilities - Roads, trails, and trailheads would be constructed to facilitate public use of the area and for limited timber harvest.
- f. Sensitive Plants - Increased access and public use could increase the risk of damage to sensitive plants.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #7, 13, or 15 (Alternatives PRF, CUR, CMD, and UNE)

- a. Recreation - In Alternatives PRF, CUR, CMD, and UNE, recreation opportunities would be similar to the cultural interpretive opportunities under SIA designation, but developments would be restricted to those that complement, or do not interfere with deer and waterfowl habitats. Alternatives RPA and CMD would result in intensive management of the area for timber production, thereby increasing motorized recreation opportunities. Visual quality would be reduced slightly in Alternatives PRF, CUR, and UNE because some development and timber harvesting would occur. Visual quality would be reduced further in Alternatives RPA and CMD because of intensive timber management. Inventory of cultural resources would occur in all alternatives.
- b. SIA Values - Alternatives RPA and CMD would be the least compatible with the ongoing program for public interpretation of wildlife habitat improvement projects and Forest management activities. Timber harvesting would be emphasized and could raise the risk to cultural resources and limit opportunities for public interpretation.
- c. Fish and Wildlife - Deer and waterfowl habitat would be protected and improved in Alternatives PRF, CUR, CMD, and UNE. Significant habitat would be protected in Alternative RPA.

- d. Timber - Timber would be harvested on a regulated basis in all alternatives. Alternatives PRF, CUR, and UNE emphasize harvesting timber to achieve wildlife objectives for the area.
- e. Water and Soils - Water quality would be maintained or improved because of wildlife habitat improvement projects in Alternatives PRF, CUR, and UNE. Water quality would be reduced because of intensive timber management in Alternatives RPA and CMD. Best Management Practices would minimize reductions in water quality. Some loss of soil productivity would result from road and facility development and timber harvest.
- f. Facilities - In Alternatives PRF, CUR, and UNE transportation facilities would be restricted to meet wildlife objectives. Alternatives RPA and CMD would permit development and maintenance of a transportation network necessary to facilitate timber harvest and other activities.
- g. Protection, Including Pest Management - Improved access would provide better protection against insect and disease problems. Fuels management would be directly related to timber harvest and would fluctuate with different harvest levels.
- h. Sensitive Plants - Increased access and activities could increase the risk of damage to sensitive plants.

9. SAGEHEN HEADWATERS (79 acres)

Located in a glacial cirque basin comprising the headwaters of Sagehen Creek (Section 16, T.18N., R.15E., MDB&M), the Sagehen Botanical Area is an excellent example of virgin red fir, mountain hemlock, and mountain mahogany communities in an 'avalanche' forest. The cirque basin is filled by an ephemeral pond containing a wide variety of aquatic invertebrates. One hundred thirty species of plants have been found in this area, including a species of lichen known only in this location in the Sierra Nevada. Because of the area's botanical uniqueness and undisturbed ecosystem, a significant opportunity exists for research. Pending further analysis, a decision on the allocation of this area will be delayed.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, CMD, NMK, and UNE).

- a. Recreation - Opportunities for dispersed recreation would only occur and be encouraged if public use did not affect SIA values. The ecosystem is quite fragile and will not support heavy use. Visual quality would be maintained and cultural resources would be protected.
- b. Timber - Commercial timber land is insignificant in this area.
- c. Minerals - The area would be proposed for withdrawal; however, the mineral potential is low.
- d. Facilities - Roads, trails, and trailheads would be permitted if compatible with the purpose of the SIA.
- e. Sensitive Plants - Designation would provide added protection of sensitive plants. If public use is encouraged, however, increasing use could raise the risk of damage to plants.

II. CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescriptions #'s 3, 5, 13, and 14 (Alternatives CUR and RPA)

- a. Recreation- In Alternative RPA dispersed nonmotorized recreation would be emphasized. Dispersed motorized recreation would occur in Alternative CUR. Visual quality would be maintained in all alternatives. Cultural resources would be inventoried and protected as needed.
- b. SIA Values - Alternatives CUR and RPA would maintain the ecological values found in the area.
- c. Timber - Regulated timber management would occur in Alternatives CUR and RPA, but would be subject to visual and recreation constraints.
- d. Water, Soil, and Air - Some reduction in water quality and loss of soil productivity could occur from intensive timber management, but Best Management Practices would be used to minimize effects. Short-term reduction in air quality may occur, but State Air Resources Board requirements would still be met.
- e. Minerals - The area would be open to mineral entry; however, the mineral potential is low.
- f. Facilities - Trails and roads necessary for research and timber harvest would be permitted.
- g. Sensitive Plants - Some impact on sensitive plant habitat could occur from timber harvest activities in alternatives CUR, RPA, and CMD.

10. SIERRA BUTTES (1,827 acres)

The major theme of this area (all or part of Sections 4, 5, 8, 9, 16, 20, and 21, T.20N, R.12E, MDB&M) is a special interest species. In a calcareous vein in the metavolcanic cliffs on the east side of the Buttes is the southernmost occurrence of green spleenwort (*Asplenium viride*). This species normally occurs in Central Washington and Oregon. Also in the Sierra Buttes area is mountain hemlock (*Tsuga mertensiana*). The purpose of SIA establishment is to preserve the green spleenwort.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK)

- a. Recreation - Opportunities for dispersed and motorized recreation and interpretive development would be permitted, thereby aiding public appreciation of the special interest plant species. Visual quality would be reduced slightly because of interpretive development. Cultural resources would be inventoried as necessary.
- b. Timber - approximately 586 acres of commercial forest land are capable of producing a maximum of 200 MBF per year. Timber harvesting would be unregulated, and recreation and visual constraints would make only sanitation and salvage harvesting appropriate.
- c. Minerals - This area would be proposed for withdrawal from mineral entry. Mineral potential is high. Some loss of mineral commodity production could occur as a result of withdrawal.
- d. Lands - Designation of the area as an SIA would be difficult since approximately one-third of the area is in private ownership. The area has potential for hydroelectric developments. One such area is planned for Upper Sardine Lake.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 2, 3, 4, 8, 13, or 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Opportunities would be similar to the current situation. Dispersed and motorized recreation would continue. Motorized recreation opportunities would increase because of timber harvesting in Alternatives PRF, CUR, RPA (portion), CMD, and UNE, with the greatest increase being in Alternative CMD. Dispersed motorized recreation would be emphasized in Alternatives PRF and UNE. Water-oriented recreation opportunities would be permitted in Alternative CUR. Visual quality would be reduced because of intensive timber management in Alternatives RPA and CMD. Visual and recreation constraints on management would minimize visual quality reduction in Alternatives PRF, CUR, and UNE. Cultural resources would be inventoried as necessary in all alternatives.
- b. SIA Values - The consequences of not designating the area as an SIA would not be significant because the green spleenwort is located on a cliff where it is unlikely to be disturbed by TNF management activities.
- c. Timber - Alternative CMD would permit the maximum annual volume of 200 MBF to be harvested. Alternatives PRF, CUR, RPA, and UNE would allow timber harvest, with visual and recreation constraints reducing the maximum annual volume.
- d. Water, Soils, and Air - Water and air quality would be reduced slightly in all Alternatives because of limited timber harvesting and water-oriented recreation development. All impacts would be minimized using Best Management Practices. All alternatives would result in a slight risk of loss of soil productivity from limited timber harvesting and from water-oriented recreation development and activities.
- e. Minerals - The area would be open to mineral entry, permitting mineral commodity production.
- f. Facilities - Alternatives PRF and UNE would develop trails and trailheads, some interpretive facilities, and roads for timber harvest. Alternative CUR would allow development of facilities necessary for water-oriented recreation development. Alternatives RPA (portion) and CMD would develop a transportation network necessary to facilitate timber harvest and other activities.
- g. Sensitive Plants - Increased access and activities could increase the risk of damage to sensitive plants.

11. LITTLE TRUCKEE RIVER TERRACE (468 acres)

This site is on geologic terraces formed by glacial dam-burst floods coming from Lake Tahoe (located in all or part of Sections 4 and 9, T.18N., R.12E., and Sections 32 and 33, T.19N., R.17E., MDB&M). The soils are scientific standard reference soils used to calibrate degrees of soil development over geologic time. The area represents a unique setting for the study of plants peculiar to the sagebrush community. The dominant plant is *Artemisia tridentata*. There is a fine collection of sagebrush-associated plants which occur in succession during the spring and summer. Yellow Bells (*Fritillaria pudica*), common to the north, apparently reach their southernmost distribution here. Sagebrush vegetation in California has not been well studied or described.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation - Opportunities for dispersed and motorized recreation and interpretive development would be permitted to facilitate public appreciation and study of the geologic terraces and sagebrush communities unique to the area. Visual quality would be reduced slightly because of interpretive development, but maintained as viewed from developments. Cultural resources would be inventoried as necessary.
- b. Timber - The maximum annual volume would be approximately 15 MBF. Timber harvest would be unregulated in the area under SIA designation. Recreation and visual constraints would make sanitation and salvage harvesting appropriate.
- c. Minerals - The area would be withdrawn from mineral entry; however, mineral potential is low.
- d. Facilities - Roads, trails, and trailheads may be built to provide public access to the area and interpretive facilities.
- e. Protection, Including Pest Management - Limited access would hinder fire suppression and limit opportunities to treat insect and disease problems.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 4, 13, and 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - All alternatives would permit water-oriented recreation development, and background visual quality would be maintained for recreationists. Alternative CMD would improve motorized recreation opportunities, but would reduce visual quality because of intensive timber management. Cultural resources would be inventoried as necessary.
- b. SIA Values - Not designating the area as an SIA would not permit emphasis of the geologic terraces or sagebrush communities. The soils study area would probably be protected.
- c. Timber - An annual contribution of 15 MBF of timber volume would be harvested in Alternative CMD. Visual and recreation constraints on timber harvesting would reduce this volume in Alternatives PRF, CUR, RPA, and UNE.
- d. Water, Soils, and Air - Little impact would be expected in Alternative CMD because of the small amount of harvestable timber. Greater impacts would be expected on both soil productivity and water quality as a result of water-oriented recreation development in Alternatives PRF, CUR, RPA, and UNE. Best Management Practices should minimize the impacts.
- e. Minerals - The area would be open to mineral entry; however, mineral potential is low.
- f. Facilities - Trails, trailheads, and roads necessary for the development and operation of water-oriented recreation facilities would be permitted in Alternatives PRF, CUR, RPA, and UNE. In Alternative CMD, a transportation network would be developed to facilitate timber harvesting.
- g. Protection, Including Pest Management - With improved access there would be greater opportunity to treat insect and disease problems, and fire suppression would be facilitated.

- h. Sensitive Plants - The increase in management activities in all non-SIA alternatives would increase the risk of damage to sensitive plants.

12. SAGEHEN CREEK BASIN (8,373 acres)

The most remarkable natural feature of the Sagehen Creek Basin is the diversity and variety of springs and spring habitats in the area. The area is located in all or part of Sections 1, 2, 10, 11, 12, T.18N, R.15E., Sections 4, 5, 6, 7, 8, 9, T.18N., R.16E, Section 36, T.19N., R.15E., and Sections 31 and 32, T.19N., R.16E, MDB&M. Water derived from rain and heavy snowfall penetrates the porous volcanic rocks characteristic of the region and collects on the impervious bedrock, creating numerous springs of superficial origin. Many small, minerotrophic peatlands (fens) occur throughout the Basin. The largest of them is Mason Fen, a wet, spongy area of a few hectares composed largely of a two-meter deep, nonsphagnum moss and sedge mat. Mason Fen is also being considered as a smaller 30 acre SIA (see number 17). Numerous research projects, including over 130 publications, films, and theses, have been conducted in the Basin. Research on fish and wildlife has been carried out since 1951, primarily by the University of California at Berkeley.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation - Opportunities for dispersed and motorized recreation and interpretive development would be permitted to facilitate public appreciation and study of the area's spring habitats and peatlands (fens), if not in conflict with research objectives. Visual quality would be reduced because of interpretive development (maintained as viewed from the developments). Cultural resources would be inventoried as necessary.
- b. Timber - The Basin contains approximately 7,461 acres of commercial forest land capable of contributing a maximum annual volume of 27 MMBF to the allowable sale quantity. Unregulated timber management and the visual and recreation constraints would make sanitation and salvage harvesting appropriate.
- c. Water, Soils, and Air - Slight degradation to soil and water quality would be expected from interpretive development. Best Management Practices would minimize impacts.
- d. Minerals - The area would be closed to mineral entry, however, mineral potential is low.
- e. Lands - 350 acres of the Basin are currently under special-use permit with U.C. Berkeley for housing and research facilities. Designation as an SIA would be consistent with the special use.
- f. Facilities - Roads, trails, and trailheads would be constructed to facilitate public use of the area if not in conflict with research objectives.
- g. Sensitive Plants - Encouraging public use of the Basin could increase risk of damage to the sensitive plant habitat.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 3, 8, 12, 13, 14, 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - In all alternatives, the current management direction of cooperative research would be continued, permitting dispersed recreation activities that would not conflict with research objectives. Visual quality would be maintained and cultural resources would probably receive little impact. Alternative CMD would provide for increased

motorized recreation opportunities because of intensive timber management. Cultural resources would be inventoried prior to timber harvest in this alternative.

- b SIA Values - Current research projects would receive protection from management activities but would have increased access in Alternatives PRF, CUR, RPA, CMD, and UNE. Regulated timber management would also be permitted. Nondesignation of the area would not preclude public interpretation of the area's spring habitats and peatlands (fens).
- c Range - In all alternatives both intensive and extensive grazing management would be implemented to the extent it did not interfere with research objectives.
- d Timber - Regulated timber management would be permitted in all non-SIA alternatives, but would be constrained by research objectives in Alternatives PRF, RPA, CMD, and UNE. In Alternative CUR, timber management would be constrained by visual resource requirements.
- e Water, Soils, and Air - Some reductions in water quality and soil productivity would occur in all non-SIA alternatives, ranging from a minimal impact from timber harvesting in Alternatives PRF, CUR, RPA, and UNE to a greater risk of loss from intensive timber management in Alternative CMD
- f Minerals - The area would be open to mineral entry; however, mineral potential is low.
- g Facilities - Trails and roads necessary to aid research and timber harvesting would be permitted in Alternatives PRF, CUR, RPA, and UNE.
- h. Protection, Including Pest Management - Improved access would aid fire suppression and treatment of insect and disease problems. Fuels management would treat activity fuels from timber harvest and would fluctuate with harvest levels
- i Sensitive Plants - Some impact on habitat could be expected because of timber harvest, but sensitive plant habitat in general would be protected as part of timber management practices.

13. INDEPENDENCE LAKE (81 acres)

This is one of the few areas (located in Section 4, T.18N., R.15E., MDB&M) in California that supports a genetically pure strain of the Federally listed as threatened Lahontan cutthroat trout. The stream that feeds into the lake is an important spawning area. Quaternary glacial deposits surround the lake. The site is a well-studied terminal glacial moraine complex that represents the northernmost extent of Sierra Nevada's classical glacial sequences. The moraines at the lake are the best preserved of any in the sequence.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a Recreation - Less than 10 percent of the entire area proposed as an SIA is on National Forest System land. Recreation opportunities would be primarily dispersed. Because the significant lake and moraine features are on private land, interpretive developments or research study would not occur on National Forest System lands. Visual quality would remain high. Inventory of cultural resources would be difficult because of poor accessibility.
- b Timber - Approximately 58 acres of commercial forest land are capable of contributing a maximum volume of 21 MBF per year to the annual sale quantity. Unregulated timber management would make sanitation and salvage harvesting appropriate.

- c. Minerals -The area would be closed to mineral entry. Mineral potential is low.
- d. Lands- Over 90 percent of the proposed Independence Lake SIA is in private ownership as well as the significant features. Acquisition of the private lands is not feasible.
- e. Facilities -Trails and trailheads may be located on portions of National Forest System lands.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 10, 11, and 13 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Dispersed and motorized recreation would occur in Alternative CMD. Winter recreation development would be emphasized in Alternatives PRF, CUR, and UNE. Alternative RPA would permit recreation activities that would not affect the exchange value of the land. Visual quality would be reduced because of intensive timber management or winter recreation development in Alternatives PRF, CUR, CMD, and UNE. Cultural resources would be inventoried as necessary in all alternatives.
- b. SIA Values - Not designating this area as an SIA would have little impact on its significant features since most are located on private land.
- c. Timber - In Alternative CMD, the maximum annual sale quantity of 21 MBF could be harvested. Timber harvesting would be unregulated in Alternatives PRF, CUR, RPA, and UNE.
- d. Water, Soils, and Air - Water quality and soil productivity could be reduced because of intensive timber management and winter recreation development in all alternatives except RPA, which maintains the exchange value of the land. Any reductions would be minimized by use of Best Management Practices.
- e. Minerals -The area would be open to mineral entry; however, mineral potential is low.
- f. Lands - Alternative RPA would maintain land and resource values necessary to retain a high value for land exchange.
- g. Facilities -Alternatives PRF, CUR, and UNE would permit all-season road construction necessary for winter recreation development and operation. A transportation network to aid timber management and other activities would be developed as necessary in Alternative CMD.
- h. Protection, Including Pest Management -The amount of protection against insect and disease activities would increase with increased accessibility.
- i. Sensitive Plants - A greater risk of impact from intensive timber management and winter recreation development would probably occur in all alternatives except Alternative RPA.

14. HEADWATERS BASIN OF THE NORTH FORK OF THE AMERICAN RIVER (9,381 acres)

This large area includes the Onion Creek Experimental Forest. It is located in all or part of Sections 1, 2, 10, 12, 16, 22, and 24, T.16N., R.14E., Sections 3, 4, 5, 9, 10, 14, 16, 20, 22, 24, 26, 27, 28, 34, and 35, T.16N., R.15E., Sections 32 and 36, T.17N., R.14E., and Section 29, T.17N., R.15E., MDB&M. Over one-half of the area is in private ownership. The river basin contains relatively undisturbed, rich flora that provides an excellent representative example of plant species and soils of the central Sierra Nevada. The variety of slope exposures, range of elevations, and different soil and parent material types create a tremendous diversity of habitat types. This provides numerous opportunities for study and research into all aspects of

plant, animal, and aquatic ecology. Over one-third of the plant families in California occur in this headwaters basin. Ongoing research includes studies of red fir, white fir, and mixed fir forest stands at the Onion Creek Experimental Forest, the establishment of eight permanent study plots in red and white fir forests from 6,000 - 7,000 feet, and collections for a floristic checklist.

Of the TNF land within the area, approximately 5,000 acres within the Onion Creek Experimental Forest are unavailable for regulated timber harvest. A portion of this area is within the Granite Chief Wilderness.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

(Management Prescription #5 (Alternative NMK))

- a. Recreation - Recreation opportunities include dispersed nonmotorized and motorized recreation and scientific and interpretive development to facilitate public appreciation and scientific study of the area's diverse plant, animal, and aquatic ecology. Visual quality may be reduced slightly because of facility development. Cultural resources would be inventoried as necessary.
- b. Wilderness - A portion of the proposed SIA is within the Granite Chief Wilderness. Development permitted in an SIA would not be compatible with wilderness designation.
- c. Timber - Approximately 6,454 acres of commercial forest land are capable of contributing a maximum volume of 2.4 MMBF per year to the allowable sale quantity. Five thousand acres of this are in the Onion Creek Experimental Forest and currently are unavailable for regulated timber harvest. The remaining commercial forest land would be unregulated.
- d. Minerals - The area would be proposed for mineral withdrawal. There is low to moderate mineral potential in the proposed SIA. Most of the Onion Creek Experimental Forest is currently withdrawn from mineral entry. A small portion of the Onion Creek Experimental Forest that is not withdrawn would be proposed for mineral withdrawal.
- e. Lands - Designation as an SIA would be difficult since over one-half of the area is in private ownership. Five thousand acres within the Onion Creek Experimental Forest are already set aside by the Chief of the Forest Service for watershed research purposes.
- f. Protection, Including Pest Management - Lack of access would make fire suppression and treatment of insect and disease problems difficult.
- g. Sensitive Plants - Sensitive plants would be studied and protected.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 1, 2, 3, 13, 14, and 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Dispersed opportunities would be permitted only in Alternatives PRF, CUR, RPA, and UNE. Both dispersed and motorized opportunities would be provided in Alternative CMD, because the theme for this alternative is intensive timber management. Visual quality would not be altered in Alternatives PRF, CUR, RPA, and UNE, and may be reduced with road development and timber harvest in Alternative CMD. Inventory of cultural resources would be difficult in all alternatives.
- b. Wilderness - A portion of the area is within the Granite Chief Wilderness and will be protected from development and management activities.
- c. SIA Values - In Alternative CMD, intensive timber management would diminish the value of this area for ecological research studies. The remaining alternatives provide for

maintenance of a nearly natural setting and would have little effect on the identified SIA values.

- d. Fish and Wildlife - No impacts are expected in Alternatives PRF, CUR, RPA, and UNE. Alternative CMD would produce changes in fish and wildlife habitats.
- e. Range - Grazing is permitted in all alternatives and extensive management would be implemented.
- f. Timber - No regulated timber harvesting would occur in Alternatives PRF, CUR, RPA, and UNE. Some regulated harvesting may occur in Alternative CMD, subject to research and visual constraints. The maximum annual volume of 500 MBF outside of Onion Experimental Forest could be harvested in Alternative CMD.
- g. Water, Soils, and Air - Water quality would remain high in Alternatives PRF, CUR, RPA, and UNE, and would be reduced to some degree in Alternative CMD because of road development and timber harvesting. No loss of soil productivity would be expected in Alternatives PRF, CUR, RPA, and UNE, and a slight risk of loss of productivity would occur in Alternative CMD from intensive timber management.
- h. Minerals - The area (with exception of the Onion Creek Experimental Forest and the Granite Chief Wilderness) would be open to mineral entry, providing some opportunity for low to moderate mineral commodity production.
- i. Facilities - Trails and trailheads only would be developed in Alternatives PRF, CUR, RPA, and UNE. In Alternative CMD a transportation network would be developed to facilitate timber harvest and other activities.
- j. Sensitive Plants - Increased activities and access could increase the risk of damage to sensitive plants in Alternative CMD.

15. SAN JUAN RIDGE (6,541 acres)

The major theme of this area is 'Paleocene to Eocene, The Emerging Dominance of Mammals.' Other themes identified include 'Economic Geology - Hydraulic Mining and Sculpture of the Land.'

The area (located in all or part of Section 12, T.17N., R.19E., Sections 4, 5, 6, 7, 8, 9, 18, T.17N., R.10E., Sections 20, 21, 22, 23, 24, 26, 28, 34 and 35, T.18N., R.9E., and Sections 19, 21, 28, 32, 33, and 34, T.18N., R.10E., MDB&M) consists of well developed Tertiary auriferous gravels, some of which were hydraulically mined in the 19th century. The mining scars have eroded to form dramatic cliffs which are characteristic of badlands topography. Portions of the Malakoff Diggins State Park are within the proposed area. The ponds in the bottom of the mining area support the only occurrence of cranberry in the Sierra Nevada. The area is also unusual in that when hydraulic mining was halted by court order in 1884, extensive gold bearing gravels were left exposed, but unmined. The area is also ideally suited for the study of plant succession.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

(Management Prescription #5 (Alternative NMK).

- a. Recreation - Recreation opportunities consist of motorized and dispersed recreation and interpretive development aiding public appreciation of the geologic and mining history of the area. Visual quality has been altered over the years because of hydraulic mining. Existing visual quality may be reduced slightly because of interpretive facility development. Cultural resources would be inventoried and could be interpreted as part of the overall interpretive program in the area.

- b. Timber - Approximately 6,271 acres of commercial forest land are capable of contributing a maximum of 2.3 MMBF per year to the allowable sale quantity. Unregulated timber management would make sanitation and salvage harvesting appropriate
- c. Water, Soils, and Air - Some reduction in water quality and loss of soil productivity could occur because of road and trail development and interpretive facility construction. Dust from these activities may cause short-term reductions in air quality, but State Air Resources Board requirements would still be met.
- d. Minerals - This area would be withdrawn from mineral entry. Mineral potential ranges from high to very high. A significant potential loss of mineral commodity production would occur as a result of withdrawal.
- e. Land - Establishment of the area as an SIA would be difficult since over 80 percent is in private or other non-Federal ownership. Some of the more significant features that are already protected are located within Malakoff State Park.
- f. Facilities - Roads, trails, and trailheads would be permitted to facilitate public use and timber harvest.
- g. Sensitive Plants - Increased access and visitor use could raise the risk of damage to sensitive plants

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 13 and 15 (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Recreation opportunities would be similar to the current situation. Dispersed motorized and developed recreation now occur on National Forest System lands and in Malakoff State Park. The State Park offers several interpretive facilities explaining the historical significance of the area. Timber harvesting would expand the transportation network and improve motorized recreation opportunities. Visual quality would be reduced because of intensive timber management in all non-SIA alternatives. A predominantly natural-appearing landscape would be maintained in Alternative UNE and portions of Alternatives PRF, RPA, and CMD. Cultural resources would be inventoried as necessary.
- b. SIA Values - Not designating San Juan Ridge as an SIA may result in the loss of a study area for natural vegetation succession and the only occurrence of cranberry in the Sierra Nevada. These and other significant attributes of the area, such as the hydraulic mining and geologic history of San Juan Ridge, are currently protected within the State Park.
- c. Timber - Regulated timber harvesting would occur, permitting the maximum annual volume production of 2.3 MMBF.
- d. Water, Soils, and Air - Water quality may be reduced because of intensive timber management. A higher loss of soil productivity may result from increased timber harvest. Short-term reduction in air quality may occur from dust from road use and timber harvesting, but State Air Resources Board requirements would be met.
- e. Minerals - This area would be open to mineral entry providing potential for significant mineral commodity production.
- f. Facilities - All non-SIA alternatives would develop a transportation network necessary to facilitate timber harvesting and other activities.
- g. Protection, Including Pest Management - Increased access would allow for better treatment of insect and disease problems and facilitate fire suppression. Fuels

management would treat activity fuels from timber harvesting and would fluctuate with harvest levels

- h Sensitive Plants - Risk of damage to sensitive plants could be greater because of increased timber harvesting.

16. MACKLIN CREEK (380 acres)

The major theme of this area is to preserve the Lahontan cutthroat trout. The creek contains the only existing remnant of the Pyramid Lake population of this species. Originally, the fish occurred in the Lahontan Basin, which in California includes the Truckee, Walker, and Carson River drainages and Lake Tahoe. The introduction of other trout species into these areas has resulted in drastically diminished and hybridized populations of Lahontan cutthroat trout. The Macklin Creek occurrence of this species is outside its former known range. The area is located in all or part of Sections 14, 15, 22, 23, T.19N., R.12E., MDB&M. This trout was introduced in the late 1800's and now represents one of the few pure Lahontan populations. This population has been used to reintroduce the species into streams within its former natural range. Approximately one-half of the area is in private or State of California ownership, including most of Macklin Creek itself. The State purchased some land along the creek to protect the trout's habitat. Logging has occurred on portions of the private lands, and some of the TNF land is under contract to be logged (Pinoli Timber Sale). Timber sale roads have already been built to aid the timber harvest. Some roads and harvest units are within the proposed SIA area.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternative NMK).

- a. Recreation - Recreation opportunities consist mainly of dispersed forms, such as hiking and camping. The creek is closed to fishing by State law. Some interpretive facilities could be developed to explain the significance of the Lahontan cutthroat and its habitat. Visual quality may be reduced slightly because of limited timber harvesting. Cultural resources would be inventoried.
- b. Fish and Wildlife - The Lahontan cutthroat trout habitat would be protected and improved.
- c. Timber - Approximately 331 acres of commercial forest land are capable of contributing a maximum of 120 MBF per year to the allowable sale quantity. Unregulated timber management would make sanitation and salvage harvesting appropriate.
- d. Water, Soils, and Air - Water quality, especially trout habitat, would be protected and Best Management Practices implemented during any timber harvesting or facility development.
- e. Minerals - The area would be proposed for withdrawal from mineral entry. The area has a moderate potential for mineral commodity production.
- f. Lands - Private and State of California property extends on both sides of Macklin Creek in the northern two-thirds of the proposed SIA.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #'s 7, 13, and 15. (Alternatives PRF, CUR, RPA, CMD, and UNE).

- a. Recreation - Alternative CUR would permit both dispersed and motorized recreation opportunities that would enhance or would not adversely impact deer, waterfowl, and fishery habitat. Dispersed nonmotorized and motorized recreation opportunities would be provided in Alternatives PRF, RPA, CMD, and UNE. Wildlife interpretive facilities would be permitted in Alternative CUR. No interpretive facilities would be emphasized.

in Alternatives PRF, RPA, CMD, and UNE. Visual quality would be reduced as a result of timber harvesting. Cultural resources would be inventoried as necessary.

- b. SIA Values - The Lahontan cutthroat would be protected regardless of SIA designation.
- c. Fish and Wildlife - Lahontan cutthroat trout habitat would be protected
- d. Timber - In Alternatives PRF, RPA, CMD, and UNE, the maximum annual volume of 120 MBF may be harvested. Alternative CUR would permit regulated timber harvest that would enhance or would not affect fishery and wildlife habitat.
- e. Water, Soils, and Air - Water quality may be reduced slightly because of timber harvest, but impacts would be minimized by implementing Best Management Practices. Some loss of soil productivity could occur and there would be short-term reduction in air quality because of dust from timber harvesting and road use. State Air Resources Board requirements would be met.
- f. Minerals - The area would be open to mineral entry. There is moderate potential for mineral commodity production.
- g. Facilities - All non-SIA alternatives would develop and maintain a transportation network necessary to facilitate timber harvest and other activities
- h. Protection - Improved access would facilitate treatment of insect and disease problems. Fuels management would treat activity fuels from timber harvest and fluctuate with harvest levels.
- i. Sensitive Plants - Risk of damage to sensitive plants could be greater in all non-SIA alternatives.

17. MASON FEN (30 Acres)

The Mason Fen represents the largest fen in the Sagehen Basin vicinity. It is one of the varieties of peatland identified in California. The fen is located near Truckee, California at the University of California Sagehen Creek Field Station (Section 7, T.18N., R.16E., MDB&M). The Mason Fen has been the subject of research since 1957. The Sagehen Creek area receives water from springs. Precipitation from rain and heavy winter snowfall penetrates the porous volcanic rocks that are characteristic of the region, and collects on impervious bedrock, creating numerous springs (Savage 1973). About 40 plant species have been identified from the Mason Fen (Erman and Erman 1975). Two carnivorous plants are common on the Mason Fen *Drosera rotundifolia* (roundleaf sundew) and *D. anglica* (English sundew). This is an unusual occurrence in California.

I. ENVIRONMENTAL CONSEQUENCES OF SIA DESIGNATION

Management Prescription #5 (Alternatives PRF, CMD, NMK, and UNE)

- a. Recreation - Opportunities for dispersed recreation would occur and be encouraged if public use did not affect SIA values. The ecosystem is quite fragile and will not support heavy use. Visual quality would be maintained and cultural resources would be protected.
- b. Timber - This area is unsuited for regulated timber production.
- c. Minerals - The area would be proposed for withdrawal; however, the mineral potential is low.
- d. Facilities - Due to the fragile nature of this area, no roads, trails, or trailheads would be permitted.

e Sensitive Plants - Designation would not change the current situation.

II. ENVIRONMENTAL CONSEQUENCES OF NONSPECIAL INTEREST AREA DESIGNATION

Management Prescription #5 (Alternatives CUR and RPA).

Because the area is located within the U C Sagehen Creek Field Station, there would be no consequences from not designating the area as an SIA, except the area would not be withdrawn from mineral entry.

18. WILD PLUM WHITE FIR FOREST (716 acres)

The major theme of this area (Section 30, T.20N., R.13E, MDB&M) is Pacific forest. Specifically, the area represents a rare old-growth white fir forest that is well suited for the study of vegetation succession and the role of fire in mixed conifer forests. It is generally believed that the Sierra Nevada was originally an open, highly productive forest with large sugar pine, ponderosa pine, incense cedar, and Douglas fir trees. The forest was kept open by frequent ground fires. With the advent of fire control, a jungle of white fir has invaded. The Sierra mixed conifer forest is changing to a white fir forest. This model of Sierran ecology is being questioned, and the old-growth white fir stands at Wild Plum are thought to contain valuable information to understand forest ecology.

Approximately one-half of the area is in private ownership (Southern Pacific Land Company), and logging has taken place since 1975, when the old-growth white fir stands were identified. Likewise, the TNF land in Section 30 is also scheduled to be logged in the near future. The area is currently under contract (Deadhorse Timber Sale), and the white fir old growth has been partially logged.

This area was considered for SIA designation, but eliminated because of current and past logging of the area, which has removed the white fir

APPENDIX D

ECONOMIC EFFICIENCY ANALYSIS

CONCEPTUAL BACKGROUND

Present net value (PNV) is the criterion used to maximize net benefits in planning benchmarks and alternatives for the Tahoe National Forest. For each alternative, PNV is the difference between the discounted value of all priced outputs and all Forest Service management and investment costs over the analysis period. The priced outputs are those that are, or can be, exchanged in the market place. They include the value of forage, the stumpage value of timber, the value of commercial fish in the stream, fur animals and other harvested miscellaneous products, the value of any increased water flow quantities, and all recreation visitor days, including those for wildlife, fishing, and wilderness experiences.

The alternatives are designed to achieve the specified nonpriced outputs and to meet constraints at the least cost. Thus, the PNV of each alternative estimates the value of the maximum attainable benefits of priced outputs. It is the value of priced benefits realized in excess of all the Forest Service costs of producing priced outputs and nonpriced outputs and meeting management constraints. PNV, therefore, is an estimate of the market value of the current forest resources after all costs of producing outputs and meeting constraints have been subtracted from the value of the expected flow of priced outputs.

Net public benefit is defined to be the overall value to the Nation of all outputs and positive effects (benefits) less all the associated Forest Service inputs and negative effects (costs) for producing those primary benefits whether they can be quantitatively valued or not. Thus, conceptually, net public benefits are the sum of PNV plus the full value of nonpriced outputs. The full value of nonpriced benefits is used because their cost of production has been accounted for in PNV. The nonpriced benefits here included are outputs such as threatened and endangered species maintenance or enhancement; natural and scientific areas: cultural site reservations such as Indian religious sites, and historical or anthropological sites: visual quality in excess of full service day standards; diversity objectives: or air quality in excess of minimum management requirements. Minimum management requirements in this context are standards that must be met in the production of any or all outputs from the Forest. The minimum level, therefore, is a cost of production in the multiple-use context.

There are also second level benefits or effects that are also the concern of National Forest policy and management. These include local income and job effects on economic development of communities: net cost impacts on taxpayers: price effects on consumers of forest products and other producers of those products: payments to communities in lieu of taxes: and benefits to specific users of National Forest products who pay no fees, or fees less than the price of the valued outputs. All these are distributive welfare effects of National Forest production. All the foregoing distributive effects and impacts have been the object of National policy issues and discussions in both the Administration and the Congress. Because they are distributive effects, they are essentially questions of equity rather than efficiency, and they involve questions of who should get benefits and who pays the costs. They cannot be assessed in the context of the efficiency criteria associated with the PNV and the net public benefit concepts.

EIS PRESENTATION

The methodology, background, and results of the economic efficiency analysis that was conducted during the planning process are presented throughout the EIS. As a result, all of the major sections of the EIS, including those listed below, must be read in order to get a complete picture of the analysis that was conducted.

Context

Discussion of how economic efficiency Analysis was used in the process of developing alternatives.

Outputs, total cost, and PNV for each of the benchmarks.

Results of the constraint analysis and a comparison of the alternatives in terms of PNV. This is the most comprehensive summary of the analysis results in the EIS

Background information on economic conditions and the resource supply-demand situation for the Forest.

How and why PNV of the alternatives differs

Technical details of the modeling and analysis process, including a description of basic estimates and assumptions on benefits, costs, and interest rates.

APPENDIX E

WILD AND SCENIC RIVER EVALUATION

Appendix E is an assessment of the eligibility of rivers on the Tahoe National Forest (TNF) included in the Nationwide Rivers Inventory (NRI) and rivers recommended by the public from response to the Forest Plan. The appendix is organized into two sections. The first section discusses the Middle Yuba River and the South Yuba River, which were included in the NRI. The second section discusses other rivers on the Forest and their disposition in regard to Wild and Scenic River eligibility. The rivers discussed are Canyon Creek, North Fork of the Middle Fork American River, Middle Fork American River, Truckee River, Laveuola Creek, North Yuba River, and the Rubicon River.

MIDDLE YUBA AND SOUTH YUBA RIVERS

The Heritage Conservation and Recreation Service (HCRS), now a part of the National Park Service, included portions of the Middle Yuba and South Yuba Rivers in the NRI made in 1980 and 1981. Based on the inclusion of these two rivers in the Nationwide list, the TNF conducted an inventory and eligibility study for the rivers as discussed below.

The portion of the Middle Yuba River included in the Inventory is from Milton Reservoir to the head of the impoundment above Our House Dam, for a distance of 31 miles. The portion of the South Yuba River is from Lake Spaulding to the Forest boundary for a distance of 21 miles. (See the maps on pages E-10 through E-18)

Both of these rivers are located in steep "V" shaped canyons covered with mixed conifers, hardwoods, and brush typical of the west side of the Sierra Nevada Mountains. Both drainages are located in the Cascade Sierra Mountains-Sierra Nevada Physiographic Province - 23. This is the same province that includes the Middle Fork of the Feather Wild and Scenic River and the North Fork of the American Wild River.

The inventory identified the best remaining examples of free-flowing rivers in each physiographic province and included only those streams that appeared to have an outstanding value or combination of notable values.

A. Notable Features

1. The NRI identified the following as potential outstandingly remarkable values for the inventoried segments of the Middle and South Yuba Rivers:
 - (a) Scenic values were identified for each river. For the most part both rivers flow through steep, rugged canyons with canyon walls rising to 2000 feet above the rivers. The box canyons in the upper portion of the Middle Yuba River are the most notable scenic features. Access is limited.
 - (b) Recreation values were identified for the South Yuba River.

Both rivers lie within a three-hour drive from the Sacramento Metropolitan area. For the more accessible portions of the rivers, recreation use is moderate to heavy and includes swimming, fishing, picnicking, camping, recreational gold mining, and hiking. Minor amounts of river floating also occur.

Recreation use is low in the remaining sections and includes fishing, swimming, recreational gold mining, hiking, and camping.

- (c) Fishery values were identified for the Middle Yuba River. Both rivers are considered a cold water fishery by the TNF and California Department of Fish and Game, with resident rainbow and brown trout. In the accessible portions, the fishery is augmented by regular plants of rainbow trout by the California Department of Fish and Game

The current quality of the fishery is fair to good in both rivers.

- (d) Historic values were identified in the South Yuba River. Both river corridors show evidence of historic gold mining for almost their entire lengths. Water was diverted from both the Middle and South Yuba Rivers for use in hydraulic mining operations downstream. Remnants of flumes and ditches may be seen at many locations in each river corridor. Current dredging and mining operations are impacting some of the historic mining sites.

While very few archaeological surveys have been completed within the actual river Corridors, it is assumed they contain a number of prehistoric sites because of surveys made in the North Yuba, the North Fork of the American, and similar river canyons. It is also assumed from experience in other similar canyons that many of these prehistoric sites have been wholly or partially destroyed by the mining activity that occurred and is occurring in the river corridors.

