provides the visually desirable appearance of a natural stand. While economic returns and timber volume production are also important, they may play a secondary role in this management area, depending on the recreation intensity and visual objectives. Tree growth rates should be sufficient to produce the characteristic large tree component within the rotation age and maintain trees in a healthy condition (combined criterion 4). In addition, trees should be managed to minimize risks from insects, windthrow, disease, and wildfire (combined criterion 5). Uneven-aged methods may require artificial regeneration to maintain the appropriate species composition and may be restricted to sites where acceptable logging methods can be applied (combined criterion 2).

Uneven-aged methods are not applicable where insect or disease conditions cannot maintain stands relatively free of risk (combined criterion 5). Serious dwarf mistletoe problems are common in western hemlock. Uneven-aged methods will perpetuate and intensify this problem and are not applicable where most mistletoe infected trees cannot be removed at one entry (combined criterion 5). Many root disease fungi infect susceptible trees by root-to-root contact. Control may require killing trees in a zone around the infected area. Uneven-aged management, particularly the single-tree selection system, can perpetuate root disease "centers" and spread infections (combined criterion 5).

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

1b. Western Hemlock - Riparian and Fish Habitat

This area will be managed to maintain riparian habitat diversity and integrity. Cover will be provided to maintain desirable water temperatures. Timber generally will be managed under extended rotations and large old-growth trees will provide an important stand component. Satisfactory growth rates should be maintained and stands protected from insects, disease, windthrow, and fire (combined criterion 5). While economic returns and timber volume production are important, they play a secondary role in this management area.

Both even-aged and uneven-aged methods are biologically applicable and may be selected here. Uneven-aged methods may require artificial regeneration to maintain the appropriate species composition and may be restricted to sites where acceptable logging methods can be applied (combined criterion 3). Uneven-aged methods may perpetuate windthrow.

Serious dwarf mistletoe problems are common in western hemlock. Uneven-aged methods will perpetuate and intensify this problem and are not applicable where most mistletoe infected trees cannot be removed at one entry (combined criterion 5). Many root disease fungi infect susceptible trees by root-to-root contact. Control may require killing trees in a zone around the infected area. Uneven-aged management, particularly the single-tree selection system, can perpetuate root disease "centers" and spread infection (combined criterion 5). Understory brush species commonly flourish in riparian zones. Uneven-aged management may favor growth of hardwoods and prevent regeneration of tall growing conifers so that shading is reduced on larger streams (combined criteria 4 and 6). Bole rots caused by wounding of leave trees during logging, when using uneven-aged methods, may reduce yields by 10 to 15 percent in the

long run. Uneven-aged methods may provide a more uniform canopy which provides the visually desirable appearance of a natural stand.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

1c. Western Hemlock - Big Game Habitat

In this area, vegetation will be managed to provide optimum habitat needs for deer, elk, and mountain goats. Vegetation will be managed to provide diverse mixtures of forage, hiding cover, and thermal cover. Although both even-aged and uneven-aged harvest cutting methods are biologically acceptable, even-aged methods can best provide for the special conditions within this management area (combined criterion 3). Uneven-aged methods are generally not applicable where the desired character is a mosaic of forest and openings. In addition, the transportation system and entry frequency necessary for management of uneven-aged stands present an undesirable probability of big game harassment.

Serious dwarf mistletoe problems are common in western hemlock. Uneven-aged methods will perpetuate and intensify the problem and are not applicable where most mistletoe infected trees cannot be removed at one entry (combined criterion 5). Prescribed burning is often recommended for site preparation and forage enhancement and cannot be used with uneven-aged methods.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

1d. Western Hemlock - Threatened and Endangered Species

Habitat management for bald eagles and peregrine falcons will emphasize large, overmature trees potentially useable as perch trees and nest sites. Suitable trees should be available throughout time and should be widely distributed. A density of at least eight large trees per acre is satisfactory. Both even-aged and uneven-aged methods are biologically acceptable and can produce the small groups of large trees over time. The selected harvest cutting method must be capable of providing the special conditions which are required to meet the resource management objectives (combined criterion 3), and they take precedence over economic considerations and timber volume production. The selected method should be capable of developing large diameter perch and nest trees at the appropriate point in the rotation (combined criteria 3 and 4).

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

1e. Western Hemlock - Timber Production

Economic returns and timber production are primary considerations in this area. Both even-aged and uneven-aged cutting methods may be biologically acceptable but uneven-aged methods are not applicable for optimum tree growth (combined criterion 4). Even-aged methods are most practical and economical in terms of transportation, harvesting, preparation, and administration of timber sales (combined criterion 7). The size, shape, juxtaposition, and timing of even-aged cutting areas can be varied to provide high levels of big game habitat while meeting visual management objectives and other multiple-use objectives (combined criterion 3). Uneven-aged methods may provide a more uniform canopy which provides the visually desirable appearance of a natural stand.

Serious dwarf mistletoe problems are common in western hemlock. Uneven-aged methods will perpetuate and intensify this problem and are not applicable where most mistletoe infected trees cannot be removed at one entry (combined criterion 5). Many root disease fungi infect susceptible trees by root-to-root contact. Uneven-aged management, particularly the single tree selection system, can perpetuate root disease "centers" and provide for the continued spread of infections (combined criterion 5).

This area often contains the greatest gross volumes per acre and the most decadent stands which often requires that logging slash be treated by prescribed burning for site preparation and/or hazard reduction (combined criteria 5 & 6). Uneven-aged methods do not normally allow prescribed burning to be used. Even-aged methods permit the use of genetically improved seedlings. Bole rots caused by wounding of leave trees during logging, when using uneven-aged methods, may reduce yields by 10 to 15 percent in the long run.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

1f. Western Hemlock - Municipal Watersheds

The primary emphasis for this group is the production of high quality and quantity water. Timber production is emphasized to the extent that the water quality goal can be met. Varying emphasis is placed on other resources depending on the specific watershed.

Even-aged methods permit the use of genetically improved seedlings and are best suited for optimum tree growth (combined criterion 4). Even-aged methods are most practical and economical in terms of transportation, harvesting, preparation and administration of timber sales (combined criterion 7) and use commonly available and acceptable logging methods (combined criterion 2). Uneven-aged methods may provide a more uniform canopy which provides the visually desirable appearance of a natural stand.

Even-aged harvest methods are most desirable to convert old-growth stands to stands of desirable species which are free of disease-causing wounds (combined criterion 5). Bole rots caused by wounding of leave trees during logging, when

using uneven-aged methods, may reduce yields by 10 to 15 percent in the long run.

Serious dwarf mistletoe problems are common in western hemlock. Uneven-aged methods would perpetuate and intensify this problem and are not applicable where most mistletoe infected trees cannot be removed at one entry (combined criterion 5). Even-aged methods reduce the frequency of soil disturbance, and reduce the need for construction of landings, haul roads, and skid roads. Over 80 years of sustained road building and heavy cutting using the even-aged method have occurred in the Cedar River Watershed; throughout this period of activity, the watershed has met the water needs of the City of Seattle.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

PACIFIC SILVER FIR SPECIES ZONE

2a. Pacific Silver Fir - Scenic Views and Recreation

The rationale described under 1a. Western Hemlock - Scenic Views and Recreation also applies to this group. This zone generally has steeper topography than the western hemlock zone, making uneven-aged management more costly and difficult. With increasing elevation, the amount of western hemlock decreases and the amount of silver fir increases, making dwarf mistletoe less of a problem.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

2b. Pacific Silver Fir - Riparian and Fish Habitat

The rationale described for 1b. Western Hemlock - Riparian and Fish Habitat also applies to this group Steeper topography may favor more even-aged methods while smaller amounts of mistletoe infected trees will favor more uneven-aged management.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

2c. Pacific Silver Fir - Big Game Habitat

The rationale described for 1c. Western Hemlock - Big Game Habitat also applies to this group, although more of this area will be managed for mountain goat habitat and less for deer and elk than in the western hemlock zone. Dwarf mistletoe is still a problem in the silver fir zone, but is usually not as

serious as in the western hemlock zone, especially in the higher elevations of this zone where the proportion of silver fir increases.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

2d. Pacific Silver Fir - Threatened and Endangered Species

The rationale described for 1d. Western Hemlock - Threatened and Endangered Species applies to the Pacific silver fir zone as well, although fewer bald eagles and peregrine falcons are found in the silver fir zone.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

2e. Pacific Silver Fir - Timber Production

The rational described for 1e. Western Hemlock - Timber Production applies to the Pacific silver fir zone as well, although dwarf mistletoe is not as serious a problem in this zone and less prescribed burning and more reliance on residual seedlings is done in the silver fir zone.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

2f. Pacific Silver Fir - Municipal Watersheds

The rationale described for 1f. Western Hemlock - Municipal Watersheds applies to the silver fir zone as well, although dwarf mistletoe is not as serious a problem in this zone and less prescribed burning and more reliance on residual seedlings is done in the silver fir zone. Even-aged harvest methods permit maximum snow pack build up and late season water runoff, by varying the size, shape, and orientation of harvest units (combined criteria 3).

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

MOUNTAIN HEMLOCK OR SUBALPINE FIR SPECIES ZONE

Rationales 3a - 3f apply only to the White River and North Bend Ranger Districts. Rationale 3g applies only to the Skykomish, Darrington, and Mt. Baker Ranger Districts.

3a. Mountain Hemlock or Subalpine Fir - Scenic Views and Recreation

The rationale described for 2a. Pacific Silver Fir - Scenic Views and Recreation also applies to this group. The mountain hemlock/subalpine fir zone has the least problem with dwarf mistletoe of any of the zones. This zone also has the lowest timber values and the most expensive harvest costs, because of steep and rough topography.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

3b. Mountain Hemlock or Subalpine Fir - Riparian and Fish Habitat

The rationale described for 2b. Pacific Silver Fir - Riparian and Fish Habitat also applies to this group. This zone has the least problem with dwarf mistletoe of any of the zones. This zone also has the lowest timber values and the most expensive harvest costs because of steep and rough topography.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

3c. Mountain Hemlock or Subalpine Fir - Big Game Habitat

The rationale described for 2c. Pacific Silver Fir - Big Game Habitat also applies to this group. Most of the big game management emphasis for this area will be for mountain goats, as this zone is generally located at higher elevations, well above deer and elk winter range.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

3d. Mountain Hemlock or Subalpine Fir - Threatened and Endangered Species

The rationale described for 2d. Pacific Silver Fir - Threatened and Endangered Species applies to this species zone as well. Bald eagles and peregrine falcons are rarely found in this high elevation zone.

Either even-aged or uneven-aged methods may be selected here. The ultimate selection should be based on specific stand and site characteristics. An environmental analysis will be used in deciding which method should be selected.

3e. Mountain Hemlock or Subalpine Fir - Timber Production

The rationale described for 2e. Pacific Silver Fir - Timber Production applies to this zone as well. Dwarf mistletoe is rarely a serious problem in this species zone and prescribed burning is usually discouraged to favor residual seedlings. Low timber values and high harvest costs in this species zone favors even-aged management.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

3f. Mountain Hemlock or Subalpine Fir - Municipal Watersheds

The rationale described for 2f. Pacific Silver Fir - Municipal Watersheds applies to this zone as well. Dwarf mistletoe is rarely a serious problem in this species zone and prescribed burning is usually discouraged to favor residual seedlings. The heaviest snowfall occurs in this species zone, thus even-aged methods have the greatest potential for increasing late season flows of water.

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics. An environmental analysis will be used in deciding which regeneration system should be selected. For this species zone, the clearcutting regeneration system is the predominant and commonly appropriate even-aged method.

3g. Mountain Hemlock - Mountain Hemlock Study

This species zone has been tentatively classified as not suited for timber production on the Skykomish, Darrington, and Mt. Baker Ranger Districts because reasonable assurance of obtaining reforestation success within five years of final harvest does not exist. Up to 250 acres will be cut in a structured study design to test various even-aged harvest methods.

Because of low timber values and high harvest costs, even-aged harvest methods are the only methods which can produce a volume of marketable trees (combined criterion 1) and are practical and economical (combined criteria 7). Only even-aged methods meet the special management objective of determining how to meet reforestation standards for even-aged harvested areas (combined criterion 3). Only even-aged methods permit control of vegetation to establish desired species composition, density, and rates of growth (combined criterion 4).

For these reasons, even-aged harvest cutting methods are recommended for this group. The final selection of the regeneration harvest system will be based on specific stand and site characteristics and the objective of the study. An environmental analysis will be used to indicate which regeneration system should be selected.

Appendix C

APPENDIX G

THE PLANS AND POLICIES OF OTHER FEDERAL AGENCIES, STATE AND LOCAL GOVERNMENTS, AND INDIAN TRIBES

Regulation requires the review of the planning and land use policies of other Federal agencies, state and local governments and Indian tribes prior to preparing a Forest Plan EIS. Below is a list of plans reviewed. A summary of the plans pertaining to National Forest land and the potential conflicts with the Forest Plan (the Preferred Alternative in this Final EIS) is also included below.

LIST OF PLANS AND POLICIES OF OTHERS

County Plans

Pierce County - Draft Environmental Impact Statement Pierce County Washington, September,1985.

Snohomish County - Shoreline Management Master Program, September 1974 amended August, 1984.

Snohomish County - Stanwood Area Comprehensive Plan Final Environmental Impact Statement, December, 1984.

Snohomish County - Darrington Area Comprehensive Plan, April, 1984.

Snohomish County - Granite Falls Area Comprehensive Plan, May, 1984.

Snohomish County - Skykomish Valley Area Comprehensive Plan, October, 1980.

Snohomish County - Stream Rehabilitation Program, 1984.

Snohomish County - Draft Comprehensive Park and Recreation Plan, June, 1986

King County - Executive Proposed General Development Guide The King County Comprehensive Plan, April, 1984.

Skagit County - Comprehensive Plan for the Eastern Planning District, May, 1982.

Whatcom County - Comprehensive plan for Whatcom County, Washington, Whatcom County Planning Commission, 1970.

Whatcom County - Lake Whatcom Subarea, a Component of the Whatcom County Comprehensive Land Use Plan, August, 1982.

Municipality Plans

City of Seattle - Cedar-Tolt Watershed Management Plan Final Environmental Impact Statement, August, 1979.

City of Seattle - 1985 COMPLAN - Seattle Comprehensive Regional Water Plan, City of Seattle Water Dept., 1985.

City of Seattle - Cedar River Watershed Cooperative Agreement, May, 1962.

City of Seattle - Cedar River Secondary Use Analysis, 1989, Ordinance #114632.

City of Tacoma - Memorandum of Understanding Between USDA Forest Service and the City of Tacoma, 1984.

City of Tacoma - Requirements For Protection of Water Supply In The Green River Watershed, City of Tacoma Department of Public Utilities Water Division, Revised January 23, 1980.

City of Everett - Sultan River Basin Resource Management Plan, Prepared by Wilsey and Ham, Inc, December, 1977.
City of Bellingham - No Plan

State Plans

Washington Forest Practices Rules and Regulations - Washington State Forest Practices Board, October, 1982.

Safety Standards for Logging Operations (Chapter 296-54 WAC - State of Washington Division of Industrial Safety and Health; Department of Labor and Industries, April, 1981.

Strategies for Washington's Wildlife: 1982-1995 - Washington State Department of Game, 1982.

State of Washington Natural Heritage Plan - State of Washington Department of Natural Resources, 1985.

Washington State Heritage Plan I - Washington Heritage Council, August, 1986.

Forest Resource Plan - State of Washington Department of Natural Resources, November, 1984.

A Statewide Comprehensive Plan for Fish and Wildlife in the National Forests in the State of Washington - Washington Department of Game, Washington Department *of Fisheries and Forest Service- USDA, November, 1978.*

Wildlife Program Plans - Washington Department of Game, April, 1984.

1984-1993 Forest Land Management Program, State of Washington Department of Natural Resources, November, 1983.

A Multiple Use Plan For Sultan Basin (DNR, 1968).

1989 Puget Sound Water Quality Management Plan, October,1988.
Puget Sound Water Quality Authority

Washington State Trails Policy Plan, draft- January,1990.
Interagency Committee for Outdoor Recreation

Washington's Statewide Comprehensive Outdoor Recreation Plan, 6th addition, 1985. Interagency Committee for Outdoor Recreation.

Federal Agencies

North Cascades National Park-Ross Lake Natural Recreation Area-Lake Chelan Recreation Area General Management Plan, United States Department of the Interior, National Park Service, June, 1988.

Mount Rainier National Park, Final Master Plan Mount Rainier National Park, Washington, Department of Interior, Prepared by Pacific Northwest Region National Park Service, June 1984.

Mount Rainier National Park Wilderness Management Plan, Department of Interior, National Park Service, May,1989.

Indian Tribes

No written plans. Refer to the discussion in Chapter IV, FEIS.

Other Plans

Snohomish River Basin Resource Management Program, Main Report. Prepared by the Snohomish Study Team for the Pacific Northwest River Basins Commission, September 29, 1981.

A Land Use Study For The Route 2 Corridor/South Fork Skykomish River, King County, Washington. King County Department of Planning and Community Development, Planning Division, December, 1983.

Sultan River Project No. 2157, Washington Draft Environmental Impact Statement, Federal Energy Regulatory Commission Office of Electric Power Regulation, April, 1980.

Sultan River Project: "Recreation Plan," Public Utility District No. 1, Snohomish County Washington and City of Everett December, 1982.

Sultan River Project Exhibit S, "Fish and Wildlife Management Plan," Public Utility District No. 1, Snohomish County Washington and City of Everett (Plan not approved).

Sultan River Project Stage II, "Erosion, Sedimentation and Slope Stability Control Plan," Public Utility District No. 1, Snohomish County Washington and City of Everett, July, 1981.

Stillaguamish Watershed Action Plan, January, 1990. Prepared by a committee representing interest groups such as farmers, the environmental committee, the forest industry, citizens, homeowners and tribes as well as Snohomish County and other agencies. Approved by the Washington State Department of Ecology. January, 1990.

Draft Management Plan for Skagit Valley Recreational Area and E. C. Manning Provincial Park and Cascade Recreation Area, Sept 1987, B.C. Parks.

Appendix G

SUMMARY OF PLANS AND CONFLICTS

County Plans

Whatcom County - Comprehensive Plan for Whatcom County: The plan's policy for forested land is that timber should be regarded as the preferred use of these lands. Care should be taken to screen uses which may tend to detract from forest production even though such uses may be appropriate or necessary within the forestry area. Local planning should emphasize protection of the forest land resource base rather than operation of management concepts.

This plan is very broad and general. There are no apparent conflicts with the Forest Plan .