2. Other values present in the inventoried river segments include:

- (a) Wildlife. Blacktail deer, black bear, and other smaller mammals inhabit the river Corridors. Golden eagles are sighted occasionally and some migratory waterfowl are present at certain times of the year. Some of the south-facing slopes at the lower elevations are important winter deer range.
- (b) Botanic: No known threatened and endangered (T&E) species are present in the river canyons. Both rivers are in ecosystem M2610-5.
- (c) Geologic: Basic rock units for both rivers are sedimentary and metasedimentary members of the Calaveras and Kanaka formations. The rivers cross these and other rock types including the Melones Fault Zone. Both rivers also pass through short sections of granitic rocks.

Both inventoried river segments contain gold-bearing gravels along their full length and contain numerous mining claims.

- (d) Timber: The inventoried portion of the Middle Yuba River contains about 3,300 acres of forest lands with a volume of about 47,500,000 board feet. The inventoried portion of the South Yuba River contains about 2,400 forested acres with a volume of about 22,000,000 board feet.

B. Water Quality

The water quality in both rivers is good, with no major sources of pollution. The town of Washington is a possible source of pollution but no problems have been identified downstream from this point.

C. River Access and Landownership

Paved access to the South Yuba River is provided by the Bowman Road at Lang Crossing and the County road to Washington.

Unpaved road access to the Middle Yuba River is to be found at Milton Dam, Gold Canyon, Footes Crossing, and the Our House Dam. An unpaved road parallels the South Yuba River from Washington upstream about six miles.

The remaining portions of the river corridors are accessible by a few foot trails or low standard vehicle trails. There are no trails that proceed up or down the canyons from the various roads and trails that access the rivers.

The inventory for the Middle Yuba River includes about 7,710 acres, of which 5,470 acres, or 71%, are National Forest System lands and the remaining 2,240 acres, or 29%, are private lands.

The South Yuba River includes about 3,550 acres, of which 1,635 acres, or 46%, are National Forest System lands, and 1,915 acres, or 54%, are private lands. About 400 acres of the private lands lie outside the TNF boundary

D. Water Resource Development

Water from both the Middle Yuba and South Yuba Rivers is used for municipal, irrigation, and power purposes.

The Yuba-Bear project of the Nevada Irrigation District stores water in Jackson Meadows and Milton Reservoirs in the headwaters of the Middle Yuba River and diverts it through the Milton-Bowman tunnel into Bowman Reservoir. From there it is transported by flumes, tunnels, and ditches into Lake Spaulding in the South Yuba River drainage. Flumes and ditches take it from there through the Deer Creek Powerhouse and into Scotts Flat Reservoir or through the Drum Powerhouse and into the Bear River drainage.

There are required year-round fishery releases of 3 c.f.s. from Milton Reservoir into the Middle Yuba River and 5 c.f.s. from Lake Spaulding into the South Yuba River. The numerous tributaries below these points augment these flows to an acceptable level within a relatively short distance.

The Yuba River Project of the Yuba County Water Agency includes the Our House Dam on the Middle Yuba River, which is the lower end of the inventoried segment. This 77-foot high dam provides storage for about 290 acre feet of water, which is diverted through tunnels to Bullards Bar Reservoir on the North Yuba River. There is a required fishery release of 50 c.f.s. from March 15 to June 15 and 30 c.f.s. for the remainder of the year.

The California Department of Water Resources has identified several potential reservoir sites in 1957 and 1964 bulletins. Yuba County Water Agency has identified several reservoir sites on the South Yuba River. The continuing interest in the development of small hydroelectric projects will certainly identify additional sites that have potential for development. Small hydroelectric projects where water is not diverted out of the drainage can probably be constructed without conflict with current water rights.

E. Threats

Both of the inventoried portions of the Middle and South Yuba Rivers are located in mineralized geological formations and have mining histories that date from 1849. There are currently about 250 mining claims on record in these river corridors. In addition, much of the private land in the river corridors is a result of mineral patents. Recent history indicates that mining activity will probably continue at current or higher levels. There is also a growing resistance on the part of mining claimants to allow the public to use their claims for recreational purposes.

For the last several years mining activity has been a major impact on both rivers, especially on the Middle Yuba River. Mining activity, including suction dredging and the extended occupancy associated with mining, has severely impacted the fishery and is creating a growing litter and sanitation problem.

The 29% private lands in the Middle Yuba corridor and 54% private lands in the South Yuba corridor are a threat in that any development or activity that occurs on these lands will probably occur within the river corridors.

Timber harvest activities on private lands within and adjacent to the inventoried river corridors affect the potential of these rivers for wild or scenic river classification. The majority of the north facing slopes in these river canyons contain commercial timber stands that go from the ridgetops down to the rivers. Many of these stands have been logged, and logging activities will continue on

these productive lands. The steeper slopes will be logged by cable, skyline, or helicopter harvest systems, which are generally only applicable to the clearcut cutting method. This will result in an increased number of clearcut blocks within and adjacent to the inventoried corridors.

This is also true to some extent for the National Forest System lands adjacent to the inventoried corridors. On the commercial lands, timber harvesting has occurred and timber management activities are planned to continue.

F. Current Protection

Those portions of the rivers on National Forest System lands are administered under multiple use management which provides for the protection of the watershed and other resource values but must provide for mineral exploration and development under various mineral-related laws.

G. Discussion of Specific River Segments

1 Middle Yuba *River*

Segment 1: That portion of the Middle Yuba from Milton Dam to its confluence with Wolf Creek, a distance of 17 miles. This segment contains about 2845 acres, or 63%, National Forest System lands, and 1690 acres, or 37%, private lands.

The only road access is by way of the Henness Pass road at Milton Dam, and the only trail access is the Tehama Trail 11 E14 that runs from Graniteville to the river and on to Palmer Ridge. There are no trails up or down the river corridor.

This segment contains approximately 50 known mining claims which contain very few permanent improvements

The box canyons are the most significant scenic features in this segment. Investigation and further review has identified the box canyons and overall scenic quality as outstandingly remarkable features when compared to features to be found in the designated and proposed rivers in the Cascade Sierra Mountains Sierra Nevada Physiographic Province - 23d.

This segment is determined to be eligible for designation.

Segment 2: That portion of the Middle Yuba River from its confluence with Wolf Creek to the head of the impoundment at Our House Dam, a distance of 14 miles. This segment contains about 2626 acres, or 83%, National Forest System lands, and 552 acres, or 17%, private lands

Access is provided by the Foote Crossing Road, the Gold Canyon Road, and the Our House Dam Road. There are no National Forest System trails to this segment, but there are several old mining trails that go to the river at Indian Creek, Bloody Run, Moores Flat Creek, and Orleans Flat. There are no trails that provide access up or down the river. There are a few private, four-wheel drive trails providing access to various mining operations, but they are not available for public use

This segment contains about 80 known mining claims and the private land portions contain a number of additional mining operations. A portion of these private lands is a result of patented mining claims.

Investigation and further review has identified the overall scenic quality as outstandingly remarkable features when compared to features to be found in the designated and proposed rivers in the Cascade Sierra Mountains Sierra Nevada Physiographic Province

This segment is determined to be eligible for designation. Segment 1 and 2 together have the potential to be classified as Wild', 'Scenic' or 'Recreation'.

2. South Yuba River

Segment 1: That portion of the South Yuba River from Lake Spaulding downstream to one-half mile below its confluence with Fall Creek, a distance of about six miles. This segment includes about 340 acres, or 30%, National Forest System lands, and 780 acres, or 70%, private lands.

Access is by the Bowman Road at Lang Crossing and by the county road that follows upriver from the town of Washington to about one mile below Fall Creek. There are no trails to the river in this segment, nor are there trails providing access up and down river.

This segment contains 20 known mining claims, and a portion of the private lands is a result of patented mining claims.

Remnants of the South Yuba Canal Company wooden flume can be seen within and adjacent to this segment of the river corridor. There is evidence of historic mining activity in the segment, although much of it is being affected by current mining activity.

Examination has identified the overall scenic quality and recreational values as outstandingly remarkable features in this segment when compared to the designated Wild and Scenic Rivers in the Cascade-Sierra Mountains-Sierra Nevada Physiographic Province.

This segment is determined to be eligible for designation, and has the potential to be classified as 'scenic' or 'Recreation'.

Segment 2 That portion of the South Yuba River from one-half mile below its confluence with Fall Creek, downstream to its confluence with Poorman Creek, a distance of about 8 miles. This segment contains about 765 acres, or 62%, National Forest System lands, and 465 acres, or 38%, private lands.

Primary access is by the paved County road from Highway 20 to Washington. From Washington, an unpaved County road follows the South Yuba River upstream to just below Fall Creek, and another follows downriver to just above the confluence with Poorman Creek, where it climbs out of the canyon toward Relief Hill and North Bloomfield in Malakoff State Park. The only National Forest System trail is the Canyon Creek Trail 12E13, which provides access from the South Yuba River up Canyon Creek to the Bowman Road.

This segment includes the town of Washington and a number of other scattered private residence located along the South Yuba River. Washington is a historic mining town that has been continuously occupied since about 1850. The present population of Washington is about 150 people.

Mining is also a significant activity, with some 60 known mining claims in this segment. Some of the private land is a result of patented mining claims.

Examination and further review has identified the overall scenic quality and recreational values of the canyon as outstandingly remarkable features in this segment when compared to features to be found in the designated and proposed rivers in the Cascade-Sierra Mountains-Sierra Nevada Physiographic Province.

This segment is determined to be eligible for designation, and has the potential to be classified as 'recreation.'

Segment 3 That portion of the South Yuba River from its confluence with Poorman Creek downstream to the Forest boundary, about three-tenths of a mile below the confluence with New York Canyon, a distance of about 7 miles. This segment contains about 525 acres, or 40%, National Forest System lands, and about 785 acres, or 60%, private lands. About 405 acres of private land are outside the TNF boundary.

There is no road access to this segment. One National Forest System trail, Missouri Bar 10E11, provides access to the river from North Bloomfield in the Malakoff Diggings State Park. There are several low-standard, 4-wheel drive trails to private lands or mining claims in the river corridor. These are generally gated, locked, and unavailable to the public. The BLM South Yuba trail comes upriver to the Forest boundary from Edwards Crossing.

There are scattered private land developments in this segment and about 35 known mining claims. Mining is the only significant activity that is occurring in this segment at this time.

Examination and further review has identified the overall scenic quality and recreational values as outstandingly remarkable features in this segment when compared to the designated and proposed rivers in the Cascadesierra MountainsSierra Nevada Physiographic Province.

This segment is determined to be eligible for designation, and has the potential to be classified as 'scenic' or 'recreation'

H. Determination of Eligibility

The NRI identifies all free-flowing streams that appear to contain features that are potentially outstandingly remarkable. These values are based upon preliminary investigations and not upon an intensive examination of the individual rivers or of the values to be found in the physiographic province.

Scenic and fishery values were identified for the Middle Yuba River inventoried segments. Scenic, recreational, and historical values were identified for the South Yuba River inventoried segments. When these values were evaluated, fisheries on the Middle Yuba and historical values on the South Yuba were found to be common to the river canyons on the west slope of the Sierra Nevada Mountains. For the Middle Yuba River Scenic values were identified as outstandingly remarkable features for the river. Scenic and recreational values were identified as outstandingly remarkable for the South Yuba River.

Therefore, it is determined that Scenic and Recreation values were identified in the inventoried portions of the Middle and South Yuba Rivers and determined to be outstandingly remarkable. Therefore, they are eligible for inclusion in the Wild and Scenic River system.

The following table summarizes this determination.

TABLE E.1 - DETERMINATION OF ELIGIBILITY - WILD & SCENIC RIVER SYSTEM

River Segment	WILD				SCENIC			RECREATION			Potential Classification Eligibility	
	Free of Impoundments?	Generally Inaccessible Except by Trail?	Watershed Shoreline Essentially Pristine?	Waters Unpolluted?	Free of Impoundments?	Accessible in Places by Roads?	Watershed Shoreline Largely Pristine and Undeveloped?	Readily Accessible by Road or Railroad?	Some Development by Shoreline?	Some Impoundment or Diversion in Past?		
Mid Yuba-Seg 1	Yes	Yes	Yes	Yes	Yes	No	Yes	No	No	No	Yes	Eligible
Mid Yuba- Seg 2	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Eligible
So Yuba - Seg 1	Yes	Yes	Yes	Yes	Yes	No	Yes	No	No	No	Yes	Eligible
So Yuba - Seg 2	Yes	No	No	Yes	Yes	Yes	No	Yes	Yes	No	Yes	Eligible
So Yuba - Seg 3	Yes	Yes	Yes	Yes	Yes	No	Yes	No	No	No	Yes	Eligible

OTHER RIVERS RECOMMENDED FROM PUBLIC RESPONSE AND FOREST REVIEW

As a part of the land management planning process, the TNF addressed the Middle and South Yuba Rivers to determine if a recommendation should be made to include them as rivers to receive study for designation as components of the Wild and Scenic Rivers system. Public comment was received regarding the plan, naming the above rivers, as well as the North Yuba River, Canyon Creek, Lavezzola Creek, North Fork of the Middle Fork American River, Middle Fork American River, and Upper Rubicon River as additional components. The Wild and Scenic Rivers Act establishes the purpose and authority for study of wild and scenic rivers. Rivers are identified for study by several means including Federal statute, which mandated study, identification by the Secretary of Agriculture or Interior, the NRI developed by the National Park Service, and through the Forest land management planning process.

The North Fork American River was named in the Wild and Scenic Rivers Act as a river to be studied for inclusion. The North, Middle, and South Yuba Rivers, the Truckee River, and the Rubicon River were considered during the NRI process. The Upper Rubicon River will be studied jointly for eligibility by the Eldorado and Tahoe National Forests.

The Truckee River will be studied for eligibility and suitability in coordination with the Lake Tahoe Basin Management Unit (LTBMU) in the next three years. Designation of the Truckee River is not included in any alternatives. Wild and Scenic River values will be protected for a quarter-mile corridor on each side of the river until such time as eligibility and, if necessary, suitability studies are completed.

In order to ensure that nothing was overlooked in the NRI as well as in the land management planning process, all additional streams named in the public comment process were given consideration to determine if there might be any outstandingly remarkable features associated with any of these rivers.

An interdisciplinary process was used to determine if there were any truly outstandingly remarkable features associated with any of the above-listed streams. Disciplines represented in the interdisciplinary process were: landscape architect, archaeologist, geologist, range conservationist, forester, wildlife biologist, hydrologist, engineer, as well as personnel from the respective Ranger Districts familiar with the rivers.

For a river to be eligible for designation to the National System it must be free-flowing and, with its adjacent land area, possess one or more of the following outstandingly remarkable values:

1. Scenic
2. Recreational
3. Geological
4. Fish and Wildlife
5. Historical
6. Cultural
7. Other values, including ecological values.

The determination that a river area contains outstandingly remarkable values is a professional judgment on the part of the study team.

It was determined that Canyon Creek, Lavezzola Creek, North Fork of the Middle Fork, and the Middle Fork American River did contain stretches of free-flowing streams with many noteworthy features. However, it was not felt that any of these four rivers contained truly outstandingly remarkable features.

For those streams that were not considered during the NRI process (North Fork of the Middle Fork American River (N.F.M.F.), Middle Fork American River, Canyon Creek, and Lavezzola Creek, the following features are noteworthy:

1. Scenic: All four flow through deep gorges with steep canyon walls and have high scenic quality. This type of landscape is relatively common on the west slope of the Sierra Nevada. The N.F.M.F. American River is very rugged, having heavily dissected landscape, with brush and oaks at the lower elevations and on the south and west facing slopes. The Middle Fork of the American River has the most defined gorge of the four rivers, characterized by steep, rugged, and rocky

slopes, with brush and oaks on the south facing slopes and conifers on the north facing slopes. Canyon Creek is characterized by generally steep to very steep slopes averaging 1,000 feet in height. The slopes are generally covered with mixed conifer stands and have a 'Wet forest' look compared to the 'dry' look of the other two canyons. Lavezzola Creek also flows in a steep canyon with riparian and mixed conifer vegetation along its slopes.

2. **Recreational:** The free-flowing stretches of these rivers are very difficult to access and recreational use is very light. The N F M.F. American River is accessed by occasional steep trails which were usually pioneered by early miners. OHV use, fishing, and hiking are the primary activities within the canyon area, characterized by light use. The Middle Fork American River is not accessed by any system trail but is accessed by one road on the north side of the river. Light fishing and rafting are the main activities along the river. Canyon Creek has occasional trails and a few rough road access points along the river. Use is very light and primarily limited to fishing and hiking. Lavezzola Creek has partial road access at its lower end and some trail access higher in the drainage. In the better access areas recreation use, primarily fishing, is moderate and in the more remote stretches recreation use is light.
3. **Geological:** There are no known outstanding geologic values for any of these streams.
4. **Fish and Wildlife:** There are no known outstanding fish or wildlife values. All four rivers are considered to be important and contain valued wildlife habitat for a wide range of species. Some of the more notable species are deer, raccoon, black bear, and spotted owls. High populations of many rodents are supported along these rivers and golden eagles are occasional visitors to these rivers. While the wildlife are diverse, important, and valued, there is nothing along these rivers that distinguish or make the wildlife more uncommon along these rivers than many rivers along the whole Sierra Nevada physiographic province. All four rivers have natural trout fisheries typical for the region. Lavezzola Creek is designated a Wild Trout Stream by the California Fish and Game Department. Certain areas along these rivers would be expected to have good fishing opportunities because of the poor access. While the fishery and fish habitat are valued and considered important, there is nothing of distinction that would indicate that there are outstandingly remarkable values for fisheries along these four rivers.
5. **Historical:** Although there are many sites in good condition, there are no known sites that would constitute outstandingly remarkable values. All three rivers have a history of early gold mining and associated settlements. While many of these sites would have local interest and be of value in themselves, they are considered typical for the region and do not stand out as being distinctive or unique for that period of history.
6. **Cultural:** There are no known sites that are considered outstandingly remarkable along these four rivers. The cultural resources along these rivers are considered typical for the region. Many of the sites are of value from a local standpoint and, due to poor access, are generally in fairly good condition and not previously disturbed by mining activities. However, none of the sites have been identified as distinctive or unusual enough to be considered outstandingly remarkable.
7. **Other values:** Although there are sensitive plants located along the N F M.F. American River, they are not considered outstandingly remarkable and none of the plant associations have been determined to have special or unique ecological qualities that would be considered outstandingly remarkable. The plant associations that do exist are considered typical for the region.

The values for each river are documented in the outstanding features matrix featured in Table E-2.

Because there are no known outstandingly remarkable features in the above mentioned streams, they are **not** eligible for consideration as components of the wild and scenic river system, and no further studies are necessary.

TABLE E-2 - OUTSTANDING FEATURES

Outstanding Feature	Canyon Creek	MFAR & Lavezzola	NFMFAR
Scenic	Deep gorge No roads except Poker Flat	Deep gorge	Deep gorge No roads except Mich. Bluff area
Recreational	None	None	None

CHANGE IN VISUAL CONDITION

Figures F 1 through F 6 illustrate the changes from the Existing Visual Condition (EVC) to the Future Visual Condition (FVC) that would result from each alternative. They show the number of acres that would be in each Future Visual Condition level and the Existing Visual Condition levels from which those acres started. Each figure is divided into five columns corresponding to the five potential FVC levels. The FVC levels are designated at the top of the columns by the Roman Numerals I (most natural, untouched condition) through V (highly altered human-dominated condition). All the blocks of acres in any one column would be in the same FVC in the year 2030. The six blocks within each column correspond to the six different levels of EVC. Thus, the acres in each block represent the acres in that FVC that originated from the EVC level designated to the left of the block.

The figures also show the number of acres in each EVC level and to what visual condition those acres would be changed. The major function of the figures is to trace the future change in the amount of human-made alterations for the lands in each EVC level. Starting with the number of acres with a given level of landscape alterations (EVC Levels I through VI), one can see how many acres would be improved and have less evidence of management activities, how many acres would not be changed, and how many acres would decline in visual condition. All the blocks of acres in any row started out in the same condition in **1982**; how they were altered by the year 2030 is shown by the FVC Roman Numeral above them.

One can determine whether the acres in any block increased, declined, or did not change in visual quality by comparing the EVC Roman Numeral to the FVC Roman Numeral above it. The shaded blocks (at the left end of the rows) in which the FVC Roman Numeral is lower than the EVC Roman Numeral represent acres that would improve in Visual Condition. The white blocks represent acres that would have about the same level of alteration in the year 2030 as in **1982**. The shaded blocks (at the right end of the rows) with FVC Roman Numerals higher than their EVC Roman Numerals would have declined in Visual Condition (have more human-made landscape alterations) by the year **2030**.

APPENDIX G

ROADLESS AREA DESCRIPTIONS AND MANAGEMENT

INTRODUCTION

The following is a description of the inventoried roadless areas designated nonwilderness by the California Wilderness Act of **1984** for the Tahoe National Forest (TNF). This appendix includes a description of each area and a description of how each area will be managed.

RARE II Further Planning areas (RARE II area #)

West Yuba - **(5172)** -This area includes a portion located on the Plumas NF.

Granite Chief - **(A 5261)** -This area includes RARE II NW area B **5261** on the Lake Tahoe Basin Management Unit and Management Unit **#8** of the Truckee-Little Truckee Rivers Land Use Plan. The RARE Further Planning (FP) area was divided into a northern and southern portion for analysis in the planning process.

North Fork American River - **(5262)**

East Yuba - **(5264)**

RARE II Nonwilderness areas (RARE II area #)

Duncan Canyon - **(5259)**

Grouse Lakes - **(5260)**

North Fork Middle Fork American River - **(5265)**

Bald Mountain - **(5981)** -This includes a portion located on the Toiyabe NF **(4981)**.

RARE I areas

Middle Yuba -This RARE I area did not meet RARE II criteria. This area has been considered to be in the same status as RARE II FP areas since no recommendation was made on this area for wilderness classification during the RARE II study.

Castle Peak - This area was originally analyzed for wilderness potential in the Truckee-Little Truckee Rivers Land Use Plan Final Environmental Impact Statement.

Lakes (Basin) -This area was originally analyzed for wilderness potential in the Mohawk Land Management Plan Final Environmental Impact Statement. The majority of this area is on the Plumas NF. The Plumas NF will complete the analysis for the entire area, which will be documented in the Environmental Impact Statement for the Plumas National Forest Plan.

There are no RARE II areas on the TNF that were cited under the State of California vs Block **(S-79-523)** lawsuit.

By Regional planning direction, neighboring Forests may elect to have one Forest assume the lead in analysis and decision making on any roadless area overlapping two Forests. The TNF is coordinating analysis of the West Yuba area on the Tahoe and Plumas, the Bald Mountain area on the Tahoe and Toiyabe, and the Granite Chief area on the Tahoe and Lake Tahoe Basin Management Unit. The Plumas is coordinating analysis of the Lakes Basin area on the Plumas and Tahoe. Each Forest has participated in the analysis and decision making for all roadless areas on the Forest, regardless of which Forest is taking the lead.

A joint study agreement is documented in a supplemental agreement to the parent agreement between the Regional Forester, Pacific Southwest Region, and the California State Director, BLM, for the 53 acres of National resource land identified by the BLM wilderness study as CA-040-102. This area is analyzed in conjunction with the North Fork American River RARE II FP area. In early 1983, the Secretary of the Interior, upon recommendation from the Interior Board of Land Appeals, removed this area from wilderness study area (WSA) status since it was smaller than 5,000 acres. Since analysis was already completed on the area by the TNF planning process, the BLM area is still included in this analysis as part of the North Fork American River (NFAR), although the BLM is no longer required to study and report this area to Congress under Section 603 of FLPMA. The BLM area is analyzed as part of the NFAR as a way of improving manageability of the NFAR.

The Truckee-Little Truckee Rivers Land Use Plan Management Unit #8 is included as part of the Granite Chief area since the direction in that Plan is to allow no activities on TNF land which would detract from its roadless character until it can be analyzed for its wilderness potential in conjunction with the entire Granite Chief roadless area.

The following descriptions of the roadless areas were developed as part of the TNF land management planning process. The information in these analyses has been summarized and placed in Table G.1, entitled Roadless Area Major Resource Emphasis Assignments by Alternative. It is provided for the reviewer as a summary of the resource allocation of each roadless area by alternative.

The objective of the Forest planning process is to resolve the status of all inventoried roadless areas. All areas are to be allocated to some intensity of multiple use management; none will be left in a further planning status. Additional information, including maps of individual areas, documents, and various working papers retained from the earlier RARE II process, are on file and available for public inspection at the Forest Supervisor's Office, Nevada City, California.

PROPOSED MANAGEMENT FOR ROADLESS AREAS

Based on the PRF alternative direction, the following roadless areas will be managed as follows:

West Yuba About 30 percent of the area will be managed for semi-primitive motorized recreation opportunities. The rest of the area will be managed for roaded natural dispersed recreation and timber management. Approximately 30 percent of the remaining area will be managed for a visual/timber emphasis and the other 40 percent for a timber/range emphasis.

Granite Chief. Seventy-four percent of the area is already in the Granite Chief Wilderness. The remaining area is primarily managed for SPNM recreation opportunities (18 percent) with six percent managed for timber harvest along the western boundary and two percent reserved for Research Natural Area (study) status.

North Fork American River: A majority of the North Fork area will be managed for primitive and semi-primitive recreation opportunities. The Wild and Scenic River (17 percent of the area) will be managed for primitive recreation opportunities. Forty-eight percent of the area on both sides of the Wild River will be managed for SPNM recreation opportunities and an additional 17 percent will be managed for SPM recreation opportunities in the Loch Leven and Long Valley areas. An additional two percent of the area will be managed as a Research Natural Area at Sugar Pine Point. The remaining 13 percent of the area will have a timber/range emphasis concentrated on the upper slopes on the south side of the North Fork American River.

East Yuba. Almost half (48 percent) of the East Yuba area will be managed for SPM recreation opportunities. The remaining area will be managed for timber with 32 percent having a timber/visual emphasis and the remainder (20 percent) having a timber/range emphasis.

Middle Yuba: Over three quarters (76 percent) of the Middle Yuba will be managed for SPM recreation opportunities. The remaining 24 percent of the area will have a timber/range management emphasis.

Grouse Lakes: Most of the Grouse Lakes area (90 percent) will be managed for SPNM recreation opportunities. An additional three percent will be managed for SPM recreation opportunities. The remaining seven percent of the area has a timber/range management emphasis.

Bald Mountain: Most of the Bald Mountain area will be managed under a timber/range emphasis (55 percent). The remaining 15 percent will be managed as a Research Natural Area (Babbitt Peak).

Duncan Canyon: A small area (seven percent) of Duncan Canyon will be managed for SPNM recreation opportunities near Robinson Flat. The rest of the area will be managed with a timber/visual emphasis (93 percent).

North Fork of the Middle Fork American River: Most of this area (90 percent) will be managed for SPM recreation opportunities. About two percent will be managed as a Special Interest Area at Grouse Falls. Another five percent will have a fish and wildlife habitat emphasis while still allowing for other commodity production in the southernmost part of the area. The remaining three percent of the area will have a visual/timber emphasis as seen from major highway corridors.

Castle Peak Castle Peak is dedicated to recreation with 93 percent managed for SPM recreation opportunities and seven percent managed for cross-country and downhill skiing opportunities.

Lakes (Basin): All of ~~Lakes~~ Basin will be managed for SPM recreation opportunities.

The individual discussion of each roadless area begins on the page shown below:

West Yuba	G.5
Granite Chief	G.7
North Fork American River	G.10
East Yuba	G.12
Middle Yuba	G.13
Grouse Lakes	G.15
Bald Mountain	G.17
Duncan Canyon	G.19
North Fork Middle Fork American River	G.20
Castle Peak	G.22
Lakes (Basin)	G.24

WEST WBA

#5172 (RARE II Further Planning) 16,601 net TNF acres, 16,639 gross acres; 6,347 net PNF acres, 6,347 gross acres. See Figure G-1.

This area is situated north of Downieville and west of Craycroft Ridge in the Rattlesnake Creek drainage contiguous to the Plumas National Forest Roadless Area in the Table Rock and Skyhigh area.

Approximately 4,300 acres located on the Tahoe National Forest are within Management Unit 7 of the Mohawk Land Use Plan which allocated this area to further planning for wilderness or other multiple use management. This area was previously identified as the Beartrap inventoried roadless area (IRA) in RARE I. The Beartrap IRA was expanded by RARE II and renamed West Yuba. The 6,347 acres (net and gross) that are on the Plumas National Forest are also described and displayed in this analysis.

A series of peaks (Fir Cap, Saddleback, Mt Alma, Democrat Peak, and Deadwood Peak) form the western boundary of the area. Craycroft Ridge marks the eastern boundary. The southern boundary roughly follows a line drawn between the former town of Monte Cristo and Craycroft Diggins. The northern boundary encompasses the canyon lands (Canyon Creek drainage) in the vicinity of Table Rock, Skyhigh Peak, Stafford Mountain, Beartrap Mountain, and Gibraltar Peak.

Elevations range 3,600 to 6,800 feet. Sixty-four percent of the unit has slopes over 50 percent. Thirty percent of the area is within sensitive watershed lands. Annual precipitation averages about 75 inches; precipitation is primarily in the form of snow on the 78 percent of the area above 5,000 feet and primarily as rain below that elevation.

The Downie River, Rattlesnake Creek, and Canyon Creek are the major streams in the area. There is a total of 45 miles of perennial streams. Water quality is very high. The terrain is dissected with steep canyons and narrow sinuous ridges characterize most of the area.

The vegetation is representative of the Sierran Forest Province (Bailey classification M2610) with primarily a mixed conifer forest community (Kuchler Vegetation Type 005).

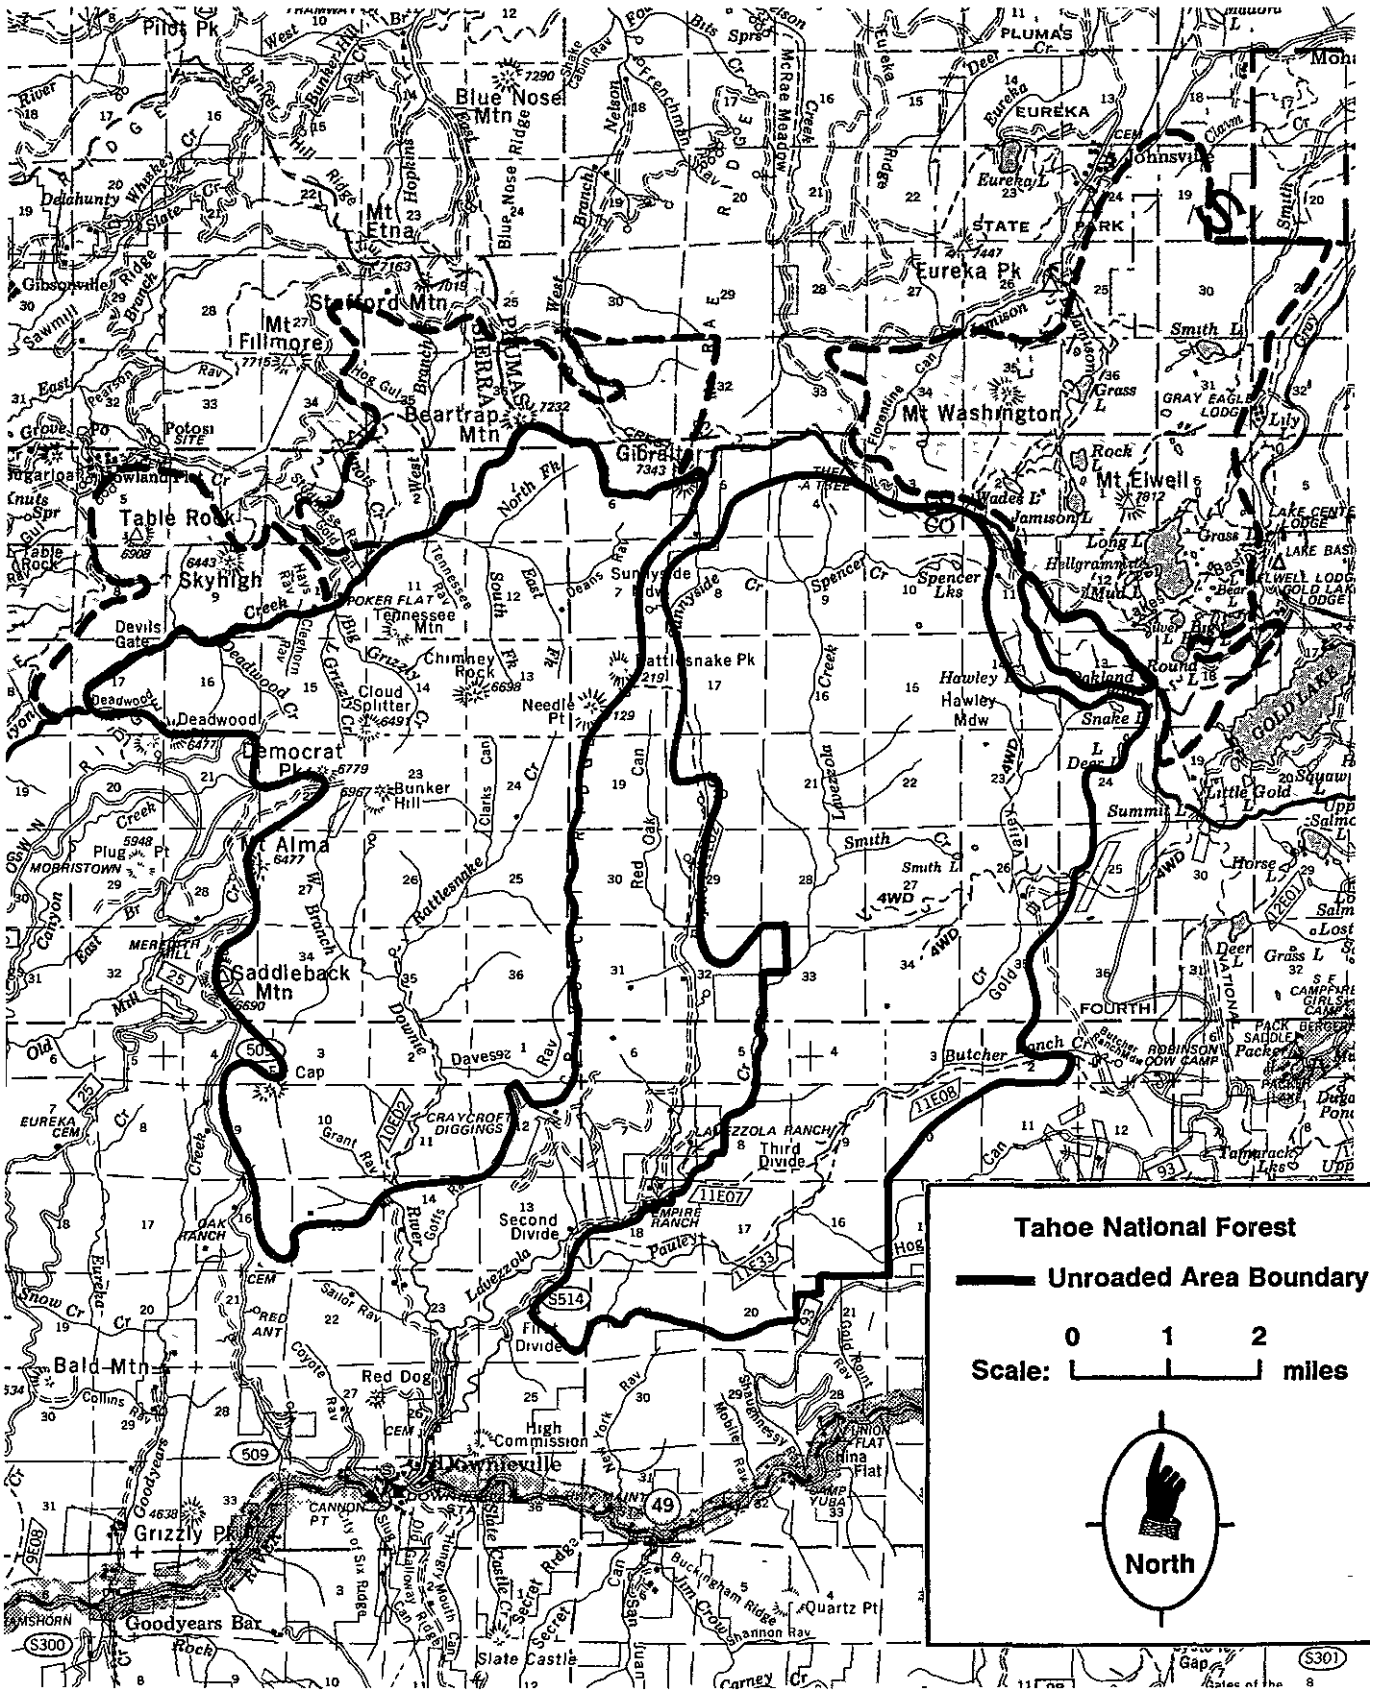

The area contains 9,671 acres of mixed conifer and 2,249 acres of red fir forest types. This forested land is scattered throughout the entire area. The remaining acres consist of hardwoods, brush, riparian vegetation, barren areas, and other nonforested land. There are 680 acres of wetlands, comprising four percent of the area.

The West Yuba area has high scenic quality throughout most of the area. Seventy seven percent of the area is in variety class 'A', which is highly distinctive landscape. The remaining 23 percent is common variety class 'B' landscape. (Most of the less scenic lands are in the southern portion of the area.)

The amount of alteration of the existing visual condition of the area varies. Less than 1 percent is EVC class I (untouched), 75 percent is class II (not noticeably altered), 14 percent is class III (alterations visible but not dominant), and 10 percent is class IV (dominated by alterations). Overall, a natural condition predominates.

There is much evidence of historic mining which has occurred during the past 100 years. Such evidence exists as roads, mine shafts, diggings, old buildings, and tailings. The historic town of Poker Flat, which Bret Harte wrote about in the 'Outcast of Poker Flat', is located in the northern portion of this area. There are numerous active mining claims throughout the area. Geological studies for this area indicate moderate to high potential for the discovery of valuable minerals.

Figure G.I: East Yuba, West Yuba and Lakes Basin Roadless Areas

The main attractions to the area are the stream bottoms and mountain peaks that create a variety of scenery.

Hunting, hiking, and fishing *are* the primary recreation uses of the area. There is OHV use associated with hunting throughout the area. The Poker Flat and Saddleback Ridge areas are also popular for summer OHV use. Annual recreation visitor days total 145,900 for the area. A portion of one cattle allotment is within the area.

National Forest System lands surrounding the West Yuba area are primarily managed for timber production, and heavily prospected and mined for valuable minerals.

GRANITE CHIEF

#A5261 (RARE II Further Planning) - **25,975** net TNF acres, **35,572** gross acres; - ~~B5261~~ (RARE II nonwilderness) **1,243** LTBMU acres - **1,243** gross acres: Management Unit #8, Truckee-Little Truckee Rivers Land Use Plan - 2,407 net TNF acres, 3,197 gross acres; **18,705** net TNF acres designated wilderness in 1984. See Figure G-2.

Note: This writeup describes the entire roadless area, including the 16,705-acre portion designated the Granite Chief Wilderness in 1984.

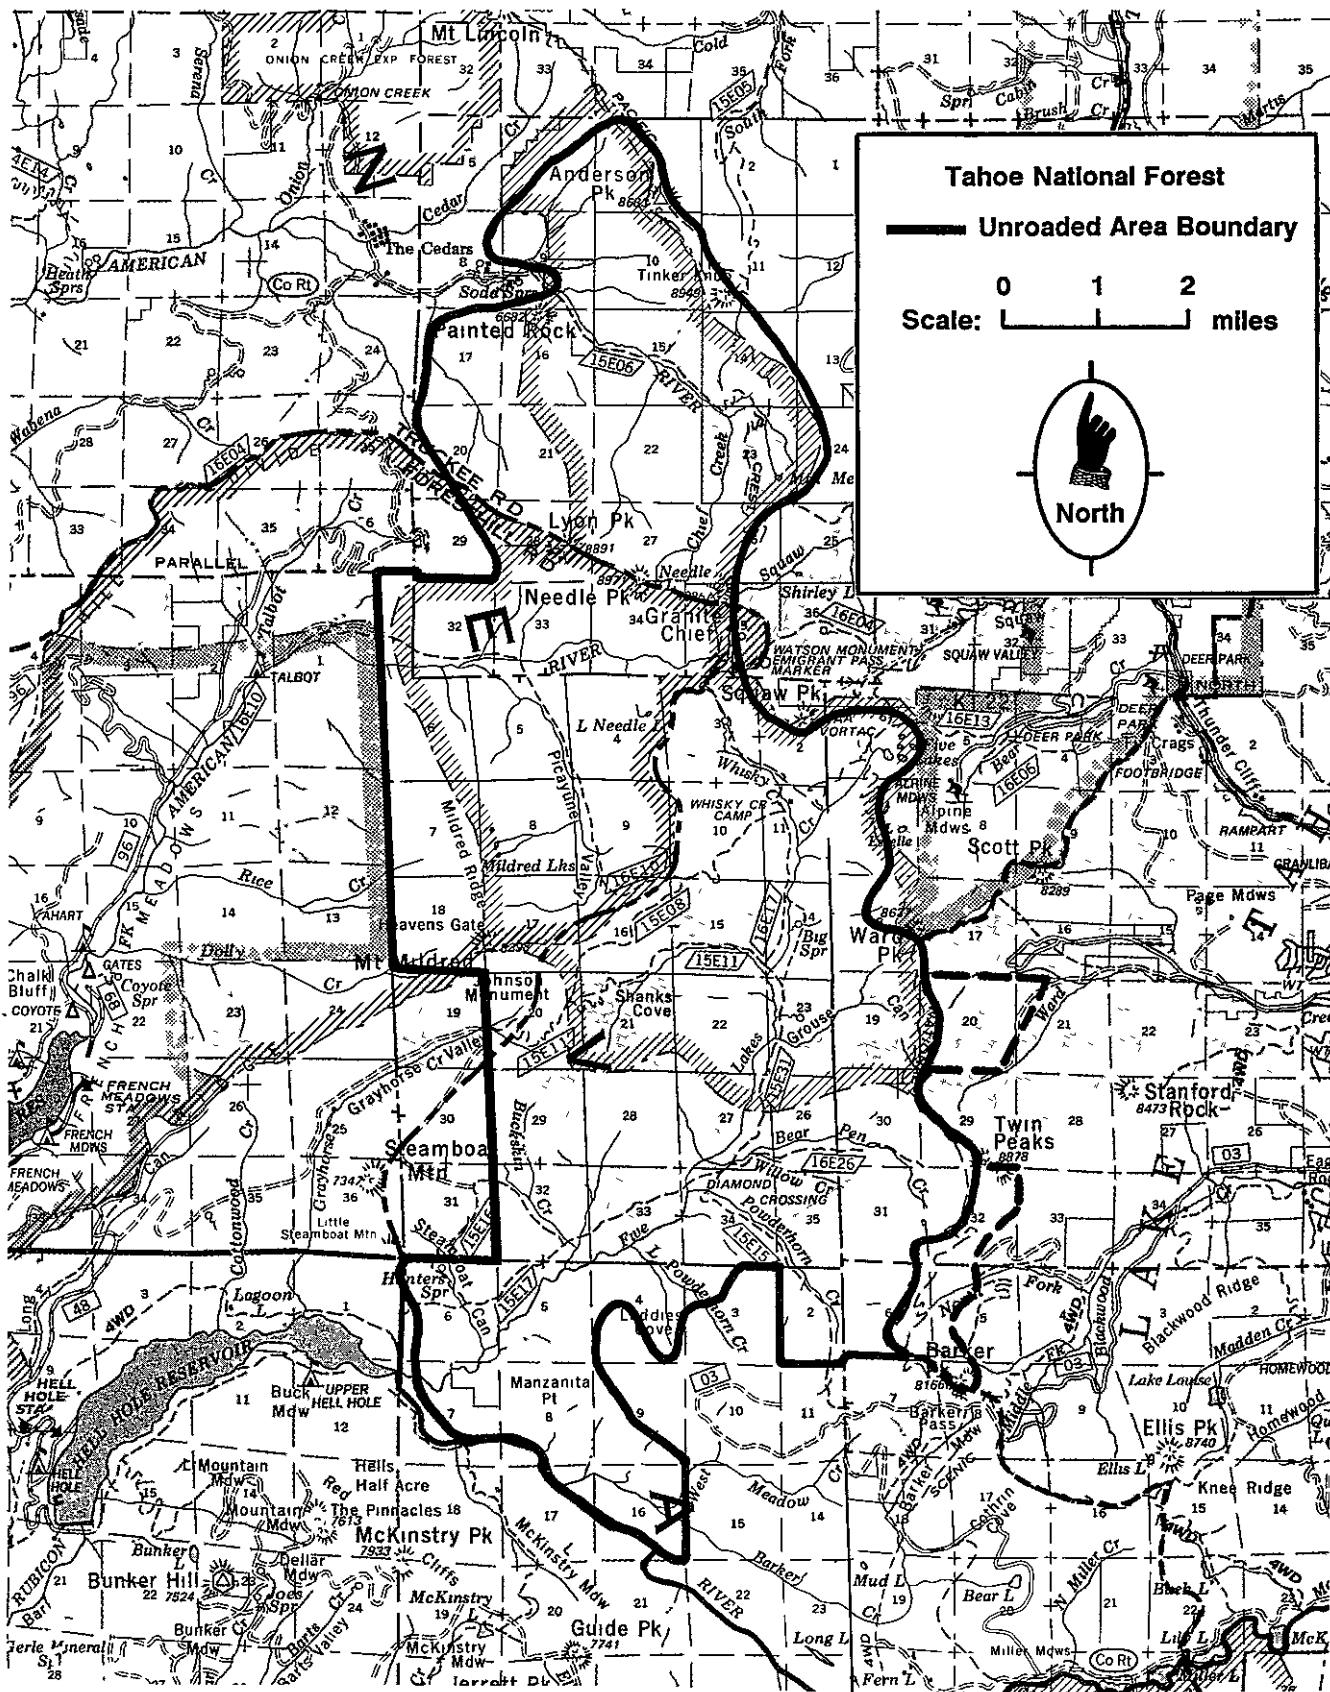

This area is located adjacent to the western watershed boundary of Lake Tahoe on the Truckee and Foresthill Ranger Districts. A small portion (1,243 acres) is located within the Lake Tahoe Basin Management Unit (LTBMU). This small area was recommended for nonwilderness (NW) in the RARE II FEIS. The area on the TNF was recommended for Further Planning (FP). The Wilderness Act of 1984 designated 18,705 acres to the Granite Chief Wilderness. The area east of the Sierra Crest was included in the Truckee-Little Truckee Rivers Land Use Plan, but land allocation was deferred until the area (Management Unit #8) could be analyzed as part of the entire Granite Chief Roadless Area. Management direction in Unit #8 is to allow no discretionary activities on National Forest System lands which would detract from its roadless character until it can be analyzed for wilderness potential in conjunction with the entire Granite Chief roadless area.

Elevations range from 5,000 to 8,800 feet. Twenty-seven percent of the unit has over 50 percent slopes. Forty percent of the area is within sensitive watershed lands. There are 49 miles of perennial streams. Precipitation averages 70 inches annually, the great majority occurring as snow. Water quality is very high.

The appearance of the Granite Chief area consists of a varied landscape of forest, meadows, and glacially exposed granitic landscapes. The area has high scenic value because of this variety. The major streams in the area are Five Lakes Creek and the headwaters of the North Fork and the Middle Fork of the American River. The topography varies from steep granitic cliffs interspersed with broad glaciated valleys in the north, to dissected landforms in the south. The most scenic class of landscapes, variety class A, comprises 98 percent of the northern part of the area, with the remainder falling in variety class B (common landscapes). The southern portion has a slightly lower proportion of variety class A (83 percent) and more variety class B (17 percent). Granite Chief Unit 8 is 98 percent variety class A and 5 percent variety class B.

The existing visual condition of the area is predominantly without visible alterations, although it is not totally pristine. In the north and in Unit 8 of the Truckee-Little Truckee Rivers Land Use Plan virtually all the area still appears natural (EVC class II). In the southern part, 12 percent is EVC class I (untouched), 83 percent is class II (natural, no noticeable alterations), 4 percent is class III (visible alterations but still predominantly natural) and, as in the north, there is a trace of class IV (alterations dominate).

Figure G.2: Granite Chief Roadless Area

The vegetation represents the Sierran Forest province (Bailey classification M2610), with primarily a coniferous forest community composed of deciduous and evergreen woodlands at lower elevations. The Kuchler vegetation type is Red Fir Forest (007). The area on the Tahoe NF contains 4,015 acres of mixed conifer, 12,425 acres of red fir, and 430 acres of lodgepole pine forest types. This forested land is concentrated in the southern portion of the area. The remaining 8,405 acres consist of aspen, riparian vegetation, brush, barren, and other nonforested land, primarily north of Whisky Creek Camp. There are 1,920 acres of wetlands comprising eight percent of the area. The area on the LTBMU contains 283 acres of mixed conifers, 111 acres of red fir, 153 acres of hemlock and lodgepole, and 696 acres of nonforested land. Most of the area was also included in the RARE I inventory. Sierra Pacific Industries is the major private landowner in this area. The company plans to intensively exchange their lands for timber production and have, in the past, received approved timber harvest plans from the State. They have also received non-cost-share road easement for access to their lands in the Five Lakes Creek drainage.

The east side of the area is bordered by electronic sites, roads, ski areas (ski lift terminals), and logged over lands. Portions of the west side are bordered by private lands logged in the past.

The northern portion of the area (north of Bear Pen Creek) is currently managed as a motor vehicle closure area. This vehicle closure area was established on April 15, 1970, by the PSW Regional Forester. A majority of the area is unsuited for OHV use due to steep topography and sensitive watershed lands. The Pacific Crest National Scenic Trail is located along the eastern boundary. A large sheep allotment is located in this area. There are no known mining claims in the area.

The southern portion of the area (south of Bear Pen Creek and the vehicle closure area) is 'Designated Routes Only' for OHV use. The Powderhorn Trail has been used in the past by OHV enthusiasts. This area is in an alternate ownership pattern, with the major private landowner being Sierra Pacific Industries. None of the private land is accessed or harvested. There are fences, some buildings, and meadow restoration structures throughout the area. There is less landscape variety in this area than in the northern section. There are four power withdrawals in the Five Lakes Creek area and along the headwaters of the Middle Fork of the American River. Sheep and cattle grazing occurs within portions of the area.

The portion of the LTBMU, recommended for nonwilderness in RARE II, is in two equal-sized parcels. The northern parcel is in Ward Valley. Alpine Meadows Ski Area does avalanche control in this area. The southern parcel is at the headwall of Blackwood Canyon and shows signs of the overgrazing that occurred prior to 1950. Blackwood Creek does not meet water quality standards because of past logging, grazing, and quarry operations. The Forest Service plans to restore the over-grazed area, including that in the roadless area, as part of the watershed restoration backlog.

Recreation use in the area totals approximately 65,500 RVDs per year. The area is used primarily by hikers, fishermen, and hunters, with some OHV use in the southern portion. Approximately 3.5 miles of trail is used for the annual Tevis Cup 100-Mile Endurance Ride. The Western States Endurance Run and the Capital-to-Capital Endurance Ride are within the roadless area boundaries. The Tevis Cup Ride has occurred traditionally every year since 1954.

The major attractions of this area are the high, rugged granitic cliffs and broad glaciated valleys found in the northern portion. The numerous streams distributed throughout the area provide opportunities for fishing, camping, and sightseeing. The abundance of game and nongame animals also attracts a large number of visitors. Portions of a State game refuge extend into the area and consist of all of Picayune Valley, Little American Valley, and the west slope of Mt. Mildred.

NORTH FORK AMERICAN RIVER

#5262 (RARE II Further Planning) **34,275** net TNF acres, 50,669 gross acres. See Figure G-3.

This area is situated on both sides of the North Fork American River. The North Fork American Wild River that was designated by Congress contains approximately **5,800** acres of National Forest System land and is included within and surrounded by the roadless area. The area extends from the western forest boundary near Giant Gap to approximately **1 1/2** miles *east* of Heath Springs, and is located within the Foresthill, Truckee, and Nevada City Ranger Districts. Most of this area was identified as a Wilderness Study Area under RARE I; it was identified for further planning in the RARE II Environmental Impact Statement (EIS).

Sixty-two percent of the unit has slopes over 50 percent. Twenty-seven percent of the area is composed of slopes greater than **70** percent. There are **84** miles of perennial streams. Water quality is very high. Annual precipitation ranges from 50 inches near Colfax to over **80** inches in the Cherry Point area; most of this occurs as rain below 5,000 feet, and snow above that elevation.

The area contains **14,831** acres of muted conifer, **4,256** acres of red fir, and **555** acres of lodgepole pine forest types. The vegetation is representative of the Sierran Forest Province (Bailey Classification **M2610**) with both muted conifer and red fir forest communities (Kuchler Vegetation Types 005 and 007). This forested land is concentrated in the southeastern and southwestern portions of the area around Sailor Meadow and Humbug Canyon. The remaining acres consist of hardwoods, brush, barren areas, riparian vegetation, and other nonforested land. There are **1,220** acres of wetlands, comprising four percent of the area. Some sheep graze in the eastern portion of the area. Livestock graze a portion of three grazing allotments. Elevation ranges from **2,100** feet in the Giant Gap - Green Valley area to 8,000 feet at Snow Mountain. The river is designated as a Wild Trout Stream by the California Department of Fish and Game.

The **natural** Scenic quality (variety class) of the area (not including the designated Wild River) is predominantly distinctive, although a large portion is common in nature. Sixty-seven percent of the area is highly scenic variety class 'A' land, **33** percent is variety class 'B' land with average scenic quality, and a trace is variety class 'C' land within minimal scenic quality.

The degree of current human-caused alterations of the natural landscape (existing visual condition) within the area covers a full range from pristine landscapes to those totally dominated by unnatural alterations. Nine percent of the area is untouched in appearance (EVC class I), 78 percent has no noticeable alterations (EVC class II), and **11** percent is predominantly natural (EVC class III), and **2** percent is dominated by alterations (EVC Class V). Despite this range, the overall appearance of the area remains overwhelmingly natural in character.

The northern two-thirds of the area has an alternate ownership pattern. Sierra Pacific Industries is the major private landowner and plans to intensively manage some of their parcels for timber production. They have applied for a non-cost-share road easement to access their lands in the Long Valley area.

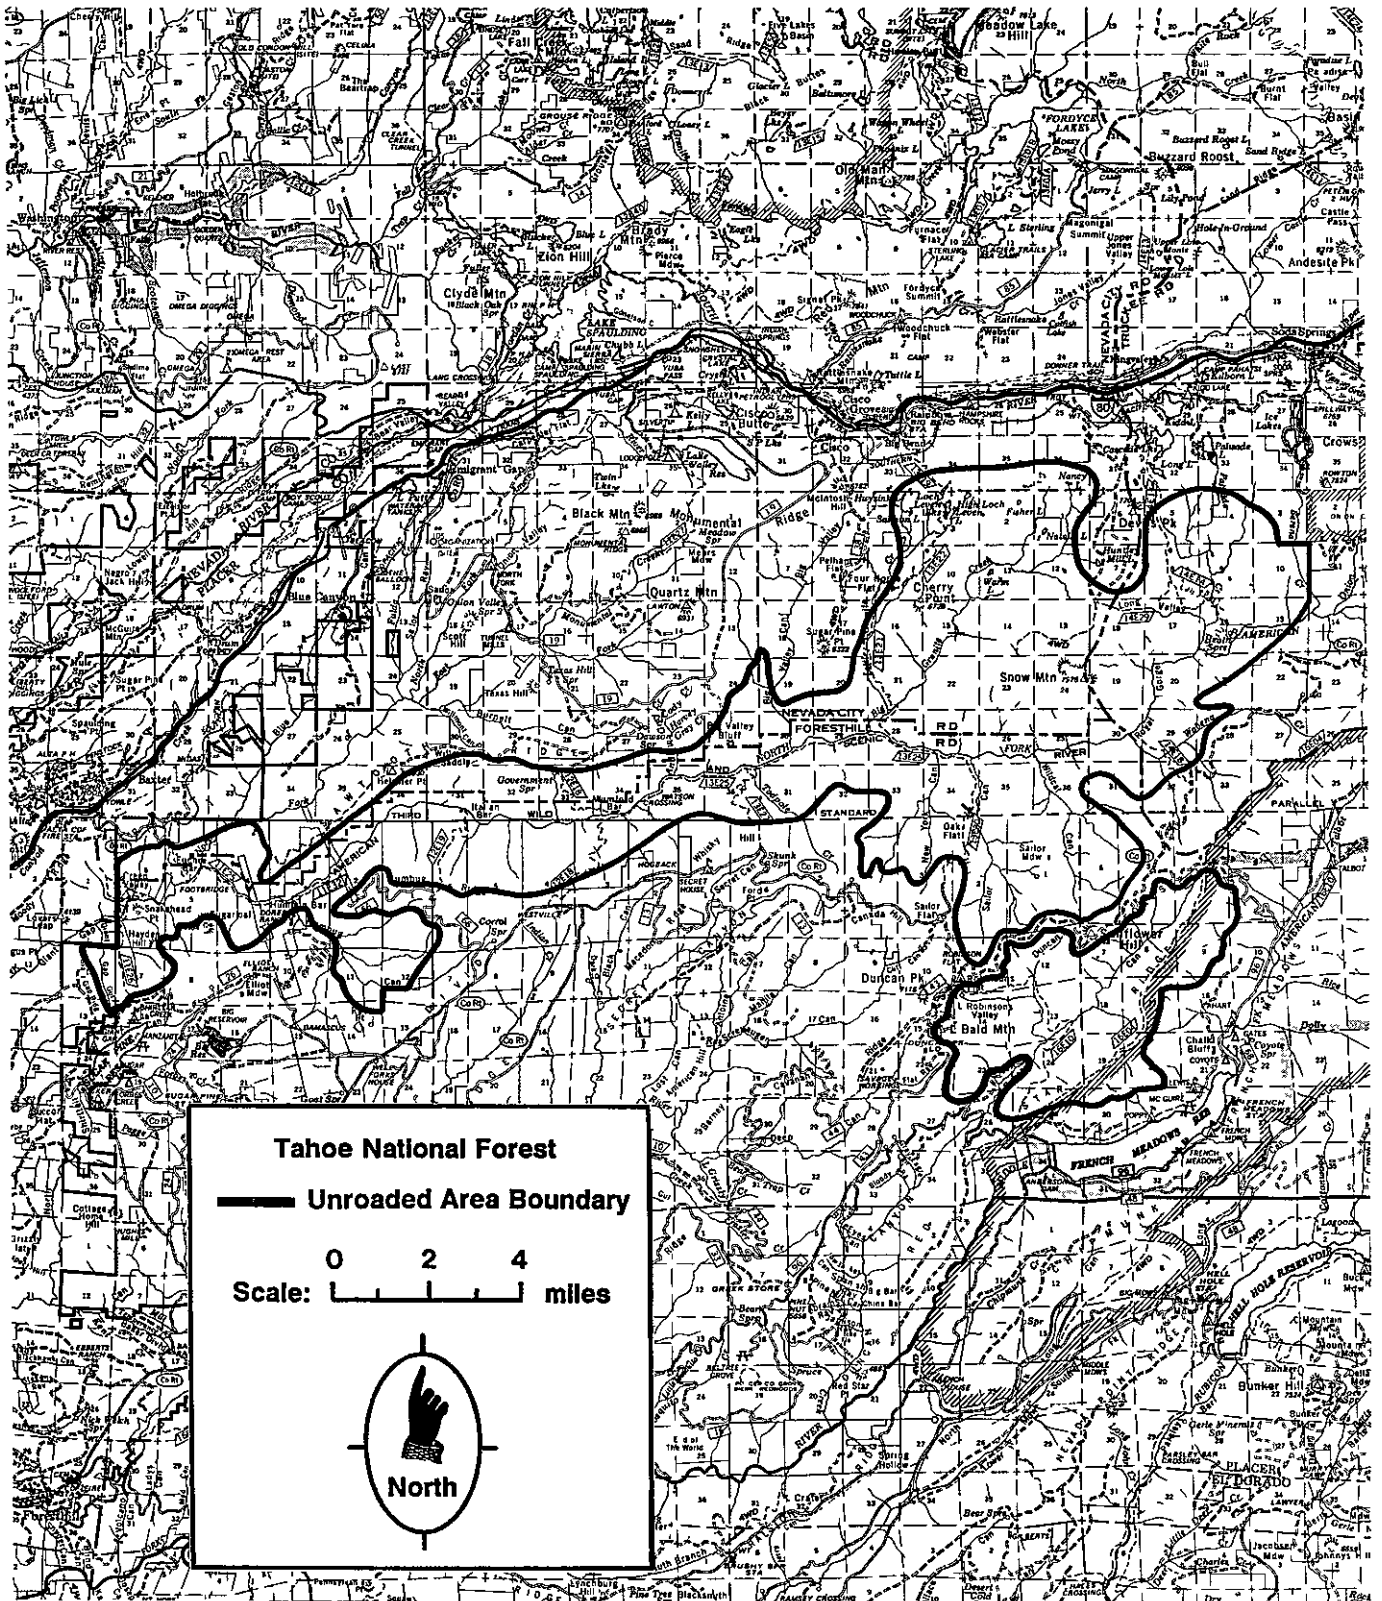

There have been over **2,000** mining locations filed within this area over the years (Bureau of Mines study). Some of these locations are within the Wild River, which was withdrawn from mineral entry in **1975**. There are **14** claims that pre-date the withdrawal.

Hiking, fishing, and hunting are the primary recreation uses of the area. Use totals 46,600 visitor days annually.

The main attractiveness of this area is the North Fork American Wild River, which is protected under the Wild River Act. Other areas include the high-elevation lakes in the Loch Leven and Huysink Lakes area, which are sensitive to heavy, extended use by man.

National Forest System lands surrounding the area are primarily managed for timber production.

Figure G.3: North Fork American River and Duncan Canyon Roadless Areas

EAST YUBA

#5264 (RARE II Further Planning) - 18,502 Net TNF Acres, 18,623 Gross Acres. See Figure G-1.

This area is on the Downieville Ranger District, bordered by the Plumas National Forest boundary in the Laveuola Creek drainage The Lakes Basin (Unit No. 1 of the Mohawk Land Management Plan, Plumas and Tahoe National Forests) is contiguous to the northeast corner. The 'A' Tree Road and a road down Empire Creek form the western boundary of this area. These are controversial travelways to both OHV users and SPNM proponents. The eastern boundary is the old Primrose Timber Sale. The western boundary is roaded from the 'A' Tree Road through Cowell Mine into Empire and Lavezzola drainages. The eastern portion of this area is accessed by OHV routes that receive heavy use. Elevations range from 3,600 to 7,240 feet and about 78 percent of the area is over 5,000 feet in elevation. An average of 70 inches of precipitation falls annually, most of it as snow.

The topography of the area is similar to that found in the West Yuba area (steep canyons and narrow ridges) except for the eastern portion, which is an area of glacially scoured rock with small lakes and meadows interspersed. Forty-nine percent of the area has over 50 percent slopes. Laveuola, Spencer, Pauley, and Smith Creeks are the major streams and are all tributaries to the North Yuba River. There are about 42 miles of perennial streams and lakeshore. Water quality is very high. There are no major peaks in the area. About 43 percent of the area has sensitive watershed lands, including five percent with slopes over 70 percent.

The vegetation of the area is representative of the Sierran Forest Province (Bailey Classification M2610), with both mixed conifer and red fir forest types present (Kuchler Vegetation Type 005 and 007.) The area contains 10,674 acres of mixed conifer and 2,445 acres of red fir forest types. The forested land is scattered throughout the entire area. The remaining acres consist of riparian vegetation, hardwoods, brush, barren areas, and other nonforested land. There are 940 acres of wetlands comprising five percent of the area.

A majority of the East Yuba area is characterized by distinctive, highly scenic landscapes; but a significant portion, most in the south, is fairly common in nature. There is 63 percent variety class 'A,' and 37 percent is the less scenic variety class 'B.' Over 98 percent of the area retains a natural, unaltered appearance (EVC class II). Less than 1 percent of the area is in either class III or IV (areas with obvious human-made alterations). The attractiveness of the area is focused on the canyon bottoms such as those immediately adjacent to Laveuola, Spencer, and Smith Creeks, and the high country around Spencer and Hawley Lakes.

The Pacific Crest National Scenic Trail crosses the northern portion of this area. There are numerous routes constructed for mining during the past 100 years. Active prospecting and exploration occurs within the roadless area, such as at the Four Hills Mine located in the northeast portion. The Boy Scouts of America recently acquired an 80-acre campsite on private land on the eastern boundary. To the east of the area is the Lakes Basin - Sierra Buttes area, which receives heavy recreation use.

Recreation use in the East Yuba area totals about 26,900 visitor days. Hunting, fishing, and hiking are the major activities. OHV use occurs in the eastern portion. Differences of opinion exist between the OHV and nonmotorized users relating to OHV use. Many travelways receive heavy OHV use.

Livestock grazing occurs in one allotment during the summer months: no structural improvements exist.

The area has been impacted by human beings over the past 100 years, primarily by the search for valuable minerals. There are many active mining claims and evidence of historic mining (primitive roads, buildings, mineshafts, diggings, and tailings) which exist throughout the area.

Adjacent TNF lands are primarily managed for recreation use with intensive timber management restricted to the northern and eastern regions. The West Yuba RARE II area is located 1 to 2 miles to the west.

MIDDLE YUBA

(RARE I AREA #266) - 7,855 net TNF acres, 13,273 gross acres. See Figure G-4.

In 1971, the first Roadless Area Review and Evaluation (RARE) identified this area as an inventoried roadless area. In 1972, Judge Samuel Conti of the Northern District Court of California ruled in *Sierra Club v. Butz* that further study and an EIS must be prepared prior to the allocation of roadless areas to nonwilderness. The Middle Yuba RARE I area was affected by this decision. This area did not meet RARE II criteria, therefore, it was not analyzed in the RARE II EIS. This area is situated on the Middle Yuba River, primarily on the Downieville and Nevada City Ranger Districts. There is a small portion on the eastern edge in the Sierraville Ranger District.

Elevations range from 3,200 to 6,800 feet. Precipitation ranges from 60 to 75 inches per year; this occurs mostly as rain on the 57 percent of the area below 5,000 feet and primarily as snow above that elevation.

The entire area is an alternate landownership pattern. Over 40 percent is privately owned. Most of the private land would be managed for intensive forest management. The area is also included in cost-share supplements. The river bottom and canyon slopes have been heavily mined, and the entire canyon bottom is encumbered by power withdrawals.

There are some active mining claims in this area. There is abundant evidence of historic mining throughout the area, such as mineshafts, buildings, primitive roads, and tailings. Mining activity continues today, particularly placer mining. Recreation use totals 1000 visitor days, most of which is fishing and river use associated with suction dredging, sluicing, and panning for gold.

This area includes the slopes of the Middle Yuba River canyon, which is typically steep and inaccessible. One section is aptly named 'Gates of the Antipodes.' Seventy-one percent of the unit has slopes over 50 percent, with 17 percent of this being slopes over 70 percent. Thirty percent of the area is within sensitive watershed lands. There are 18 miles of perennial streams. Water quality is very high. A portion of this area was proposed for evaluation as a wild and scenic river by the Department of the Interior's Heritage Conservation and Recreation Service. (Refer to Appendix E, Wild and Scenic River Evaluation.)

The majority of the Middle Yuba area has high scenic quality. Sixty-one percent of the acreage is categorized as variety class "A," signifying distinctive landscape features and a high level of variety. The sizeable acreage that remains is basically common in scenic nature. The remaining is 37 percent variety class "B" (common scenic quality), and two percent variety class "C" (minimal scenic features).

Most of the area retains its natural appearance without noticeable signs of alteration. Seventy-seven percent is in existing visual condition II, which denotes natural appearance: 17 percent appears predominantly natural but has visual alternations (EVC class III); and six percent is dominated by the effects of man (EVC class IV.)

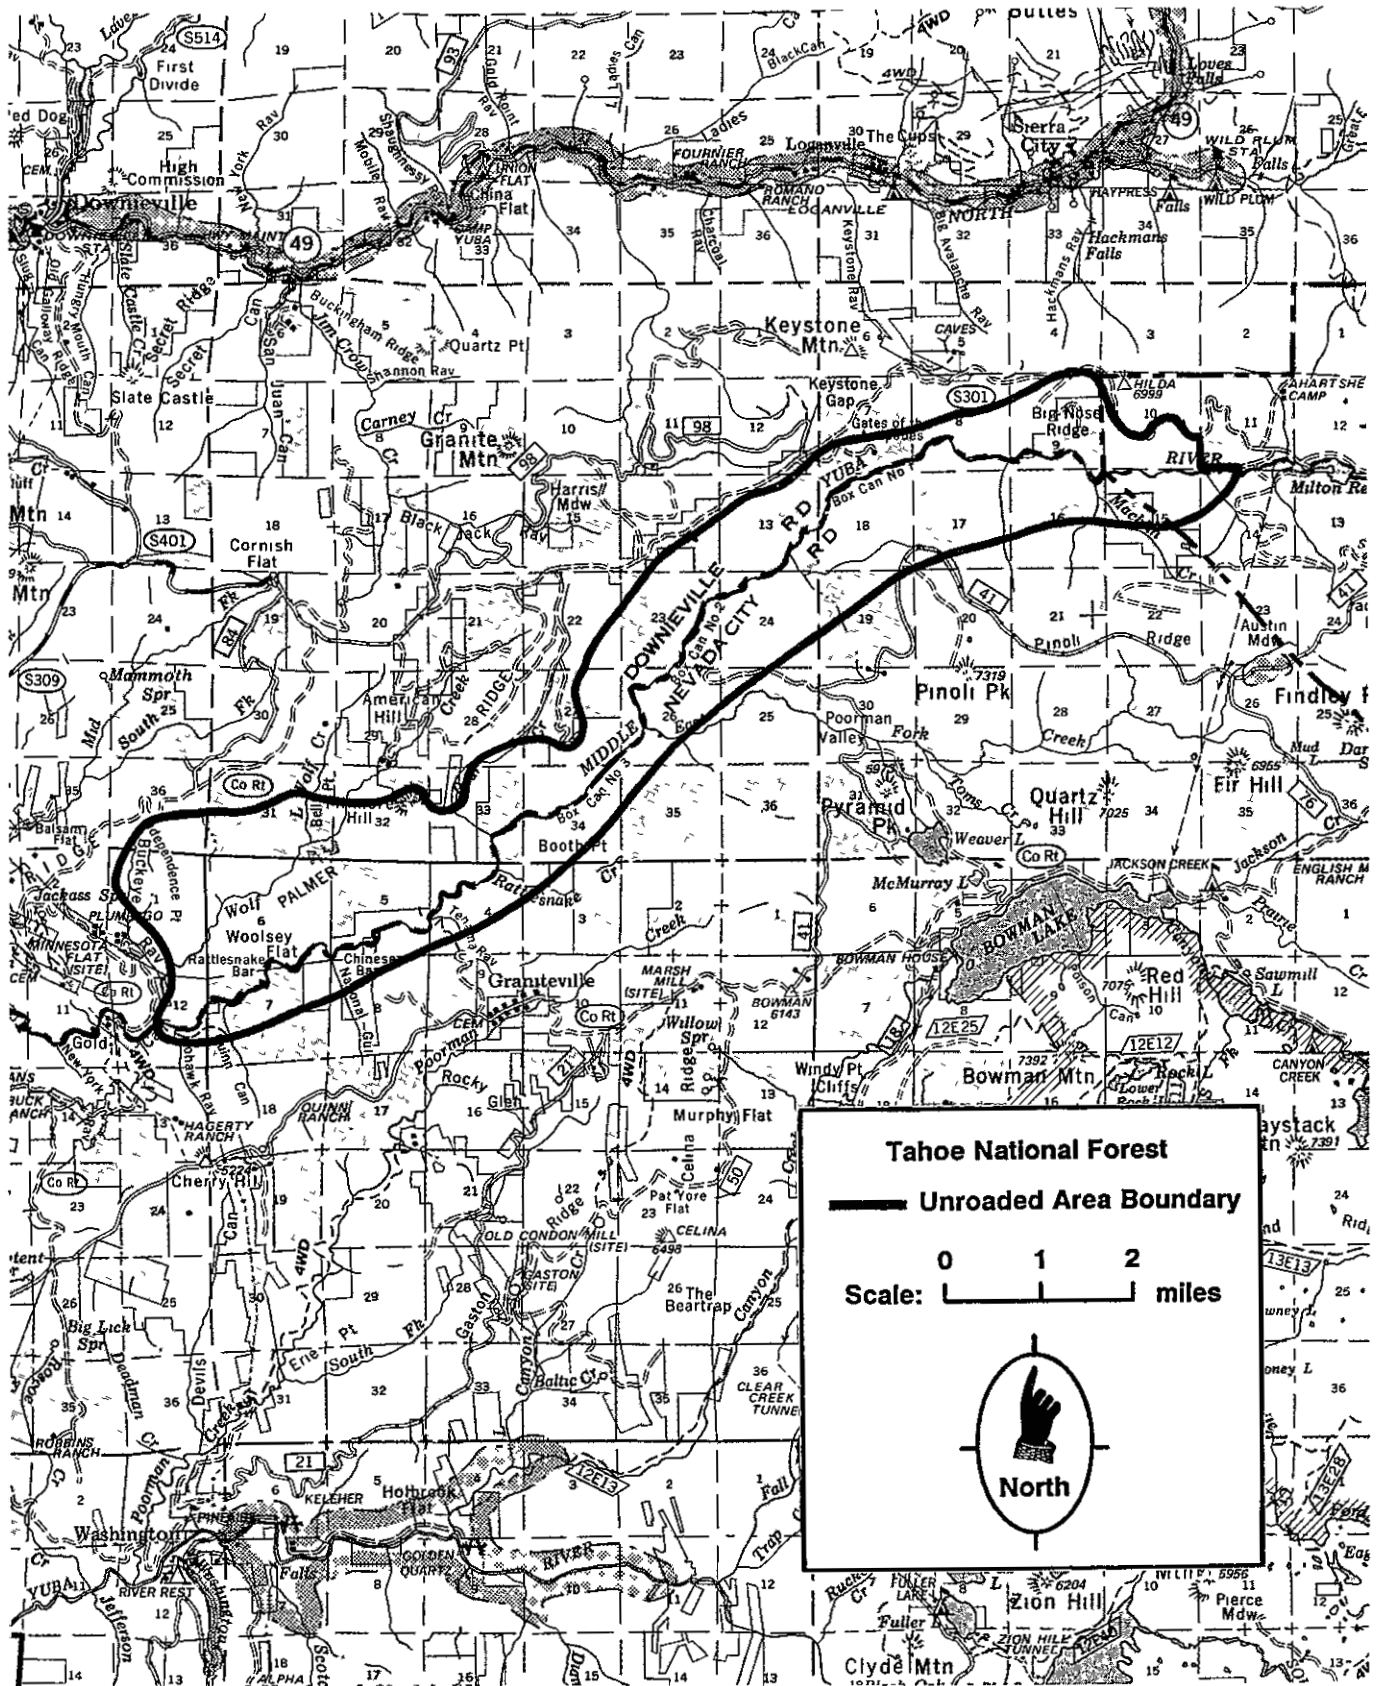

The vegetation is representative of the Sierran Forest Province (Bailey Classification M2610) with primarily a mixed coniferous forest community (Kuchler Vegetation Type 005).

The area contains 5,348 acres of mixed conifer and 94 acres of red fir forest types. The forested land is located on the upper slopes above the Middle Yuba River canyon. A large portion of this area has been logged and roaded. The remaining 2,424 acres consist of hardwoods, brush, barren areas, riparian vegetation, and other nonforested lands, which are located on the steep canyon slopes. This includes about 200 acres of wetlands, comprising less than three percent of this unit. The Gold Creek Fire burned over a large portion of the southeast end of this area. A portion of one cattle allotment is within this area although grazing is limited by the terrain.

The main attractiveness of this area is the Middle Yuba River and canyon walls, which are located in the center of the area. Other scenic attributes are the tributary creeks with their steep drainages and vegetated slopes. The area is popular for fishing.

National Forest System lands surrounding the area are managed primarily for timber production.

Figure G.4: Middle Vuba Roadless Area

GROUSE LAKES

#5260 (RARE II nonwilderness) - 10,096 net TNF acres, 20,996 gross acres See Figure G-5

The Grouse Lakes area is located in western Nevada County on the Nevada *City* Ranger District. The area includes numerous lakes and streams that are the focus of much recreation use. It includes about 17 miles of perennial streams and lakeshore. Water quality is high.

Annual precipitation averages 70 inches, largely falling as snow.

The landscape is broken, with much of the area characterized by glaciated granitic landforms. Elevations in the area range from 5500 feet near Eagle Lakes near the southwestern boundary to over 8000 feet in the Black Buttes region. Signal Peak and Old Man Mountain, near the southeastern boundary, both rise above 7700 feet in elevation. The area was recommended as nonwilderness in the RARE II EIS.

About 21 percent of the area has over 50 percent slopes. Fifty-seven percent of the watershed lands are sensitive.

The vegetation is representative of the Sierran Forest Province (Bailey Classification M2610) with both red fir and mixed conifer forest communities. (Kuchler vegetation type 045 predominates according to the RARE II analysis. This determination is erroneous, however, as red fir (007) and mixed conifer (005) are the correct types for this area.) The remaining acres consist of riparian vegetation, hardwoods, barren ground, brush, and water. There are 550 acres of wetlands, comprising five percent of the area.

The high natural scenic quality of the area is underscored by the fact that 99 percent is variety class "A," highly scenic.

The degree of current man-caused alterations of the natural landscape (existing visual condition) is minimal within the area. Approximately 99 percent of the area shows no evident change to the natural condition (EVC classes I and II).

Over one-half of the Grouse Lakes area is in private ownership. The primary owner is Sierra Pacific Industries. The company manages most of their forested land for timber production. They plan to construct a road into their most productive land through Sections 18 and 19, T. 17N., R. 13E., MDM, under a non-cost share easement. SPI has also expressed an interest in a cooperative agreement with the Forest Service in the same area.

There was a great deal of mining activity in the eastern and southern portions of the area during the late 19th century and early 20th century, but little gold was recovered due to the nature of the ore. The granitic nature of most of the area makes for an overall low mineral potential.

Dispersed recreation (hunting, fishing and hiking) is the primary use of the area. The majority of the area is closed to OHV use, with several exceptions. One is a small segment of the Meadow Lake jeep road which passes through a portion of the motor vehicle closure area. The area south of Fordyce Creek is open to OHV use with moderate to heavy use of Red Mountain and Signal Peak jeep trails.