Whatcom County - Lake Whatcom Subarea, Whatcom County Comprehensive Land Use Plan: The plan states that the principal use of Forestry areas, in the Lake Whatcom Subarea, shall be sustained yield forest management which is conducted in accordance with the Washington State Forest Practice Act.

Environmental policies include promoting groundwater quality which is suitable for domestic consumption, recognizing and protecting wetlands, fostering continued fish and wildlife habitat integrity in the subarea, encourage air pollution abatement, minimize noise impacts and identify, designate and protect environmentally sensitive areas.

There should be no conflicts between this plan and the Forest Plan.

Skagit County - Comprehensive Plan for the Eastern Planning District: The Plans forestry land use goal is that timber resource of the Eastern District should be protected, enhanced and appropriately utilized. The plans policies are: Sustained yield practices and policies of forestry management should be utilized and encouraged; The multiple use concept of forest management should be encouraged and utilized in appropriate areas; Commercial timber lands should be protected from incompatible land uses for economic, safety and aesthetic reasons: Recreational uses and areas should be encouraged in appropriate forest areas provided they do not conflict with or become burdensome to commercial timber operations and; The area watersheds should be managed to the highest levels possible to maintain the integrity of our water resources.

There appears to be no conflict with the Forest Plan.

Snohomish County - Shoreline Management Master Program: No apparent conflict with Forest Plan.

Snohomish County - Stanwood Area Comprehensive Plan: No apparent conflict with Forest Plan.

Snohomish County - Darrington Area Comprehensive Plan: The plan recommends sustained yield forest management practices should be employed on all private, state and federal land which has been designated for timber production.

There is no apparent conflict between the Darrington plan and the Forest Plan.

Snohomish County - Granite Falls Area Comprehensive Plan: The plan's goals and policies for forested lands (including National Forest lands over which the county has no regulatory authority) are:

1. Conserve and protect forest land in Granite Falls area for long term forestry related uses.

2. Support all governmental or private actions which will maintain or increase the viability of forestry in designated areas.

No apparent conflicts with the Forest Plan.

Snohomish County - Skykomish Valley Area: The plan's goals and policies as they relate to National Forest Lands are:

Forestry: Goal: To conserve and protect forest land in this county for long-term forestry and related uses.

Policies:

Recognize that timber harvesting is an important part of the Skykomish Valley's economy and lifestyle.

Recognize the Forest Practices Act and it's rules and regulations as the regulator of forest practices.

Compatible recreation activities should be encouraged on forest land.

The periodic evaluation of forest practices should be encouraged in order to promote the maximum economic return consistent with the protection of resource productivity, fish and wildlife habitats, and water quality.

Water Resources: Goal: Maintain the existing quality of valley water supplies, maintain in-stream flow of rivers and integrity of circulation systems and natural drainageways.

Policies:

Disruption of fish and wildlife habitat should be minimized.

Instances where water quality is especially critical to biological productivity or ecosystem integrity, strict standards should be applied to protect the resource.

Manage wetlands and riparian areas as directed by the Forest Practices Act.

Scenic Resource: Goal: Retention of the existing scenic vistas.

Policies:

Land forms should be respected.

Logged areas replanted to remove visual blight.

Protect the Skykomish River as a valuable scenic resource.

No apparent conflict with the Forest Plan.

Snohomish County - Stream Rehabilitation Program - Summary of the steps Snohomish County has taken to restore streams in specific areas where the

natural systems have been altered by new residential and industrial development, agriculture and timber harvesting.

There are no apparent conflicts with the Snohomish County stream rehabilitation program and the Forest Plan.

King County - Executive Proposed General Development Guide The King County Comprehensive Plan - The King County plan proposed that National Forest lands within King County be designated as resource lands where incentives and land use regulations will promote long term agriculture, forestry, extraction of minerals and for other resources.
No apparent conflicts with the King County plan and Forest Plan.

Pierce County - Draft Environmental Impact Statement: The plan's policies encourage that public and private forest lands be wisely managed and protected from conflicting uses. Activities associated with timber production, such as road building, brush control, lumber milling and construction of fire facilities are all allowed.

No apparent conflict with the Forest Plan.

Municipality Plans

City of Seattle - Watershed Management Documents: (Cedar-Tolt Watershed Management Plan, 1979; Seattle Comprehensive Regional Water Plan, 1985; and Cedar River Watershed Cooperative Agreement, May, 1962.)

These plans state that timber harvest activities are compatible with water quality standards. They call for a variable rotation age for different growing sites, resulting in approximately a 110 year rotation for all sites. Average acreage harvested annually would be about 550 acres or 35 MMBf.

As old growth is harvested in the Cedar Watershed the City of Seattle plans to acquire the harvested areas through land exchange. Eventually the City would become sole property owner within the Cedar Watershed (20-30 years).

In the Tolt River Watershed, the goal of the City of Seattle is to remain a minority owner and not assume total ownership.

The wildlife population within the Cedar Watershed would fluctuate, controlled by available food supply. Snags would be left for cavity nesters. Nesting sites of Peregrine Falcon, Bald Eagle, Osprey, Spotted Owl and Heron would be protected according to applicable laws and recommended practices contained in the Forest Practices Act.

The plans call for recreational use of the watersheds to remain closed to public access except for periphery use of National Forest lands in the Cedar Watershed and National Forest lands in the east end of the South Fork Tolt River.

The Forest Plan has been coordinated with these documents with no apparent conflict between them.

City of Seattle - (Cedar River Secondary Use Analysis, 1988; Ordinance 114632, 1989; Resolution 27916, 1989) The City of Seattle has adopted this plan; it details alternatives for timber harvest, recreation use, fisheries, education,

research, and cultural resources on City-owned lands. The key feature of the Ordinance and Resolution is to balance City-owned land management between habitat preservation and timber management. Also, the City is interested in acquiring National Forest land with standing old growth in selected portions of the watershed. All unsupervised recreation is prohibited on City-owned lands.

The City's official response to the Forest Plan strongly urges the Forest to designate three old-growth areas (SOHA')s. The Preferred Alternative of this FEIS for the Cedar River watershed features a new prescription (20D) calling for renegotiation of a Cooperative Agreement with the City. It includes one SOHA in the watershed. Until this new agreement is negotiated, the Forest will continue to follow the 1962 Agreement; no new land exchanges affecting National Forest land will be initiated. When Management Area 20D is implemented and a new Agreement reached, the Forest Plan will be amended to include the direction in the new Agreement.

City of Tacoma - Memorandum of Understanding, 1984, Watershed Management and Water Treatment Plan, Vol. II, 1987: For the purpose of managing the water supply values on the National Forest in the Green River drainage and providing for management to best harmonize resource use with domestic water supply needs for the City of Tacoma.

City policy strictly controls public and commercial access on the western one-half of the watershed. The eastern half is a checker-board ownership of Federal, private, and some City-owned lands, and these are accessible to the public via Stampede and Tacoma Passes. The MOU provides for land exchange, relinquishment of certain public use access over roads; control of timber sale purchasers and firewood cutters to protect water quality; discouraging overnight camping within 200 feet of any perennial stream; agreement by the FS not to develop campgrounds within the drainage without water quality safeguards and consultation with the City; and to discourage issuance of recreation event special use permits.

The Forest Plan acknowledges this MOU and there is no conflict between them.

City of Everett - Sultan River Basin Resource Management Plan - The objective of the Sultan River Basin management plan is to provide a common framework to guide the desired activities of a variety of government agencies having jurisdiction and interests in the Basin in a way which will allow maximum utilization of resources while preserving and maintaining the highest levels of water quality. The plan identifies a need for a management agreement (probably in the form of a memorandum of understanding). It also contains general management guidelines for the management of the timber resource in the basin. There are no apparent conflicts with this plan and the Forest Plan.

State Plans

Washington Forest Practices Rules and Regulations - These are the rules and regulations for road construction, timber harvesting, reforestation, and the use of chemicals on forest lands in the state of Washington.

There are no apparent conflicts between the Washington Forest Practices rules and regulations and the Forest Plan.

Safety Standards for Logging Operations State of Washington - Snag management policy could result in a conflict between the Forest Plan alternatives and

State Standards. The State Safety Standards for Logging Operations requires that snags within other than tractor units should be felled for safety.

Strategies for Washington's Wildlife: 1982 - 1995 - This document contains a comprehensive strategy for the management of Washington's wildlife and fish resources until 1995, and projects state wide goals for population levels. Management emphasis for the state plan is habitat protection and improvement.

This plan calls for increase in deer and elk populations. The Forest plan does not project increased deer and elk populations sufficient to meet the recommended goals of this plan.

Wildlife Program Plans - Washington Department of Game - The plan states population objectives and harvest objectives for wildlife in 1989. It lists key elements needed to complete the population and harvest objectives and shows the priorities for activity within a plan. See Appendix 1.

Possible conflicts between this document and the Forest Plan exist. They would be similar to those in the preceding document.

State of Washington National Heritage Plan - This plan presents criteria for selection and approval of natural areas and lists the natural heritage resources to be considered for protection, including threatened and endangered plant and animal species. In addition, the plan identifies priorities for protection, outlines methods of protection and identifies the rolls of various agencies and groups in natural area protection.

No apparent conflicts with the Forest Plan.

Washington State Heritage Plan I - The plan identifies principle state agencies responsible for the management of cultural resources and places them in the context of other public and private agencies. The plan makes programmatic recommendations for state cultural heritage agency activities.

No apparent conflicts with the Forest Plan.

A Statewide Comprehensive Plan for Fish and Wildlife on the National Forests in the State of Washington - The goal of the plan is to maintain and enhance existing fish and wildlife populations. For fish and wildlife habitat objectives for 1990, see Chapter III, Wildlife, FEIS. Figures broken out by the Mt. Baker-Snoqualmie's share of the statewide objectives are not available.

No apparent conflict with this document and the Forest Plan.

1984-1993 Forest Land Management Program - The ten-year forest land management program is intended to guide forest management by the State Department of Natural Resources on state owned lands. The plan is intended to provide a general level of guidance for DNR activities (Financial planning, forest land planning, heritage protection. forest protection. forest production and timber harvest).

There should be no conflict between this plan and the Forest Plan.

A Multiple Use Plan for Sultan Basin (DNR) - DNR management plan for their lands in the Sultan Basin. There should be no conflict with the Forest Plan.

Puget Sound Water Quality Management Plan - Puget Sound Water Quality Authority's management plan. The purpose of this plan is to restore and protect biological health and diversity of Puget Sound. The strategy of achieving this purpose is to protect and enhance three resources, the Sound's water and sediment quality; its fish and shellfish; and its wetlands.

There is no apparent conflict between this plan and the Forest Plan.

Washington State Trails Policy Plan (draft- 1990) - This plan was prepared by the Interagency Committee for Outdoor Recreation in cooperation with the National Park Service. The purpose of this plan is to prepare a state trails plan as part of the state-wide outdoor recreation and open space plan. The goal of this plan is to improve and expand the trails system for a wide variety of users from hikers to snowmobilers.

Washington's Statewide Comprehensive Outdoor Recreation Plan - This plan was prepared by the Interagency Committee for Outdoor Recreation. Comprehensive plan for the State of Washington on which outdoor recreational policy decisions can be based. The plan shows the relationship of physical resources and developed facilities to opportunities for participation now and in the future.

No apparent conflicts with the Forest Plan.

Federal Agency Plans

North Cascades National Park Land Protection Plan - The plan identifies methods of assuring the protection of the national, historic, scenic, cultural, recreational or other significant resources, and to provide for adequate visitor use.

No apparent conflict with this plan and the Forest Plan.

Mount Rainier National Park Master Plan - The master plan proposed concepts to facilitate existing visitor use of the park and to accommodate increased visitation according to the ability of the park resources to sustain visitor use. The plan proposed removing unessential facilities from prime resource areas of the park, conducting a transportation study for future reduction of private vehicle use in the park, and adopting an interim bus system for Paradise and Sunrise to reduce private vehicle use.

The plan proposed that lands along the west and north boundaries of the Park have a primary objective of preservation and that greater control over visitor use, especially within the subalpine meadows be exercised. These adjacent lands are located within the Mt Baker-Snoqualmie N.F. Conflict between this plan and the Forest Plan could arise when these lands are designated other than preservation.

Other Plans

Sultan River Project No. 2157 - Washington, Draft Environmental Impact Statement - This document is the EIS for the license amendment (1980) to phase II if the Sultan River Project. There should be no conflicts between this EIS and the Forest Plan.

Sultan River Project; Recreation Plan (revised) - The plan reflects the continued concerns of protecting water quality, but given the new treatment facilities, proposes a removal of some of the previous use restrictions.

Restrictions on use of organic or live bait, shoreline fishing and rubber rafts in Spada lake will be lifted and electric motors will be permitted. Swimming will not be permitted.

The plan would continue to prohibit camping adjacent to the reservoir on NF lands. It proposed multiple boat launching sites and day use facilities at Spada Lake, developing fishing access on the west bank of the Sultan River City of Everett property, Spada Lake overlooks on NF and DNR lands, and backcountry camp facilities at Wallace lake in lieu of facilities in Sultan Basin.

No apparent conflict with the Forest Plan.

Sultan River Project Exhibit S, Fish And Wildlife Management Plan - This plan has not been approved. However, there is no apparent conflict with this plan and the Forest Plan.

Sultan River Project Stage II, Erosion, Sedimentation and Slope Stability Control Plan - Defines specific procedures for the stabilization and retention of soil disturbed by construction activities in the Sultan River Project.

No apparent conflicts with the Forest Plan.

Stillaguamish Watershed Action Plan - This is a plan for the reduction and elimination of Non-Point Source Pollution in the Stillaguamish Watershed. Development and implementation of a resource management plan for the Stillaguamish could affect the rate and location of future harvest and other management activities in order to reduce the cumulative impact from all forestry activities in the watershed.

All of the recommendations of the plan that involve the Forest Service are consistent with the Forest Plan.

Draft Plan for Skagit Valley Recreation Area and E. C. Manning Provincial Park and Cascade Recreation Area - The purpose of this plan is to enhance conservation and recreational opportunities within these recreational areas and within the Park.

No apparent conflict with the Forest Plan.

INTRODUCTION

This appendix is included in the Final Environmental Impact Statement for the Forest Plan in response to decisions of the Chief of the Forest Service and the Deputy Assistant Secretary of Agriculture regarding appeal No. 1770, brought by the Northwest Forest Resource Council on September 18, 1989. The appeal centered on direction from the Regional Forester to incorporate "minimum management requirements" (MMR's) in forest plan alternatives. The appellant requested that the appropriateness of the MMR's be examined through the environmental impact statement process. The information in this appendix also responds to comments about Management Requirements (MR's) that were raised during the review of the Draft Environmental Impact Statement.

A summary of Management Requirements is provided in Chapter II, "Management Requirements" section. Additional information is in Appendix B "Development of Management Requirements " The Standards and Guidelines (or specifications) for implementation of the management requirements are found in the Forest Plan.

This appendix addresses the issue raised by the appellant: For those management requirements which cause significant reductions in allowable sale quantity (ASQ) or present net value (PNV), alternate ways of meeting the management requirements are examined and their opportunity costs (reductions in ASQ and PNV) are compared.

Appendix J of the Draft Environmental Impact Statement, "Sensitivity Analysis of Significant Forest Minimum Management Requirements" has been completely replaced by the material presented here. The Appendix J of the Draft is part of the planning record.

CHANGES BETWEEN DEIS AND FEIS

- Spotted Owl Habitat Areas were changed to meet the Record of Decision for the FSEIS to the EIS for an Amendment to the Pacific Northwest Regional Guide.

- Management requirements for mountain goats were enlarged, and the MR for deer and elk was dropped to meet regional direction, as discussed in the DEIS Appendix I.

- A new way of meeting water quality MR's was developed in response to public comment. The hydrologic cumulative effects constraint developed with public and scientific review is designed to ensure that unacceptable adverse hydrologic cumulative effects will be avoided.

BACKGROUND OF MANAGEMENT REQUIREMENTS

WHAT ARE MANAGEMENT REQUIREMENTS?

Many laws and regulations guide Forest Service activities. One law in particular, the National Forest Management Act of 1979 (NFMA), and its implementing regulations provide direction for the Forest planning process. The direction for National Forest Systems Land and Resource Management Planning, in Section 36 of the Code of Federal Regulations, Part 219 (36 CFR) specify: (1) the minimum specific management requirements to be met in

accomplishing the goals and objectives of the National Forest System (36 CFR 219.27) and (2) the minimum requirements for integrating individual forest resource planning into the Forest Plan (36 CFR 219.14 through 219.26). The term "management requirements (MR's)" will be used in this appendix to refer to these NFMA regulations instead of "minimum management requirements (MMR's)" which were used in the Draft Environmental Impact Statement and Proposed Forest Plan.

Some management requirements are procedural in nature and need not be dealt with here. Some requirements were analyzed and were available for review during the Regional Guide Environmental Impact Statement process and are not dealt with here. See Appendix B for a more complete discussion. The management requirements which have not been fully dealt with elsewhere, and which require additional analysis due to significant opportunity costs associated with implementation are:

1. Dispersion of timber harvest openings.

2. Maintenance of habitat (particularly mature and old growth habitat) to assure viable populations of wildlife.

3. Protection of riparian areas, water resources, and water quality.

These management requirements are described in greater detail in later sections of this appendix. MR's for other wildlife habitats and other requirements noted in 36 CFR 219.27 which have not been addressed in other Environmental Impact Statements do not cause significant opportunity costs when implemented.

LEGAL REQUIREMENTS VERSUS IMPLEMENTATION METHODS

The management requirements from NFMA and its implementing regulations are legal requirements. They represent "ends" which must be met during forest plan implementation. For example, the NFMA implementing regulations require that "fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area." It is mandatory that, whatever implementation methods are chosen, the management requirement be met.

Specifications or standards for achievement for each management requirement are established at the national level or through analysis at the regional level for most of the management requirements. These are listed in the regulations or as Standards and Guidelines in the Regional Guide. Additional specifications identified on the Forest are listed as Standards and Guidelines in the FEIS, Appendix D, and the Land and Resource Management Plan, Chapter IV. The specification must be based on knowledge of the resources involved. For example, in meeting the management requirement for viable populations of vertebrate species it is necessary to define the type of habitat required by the species, the maximum distance between habitats which will still provide reasonable assurance of genetic interaction, and the size of habitat area needed to support a breeding pair.

Often, the pool of scientific knowledge is insufficient to provide the entire basis for defining the specific conditions or standards that will satisfy or meet a management requirement. When this happens it is necessary to rely on the field experience and the professional judgement of knowledgeable

professionals and to establish monitoring and research that will provide better information for future planning efforts.

Implementation methods are the "means" or "ways" in which the management requirements will be met. Usually there is more than one way in which a management requirement can be met. Determining the most appropriate means of meeting the specifications for each management requirement involves careful analysis at the Forest level. Considering and analyzing different means or ways of meeting a specific management requirement are particularly important if there are potentially significant reductions in present net value (PNV) or allowable sale quantity (ASQ) involved.

HOW IMPLEMENTATION METHODS TO MEET THE MANAGEMENT REQUIREMENTS ARE DEVELOPED

The selection of means sufficient to meet management requirements is based on effectiveness in meeting resource protection and on minimizing reductions to PNV or ASQ. The general process used in evaluating alternative ways of meeting the management requirements is as follows:

1. Identify the desired "end" for each management requirement.

2. Assemble existing information about the resources addressed by the management requirement.

3. Analyze the existing information to determine what conditions or specifications need to exist on-the-ground to assure meeting the "ends" of the management requirement. (See Table H-1.)

4. Develop various ways or means to meet the management requirement. (See Table H-2.)

5. Evaluate the effectiveness of the alternative means in meeting the managements. Estimate the environmental effects of each set of means.

6. For each set of means, estimate the effects on economic efficiency (as measured by changes in present net value) and the effects on timber availability (as measured by allowable sale quantity).

7. Where opportunity cost of meeting a management requirement exceed two percent of PNV or ASQ of the present net value benchmark, the analysis used to select the means are presented. Two percent was used because differences less than two percent would not be significant in terms of opportunity costs of alternative means. A higher threshold would preclude evaluation of many alternatives.

For discussion purposes, opportunity costs are reductions in present net value (PNV) and reductions in allowable sale quantity (ASQ) that result from implementing resource protection measures (means or ways) to meet the *management requirements set forth in NFMA regulations. In order to meet timber* harvest dispersion requirements; provide for wildlife habitat; and protect riparian areas, water resources, and water quality requirements of NFMA on Mt. Baker-Snoqualmie National Forest land, some opportunities to maximize present net value or to maximize timber production must be foregone.

Discussions are grouped by harvest dispersion, by wildlife habitat, and by riparian and water quality management requirements in separate sections. In each section, the management requirements are displayed along with relevant specifications from national and regional guidelines, and, where appropriate, alternative implementation methods (means or ways) are analyzed.

Table H-1 summarizes each of the management requirements (ends) subject to analysis of opportunity costs on the Mt. Baker-Snoqualmie National Forest and summarizes the specifications or standards of achievement for those ends. Table H-2 shows the alternative means considered for implementing each management requirement where the opportunity cost exceeded two percent.

In analyzing the effects of meeting the MR's on present net value (PNV) and allowable sale quantity (ASQ), FORPLAN runs were made with and without constraints designed to simulate meeting the management requirement. The PNV benchmark was used for this analysis. This benchmark is a FORPLAN run which identifies the mix of management activities which would result in the highest level of economic efficiency (i.e , the highest PNV) in managing Mt. Baker-Snoqualmie National Forest resources. It also identifies the ASQ associated with the most economically-efficient mix of management activities.

A benchmark was chosen to use in the with-and-without-constraint comparison, rather than an issue-based Forest Plan alternative, because management practices necessary to meet other objectives of the issue based alternatives may partially or fully meet the MR, thus clouding any analysis of opportunity costs induced by the management requirement. The true effect when measured against a fully developed alternative is significantly less because the objectives of that alternative may satisfy the management requirements to a large extent.

IMPLEMENTATION METHODS WITH HIGH OPPORTUNITY COSTS

Table H-3 displays the opportunity costs of the implementation measures selected for meeting management requirements on the Mt. Baker-Snoqualmie National Forest. Only those implementation measures with opportunity costs of two percent or larger are shown: dispersion of harvest units to meet silvicultural guidelines and NFMA vegetation management and diversity specifications; maintaining mature and old growth habitat for wildlife; protection of riparian area values; and limiting timber harvest acres to prevent unacceptable adverse hydrologic cumulative effects.

IMPLEMENTATION METHODS WITH LOW OPPORTUNITY COSTS

Management requirements for other wildlife habitat requirements for threatened and endangered species, sensitive species (except spotted owl), special habitats, and dead and defective tree habitat are not addressed in this analysis because opportunity costs of providing sufficient habitat to maintain viable populations are less than two percent.

Table H-1. Summary of Management Requirements and Associated Specifications.

Ends	Summary of Specifications
Disperse timber harvest openings	Insure timber harvest openings meet size limits and spacing requirements established by the Regional Guide.
Provide habitat to maintain viable populations of existing native and desired non-native vertebrate species	
Northern spotted owl	Maintain mature and old-growth conifer stands (for nesting and feeding) per FSEIS requirements. (see Table H-5.)
Pileated Woodpecker and Pine Marten	Maintain mature growth conifer stands (for nesting and feeding) of adequate size and distribution to permit interaction among breeding pairs of dependent species. (See Tables H-7 and H-8.)
Mountain goat	Maintain mature and old-growth conifer stands of adequate size and conditions, in critical goat use areas, to maintain viable goat populations on the Forest. (See Table H-9.)
Protect Riparian Areas and Water Quality	Allow no management practices which seriously and adversely affect water conditions or fish habitat through detrimental changes to stream temperatures or chemical composition, blockage of water courses, scouring of stream channels, or deposits of sediment. Comply with the requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provision of public water systems and the disposal of waste water.

Table H-2 Summary of Alternative Means Considered for Implementing Each Management Requirement.

Management Requirements	Alternative Means
Locate timber harvest openings to achieve desired combination of multiple-use objectives.	Harvest not more than 30% of each watershed in the first decade, 30% in the second decade, and 20% in each succeeding decade. No alternative means was analyzed for this MR
Provide for adequate habitat to maintain viable populations of existing native and desired non-native vertebrate species.	
Northern Spotted Owl, Pileated Woodpecker, and Pine Marten	Dedicate habitat sites for no timber harvest. Manage habitat sites on long rotations to provide adequate suitable habitat at all times.
Mountain Goats	Dedicate habitat sites for no timber harvest. Manage habitat sites on an extended rotation to provide adequate optimal thermal cover acres at all times
Protect Riparian Areas	Allow no removal of vegetation from riparian areas. Allow no timber harvest in 25% of the riparian area, allow harvest using a minimum 160-year rotation on 50% of the riparian area, and manage the remaining 25% of the riparian area in the same manner as the adjacent land allocation.
Protect Water Quality	Watershed by watershed classification and evaluation of watershed conditions. Determine limits on acres harvested by decade by watershed to prevent unacceptable adverse hydrologic cumulative effects. Review of literature and discussions with academic and scientific community members indicates no process for assessing and mitigating hydrologic cumulative effects applicable to the Mt. Baker-Snoqualmie National Forest exists.

Table H-3. Opportunity Cost of Meeting the Management Requirements with the Selected Implementation Methods

Selected Implementation Method	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with No Protection Measures	63.9 (306)	-	2631	-
Opportunity Cost of Timber Harvest Dispersion	59 1 (283)	-8	2484	-6
Opportunity Cost of Mature and Old Growth Habitat for Northern Spotted Owl, Pileated Woodpecker, Pine Marten, and Mt. Goat	50.1 (240)	-22	2410	-8
Opportunity Cost of Riparian Protection	59.6 (285)	-7	2580	0
Opportunity Cost of Water Quality Protection	41.0 (196)	-36	2297	-13

1/ Percent change calculated on cubic foot basis

IMPLEMENTATION METHODS THAT MEET MORE THAN ONE MANAGEMENT REQUIREMENT

Implementation methods selected to meet water quality management requirements also provide fish habitat in streams and riparian habitat adjacent to streams to assure the maintenance of viable populations of species dependent on these habitats. Alternative implementation methods for meeting water quality management requirements will also meet fish habitat and riparian habitat requirements. No additional discussion or analysis is displayed in Appendix H for these management requirements.

TIMBER HARVEST DISPERSION MANAGEMENT REQUIREMENT

SOURCE OF THE TIMBER HARVEST DISPERSION MANAGEMENT REQUIREMENT

Management requirements for dispersion of timber management openings are based on NFMA which states: "Openings shall be located to achieve the desired combination of multiple-use objectives. The blocks or strips shall be shaped and blended with the natural terrain, to the extent practicable, to achieve *aesthetic, wildlife habitat, or other objectives established in the Plan* (36 CFR 219.27(d)(1).

Direction in the Regional Guide relating to harvest openings states, "Created openings will be separated by blocks of land that generally are not classed as created openings and that contain one or more logical harvest units. A harvested area will no longer be considered a created opening for silvicultural purposes when stocking surveys indicate prescribed tree stocking that is at least 4-1/2 feet high and free to grow."

SPECIFICATIONS FOR THE TIMBER HARVEST DISPERSION MANAGEMENT REQUIREMENT

The Forest utilized the theoretical harvest dispersion factor formula developed by the Region, which resulted in a harvest dispersion factor of 30%. This 30% represents the maximum amount of land that can be assigned to a regeneration timber harvest prescription in a 10 year period. An accessibility constraint of 30% applies to each allocation zone on the Forest for Decades 1 and 2. The accessibility constraint increases to 20% in the third and fourth decade to reflect the harvest occurring in the first two decades. After the first 4 decades, a 20% constraint is applied to the North and South portions of the Forest rather than to the allocation zones.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENT FOR TIMBER HARVEST DISPERSION

No alternative means of meeting this management requirement were identified. The modeling results of the accessibility constraints were tested by plotting units scheduled for harvest in a benchmark run onto an allocation zone/analysis area map. The resulting pattern indicated that the adjacency requirements could be met in most instances, though not with a lot of leeway. This evaluation and the experiences of adjacent Forests where harvest dispersion factors ranged from 25 percent to 30 percent indicates alternative means of meeting this MR are extremely limited or do not exist.

EVALUATION OF IMPLEMENTATION METHODS TO MEET TIMBER HARVEST DISPERSION MANAGEMENT REQUIREMENT

Only a single method was developed and investigated for this management requirement.

OPPORTUNITY COSTS

The opportunity costs of the implementation method for meeting the timber harvest openings management requirement were estimated by comparing the differences in PNV and ASQ that would occur with and without the constraints that meet the requirements.

Table H-4 Displays the PNV and ASQ opportunity costs of the harvest dispersion management requirement.

Table H-4. Opportunity Cost of Meeting the Harvest Dispersion Management Requirement

Selected Implementation Method	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with No Protection Measures	63.9 (306)	-	2631	-
Opportunity Cost of Timber Harvest Dispersion	59.1 (283)	-8	2484	-6

1/ Percent change calculated on cubic foot basis

RATIONALE FOR THE SELECTED IMPLEMENTATION MEANS

The harvest dispersion constraint was developed on the assumption that harvest units would be 40 acres in size and that it would take 11 to 16 years (depending on elevation and method of reforestation) for trees to reach 4-1/2 feet in height. These assumptions may overestimate or underestimate actual conditions on the ground.

Region-wide criteria and a suggested method for calculation of a theoretical harvest dispersion constraint were available to all Forests. The calculation of the harvest dispersion constraint includes two variables, the size of the harvest unit, and length of time for reproduction to reach 4-1/2 feet in height.

Coordination with the Wenatchee, Gifford Pinchot, and Olympic National Forests indicated that there were differences between Forests that could potentially result in differences in modeling proxies for harvest dispersion. There are differences between Forests in the amount of the Douglas fir type (maximum size of harvest unit of 60 acres) and other forest types (maximum size of harvest unit of 40 acres). The length of time required for a tree to reach 4-1/2 feet also varies between Forests because of differences in species composition, growth rates and methods of reforestation.

The harvest dispersion factor selected by the four Forests varies from 25% to 30%. This difference appears reasonable based on the physical and biological differences between the Forests.

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

FEIS Chapter II and Appendix B discuss the effects of this method of meeting the harvest dispersion requirement in FEIS Alternatives. The analysis of opportunity costs of the selected means of harvest dispersion in Table H-4 shows the maximum PNV and ASQ effects. Actual Plan alternatives will have somewhat less opportunity costs as overlaps from lands withdrawn for wildlife, scenery, recreation, or other nontimber objectives will help provide dispersion of harvest units.

ROLE OF MONITORING AND RESEARCH

The Forest Monitoring Plan (Forest Plan Chapter 5) calls for monitoring of size and dispersion of harvests units to insure NFMA requirements are met. At scheduled Plan reviews, monitoring data will be evaluated to determine the effectiveness of the means selected to model the requirement for harvest dispersion.

EXISTING NATIVE VERTEBRATE SPECIES VIABLE POPULATIONS MANAGEMENT REQUIREMENT

SOURCE OF THE MANAGEMENT REQUIREMENT

The NFMA regulations require that:

"Fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure continued existence in the planning area. In order to insure that viable populations will be maintained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area." (36 CFR 219. 19).

DESCRIPTION OF THE MANAGEMENT REQUIREMENT

All vertebrate species in Region Six were assessed with regard to population numbers and/or distribution that could result in either Forest or Regional extinction during the next five decades. Management requirements were developed for species whose viability would be at risk if no management actions were taken to protect their habitats.

The focus was on habitats that were likely to be limiting in the future (in short supply either in total acreage or in distribution) and on identification of particular species that could be used to represent all species dependent on those habitats. This identification was done on a subregional basis, recognizing the variability of situations within the Region. Once these species were identified, the Region defined their habitat requirements and biological characteristics. The species are included in the list of Management Indicator Species (MIS) that the Forests address in forest planning and subsequent monitoring.

Table H-5 displays current Regional management requirement direction regarding limited habitats and wildlife species by sub-regional zones The Mt. Baker-Snoqualmie National Forest is in Zone 2.

Northern spotted owl, pileated woodpecker, pine marten, and mountain goat are the only species for which alternative ways of meeting management requirements are evaluated. Management requirements for threatened and endangered species, sensitive species (except spotted owl), special habitats, and dead and defective tree habitat are not addressed in this analysis because opportunity costs associated with providing sufficient habitat to maintain viable populations are less than two percent. The management requirements for fish

are met with the same management practices which provide the requirements for riparian area and water quality, therefore further analysis is not provided.

Table H-5. Species Matrix for Addressing Management Requirement for Wildlife and Threatened and Endangered Species.

Zone Habitat	Zone 1 North Coastal	Zone 2 Westside Cascades	Zone 3 Eastside Cascades	Zone 4 Blue Mountain
Mature and Old Growth (Seral Stages V and VI)	*Northern Spotted Owl Pine Marten Pileated Woodpecker	*Northern Spotted Owl Pine Marten Pileated Woodpecker	*Northern Spotted Owl Pileated Woodpecker Northern three-toed woodpecker	Pine Marten Pileated Woodpecker Northern three-toed woodpecker
	*The Final Supplemental Environmental Impact Statement and subsequent Record of Decision provide direction for management of spotted owl habitat in Region Six.			
Dead and Defective	Primary Cavity Excavators	Primary Cavity Excavators	Primary Cavity Excavators	Primary Cavity Excavators
Riparian	The Forest determined and documented as part of the planning records, whether it needed to address wildlife in addition to fish, and if so which wildlife species would represent the riparian habitat. Coordination of this process with adjacent Forests was necessary to determine consistency.			
Big Game		Mountain Goat	Mountain Goat (Wenatchee)	
Threatened *Endangered* Species	Bald Eagle *Peregrine* Falcon Brown Pelican Aleutian Canada Goose	Bald Eagle *Peregrine* Falcon	Bald Eagle *Peregrine* Falcon Grizzly Bear Woodland Caribou (Colville)	Bald Eagle *Peregrine* Falcon

HABITAT NEEDS

Once the species needing management requirements were identified, the Region defined habitat requirements and biological characteristics. These are the basis for providing habitat and also for deciding how best to represent the species' needs in the planning process and in the FORPLAN Model. Regional specifications for MR species are summarized in "A Report on Minimum Management Requirements for Forest Planning on National Forests of the Pacific Northwest Region, USDA Forest Service" (USDA Forest Service, June 1986).

Habitat needs were defined using information from existing research whenever possible (see bibliography). This information was used to define the habitat conditions, habitat dispersal, and habitat size necessary to meet the management requirement. When information was available, but did not fit exactly the management requirement context, professional judgement was used to apply the information in estimating habitat needs. When information was not available, habitat needs were developed using professional judgment of a number of more knowledgeable biologists on the subject. Information from existing research was used whenever possible (Note: Habitat needs of spotted owls are described in the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide, USDA Forest Service 1988).

Specific information on habitat needs, specifications for meeting habitat requirements, and alternative ways of meeting the management requirements for northern spotted owls, pileated woodpecker, pine marten, and mountain goats are presented in the following sections. For each species, information is provided for these three habitat factors:

Principal Habitats Used

Information about the seral stages and Kuchler vegetation types which are used by the various species is documented in many research papers for individual species. Information as to which Kuchler type and/or seral stage are primary or secondary habitat, and the amount of dependency upon each habitat, is based mostly on professional judgment (Guenther and Kucera 1978, Phillips and others, 1981).

Dispersal Distance Between Habitats

Usually no research information is available for optimum dispersal distance between habitats. As a result, dispersal distance is often determined on the basis of observations, experience, and professional judgment. Dispersal distance is based on the ability of an individual species to travel to the next habitat often enough to prevent isolation of sub-populations. Distances are adjusted to consider the network and overlap of habitat formed by the species (e.g., Pileated woodpecker and pine marten).

Size of Habitat Areas

The size of individual habitat areas provided for each wildlife species is based on the habitat acreage needed to support the basic social or reproductive unit of the species, i.e., breeding pairs. Both home range and species density information are used to estimate the needed size of habitat area. This was supplemented with professional judgement where no data were available for the specific habitat types being managed.

SPECIFICATIONS FOR MEETING THE HABITAT REQUIREMENTS FOR NORTHERN SPOTTED OWL

Specific Regional direction for the northern spotted owl is found in the Final Supplement to the Environmental Impact Statement (FSEIS) for an Amendment to the Pacific Northwest Regional Guide released in August, 1988. In response to an appeal of the R-6 Regional Guide, the Supplement was prepared to address planning direction for spotted owl habitat management. Standards and guidelines adopted as a result the Supplement will be used by National Forests

in the Region to meet the management requirement to maintain viable populations of spotted owls.

The final SEIS was prepared after a series of public meetings and study of the nearly 42,000 comments received on the Draft Supplement issued in the summer of 1986. A summary of the analysis of public comments, substantive comments, and copies of letters received from government agencies and elected officials can be found in Appendix G of the FSEIS.