There are a number of heavily used trails within the area. Many of these allow hiker access to the lakes in the region. Recreation use is concentrated around these lakes and totals 26,100 visitor days.

Grazing use occurs within the area during the summer months. Portions of two allotments are within the Grouse Lakes area. There are no fences or other range structural improvements. The main attractiveness of the area is the many lakes and highly scenic quality of the area.

Interstate 80, which has a heavy volume of traffic and noise, is adjacent to the southern edge of the area. Most of the surrounding area contains heavily used recreation complexes.

Figure G.5: Grouse Lakes Roadless Area

BALD MOUNTAIN

#5981 (RAREII nonwilderness) - 6,253 net TNF acres, 65,453 gross acres: Bald Mountain 4091 (RAREII nonwilderness) - 960 net Toiyabe NF Acres, 960 gross acres. See Figure G-6.

The Bald Mountain area is located east of the Sierra Nevada range on the Sierraville Ranger District. Approximately 960 acres are located within the Toiyabe NF.

The area is characterized by dry, rugged canyons and forested ridges. The landscape is rocky and soils are often poor. Elevations range from 8,760 feet at Babbm Peak on the eastern boundary to 6,300 feet on Rock Creek near the western boundary.

About three percent of the unit has over 50 percent **slopes**. Twenty-three percent of the area is within sensitive watershed lands. There are eight miles of perennial streams. Precipitation averages about 25 inches annually, largely as snow. Water quality is very high.

The vegetation is representative of the Sierra Forest Province (Bailey Classification M2610) with primarily an eastside pine forest type (Kuchler vegetation type 005).

There are 4,866 acres of eastside (primarily Jeffrey) pine, about 350 acres of Washoe pine, juniper, and pinyon pine. The remaining acres are brush, grass, barren areas, or riparian vegetation. There are 300 acres of wetlands, comprising five percent of the area.

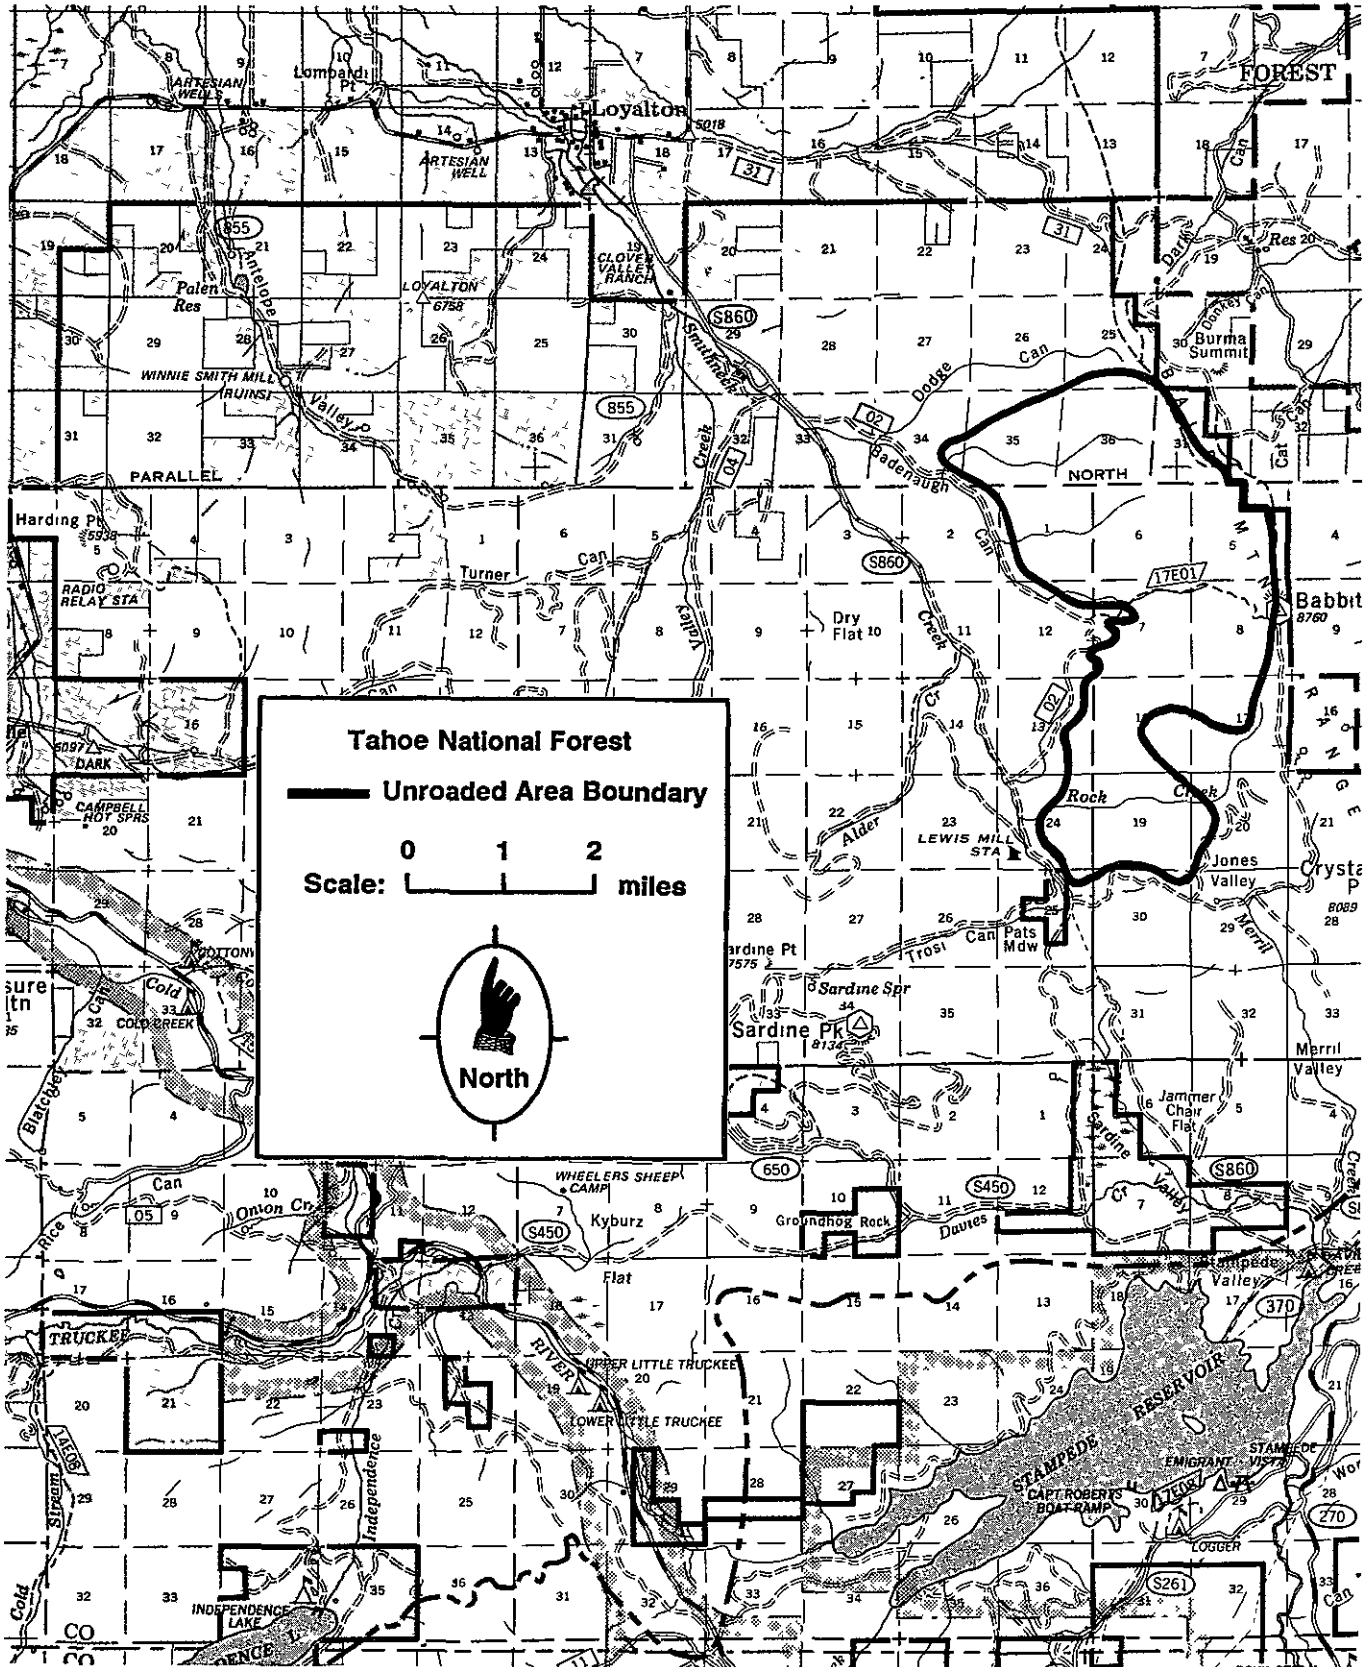

The majority (77 percent) of the area is of average scenic quality (variety class 'B'), with only 22 percent classed as being highly scenic (variety class 'A').

The degree of human-caused alterations of the natural landscape (existing visual condition) ranges from no evident ecological change (EVC II) to moderate change (EVC V). The areas of moderate change are those which have been logged in the past few years. Timber harvesting has occurred in the past and recently (1982) in an area covering approximately 200 acres in the central portion of the area. An additional 480 acres was logged in 1983.

A small portion of the Bald Mountain area is in private ownership. This private land is located near the northern boundary. Recreation use is low, averaging around 6,100 RVDs each year. Most of this is hunting, hiking, and OHV use. There are a number of unimproved roads, trails, and dispersed camping locations within the area. There are some rock exposures and steep terrain which provide some challenge for recreationists. The primary attractiveness of the area is the good hunting which may be found there.

Approximately 1,061 acres have been recommended for establishment as a Research Natural Area (RNA). This acreage has been revised upwards from the 900 acres documented in the working copy of the Environmental Assessment for the Babbm Peak RNA, available at Tahoe National Forest Forest's Supervisor's Office, Nevada City, California, and Toiyabe National Forest Supervisor's Office, Reno, Nevada. A portion of a cattle grazing allotment is also located within the Bald Mountain area. The City of Santa Clara has proposed establishing windmills within and adjacent to the area to generate electricity.

Figure G.6: Bald Mountain Roadless Area

DUNCANCANYON

#5259 (RARE II Nonwilderness); 8703 net TNF acres, 9403 gross acres. See Figure G-3.

This area is situated in eastern Placer County on the Foresthill Ranger District. It includes portions of the State Game Refuge encompassing the French Meadows Reservoir recreation area.

The major feature of the area is the rugged Duncan Canyon. Red Star ridge forms the eastern and southern boundary of the area while Little Bald Mountain and Sunflower Hill mark the western boundary. The northern boundary is the French Meadows - Soda Springs Road.

About seven percent of this unit has over 50 percent slopes. Twenty percent of the area is within sensitive watershed lands. There are about 13 miles of perennial streams. Precipitation averages about 70 inches annually, most of it as snow. Water quality is very high.

This area was recommended as nonwilderness in the RARE II EIS.

The vegetation is representative of the Sierran Forest Province (Bailey Classification M2610) with both red fir and mixed conifer forest communities (Kuchler Vegetation Types 005 and 007). The area contains 3,448 acres of mixed conifer and 4,536 acres of red fir. The remaining acres consist of riparian vegetation, hardwoods, brush, barren areas, and other nonforested land. There are 400 acres of wetlands, comprising five percent of the area.

Elevations within the area range from 5,100 feet along Duncan Creek to 7,182 feet at Little Bald Mountain.

The natural Scenic quality (variety class) of the area is predominantly lands with average scenic potential. As inventoried by the TNF Landscape Architect, the area is 34 percent highly scenic variety class 'A' and 66 percent of the area is variety class 'B', average scenic quality land. The degree of current human-caused alterations of the natural landscape (existing visual condition) within the area is minimal with most of the area appearing natural. Approximately 91 percent of the area has no noticeable alterations (EVC class II), 8 percent is predominantly natural (EVC class III), and one percent is dominated by alterations (EVC class IV).

One section (640 acres) near Sunflower Hill is in private ownership. In 1979, Erickson Lumber Company constructed a road under special-use permit to access their lands. The company plans to manage their land for timber production.

There are several unpatented mining claims within the area. The overall mineral potential is not considered significant.

Portions of two grazing allotments are located within the Duncan Canyon area. There are no range improvements.

Hunting, fishing, hiking, and plant study are the principal recreation uses, totaling 2,300 visitor days annually. The Tevis Cup Loop passes through the area along Red Star Ridge. This trail is used for an annual endurance ride and run.

The main attraction in this area is Little Robinson Valley in the western portion of the area. TNF lands surrounding the roadless area are managed primarily for timber production.

NORTH FORK OF THE MIDDLE FORK OF THE AMERICAN RIVER

#5265 (RARE II nonwilderness) - 10,653 net TNF acres, 11,153 gross acres. See Figure G-7.

This area is located in Placer County on the Foresthill Ranger District between Mosquito Ridge and the Foresthill Divide. The area is characterized by steep and rugged canyons. Ninety-seven percent of the area has over 50 percent slopes. The major attraction is the North Fork of the Middle Fork of the American River. There is a total of about 41 miles of perennial streams. Water quality is very high. Elevations in the area range from around 4800 feet near the eastern boundary to 1600 feet along the river at the western boundary.

The area receives an average of 50 inches of precipitation annually, nearly all of it in the form of rain; snow accumulation is rare.

The scenic quality of the area is characteristic of most of the western Sierra Nevada intermediate elevation areas. Over 50 percent of the area is classed as highly scenic with 44 percent of the area having only average scenic quality. Four percent of the area has low scenic quality.

The degree of human-caused alterations of the natural landscape (existing visual condition) ranges from no apparent ecological change to moderate change to the natural condition. A total of 9,461 acres show no evident change (EVC I), 336 acres show little change (EVC II), 850 acres exhibit noticeable change (EVC III), and six acres show moderate change to the natural condition.

About 57 percent of the area is described as being within sensitive watershed lands, virtually all of this on slopes over 70 percent.

The vegetation of the area is representative of the Sierran Forest Province (Bailey classification M2610) with a mixed conifer forest community (Kuchler Vegetation Type 005). There are 6,374 acres of mixed conifer, 3,723 acres of commercial and noncommercial hardwoods, and most of the remaining acres are either digger pine, brush, or barren. Only about two percent of the area is wetlands.

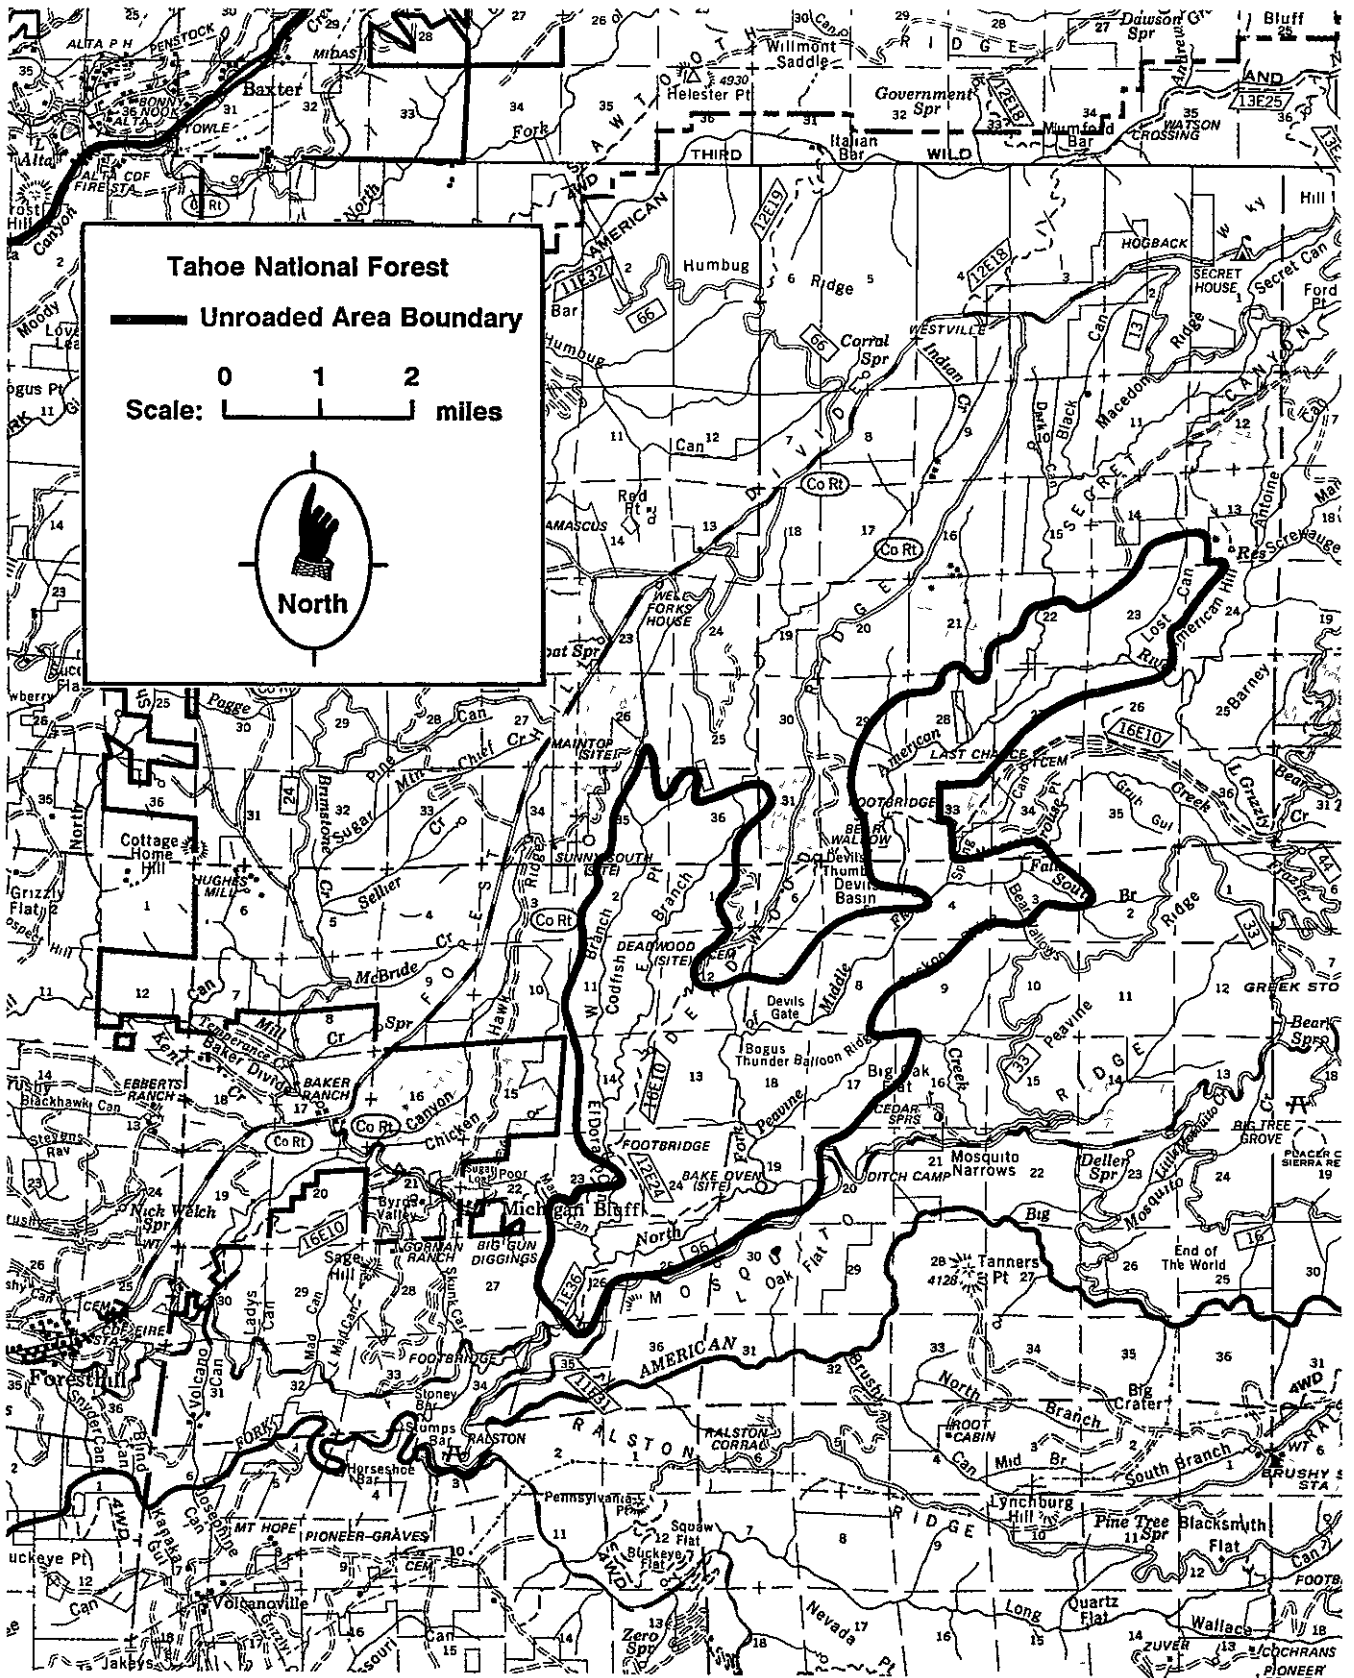

Only 500 acres is in private ownership. Mining has been an important activity in the area since the early days of the Gold Rush. Numerous active mines occur in the area. Recreation use is low (2,700 visitor days) and primarily involves hunting, fishing, and hiking.

The remains of former mine structures and cabins are numerous and there are two standing structures.

Virtually all of the area is open to OHV use but the steep topography and lack of many roads limits use. There are several trails through the area which have a long history of use. Two annual competitive events use the trail system. Portions of three grazing allotments occur in the area. Use in the area by cattle is light due to terrain and lack of forage.

The area was recommended for nonwilderness in the RARE II FEIS.

Figure G.7: North Fork of the Middle Fork American River

CASTLE PEAK

(RARE I)- 9301 net TNF acres, 17251 gross acres See Figure G-8.

This area is located along the crest of the Sierra Nevada between Castle Peak on the south and Mt. Lola on the north. The area is characterized by sparse vegetation, high elevations, steep, rocky terrain, and shallow soils. About 21 percent of the area has over 50 percent slopes. Forty-one percent of the area is within sensitive watershed lands. Mt. Lola and Basin Peak, both over 9,000 feet, are the highest peaks in the area. The lowest point within the area is along Lower Castle Creek near the southwestern boundary where the elevation drops to 6,900 feet. Precipitation averages about 65 inches annually, an estimated 90 percent of it as snow.

This area was inventoried as a roadless area in the RARE I process and it was analyzed for wilderness potential in the Truckee-Little Truckee Rivers Land Use Plan (T-LTRUP) EIS. Management direction in the Plan is to protect soil and water, maintain visual qualities, and manage for dispersed recreation. Because the area was analyzed for wilderness allocation in the T-LTRUP, it was not included in the RARE II inventory.

There are several lakes within the area; White Rock and Warren are the largest. Prosser, White Rock, and Lower Castle Creek are the principal streams. There are over 12 miles of perennial streams and lakeshore in this area. Water quality is high.

Castle Peak and its surroundings are among the most scenic areas on the Tahoe National Forest. This is due to the rugged topography, presence of vistas of lakes, rock outcrops, etc. Nearly the entire area (99 percent) is variety class "A", highly scenic. The degree of human-caused alterations of the natural landscape (existing visual condition) within the area is minimal.

Approximately 97 percent of the area shows no evident change to the natural condition (EVC classes I and II). The remaining 3 percent shows little change to the natural condition.

The vegetation of the area is representative of the Sierran Forest Province (Bailey Classification M2610) with both red fir and mixed conifer forest communities (Kuchler Vegetation Type 007, red fir forest). The area contains 5,206 acres of red fir, 468 acres of mixed conifer, and 469 acres of lodgepole pine. The remaining acres consist of grass, riparian vegetation, brush, or are barren. There are 960 acres of wetlands comprising ten percent of the area.

Nearly one half of the area is in private ownership. The primary landowner manages its land for timber production. Logging has occurred on their land in the White Rock Lake area.

The Castle Peak area has been used primarily for recreation over the last 100 years. No major mining activity has occurred in the area and there is little mineral potential. Several timber sales are planned in the area. The Perazzo Sale (15,6 MMBF) has sold and is partially logged.

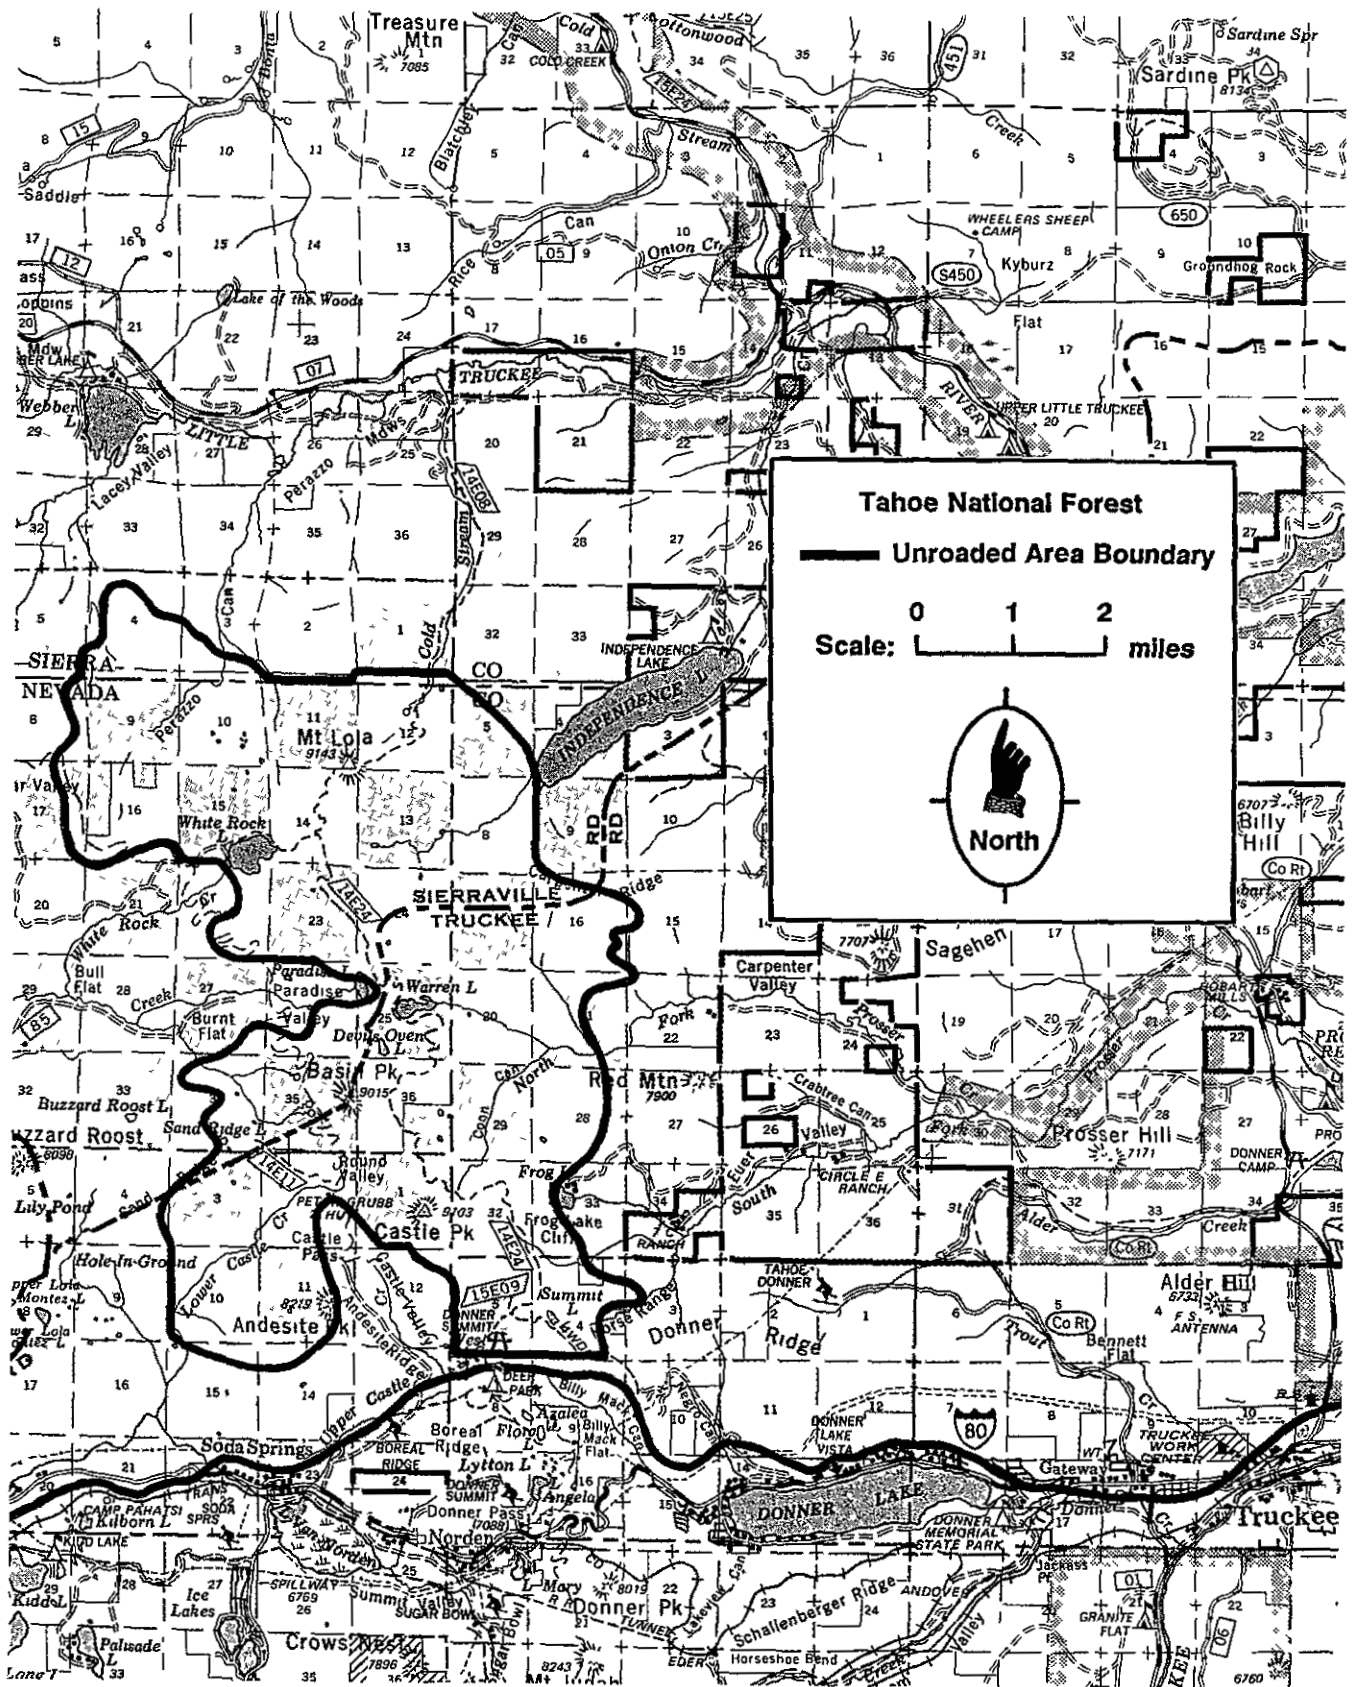

There is no accurate information on the amount of recreation use but the area is popular for hiking in the summer and sees heavy cross-country skiing and snowmobile use in the winter. The Sierra Club maintains a cabin (Peter Grubb hut) for recreation users in the Round Valley area.

Most of the area is open to OHV use on designated routes only. The general lack of OHV routes, however, contributes to low use except for snowmobiling in winter. There are several trails through the area, including a portion of the Pacific Crest Trail, but few roads. Through cooperative agreement a road has been constructed through Sections 3 and 9, T 18N, R. 14E., MDM.

Portions of three grazing allotments are located within the area. Most of the grazing is by sheep. The White Rock allotment is currently closed.

The main attractiveness of the area is its highly scenic character and the lakes and streams.

Figure G.8: Castle Peak Roadless Area

LAKES (BASIN)

(RARE I) - 551 net TNF acres, 551 gross acres* See Figure G-1.

This area is situated on both the Plumas and Tahoe National Forests. It is about seven miles south of Blairsden and Plumas Eureka State Park. Principal access is via the Gold Lake Highway or the State Park. Access from the TNF is via a **jeep** road through Gold Valley. **The** portion of the area on the TNF is very rocky and sparsely vegetated. The southern boundary follows a **jeep** road from the vicinity of Oakland Pond to Snake Lake then extends westerly to the private lands near Hawley Lake. These private lands form the western boundary.

The Tahoe portion ranges in elevation from 66,640 feet to 7,440 feet. About 3 percent of this area has over 50 percent slopes. Twenty-five percent of the watershed lands are sensitive. There are no perennial streams or lakes on the Tahoe portion. Precipitation averages 60 inches annually, nearly all of it as snow. Wetlands are negligible.

The Pacific Crest Trail (PCT) passes through the area near the administrative boundary between the Plumas NF and Tahoe NF. OHV use occurs on several **jeep** roads adjacent to the area, but overall the steep terrain of the TNF portion limits recreation use.

The TNF portion is highly mineralized, and mining has occurred in the vicinity since the 1850's. The Four Hills mine is located just west of the roadless area boundary.

There is a portion of one grazing allotment in the Lakes Basin area.

The Lakes Basin area was not evaluated for wilderness under RARE II. The Plumas NF is coordinating the analysis of the area and a complete discussion of the capability, availability, need, and consequences of wilderness or nonwilderness allocation may be found in the Plumas NF Forest Plan FEIS.

* The entire roadless area contains 7,140 acres (gross and net); the remainder of the acreage (6,939 acres) is on the Plumas NF.

APPENDIX H

SOIL PRODUCTIVITY

This appendix provides background information on how Forestwide **S&G 55, Maintain Soil Productivity**, was developed. It includes the assumptions made, references to the published research these assumptions were based on, and the logic used to develop the **S&G**. This appendix also supplements the analysis of environmental consequences in Chapter 4 by explaining how the implementation of **S&G 55** would mitigate adverse impacts of land management activities on long-term soil productivity.

Maintaining the long-term productivity of forest soils is a complex issue not readily reduced to simple terms. While much is known about the general effects of land management activities on forest soils, much less is known about the effects of specific activities. Therefore, predictions about how local soils will respond to management treatments must be based on application of general principles, and on extrapolation of experience and research from other areas. Soil qualities and characteristics related to soil productivity can provide a conceptual framework for: (1) applying general principles to specific soils, (2) extrapolating experience and research from other areas to local soils, and (3) developing forestwide standards and guidelines for maintaining soil productivity.

SOIL CHARACTERISTICS: INDICATORS OF SOIL PRODUCTIVITY

Soil productivity is the inherent capacity of the soil to support the growth of specified plants, plant communities, or a sequence of plant communities. Soil productivity is based on soil properties (characteristics and qualities) inherent to the soil itself. In contrast, forest productivity is a much broader concept that encompasses silvicultural factors such as stocking level, control of insects and disease, genetic quality of stock, etc. The effect of these silvicultural factors can mask small but significant changes in soil productivity. Also, several years of forest growth are needed before changes in site conditions are reflected in measurable changes in the growth of trees. For these reasons, carefully selected soil properties can be more sensitive indicators of changes in long-term soil productivity than forest growth.

Many soil properties affect soil productivity. To be useful as an indicator of changes in soil productivity a soil property should be: (1) readily changed by management activities; (2) easy to measure or observe (or directly correlated with a property that is); (3) strongly correlated with the growth of forest vegetation; and (4) sensitive to incremental changes that can cumulatively reduce soil productivity. Three soil characteristics that meet these criteria are: (1) soil porosity; (2) soil depth; and (3) soil organic matter. Measurable changes in these three soil characteristics are strongly correlated with changes in long-term productivity.

SOIL PROPERTY STANDARDS AND GUIDELINES

Soil productivity standards and guidelines serve several functions. They define minimum requirements for protecting the soil resource when management prescriptions are developed; they provide a tool for predicting the need for mitigation measures or restoration treatments, and they provide a basis for monitoring management practices to determine whether or not soil productivity is being maintained.

Effective standards and guidelines should be expressed in terms of readily measurable soil characteristics; be supported by research reported in the scientific literature, or based on local experience and observation; and have a reasonable chance for effective implementation. Forestwide **S&G 55, Maintain Soil Productivity**, was developed with these three criteria in mind.

SOIL POROSITY

Over half the volume of a typical forest soil is pore space consisting of large and small pores (macropores and micropores). About half of this pore space consists of micropores, occupied by water when the soil is moist, the other half, the macropores, is occupied by air, and is important in gas exchange and root

respiration. Fine plant roots must expand to new soil volume to obtain nutrients and moisture. Because roots can exert very little axial pressure, they are dependent on macropores for root expansion (Alexander and Poff, **1985**). Reductions in macroporosity are strongly correlated with reductions in plant growth

Porosity is reduced when heavy equipment is operated on the soil when its strength is low (Alexander and Poff, **1985**). When soil is subjected to a load it cannot bear, it compacts until it has enough strength to bear the load. This compaction causes a loss of soil porosity and an increase in density. All management activities that involve ground-based equipment carry a risk of reducing soil porosity. Examples are yarding logs with tractors, rubber-tired skidders, or feller-bunchers, and using tractors to pile logging slash. Porosity can also be reduced by oxidation or consumption of organic matter or by **loss** of soil to erosion or displacement, but these **losses** in porosity are usually smaller than those associated with compaction.

The relationship between loss of soil porosity and reduction in plant growth is almost linear (Froehlich and McNabb, **1984**), and has been demonstrated for forest stands (*wen* and Thomas, **1981**) as well as for individual trees. These reductions can persist for decades (Froehlich and McNabb, **1984**). **Loss** of porosity is primarily a short-term impact, but long-term impacts can occur when a decrease in infiltration causes increased runoff and soil erosion.

Repeated stand entries with ground-based equipment can cause a cumulative loss in soil porosity. The small decreases in porosity caused by each entry, not individually significant, can add up to significant losses in stand growth with repeated entries (Froehlich and Berglund, **1976**).

The standard for soil porosity in S&G **55**, Maintain Soil Productivity, is the same as the Pacific Southwest Region standard contained in FSH **2509.18**, Soil and Water Conservation Handbook (USDA-FS, **1988**). This standard was developed in the winter of **1986** by a task force of experts on soil compaction that included a university professor, a researcher, a field *soil* scientist, an extension soil specialist, a forest supervisor, and Regional specialists in logging systems and watershed management.

Soil porosity and soil density are numerically related; as density increases, porosity decreases, but the relationship is not linear. A reduction in soil porosity, rather than an increase in density, was selected as an indicator of soil productivity because using porosity as the threshold allows a slightly larger increase in density for soils with low densities, but allows a smaller increase for soils with high densities. The logic is that soils with initially high densities are already close to densities that limit plant growth, and therefore cannot tolerate as much of an increase in **density** as can soils with initially low densities.