The Forest Service Preferred Alternative (F) directs that the amount of suitable habitat at each designated SOHA will vary by physiographic province. Specific criteria were followed in locating designated SOHA's on the Mt. Baker-Snoqualmie. Current distribution of owl habitat on lands unsuitable for timber production was evaluated for adequacy of distribution. SOHA's were designated on lands suitable for timber production only where necessary to meet distribution standards. Standards and Guidelines for the Forest Service preferred alternative (F) are briefly summarized in the following discussion. Chapter II of the Final Supplement should be reviewed for detailed description of the direction. These Regional Standards and Guidelines provide specifications or standards for achievement of management requirements for northern spotted owls:

1. **Amount of suitable habitat in designated habitat areas:** Designated habitat areas shall contain the following amount of suitable habitat: 2200 acres within 2.1 miles of the nest site or likely nest site if the exact nest site is unknown. Habitat shall occur as one contiguous stand if possible or, as a 300 acre stand containing the known or suspected nest site with the remaining habitat as contiguous as possible. Each stand shall be larger than 60 acres.

2. **Spacing of Designated Habitat Areas:** Designate habitat areas where: greater than six miles separates areas which occur in reserved lands or in lands unsuited for timber production, and which are capable of *supporting less than three breeding pairs of spotted owls; or where* greater than 12 miles separates such areas capable of supporting three or more pairs

3. **Threatened and Endangered Species:** No spotted owl habitat management activities shall adversely effect Federally listed threatened or endangered species or their habitat.

4. **Identification of Suitable Habitat:** Suitable habitat shall be identified in Forest Plans according to the general definition in the spotted owl Final Supplement and with concurrence by the Regional Forester.

5. **Management of Habitat:** Spotted owl habitat can be provided through prescriptions using even-aged or uneven-aged silvicultural systems, or no scheduled harvest Prescriptions to be used and where they will apply shall be specified in the Forest Plans.

6. **Location of designated Habitat Areas:** Designate habitat areas only on lands suitable for timber production as needed to meet spacing standards.

7. **Priority for Locating Designated Areas:** Priority for locating designated areas follows status of occupancy by spotted owls. The highest priority is given to locations with verified occupancy by spotted owl pairs; next highest to locations with confirmed sightings of owls; lowest priority to locations where the presence or absence of owls is unknown.

The Final Supplemental Environmental Impact Statement (FSEIS) to the Regional Guide (for spotted owl habitat management guidelines) does not include the number of designated habitat areas as part of any alternative. The number of habitat areas are not specified in the Regional Guide, but will be a consequence of applying standards and guidelines in Forest Plans.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENTS FOR NORTHERN SPOTTED OWL

The Forest considered two alternative ways of providing mature and old-growth habitat for viable wildlife populations. These were the dedicated approach, where the required acres would be constrained to a no timber harvest prescription and a managed approach which provided for managing the habitat on an extended rotation basis to provide the desired structural characteristics of the stand.

ALTERNATIVE 1: Dedicated Sites

Under a dedicated habitat strategy, each acre of spotted owl habitat is withdrawn from timber production. Dedication of existing stands assures that desired structural characteristics will be available, but may risk loss of individual stands through catastrophe or decay. Recent literature on old-growth suggests this risk is much less than once thought.

ALTERNATIVE 2: Managed Sites

Management of sites assumes that existing old growth stands can be harvested as they are replaced by other stands that grow into an old-growth condition Delay in harvesting the existing old-growth stands would occur if replacement stands fail to develop desired structural characteristics on schedule. Management of old growth on a harvest basis and replacing it removes structural characteristics important to old-growth and may hasten the decline of the residual stand (Franklin 1981). There is a risk that all habitat components are not well-enough understood to manage for the full complex of habitat characteristics needed.

EVALUATION OF IMPLEMENTATION METHODS TO MEET NORTHERN SPOTTED OWL MANAGEMENT REQUIREMENT

An efficiency analysis was conducted to compare the dedicated versus managed approach utilizing the methodology developed by the Siuslaw National Forest. This analysis indicated that a dedicated approach was more efficient than a managed strategy in terms of timber outputs. An economic evaluation was conducted for marten habitat areas, comparing the managed and dedicated strategies. This analysis confirmed that dedicated was more efficient in terms of PNV at a 4% discount rate. In addition there is uncertainty about whether the structural characteristics of mature and old growth habitat can be duplicated through management.

The minimum time required to produce mature forest habitat is 100 years. It requires at least 250 years to produce old-growth forest habitat. At both 100 and 250 years, the average replacement area would contain more volume than the original habitat area. Rotating the areas would result in less timber yield than harvesting the potential replacement area and leaving the original area to continue providing habitat. Dedicating the habitat minimizes the opportunity costs of ASQ and PNV. Thus the dedicated stand option was selected to provide for all mature and old-growth habitat management requirements.

Table H-6 compares the empirical yield table volumes after 100 and 250 years with the volumes from the intensive managed yield tables at ages 100 and 250.

Table H-6. Comparison of Stand Volumes After 100 and 250 Years.

	Stand Volumes After 100 and 250 Years (MCF/Acre)			
	100 Years		250 Years	
Site 1/	Empirical	Managed	Empirical	Managed
North

Average	6.776	--	8.527	--
South				
DF High	--	10.008	--	17.638
DF Low	--	9 196	--	11.433
PSF Low	--	9.412	--	9.368
Average	5.467	--	10.374	--

1/ DF = Douglas-fir
PSF = Pacific silver fir

OPPORTUNITY COSTS

The opportunity costs of designating the habitat areas (selected method) were not determined for spotted owls alone. Because of the interactions of habitat needs of all the mature and old growth species (Spotted owl, pileated woodpecker, pine marten, and mountain goat), opportunity costs were determined for the combination of all species requiring mature and old growth habitat. The discussion of opportunity costs for these management requirements are found at the end of this section (page H-27).

CONSEQUENCES OF THE DIFFERENT WAYS OF MEETING THE MANAGEMENT REQUIREMENT

Populations of spotted owls would not be expected to differ significantly under any of the options available to meet the management requirement. There are,

however, differences in the opportunity costs as dedicated habitat areas would have the least impact on timber outputs and therefore PNV.

RATIONALE FOR THE SELECTED METHOD

The Mt. Baker-Snoqualmie National Forest chose to provide spotted owl habitat by dedicating habitat sites. This alternative maintains necessary habitat, and has the least effect on timber outputs; it is an economically efficient way of meeting the management requirement with the least opportunity costs.

The dedicated habitat approach has the advantage that the location of the habitat site does not change over time, making implementation less complicated than continuously relocating the habitat site as the stands are harvested and replaced

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

Plan alternatives were designed to address public issues. As a result most alternatives, including the preferred, incorporate objectives for retention of old-growth and mature timber for a variety of reasons, such as wildlife, visual, and recreation. To the extent possible, spotted owl habitat areas overlap with areas selected for other purposes (such as Wilderness, unroaded recreation areas, special interest areas and other lands determined as not appropriate or unsuited for timber production), wherever these meet habitat suitability and distribution requirement.

ROLE OF MONITORING AND RESEARCH

The Forest Monitoring Plan (Forest Plan Chapter V) calls for monitoring populations and habitats of spotted owls.

The Final Supplemental Environmental Impact Statement to the Regional Guide (Appendix D) identifies specific monitoring and research needs and describes how the information will be obtained. Intensive inventory, monitoring, and research being conducted by the Spotted Owl Research, Development, and Application Program will provide new information. This should allow an opportunity to re-evaluate and possibly adjust management direction within five years

SPECIFICATIONS FOR MEETING HABITAT REQUIREMENTS FOR PILEATED WOODPECKER AND PINE MARTEN

A number of wildlife species are known to depend on or prefer mature conifer habitat during some part of their life cycle on the Mt. Baker-Snoqualmie National Forest. By providing a dispersion of mature conifer habitat sites for the pileated woodpecker and pine marten, we are assuming that the other species preferring mature conifer habitats will have adequate habitat to maintain viable populations throughout the planning period.

Regional specifications for pileated woodpecker and pine marten are discussed in the following sections. The specifications are summarized from "A Report on Minimum Management Requirements for Forest Planning on the National Forest of the Pacific Northwest Region, USDA Forest Service" (USDA Forest Service, June 1986). In developing the report, various habitat sizes and dispersal distances

were considered. Based on that analysis, minimum habitat sizes and maximum dispersal distances were identified for each species. This information is based on the best available data. Alternatives which addressed changes to size or distribution were not considered in developing the Forest Plan for the Mt. Baker-Snoqualmie National Forest.

Habitat specifications for pileated woodpecker and pine marten are summarized in Table H-7 and H-8.

PILEATED WOODPECKER SPECIFICATIONS

Principal Habitats Used

Pileated woodpeckers need mature or old growth stands of timber for nesting and feeding. Habitats were identified in Bull and Meslow (1977), Guenther and others (1978), and Thomas (1979).

Dispersal Distance Between Habitats

An initial five-mile maximum dispersal distance between habitats from professional judgment documented in Phillips and Roberts (1985). In June of 1986, the distance between habitats was modified to one habitat area for every 12,000 to 13,000 acres (about five miles apart) to allow greater flexibility in application.

Size of Habitat Areas

The size of nesting areas in Region Six for the pileated woodpecker has been identified as a range of 100 to 540 acres. To meet the needs of pileated woodpeckers both east and west of the Cascades, 300 acres of old growth or mature timber for nesting area, plus 300 acres of feeding area was defined as a Region-wide requirement. Three hundred acres of nesting area appears to be an average for different habitats. As more data specific to westside and eastside habitats (eastside may be further subdivided) become available, the size of the nesting area may be adjusted (Bull and Meslow, 1977; Bull, 1975; Mannan, 1982; Mellen, 1986). A 1,000-acre unit was established as the minimum size territory that a pair of woodpeckers would defend. This was determined from research data. Snag size and density were taken from Thomas (1979), and acreage figures from Bull (1975), and Bull and Meslow (1977). See Table H-7 for summary of habitat specifications.

Table H-7. Pileated Woodpecker Habitat Requirements.

Principal Habitats Used Zone 2 (West Cascades) 1/	Dispersal Distance Between Habitats	Size of Area to which wildlife Prescriptions Apply	Habitat Requirements to be Used in Analyses
		All Zone	600 acres/pair Within a 1,000-acre unit:
A. Reproducing			
Seral Stages V and VI of Kuchler types K2, K5, K29, and riparian	One habitat area for 12,000 to 13,000 acres.		Maintain 300 acres of conifers in seral stages VI and/or V, per pair for reproducing.
B. Feeding			Maintain a minimum average of two hard snags per acre greater than or equal to 12 inches dbh within the 300-acre reproductive area. Forty-five of these 600 snags should be greater than or equal to 20 inches dbh.
All seral stages of Kuchler types listed for reproducing habitat, provided snags are present.			When possible, maintain reproductive area in 300 contiguous acres. If not possible, habitat may be arranged in blocks no less than 50 acres and no more than 1/4 mile apart.
			Maintain a minimum average of two hard snags per acre greater than or equal to 10 inches dbh on an additional 30 acres for feeding.

1/ Mt Baker-Snoqualmie National Forest is in Zone 2, Westside Cascades. Principal habitats used vary by zone in the Region.

PINE MARTEN SPECIFICATIONS

Principal Habitats Used

The pine marten uses seral stages III-VI--closed sapling-pole, large mature, and old growth (Thomas, 1979; Guenther and Kucera, 1978; Phillips and others, 1981). The Kuchler types used are from Guenther and Kucera (1978). The principal habitat for pine marten is seral stages V and VI (mature and old growth).

Dispersal Distance Between Habitats

Burke (1982) recommends that the maximum dispersal distance between habitat areas for pine marten should be two miles. In 1984 the Regional Forester changed the dispersal distance from two miles to three miles. This change was made because it was felt where more than one adjacent habitat is available for dispersal, the dispersal distance can be extended to three miles for pine marten. This change has been reviewed by a number of biologists within and outside the Forest Service and most agree that it would appear not to create a population viability problem for represented species In June of 1986, the dispersal distance specification for pine marten habitat was changed to one habitat for every 4,000 to 5,000 acres (about three miles apart) to allow greater flexibility in application.

Size of Habitat Areas

In the professional judgment of the biologists listed in Phillips and Roberts (1985), a breeding female pine marten can be supported on 160 acres of quality habitat. Research is variable as to the size of area needed, but the female pine marten home range is estimated to be 160 acres (Campbell, 1979). The biologist listed in Phillips and Roberts (1985) judged that this area should be contiguous to ensure that there would be enough habitat within the home range of the female. They also judged that crown closure should equal or exceed fifty percent. Research papers indicate that areas with a low percent crown closure receive little or no use by pine marten. Therefore, to ensure an adequate crown closure, a minimum requirement of 50 percent closure was selected.

Research shows that pine marten require dead and down material for foraging, cover, and denning. Six down logs/acre (Burke, 1982) was selected as the minimum down material requirement. The number and size of snags required was selected to ensure that the amount of down material was achieved. The specifications for pine marten habitat are summarized in Table H-8.

Table H-8. Pine Marten Habitat Requirements.

Principal Habitats Used Zone 2 (West Cascades) 1/	Dispersal Distance Between Habitats	Size of Area to which wildlife Prescriptions Apply	Habitat Requirements to be Used in Analyses
	One habitat area for every 4,000 to 5,000 acres	160 acres per habitat area.	Maintain 160 contiguous acres of conifer in seral stages V or VI with a crown closure 59 percent or greater.
A. Reproducing			
Seral stages V and VI of Kuchler types K2, K5, K6, K29.		(This figure represents the territory of one female and part of the territory for a male)	Within 160-acre unit: Maintain an average of two hard snags per acres *greater than or* equal to 12 inches dbh.
B. Feeding			
Seral stages III-VI of Kuchler types listed for reproducing habitat.			Twenty-four of these 320 snags should be greater than or equal to 20 inches dbh. Maintain a minimum average of Six down logs per acre at least 12 inches dbh and 20 feet long.

1/ Mt. Baker-Snoqualmie National Forest is in Zone 2, Westside Cascades. Principal habitats used vary by zone in the Region.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENT FOR PILEATED WOODPECKER AND PINE MARTEN

On the Mt. Baker-Snoqualmie National Forest, mature conifer habitat is defined as a stand of predominantly conifers which are over 100 years old.

Habitat areas for pine marten and pileated woodpeckers were mapped using Regional spacing, size, and habitat suitability criteria. Pine marten sites area to be located every 4,000 to 5,000 acres and pileated woodpecker sites every 12,000 to 13,000 acres.

Whenever possible sites were place within Wilderness, Wild River, RNA's other areas unsuitable for timber production, and in areas of reduced harvest levels, wherever these met habitat quality and distribution requirements.

Once the minimum number of habitat sites was determined using Regional spacing and habitat suitability specifications, the Forest considered two options for providing mature conifer habitat. One was to dedicate the required number of acres of suitable habitat in each site. These areas would not be managed for timber production and would be expected to remain in suitable habitat condition for several decades. The second option was to manage timber stands on a larger area in order to harvest timber and produce replacement stands over time.

ALTERNATIVE 1: Dedicated Sites

Under a dedicated mature conifer strategy, the required amount of mature conifer is withdrawn from timber production. Dedication of mature conifer sites has the advantage that the location of the stand does not change over time, making implementation less complicated. Dedication also assures that desired structural characteristics will be available for wildlife. There may be some risk of loss of individual stands through catastrophe.

ALTERNATIVE 2: Managed Sites

This option involves the projection of long rotations on enough acres to maintain the necessary habitat through time, with all areas being rotated. The "normal" rotation age for stands in General Forest is projected to be about 100 years. Production of mature conifer habitat is expected to take around 100 year; rotations of 140 are used to model a managed regime providing mature habitat from age 100 to 140. This means that for every acre of suitable habitat, 2-1/2 acres would be managed as replacement stands when the original acre is harvested.

Management of mature conifer sites assumes that existing stands can be harvested as other stands grow into a mature conifer condition to replace them. If replacement stands fail to develop desired structural characteristics (ie. large diameter snags and down material) as predicted mature conifer habitat would either be lost for a period of time or further delay in harvesting the existing mature conifer stands would occur.

EVALUATION OF IMPLEMENTATION METHODS TO MEET PILEATED WOODPECKER AND PINE MARTEN MANAGEMENT REQUIREMENTS

A discussion of the evaluation of alternative means of meeting all mature and old-growth habitat management requirements is included in the section on northern spotted owl.

OPPORTUNITY COSTS

The opportunity costs of designating the habitat areas (selected method) were not determined for pileated woodpecker or pine marten alone. Because of the interactions of habitat needs of all the mature and old growth species (Spotted owl, pileated woodpecker, pine marten, and mountain goat), opportunity costs were determined for the combination of all species requiring mature and old growth habitat. The discussion of opportunity costs for these management requirements are found at the end of this section (page H-27).

CONSEQUENCES OF THE DIFFERENT WAYS OF MEETING THE MANAGEMENT REQUIREMENT

Populations of pileated woodpeckers and pine marten would not be expected to differ significantly under either alternative. Both would maintain the same amount and distribution of Habitat. There are, however, differences in the opportunity costs as dedication of habitat areas would have the least impact on timber outputs and therefore PNV.

RATIONALE FOR THE SELECTED METHOD

The Mt. Baker-Snoqualmie National Forest chose to provide mature conifer habitat for pileated woodpecker and pine marten by dedicating sites where needed on tentatively suitable timber land. This alternative achieves the desired habitat with the least effect on timber outputs and is and economically efficient way of meeting the management requirement. Modeling these areas as designated for this planning period does not preclude future planners from designating replacement areas as substitution opportunities can be identified (i.e., some existing pole stands could be substituted for originally designated area by the 5th decade). Whether areas are modeled as designated or rotated, there would be little difference in implementation for the first planning period.

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

Plan alternatives were designed to address public issues. As a result most alternatives, including the preferred, incorporate objectives for retention of old-growth and mature timber for a variety of reasons, such as wildlife, visual, and recreation. To the extent possible, pileated woodpecker and pine marten habitat areas overlap with areas selected for other purposes (such as Wilderness, unroaded recreation areas, special interest areas and other lands determined as not appropriate or unsuited for timber production), wherever these meet habitat suitability and distribution requirement.

Spotted owl, pine marten, pileated woodpecker and goat areas overlap with each other in some cases, and they overlap with areas selected for other purposes (such as unroaded recreation areas and special interest areas) wherever these sites meet habitat suitability and distribution requirements. Methods

resulting in the opportunity cost shown in Table H-3 would benefit other resource uses as well.

ROLE OF MONITORING AND RESEARCH

The Forest Monitoring Plan (Forest Plan Chapter V) calls for monitoring populations and habitats of pileated woodpecker and pine marten. At scheduled plan review, monitoring data will be considered in determining the suitability and effectiveness of the selected method for meeting the management requirement for viable populations. This will be an important test of the appropriateness of the selected modeling assumptions.

Information needs for both pine marten and pileated woodpecker include:

1. Dispersal distances:

   a. How far can juveniles successfully disperse?
   b. As habitat becomes increasingly fragmented, what is the ability of dispersing individuals to locate habitat islands?
   c. What effect does the size of habitat areas have on the ability of dispersing individuals to locate these sites?

2. Size of mature conifer habitat sites:

   a. Occupancy and use of habitat sites, particularly as the sites become more isolated.
   b. Reproductive success within habitat sites.
   c. Home range size in fragmented forests.

3. Utilization and reproductive success of pine marten and pileated woodpeckers in mature conifer sites managed on a 100 year rotation (ie. are managed sites meeting habitat needs as compared to natural stands).

4. Population density, home range size and distribution of pine marten in reserved and other no-timber-harvest areas.

5. Reliable cost-effective methods of inventorying and monitoring pileated woodpecker and pine marten numbers are needed. Research is underway to improve these techniques.

SPECIFICATIONS FOR MEETING THE HABITAT REQUIREMENTS FOR MOUNTAIN GOAT

Principle Habitats Used

The mountain goat uses rock outcrops, cliffs, avalanche chutes, rim rocks, and seral stages V and VI (mature and old growth) of Kuchler types K1, K2, and K3.

Size of Habitat Areas

On the Mt. Baker-Snoqualmie, it was determined that habitat areas would be 45 acres per goat, based on the regional requirement of 10 acres per goat for each month on the winter range. Mountain goat habitat on the Forest was mappped by goat family group habitat areas, using the best available information on goat

occurrence and habitat requirements. The total number of family group areas mapped was 124: 16 in wilderness, 34 partially in wilderness, and 74 outside wilderness.

Once the family groups were established, an MR area was determined for each family group area, using the habitat specifications described in Table H-9. To the extent possible, 585 acres (45 acres per goat for an average 13 goats in the family) of MR habitat was delineated. In a number of areas, this amount of suitable cover was not present; in these cases, all of the existing suitable cover was delineated. Wilderness family groups had larger amounts of suitable cover available in a number of cases. Since these areas are what is minimally required and, therefore, very important if that is the only thermal cover left, they must be set up in areas of high use and/or critical need during winter months. The following criteria describe those needs.

PRIORITIES:

Seral Stage	Seral stages V and VI are required to fulfill the optimal cover and thermal cover needs of mountain goat. These stages correspond with the R2Map codes, S1 and S2, used to map the optimal cover/thermal cover MR's.
Aspect	Because winter range is most critical and goats concentrate primarily on south, southwest, and west-facing slopes during winter, these locations were preferred over other exposures. Wilderness cells (R2Map cell = 21.12 acres) were not chosen if they were on north-facing slopes.
Road Proximity	Mountain goats are highly sensitive to road disturbance (vehicle traffic, poaching, snowmobiles, and cross-country skiers on closed roads), therefore cells furthest from adjacent roads were selected.
Continuous Edge	Optimally, old growth cells were maintained along the flanks of rock outcrops, cliffs, etc., to provide an adequate distribution of adjoining thermal cover.
Adjacent Rock	Because mountain goats require steep ledges, cliffs, and rock outcrops, cells contiguous with this habitat were chosen first.
Wilderness Areas	Cells with wilderness designation were chosen first, if they also met the above criteria.
Tentatively Suitable Timber	Tentatively suitable timber was not chosen as part of the MR area if other cells were as appropriate for goat range.

Table H-9. Mountain Goat Requirements.

Principal Habitats Used Zone 2 (West Cascades) 1/	Dispersal Distance Between Habitats	Size of Area to which wildlife Prescriptions Apply	Habitat Requirements to be Used in Analyses
Rock outcrops, cliffs, avalanche chutes, rim rocks, and seral stages V & VI of Kuchler types K1, K2, and K3 adjacent to state landforms.	Not Established	45 acres per goat.	Forage and thermal cover within defined winter range boundaries. Maintain 50% of conifer habitat in seral stages V and VI on identified winter ranges. Allow 7-20 acres of winter range per goat per month.

1/ Mt. Baker-Snoqualmie National Forest is in Zone 2, Westside Cascades. Principal habitats used vary by zone in the Region.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENT FOR MOUNTAIN GOATS

Once the family groups were established, the management requirement areas determined, and the management requirement habitat delineated, the Forest considered two options for providing adequate mountain goat habitat.

ALTERNATIVE 1: Dedicated Sites

Under a dedicated site strategy, the required amount of mature and old-growth habitat needed for thermal cover is withdrawn form timber production. Dedication of habitat has the advantage that the location of the stand does not change over time, making implementation less complicated. Dedication also assures that desired structural characteristics will be available for wildlife. There may be some risk of loss of individual stands through catastrophe.

ALTERNATIVE 2: Managed Sites

The managed sites option requires the projection of long rotations on enough acres to maintain the necessary thermal cover through time with all acres being harvest over time.

EVALUATION OF IMPLEMENTATION METHODS TO MEET MOUNTAIN GOAT MANAGEMENT REQUIREMENTS

As discussed above, it was necessary that habitat areas designated as MR areas be areas actually used by goats and containing, to the full degree possible, all of their habitat requirements. Current goat numbers are lower than expected, based on what is known about habitat requirements and available

habitat. There is a risk that their habitat requirements are not fully understood. Because of the lowered number of goats, it was determined that it was necessary to choose areas for MRs with the best indications, based on actual goat use, that they are suitable. This does not allow for managing larger areas to contain different areas of suitable habitat over time. The current literature does not support the idea that goat optimal cover and escape cover conditions can be provided through timber management.

Therefor, dedicating MR goat habitat areas of actual use and the best possible habitat conditions was selected.

OPPORTUNITY COSTS

The opportunity costs of designating the habitat areas (selected method) were not determined for mountain goat alone. Because of the interactions of habitat needs of all the mature and old growth species (Spotted owl, pileated woodpecker, pine marten, and mountain goat), opportunity costs were determined for the combination of all species requiring mature and old growth habitat. The discussion of opportunity costs for these management requirements are found at the end of this section (page H-27).

CONSEQUENCES OF THE DIFFERENT WAYS OF MEETING THE MANAGEMENT REQUIREMENT

Populations of mountain goats would not be expected to differ significantly under either alternative if each alternative would maintain equal quality of habitat. As discussed above, there is a risk that habitat requirements are not fully understood and managed sites therefore might not provide all needed habitat characteristics. Both would maintain the same amount and distribution of Habitat. In addition, there are differences in the opportunity costs as dedication of habitat areas would have the least impact on timber outputs and therefore PNV.

RATIONALE FOR THE SELECTED METHOD

The Mt. Baker-Snoqualmie National Forest chose to provide habitat for mountain goat by dedicating sites where needed on tentatively suitable timber land. This alternative achieves the desired habitat with the least effect on timber outputs and is and economically efficient way of meeting the management requirement. In addition, the managed habitat alternative was not favored because current literature does not support the idea that goat optimal cover and escape cover conditions can be provided through timber management.

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

Plan alternatives were designed to address public issues. As a result most alternatives, including the preferred, incorporate objectives for retention of old-growth and mature timber for a variety of reasons, such as wildlife, visual, and recreation. To the extent possible, mountain goat habitat areas overlap with areas selected for other purposes (such as Wilderness, unroaded recreation areas, special interest areas and other lands determined as not appropriate or unsuited for timber production), wherever these meet habitat suitability and distribution requirement.

Spotted owl, pine marten, pileated woodpecker and goat areas overlap with each other in some cases, and they overlap with areas selected for other purposes

(such as unroaded recreation areas and special interest areas) wherever these sites meet habitat suitability and distribution requirements. Methods resulting in the opportunity cost shown in Table H-3 would benefit other resource uses as well.

ROLE OF MONITORING AND RESEARCH

The Forest Monitoring Plan (Forest Plan Chapter V) calls for monitoring populations and habitats of mountain goat. At scheduled plan review, monitoring data will be considered in determining the suitability and effectiveness of the selected method for meeting the management requirement for viable populations. This will be an important test of the appropriateness of the selected modeling assumptions.

OPPORTUNITY COSTS FOR ALL MATURE AND OLD-GROWTH MANAGEMENT REQUIREMENTS

The opportunity costs of the implementation methods for meeting the habitat requirements for northern spotted owl, pileated woodpecker, pine marten, and mountain goat were estimated by comparing the differences in PNV and ASQ that would occur with and without the constraints that meet the requirements.

Table H-10 Displays the PNV and ASQ opportunity costs of the mature and old-growth habitat management requirements.

Table H-10. Opportunity Cost Meeting the Mature and Old-Growth Habitat Management Requirements.

Selected Implementation Method	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with No Protection Measures	63.9 (306)	-	2631	-
Opportunity Cost of Mature and Old Growth Habitat for Northern Spotted Owl, Pileated Woodpecker, Pine Marten, and Mt. Goat	50.1 (240)	-22	2410	-8

1/ Percent change calculated on cubic foot basis

Appendix H

WATER QUALITY MANAGEMENT REQUIREMENTS

SOURCE OF THE WATER QUALITY MANAGEMENTS REQUIREMENTS

Management requirements for water quality are based on NFMA which states: "Forest planning shall provide for compliance with requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provision of public water systems and the disposal of waste water." (36 CFR 219.23(d).

"Special attention shall be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes and other bodies of water. This area shall correspond to at least the recognizable area dominated by the riparian vegetation. No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses, or deposits of sediment shall be permitted within these areas which seriously and adversely affect water conditions or fish habitat." (36 CFR 219.27 (e).

The Clean Water Act seeks to control nonpoint sources of water pollution. To comply with Section 208 of the Act, Forest Service Region Six, the states of Oregon and Washington (which manage implementation of the Act in the respective states), and the Environmental Protection Agency agreed on a process whereby each state reviews Forest Service management practices to determine if they meet or exceed state water quality standards Practices that are judged to meet or exceed the standards are certified as Best Management Practices (BMP's) which the Forest Service then agrees to continue.

SPECIFICATIONS FOR THE WATER QUALITY MANAGEMENT REQUIREMENTS

Requirements set forth in NFMA regulations require the Forest Service not allow management practices which seriously and adversely affect water conditions or fish habitat through detrimental changes to stream temperatures or chemical composition, blockage of water courses, or deposits of sediment. In addition direction established in the Forest Plan must comply with the requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provision of public water systems and the disposal of waste water.

On the Mt. Baker-Snoqualmie National Forest, most of the activities which affect water quality are related to timber harvesting. They include removal of trees and road construction. (For more discussion, see FEIS, Chapter IV, "Soils and Water" section).

The primary approach to maintaining water quality on Mt Baker-Snoqualmie National Forest lands is to: 1) limit or prohibit timber harvest on certain unstable slopes (by designating such lands as unsuitable for timber production), 2) limit amount of harvesting in riparian areas to protect riparian values and fisheries habitat, and 3) limit the amount of timber harvest per decade in individual watersheds to prevent unacceptable adverse cumulative effects on water quality.

In the FEIS, the specifications established by the Forest are called Standards and Guidelines. The required watershed condition, and the standards that

indicate achievement of the water quality management requirement, are described in the Land and Resource Management Plan, Chapter IV. The following specifications are addressed in this appendix.

Water Quality and Riparian Area Standards and Guidelines:

Emphasize maintenance and/or improvement of water quality and fish habitat capability.

Retain instream woody material plus standing trees adjacent to the stream, needed for future debris recruitment plus bank and channel stability.

Maintain streamside vegetation so at least 80% of the fish habitat stream surface has shade during the summer low flows. Maintain or restore 75% of other small woody and herbaceous vegetation.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENTS FOR WATER QUALITY

Alternative ways for the meeting specification shown above could be modeled in FORPLAN to simulate the required end conditions. These become alternative constraints in the model that set limits on how FORPLAN schedules timber harvest to maximize PNV. (FORPLAN constraints are discussed in the FEIS, Appendix B, "Development of Management Requirements.") The following alternatives were considered:

ALTERNATIVES CONSIDERED IN DETAIL

ALTERNATIVE 1: Schedule No Timber Harvest in Riparian Areas

This alternative is designed to minimize vegetation disturbance and schedules no timber harvest in riparian areas.

ALTERNATIVE 2: Schedule Reduced Yield Timber Harvest in Riparian Areas

This alternative allows a moderate level of removal of trees from the riparian area. No timber harvest is allowed in 25% of the riparian area, harvesting on a minimum 160-year rotation is allowed on 50% of the riparian area, and the remaining 25% of the riparian area is managed in the same manner as the adjacent land allocation.

ALTERNATIVE 3: Use Existing Watershed/Sediment Model(s) to Assess and Mitigate Unacceptable Adverse Hydrologic Cumulative Effects of Management Activities

This alternative was abandoned when review of literature and discussions with academic and scientific community members indicated that no process for assessing and mitigating hydrologic cumulative effects applicable to the Mt. Baker-Snoqualmie National Forest exists.

ALTERNATIVE 4: Develop Local Process to Prevent Unacceptable Adverse Hydrologic Cumulative Effects Forestwide

This alternative requires the development and use of a watershed by watershed classification and evaluation of watershed conditions. The process determines limits on acres harvested by decade by watershed to prevent unacceptable adverse hydrologic cumulative effects.

EVALUATION OF IMPLEMENTATION METHODS TO MEET WATER QUALITY MANAGEMENT REQUIREMENTS

Of the two alternatives that address riparian areas, Alternative #1 (No Harvest) was determined to be more restrictive than necessary to achieve the goals and objectives for protection of riparian values. Allowing the level of harvest in Alternative #2 is considered to be consistent with the requirement to protect riparian values.

Of the two alternatives that address the hydrologic cumulative effects issue, only Alternative #4 provides a means to respond to the needs to insure management activities do not result in unacceptable adverse hydrologic cumulative effects.

OPPORTUNITY COSTS

The opportunity costs of implementation meeting water quality management requirements were estimated by comparing the differences in PNV and ASQ that would occur with and without the constraints that simulate the means for accomplishing the required condition.

Table H-11. compares the PNV and ASQ opportunity costs of the implementation methods (means) for water quality protection.

Table H-11 Opportunity Cost Associated with Means for Meeting the Water Quality Management Requirements.

Selected Implementation Method	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with No Protection Measures	63.9 (306)	-	2631	-
Opportunity Cost of Riparian Protection	59.6 (285)	-7	2580	0
Opportunity Cost of Water Quality Protection	41 0 (196)	-36	2297	-13

1/ Percent change calculated on cubic foot basis

CONSEQUENCES OF ALTERNATIVE WAYS OR MEANS OF MEETING WATER QUALITY

While opportunity costs were not determined for the no harvest in riparian areas alternative, it is clear that this alternative would have a higher opportunity cost in terms of ASQ and PNV than would the alternative that allows a moderate level of harvest. The no harvest alternative would go beyond the requirements of protecting the riparian area values.

RATIONALE FOR THE SELECTED IMPLEMENTATION MEANS

The Forest chose to meet riparian area protection needs while allowing timber management activities to occur at moderate levels in the riparian areas (Alternative #2) This alternative achieves the desired condition of the riparian areas with the least effect on timber outputs and is an economically efficient way of meeting the management requirement.

The application of the hydrologic cumulative effects analysis (Alternative #4) was necessary to insure activities outside riparian areas did not contribute to unacceptable adverse hydrologic cumulative effects. At this time, the method used is the only known method of meeting the management requirement for water quality on the Mt. Baker-Snoqualmie National Forest. The MR's for water quality are in full compliance with NFMA.

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

FEIS Chapter II and Appendix B discuss the effects of the means used to meet riparian area and water quality management requirements. The analysis of opportunity costs of riparian area and water quality protection shown in Table H-11 shows the maximum PNV and ASQ effects of meeting these requirements. Actual Plan alternatives will have somewhat less opportunity costs as overlaps from lands withdrawn for other allocations or constrained for other management requirements will help meet water quality requirements.

ROLE OF MONITORING AND RESEARCH

Protection needs and methods for protecting riparian areas are well documented. The Monitoring Plan in Chapter 5 of the Forest Plan provides for continued monitoring of riparian areas and fish habitat conditions. Reviews of the results of this monitoring will be used to determine the suitability and effectiveness of the means selected to meet management requirements for protection of riparian areas.

The needs for protection of water quality and the potential unacceptable adverse effects on water quality of some management activities are well documented. However, the means for ensuring the cumulative effects of management activities will not have an unacceptable adverse effect on water quality are not well established or accepted. Again, the Monitoring Plan provides for continued monitoring of management activities and their effects on water quality. Results of this monitoring will be used to evaluate the hydrologic cumulative effects analysis process and insure its efficiency and effectiveness in meeting the water quality management requirement. If necessary, the process will be modified to correct deficiencies found during the monitoring process.

Research in the area of hydrologic cumulative effects of forest management activities is receiving considerable attention by the scientific and academic community. Any new research findings concerning hydrologic cumulative effects and forest management will be reviewed and if appropriate, incorporated into the process used by the Forest. The Forest will continue to work with the scientific and academic community to refine and further validate the hydrologic cumulative effects analysis process used in the Forest Plan.

DEVELOPMENT AND APPLICATION OF A HYDROLOGIC CUMULATIVE EFFECTS ANALYSIS PROCESS ON THE MT. BAKER-SNOQUALMIE NATIONAL FOREST

1990

In response to comments received on the DEIS, additional analysis (with considerable peer review and involvement of interested public groups) was done to address the issue of hydrologic cumulative effects and develop a procedure to meet water quality management requirements on the Mt. Baker-Snoqualmie National Forest.

Public Comments to the DEIS on Hydrologic Cumulative Effects

There were a total of 117 substantive comments from the public on fishery resources; 66 of these comments directly or indirectly addressed cumulative effects of forest practices on fishery and water quality values. In addition, 60 of the 75 substantive comments regarding the management of riparian areas were directed to impacts or effects to riparian values from forest management activities over space and time. The general public comments also included a number of comments in this area, including: "cumulative effects analysis for fish is inadequate;" "cumulative effects of forest activities on watersheds and water resources are not addressed;" "need more MMR's (MR's) for soils, watershed;" and "protect vital watersheds."