The threshold of a 10 percent loss in soil porosity was based on the assumption that this change in porosity is required before a significant loss in forest stand growth can be detected. Apparently, forest stands can compensate for smaller losses in **porosity**.

Four broad management strategies can be used to limit the **loss** in soil porosity to less than 10 percent: (1) avoid compacting forces—for example, use aerial logging systems, (2) reduce compactive forces—for example, operate on a cushion of slash or use low-ground pressure equipment, (3) operate when soil strength is high—for example, on frozen ground or when moisture is low, and (4) confine compactive forces—for example, use directional felling, end-lining, and designated skid trails (Alexander and Poff, **1985**).

A loss of soil porosity may be mitigated by tillage (Froehlich, **1984**). Tillage can be effective when compaction has been confined to designated skid trails. Effective restoration of porosity by tillage requires the use of specially designed or modified equipment, and must be conducted under proper moisture conditions (Froehlich, **1984**). The objective is to restore the soil to a friable condition, which is defined as a condition where 50 percent of the volume of the tilled soil will pass through a **2 mm** sieve.

The soil is considered to be in an acceptable condition when the loss of soil porosity does not exceed 10 percent. When at least 85 percent of an activity area on which ground-based equipment has been used is in an acceptable soil condition, adverse effects on long-term soil productivity are considered mitigated. Effective and implementable management strategies are available to meet this standard.

SOIL DEPTH

In xeric moisture regimes, where nearly all precipitation occurs during a rainy winter season, soil productivity is strongly correlated with soil depth. This is largely because plant growth during the dry summer season is dependent on the available water capacity (AWC) of the soil, which is strongly dependent on soil depth.

A loss in soil depth can occur when there is insufficient soil cover to protect the soil from erosion by raindrops and overland flow. All management activities that reduce soil cover can increase erosion and reduce soil depth. Examples include broadcast burning, tractor piling of logging slash, and overgrazing.

Soil erosion and soil formation are both natural processes. Under natural conditions, the balance between these two processes often determines how deep and productive a soils will be. Deep soils usually occur on gentle slopes, where the rate of soil formation exceeds the rate of erosion, whereas shallow soils usually occur on very steep slopes, where the rate of soil formation barely keeps up with the rate of soil erosion. On productive soils, erosion is considered "accelerated" when the erosion rate exceeds the soil formation rate.

Forest Planning Regulations (36 CFR 21.9.27, Part A) state that "management prescriptions shall conserve soil and water resources and not allow significant or permanent impairment of the productivity of the land." Soil provides the basis for land productivity. When the rate of soil erosion exceeds the rate of soil formation, the productivity of the land is being permanently impaired because, if allowed to continue unchecked, the loss of soil depth will irreversibly reduce the capacity of the soil to support plants. Such losses, highly significant in the long-term, may not result in measurable short-term losses in plant growth.

In his review of the scientific literature on rates of soil formation, Alexander (1985) found that rates of soil formation on consolidated bedrock ranged from about 0.25 to 1.0 tons/acre/year. Rates of soil formation are used to develop soil loss tolerance limits, or T factors, for soils. The T factor is the amount of soil that can be lost annually without affecting long-term soil productivity. The logic is that the soil will not be irreversibly damaged if the rate of soil loss does not exceed the rate of soil formation. Specific T factors are not available for Tahoe N.F. soils. A T factor of 0.75 tons/acre/year was selected, based on Alexander's findings (1985, 1986).

Soil loss tolerance limits developed for use in the Universal Soil Loss Equation (USLE) (USDA-SCS, 1976) assume annual losses of soil associated with agricultural cropping systems. However, in forest management soil is exposed to erosion for short periods of time, followed by longer intervals with complete cover. The rate of surface soil erosion in a mature forest is negligible. During the first two years of the harvest period, erosion rates can increase to 10 times the pre-harvest rates (Clayton, 1983). These accelerated rates then diminish rapidly, and gradually return to the very low pre-harvest levels as the forest canopy closes and forest duff and litter accumulate. These irregular periods of erosion create a scheduling problem too complex to deal with at the forest planning level. Working through sample problems revealed that the largest variable in scheduling erosion rates under forest management was rotation length. This problem was therefore dealt with by using rotation length to adjust the calculated Effective Soil Cover (ESC) amounts.

It is difficult to accurately measure soil erosion, especially at the low rates involved. Erosion is also strongly dependent on rainfall, which in the Sierras varies considerably in amount and intensity from year to year. This means measurements must be taken over long periods (perhaps 10 years or more) to develop meaningful averages.

Soil cover is strongly correlated with reduced rates of erosion, of the factors that affect erosion, cover is the only one readily controlled by management. In addition, predictive models--such as USLE--can be used to calculate the cover amounts needed to keep erosion within specified limits. For these reasons, Effective Soil Cover (ESC) was selected as the standard for maintaining soil depth.

Effective Soil Cover (ESC) is defined as including all materials that will dissipate the energy of falling raindrops. ESC includes plant litter and forest duff (which can be intact, displaced, or disturbed), woody material in contact with the soil, living vegetation, and rock fragments with a diameter of 1/2 to 3 inches. Living vegetation qualifies as ESC if it is no more than 60 inches above the soil surface. The intent of ESC is to prevent the detachment and transport of soil particles downslope by raindrop splash and overland

flow ESC is not intended to trap sediment already mobilized, as is the purpose of Effective Ground Cover (EGC) defined for Streamside Management Zones in Forest Plan Appendix F.

The minimum values for ESC listed in S&G 55, Maintain Soil Productivity, were developed using the following process. A T factor of 0.75 tons/acre/year was selected for the reasons given above. The USLE was then used to compute cover values that would keep erosion rates at or below this T factor. The factors used for cover coefficients were those for 'no appreciable canopy' and for 'cover type G' (duff and litter at least 2 inches thick), given in Table IV 4, page IV 25 of EPA Publication 600/8-80-012 (EPA, 1980). Coefficients for the other USLE factors were developed following Forest Service Pacific Southwest Region instructions (USDA-FS, 1977). These instructions recommend the use of USLE when quantifying erosion and provide USLE factors based on the Pacific Southwest Region's Erosion Hazard Rating System (EHR). The R values (climatic factor) in these instructions are comparable to R values in other published sources, including the EPA document cited above. A 2-year, 6 hour precipitation event was the basis for the calculations.

ESC values were developed for a range of slopes using EHR values of 2 for slope uniformity and water concentration potential. The K factors (soil erodibility factor) published by the SCS and included in the Tahoe National Forest Soil Resource Inventory (Hanes, 1986) were not used. Local experience, and data collected during special studies on the Tahoe NF (Glines, 1987), suggest these values are not applicable to local conditions. The K factors used were from locally developed EHR forms.

ESC requirements were calculated for each soil type on the forest over a range of slope gradients. The problem of a periodic vs. annual soil loss was dealt with by using rotation length to adjust ESC as discussed above. A rotation length was assigned to each soil type based on productivity (the rotation lengths in FORPLAN were used), with shorter rotation lengths assigned to the more productive soils. This gave the more productive soils higher ESC values than comparably erodible soils with longer rotation lengths. The logic is that the shorter the rotation length, the greater the proportion of the rotation in a disturbed soil condition.

The calculated ESC values for each soil type were then listed for 30 and 60 percent slopes and, using a pseudo-ordination procedure, soils were grouped by ESC values, which resulted in four soil groups. Minimum ESC values for three slope ranges were displayed in a table for each soil group, and these values averaged and rounded off.

Maintaining ESC is the primary method for controlling erosion and limiting the loss of soil depth. The two management operations with the greatest potential to reduce ESC are broadcast burning and tractor piling of logging slash. Grubbing to remove competing vegetation in plantations, and biomass harvest as an alternative site preparation treatment, also have the potential to reduce ESC.

ESC standards are not in conflict with the need to reduce fuels to acceptable levels. The materials most effective as soil cover are generally smaller-sized and in contact with the soil, not the larger-sized heavy fuels which create the greatest fire hazard.

Where duff is more than 1/2 inch thick, ESC levels can be maintained under broadcast burning if the burning is done when the moisture content of the lower half of the duff is not too low (Shearer, 1981). Where tractor piling, or other mechanical means of treating slash are used, ESC levels can be maintained with good contract specifications and contract administration.

The loss of soil by erosion is irreversible. Soil cover, however, which reduces the risk of erosion, can be replaced. Chipped woody material, slash, straw, or even seeding with grasses are all effective replacements for lost soil cover, and can effectively reduce the risk of soil erosion and loss of soil depth. A loss of soil defined as significant in the long-term may not cause measurable short-term reductions in plant growth, therefore, maintaining soil depth by controlling erosion is considered mitigation of a long-term cumulative effect on soil productivity.

SOIL ORGANIC MATTER

Organic matter is of primary importance in maintaining the long-term productivity of forest soils. The availability of several key nutrients—most notably nitrogen, phosphorus, and sulfur—is dependent on the

organic fraction of the soil (Prichett, 1979). The organic surface layers of forest soils modulate temperature and moisture fluctuations at the **soil-litter** interface which is the habitat for a myriad of micro-organisms, insects, and small animals important in nutrient cycling (Maser and Trappe, 1984). Large woody material on the forest floor retains moisture during the dry summer months, providing critical survival habitat for non-symbiotic **nitrogen-fixing** bacteria (Harvey, et al., 1978; 1980). The biological activity associated with the gradual decay of large woody material accumulates nutrients that might otherwise be lost from the forest ecosystem (Maser and Trappe, 1984).

The importance of surface litter and soil organic matter to forest soil productivity is not new. Studies on yield reductions associated with litter gathering were reported for European forests in the **1800s** (Powers, 1988). More recently, research in Australia has documented a strong correlation between declining yields and the **loss** of organic matter (Squire, et al., 1985).

Large woody material and soil organic matter provide essential habitat for invertebrates, insects, reptiles, and small animals and mammals (Maser and Trappe, 1984), the life cycles of which are interdependent with the growth of higher plants. For example, large woody material provides habitat for the California red-backed vole, which feeds on the fruiting bodies of mycorrhizae, spreading them throughout the forest (Maser and Trappe, 1984). Mycorrhizal associations are essential for the growth of many plants and allow more effective extraction of nutrients from the soil.

Management activities that remove or consume forest duff, litter, and large woody material, or that displace the surface soil, all have the potential to reduce long-term soil productivity. An example of a short-term effect is the **loss** of surface duff and litter, which can alter the habitat of micro-organisms important in nutrient cycling. A long-term effect can result from the loss of large woody material, because this material accumulates nutrients that otherwise would be lost from the **site**. A loss of large woody material could also have a cumulative effect on long-term soil productivity because the accumulated nutrients are held in reserve to be released hundreds of years in the future (Maser and Trappe, 1984). It could take decades, or possibly centuries, to replace the lost soil organic matter, and centuries to replace large woody material (Harvey, et al., 1981). However, these losses are not irreversible if the soil retains **its** ability to produce vegetation.

The specific amounts of soil organic matter, forest duff and litter, and large woody material needed to maintain long-term soil productivity on specific soils and under specific plant communities are not known. The published research, however, provides very strong circumstantial that organic matter is important in maintaining long-term soil productivity (Harvey, et al., 1978, 1980, 1981, 1987, Maser and Trappe, 1984, Powers, 1988, Squire, et al., 1985).

The organic matter requirements in Fowstwide **S&G 55**, Maintain Soil Productivity, are based on the application of general principles, and are considered prudent minimum levels that will serve as a starting point until more information is available. The guidelines for large woody material were adapted from a **position** statement for the Siskiyou N.F. (1987), and are considered a practical level to implement at this time. Decomposition classes for large woody material are defined in Agriculture Handbook 553 (Thomas, 1979). A range is given for large woody material to allow flexibility in applying the standard. Maintaining large woody material is believed to be most critical on the harsher, dryer sites with **less** productive soils (Harvey, et al., 1987). The requirement that at least two logs per acre be in decomposition classes 1 or 2 was included to provide wildlife habitat as recommended in Agriculture Handbook 553 (Thomas, 1979).

There is a concern that it may not be possible to maintain forest duff under plantations. Maintaining forest duff appears dependent on an annual replenishment of needlecast and small woody material and, once the forest canopy has been removed, may not persist until the new plantation is mature enough to provide needlecast. For these reasons it was felt unreasonable to establish higher standards for forest duff at the present time.

The strategies for maintaining soil organic matter, duff, litter, and large woody material are very similar to those for maintaining ESC. Activities with the greatest potential for impacts are broadcast burning, tractor piling and burning logging slash, and biomass harvest. The minimum amounts of organic matter in the standard do not conflict with other resource objectives such as preparing sites for planting and removing high hazard fuels. Large woody material could potentially be a fuel hazard, but the number of pieces

called for, and the fact that more than half are in decomposition classes that are not high hazard fuels, minimizes the conflict. Also, the requirements for large woody material are waived in areas designated as fuel breaks. This is a prudent trade-off, since fuel breaks maintained along ridge tops may allow more woody material to be left elsewhere, further downslope, for instance.

In the case of large woody material, resource objectives for wildlife management and soil productivity are complimentary. The snags left to provide habitat for cavity nesters and other wildlife—and the green trees left for snag recruitment—will eventually fall and, as they pass through the various stages of decay, meet the needs of both soils and wildlife.

The loss of soil organic matter, duff, litter, and large woody material is not readily mitigated because these materials cannot be replaced in the short run. This makes it imperative to maintain reserves of large woody material until more is known about the amounts needed on specific sites.

INTERRELATIONSHIPS AMONG THE INDICATOR SOIL CHARACTERISTICS

The three soil characteristics selected as indicators of long-term soil productivity are highly interdependent. This helps make them good indicators of long-term soil productivity. For example, a loss of soil porosity decreases infiltration; this causes increased runoff and erosion, reducing soil depth. Another example is that an increase in organic matter reduces the risk of a loss in porosity by increasing resistance to compaction and by cushioning the impacts of ground-based equipment. The important point is that the measures taken to maintain any one of these soil characteristics also maintain one or both of the others, and, an adverse impact on one soil characteristic is likely to impact one or both of the others.

APPLICATION AND MONITORING

The relative risk of a significant reduction in long-term soil productivity is considered to be acceptably low when the requirements for maintaining the soil characteristic's porosity, depth, and organic matter have been met on at least 85 percent of an activity area (95 percent where ground-based equipment is not used). An activity area is the area on which a potentially soil-impacting treatment is planned for or has occurred: it includes temporary roads, landings, skid roads and trails, but not system roads. Normally, system roads make up less than 3 or 4 percent of an area, and are considered a dedicated use necessary for the management of the forest. Temporary roads, landings, and skid trails, however, need not remain dedicated. The intent of the standard is to minimize this kind of disturbance where ground-based equipment is used, and to restore impacted areas as soon as it is practical. When less than 85 percent of an activity area meets the standard, rehabilitation measures must be taken. The 15 percent threshold is derived from the Pacific Southwest Region standard for soil compaction (USDA-FS, 1988), which was based on the amount of change in a soil quality needed to produce a measurable change in forest stand growth.

A provision for developing site-specific ESC requirements was included as an alternative to using values in the ESC table. This alternative method also provides flexibility in developing site-specific management prescriptions.

SUMMARY

The application of S&G 55, Maintain Soil Productivity, will reduce the risk of causing a significant reduction in long-term soil productivity while conducting land management activities, especially those associated with timber management. It accomplishes this by setting thresholds for the amount of change allowed in soil porosity, soil depth, and soil organic matter, three soil characteristics basic to long-term soil productivity. Where these threshold values are exceeded, restoration treatments are prescribed.

The soil characteristics selected, and the threshold values selected for each of them, reflect the state-of-the-art in forest soil management on the Tahoe N F , and will change as research findings become available and as information and experiences on other forests is shared. The most valuable feedback, however, will be provided by observing and monitoring the effects of specific treatments on soils that occur on the Tahoe N F . Guidance and direction for monitoring is given in Chapter 2 of FSH 2509.18 (USDA-FS, 1987) Table 6.1 and Forest Plan Appendix K, Soil Monitoring, also provide information on this on-going monitoring effort.

APPENDIX I

BUDGETS AND THEIR RELATIONSHIP TO THE FOREST PLAN

Purpose

The purpose of this appendix is to explain Tahoe National Forest (TNF) funding and what effect different funding levels will have on implementation of the land and resource management plan (LMP). The appendix explains 1) the Federal budget process, 2) alternate sources of funding, 3) the TNF management priorities, and 4) monitoring for Plan compliance.

The Budget Process

The Federal budget process is lengthy and complex. The Forest's budget becomes part of the Region's budget, which becomes part of the Forest Service's budget, which becomes part of the Department of Agriculture's budget, before it enters pertinent Congressional subcommittees. Needless to say, the budget gets negotiated every step of the way. Figure 1.1 highlights the chain of events a Forest budget undergoes on its way to and from Congress.

The factors influencing the Forest's final budget are many and relatively uncontrollable from the Forest's perspective. The role of the Plan in this process is to identify for the Secretary of Agriculture, Congress, and the public what appears to the Forest Service to be the programs and funding level for the TNF that would maximize net public benefits. It is anticipated that the parties involved in the budget process will use the Forest's LMP for guidance and long range direction in deciding budget priorities. However, Congress retains the ultimate decision making power over the total Forest Service budget, and the individual budget items such as timber sales, recreation, development, and wildlife habitat enhancement on a Nationwide basis. Therefore, it is probable that the actual TNF budgets will never exactly match the budget's shown in the Plan.

In order to compare the budget and the Plan's Preferred Alternative, we have converted recent budgets and the costs for the LMP Preferred Alternative into pie charts for broad resource categories. Figure 1.2 shows the TNF's budget trends and priorities by resource (function) averaged for fiscal years 1986, 1987, and 1988 and for the Preferred Alternative. The pie on the left shows budget dollars, the pie on the right shows LMP Preferred Alternative dollars.

While not identical, the two pie charts show a similar distribution of funds to major resource areas. The LMP Preferred Alternative pie shows a lowering in road building dollars, and an increase in recreation dollars. The comparison of recent budgets with the LMP Preferred Alternative shows that almost all budget category expenditures would have to increase to achieve full implementation of the Plan. Should Congress continue to fund individual resource programs or provide inadequate overall funding, adjustments would be required in planned output levels and the rate at which some provisions of the Plan would be implemented. For example, should allocated funds to the TNF for recreation construction projects stay at the current level, most of the planned campground and trail construction projects will not be completed in the coming decade. However, if individual resource program funding were not prescribed and overall funding was less than the planned budget, then all Forest activities and outputs would need to be reduced in approximately equal proportion, tempered by minimum needs for resource protection.

Figure 1.1: BUDGET PROCESS FLOW CHART

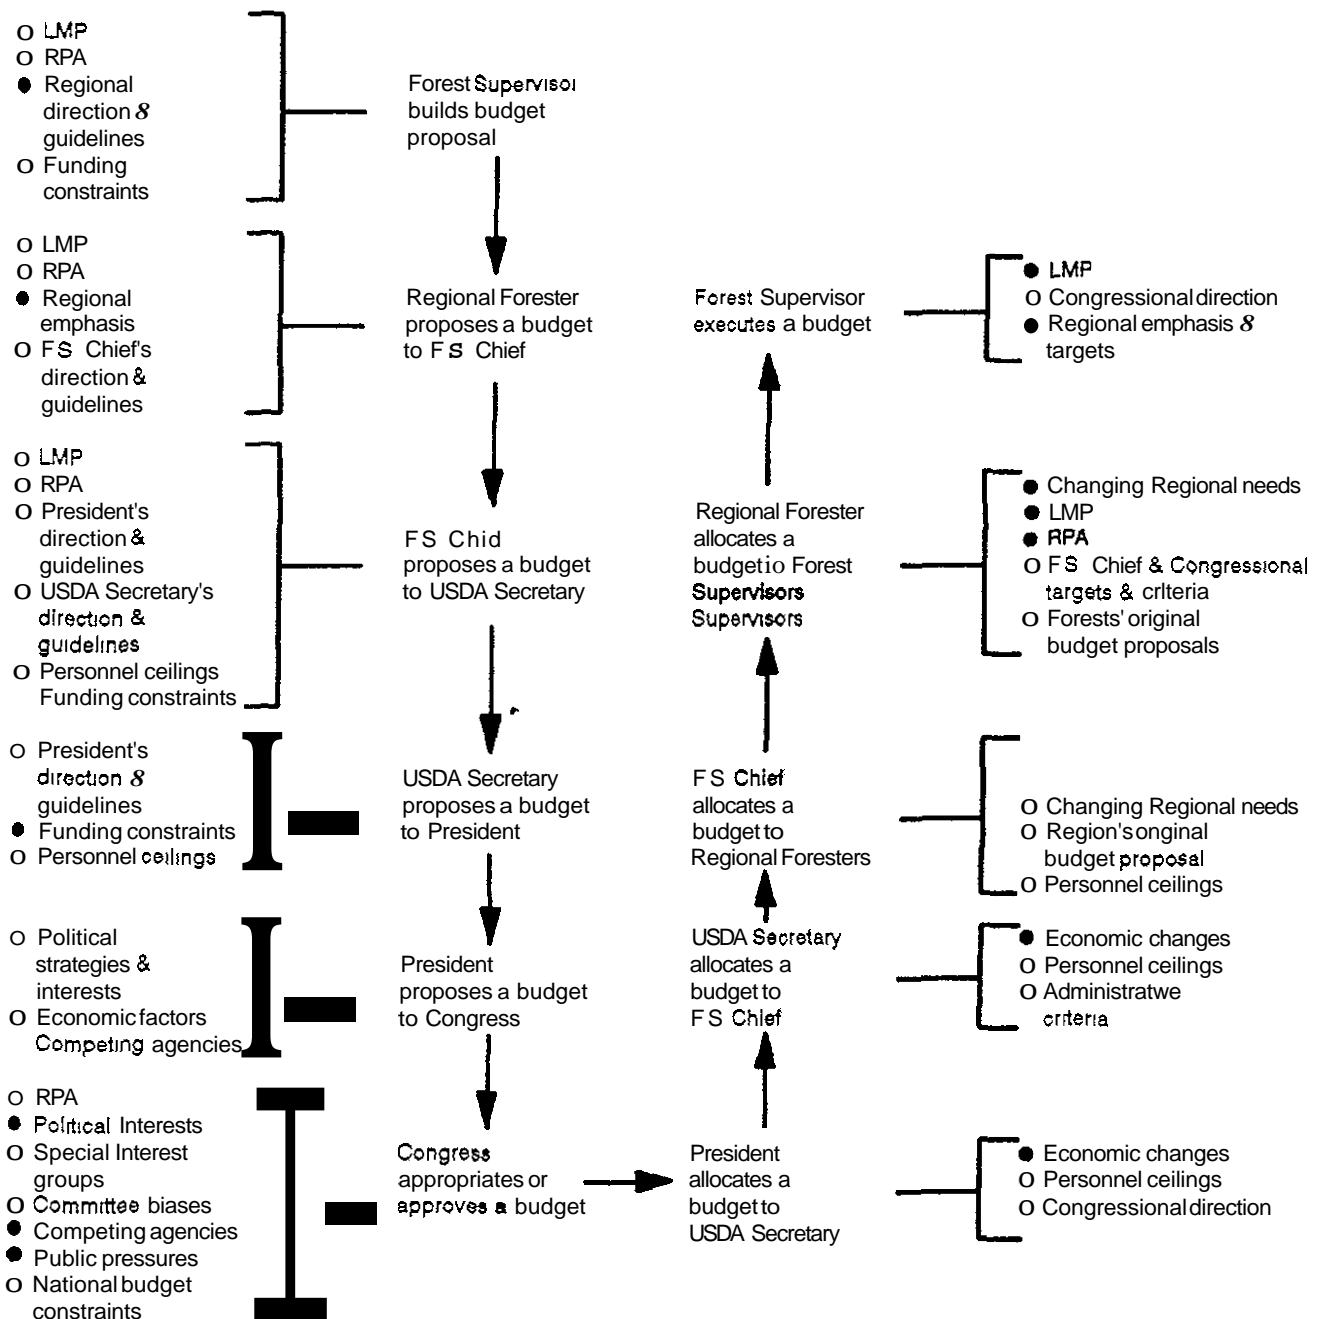

Figure 12: Historical and Planned Budgets Percent of Total

1986 - 1987 Average Annual Budget

Total Budget \$17,000,000

Forest Plan First Decade Average

Total Budget \$21,200,000

• Amounts in 1982 Dollars.

Other Financing

The budget given to the Forest Service by Congress authorizes it to spend both appropriated and trust funds. However, while the budget is paramount in a National Forest's ability to carry out activities, it is not the only factor that allows a Forest to get work done. Forests also receive money and services from many other sources. These other sources are becoming increasingly important.

From FY 1982 through FY 1989 it is estimated that the State of California Green Sticker grant will provide funding of \$2,600,000 for the purpose of operation, maintenance, designing Forest corridors, purchase of land, and construction projects in support of off-highway vehicle activities.

In FY 1988 an estimated total of \$661,000 will be provided by cooperators for the following.

Cooperator	Purpose	Amount
CA Dept. of Fish & Game	Fish & wildlife habitat improvement	\$163,000
Wildlife Conservation Board	Construction of launching facility	61,600
CA Dept. of Boating & Waterways	Erosion control	30,000
State of CA - CDF	Construction of dispatch facility	120,000
Various timber cooperators	Re-marking of timber sales	12,300
Various cooperators	Hydroelectric EA's	6,200
	Recreation maintenance of campgrounds	18,500
	Avalanche control, etc	
	Road maintenance	149,400
Total		\$661,000

In addition, the Forest is continually investigating ways to improve efficiency and productivity. By operating more efficiently, more can be accomplished with available resources.

Forest Priorities Under the Plan

While output levels listed in the Plan are tied to budget levels, they are not the sole or even the primary product of the Plan. The Land Management Plan establishes management direction for the Forest. This includes the minimum management requirements (MMR's), minimum implementation requirements (MIR's) and standard and guidelines discussed in Chapter 2 of the FEIS and Chapter 5 of the Forest Plan. The Plan also establishes those activities appropriate for each section of the Forest (see management prescriptions and management area direction in the Plan). For example, areas managed as semi-primitive nonmotorized will be managed primarily for dispersed recreation with no road building or timber harvesting. Other areas are managed for range or timber production as their primary function. The Forest goals and policies and land allocations are budget-independent. They will be adhered to no matter what budget level is appropriated in the yearly funding process.

Some of the Plan's management direction is budget-dependent. The Preferred Alternative shows the maximum potential the Forest can achieve (the amount of timber which can be sold, the number of cattle grazed, etc) within the bounds of the management direction the Forest has set for itself. The amount of output actually produced and number of activities and projects actually implemented depends on available funding.

Should Congress not provide the budget levels required for plan implementation, management intensity and production levels will be lower. In no case would management standards and guidelines be violated in order to meet production goals. For example, the Plan requires that in riparian areas the emphasis is to protect riparian-dependent resources. This standard can not be relaxed to increase timber harvesting or grazing.

Generally speaking, standards and guidelines fall into two categories 1) those associated with project mitigation, and 2) those which will maintain or possibly enhance the Forest environment.

Standards and guidelines established by the Plan to regulate implementation of projects will not be relaxed simply to meet production levels. Under NEPA, an environmental analysis is prepared for every project that affects other resources. If the environmental analysis shows that the project cannot be accomplished without violating the Forest's standards and guidelines, then the project will be modified or revised to ensure it meets the established standards and guidelines. Other standards and guidelines address maintenance and/or enhancement of the environment but are not tied to specific projects. Lower budget levels will alter their rate of accomplishment.

Monitoring

Each Forest Plan includes a monitoring plan that lets the Forest know how it is doing in meeting the goals it has set for itself. This monitoring plan is given in Chapter VI of the Forest Plan. If the Forest strays too far from accomplishing the objectives set in the Plan, a plan amendment or revision is required. However, because Plan objectives are expressed in average annual terms for a ten-year period, accomplishment levels at less than the annual average will not automatically trigger a plan amendment. The allowed variability for each monitoring item is shown in the monitoring plan. If Forest activities fall outside of the allowed variability, a plan amendment or revision could be triggered.

APPENDIX J

NATIONAL TRAIL EVALUATION

A INTRODUCTION

Congress passed the 'National Trails System Act' on October 2, 1968 which provided for the designation of a system of trails throughout the Nation intended to promote the preservation of, provide public access to, travel within, and enjoyment and appreciation of the open-air, outdoor areas and historic resources of the Nation. The Act provided for the establishment of trails primarily near urban areas of the Nation, and secondarily within scenic areas and along historic travel routes of the Nation

The Act provided for a system of trails composed of the following:

(1) National Recreation Trails are established to provide for a variety of outdoor recreation uses in or reasonably accessible to urban areas. Recreation trails are established by either the Secretary's of Agriculture or Interior, as appropriate

(2) National Scenic Trails are extended trails (usually 100 miles in length or longer) so located to provide for maximum outdoor recreation potential and for the conservation and enjoyment of the Nationally significant scenic, historic, natural, or cultural qualities of the areas through which such trails may pass. National scenic trails may pass through deserts, marsh, grasslands, mountains, canyons, rivers, forests and other areas, as well as landforms which exhibit significant characteristics of the physiographic regions of the Nation. Examples of Scenic trails include the Pacific Crest National Scenic Trail, the Appalachian National Scenic Trail, and the Continental Divide National Scenic Trail. Scenic trails are established by Congress.

(3) National Historic Trails are extended trails that follow as closely as possible and practicable the original trails or routes of travel of National historic significance. National historic trails shall have as their purpose the identification and protection of the historic route and its historic remnants and artifacts for public use and enjoyment. Examples of historic trails include the Oregon Trail and the Mormon Trail. Historic trails are established by Congress.

Publics responding to the Draft Forest Plan have identified the Western States and the Tevis Cup Trails as possible additions to the National Trail System. Interest in designation has gone as far as having a Bill, H.R. 2988, introduced in the House of Representatives on July 22, 1987 for National designation. In response to this bill, the Associate Chief of the Forest Service asked the Regional Forester, who in turn asked the Forest Supervisor, to proceed with determination of eligibility for nomination as National Scenic, National Historic, or National Recreation Trails. Both trails have been used for organized events, including a horse race, a 100-mile endurance run, and other similar races or events that occur over the trail each summer. Both of these trails provide access across private and National Forest System lands between Squaw Valley and Auburn. In addition, the Western States Trail at the western boundary of the Forest connects with the existing National Recreation Trail that comes from Sacramento, and finally ties in with the Pacific Crest National Scenic Trail near Squaw Valley.

Within the Forest, the Western States Trail is approximately 55 miles long and the Tevis Cup Trail is 21 miles long. The total mileage of the portion proposed for designation in this Plan, together with the already designated portion west to Beal's Point, exceeds 125 miles in length.

The Western States and the Tevis Cup Trails are shown on the Transportation Map provided with the Plan.

The State of California, Placer County, and private organizations and individuals have been actively working toward designation of a trail route, with National status, to connect Carson City and Sacramento, the State Capitols of Nevada and California. The California Department of Parks and Recreation was the lead agency in the earlier designation of the Western States Trail located west of the Forest boundary. The Placer County Board of Supervisors has, by resolution, endorsed Federal designation, as has the California Recreational Trails Committee. The Nevada State Parks Department has expressed interest in obtaining designation for that portion through Nevada.

The Tahoe National Forest decided to nominate the Western State Trail as a National Recreation Trail and completed an Environmental Assessment and decision notice on January 17, 1979. The decision notice stated that the nomination process would be initiated once rights-of-way across private lands have been obtained. The process of securing rights-of-way is on-going. This decision is still valid.

The purpose of the following analysis is to evaluate eligibility and/or suitability of the Western States and Tevis Cup Trails for designation as either: (1) recreation trail, (2) scenic trail, or as a (3) historic trail.

B. DETERMINATION OF ELIGIBILITY

The National Trails System Act establishes specific criteria that must be met to qualify for each class of trail.

National Recreation Trail

- 1) trails represent the more outstanding trail opportunities within the Forest.
- 2) provide a day-use or extended trail experience for a variety of outdoor recreation opportunities reasonably accessible to a population center.
- 3) provides for an interconnecting network of National trails.

National Scenic Trail

- 1) extended trail systems (usually 100 miles or more).
- 2) access Nationally significant scenic, historic, natural, or cultural sites.
- 3) represent significant characteristics of the physiographic region of the Nation.

National Historic Trail

- 1) route established by historic use must be historically significant as a result of that use.
- 2) be of National significance with respect to any of several broad facets of American history, such as trade and commerce, explorations, migration and settlement, or military campaigns.
- 3) significant potential for public recreational use or historical interest based on historic interpretation and appreciation.
- 4) must meet all three criteria to qualify.

C. ELIGIBILITY EVALUATION FOR NATIONAL HISTORICAL TRAIL CLASSIFICATION

The Western States and Tevis Cup Trails were reviewed in July, 1988 and evaluated in light of the criteria established for a National Historical Trail. Although the Western States and the Tevis Cup Trails contain historic and scenic values, the Forest Service determined the trails are not of National significance with respect to broad facets of American history. Based on the historical evidence, the Western States and Tevis Cup Trails, in part a successor to the Placer County Emigrant Road, was of local importance and perhaps of Regional or State importance. A seven-mile section of the Trail does qualify for listing in the National Register of Historic Places. However, overall the trail was not an important link to the overland wagon roads of the 1840's and 1850's used during the height of the Gold Rush. In addition, only superficial evidence supports the assumption that the trail was first crossed by the Murphy-Stevens-Townsend Party.

Each of the existing National historical trails had a dramatic effect upon American culture and development of the American frontier, e.g., Santa Fe, Oregon, and California trails. The Western States and Tevis Cup Trails did not have this same level of effect on California or the Nation. The historical evaluation was done by a Forest Service historian in consultation with the California State Historic Preservation Officer.

The Forest Service recognizes that other groups have reached a different conclusion relating to the historic significance of the Trails. This Plan is not intended to preclude such designation, if deemed appropriate by the Congress.

D. ELIGIBILITY EVALUATION FOR NATIONAL SCENIC TRAIL CLASSIFICATION

The criteria used to determine eligibility for scenic classification indicate that a trail should have National or Regional significance in accessing a variety of Nationally significant scenic, historic, natural, or cultural qualities of the areas of which the trail passes through. A National Scenic Trail is intended to be the 'focal point' which serves as a link through a whole range of environmental conditions, from deserts to glaciated peaks, and generally is very long, usually over 200 miles in length. The Pacific Crest Trail, which runs the length of the Cascades and Sierra Nevada from Canada to Mexico, is one example of the quality and significance that a National Scenic Trail should exhibit. The Western States and Tevis Cup Trails contain outstanding scenery and recreational opportunities, but in the Forest Service view do not provide the same variety of recreational experiences and challenges, nor are they Nationally significant from a scenic viewpoint.

As with the Historic Trail evaluation, there are groups that have reached a different conclusion relating to the scenic values of the Trails. This Plan is not intended to preclude such designation, if deemed appropriate by the Congress.

E. ELIGIBILITY EVALUATION FOR NATIONAL RECREATION TRAIL CLASSIFICATION

As stated above, the Western States Trail was evaluated as a possible addition to the National Recreation Trails system in 1979 and in fact was recommended for nomination pending securing rights-of-way across private lands within the Forest boundary. Conditions described in the 1979 Environment Assessment have not significantly changed, and the trail meets all the criteria established for a National Recreation Trail.

The Tevis Cup Trail, approximately 21 miles in length, was also evaluated and found suitable, although it was not designated at the time because of potential problems with location and trail construction standards. The existing trail along Red Star ridge, or Tevis Cup Trail, would be a logical addition for designation along with the proposed Western States National Recreation Trail. Some minor trail relocation, improvements, and acquisition of rights-of-way are needed for the Tevis Cup Trail. The designation of both the Western States and Tevis Cup Trails would tie in with the existing National Recreation Trail from Sacramento to the Forest boundary on the west and with the Pacific Crest Trail on the east.

F. ENVIRONMENTAL OR RESOURCE IMPACTS ASSOCIATED WITH NATIONAL RECREATIONAL TRAIL DESIGNATION

Impacts of designation of both the Western States and the Tevis Cup Trails are described in the Environment Assessment approved on January 17, 1979. This report is incorporated by reference. The primary purpose of a National Recreation Trail is to provide for outdoor recreation uses. The act of designation of a National Recreation Trail will not produce any significant adverse changes or modification of existing uses or management along this trail. Recreation use will be expected to increase gradually with increased publicity about the trail, but these increases are not expected to significantly alter existing uses nor have any significant adverse environmental or resource impacts. There is a need for some minor relocation and reconstruction to accommodate existing uses. This work would still be needed without designation.

G. RECOMMENDATION

Based on the Environmental Assessment (EA) completed in 1979, and review of that EA, along with the public input that the Forest has received both as a result of review of the Draft Forest Plan and at meetings related specifically to management of the trail, designation of both the Western States and the Tevis Cup Trails to the National Recreation Trail System is recommended when rights-of-way (ROWs) across private land have been secured. In the interim, the Trails will be managed in a manner compatible with National Recreation Trail status. In addition, it must be recognized that although neither trail qualifies for National Historic or Scenic Trail status, the trails do have historic and scenic values and significance to some users, and strong considerations should be given to maintaining the integrity of these qualities in management decisions.

Within one year of approval of this Plan, a Trail Management Plan will be developed and will include at least the following:

- 1) Broad trail management objectives.
- 2) Action plan or schedule to secure all necessary ROWs
- 3) Trail project priority listing and proposed scheduling.
- 4) A schedule to nominate the qualified seven-mile segment of Western States trail to the National Register of Historic Places.

APPENDIX K

IDENTIFICATION OF LANDS TENTATIVELY CAPABLE, AVAILABLE, AND SUITABLE FOR TIMBER MANAGEMENT

I. INTRODUCTION

Section 6(g)(2)(A) of the Resource Planning Act of 1974, as amended by the National Forest Management Act of 1976, is quoted as follows:

"Require the identification of the suitability of lands for resource management."

Section 6(g)(3)(A) states that guidelines for land management plans developed to achieve the goals of the program (RPA) which insures consideration of the economic and environmental aspects of various systems of renewable resource management, including the related systems of silviculture and protection of forest resources, will provide for outdoor recreation (including wilderness), range, timber, watershed, wildlife, and fish. The land suitability assessments required under the RPA/NFMA planning process state there shall be a systematic interdisciplinary approach to achieve integrated consideration of physical, biological, economic, and other sciences.

The Act provides very little direction to the form which this 'systematic interdisciplinary approach' plan shall take. The Secretary is directed under Section 6(g) to issue regulations which set forth the process for developing land and management plans, and which provide guidelines and standards for analyzing suitability of various forms of resource management

Section 219.3, Definitions of National Forest Management Act Regulations (9/17/79), and the amended version of 36 CFR 219 (1/1/82), provide the same definition of suitability as follows:

"The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of economic and environmental consequences and the alternative uses forgone. A unit of land may be suitable for a variety of individual or combined management practices"

Furthermore, under 36 CFR 219.3, the National Forest Management Act Regulations (9/17/79) and the amended Regulations, effective 11/1/82 and referenced above, state capability as follows:

"**Capability:** the potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils, and geology, as well as the application of management practices such as silviculture or protection from fire, insects, and disease"

In concurrence with the TNF Management Team's recommendation, the Forest Supervisor approved the process titled, 'Guidelines for Identification of Suitable Practices (7/23/80, revised 2/81)' as documented in the 'Tahoe National Forest Reference Book of Practices', specifically, page A7 of the Appendix. This process emphasized that it was a guideline for the identification of capable and suitable lands for resource management. It also indicated that since capability determination is clearly linked with suitability, guidelines for identifying capability and suitability are necessary.