Substantive public comments were received from the following agencies and tribal governments:

Washington State Department of Fisheries
Washington State Department of Wildlife
U.S. Fish and Wildlife Service
Environmental Protection Agency

Lummi Indian Tribe
Nooksack Indian Tribe
Sauk-Suiattle Indian Tribe
Skagit System Cooperative
Tulalip Indian Tribe
Muckelshoot Indian Tribe

There were two predominant areas of concern: the relationship between timber management activities (harvesting, road construction) and the viability of fish and fish habitat. (For example, what are the effects of sedimentation and bedload movement generated by Forest management activities to on- and off-Forest fishery resources, over space and time?) A second area of concern was the effectiveness of Best Management Practices to protect and maintain fish habitat and riparian areas, and the effectiveness of fish habitat restoration/improvement as a measure to mitigate the effects of forest management activities, over space and time. In one section of their input, The State strongly recommended, in place of BMP's, the need for MR's be developed for fish, in order to provide strengthened Forest-wide requirements for the protection of habitat.

Chronology of Developing a Process to Address the Issue

During preparation of the DEIS, the Forest recognized the need for a method to address hydrologic cumulative effects on all areas of the Forest including riparian lands so that a more effective range of management options could be developed. However, no methodology was identified that could be directly adopted to the Forest to meet management requirements, specifically for water quality and riparian areas. As a result, in the draft EIS, consideration of *hydrologic cumulative effects was focused on: 1) identifying the major causes* of adverse cumulative effects on water quality and/or quantity; and 2) identifying watershed potentials for unacceptable adverse cumulative effects.

At the June 16, 1988 meeting with the Regional Forester to "Set the Course," highlights of public comments to the DEIS were presented. The Forest identified cumulative effects as one of two major issues identified in the public response that needed attention in progressing to a final forest plan.

Strategies to address the hydrologic cumulative effects issue were developed at this meeting. Included were additional public consultation, a literature search and work to determine if predictive models to determine hydrologic effects on westside Cascade watersheds were available (working with the Director of Watershed, Regional Office).

An informal progress report was made to Regional Office Resource Directors in early December, 1988 and a formal "Check the Course" meeting was held December 21, 1988.

At the "Check the Course" meeting, work to date on the hydrologic cumulative effects analysis was presented No suitable model had been found, and the Forest had proceeded to develop an MBS-specific process (discussed in detail below.) In addition, no predictive model had been found to tie sediment production to fish habitat capability. This led to inclusion of fisheries as a major component of hydrologic cumulative effects analysis. Final results of the analysis were not available yet and the Forest was directed to continue work, with an additional "Check the Course" meeting scheduled.

On June 14, 1989, at a second "CTC" meeting, the results of the Forest's work were presented. The procedure for identifying a method to meet water quality and riparian MR's would be applied in all alternatives It's intent, again, is to insure that effects of management activities prescribed by the Forest Plan meet the intent of water quality laws and regulations. Arrangements for peer (scientific community) and industry review were discussed

During the summer and fall of 1989, meetings were held with State and Federal agencies, timber industry representatives, members of the academic and scientific communities, and representatives of environmental groups. The purposes of the meetings were to describe the process being used, solicit reactions to the process, and identify opportunities to improve the process.

The meeting with timber industry representatives created considerable interest and apprehension on their part, as expected. In a letter dated Oct 6, 1989, they stated their understanding of the issues that were presented at the meeting and requested additional information that has been subsequently given to them. They also stated in their letter that they would submit written comments in the near future No additional comments had been received on May 7, 1990.

The meeting with members of the scientific community resulted in several useful comments. Comments made by the scientists at the meeting and subsequent written comments indicate they had a favorable impression of the procedure. Dr. Terrance Cundy (hydrologist) stated in written response (11/13/89) that the approach should be thoroughly documented and described so that outside analysts can understand the procedure, assumptions, and the philosophical context. He also stated: "As described, the approach is based on watershed and stream processes and functions. I believe this is a good strategy."

Dr. R. Dennis Harr, research hydrologist, also provided written feedback (11/10/89). He provided some comments related to how we displayed the acceptable and unacceptable criteria relative to upper and lower watersheds, and the dynamics of woody debris He stated that "any additional information you can include to describe how you arrived at the harvestable acreage by decade figures would improve the credibility of these figures". He further stated that rain-on-snow criteria was an important issue that was not addressed on the example watershed (Finney Creek) used at the meeting. In conclusion he stated: "All in all, I think what you have developed is the best that could have been developed given the current state of knowledge."

Drs. Jim Sedell and Gorder Reeves (fisheries biologists) were also at the meeting and provided written feedback (12/13/89). They provided comments as to how we we might better define acceptable and unacceptable criteria for in-channel stability, pool condition, and large woody debris.

We have also presented the process to the Washington State Department of Natural Resources (DNR), the Greater Forest Ecosystem Alliance, and at meetings sponsored by the National Audubon Society's Adopt-a-Forest Program. People at these presentations showed considerable interest and we felt that our information was well received. The DNR was especially interested but somewhat apprehensive as they are concerned that this process could have a significant effect on them.

Background and Legal Requirements

The Organic Act of 1897 provides that "No national forest shall be established except to improve or protect the forest within the boundaries, or for the purpose of securing favorable conditions of water flows, ..."

The Multiple-use Sustained-Yield Act of 1960 also requires that the National Forests be administered for among other things, watershed, wildlife and fish purposes.

In addition, the Council on Environmental Quality (CEQ) regulations require that all Federal Agencies consider cumulative impacts in environmental analysis. CEQ regulation 40 CFR 1508.7 defines cumulative impact as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions." General requirements for cumulative effects analysis are identified in the National Environmental Policy Act (NEPA) regulations, 40 CFR 1508.25, (a)(2) & (c) and 1508.27 (b)(7).

The National Forest Management Act (NFMA) regulations require a systematic Planning process and state that, to the extent feasible, this process be used to meet both Planning and National Environmental Policy Act requirements. Therefore, it is necessary to analyze cumulative effects as part of our Forest Plan.

Through the Boldt Decision (Phase II) we are managing through cooperative efforts fish habitat on National Forest lands in usual and accustomed fishing areas of Puget Sound Treaty Tribes. Responses to our Draft Forest Plan from tribal biologists, as well as State Agency biologists and other Federal

agencies such as EPA and the U.S. Fish and Wildlife Service, dictate we display a hydrologic cumulative effects analysis in our Final Forest Plan.

Section 208 of the Clean Water Act and Section 319 of the Water Quality Act of 1987 are the legal precedents that most affect forest management because they address nonpoint source pollution. The Region has established some guidelines on how we will comply with those water quality requirements.

1. Requirements of the Clean Water Act will be met by applying Best Management Practices. (See FSM 1561.5, R-6 Supplement 48 (8/79), agreement with the State of Washington.)

2. Within the concept of Best Management Practices, cumulative effects should be addressed and impacting activities scheduled and dispersed, when water quality might be unacceptably impacted. This is particularly important for high risk areas where management activities have been or might be concentrated over a short period of time.

3. Within the bounds of the above direction, Forest should address water quality in their analysis in the manner most appropriate given their information base and particular conditions.

Guideline 2 above is of particular concern on the MBS because of the occurrence and frequency of management activities in watersheds having a large amount of unstable soils.

Regional direction (1920 Regional Forester letter dated 9-24-84) states, "To avoid adverse cumulative soil and water effects, management actions should be dispersed rather than concentrated. Beyond that precept there was little in the way of hard scientific facts that could be relied upon." The concern on the MBS is that in many of the more sensitive watersheds on the Forest, dispersing management activities and state-of-the-art BMP's are not adequate to avoid unacceptable adverse hydrologic cumulative effects. It appears in some cases such things as reducing future outputs or foregoing outputs for a period of time may be necessary

Process Used by the Forest

Refer to Attachment 1 for the References used to develop the Forest's hydrologic cumulative effects strategy.

The process used by the Forest to complete its hydrologic cumulative effects analysis consisted of two separate parts. These were: 1) Watershed Sensitivity Analysis - a preliminary analysis of the sensitivity of all watersheds and the assignment of each watershed to one of three categories of sensitivity and 2) Watershed Condition Analysis and analysis to determine the actual method or constraint to be used to meet MR's - a three step site-specific analysis of each watershed in the two most sensitive categories from the Watershed Sensitivity Analysis The first step of this second analysis further examined the stream channel conditions and upslope conditions for each watershed. The next step was to determine, based on the above conditions and other considerations, whether the watershed was in an acceptable or unacceptable condition. The final step in the second analysis was to establish a maximum level of harvest on national forest lands that will maintain a watershed in an

acceptable condition or will improve an unacceptable watershed to acceptable conditions.

Watershed Sensitivity Analysis

A preliminary analysis was made of the sensitivity of all watersheds on the Forest using the following set of watershed condition factors: 1) management history, 2) climatic conditions, 3) presence of landslides, 4) inherent soil stability, 5) stream channel stability, and 6) off-site impacts. A team of the Forest's Soil Scientist, Hydrologist, Fishery Biologist, and Geotechnical Engineer made the first-cut analysis based on information at hand and their extensive field experience. This analysis was based on the planning guidance found on pages 8-9 of the "Process for Cumulative Effect Analysis" (RO letter 9/24/84). As a result of this analysis, watersheds were placed in one of three categories defined as follows:

Category I: watersheds where there has been little or no effect on water quality or quantity values. The existing natural and geomorphic features produce stable watershed conditions within the watershed and off-site. Of the total on the Forest, 8 watersheds were rated as Category I.

Category II: watersheds with recent management activity (over the last 30 to 40 years) that, together with some natural events, have caused adverse impacts to water quality - quantity values within and/or outside the Forest's watershed boundaries. The existing natural and geomorphic features can and have produced unstable conditions in some areas of the watershed. There are 53 Category II watersheds on the Forest.

Category III: watersheds with a very high frequency of management activities over the past 30 to 40 years. The magnitude of these activities has been significant within the watershed (large areas with activity occurring in a very short time period - 5 to 15 years). The existing natural and geomorphic features have produced and can continue to produce highly unstable and dynamic watershed conditions (within the watershed and off-site). Significant impacts have occurred within and outside the Forest's watershed boundaries. Of the total, 17 watersheds were rated as Category III. All of these lie north of Highway 2.

Watershed Condition Determination of Method/Constraint to Meet MR's

After the watershed sensitivity analysis, it was determined that an additional, more site-specific, analysis of the Category II and III watersheds would be necessary because of past level of management activities in most of these watersheds The results of this additional analysis would identify limits of activity necessary to protect or allow recovery of these watersheds. The sensitivity of the Category I watersheds was determined to not be as critical and normal silvicultural created opening constraints would mitigate any unacceptable adverse cumulative effects.

The Forest organized individual District Interdisciplinary (ID) teams to *conduct the watershed condition and method or constraint analysis for Category* II and III watersheds.

The ID teams were composed of the most experienced personnel (with up to 25 years experience on the Forest) from the Supervisor's Office and each District, many of whom could offer insight from their personal experience over the years of working on the Mt. Baker-Snoqualmie. The team reviewed in-place empirical data and developed historical perspectives on watershed conditions from examination of aerial photos taken over the past 30 to 40 years. This process was applied to every Category II and III watershed on the Forest (a total of 70 watersheds).

The Regional Hydrologist worked with the Forest in developing a format for a worksheet for documenting the process in each watershed. That format required the IDT to direct their analysis and answer questions about stream channel conditions. We separated the analysis and discussion between the upper watershed (1st and 2nd order streams) from the lower watershed (3rd and 4th order streams). For both the upper and lower watershed areas, we looked at present and past in-channel stability, streambank stability, status of large woody debris, and channel pattern (lower watershed only). (See Attachments 2 and 3: diagram defining Upper and Lower watershed limits and a text: Evaluation of Present Stream Channel Conditions.)

The team also looked at upslope conditions by reviewing past harvest rates, road density and condition, presence of landslides, amount of unstable soils, and ability to revegetate and recover.

Some other considerations were incorporated, such as: 1) our expectations of the effect of new or improved Best Management Practices (BMP's), 2) what the estimated effects of mitigation measures would be if prescribed, 3) the relationship of the mature sawtimber left in a watershed to streams and unstable soils, 4) the amount of roading necessary to harvest the remaining timber and potential location to streams and unstable soils, and 5) the practicability of helicopter logging.

All of the above analysis and documentation was summarized in order to provide an overall evaluation of the existing watershed conditions. It was also used to reach an agreement on a desired future condition measured at the Forest boundary. (See Attachment 2 - Determining Watershed Boundaries). Thus, extensive state and private logging outside the National Forest was not considered. Depending upon the consensus of the IDT on the magnitude of the past cause and effect relationships projected to the future, a maximum harvest acreage per decade was assigned for each watershed. In addition, each watershed was rated as being in an acceptable or unacceptable condition. (See Table 1 for a summary of the criteria used to rate watershed condition as acceptable or unacceptable.)

The harvest rate assigned to a watershed is meant to maintain an acceptable condition, or improve an unacceptable condition within the National Forest. The harvest rate was developed based on the tentatively suitable acres identified in the EIS and became a dispersion constraint - the method to meet management requirements and applied to all alternatives.

Preliminary Results of Analysis and Steps to Proceed to Final Forest Plan

A total of 70 Category II and III watersheds were analyzed by the ID teams at the Ranger Districts. The documentation and results of the watershed condition

and management requirement analysis were reviewed by a Forest Supervisor's Interdisciplinary (ID) team and a Regional ID team to assure consistency in application of the principals of this analysis strategy.

Table 1
Criteria for Determining Watershed Condition

Criteria applicable to all stream orders (1st, 2nd; 3rd, 4th). Acceptable/ unacceptable rating is determined by considering the upper and lower watershed and arriving at an overall score.

ACCEPTABLE	UNACCEPTABLE
In-Channel Stability	
Channel scouring is evident but not excessive and can be attributed to natural causes.	*Considerable amount of deep downcutting* with evidence of continued scouring. Documentation indicates majority is the result of management activities.
Pool Condition	
Pool area occupies as much surface area as riffles. Ratio of 50/50 or better (pools/riffles). Pools are 2 feet or deeper (3rd & 4th order).	Pools are consistently shallow, usually being less than 2 feet deep and tend to be much less than 50% of the surface area. Pools tend to be filled in by sediment and/or bedload.
Streambank Stability	
80% to 85% of banks appear stable.	Extensive exposed banks with instability conditions predominating.
Wood Debris	
Adequate moments of embedded, well-anchored LWD are in place. Riparian area condition provides for recruitment of LWD into the future.	LWD is not in place and well-anchored. Because of lack of LWD, system lacks structure to provide stable pools and channel stability. Riparian area is lacking in the ability to recruit future supply of LWD.

As a result of the watershed condition analysis, 19 watersheds were rated as *being in an unacceptable condition and 51 in an acceptable condition. The* preponderance of the unacceptable watersheds were found on the more geological sensitive north end of the Forest - 15 of 19, approximately 80%. (see Chapter III of the EIS for a description of the geology of the Forest.)

The consequences of a watershed being rated in an unacceptable condition would be the application of a tighter harvest level for some period, usually at least the first two decades of the Plan. This allows for hydrologic recovery to take place before resuming what could be a higher harvest level and still avoid

adverse hydrologic cumulative effects. However, only one unacceptable watershed (AZ #31, Deer Cr. SE) was assigned to a "no harvest" level because of the seriousness of the watershed condition. This "no harvest" would occur for the first two decades of the Plan and harvesting could resume at an acceptable level in the third decade.

All of the other unacceptable watersheds showed some level of harvest. In most cases, the level was reduced for the first two decades increasing in the third and fourth decades. The ID team's rationale was that some harvest could take place in a watershed while recovery was taking place if the harvest activity would be conducted using improved BMP's and located in the less sensitive portion of the watershed.

This analysis is not meant to be an end in itself. It is viewed as a programmatic level of analysis that will be used for the Forest Plan. It is the intent of the Forest to continue to monitor these effects of management in an effort to fine-tune many of the assumptions we made at this programmatic level of analysis. We are presently developing a strategy for project level analysis of hydrologic cumulative effects which would be a source of more specific information that would help us: 1) develop and design better options for project implementation and 2) adjust any planning level assumptions. We view this as adaptive management.

A summary of the results of the watershed condition analysis and the results of the analysis - a set maximum number of acres available for timber harvest, per decade, by watershed - is shown in Table 2. Table 3 displays additional information about watersheds found to be in unacceptable conditions. Also, refer to the Attachments for additional documentation of the analysis and the rationale for the watershed condition and the constraint Summary sheets are included for all watersheds considered, plus one completed worksheet for a watershed.

Modeling

The hydrologic cumulative effects analysis procedure developed by the ID team is incorporated into the Forest's FORPLAN model as a set of constraints. To meet the water quality and riparian management requirements, there is a set maximum number of acres available for final harvest by watershed.

Accessibility constraints applied by watershed set a maximum on the amount of an area that can be scheduled for harvest in a decade. For the first decade, the accessibility constraints were developed by calculating the percent of the area that can be entered, while still "keeping" watersheds that rated acceptable from deteriorating, and allowing watersheds in an unacceptable condition to recover (eventually to an acceptable condition). The percents that went into FORPLAN modeling were based on the maximum harvest acreage limits developed by the ID team.

For the second and subsequent decades, the method or constraint to meet MR's was modeled by "flow constraints" on acres of final harvest Forest-wide (by North and South). Accessibility constraints were not used in these decades because of insufficient information available from the model to track the vegetation condition class by zone after management is implemented in the first decade. The flow constraints were developed in concert with the Forest's

resource specialists to reflect the continuing need to manage, in order to keep cumulative hydrologic effects below the unacceptable levels. The flow constraints allow final harvest acres in Decade 2 to increase by 4% over the Decade 1 final harvest acres; by 10% in Decade 3 over Decade 2; by 4% in Decade 4 over Decade 3; and 0% increase thereafter - a total increase in final harvest acres of approximately 18% over the first decade levels.

Individual Watershed Worksheets

Again, refer to the Attachments for more detailed information. The complete worksheets and maps for all watersheds analyzed are available in the Planning Records.

The following Attachments provide more documentation of the hydrologic cumulative effects analysis, including a completed worksheet for one sample watershed and the Summary Sheets for all watersheds.

Attachment 1

Support Documentation for MBS Forest Plan
Watershed Cumulative Effects Assessment

The following listed references (citations, publications) were used to develop the Forest's hydrologic cumulative effects strategy for the Forest Plan. This Forest strategy development began in 1984 and has evolved for the past five years to its present form. Because of the complexity and gaps in knowledge in this subject area, our strategy has been dynamic; as new information and knowledge as been published, we have reviewed and incorporated, it appropriate, this into our strategy.