II. PURPOSE

There are three purposes for identifying available, capable, and suitable criteria for each resource: inventory, management potential, and priorities for allocating and scheduling prescriptions.

Inventory of lands that are currently available, capable, and tentatively suitable for each resource activity or opportunity is necessary to determine how much (acres of) land we have for different resources. In some instances we know that certain lands are currently being used to support a specific resource or opportunity; e.g. cross-country skiing. We need to determine exactly what the intrinsic or inherent characteristics (capability criteria) are for these lands that make them desirable and capable to support cross-country skiing. After we determine which lands are capable for supporting cross-country skiing, we would need to determine which ones are available. Availability was determined by legislative or administrative actions; e.g., certain areas of the Onion Creek Experimental Forest, established for watershed research, such as experiments determining depth of snow, etc., would not be compatible with cross-country skiing. Therefore, cross-country skiing would probably be prohibited.

Following the determination of the criteria for available, capable, and tentatively suitable lands, they were documented on the "TNF Capability/ Suitability Criteria" form with necessary supporting narratives. These criteria will next serve the second purpose to determine the resource potentials on the Forest.

Identification of the existing resource potential on the Forest for any particular resource activity or Opportunity using the ACS criteria identified above will display the extent to which the Forest can meet expected future resource demands. The TNF Planning File, other resource data bases (maps, computer programs, etc.) and knowledge of the ID and Management Teams will be used to identify the lands that are tentatively available, capable, and suitable for this potential improvement, development, or opportunity.

Prioritizing the forest land for resources tentatively suited for the land will ultimately result in the final decision of the best management prescription for each area. This is not only a complicated analytical process, but also involves a great deal of common sense. FORPIAN will provide some of the information for this allocation, particularly for resources with quantitative information in the model. The Management Team will make the final decision augmenting FORPIAN with a well thought out, logical, and documented planning process.

III. PROCEDURE

Members of the Management Team selected resource practices, activities, and opportunities for which available, capable, and suitable criteria were developed.

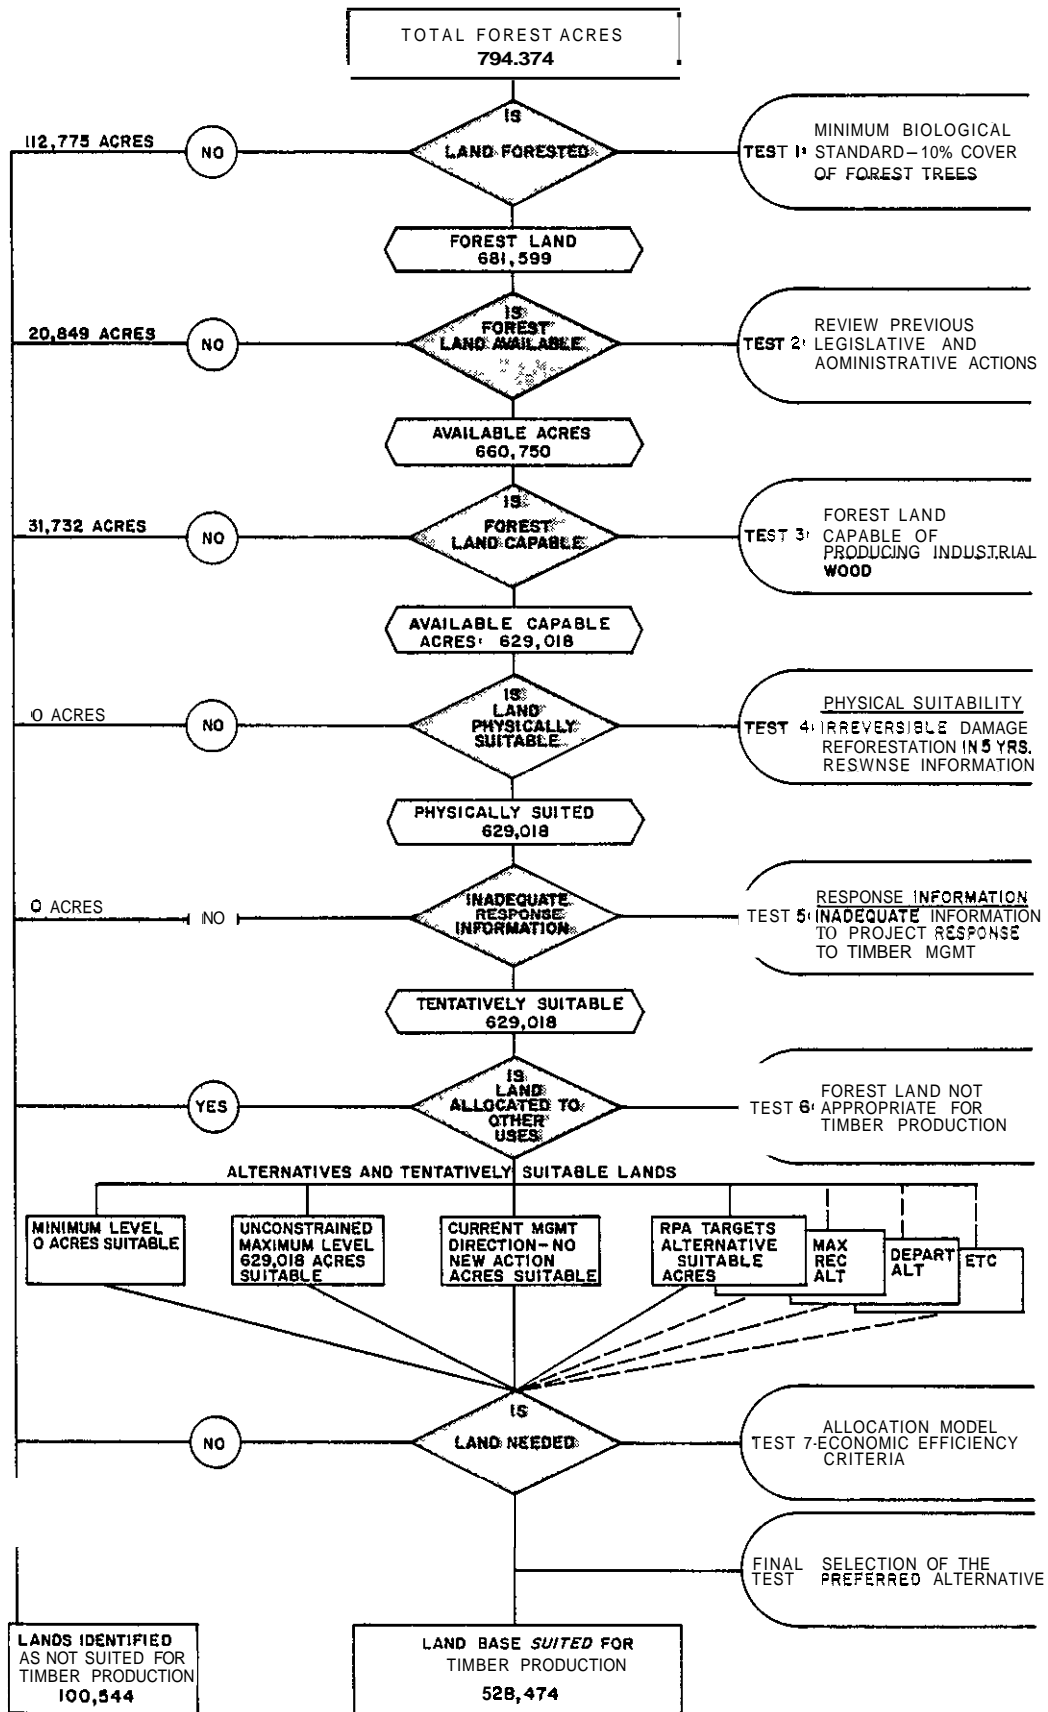

The three major headings for which criteria were developed are recreation, fisheries and wildlife, timber and range (including roads and fuels). This appendix deals exclusively with the timber resource.

IV AVAILABLE, CAPABLE, AND SUITABLE CRITERIA

The following is the list of available, capable, and suitable criteria developed for the timber resource as determined appropriate by the ID and Management Teams. These criteria were recommended for approval by the Management Team and approved by the Forest Supervisor on February 22, 1982. Some of these criteria differ in format based on WO and RO requirements. For example, the timber ACS criteria involve narratives describing the criteria along with acreage figures.

As stated earlier in this document, the purpose for the tentative identification of available, capable, and suitable criteria is in the development of prescriptions and the final resolution of conflicts between competing resources or activities. A compatibility matrix was completed and approved by the Forest ID and Management Teams in February of 1981. The purpose of this compatibility matrix was to identify which practices or activities were incompatible with other practices or activities. This is documented in the Practice/Compatibility Matrices and Guidelines in the 'Reference Book of Practices', issued May 1981.

Figure K.1 - Process of Identifying Lands Suited for Timber Production

V. POLICY REQUIREMENTS

The TNF identified all lands available, capable, and suitable for timber production on 1:24000 scale color aerial photographs. These land classifications were transferred to 1:24000 scale primary base topographic maps in the form of timber type designations. The aerial photographs and timber type maps are part of the planning records filed at the Supervisor's Office in Nevada City. The timber type maps along with other resource maps were used to establish capability areas for the Forest plan map (see TNF Planning File, August 1988). The policy for identifying timber resource land suitability is described in FSM 2412, 1/84 Amendment 134.

VI. TIMBER RESOURCE LAND SUITABILITY

Tahoe National Forest System lands were analyzed in the systematic process required by FSM 2412. See Figure K.1. All 794,374 acres within the National Forest boundary were classified using 5/10/85 Planning File data in the following categories:

A Forest and Nonforest Land

1. Nonforest Land

The TNF identified land that has never supported forests and lands formerly forested where use for timber utilization is precluded by development for other use. [Note: Includes areas used for crops, improved pasture, residential or administrative areas, improved roads of any width and adjoining clearings, and powerline clearing of any width. If intermingled in forest areas, unimproved roads (the Forest includes approximately 15,000 acres of unimproved roads that are less than 120-foot wide. (See FSM 2410.5--3)) and nonforest strips must be more than 120-foot wide, and clearing more than ten acres in size to qualify as nonforest land.] The nonforest land is classified as land not suited for timber production.

Table K.I lists nonforest lands which are classified as not suited for timber production.

TABLE K.I - TAHOE NATIONAL FOREST NONFOREST LAND

Stratum *	Description	Acres	% of Nonforest Land
NW	Water	10,124	9.0
GX	Grass	6,974	6.2
SX	Mixed brush	64,535	57.2
NB	Barren (includes improved roads)	30,910	27.4
CL	Cultivated	119	0.1
ND	Urban	113	0.1
	TOTAL NONFOREST	112,775	100.0

* Strata labels used throughout this appendix are described in Appendix H of the Forest Plan.

2. Forest Land Land at least 10-percent occupied by forest trees of any size or formerly having had such tree cover and not currently developed for nonforest use. Lands developed for nonforest use include areas for crops, improved pasture, residential or administrative areas, improved (constructed) roads of any width and adjoining road clearing, and powerline clearing of any width. The term occupancy, when used to define forest land, shall be measured by canopy cover of live forest trees at maturity. On the TNF, forested land includes the following.
 - a. All forested land with at least ten percent crown closure of forest trees as viewed on the 1977 color 1:24,000 aerial photography.
 - b. Reforestation backlog lands identified by Ranger District field inventories and coded into the TNF planning file as BL
 - c. Current clearcuts coded as NX in the TNF planning file.
 - d. Release and precommercial thinning backlogs identified by Ranger District personnel and coded into the planning file with appropriate backlog codes and not containing merchantable timber.
 - e. Existing plantations as coded into the TNF planning file as MPL, RPL, or EPL

Timber type maps were updated in 1980 and 1983 to reflect major changes from timber harvest, such as new plantations. Note: Strata acreages in Appendix H of the Forest Plan are from the original 1980 inventory and do not reflect type map updates.

Table K.2 lists the forest land on the Tahoe National Forest.

- B. **Forest Land Withdrawn From Timber Production.** Forest land which has been legislatively withdrawn or administratively withdrawn from timber production by the Secretary or Chief of the Forest Service is not available. Forest land not available is classed as not suited for timber production. Lands currently designated
 1. The Onion Creek Experimental Forest was established under Reg. U-4, 12/4/58, by Acting Chief Harper for watershed research purposes.
 2. The North Fork American Wild River was classified by Congress (P.L. 95-625, 11/10/78, amended P.L. 90-542, 10/2/68), and subsequent Management and Development Plan 10/3/79, 'precludes cutting of trees except when needed in association with a primitive recreation experience.' (North Fork American Wild River Management and Development Plan. October 3, 1979)
 3. The California Wilderness Act of 1984 designated 18,705 acres of the Granite Chief RARE II Area as Wilderness.

TOTAL TNF FOREST LAND NOT WITHDRAWN FROM TIMBER PRODUCTION - 660.750 ACRES.

- C. **Forest Land Incapable of Producing Industrial Wood.** Lands that are not capable of producing crops of industrial wood (industrial crops of wood are conifer sawlogs with dimensions defined in the Regional Guide.) are by definition to be classified as unsuitable for timber production. Species of trees that are not currently utilized or not expected to be utilized within the next 10 years constitute the primary criterion for assigning lands to this category. Incapable forest land is classed as land not suited for timber production. Lands classed as nonproductive forest land on the TNF are indicated in Table K 4 and will be considered as not capable of timber production for industrial wood products

TABLE K.4 - TAHOE NATIONAL FOREST INCAPABLE FOREST LAND

Stratum	Description	Acres	Nonproductive Forest Land
HA HL	Hardwoods - Aspen Hardwoods - Noncommercial species, i.e., liveoak	75 24,049	0.3 75.0
HB	Hardwoods - Commercial species i.e., blackoak, madrone, tanoak. NOTE: Even though the label describes these forested lands as 'commercial species,' they are considered as nonproductive forest land for this planning period. They are potentially commercial hardwood species. Current use for these species include fuelwood, chips, and some sawlogs.	5,650	17.8
KK	Knobcone pine - Noncommercial species	285	0.9
KF	Juniper or pinyon pine - Non-commercial species	1,534	4.8

	TOTAL NONPRODUCTIVE FOREST LAND	31,732	100.0

TOTAL AVAILABLE AND CAPABLE FOREST LAND FOR TIMBER PRODUCTION - - 629,018 ACRES

D. **Physically Suitable Forest Land.** Determination of suitability is the process of ascertaining 'the appropriateness of applying certain resource management practices to a particular area of land, as determined by analysis of economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices' (219.3). Lands capable and available for timber production as previously described are evaluated for physical suitability utilizing a two-stage test (219.12(b), and FSM 2412 14).

All timber producing lands capable and available were evaluated for two tests of physical suitability. The first test was to determine if technology is available that will ensure timber production, including harvesting, from the land without irreversible resource damage to soil productivity or watershed condition. Availability of technology was judged on whether technology is currently developed and available for use. This is not an economic test, and the technology did not have to be available in the TNF. The second test for physical suitability is whether there is reasonable assurance that such lands can be adequately restocked within five years after final harvest.

1. Test 1 - Is technology available that will ensure timber production, including harvesting, from the land without irreversible resource damage to soil productivity or watershed condition?

The test determining the potential for irreversible damage to soil productivity found that no productive forest land could be classed as not suited for timber production. This determination was based upon consideration of current technology, available information and research.

data, soils resource information, current harvesting and post-sale practices and impacts, lack of land instability, and required erosion control practices.

The second aspect of this test concerns irreversible damage to the watershed condition. Considering all of the factors described above plus the requirements contained in Best Management Practices and existing water quality standards, no productive forest land is classified as not suited for timber production.

As a result of the first test of physical suitability, no productive forest land on the TNF is classed as not suited for timber production.

2. Test 2 -The second test for physical suitability is whether there is reasonable assurance that such lands can be adequately restocked within five years after final harvest. The criterion for determining adequate restocking and guidelines for determining final harvest are found in FSM 1922.24(f) as follows.

When trees are cut to achieve timber production objectives, the cuttings will be made in such a way as to assure that lands can be adequately restocked within five years after final harvest. Research and experience indicate that the harvest and regeneration practices planned can be expected to result in adequate restocking. Adequate restocking means that the cut area will contain the minimum number, size, distribution, and species composition of regeneration as specified in regional silvicultural guides attached to the Forest Plan for each forest type. Five years after final harvest means five years after clearcutting, five years after final overstory removal in shelterwood cutting, five years after the seed tree removal cut in seed tree cutting, or five years after selection cutting.'

The minimum number of trees per acre for adequate restocking was established in the Regional Guide by Forest type as follows

Forest Type	R-5 Site Class	Number of Trees Recommended	Minimum Acceptable for Certification
Ponderosa Pine	I	200	150
	II	200	125
	III	150	100
	IV	125	75
Red & White Fir	All	300	200
Douglas-fir	All	225	125
Mixed Conifer	All	200	150
Lodgepole Pine *	All	200	150

* The Regional Guide did not establish minimum stocking goals for lodgepole pine type.

Productive forest lands capable and available for timber production are considered physically not suited for timber production if they cannot be reforested according to the standards described above.

Analysis of previous reforestation efforts indicate all productive forest land on the TNF can be reforested in accordance with the established standards. This determination is based upon consideration of current reforestation practices; improvements in nursery technology and seedling physiology; planting stock processing from the nursery to the planting site, local studies concerning reforestation of harsh sites; planting site requirements necessary for seedling survival and growth, and use of the shelterwood cutting method to aid in reforesting difficult sites

Reforestation problems on the TNF have been associated primarily due to inadequate site preparation or lack of prompt control of competing vegetation. The competing vegetation determines what plants are allowed to use the water stored in the soil profile. Available technology for discriminating against undesirable plants competing with conifers for survival and growth include site preparation and release using mechanized equipment, selective herbicides, manual cutting, grazing by cattle and sheep, fire, and combinations of these methods

Under this second test of physical suitability, therefore, all capable and available productive forest land is tentatively suitable for timber production.

TOTAL FOREST LAND CAPABLE AND AVAILABLE FOR TIMBER PRODUCTION AFTER THE PHYSICALLY SUITABLE TEST - - - - - 629,018 ACRES.

- E Inadequate** Response Information. Forest land shall be classified as unsuitable for timber production if there is not adequate information available, based on current research and experience, to project responses to timber management practices. These lands shall be identified as needing further inventory, research, or information and shall not be considered as part of the tentatively suitable land base until such time that adequate response data are available. These lands included forest types such as pinyon-juniper, knobcone, digger pine, and sites with less than ten percent crown closure. These forest lands were eliminated from the suitable land base as incapable forest land.

TOTAL FOREST LAND CAPABLE AND AVAILABLE FOR TIMBER PRODUCTION AT THE INADEQUATE RESPONSE INFORMATION TEST - - - - - 629,018 ACRES.

- F. Tentatively Suitable Forest Lands** Tentatively suitable forest lands include all 629,018 acres determined available, capable, physically suited, and having adequate response information from the criteria previously described. Table K.5 indicates the tentatively suitable forest lands by stratum for the TNF

VII. FINANCIAL ANALYSIS

A. Introduction. The financial analysis test of forest land for suitability does not by itself classify land as not suited for timber production. The purpose of the test is not to say that a single analysis area (e.g., reforestation areas on slopes greater than 30%) is not economically efficient. The purpose of the analysis is to organize capable, available, and tentatively suitable timber producing lands into analysis areas that significantly affect timber management costs and values at various levels of management intensities (prescriptions). Capable and available forest land will be considered as economically suitable for timber production if, and only if, it is included in the set of lands that are efficient in meeting the timber production goals for the Forest Plan

Lands on the Tahoe National Forest were organized into approximately 80 separate analysis areas (see Appendix E, The Modeling and Analysis Process, FORPLAN, for complete details) Following is a description of each level identifier and a brief discussion on how it will be used to effect economic efficiency and suitability for timber productions

B. Level identifiers.

1. Level I - Land Designation. Special areas within the TNF such as Granite Chief Wilderness, recreation development sites, ski areas, etc., where timber management activities are precluded or have special cost factors associated with management of the timber resource.
2. Level II - Special Land Designations. Specific areas such as special use areas, research sites, developed recreation sites, etc., are displayed in this identifier. Such land areas can be unsuited for timber production due to other multiple-use reasons depending upon the theme and objective of the alternative.
3. Level III - Access or designated land type. Lands are described as being currently accessed or not accessed. Lands that are accessed will require road reconstruction and maintenance. Lands unaccessed will require new road construction and maintenance. Each has a separate cost per mile and will be included as a portion of the cost analysis for the economic efficiency determination.
4. Working Group - Forest type classification. Affects the timber yield values for existing and regenerated timber stands.

5. Land Class - Represents the average slope class of an analysis area. Three slope group classifications are used and affects the following cost. Logging, post-sale treatments, and road construction, reconstruction, and maintenance.
6. Condition Class - Size class of the existing timber. Affects the value of the existing timber and applicability of prescription

For example, M3P is not suitable for a shelterwood prescription because of a lack of suitable seed trees.

Timber producing lands are divided by these six analysis area characteristics for FORPLAN computer analysis. When a certain resource management emphasis and prescriptions are applied to each analysis area, the FORPLAN program analyzes and displays economic data, such as present net value (PNV), discounted cost, and values for the lands economically efficient in meeting the objective of the alternative under consideration. (See resource management emphasis for FORPLAN for further information.) If lands with a marginal or low economic opportunity are not necessary to solve the objective, they will not be selected as suitable timber producing lands.

Following is a PNV analysis of two analysis areas to demonstrate the relative economic values of the best and worst cases. Analysis area one is an Undesignated, Accessed, Mixed Conifer, 6 size class, good stocking, on 0 to 30 percent slope. Analysis area 2 is Undesignated, Unaccessed, Eastside Pine, 3 size class, sparse stocking, on 51+ percent slope, without the use of herbicides. The economic analysis uses a 4 percent rate for discounting as described in FSM 1971.51.

TABLE K.7 - ECONOMIC ANALYSIS OF SAMPLE ANALYSIS AREA 1 representing stratum M6G, 0 to 30 percent slope group, and accessed. A 4 percent interest rate was used for discounting All values, cost and yield are per acre.

APPENDIX L

MAJOR SILVICULTURAL SYSTEMS AND THEIR APPLICATION

INTRODUCTION

This appendix describes the major silvicultural systems used in land management planning for the Tahoe National Forest, and the advantages and disadvantages of each, *considering both* biological and managerial perspectives. Additionally, almost all of the information in this appendix applies to selecting an appropriate silvicultural system for a particular stand.

Silvicultural systems are used to manage forest stands. A **silvicultural** system is a planned sequence of treatments for controlling the species composition and structure of the vegetation during the life of a stand. A stand is a community of trees sufficiently uniform to be distinguishable as a silvicultural or management *unit*. Typically, stand sizes vary from about 5 to over 30 acres on National Forest System lands.

Management objectives for stands typically are **combinations** of forest products and amenities. An example is: specific amounts of livestock forage, water runoff, and wood products; kinds of wildlife habitat; and specific scenic view qualities. No single silvicultural system can produce all desired combinations of products and amenities from a particular stand, or from a National Forest.

Forests are managed by using combinations of silvicultural systems to achieve the forest management objectives. All of the silvicultural systems discussed here are used in the National Forests in California. The combinations vary greatly, depending on the characteristics of local forest ecosystems and differing management objectives.

Selection of the appropriate silvicultural systems occurs at both the National Forest land management planning level and Ranger District project level. The Forest's selection is based on a broad match of silvicultural systems with the overall planning objectives and ecological characteristics of broadly-defined land classes. Examples of land classes are: areas capable, available, and suitable for growing commercial wood products; streamside management zones; and spotted owl habitat management areas. At the Ranger District, project-level selection of silvicultural systems is typically made by a certified silviculturist. Choices are based on matching the attributes of the silvicultural systems with specific management objectives and the ecological characteristics for specific stands.

DESCRIPTIONS OF THE SILVICULTURAL SYSTEMS

A silvicultural system typically includes cutting trees, growing new trees, and controlling competing plants. Cuttings are classified as regeneration cuttings (those that help to replace stands), and Intermediate cuttings (those that maintain or improve the character of existing stands).

Silvicultural systems are not just the creation of foresters; rather, they are adaptations of natural occurrences. Nature makes 'regeneration cuttings' by means of fire, insects, disease, wind, and other phenomena by removing a single tree, a small group of trees, a stand, or sometimes a whole forest.

Regeneration cuttings strongly influence stand Characteristics and management options. Therefore, the 5 major silvicultural systems are named after them: clearcutting, seed-tree, shelterwood, **single-tree selection**, and **group selection**. Each of these systems includes regeneration cuttings to establish new tree seedlings or sprouts, and intermediate cuttings (see glossary) to develop the desired stand characteristics, such as species composition, spatial distribution, and plant vigor.

The clearcutting, seed-tree, and shelterwood systems are even-aged systems: this means that all of the trees in the stand are about the same age for almost all the life of the stand. The single-tree and group

selection systems are uneven-aged systems: the trees in the stand differ markedly in age, with at least three major age classes present. Uneven-aged stands have no beginning or end points in time.

Even-aged Systems

Clearcutting is the harvesting, in one operation, of all merchantable trees in a stand or a larger area to reestablish a new even-aged stand. The new stand may be created by natural processes such as seeding from trees in adjacent stands, or by sprouting from the stumps or roots of the cut trees. The new stand can also be created by man through broadcast scattering of seeds or by planting seeds or seedlings. In California, clearcut stands are usually regenerated by planting seedlings. (The clearcutting silvicultural system is illustrated in Figure 1.)

Clearcutting does not necessarily mean that all unmerchantable trees are removed. Where feasible, high-quality unmerchantable trees are saved to become part of the new stand. A 1987 survey showed that on gentle terrain in the National Forests on the western slope of the Sierra Nevada mountains, high-quality unmerchantable trees are being retained on an average of about 10 and 20 percent of the acres being regenerated to ponderosa pine, and to red fir or white fir, respectively.

The shelterwood system (Figure 3) requires leaving sufficient trees per acre (typically 10 to 20) during the regeneration cutting to provide an environment that protects (shelters) the seedlings of a new even-aged stand. Protection may be needed from excessive moisture stress or frosts in some forest areas. The new stand can be created by the natural or artificial processes described above.

Regeneration by planting seedlings under shelterwoods is a common practice on National Forest lands in the Region. The shelterwood trees are harvested following establishment of the seedlings of the new even-aged stand. The shelterwood system is the second-most commonly used even-aged system on National Forest lands in Region 5, after the clearcutting system. The shelterwood system is most commonly used in stands where red or white fir are to be regenerated.

The seed-tree system (Figure 2) requires leaving a few good seed-producing trees per acre (typically about 3 to 10) during the regeneration cutting. These trees produce the seed needed to establish a new even-aged stand. Following seedling establishment, the seed trees are harvested. This system has seldom been used for intensive timber management on the Tahoe National Forest. The primary reasons are frequent unreliability of natural regeneration, invasion of cleared lands by unwanted vegetation (particularly shrubs), and the poor economics of harvesting the few seed trees after natural seedlings were established.

Uneven-aged Systems

In the single-tree selection system (Figure 4), each tree is evaluated for its contribution to the desired characteristics of the uneven-aged stand. Regeneration and intermediate cuttings are usually done in one operation. The desired seedlings or sprouts grow in the spaces created by harvesting of individual trees.

Repeated selection cuttings, part of the single-tree selection system, have been used frequently to manage National Forest lands, particularly in the Sierra Nevada and Cascade Mountain Ranges. A major shift to using the clearcutting or shelterwood systems has occurred over the last two decades. The primary reason is that the selection cuttings caused significant understocking in many stands, thereby reducing productivity. Many examples of poor selection cuttings exist in California. This cutting occurred under the guise of the single-tree selection system. High quality, large trees were cut, leaving inferior, small trees. Genetic principles were ignored. Many stands were left understocked with slow-growing, small trees that are more susceptible to attacks by insects and diseases. In these situations, establishing a new even-aged stand typically is the most efficient way of regaining desired productivity levels and other stand qualities.

The group selection system requires harvesting trees in small groups (less than about 2 acres). The openings created in the stand resemble miniature clearcuts. The uneven-aged stand consists of a mosaic of even-aged groups. Thus, the group selection system uses the principles of even-aged systems described above to manage much smaller units of land. Currently, the group selection system is used less frequently than the single-tree selection system on the National Forest lands in Region 5.

Even-aged systems are more practical than uneven-aged systems for intensive management of wood products. The reasons are explained in the section below on 'MANAGERIAL CONTRASTS..'

TIMBER YIELD AND REGULATION OF FORESTS AND STANDS

Timber yield is the amount of wood that is harvested periodically from a specified forest area. The maximum yield allowed from a National Forest for a planning period (typically one decade), is called the allowable sale quantity, or ASQ. By Federal law, the allowable sale quantity generally cannot exceed the long-term, sustained yield capacity of that Forest to grow wood. Within each National Forest, stands are managed by silvicultural systems to achieve continuous production of the allowable sale quantity.

When this continuous production level is achieved, the Forest and stands are said to be 'regulated'. Where the single-tree selection or group selection silvicultural systems are used, each regulated stand would produce approximately the same yield from each harvest, which would occur about every 10 years. In contrast, where the even-aged systems are used, yields from each harvest in a regulated stand would not be equal, but the average yield for the Forest would be the same. The conversion of wild stands to regulated stands in many of California's forests has just begun. The goal of regulation will take many decades to achieve. No major forest in California has yet been regulated.

BIOLOGICAL CONTRASTS AMONG FORESTS AND STANDS MANAGED BY DIFFERENT SILVICULTURAL SYSTEMS (The key biological contrasts discussed in this section are summarized in Table 1.)

Appearance

- **Variation** In tree age. A forest managed by even-aged silvicultural systems consists of a mosaic of even-aged stands. Every age class would be represented in a regulated forest, and each age class would be represented by approximately the same number of stands. A regulated forest managed by the group selection system would resemble forests managed by the even-aged silvicultural systems, except that the even-aged components (groups) would be much smaller and more numerous. In contrast, each stand in a regulated forest managed by the single-tree selection system would have trees of many ages (perhaps all ages).

The oldest (or largest) trees in any managed forest depend primarily on the management objectives, not on the silvicultural systems. In particular, the amounts of large- or old-growth to be produced or maintained depend more on the willingness to forego yields than on the kinds of silvicultural systems used to manage stands.

- **Variation** In developmental stages. In the even-aged and group selection systems, all stages of forest development are present in the forest, including grasses, forbs, shrubs, tree seedlings, and larger trees. Each stage is represented by entire stands or groups. In contrast, in the single-tree selection system the areas dominated by small plants such as grasses, forbs, or shrubs are commonly very small (for example, less than one-hundredth of an acre), but they typically occur somewhere in every stand. In a regulated forest, the total area occupied by each stage should be about the same, regardless of the silvicultural system.

-- Occurrence of shade-tolerant and intolerant plants. Even-aged and group selection systems favor plants that can be readily established and grow well in full sunlight (shade-intolerant plants). These include grasses, most forbs and shrubs, and many of the most valuable commercial tree species, such as ponderosa pine and Douglas-fir. The single-tree selection system favors plants that can be readily established and grow well at low light levels (shade-tolerant plants). Examples in California forests are many ferns; some grasses, forbs, and shrubs; many non-commercial hardwood tree species; and a few commercial conifer tree species, such as white fir and incense-cedar.

Figure L.1: Clearcutting

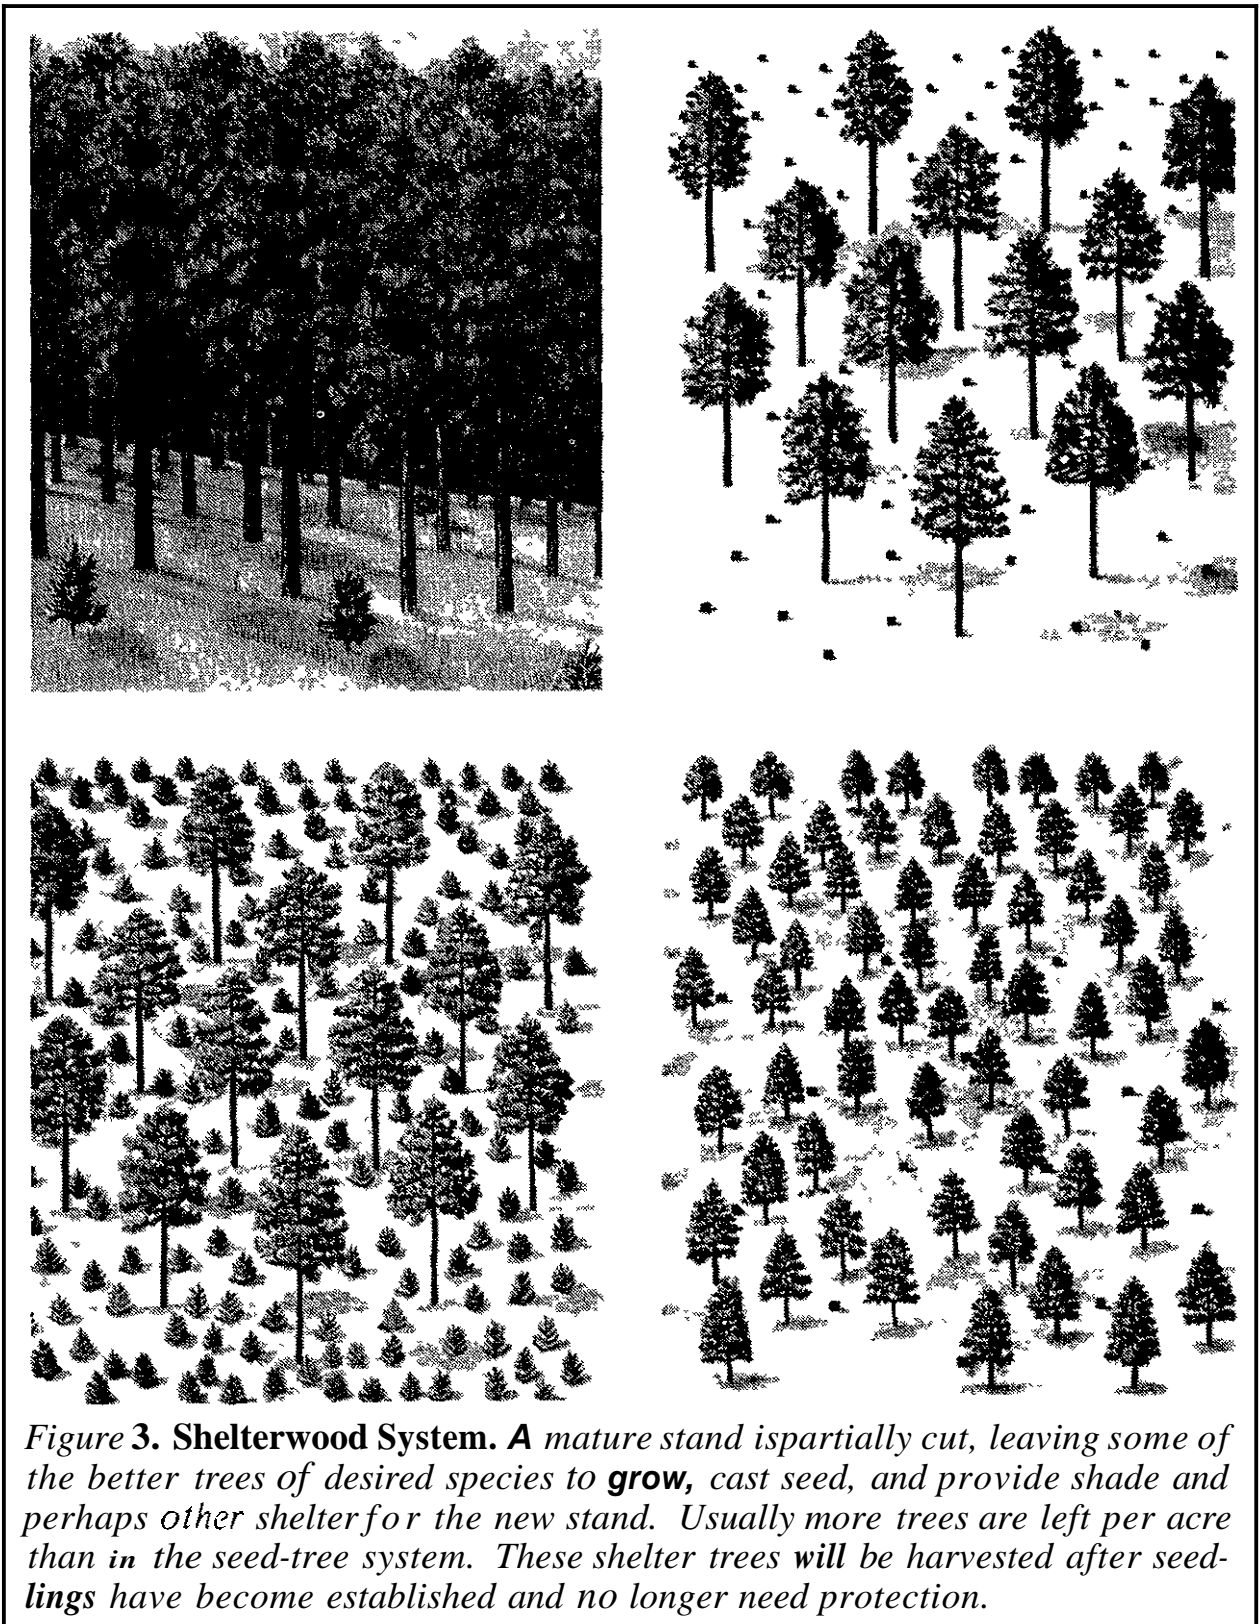

*Figure 1. Clearcutting. Part of a mature stand is cut, removing all trees. A new stand arises from seeds of surrounding trees or from sprouts sent up by roots or stumps. Seedlings may also be planted or seeds broadcast. When the new trees are well on their way in the unobstructed light of the clearing, a neighboring stand of mature trees is cut in turn. (The illustration is from *The Secret Life of the Forest* by Richard M. Ketchum, copyright 1970 by American Heritage Press, and is used with the permission of McGraw-Hill Book Company.)*

Figure L.2: Seed-tree System

*Figure 2. Seed-tree System. The mature stand is logged, but enough trees are left to reseed the area. The seed trees usually are large and valuable, and may be harvested when they have fulfilled their purpose. Like clearcutting, the system favors light-demanding species. (The illustration is from *The Secret Life of the Forest* by Richard M. Ketchum, copyright 1970 by American Heritage Press, and is used with the permission of McGraw-Hill Book Company.)*

Figure L.3: Shelterwood System

*Figure 3. Shelterwood System. A mature stand is partially cut, leaving some of the better trees of desired species to **grow**, cast seed, and provide shade and perhaps other shelter for the new stand. Usually more trees are left per acre than in the seed-tree system. These shelter trees will be harvested after seedlings have become established and no longer need protection.*

Figure L.4: Single-tree Selection System

Figure 4. Single-tree Selection System. Cuts are made more often than in other systems, but since the entire stand is never removed, appearances are not much affected. Undesirable trees are removed, overly dense areas are thinned, and mature trees are harvested during each cut. Seedlings of shade-tolerant species develop wherever they can find room. The stand contains trees of many ages.