Basic Documents Used to Develop the CEA Strategy

1. **"Management of Wildlife and Fish Habitats in Forests of Western Washington and Oregon, Part 1", 1985.**

   Chapter 10 Salmonids, principal authors: Fred Everest, Neil Armantrout, Steven Keller, William Parante, James Sedell, Thomas Nickelson, James Johnston, Gorden Haugen.

2. **"Streamside Management: Forestry and Fishery Interactions", 1987.**

   Variables Related to Fish Habitat - Chapters 1-6.

   Forest Management of the Streamside Zone - Chapters 8-9.

Supporting Documents Used to Develop the CEA Strategy

1. **"Cumulative Effects of Forest Practices on the Environment: A State of the Knowledge", Geppert, Lorenz, Larson, 1984.**

   * validation that there is a potential for cumulative effects from current forest practices.

   * control of much of the cumulative effects is possible by manipulating future application of forest practices in time and space.

   * using basin examination approach to analyze watershed cumulative effects.

2. **"Watershed Workbook: Forest Hydrology Sensitivity Analysis for Coastal British Columbia", D. J. Wilford, 1987.**

   * identification of important in-channel attributes and how these respond to past and proposed timber management activities.

   * change in channel morphology linked to changes in upslope conditions.

   * recovery aspects of impacted in-channel conditions as well as upslope recovery.

* use of empirical data and professional judgement to establish linkages between forest management activities of past and present to upslope conditions, to in-channel conditions, and finally to fish habitat.

3. **"Cumulative Watershed Effects: Problem and Approach, L. M. Reid, G. Ziemer", 1988.**

   * framework for linking upslope conditions to in-channel conditions.

   * use of empirical correlations, process-based studies, local watershed studies, and professional experience and judgement together or in combination to assess watershed cumulative effects.

4. **"Cumulative Watershed Effects: An Empirical Evaluation of Responses by Stream Biota, Charles Hawkins, L. Decker", (current).**

   * approach to establish relationships between physical variables (upslope physical features, in-channel morphical attributes, and management activity) to biotic variables (fish abundance) within the stream system.

   * use of basin-wide approach.

   * reliance on establishment of empirical relationships between forest management activities (type and intensity) and biotic variables to predict cumulative effects on a basin basis.

5. **"Fish Habitat Evaluation Handbook (Monitoring), FSH 2609.23, USDA/USFS/R-6", 1985.**

   * identification of in-channel attributes likely to be influenced by forest management activities.

   * identification of in-channel attributes that could be estimated and or measured from existing District knowledge and data.

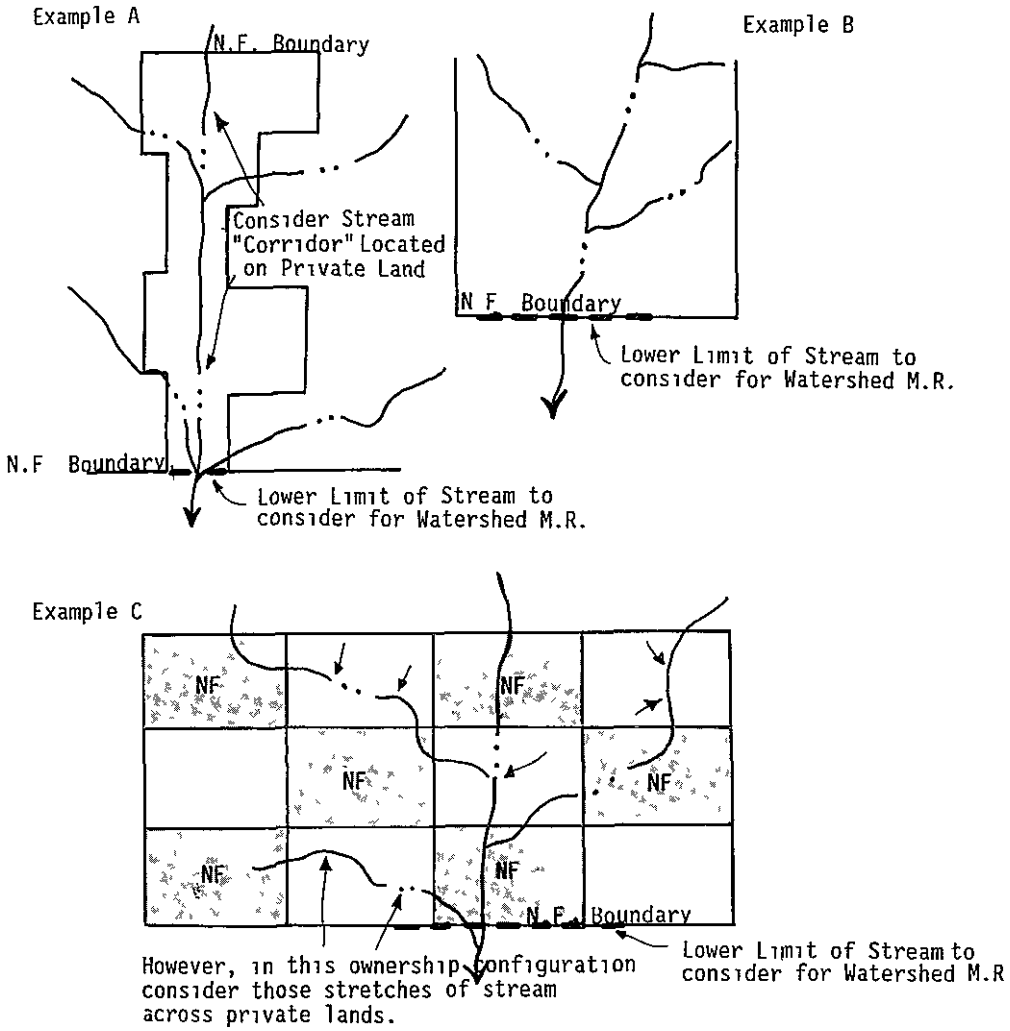
   * identification of in-channel attributes that could be quantitatively be measured now in the future.

Attachment 2

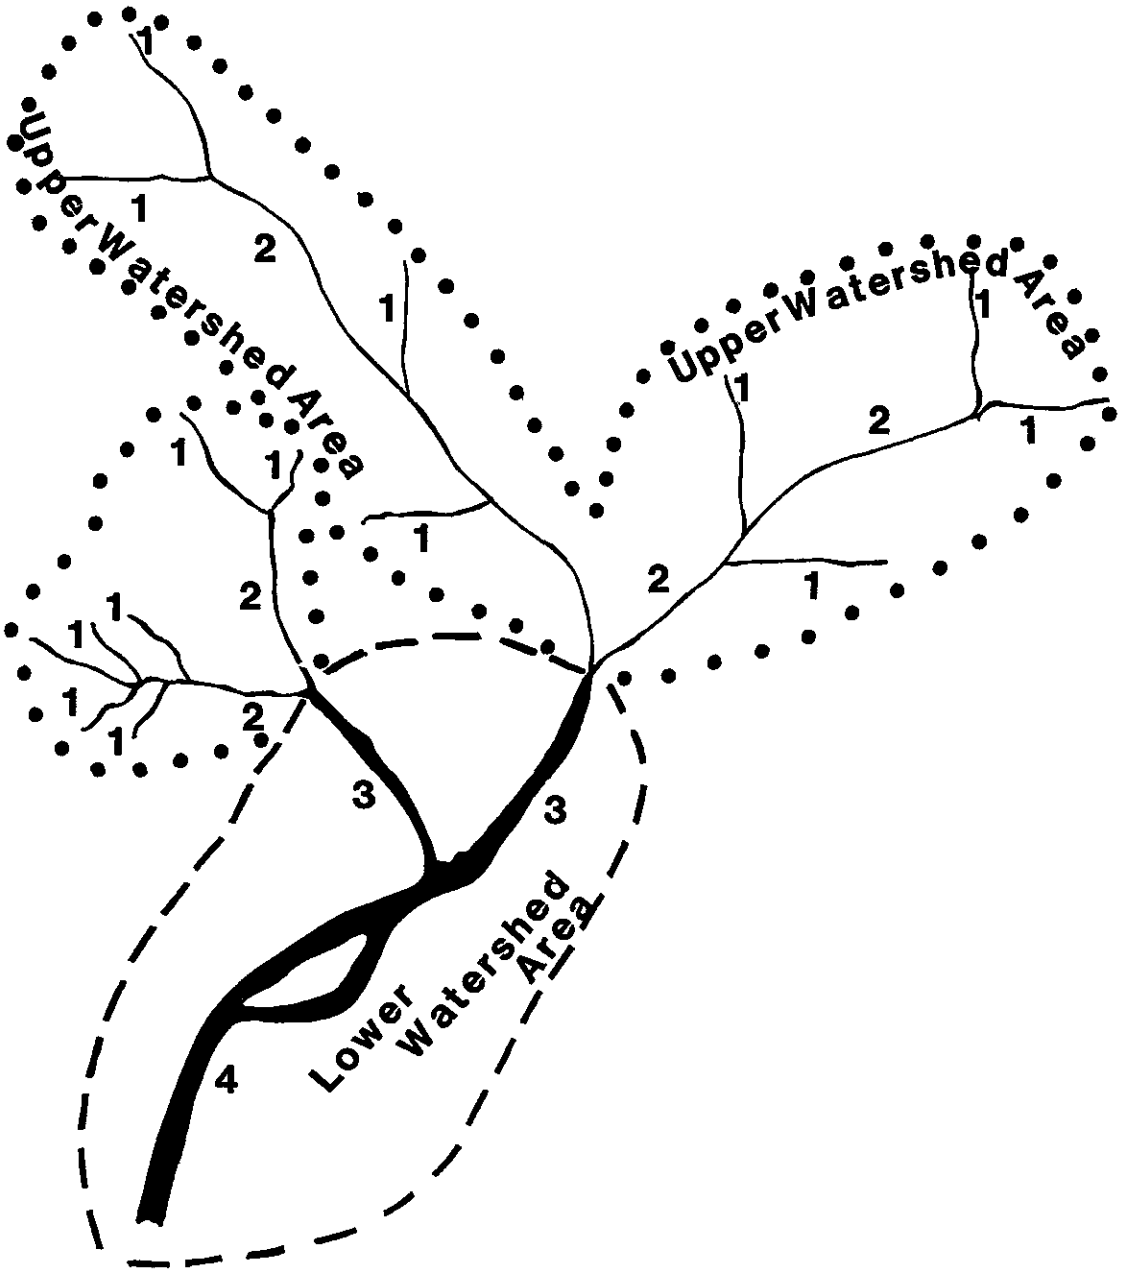
Determining Watershed Boundaries for the Hydrologic Cumulative Effects Analysis

The constraint on number of acres available for final harvest, to meet management requirements, applies only to National Forest lands. Because of landownership patterns on this Forest, it was necessary to develop guidelines for the Interdisciplinary Teams to follow as they delineated watershed boundaries for the analysis procedure.

Examples of NF Boundary configurations to establish boundaries of watersheds:



Attachment 3



This diagram depicts the boundary or limits of the upper and lower watershed areas, based on the stream channel network system. Generally, most of the first and second order channels are in the upper watershed area, while the third and fourth order channels are in the lower watershed. Note that these orders DO NOT correspond to the Class I, II, III, and IV Stream Classes referred to elsewhere in the documents.

Attachment 4

Process used to Evaluate Present Stream Channel Conditions

Introduction

A generally accepted way of determining whether we are meeting management requirements in our watersheds is to evaluate the condition of some key stream channel factors, which can provide a measurement for assessing effects of management on instream and/or downstream beneficial uses. The primary beneficial use in most all of the MBS watersheds is habitat for substantial salmon and trout populations. Protecting and maintaining viable populations of these species requires a significant amount of high quality spawning and rearing habitat. In a number of these same watersheds, there are also secondary benefitting uses such as providing a supply of water to a municipality or for a downstream fish hatchery operation.

To determine the present Forest-wide methods for meeting management requirements for watersheds in this planning period, the requirements need to be stated in terms and conditions that translate to measurable or estimable factors. The rate or degree of change due to management activities is of primary importance. At this time, the forest does not have an adequate Forest-wide data base on salmonid spawning/rearing habitat condition or capability that could be used as criteria to establish a method to meet water quality and riparian management requirements. But by examining some key in-channel factors of stream systems and assessing how they have changed over time it is possible to measure (from the data sets and empirical data we do have) or to estimate (using our best professional judgement which includes extensive field experience) stream channel conditions and establish a method to meet management requirements based on the acceptability or unacceptability of their present condition.

Rationale

The stream channel evaluation factors identified are reasonable and proximate surrogates for the quality and condition of the spawning and rearing habitat on the Forest for that time period when such evaluations are made. This is supported by current research (see "Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington", 1985) and current management (see "Fish Habitat Evaluation Handbook, FSH 2609.23", 1987).

These factors can be used to determine past, present, and future effects of proposed management activities.

For most of the Forest's watersheds, the protection and maintenance of high quality salmoid habitat will also afford the secondary beneficial uses within these watersheds the same degree of protection.

Furthermore, the protection and maintenance of substantial amounts of high quality salmonid habitat in the stream and river systems within the Forest boundaries will influence downstream, off-Forest, non-USFS beneficial uses within these watersheds.

To measure and/or to estimate the rate of change or the degree of change over time, assume the time period (at a minimum) to be from 1950 to the present (the past 35-40 years). In most of the Forest's watersheds, this time period has

resulted in the most significant changes to stream channel conditions. We are interested mainly in the changes due to management activities during this time. The ID Team will examine and note the difference between changes related to management as opposed to those changes caused by major natural events such as floods or landslides.

In most, if not all the major Forest watersheds, the salmonid populations, especially the salmon and steelhead runs, have been able to adapt, over time, to a range of natural or background conditions and events to reproduce and maintain viable populations. Within the major watersheds, there is no known evidence of where a population of salmon or steelhead has been lost or become unviable due to a natural condition or event.

The resource objectives for fish habitat and watershed restoration or improvement activities within the forest's watersheds are to accelerate the natural recovery of fish habitat, unstable channel and upslope conditions.

The entire watershed will be analyzed. However, it is appropriate to examine upper watersheds (1st and 2nd order streams and their adjacent riparian areas) separate from lower main-stem channels (3rd-5th order streams and associated floodplains).

Evaluating on a watershed basis creates a problem in coming up with the final product because the boundaries of the Forest AZ's are not always pure watershed boundaries. In a number of situations, more than one (sometimes 3 or 4) AZ constitutes a watershed. In these cases, the ID Team should evaluate the stream channel conditions on a watershed basis (not on an AZ basis).

Documentation during this step is critical. At a minimum, a time-series of aerial photos should be used to make these stream channel evaluations. Use of this resource tool needs to be supported by empirical data and file data where it is available Be sure to record data or work from external sources (agency, tribes, and research).

Determination

Evaluate the upper watershed area, the fish bearing first and second order channels (these are the Forest's lightly and deeply incised Class III and IV streams) The ID Team needs to determine the existing overall stream channel condition (for the entire upper watershed area) based on three in-channel factors of in-channel stability, streambank stability and LWD.

In assessing in-channel stability:

Determine how many of these channels are either down-cut or have scoured to bedrock.
Is channel scouring evident now and in the past.
What is the pool frequency in these small channels. Has it changed?
What is the present and past ability of these channels to store/transport sediment to downstream third to fifth order channels.

In assessing streambank stability:

Determine how many or what percent of these channels have significant area of exposed streambanks as evident from present and past bank

erosion. (If possible, make qualitative estimate of natural versus man-caused bank erosion.)

In assessing Large Woody Debris (LWD):

Determine how many or what percent of channels having an adequate amount of LWD in the channel (structures for pool formation). Has there been a significant change over time?
What is the recruitment for future LWD into these channels from the adjacent riparian areas.

Evaluate the lower watershed area, the third to fifth order channels, and determine the existing overall stream channel condition based on the following channel factors of in-channel stability, LWD, and channel pattern.

In assessing in-channel stability:

Examine the entire channel length and determine the extent of downcutting and widening.
Determine what has been the ability of these channels to store/transport sediment.
Determine the frequency or amount of bedload deposition in these channels over time.
Determine the overall pool quantity and quality (size and depth) in these channels.

In assessing LWD:

Determine the presence or amount of LWD along the entire channel length.
Determine if it is stable and if it is well distributed or is it all concentrated in one or two areas.

In assessing channel pattern:

Determine what type of channel, straight or meandering; is it one channel or is it braided. Assess overall changes.
If possible determine the sinuousity of the channel in order to describe channel response to changes in sediment loading and flow. (See page 23.77 in FSH 2609.23)

When attempting to determine these in-channel factors, focus attention on those channels where there has been timber harvesting and road building activities during the past 30-40 years. Also determine what percent or portion these impacted channels are in relation to all the streams in the watershed.

Based on how the ID Team evaluated the upper and the lower watershed areas, make an overall determination if the present stream channel conditions of that watershed are acceptable or unacceptable. In some cases acceptable and unacceptable conditions may exist in the same watershed. Document where such condition exist and consider this in the final analysis. Again, keep in mind the analysis should be in the context of changes due to past management activities.

Description of Present Condition Upslope

Past Harvest Rate

Determine clearcut acres harvested per decade by ownership. Consider the effects of location of existing clearcuts to streams and unstable soils.

Road Density and Condition

Roads decrease slope stability and modify slope hydrology.

Determine miles of road constructed per decade and present density in miles/mi2. Add supporting statements where applicable to address factors such as:

- Relation to unstable soils.
- Stacked roads on hillslopes.
- Condition of fills and cutslopes.
- Condition of road drainage system.

Presence of Landslides

Landslides are a major source area for sediment.
Consider and document:

- Size.
- Distribution.
- Delivery of sediment to channel.
- Source whether natural, in unit, or road related.
- Observed changes in rate of occurrance.
- Compare with effects in adjacent undeveloped drainages.

Attachment 5

Sample Completed Worksheet - For One Watershed

WATERSHED: _FINNEY CREEK_ **ALLOCATION ZONE:** _#30_

	ACRES
TOTAL WATERSHED:*	**21,226**
NATIONAL FOREST	20,888
TOTAL HARVESTED	10,012
TENTATIVELY SUITABLE	17,019
PRIVATE LAND	338
TOTAL HARVESTED	202
TOTAL AZ:	**21,226**
NATIONAL FOREST	20,888
TENTATIVELY SUITABLE	17,019
MATURE (MLS & MSS) TIMBER	5,574
PRIVATE LAND	338

* All w/in NF boundary

I. STREAM CHANNEL CONDITIONS:

UPPER WATERSHED AREA

A. IN-CHANNEL STABILITY :

How many 1st & 2nd order channels are down-cut or scoured to bedrock?