However, on low-quality forest lands where lack of available soil moisture or other soil conditions cause low plant densities, shading by trees is greatly reduced. There, shade-intolerant plants will persist if the single-tree selection system is used.

-- **Diversity of plant species** Species diversity depends on the biological and physical environments, on how the stands are managed under the different silvicultural systems, and evaluation standards of diversity

On moderate- to high-quality lands, stands managed by the single-tree selection system shift toward shade-tolerant species. In California, many stands and forests that were previously dominated by commercially more valuable pine and Douglas-fir now have large components of **less** valuable tanoak, madrone, or white fir. This process could reduce tree species diversity in such stands, compared with management by other silvicultural systems. The shift toward more shade-tolerant species also means that the species diversity of plants near the ground would eventually be lower in stands managed by the single-tree selection system.

The composition of commercial tree species may be significantly increased or decreased during stand regeneration, depending on the environmental conditions, availability of natural seed, selection of species to be planted, and the success of the plantings. If artificial regeneration fails in stands with mixed species, the diversity in the naturally-regenerated stand may be reduced significantly. Potential seed trees of some species could have been harvested, or only certain species (for example, white fir) could regenerate naturally under the brush that rapidly occupies newly harvested areas.

If both artificial and natural regeneration fail, the species diversity of commercial trees has been significantly reduced. The risk of a complete regeneration failure is least for the single-tree selection system. There is high probability **of** successful natural regeneration of all species where openings are small, seed sources are present, and ground environmental conditions are suitable for tree seedling establishment. The **risk** of **loss** of diversity in large openings can be reduced by planting all appropriate species, or by designating appropriate **seed** trees or **shelterwood** trees of mixed species.

--**Vertical diversity.** The vertical diversity in stands managed by the even-aged or group selection systems could be quite limited. Typically there is a single dominant layer of seedlings, saplings, or larger trees. However, usually there is considerable diversity in stands with larger trees because some trees are significantly taller and have fuller crowns than others. Full vertical diversity still occurs over the forest, but not in each stand or group. In contrast, the vertical diversity within each stand should be much greater in the single-tree selection system. Seedlings, saplings, and trees in larger tree classes should be seen from any point in the stand.

-- **Tree vigor.** If the stands are well managed, tree and stand vigor should be independent of silvicultural systems, with three exceptions. First, new seedlings in openings (particularly shade-tolerant species such as red fir and white fir) are heavily stressed by heat and lack of adequate water, until they develop good root systems. These stresses often cause heavy mortality (especially of natural seedlings, or of low-quality or mishandled or poorly planted seedlings from nurseries). Second, seedlings in openings are more susceptible **to** damage or mortality from frosts, particularly at high-elevation sites. Where seedling mortality (even of high-quality or properly handled and planted nursery seedlings) is expected to be excessive, **use** of the single-tree selection, shelterwood, and group selection (where groups are small) systems are favored. Third, maintaining good vigor of small shade-intolerant species, such as ponderosa pine, can be very difficult in stands managed by the single-tree selection system. To promote vigor and growth of these trees, tree density may have to be reduced, which can significantly reduce timber yields.

Many stands on National Forest lands are severely infected with certain root diseases or dwarf mistletoes. It is very difficult and costly **to** maintain or improve tree vigor and productivity if the single-tree selection system were used. These root diseases and dwarf mistletoes infect other trees more easily when this system is used.

Table 1: Ratings of the Major Silvicultural Systems by Principal **Biological** Attributes

	CLEARCUTTING	SHELTERWOOD	SEED TREE	GROUP SELECTION	SINGLE-TREE SELECTION

c. Potential for conserving genes in a forest ²	○	○	○	○	○
Productivity (potential for producing biomass)	○	○	○	○	○

1 Exclusive of roads and natural openings such as meadows or rock outcrops

2 Assumes all harvested species are planted successfully, or will regenerate naturally, otherwise *Poor*.

3 Assumes no major fires; otherwise *Poor*

Genetic Resources.

-- **Conservation of genes.** Genetic diversity is basically unaffected when natural or artificial regeneration of commercial tree species is successful (Successful artificial regeneration means that appropriate procedures are used during seed collection to ensure a large genetic diversity in the collected seed) However, genetic diversity would be reduced if regeneration of a particular species were to fail repeatedly over broad areas.

-- **Quality of genes.** Where improperly applied, the single-tree selection system can lead to 'high-grading', which in turn reduces genetic quality for future wood production. High grading is the selective removal of the best trees (most rapidly growing, largest, and most valuable for wood), so that most regeneration comes from seed produced by the lower-quality, remaining trees.

The average genetic quality may be significantly lowered in a stand managed by the single-tree selection system because of higher rates of inbreeding. Some forest geneticists theorize that inbreeding would also increase under the shelterwood or seed-tree systems. Nearby trees of the same species usually are closely related, and they can pollinate each other. The natural seedlings should be even more inbred. In contrast, artificial regeneration or natural regeneration from edges of large openings reduces the probability of significant inbreeding. Large openings facilitate pollen movement from more distant, less closely related trees.

--**Productivity.** Scientific long-term comparisons of wood production using the different silvicultural systems have not been made anywhere in the world. This comparison will be possible many decades from now at Blodgett Forest, a University of California research facility. Theoretically, the total biological productivity (biomass) may be greatest for stands managed by the single-tree selection system. This is because of more continuous tree cover, compared to the other systems. However, merchantable stand growth and timber yields may not be higher for the single-tree selection system. Merchantable yields are strongly influenced by managerial factors.

MANAGERIAL CONTRASTS AMONG FORESTS AND STANDS MANAGED BY DIFFERENT SILVICULTURAL SYSTEMS (The major managerial contrasts described in this section are summarized in Table 2)

Public Concerns. In the last two decades the clearcutting system and to a lesser extent the shelterwood and seed-tree systems, have generated controversy in the United States and Europe

There are at least six major concerns in the Tahoe National Forest:

- (1) Clearcut areas are regarded as visually unattractive
- (2) The risks of significant soil erosion and loss of soil productivity are thought to be much greater for the clearcutting system.
- (3) Regeneration of clearcut stands is thought to be unreliable.
- (4) The risks of significant genetic losses are thought to be much greater for the clearcutting system because new stands may be monocultures
- (5) The use of chemical herbicides (strongly opposed by some groups and individuals) is thought to be much greater if even-aged systems are used, particularly the clearcutting system.
- (6) Artificial regeneration, particularly of even-aged stands, is thought to be too costly

All of these undesirable effects can occur under any silvicultural system. However, the risks of some are significantly different among certain systems. The concerns about genetic losses were addressed earlier in the sections on Diversity of plant species and Genetic Resources. The other five concerns are discussed in the following sections on Effects on Scenic Quality, Risks of Adverse Effects on Watersheds and Soils, Scientific Knowledge Base, Management Experience, Need for control of competing vegetation (Including the use of herbicides), and Treatment costs

Other managerial aspects of the silvicultural systems are also discussed in the sections below. They cover: risk of major wildfires; risk of damage by insect, disease, or wildlife pests, production of livestock forage; protection of archeological resources; administration of silvicultural projects; timber harvesting efficiency; genetic improvements in forests; and effects on fisheries and wildlife.

Effects on Scenic Quality. Uneven-aged silvicultural systems are usually better than even-aged systems for creating or maintaining natural-appearing landscapes. Uneven-aged systems apply treatments on a small scale. The treatments are also more selective and are well distributed in the forest. However, long-term maintenance of natural-appearing landscapes could be more difficult under the uneven-aged systems because natural wildfires are more difficult to control. (See the section on Risk of Major Wildfires.)

Where timber management activities are not permitted to be visually evident, the single-tree selection system may be the only feasible alternative. All silvicultural systems may be feasible where the management objective is to maintain the desired landscape character, depending on the circumstances. However, the uneven-aged systems would generally be better than the even-aged systems. All silvicultural systems may also be feasible where timber management objectives are dominant over visual quality objectives. Similarly, if the landscape character needs to be improved, any silvicultural system could be appropriate. For example, small or large temporary openings that blend with the topography, which are created by group selection or clearcutting regeneration cuttings, can help to achieve a pleasing landscape.

Risks of Adverse Effects on Watersheds and Soils These risks depend more on the characteristics of the watershed and soils, and on the care and quality of forest practices, than on the kind of silvicultural system used. Adverse effects associated with any silvicultural treatment can usually be avoided or mitigated. The major possible adverse effects are erosion, sedimentation in waterways, soil compaction, and loss of soil productivity through soil or nutrient loss.

The risks of significant, cumulative erosion and sedimentation effects in watersheds usually depend more on road design and location than on silvicultural treatments.

The risk of significant erosion within stands depends on how much protective vegetation and litter cover is removed, as well as on road design and location. This risk is generally higher for the clearcutting system because more cover is temporarily removed by clearcutting and preparation for seedling establishment. The risk is least for the single-tree selection system.

Extensive and frequent use of heavy machines can cause significant soil compaction of some soils. The risk of this occurring should not be different among the silvicultural systems.

The risk of soil nutrient losses is increased where vegetation or litter is cleared or high-intensity fires occur. Again, the risk due to clearing vegetation or litter is greater for the even-aged silvicultural systems. High-intensity fires may occur in any stand if controlled fires are used improperly. However, the risk of high-intensity fires is greater for the single-tree selection system because crown wildfires are more likely. (See the section on Risk of Major Wildfires.)

Scientific Knowledge Base. Knowledge is least for the single-tree selection system for National Forest lands in California.

-- Biological. Considerable research has been completed on the biological foundations for all of the silvicultural systems. Planting, natural regeneration, and genetic principles have been extensively studied for all systems. Research is more complete on early growth of young potential crop trees and control of competing plants for the even-aged and group Selection systems. Similarly, stand growth model research is more complete for the even-aged and group selection systems. There are no major differences in the knowledge base about intermediate cuttings or about insect and disease pest management among the silvicultural systems.

Table 2: Ratings of the Major Silvicultural Systems by Key Managerial Attributes

MANAGERIAL ATTRIBUTE	CLEARCUTTING	SHELTERWOOD	SEED TREES	GROUP SELECTION	SINGLE-TREE SELECTION
	<p>○ is Good, Excellent, or Many</p> <p>◐ is Moderate or Few</p> <p>● is Poor or None</p>

c. Potential for soaring hawks and eagles				○	○	○	◐ ²	● ³

1 Assumes gentle slopes; otherwise Moderate, but Poor for the Group and Single-Tree selection systems.

2 Assumes openings of about 1-2 acres; Poor if smaller

3 Assumes highly productive land: otherwise Moderate or Good

-- Managerial aspects. Research on the managerial aspects of California's forests has focused on the even-aged and group selection systems. Only in the last decade have concerted efforts been made to research the long-term practicality of the single-tree selection system. Earlier studies were not completed because of difficulties with controlling regeneration of some desired species, controlling stocking, or sustaining the desired stand structures and merchantable yields. This resulted in strong recommendations against the system by many forest research scientists. New interest has been generated by demands for continuous forest cover, maintenance of an unmanaged appearance, and for an alternative to management by the even-aged systems. However, several decades of management will be required before analyses of overall effectiveness can be made.

Research in the group selection system is also underway in California. It too will require several decades of treatments to achieve regulated stands.

Management experience. Timber harvesting has occurred in California for over 140 years. However, experience with managing forests with the goal of regulating potential yields has been limited to the last several decades. Regulation of National Forest lands has only involved the even-aged silvicultural systems, particularly clearcutting. However, extensive experience has been gained with all of the silvicultural systems in managing certain stands.

-- Single-tree selection. Most of the harvesting from National Forest and many private timber lands in California has been selection cuttings of large trees. These cuttings were typically made with no long-term plan for managing the stands by the single-tree selection system. This system can require cutting trees in all size classes during each operation. Regeneration from natural seeding was usually counted on. Also, growth of the young trees and the uncut smaller merchantable trees was counted on to offset the reduction in the forest inventory due to harvesting the largest trees. Unfortunately, repeated harvests of the largest trees have often caused undesirable results: understocked residual stands with lower quality, lower value trees. These stands will have to be regenerated using one of the even-aged silvicultural systems or the group selection system to reestablish full stocking of desired species.

-- Group selection. The group selection system was tried extensively on National Forest land in the Region about 20 years ago. Small openings were made to encourage natural regeneration, particularly of sugar and ponderosa pines. Special cutting guidelines were developed for different kinds of naturally-occurring groups of trees. The system, called Unit Area Control, failed for three reasons. First, the many small groups of natural regeneration could not be managed efficiently. They could not be monitored. Needed subsequent treatments were not made. The young trees did not grow well or died. Some groups could not be treated because of the higher costs of treating small areas. Second, the cutting guidelines could not be used consistently. There was great difficulty in determining which kinds of groups were actually present in the stand, and the location of their boundaries. Third, many of the small groups were unavoidably destroyed in later harvesting projects when large trees in adjacent groups were felled, or when logs were moved out of the stand. It is particularly difficult and costly to save small groups of trees on steep slopes from excessive damage during harvesting or preparation of the site for successful establishment of tree seedlings.

-- Even-aged systems. The oldest plantations on National Forest System lands in the Region are about 60 years old. Some are soon to be harvested and replaced, thus completing the cycle of an even-aged silvicultural system. Extensive experience has been gained in the regeneration, promotion of young tree growth, intermediate cutting, and regeneration cutting treatments for even-aged systems in all major timber types in the Region. Overall, artificial regeneration following clearcutting has been very reliable in ponderosa pine, Douglas-fir, and mixed conifer stands. Artificial regeneration has been significantly less reliable in red or white fir stands. The primary causes of planting failures are (1) difficulties with consistently producing high-quality seedlings in the nurseries and (2) planting when the environmental conditions are inappropriate.

The shelterwood system with natural or artificial regeneration is presently used in red or white fir stands where regeneration after clearcutting is expected to be unreliable.

Wood Production

-- Need for control of **competing** Vegetation (Including the use of herbicides). Control of competing vegetation is needed in all of the silvicultural systems to ensure establishment and good growth of tree

seedlings or sprouts. Some have theorized that less control is needed in the single-tree selection system. Under this system tree cover is more continuous, resulting in fewer competing grasses, forbs, and shrubs. However, these competitors cause significant moisture stress in the potential seedling and sapling crop trees (in addition to the substantial moisture stress caused by the larger trees), thereby reducing their survival and growth. There is no compelling theoretical basis for concluding that the need for control of competing vegetation should be reduced if the single-tree selection system were used. Certain commonly-occurring, major competing plants can retain good vigor when shaded by most conifers (such as manzanita, bear clover, tanoak, or madrone). Using the single-tree selection system would definitely not reduce the need for controlling competition from such plants.

Frequency of control treatments varies by silvicultural system. Treatments under the single-tree selection system could be needed somewhere in every stand as often as every 5 to 10 years. The average treatment frequencies in the other systems are much lower. For example, in any of the even-aged systems, up to about three treatments could be needed in the first ten years of a new stand. No additional treatments may be needed until the stand is regenerated -- a period that should exceed 50 years. Thus, the average period between treatments would be greater than 20 years. Regardless of the silvicultural system used, the total acres treated (and the total pounds of herbicide applied per acre, if herbicides were used) should be about the same over the long term.

The aerial application of herbicides (usually the most cost-effective, and frequently the most controversial, method of applying herbicides) could not be used in the single-tree selection system. Depending on topography and vegetation structure, it could also be impractical in the group selection system.

-- Treatment costs. The size of a treatment area is a major factor in determining treatment costs and managerial feasibility. Generally, costs per acre in intensively managed forests are higher when the treatment units are smaller. Therefore, the even-aged systems are the most cost-efficient, and the group selection and the single-tree selection system (in that order) are the least cost-efficient.

Regeneration by clearcutting is the most cost-efficient even-aged system. Shelterwood and seed-tree systems are less so, in decreasing order. The removal of shelterwood trees or seed trees, after the seedlings are established, is a second cost not required in the clearcutting system.

In theory, the total cost of natural regeneration should be less than for artificial regeneration. The costs of seed collection, nursery operations, seedling handling, and planting are eliminated. However, these savings are often offset by increases in pre-commercial thinning costs. Natural regeneration often results in much greater densities of trees than would be planted, or are desirable. Also, unreliable seed production by many commercial tree species often delays natural regeneration. This reduces wood productivity. When natural regeneration is delayed, the sites are occupied by competing plants, the control of which can be costly. Overall, artificial regeneration insures prompt reforestation of preferred species at desirable densities. If natural regeneration is used, the shelterwood and seed-tree systems are usually more cost-efficient than the uneven-aged systems. The reason is the economies of scale associated with larger treatment areas. Where artificial regeneration is used, the clearcutting and shelterwood systems are more cost-efficient, for the same reason.

- Achieving regulated forests, while maintaining Forest timber harvest levels. Regulation can be accomplished most easily with the even-aged or group selection silvicultural systems. There are two critical disadvantages of the single-tree selection system. First, foresters lack the detailed information about individual trees needing cutting on a stand-by-stand basis. There are tens of thousands of stands on a typical National Forest in California, with up to about ten thousand potential crop trees per stand. Currently, inventory data needed for the single-tree selection system are lacking for about two-thirds of these stands. Second, in the Mediterranean climate in California, large forest wildfires are inevitable. Reforestation after these fires creates many, new, even-aged stands. It is very difficult to regulate a forest under a single-tree selection system when substantial acreages of unplanned even-aged stands occur.

-- Planning, contracting, and record keeping. The many small units used in the uneven-aged systems makes for ineffective and costly operation and administration. If stands in a typical Ranger District were managed by uneven-aged systems, in excess of 50,000 separate areas would have to be inventoried, planned for, treated, and monitored. Even with computers the management complexity would be excessive.

Therefore, the extent to which uneven-aged management systems are used for intensive timber management will necessarily be very limited.

-- Timber harvesting. Five important aspects of timber harvesting are strongly influenced by the choice of a silvicultural system: (1) variability in sizes of harvested trees, (2) area to be harvested, (3) complexity of the harvesting treatments, (4) the probability of causing significant damage to trees to be left in the stand or adjoining stands, and (5) the probability of causing long-term root disease problems. The first three influence harvesting efficiencies, and the last two affect the vigor, tree stocking, and value of the residual stand.

There is wide size variation in trees harvested in each operation under the single-tree selection system. This reduces harvesting efficiency because logging equipment is size-dependent. However, this disadvantage could be insignificant in young-growth stands.

Harvesting in the single-tree selection system is much less efficient than for the other systems because more land must be treated in each operation to harvest the desired yield from the forest.

The complexity of harvesting treatments is also greatest in the single-tree selection system. Identifying which trees to cut, determining where they are to be felled, felling the trees in the designated areas, and removing the trees or logs out of the stand without damaging the residual trees can be very difficult and costly. In the single-tree selection system, cuttings occur as frequently as every five to ten years. In the other systems, only the intermediate cuttings are as complex. The regeneration cuttings in the other systems are more straightforward operations. Group selection and clearcutting are the most efficient.

Logging damage to trees left to grow in the stand is typically greatest for the single-tree selection system. It is very difficult to selectively harvest trees in dense stands without damaging many residual trees, particularly on steep slopes. Damaged trees are often infected by wood-decaying fungi that can persist in the soil for long periods, thus retaining the ability to infect new trees. The fungi reduce the windfirmness, vigor, commercial value, and stocking of residual trees. This characteristic is a particular concern in developed recreation areas where selection systems are often applied. Stands with red or white fir have an especially high probability of being infected with wood-decaying fungi when damaged.

-- Genetic Improvements in Forests. Genetic improvements to increase timber growth, improve tree form and wood quality, or increase resistance to disease and insect pests, depend primarily on planting trees with desirable genetic characteristics. Therefore, the potential for genetic improvement is greater for silvicultural systems that use artificial regeneration. The clearcutting, group selection, and shelterwood systems (if artificial regeneration is used) have the greatest potential for improving the genetic quality of forest trees. The single-tree selection system, with its natural regeneration and higher rates of inbreeding, has the least potential.

Risk of Major Wildfires. The even-aged systems (clearcutting in particular) are best for reducing the risk of major wildfires because the greater control of fuel distribution makes wildfire prevention and suppression easier and less costly. The single-tree selection system is least desirable because fires burn intensely and are more difficult to control. Openings that serve as fuel breaks occur less frequently in forests or stands managed by this system. Also, the multiple tree layers create fuel 'ladders', permitting ground fires to spread into the crowns of the large trees. Crown fires are more destructive and more difficult to control than ground fires. Finally, the use of prescribed fires to reduce the risks of large wildfires is most difficult and costly in the single-tree selection system.

Risk of **Significant** Pest Damage. Silvicultural treatments reduce risks by selecting appropriate tree species, by diversifying within and among stands, and by maintaining tree vigor. Diversification within stands is increased through use of multiple species or uneven-aged silvicultural systems. Vigor is promoted by preventing the trees and other plants from becoming too dense. Competing plants also provide habitat for animal pests such as pocket gophers and rabbits. Well-managed stands in all systems reduce the risk of significant pest damage. However, there are significant exceptions.

Risk of significant insect or disease damage to trees increases if the trees have been wounded. Many wounds occur during silvicultural treatments. Accidental scarring of trees can be caused by felling nearby

trees, or by bumping them with machines or logs moving through the forest. Risk increases with the frequency of stand treatments, particularly cutting. Cutting frequency is much higher for the single-tree selection system than for others, so the risk of significant insect and disease damage is highest.

Two serious diseases, dwarf mistletoes and some root rots, can be difficult, costly, and in some cases, impossible to control under selection systems. Damage from these diseases is most easily controlled by managing stands as wholes. Dwarf mistletoe plants can project seeds down on trees within about 100 feet horizontally, thereby infecting nearby susceptible species. Even-aged systems allow the manager to control damage from this pest through cutting treatments.

Many root disease fungi infect susceptible trees by root-to-root contact. Some root diseases start at time of harvest and spread to other trees in the stand. Control may require killing trees in a zone around the infected area. Uneven-aged management, particularly the single-tree selection system, can perpetuate root disease "centers" and spread infection.

Generalizations about wildlife pest damage and silvicultural systems are difficult. The major potential wildlife pests in the Region include pocket gophers, deer, porcupines, and rabbits. These animals feed in vegetation dominated by grasses, forbs, shrubs, or tree seedlings. Use of the even-aged or group selection systems can create large areas temporarily dominated by this kind of vegetation. This can cause higher densities of potential pests, which increases the risk of significant damage to potential crop trees. However, often the actual damage levels are not increased where this occurs.

Production of Livestock Forage and Browse. Even-aged systems and the group selection system are best for livestock production. Grasses, forbs, and shrubs used by livestock occur in the greatest quantity in openings. Management efficiency increases in large forage areas because livestock control and access is easier and less costly.

Protection of Archeological Resources. There should be no significant differences among the silvicultural systems in their risk of damage to undetected archeological resources. Damage depends more on the intensity and frequency of management treatments than on the kind of silvicultural system, particularly when large machines are used.

Effects on Fisheries and Wildlife Habitat. Fisheries habitat is most easily protected where the water quality is high, stream temperatures are kept moderate through shading, and where the runoff quantity is sufficient to maintain spawning areas. The single-tree selection or group selection systems are usually more advantageous than the even-aged systems for managing the vegetation in streamside management zones and riparian areas. However, the silvicultural systems used outside these zones does influence the amount of sediment in the water. (See the discussion in the section titled **Risks** of Adverse Effects on Watersheds and **Soils**.)

The choice of silvicultural systems to best manage wildlife habitat depends on which species are to be emphasized. Regardless of which treatment is used in a stand, some species will benefit and others will not. Most wildlife species are adapted to thrive in *specific* structures and species of forest vegetation. For example, the use of the even-aged or group selection systems favors deer, quail, and rabbits that use herbaceous and shrubby vegetation most abundant in large openings in the forest. The single-tree selection system may favor animals that need vertical diversity, such as spotted owls and tree squirrels.

Almost all forest wildlife species could use a particular young-growth stand at some time in **its** development, regardless of the silvicultural system. (The exceptions are the few species that may be totally dependent on very large, decadent trees for habitat.) The kind of system would influence the proportions of species and when and how they could use the stand as habitat. A significant exception is single-tree selection management applied to large areas. The absence of large openings could prevent use by wildlife adapted to this kind of habitat, such as soaring hawks. Overall, a mix of the silvicultural systems in the forest would probably best achieve most wildlife management objectives.

APPENDIX M

BACKGROUND TO THE HERBICIDE POLICY ANALYSIS

In late 1988 pending outcome of the Region 5 FEIS for Vegetation Management for Reforestation, alternatives for the management of the Tahoe National Forest (TNF) were analyzed under four different policy options for herbicide use

1. Recommended (essentially all vegetation management tools available).
2. No aerial application of herbicides.
3. No herbicides used, but unlimited budget for other methods
4. No herbicides used, but budget constrained to level of 'Recommended.'

TNF data, used for the R5 FEIS for Vegetation Management for Reforestation, was reviewed, updated, and further customized for this analysis. The information was run through a Regional computer program and the tabular summary results are presented in Table 2.4 in the EIS. The purpose of this appendix is to provide more detailed information about the analysis. The complete analysis is part of the planning records and is available for review in the Supervisor's Office in Nevada City, California.

The analysis was done with a specialized program and was not run through the FORPIAN model (see Appendix B). There are some differences in values generated by FORPIAN and, therefore, the tables should be used for comparative relationships only.

TREATMENT COSTS

Costs of treatments were reviewed and changed as necessary to reflect recent TNF figures. The base year used was 1987 for all treatments except herbicide application. Herbicide costs were derived from 1983 data adjusted to a 1986 base year. Costs are on a per-acre basis.

Broadcast burn	\$300	Plant	\$225
Tractor pile	\$200	Precommercial thin	\$150
Cover piles & burn	\$100	Grazing	\$10
Jackpot burn	\$200	Handpile-steep slopes	\$400
Mastication	\$180	Handpile-gentle slopes	\$290
Feller-buncher	\$200	Hand grub	\$300
Disk/till	\$150	Hand cut	\$280
Terrace	\$195	Hand cut & daub	\$330
Collars/mulches	\$190	Aerial spray	\$75
Tractor spray	\$70	Hand spray	\$140

GROWTH AND YIELD ASSUMPTIONS

Projected yields (mean annual increment) by forest type and site were customized based on actual figures from the TNF inventory and yield tables. TNF yields for mixed conifer were slightly lower than the Regional average and slightly higher for eastside pine and red fir. Site classes were dropped one class for slopes greater than 60 percent.

Mixed conifer, 90-year rotation, Dunning site 2, MAI 510 board feet/acre/year

Red fir, 95-year rotation, Dunning site 3, MAI 570 board feet/acre/year

Eastside pine, 110-year rotation, Dunning site 4, MAI 200 board feet/acre/year

LANDBASE

Acreage by slope class and vegetation type by forest type was adjusted to approximate the total intensively managed landbase of the Preferred alternative in the Forest Plan FEIS (Alternative PRF) Projection of effects of various herbicide policy scenarios was made by applying the same percentage changes shown in Table 2 4 for Alternative PRF to the other alternatives. A projection was not made for the Nonmarket alternative (Alternative NMK) because that alternative assumed no herbicide use and was so modeled in FORPLAN.

ESTIMATED ACRES BY SLOPE CLASS AND VEGETATION TYPE FOR TAHOE NF FOREST TYPES
[PREFERRED ALTERNATIVE INTENSIVELY MANAGED LANDS]

VEGETATION TYPE	TRACTOR GROUND	CABLE <60%	CABLE >60%
Sprouting manzanita	22,200	26,600	17,800
Non-sprouting manzanita	6,700	8,900	6,700
Bear clover *	13,300	17,800	13,300
Other brush	22,200	26,600	17,800
Grass/forbs	6,700	8,900	6,700

VEGETATION TYPE	TRACTOR GROUND	CABLE <60%	CABLE >60%
Other brush	11,300	14,000	Negligible
Grass/forbs	7,700	9,500	Negligible

VEGETATION TYPE	TRACTOR GROUND	CABLE <60%	CABLE >60%
Sprouting manzanita	10,400	5,600	Negligible
Other brush	20,700	11,200	Negligible
Grass/forbs	20,000	12,000	Negligible

analysis purposes only. They are not policy direction for how the actual site-specific prescriptions are to be developed.

The typical prescriptions are summarized by vegetation type and presented below.

SITE PREPARATION

Tractor ground

Recommended program

- **80%** tractor pile & burn, 20% plant through slash
- herbicides used on bear clover and grass/forb types

No aerial herbicide application

- same as recommended, except no aerial application

No herbicides

- 70% of bear clover unsuitable for TM (cannot reliably regenerate within 5 years), remainder to be terraced; site prep as above supplemented by grubbing, collars/mulches & disking, rather than herbicides

Cable ground <60% slope

Recommended program

- 70% broadcast burn, 30% plant through slash
- herbicides used on bear clover and grass/forb types

No aerial herbicide application

- same as recommended except no aerial application

No herbicides

- All bear clover unsuitable; site prep same as recommended, supplemented by grubbing and collars rather than herbicides

Cable ground >60% slope

Recommended program

- 70% broadcast burn, 30% plant through slash
- aerial herbicides used on bear clover and grass/forb types

No aerial herbicide application

- Bear clover unsuitable for TM, some acres of other types go to non-intensive mgmt; site prep same as recommended, but supplemented by grubbing and collars, rather than herbicides

No herbicides

- same as 'no aerial herbicides'

RELEASE

Tractor ground

Recommended program

- **90%** herbicide application (**40%** tractor, 30% hand, 20% aerial), **5%** mastication, **5%** grubbing

No aerial herbicide application

- **90%** herbicides (**50%** tractor, 40% hand), **5%** mastication, 5% grubbing

No herbicides

- **50%** mastication, **10%** grubbing, 10% livestock, 10% tractor pile, 10% collars, 10% none [70% bear clover unsuitable for TM]

Cable ground <60% slope

Recommended program

- **90%** herbicide application (**50%** aerial, 40% hand), 10% grubbing

No aerial herbicide application

- same as recommended except no aerial application

No herbicides

- All bear clover unsuitable for TM; **85%** grubbing, **5%** livestock, 10% collars/mulches

Cable ground >60% slope

Recommended program

- 70% broadcast burn, 30% plant through slash
- aerial herbicides used on bear clover and grass/forb types

No aerial herbicide application

- Bear clover unsuitable for TM, some acres of other types to nonintensive mgmt, **95%** grubbing, 5% livestock

- No herbicides
- same as 'no aerial herbicides'

PRECOMMERCIAL THINNING

Tractor ground

- Recommended program
- 70% hand felling, 20% feller/buncher, 10% mastication
- No aerial herbicide application
- same as recommended
- No herbicides
- 70% of bear clover unsuitable; otherwise, same as recommended

Cable ground <60% slope

- Recommended program
- hand felling
- No aerial herbicide application
- same as recommended
- No herbicides
- All bear clover unsuitable; otherwise, same as recommended

Cable ground >60% slope

- Recommended program
- hand felling
- No aerial herbicide application
- All bear clover unsuitable, otherwise, same as recommended
- No herbicides
- All bear clover unsuitable. otherwise same as recommended

BUDGET LIMITATION

For the herbicide policy alternative of 'no herbicides, constrained budget,' some of the least efficient acres would drop out of the landbase to meet the budget limit:

- Eastside pine, cable ground, sprouting manzanita
- Mixed conifer, cable >60%, non-sprouting manzanita
- Eastside pine, tractor ground, non-sprouting manzanita
- Eastside pine, cable, grass/forb
- Mixed conifer, cable >60%, sprouting manzanita
- Mixed conifer, cable <60%, non-sprouting manzanita [some]

APPENDIX N

THE REGIONAL TIMBER SUPPLY-DEMAND SITUATION IN CALIFORNIA

INTRODUCTION

This appendix was created to address public comment that requested additional information on the broad level timber supply and demand situation in relation to supplies from individual National Forests. Existing information from recent RPA assessments, the Pacific Southwest Regional Guide, Forest Service research publications, and the State of California's Forest and Range Resource Assessment Program was used for this purpose.

I. Historical Harvests from Public and Private Lands - Statewide

Timber harvest in California has been in a downward trend for over 30 years. In 1955, timber harvest in the State from all lands totaled 6 billion board feet. In that year, harvest from private lands was 4.9 billion, and harvest from National Forest was 1.0 billion. Less than 100 million board feet were harvested from other public lands. Since that time, total harvest in the State has fallen steadily. By 1982, at the bottom of the last recession, harvests had fallen to 2.5 billion board feet. Since then, annual harvests have rebounded to 4 billion board feet. Harvest from private lands fell to 1.5 billion board feet in 1982 and have since rebounded to 2.2 billion board feet. Harvest from National Forests increased to a peak of 2.36 billion board feet in 1968. National Forest harvests then trended downward to a low of 0.9 billion board feet at the bottom of the last recession and have since rebounded to 1.96 billion board feet. Harvests from other public lands have been relatively stable at near 100 million board feet for the last three decades. (See Table N.1.)

As shown in Table N.1, harvest levels fluctuate widely from year to year rather than following a smooth pattern. The long-term harvest trend is influenced primarily by timber inventory and growth levels, while year-to-year variations are influenced primarily by changes in housing markets and general business conditions.

II. Statewide Demand for Timber Products and the Relationship to Harvest Levels

With a population that has grown faster than the National average to over 26 million people and a high level of income per capita, California is one of the largest markets for lumber, wood, and paper products in the world. When discussing the relationship between the demand for timber products and the demand for timber harvest (stumpage), it is necessary to translate the demand for timber products into its raw timber equivalent. Expressed in these terms, the demand for timber has been increasing, but at a slower rate than the growth in population. While the population has been growing, per capita consumption of raw timber has been declining. This has occurred due to the introduction of labor and material saving technologies in both timber product manufacturing and in industries that use manufactured timber products. Some examples in timber product manufacturing include the use of thinner saws and computerized controls to reduce the amount of sawdust and trimmings during lumber manufacturing, the increased use of reconstituted board products (particleboard, flakeboard, waferboard, etc.) to make use of raw material that was previously underutilized, and the use of computerized controls and improved chemical processes to improve product yields in paper manufacturing. Some examples in industries that use timber products include increased use of concrete slabs in housing construction, use of gypsum board and similar products instead of wooden lath in wall construction, increased use of synthetic materials for roofing and walls, and increased use of built-up 2x4 trusses and similar products instead of larger solid wood members. The result of these technological innovations has been a drop in per capita consumption of raw timber from 390 board feet annually in 1950 to 360 board feet annually in 1983. Because population in the State grew from 10.6 million in 1950 to over 26 million at present,

total demand increased from 4.1 billion board feet annually in 1950 to 9.3 billion board feet annually at present.

While the demand for timber products (measured in raw material equivalents) has been increasing, timber harvests in the State have been decreasing. The difference between the growing demand and the declining supply has been made up by increased imports to the State, primarily from Oregon, Washington, and Canada. The State has changed from a net exporter to a net importer of timber products over the last three decades.

Table N.1. - California Timber Harvests by Ownership, 1952-86

Year	Private	Other Public billion board ft.	National Forest billion board ft.	Total billion board feet
1952	4.40	.05	.61	5.06
1953	5.32	.04	.63	5.99
1954	4.79	.05	.76	5.60
1955	4.93	.06	1.03	6.02
1956	4.69	.08	1.09	5.86
1957	4.36	.07	.92	5.35
1958	4.47	.09	1.11	5.67
1959	4.29	.12	1.48	5.89
1960	3.70	.11	1.33	5.14
1961	3.85	.11	1.38	5.34
1962	4.05	.11	1.38	5.54
1963	3.69	.11	1.66	5.46
1964	3.50	.11	1.86	5.47
1965	3.21	.14	1.92	5.27
1966	2.97	.11	1.93	5.01
1967	3.06	.11	1.89	5.06
1968	2.82	.16	2.36	5.34
1969	2.88	.12	2.00	5.00
1970	2.62	.10	1.84	4.57
1971	2.59	.13	2.06	4.78
1972	2.66	.12	2.22	5.00
1973	2.81	.10	2.01	4.92
1974	2.86	.11	1.73	4.70
1975	2.71	.10	1.52	4.33
1976	2.76	.08	1.89	4.73
1977	2.96	.09	1.74	4.79
1978	2.78	.08	1.80	4.66
1979	2.26	.09	1.73	4.08

California now relies on imports for more than one half of its overall timber product needs. Although California receives only a small proportion of its imports from Canada, Canadian shipments to the U.S. have a significant effect on the State's ability to import timber products from the Pacific Northwest. In contrast to California's reliance on imports, the bulk of the timber products produced in both Washington and Oregon is exported to other States and countries. Increases in Canadian shipments to the eastern half of the U.S. have displaced timber products from the Pacific Northwest. The result has been an increase in the availability of timber products from the Pacific Northwest for California markets. Increased production in the South has also been displacing the Pacific Northwest in eastern markets, which has also increased the availability of products from the Northwest in California markets.

III. Broad Level Socioeconomic Effects

About 95 percent of California's population lives in urban areas. As consumers, the primary effect of changes in harvest levels in the state on them is a change in prices paid for timber products. A reduction in timber harvests in the State reduces competition among suppliers, raises market prices, and leads to increased use of imported products. Econometric analysis done for the 1985 RPA indicates that a one billion board foot change in harvest level would change lumber prices by about three percent. This translates into a \$250 change in the price of the typical new house. For the U.S. economy as a whole, this would amount to a cost to consumers of about \$400 million annually.

Another effect on the urban population is through 'indirect and induced' employment. While the employment effects of changes in harvest levels is felt most strongly in the communities where the logging and sawmilling takes place, some broader level employment effects also occur. This is because most firms that manufacture and supply goods and services to logging and sawmill companies are typically located in the major urban centers rather than in the rural areas where the logging and milling takes place.

Logging and milling by itself typically requires 4 to 7 person years of employment per million board feet processed. This direct employment generates indirect employment in firms that supply goods and services to logging and milling firms and induces employment in firms and governments providing goods and services to those employed directly and indirectly. In undeveloped rural areas there is little if any indirect and induced effect because suppliers are located outside of the area and logging and sawmilling employees must 'drive into the city' to make major purchases. In addition, on most National Forests a portion of the logs harvested are trucked well outside of the primary zone of influence for manufacturing into lumber products. As a result, total Statewide employment effects of changes in harvest levels are larger than employment effects occurring in the primary zones of influence for individual National Forests. Employment effects on a Statewide basis range between 10 and 20 person years per million board feet of timber harvested.

IV. The Outlook for Timber Supplies - Private Lands

Based on an examination of timber growth and inventory levels compared to historical harvest levels, timber supplies from private lands in California are likely to be maintained at present levels or increase over the 10 to 15 year life of the Forest Plans. Recent harvest levels and timber growth and inventory levels are shown in Table N 2. Private harvests averaged 2 billion board feet annually over the period 1978-1985. This compares with sawtimber growth on private lands of 2.3 billion board feet annually. Current private sawtimber inventory is 86.8 billion board feet, or the equivalent of a 43-year supply (not counting growth) at current harvest rates.

The picture changes somewhat when growth and inventory levels are divided among the major private ownership classes. Nonindustrial private owners hold 38 percent of the sawtimber inventory. These owners account for a similar percentage of annual sawtimber growth. Historically, these owners have harvested a much smaller percentage of the timber growth and inventory on their lands than have large industrial owners. Statewide, harvests from nonindustrial private owners have averaged only about 30 percent of annual sawtimber growth. This proportion has been higher in the northern parts of the State and lower in the central and southern Sierra.

With increasing urbanization there is also the likelihood that the harvest rates on nonindustrial private ownerships may decline in the future.

Industrial owners hold **62** percent of the private sawtimber inventory. In contrast to nonindustrial private ownerships, harvest rates on industrial ownerships are **23** percent higher than annual growth. This means that without significant increases in growth, inventory depletion could lead to declining harvest levels in the next century. Inventory statistics suggest that such a decline is not likely to occur during the **10 to 15** year life of the Forest Plans. Moreover, the need of some of the larger industrial ownerships to increase cash flow as a result of recent corporate mergers, acquisitions, and industrial timberland purchases is resulting in increased harvest levels on these ownerships that are likely to persist during the life of the Forest Plans.

Area	Average Annual Harvest, MMBF 1978-1985	Net Annual Sawtimber Growth MMBF, 1982-1984	Sawtimber Inventory BBF, 1982-1984
North Coast	949	981	34.9
Northern Interior	520	563	18.0
Sacramento	415	502	20.7
San Joaquin	131	145	5.8
Other Areas	22	141	7.4
All Private Land	2037	2332	86.8
Industrial Private	1785	1458	53.8
Nonindustrial Private	252	874	33.0

V. Outlook for Timber Supplies - Imports

As discussed above, the Pacific Northwest is the primary source of imported timber products in California. Through displacement effects in national markets, Canada and the South also play a major role in determining the supply of timber products from the Northwest that is available to California markets.

According to studies conducted in Canada and studies by Forest Service research units, timber supplies from Canada and the South are likely to increase, but at a slower rate than experienced over the last **20** years during the life of the Forest Plans. Moreover, a decline or fall down in supplies from Canada and the South is in prospect for the next century without an increase in investment and timber growth.

A decline in timber harvests in the Pacific Northwest over the next **10 to 15** years is expected. This is due to reduced availability of timber inventories on both public and private lands.

The overall outlook is that imports will continue to grow to support increased demands by California consumers over the next **10 to 15** years. However, imports will likely increase at a lower rate than over the last **20** years and may decrease in availability beyond the year **2000**.

VI. The Outlook for Timber Supplies - National Forests

The allowable sale quantities set in individual Forest Plans are an indicator of future timber supply levels from National Forests in California. The allowable sale quantity places an upper limit on the average annual amount of green sawtimber from suitable timberlands that can be sold from a National Forest in the first ten year period of the Plan. Nonchargeable timber (dead timber and fuelwood from either suitable or unsuitable timberlands) is in addition to the allowable sale quantity. The addition of nonchargeable volume usually increases the total amount sold by a few percentage points. (See Table N.3.)

The amount of timber offered for sale in an individual year is determined through the budget process. When the amount of timber sold in an individual year is less than the allowable sale quantity, sales in future years may be higher than the allowable sale quantity, since the ASQ is a limit on the average annual amount that can be sold over a ten year period.

The total of planned timber sales in the individual National Forest Plans in Region 5 is about 1.8 billion boardfeet annually. This is slightly above the average volume sold and above the 1.6 billion boardfoot average volume harvested over the past decade. Excluding the period of severe economic recession that occurred in the early 1980's, timber output under the Plans is slightly less than the 1.85 billion boardfoot average annual harvest during the decade of the 1970's. Output under the Plans is equal to the 1985 RPA 'high bound' program sale offering goal of 1.8 billion board feet for the year 1990.

VII. The Subregional Outlook - Overview

The picture is somewhat different when observed at the subregional level. Based on the historical pattern of log flows to mills, the State can be divided into six timber market areas: North Coast, Northern Interior, Sacramento, San Joaquin, Central Coast, and Southern California. National Forests play a significant role in the North Coast, Northern Interior, Sacramento, and San Joaquin areas.

Virtually all of the decline in the State's timber harvest that has occurred over the last 30 years has taken place in the North Coast market area on private lands. The outlook now is for relatively stable output from private lands over the 10 to 15 year life of the Forest Plans in all major market areas.

The relative contribution of National Forests to the timber supply differs markedly between market areas. In the North Coast area where the private timber supply has been falling most rapidly, National Forests supply only 13 percent of the timber. In the Northern Interior and Sacramento areas, National Forests supply 50 percent of the timber. In the San Joaquin area they supply 70 percent.

Allowable sale quantities under the Forest Plans are lower than historical average harvest levels in the Northern Interior area and higher than historical average harvest levels in all other areas. This means that adverse impacts on local economies resulting from the Plans will be centered in Northeastern California.

VIII. The Subregional Outlook in the North Coast Timber Supply Area

Timber harvests in the North Coast area over the past eight years have averaged 1.08 billion boardfeet annually. Harvests from National Forests account for 13 percent of the total volume harvested. The Six Rivers National Forest supplies 70 percent of the National Forest sawtimber milled in the area and the Klamath, Shasta-Trinity, and Mendocino National Forests supply the rest. Allowable sale quantities under the Forest Plans are above average sale levels during the last eight years by about 25 million boardfeet.

Private harvests in the area have averaged 949 million boardfeet annually over the past eight years. This is slightly less than annual sawtimber growth on private lands of 981 million boardfeet.

feet annually. Private sawtimber inventory is **35** billion board feet -- the equivalent of a 37-year supply (not counting growth) at recent harvest rates. Harvests on industrial lands are expected to increase by about **140** million board feet annually during the life of the Forest Plans as a result of the takeover of the Pacific Lumber Company by the Maxxam Group. The overall outlook is for relatively stable private harvests, but with declining average log diameters during the life of the Forest Plans.

There are **39** sawmills with a combined 8-hour shift capacity of **5.2** million board feet, lumber tally, in the North Coast area. This means that mill capacity is approximately double the available sawtimber supply on an annual basis.

Table N.3 - Average National Forest Timber Sales Compared to Allowable Sale Quantities in Forest Plan Preferred Alternatives

Timber Supply Area	National Forest	1979-86 Average Volume Sold, MMBF	Forest Plan Preferred Alternative MMBF
North Coast	Six Rivers	150.0	175.0
Northern Interior	Klamath (1)	223.6	198.0
	Modoc	59.5	52.0
	Lassen	174.7	154.0
	Shasta-Trinity	215.7	226.0
Sacramento	Mendocino (2)	80.7	93.0
	Plumas (3)	208.0	265.5*
	Tahoe	141.7	142.3*
	Eldorado (4)	146.7	138.0
San Joaquin	Stanislaus (5)	117.4	134.0
	Sierra	128.4	125.0
	Sequoia	77.2	97.0*
	Inyo (6)	12.8	7.0*
	San Bernardino	8.8	5.3*
	R5 Total	1,747	1812.0

- (1) Typically **100-130** MMBF of logs flow into Oregon. Most of this amount is from the Klamath National Forest.
 - (2) Mendocino logs typically flow **40** percent to the Sacramento area, **40** percent to the Northern Interior area, and **20** percent to the North Coast.
 - (3) Plumas logs typically flow **40** percent to the Northern Interior area, **60** percent to the Sacramento area.
 - (4) Eldorado logs typically flow **60** percent to the Sacramento area and **40** percent to the San Joaquin area.
 - (5) Stanislaus logs typically flow **20** percent to the Sacramento area and **80** percent to the San Joaquin area.
 - (6) Inyo logs typically flow **50** percent to the San Joaquin area and **50** percent to the Northern Interior area.
- * Indicates Final Plan value. All other figures are from Draft Plans.

IX. The Subregional Outlook In the Northern **Interior** Timber Supply Area

Timber harvests in the Northern Interior area over the past eight years have averaged 1.04 billion board feet annually. Harvests from National Forests account for 50 percent of the total volume harvested. The Klamath, Modoc, Lassen, Plumas, Shasta-Trinity, and Mendocino are the major National Forest suppliers in the area. Small volumes from other Forests have also been milled in the area (Six Rivers, Eldorado, Inyo, etc). Allowable sale quantities under the Forest Plans are below average sale levels during the last seven years by about 15 million board feet.

Private harvests in the area have averaged 520 million board feet annually over the past eight years. This is slightly **less** than annual sawtimber growth on private lands of 563 million board feet annually. Private sawtimber inventory is 18 billion board feet --the equivalent of a 35-year supply (not counting growth) at recent harvest rates. Harvests on industrial lands are expected to increase slightly because of the need to enhance profitability as a result of recent ownership changes.

There are 22 sawmills with a combined 8-hour shift capacity of 2.5 million board feet, lumber tally, in the Northern Interior area. This means that mill capacity is somewhat above the available sawtimber supply on an annual basis.

X. The Subregional Outlook In the Sacramento Timber Supply Area

Timber harvests in the Sacramento area over the past eight years have averaged 880 million board feet annually. Harvests from National Forests account for 50 percent of the total volume harvested. The Plumas, Tahoe, and Eldorado are the dominant National Forest suppliers, but volume from the Lassen, Shasta-Trinity, Mendocino, and Stanislaus is also milled in this market area. Allowable sale quantities under the Forest Plans are above average sale levels during the last eight years by about 60 million board feet.

Private harvests in the area have averaged 415 million board feet annually over the past eight years. This is less than annual sawtimber growth on private lands of 502 million board feet annually. Private sawtimber inventory is 21 billion board-feet-- the equivalent of a 42-year supply (not counting growth) at recent harvest rates. Harvests on private lands are expected to be maintained near present levels during the 10 to 15 year life of the Forest Plans.

There are 22 sawmills with a combined 8-hour shift capacity of 2.8 million board feet, lumber tally, in the Sacramento area. This means that mill capacity is about 25 percent above available sawtimber supply on an annual basis.

XI. The **Subregional Outlook** In the San Joaquin Timber **Supply** Area

Timber harvests in the San Joaquin area over the past eight years have averaged 407 million board feet annually. Harvests from National Forests account for 70 percent of the total volume harvested. The Stanislaus, Sierra, and Sequoia are the dominant National Forest suppliers, but volume from the Eldorado, Inyo, and San Bernardino is also milled in this market area. Allowable sale quantities under the Forest Plans are above average sale levels during the last eight years by about 25 million board feet.

Private harvests in the area have averaged 131 million board feet annually over the past eight years. This is less than annual sawtimber growth on private lands of 145 million board feet annually. Private sawtimber inventory is 5.8 billion board feet -- the equivalent of a 44-year supply (not counting growth) at recent harvest rates. Harvests on private lands are expected to be maintained near present levels during the 10 to 15 year life of the Forest Plans.

There are 14 sawmills with a combined 8-hour shift capacity of 1.8 million board feet, lumber tally, in the San Joaquin area. This means that mill capacity is over 60 percent above the available sawtimber supply on an annual basis.

APPENDIX A

PUBLIC PARTICIPATION ISSUES, CONCERNS, AND OPPORTUNITIES FOREST SERVICE RESPONSE TO COMMENTS

This appendix consists of four main parts. (I.) early public participation and scoping of issues before the Draft Environmental Impact Statement (DEIS) and Proposed Forest Plan were issued, (II) public review of DEIS and PFP, (III) list of respondents, and (IV) Forest Service response to public comments.

I. EARLY PUBLIC PARTICIPATION AND SCOPING OF ISSUES

A. Initial Scoping, 1979

The Forest planning process is based on public issues, management concerns, and resource **use** and opportunities. These issues, concerns, and opportunities were instrumental in formulating and understanding the consequences of implementing the alternatives. They enable the Forest Plan to be responsive to changing conditions.

During the initial scoping phase, the Pacific Southwest Regional Forester notified the public and other agencies of intentions to prepare a Land and Resource Management Plan for the TNF in the Federal Register, August 18, 1979. In November 1979, the Forest Supervisor published notices in local newspapers and in the Tahoe Planner newsletter that meetings would be held to accept public comment. Meetings were held in Sacramento, Nevada City, Auburn, Downieville, Sierraville, Reno, and Truckee. Approximately **50** people attended these meetings and 80 responses were received containing 500 individual issues. (Refer to TNF planning records, specifically 1922 16a2 These records are available for review at the TNF Supervisor's Office)

B. BROAD ISSUE CATEGORIES

Public comments and concerns were consolidated into 31 broad categories which included:

1. Wildfire **Losses**
2. Prescribed Fire
3. Administrative Facilities
4. Road-Trail Development
5. Transportation System Management
6. Private Development and Road Jurisdiction
7. Economic Feasibility of Regulation, Enforcement
8. Energy Efficiency in Transportation
9. Transportation Interface between Tahoe Basin and Tahoe National Forest
10. Soil Productivity and Capability - Retention
11. Kind, Type, Distinction - Fish, Wildlife
12. Range Capacity
13. Management of Sensitive Plants
14. Water Quality, Quantity
15. Water Production Allocation (Retention, Storage, Export)
16. Flood Plains, Wetlands
17. Minerals Area Management (Occupancy and Effect on Other Resources)
18. Energy Minerals (Geothermal)
19. **Use** of National Forest Lands for Offsite, Private (Non-National Forest) **Use**
20. Ownership Pattern (Effects of Interface)
21. Wilderness (Rare II Further Planning)
22. How Should Areas **be** Managed? (Motor Vehicle Closure)

- 23 Dispersed Recreation
- 24 Alpine Ski Area Expansion (Allocation)
- 25 Commodity Production - Impacts on Visual Quality
- 26 Developed Sites
- 27. Reforestation Release and Thinning Backlog (Vegetation Management)
- 28 Departure from Even Flow/(Socio) Economics/Employment/Economics of Management (Efficiency)
- 29. Management of Low Value Species (Hardwoods)
- 30 Fuels Treatment in Marginal Component
- 31 Silvicultural Prescriptions for Other Resources

C. ISSUE EVALUATION CRITERIA

The Interdisciplinary Team developed criteria in October 1979 to evaluate each issue and its relevance in the Forest's land management planning process. The scope, intensity, duration, resolvability, and consequences of the 31 categories were analyzed using the following criteria:

1. **Mandatory** - There is no discretion in using these criteria. They determine legality rather than priority of importance.
 - a. **Required** by NFMA, Regional **Guide**. The regulations require that certain mandatory issues be addressed in all Forest Plans, i.e., **RARE II**, inventoried roadless areas, timber allowable harvest, etc.
 - b. **Responsibility or** authority for resolution. The responsible official (Regional Forester, or as delegated by him, the Forest Supervisor) must have the responsibility **or** authority to resolve the issue.
 - c. **Scope**. The land or activities involved must be within the Tahoe National Forest or influenced directly by activities on the **Forest**. In addition, the issue must be specific to the Tahoe and not too broad (a Regional or National issue) or too localized (a single project-level issue). These criteria indicate the Forest Plan is the best place to address the issue (rather than in another level of plans).
2. **Discretionary** - The criteria under this subheading are optional since they have been developed to prioritize the remaining issues that will be addressed in the Forest Plan. They involve judgmental decisions by the Interdisciplinary Team and responsible official.
 - a. **Consequences**. The issue involves significant environmental (biological, physical, social, economic) cost or potential for irreversible environmental damage. Cost, in this sense, includes the reduction of a resource or activity for the benefit **of** a competing resource or activity.
 - b. **Resource Knowledge**. The resource specialists on the Tahoe National Forest must have the technical and scientific data, or the capability to collect this data, which is necessary to address the issue within the Forest Plan time frame.
 - c. **Intensity**. The issue has generated public response from a variety of groups representing different views or interests. **Some** indicators of this are lawsuits, appeals, polarization of groups, public comment, proposed legislation, etc.
 - d. **Land Allocation**. The issue involves what resources, goods, or services will be emphasized and where management activities will occur, rather than emphasizing how or when something will **be** done.
3. **Action to be Taken** - This involves the evaluation and degree of analysis **of** each of the public issues, management concerns, and resource **use** and development opportunities, including those identified through public participation activities.

D. NINE MAJOR ISSUES

The 31 broader categories were narrowed to nine major issues to be addressed in the planning process. These issues helped formulate alternatives and were included in a booklet entitled 'Planning Issues' which was approved by the Regional Forester in October 1980. (Refer to the TNF **EIS**, Chapter 2, for information on how the issues, concerns, and opportunities were used to formulate alternatives and their impact on present net values.)

Briefly stated, the nine major issues are.

- Ownership - Land Uses
- Minerals
- Energy
- Inventoried Roadless Areas*
- Water
- Recreation
- Facilities
- Forage, Wood, and Soils
- Wildlife

(* Name changed from Further Planning Areas, revised, 6/28/88)

Following are the issue statements for the nine major issues.

1. Ownership Patterns and Land Uses

Issue:

In what ways and to what extent can the Forest Service lessen or resolve conflicts between uses on National Forest, private, and other public ownerships within the Tahoe National Forest boundary? Some of these conflicts result from the conflicting desires and needs of different owners and the public in their resource management objectives.

Components and Indicators:

- a. What landownership adjustments should be made for community development or expansion?
- b. What ownership adjustments should be made for improved land and resource management?
- c. What should be the Forest Service direction within the Tahoe National Forest toward fire protection (structural and wildland) on intermingled private lands?
- d. How much of the non-Federally owned lands within the Tahoe National Forest boundary should be added to the National Forest System?
- e. When, where, and how should the Forest Service allow support services (sanitary landfills, green belts, roads, parking lots, etc.) required for adjacent private developments to be placed on National Forest System lands?
- f. What new areas should be allocated to utility rights-of-way, electronic transmission sites, and other public utilities?

2. Minerals

Issue:

What emphasis by the Forest Service should be placed on the surface management of mineralized areas within the Tahoe National Forest? This includes both locatable and leasable mineral resources.

Components and Indicators:

- a. Where conflicts between mineral operations and other resource programs occur, how can they best be mitigated?
- b. What should be the Tahoe National Forest direction for the development of common variety materials (sand, gravel, etc.)?
- c. What should be the Tahoe National Forest policy for suction dredging in the river system open to mineral entry?

d How should occupancy trespass be resolved?

3. Energy

Issue:

How should management of the Tahoe National Forest contribute to conserving energy and meeting future energy needs?

Components and Indicators:

- a. To what extent can the Tahoe National Forest land and resource management direction improve the energy efficiency of existing and planned facilities, including transportation and communication systems and buildings?
- b. Where, and to what extent, should energy resources such as fuelwood, hydropower, wind energy, and fissionable and geothermal energy be developed?
- c. What are the most energy efficient modes of transportation, such as mass transit for recreationists, off-highway routes for larger log haul trucks, etc.? Where and how can the Forest Service encourage the use of these transportation systems?
- d. What logging systems should be prescribed to harvest National Forest resources to balance energy conservation with other resource considerations?

4. Inventoried Roadless Areas (Revised 6/28/88)

Issue:

How should all inventoried roadless areas be managed on the Tahoe National Forest? (NOTE The California Wilderness Act of 1984 designated about 18,705 acres of National Forest System land of the Granite Chief RARE II area as wilderness and released the remaining ten roadless areas for nonwilderness uses in this round of planning.)

Components and Indicators

- a. What are the economic, social, and political consequences resulting from allocation of inventoried roadless areas on the Tahoe NF?
- b. Intense interest by some groups to obtain wilderness classification for certain areas on the Tahoe National Forest.
- c. Opposition by off-road vehicle users, the wood products industry, and some local governments to further withdrawals of National Forest System lands for wilderness use
- d. RARE II and recent United States Department of Agriculture directions require the Forest Service to study wilderness potential for Granite Chief, East Yuba, West Yuba, North Fork American River, Middle Yuba, Castle Peak, Bald Mountain, North Fork of the Middle Fork of the American River, Grouse Lakes, Duncan Canyon, and Lakes Basin
- e. Conflicts between developed and dispersed recreation uses and wilderness allocations

5. Facilities

Issue

How can the Tahoe National Forest management, operation, and development of its facilities (roads, trails, administrative facilities) be optimized with respect to user interests, resource management and human resource needs, private landowner concerns, and economic efficiency?

Components and Indicators:

- a. What road and trail systems are needed to access lands for National Forest resource management and public use? What policy should direct use of National Forest System lands for other ownership access, development, and protection needs?
- b. How should the Tahoe National Forest plan, manage, and operate its transportation system to integrate it effectively with private land access needs and with the 26 percent of the TNF's transportation system under State or county jurisdiction?

- c. In what areas do resource protection or user safety require control of recreation vehicles (both on- and off-road) or other traffic? What restrictions are necessary to accomplish this?
- d. What Tahoe National Forest administrative facilities are necessary to best meet the needs of future resource programs?

6. Forage, Wood, and **Soils**

Issue:

How much area of the Tahoe National Forest should be managed for renewable commodity outputs (forage and wood)? How intensively should vegetation be managed to optimize commodity outputs? What Forest Service emphasis should be placed on the soil resource to maintain or enhance productivity?

Components and Indicators:

- a. How much wood should be harvested and where should this production be emphasized?
- b. What should be the amount, methods, and location of timber harvest and other silvicultural systems.
- c. How should the forage production potential be allocated among competing uses?
- d. What should be the level of use and development of National Forest System ranges on the Tahoe National Forest.
- e. RPA emphasizes red meat production.
- f. Losses of grazing land to urban development and other uses.
- g. Public scrutiny of current management practices.
 - (1) Public controversy over the use of herbicides.
 - (2) Criticism of clearcutting practices on Tahoe National Forest System land
 - (3) Public concern that current Forest Service timber management practices promote monoculture and that genetic diversity of timber land is being diminished.
 - (4) Recent criticism that the Forest Service is managing marginal land for timber production. Current USFS definition of commercial forest land is that which is capable of producing 20 cubic feet/acre/year Critics maintain that 50 cubic feet/acre/year is more appropriate
- h. The reforestation and timber stand improvement backlogs are a political issue.
- i. Employment and stability in local communities dependent on, or affected by, Tahoe National Forest timber supply.
- j. Direction that consideration be provided to timber harvest schedules which depart from the current policy of even-flow, nondeclining yield
- k. There is a continuing interest to increase the timber harvest on Federal lands.
- l. The demand for wood fiber for home heating as an alternative or supplemental energy source.
- m. What should the Forest Service policy be to maintain or enhance soil productivity?
- n. Forest management activities are being intensified without the full knowledge of the soil's potential for long-term production.
- o. Some old logging and mining areas have large areas of disturbed soils.
- p. Forest regeneration has not been successful on some soils.
- q. Some commercial forest land should be classified as noncommercial or marginal for timber production.
- r. How should the Tahoe National Forest manage woodlands not presently managed for sawtimber (e.g., oak woodlands, pinyon-juniper, low-site conifers)?

7. Water

Issue:

How should the management of Tahoe National Forest resources respond to the demands and allocations for water quality, quantity, storage, and transmission?

Components and Indicators

- a. What should be the management emphasis to increase available runoff or to alter timing of flow?
- b. What are the water requirements for on-Forest use for management of resources? What quality standards should be established to meet these requirements?
- c. To what extent can the Tahoe National Forest respond to increasing off-Forest needs for water, including timing of flows and water quality?
- d. How should existing and future water storage projects be used for recreational and fishery purposes?
- e. What is the role of the Tahoe National Forest in providing land for future impoundments?
- f. What is the Tahoe National Forest's role in providing off-stream storage to meet peak power demands through hydroelectric generation?
- g. How does the Tahoe National Forest assess the instream flow needs with other beneficial uses?
- h. What is the fair share of change in water quality to be allocated to on-site National Forest uses versus off-site uses?
- i. To what extent should overall watershed integrity and water quality (cumulative watershed effects) be influenced by Tahoe National Forest activities

8. Recreation

Issue:

To what extent should Tahoe National Forest lands be allocated for recreation and scenic purposes? What should be the mix of recreation uses on Tahoe National Forest land?

Components and Indicators:

- a. What is the demand for developed winter sport sites, and how can and where shall the Tahoe National Forest meet the Regionally allocated share?
- b. What is the desired mix of recreational activities on the Tahoe National Forest?
- c. How should areas previously identified as roadless be allocated in terms of recreational opportunities?
- d. Public demand is increasing for nonmotorized access to backcountry areas and for primitive or limited facility recreation experiences. At the same time, demand is increasing for off-road vehicle access to the same areas.
- e. Increased demand for use of other commodities in backcountry areas could depreciate the backcountry experience or the perceived undeveloped environment
- f. Conflicts between off-road vehicle use, nonmotorized recreation access, and hunting and fishing use.
- g. There are existing and potential conflicts with adjacent private land.
- h. Popularity of Nordic skiing and snowmobiling on the same areas
- i. Crowding of existing parking areas for dispersed use occurs during winter
- l. There is a high demand for alpine skiing. Existing developed sites are becoming overcrowded on weekends and holidays.
- k. Continuing interest in interconnecting ski developments in the Sierra Crest area.
- l. Increased popularity in Nordic skiing is resulting in a demand for base facilities. Should these facilities be located on private or public lands?
- m. There is a continuing interest in developed snowplay areas.
- n. What priority should be given to managing the scenic values of the Tahoe National Forest?
- o. Application of VQO's, according to current visual resource management direction, to land adjacent to or visible from Forest development roads can, in turn, restrict use of the resources for which the roads were built.
- p. What should be the Tahoe National Forest management direction along scenic highways?
- q. Energy shortages may cause some shift in recreation use, the trend is inconclusive to date.
- r. How should the conflicts between visual resource management Objectives and other resource Objectives be resolved?

- s There is a public demand for vistas of natural-appearing forest landscapes.
- t What areas now allocated to summer homes should be retained or be reallocated to different uses?
- u There are conflicting interests for additional Wild and Scenic River designation on some rivers. How should the Tahoe National Forest study and recommend rivers for additions to the National Wild and Scenic River System?
- v. Cultural resource protection is mandated by law. Forest Service management must meet these legal requirements

9. Fish and Wildlife Habitat

Issue:

What Forest Service emphasis should be placed on wildlife habitat to maintain or enhance productivity, quality, and diversity?

Components and Indicators:

- a How will viable populations be maintained over time?
- b. What level of protection should be given to important Forest diversity components?

E. INVENTORIED ROADLESS AREAS SCOPING - 1983

In November 1983, another formal scoping session was held in response to the decision by the U S. Ninth Circuit Court of Appeals which affirmed a lower court decision that the RARE II (Roadless Area Review and Evaluation) EIS was inadequate. This ruling did not apply to any areas on the Tahoe National Forest, however, it established a binding precedent in any Federal District Court within the Ninth Circuit. Due to this ruling, all inventoried roadless areas on National Forests in California were reevaluated and considered for recommendation as potential wilderness.

Over 50 people attended the scoping session on November 2, 1983. More than 60 individual responses were received regarding the roadless areas. (Refer to TNF planning records 1922-16) These responses were used to modify the descriptions for each area, the formulation of alternatives, and the revision of the issue statement. Respondents provided information on whether the areas were suitable or not for wilderness designation.

The California Wilderness Act of 1984 designated Granite Chief as Wilderness and required that the other areas be designated for uses other than wilderness. Therefore, the existing unroaded areas on the Tahoe were not evaluated for wilderness in this plan. Appendix G of the FEIS describes the management direction for each 'Roadless Area'.

F. CONSULTATION WITH OTHERS

In addition to the formal initial scoping process, numerous meetings and contacts were made with County governments, other agencies, private landowners, Indian tribes, and interest groups.

A workshop was held in January 1980 with representatives from the Central Sierra National Forests, California Resources Agency, Department of Parks and Recreation, Air Resources Board, Department of Fish and Game, California Boating and Waterways, Regional Water Quality Control Board, Department of Forestry, Department of Conservation, Department of Water Resources, Office of Planning and Research, State Lands Commission, and Division of Mines and Geology. Later in the month, the State's regional issues were received from the Resources Agency. These were general in nature and were considered in the Tahoe National Forest issue formulation process.

In April 1980, a letter was sent to Nevada, Placer, Plumas, Sierra, and Yuba County Planning Departments that provided an update on the current status of the planning process and an offer to meet with the Forest Planning Officer. Based on the response to this letter, the Forest planning staff met with Sierra, Nevada, and Yuba County planners during May 1980. The county planning departments discussed several issues and concerns with the Forest planning staff which were included in the Forest Issue package.

During that same month a letter was sent to 58 agencies, landowners, and Indian tribes to coordinate all planning events among the various entities. Responses and management plans were received from the following individuals and groups. Bureau of Land Management, Maidu Elders Organization, Mr. Sherman Chickering, Erickson Lumber Company, University of California at Berkeley - National Land and Water Reserves System, Placer County Planning Commission, Alpine Meadows Ski Area, Cal-Pacific Foresters, Inc., Nevada Division of Forestry, California Regional Water Quality Control Board - Lahontan Region, North Fork Association, DART Industries, and the Bureau of Reclamation. Letters were also received from several mining companies and associations. In addition to these comments and plans, the Sierra County Grand Jury Report, 1979 (Sierra County), Squaw Valley General Plan (Placer County), Nevada County General Plan (Nevada County), and the Management Plan for the Blue Canyon Deer Herd (California Department of Fish and Game) were reviewed and those concerns that were appropriate to the Tahoe were noted and used as the Forest Issues were formulated.

Continuing informal communication with the Sierra Club, Western Timber Association, County Boards of Supervisors, County Planning Departments, individuals, and adjacent National Forests (Plumas, Eldorado, and Lake Tahoe Basin Management Unit) had taken place since the early scoping period.

II. PUBLIC REVIEW OF THE **DEIS** AND PROPOSED FOREST PLAN

A. Document Distribution

On January 17, 1986, the Proposed Tahoe National Forest Plan and Draft Environmental Impact Statement were issued and the public review period began. Approximately 1500 documents were distributed to those on the Forest Plan mailing List (592) and to others who requested copies. The availability of the Proposed Plan was announced by news releases, notice in the Federal Register, and by letters to potentially interested individuals. All documents were dispersed and requests for copies exceeded supply. Interested individuals were referred to the following libraries that had loan copies, or sets of documents were loaned from the Forest Headquarters. With each set of documents, a letter to the reader was included which requested public suggestions and comments.

Libraries That Were Sent Copies of the Plan and DEIS

Placer County Library, Auburn; Placer County Library, Tahoe City; Sierra County Library, Alleghany, Sierra County Library, Downieville, Sierra County Library, Loyaltown, Sierra County Library, Sierra City; Sierra County Library, Sierraville, Nevada County Library, Grass Valley; Nevada County Library, Nevada City, Nevada County Library, Truckee, Sierra Club Library, San Francisco; Washoe County Libraries, Reno, NV, Yuba City Library, Yuba City; Yuba County Library, Marysville; North Columbia Schoolhouse Cultural Center, North Columbia, Sacramento Public Library, Central Library

California State University, Miriam Library, Chico, California State University Library, Sacramento, Sierra College Library, Rocklin; University of California Library, Berkeley; University of California Library, Davis, University of Nevada, Main Library and Life and Health Sciences Library, Reno

Forest Service Offices With Copies of the Plan and **DEIS**

Pacific Southwest Regional Office, San Francisco, Plumas National Forest Headquarters, Quincy, Mohawk Ranger Station, Blairsden; Challenge Ranger Station, Challenge, Lake Tahoe Basin Management Unit, South Lake Tahoe; Eldorado National Forest Headquarters, Placerville, Georgetown Ranger Station, Georgetown, Pacific Ranger Station, Pollock Pines; Toiyabe National Forest Headquarters, Reno, NV; Carson Ranger Station, Carson City, NV; Tahoe National Forest Headquarters, Nevada City; Nevada City Ranger Station, Nevada City; North Yuba Ranger Station, Camptonville; Foresthill Ranger Station, Foresthill, Sierraville Ranger Station, Sierraville, Truckee Ranger Station, Truckee;

B. Public Meetings/Open Houses/Hearings

During the first month of the comment period 8 meetings were sponsored by the Forest Service to introduce the plan to the public. Meetings were held in the evenings in Truckee, Sierraville, Downieville, Camptonville, North Columbia, Grass Valley, Foresthill, and Auburn. The meetings were generally 3

to 4 hours long and explained the LMP process in general, the history of the National Forest Management Act, an overview of the Forest, the alternatives in the DEIS, and a summary of the Proposed Plan and its effects on the Forest. A question and answer period was held at the end of each meeting. Over 500 individuals attended these sessions.

In the third month of the comment period, open houses were held during the afternoon and evening at each Ranger District to individually work with members of the public with questions or concerns about some aspect of the Forest Plan. Approximately 46 people attended these open houses.

When invited by various groups or boards, presentations by members of the Interdisciplinary and Management Teams were made at approximately 25 additional meetings to further introduce or explain the Proposed Plan.

The comment period was extended from April 18, 1986 to June 2, 1986, for a total of 137 days, to provide additional public review and comment time.

Three hearings were held two in Grass Valley and one in Truckee to give the public a chance to voice their concerns to the Forest Supervisor. Originally only two hearings were planned; however the interest in the Grass Valley hearing was so high that another one was scheduled to accommodate those who preregistered. Letters and news releases were mailed out announcing the hearings. Preregistration was advised, but registration at the door was also possible. Testimony was limited to 5 minutes per individual. The testimony was tape recorded and transcribed by a transcription service and included in the public comment analysis. Over 375 individuals attended the hearings with a total of 188 individuals presenting testimony to the Forest Supervisor.

A hearing was also sponsored by the Sierra County Board of Supervisors in Loyalton. The testimony was transcribed and entered as official comments.

C. Public Comment Analysis Process

As each letter was received, it was assigned a unique identification number. Each letter was coded to indicate the type of respondent (i.e., individual, elected official, organization, etc.), the number of signatures, and the location of residence or office origin. The letters were then read for content, and codes were given to each substantive comment to identify the subject matter of the various resource issues. A comment was assigned codes to indicate the major subject areas of the concern, reasons for the concern, geographical areas of the Forest of concern, and any alternatives mentioned. The verbatim comment was entered into the computer along with the corresponding identifier codes. Copies of each letter were also sent to the Forest Supervisor, Forest Planner, Public Affairs Officer, and the appropriate District Ranger.

A total of 12,253 letters, including form letters and petitions, were received within the comment period. An additional 516 letters were received after the comment period closed. Over 90,000 subject codes, 49,000 reason codes, 11,000 geographic location codes, and 8,700 alternative codes were recorded. The coding process was designed to assist in the sorting of and responding to those comments. The results were used to give general indications of interests and concerns as well as the range and intensity of thoughts and feelings.

1. Demographic Analysis

Letters were received from throughout the United States but primarily from California. Out of the 12,253 letters received, 46% were from residents in or adjacent to the Forest, including Placer, Nevada, Sierra, and Yuba Counties. Responses from the Bay Area accounted for 14%, and those from the Sacramento-Yolo Counties accounted for an additional 23%. Locally, the response percentages of the total number of letters were: Nevada County - 33%; Placer County - 10%; Sierra County - 2%; and Yuba County - 2%. Within Nevada County, the Grass Valley-Nevada City area generated the greatest number of responses with 27% of the total

Responses were received from many organizations, interest groups, agencies and elected officials. Over 87%, however, were received from individuals. Letters were received from 24 agencies and 27 elected officials.

2. Form Letters

Over 55% of the responses to the Proposed Plan were form letters. Two main types were received: one supporting the Sierra Club's Citizens' Alternative, and the other expressing concern for a decreased timber harvest volume and the resultant effects on the local economy and dependent jobs in local communities (including Butte County). Approximately 97% of the form letters represented the environmentally-oriented point of view and 3% the timber-oriented point of view. The majority of these form letters came from Grass Valley-Nevada City, Sacramento-Yolo Counties, and the Bay Area.

3. Issue Analysis

As previously noted, over 90,000 subject area codes and 49,000 reason codes were documented. Overall, the concern for clearcutting (12%) and maintaining the roadless Characteristics of previously designated roadless areas (8%) generated the most comment codes, with reforested timber plantations (5%), old-growth timber (5%), use of herbicides (5%), and the demand for timber (4%) following in frequency.

Timber - Over 47% of the comment codes concerned timber-related issues. Clearcutting received the greatest number of comment codes in the timber department. Many individuals also expressed concerns about the Forest's ability to help meet the Nation's timber demand and the economic effects on the local economies and jobs if the timber harvest volume were lowered.

Recreation - Comments on recreation-oriented subjects made up 21% of the total number of subject codes. The three issues that surfaced most often included roadless areas and the concern for building roads or harvesting timber in these areas, scenic quality, and non-motorized backcountry use.

Wildlife - Wildlife concerns accounted for 4% of the total number of subject codes. The main concern for wildlife was for its habitat. Other concerns were for fisheries and wild trout streams as well as wildlife in general.

Grazing - Opposition to grazing along streams and a need to increase fees for grazing were the two areas mentioned most often under the grazing category. The number of comment codes that addressed grazing accounted for 9% of the total. Approximately 85% of the comments on grazing were form letters.

Soil and Water - The major concerns addressing soil and water were for increased watershed and wetlands protection, and for a reduction of erosion or the potential for erosion. Approximately 1% of the total comment codes addressed soil or water.

Facilities, Lands, and Fire - With the exception of road building in previously designated roadless areas, very few comments were received on facilities, land ownership issues, and fire. Prescribed fire was associated with timber management practices. Comment codes on mining generated less than 1% of the total number of codes.

Economics - Economic comment codes accounted for 4% of the total. Concerns included effects of Forest Management on local jobs, economic value of both timber and recreation to the local communities, and 25% fund receipts to the local counties (twenty-five percent of the monies paid to the Forest Service for recreation, timber sales, etc. are returned to the local counties for roads and schools).

General Forest Management - Many of these comments were very general in nature. The number one concern from this category was a general desire to protect forest resources with or without the production of timber.

Specific Areas of the Forest - Over 200 areas in the Forest were mentioned with recommendations for those areas. The forest areas mentioned most often included the North Fork American River, Mt. Lola, Grouse Lakes, East Yuba, and Castle Peak. The majority of comments on these areas came from form letters. Other areas of concern included Bear Valley Campground, Rock Creek, Granite Chief, Truckee River, and the Scott Management Areas. The concerns for the North Fork American Wild River included the protection of the resources in the canyon and keeping the area in a roadless state for backcountry nonmotorized recreation. The majority of the letters addressing the Mt Lola-Independence Lake area requested the protection of Forest resources and opposed commercial ski development of the area.

Alternatives - Comments were received on all eleven alternatives proposed in the DEIS. In addition, a great deal of support was expressed for the Citizens' Alternative proposed by the Sierra Club (70% of which were from form letters). Considerable support was also expressed for Alternative I or a modified version of I, which would increase timber harvest levels over current amounts (21% were from form letters)

4. **Topics** and Responses

The comments pertaining to each resource were provided to the appropriate staff officer and the interdisciplinary team member. Comments were grouped into similar concerns called topics. These topics and corresponding responses *are* displayed in the following section. Over 1200 topics were developed. Each topic may represent one unique comment or the aggregation of hundreds of similar comments. The Forest Service answer to the topic is listed as the 'Response'.

D. Additional Consultation

As the Final Plan was developed, members of the Planning Team met with various agencies, industry representatives, and the environmental community. These groups assisted as alternatives were modified and the Final Plan developed.

Tahoe Free Public Camp, c 1925

RESOURCE CATEGORY	CODE	TOPIC NUMBERS	PAGES

LIST OF RESPONDENTS

HOW TO USE THIS SECTION

All who commented on the Proposed Plan are listed alphabetically in this section. The codes listed behind each name on the following pages refer to the subject matter of their letter. The chart on the previous page defines the codes. It also shows the pages where the topics for each subject are found.

Because of the substantial number of letters that were received, the letters that were postmarked after the comment period closed were not included in the content analysis process unless the comments were new or unique. Those letters received after the comment period closed were numbered starting with 20,000.

LIST OF RESPONDENTS

This section contains a list of all public comments that were provided to the Draft Plan and DEIS. The general subject categories addressed by each of the comments are displayed next to the name and identification number of the respondent. Comments that were received after the comment period closed were not included in the content analysis unless the comments were new or those responses that were received during the comment period closed were given identification numbers beginning with 20,000.