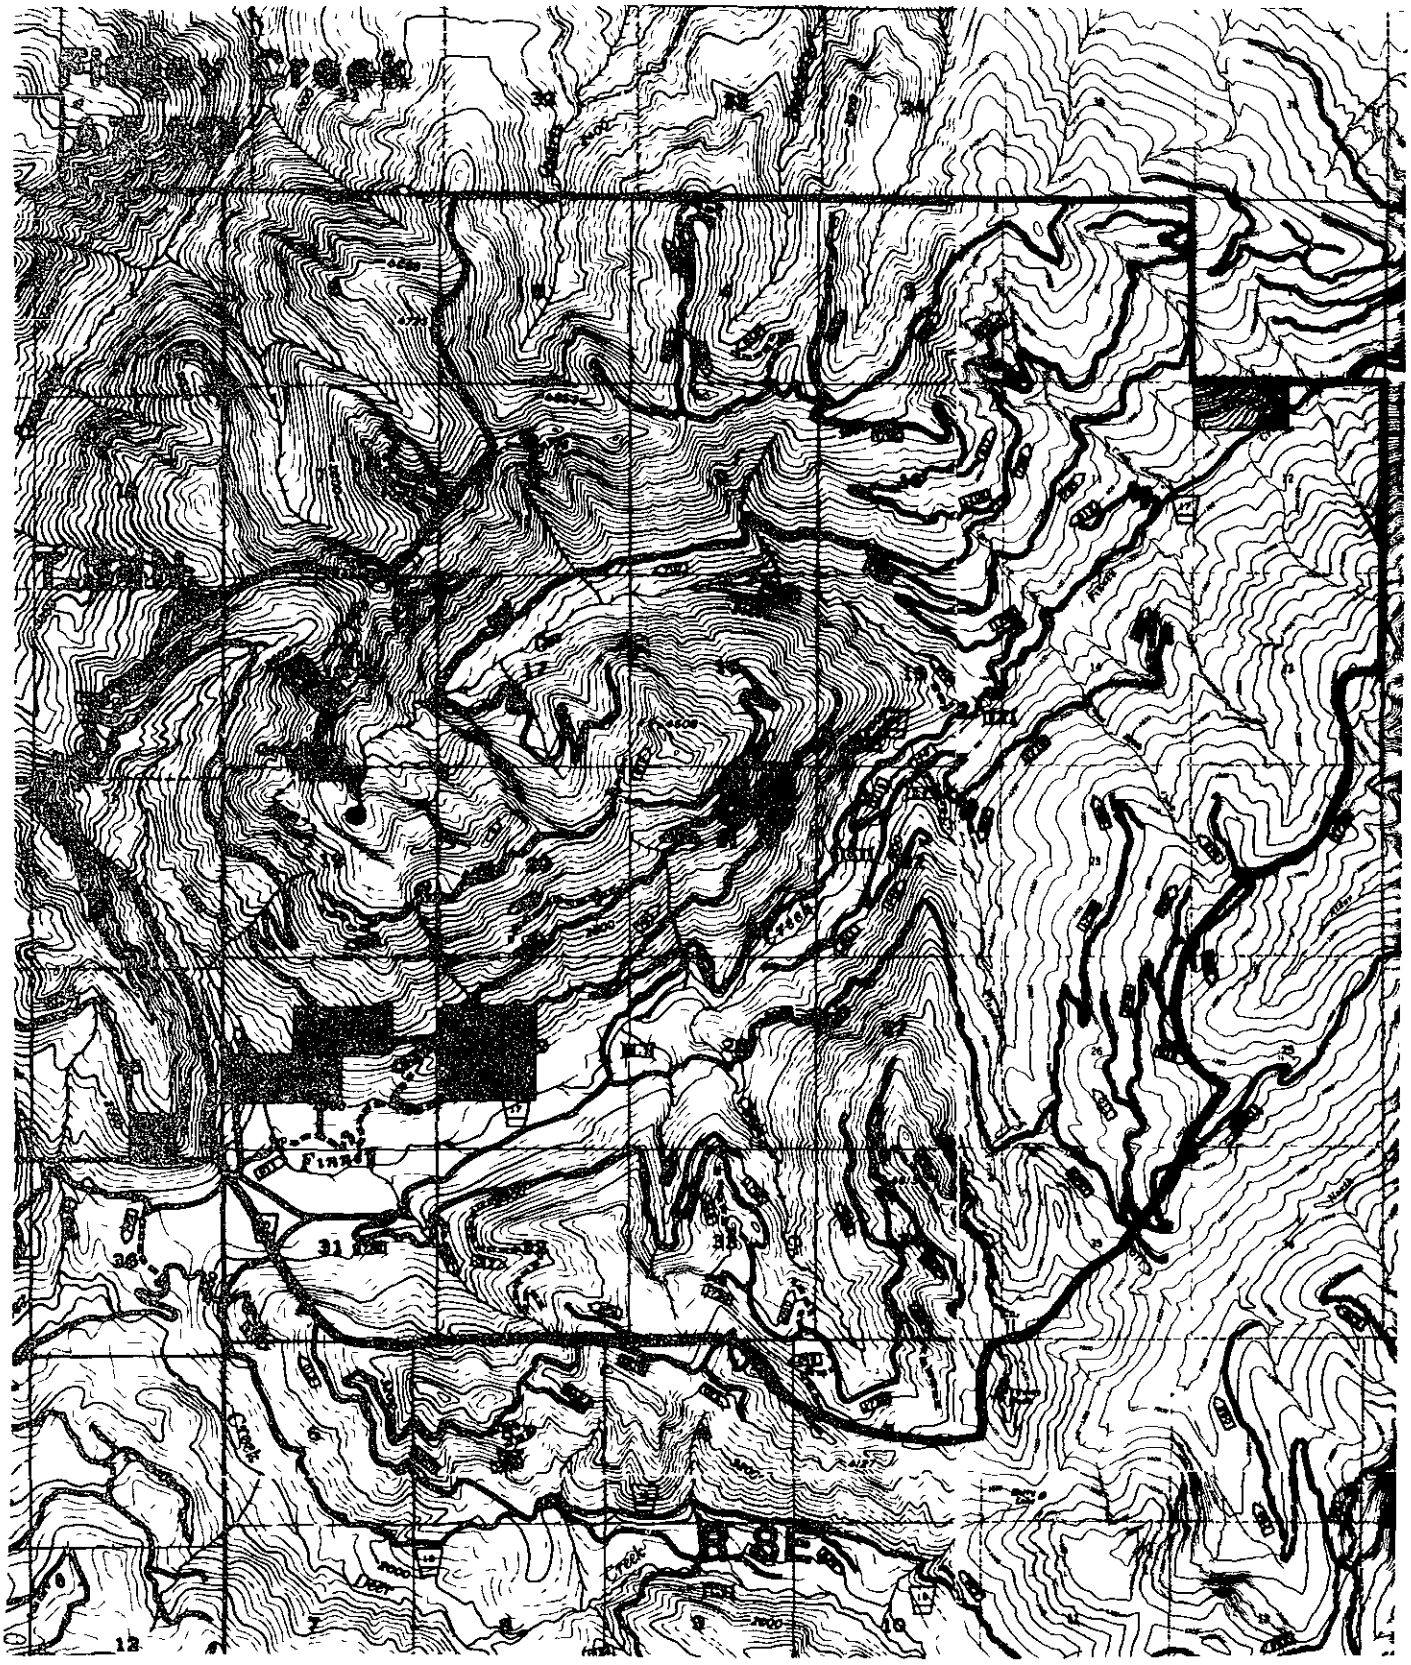
Approximately 75% (12 of 16 streams) of the major channels that are tributary to Finney Creek are affected.

Comment on the channel scouring that is evident (past and present):
Debris torrents originating in the upper watershed have scoured channels to bedrock in the streams described above. Some natural scouring in highly unstable soils (Nervous Bride Creek area) prior to the mid 1970s did occur. There has been increased scouring since the mid 1970s largely due to human related activities.

Comment on the pool frequency:
Pool frequency has decreased due to the increased scouring activity.

Comment on the ability to store/transport sediment to downstream 3rd to 5th order channels:

Due to the steepness of channel gradients and loss of pool storage & in-channel woody debris, streams have lost ability to store sediment.



B. STREAMBANK STABILITY:

How many, or what percentage of these channels have exposed banks as evident from present or past bank erosion?
Approximately 80 - 85% of the 1st and 2nd order channels.

C. LARGE WOODY DEBRIS:

Comment on the amount and stability of LWD in these channels:
There is very little large woody debris remaining.

Comment on the recruitment potential of LWD into these channels from the adjacent riparian areas:
On the north side tributaries: Six major tributaries are lacking LWD recruitment potential due to past harvest activities adjacent to them.

On the south side tributaries: Moderate to high potential for LWD recruitment is possible adjacent to these streams.

LOWER WATERSHED AREA

A. IN-CHANNEL STABILITY:

Comment on the extent or the amount of down-cutting along the entire channel length:
Some downcutting in the intermediate reaches of Finney Creek itself (below the slide @ MP 9.0 on Rd. #17). Some deposition is apparent in other reaches.

Comment on the ability of these channels to store/transport sediment:
Low to moderate ability to store sediment and moderate to high ability to transport, due to the fact that fine sediments have been removed leaving a coarse, cobble-sized substrate.

Comment on the overall pool quantity and/or quality (size and depth) in these channels:
Pool quantity and quality is significantly decreased.

Comment on the extent or frequency, over time, of bedload deposition in these channels:
Significant deposition began in the mid-1970s due to debris torrent activities in the side channels (tributaries to Finney Cr.).

B. LARGE WOODY DEBRIS:

Comment on the extent or amount of LWD along the entire channel length:
Due to increase in sediment transport and dam break activity, the majority of the large woody debris has been removed from the system.

Comment on the stability and the distribution of LWD along the entire channel length:
Poor - largely not there and what is present is in a few scattered jams or clumps above the mean water level. A few individual scattered, loose pieces are present, but not stable.

C. CHANNEL PATTERN:

Comment on the predominant channel type (straight or meandering, 1 or 2 main channels or braided channels):
Primarily straight - mostly one main channel.

Comment on the sinuosity of the channel:
Historically, there was some sinuosity in the headwaters area, but this has since been lost.

II. UPSLOPE CONDITIONS

A. PAST HARVEST RATE:

Percent cut per decade: (Of Entire Watershed)

NF ownership	Private
≤1% cut 30's	_0% cut 30's
_0% cut 40's	_0% cut 40's
_4% cut 50's	≤1% cut 50's
13% cut 60's	≤1% cut 60's
17% cut 70's	≤1% cut 70's
14% cut 80's	_0% cut 80's
48% total	_1% total

Comments on location of previous cutting in relation to streams, unstable soils, etc:
Prior to the mid-1970s, harvest was fairly well dispersed. Following extensive blowdown in the mid to late 1970s harvest became concentrated in the upper watershed. Less attention was given to riparian protection and unstable soils prior to 1980.

B. ROAD DENSITY AND CONDITION:

What is the avg. Rd mi/sq mi density in the tent suit area? - 4.0 miles/sq. mi.
(There are a total of 106.4 miles in the WS)

15% constructed 30's-50's
41% constructed 60's
40% constructed 70's
_4% constructed 80's

Comments on location of roads in relation to unstable soils:
In several areas existing roads cross unstable soil areas. Generally, these unstable soil areas are limited to stream draws.

Comments on placement of roads on hillsides (stacking):
There is a high degree of stacking in the entire watershed.

Comments on conditions of cuts and fills:
Prior to the mid-1970s, road construction specifications called for sidecast excavation with uncontrolled fill placement. This amounts to 50 - 60% of the existing road system. Approximately 19 miles of the maintenance level 1 & 2 roads have been treated (sidecast pullback, waterbarring, insloping, etc.). An extensive watershed/road deficiency inventory is currently underway with FRP funds planned to correct existing deficiencies prior to future failures occurring.

Comments on condition of road drainage system:
Prior to the mid-1970s constant grades were prevalent with culvert spacing and sizing inadequate. Waterbar activities were limited to temporary roads and the work that was done in this regard was largely inadequate. We have begun road rehabilitation efforts in the drainage to correct existing deficiencies. (See inventory note above.)

C. PRESENCE OF LANDSLIDES:

The following are the known major landslides in the watershed:

1. Nervous Bride Creek area (natural slide area)
2. Gee Point/Upper Finney area (occurred in 1960 to 1970's)
3. Clendenen Creek slide (1940's/natural)
4. Rd. #17, MP 9.0 (1986)
5. Homestead Creek area (1970's/80's)
6. Hatchery Creek
7. Quartz Creek

Comment on size of landslides:
Other than the MP 9.0 slide & Homestead Cr. area, most landslides are relatively small in area & translate into debris torrents downstream channels (See Section A - In-channel Stability).

Comment on distribution of landslides:
They are evenly distributed.

These slides have contributed to the instability of streambanks:

There have been 8 slides in 7 years along 2 miles of Finney Creek--all triggered by rain-on-snow storm events. The largest is about 20,000 CY and the smallest about 8,000 CY--all initiated in harvested areas.

During 1983, Deer Cr. and Finney Cr. had 37 significant slides in harvested areas triggered by rain-on-snow storm events.

Comment on delivery of landslide material to the channel:
Most landslide material reaches 3rd and 4th order channels due to the steepness of gradients.

What is the major source of landslides?

Natural: There have been five natural landslides associated with fault zones and rock type changes:

1. Nervous Bride Creek area
2. Gee Point/Upper Finney area
3. Clendenen Creek slide area

4. Hatchery Creek
5. Quartz Creek

(Ref. 1978 Geologic Map by Morrison)

In unit: Most are related to yarding road or landing failures from concentrated water near stream courses. There has been one major in-unit failure (Homestead Creek area).
Road related: There have been several small-sized sidecast road failures with one major event (Rd. #1721 which is known as Finney Cr. 9 Mile Slide). Also, there have been numerous road drainage structure failures due to inadequate sizes and/or upslope debris torrents.

Comments on observed changes in rate of occurrence:
Aerial photography was reviewed from 1940, 1956, 1964, 1972, 1979, & 1983. From studying these photos it has been determined that the rate of occurrence significantly increased after the mid-1970s. 34% of the National Forest acres were harvested between 1964 and 1983. This heavy harvest had no or very little apparent impact on downstream channel condition until rain-on-snow flood events in 1975,1977,1979, and 1980 (higher elevation). These flood events are documented by ERFO damage reports and changed channel conditions.

D. UNSTABLE SOILS:

24% of the tentatively suitable area is unstable as shown in the SRI.

Comments on distribution, extent and effect of unstable soils:
The lower north side and the entire south side of the drainage, as well as the west side of the headwaters are the main areas of unstable soils in the Finney Creek watershed

The potential for debris torrents and scouring due to management activity (harvesting and road construction) is greatly increased in the areas of unstable soils.

It should be noted that large management related landslides have occurred in areas not identified as unstable soils.

E. ABILITY OF LAND TO REVEGETATE:

Describe major areas not revegetated:
Major areas scoured to bedrock are limited for the most part to the 9 Mile Slide and stream sluice-out tracks. In addition, steep road cutbanks, and undercut channel banks along main stream channel.

Comments on Recovery Rate:
Where debris torrent activity is occurring, channel banks are not revegetating due to constant disturbance.

Natural revegetation occurs readily wherever denuded areas are mechanically stable.

Clearcut areas: Most harvested areas are well revegetated. Recovery of cutover areas occurred in 20 years (comparison of 1964 & 1984 aerial photos).

Note: Past prescribed broadcast burning practices have significantly contributed to soil loss, increased sedimentation, and delayed revegetation recovery in certain areas of the watershed.

III. OTHER CONSIDERATIONS

A. Comment on the expected effectiveness of new BMP's:
BMPs are identified as such things as: yarding methods, temporary and system road construction specifications/methods, landing construction control, riparian area protection, etc.

Effectiveness will be limited to the immediate area of application. BMPs will not be significantly effective due to the past widespread activity in the watershed

B. *Describe other mitigating measures needed to meet MR,s (sidecast pullback etc.):*
Sidecast pullback (landings & road fills), insloping, installation of waterbars on closed roads, installation of driveable waterbars on open, high clearance roads, addition of more drainage structures including dipped and hardened crossings, revegetation, in-channel stabilizing structures, have been identified in general as being needed. Detailed mitigation measures will be documented when the Finney Creek Inventory is completed.

C. Determine the location of mature saw timber in relation to streams and unstable soils:
Of the remaining mature saw timber, a large portion (approx. 50%) is located adjacent to streams or within unstable soil areas.

D. Determine future road needs:
Minimal new system road construction is identified as being needed. Construction of temporary roads will be minimal also and only as needed to obtain adequate deflection or better directional angle for yarding operations.

E. How many acres are to be helicopter logged? 400 acres
(Forest Plan review, 1988)

IV. SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photography revealed that past harvest activities up to 1975 (29% of N F. lands in the watershed) had little apparent impact on stream condition. Between 1976 and 1988 additional heavy harvesting in the upper watershed (20% of N F. lands), coupled with rain-on-snow flood events (1975,77,79, & 80) caused a large increase in sediment yield and transport through debris torrents & landslides. Dispersion of harvest was not provided for. Upper watershed, in-channel streambed and bank conditions are highly disturbed where debris torrents have occurred. This has affected 75% of the major 1st and 2nd order streams. Sediment from these events and other landslides has been deposited in the mainstem of Finney Cr. The ability to retain sediment in the side channels has been greatly reduced. Pools have been filled in and/or scoured which has severely impacted the resident trout habitat The main channel of Finney Creek has been scoured, widened, and straightened. Woody debris has been re-distributed and/or lost from the system. Because of these factors the ID team rated the condition of the AZ as unacceptable.

The average harvest rate in the 1960's, 70's and 80's was 3137 acres per decade on the AZ. This rate resulted in an unacceptable watershed condition. The Finney Creek watershed is still in an unacceptable condition This condition will not change until natural recovery and watershed restoration measures are completed in the first decade. The decline in watershed condition must be halted before any timber harvest and road construction activities can take place.

Watershed condition in 1976 was determined to be unacceptable based on observation of stream conditions in the lower WS. Considering that rooting strength deteriorated for 8 years, it is assumed this condition was triggered at the 1968 harvest level. This rate was 16% on NF land. In order to provide for adequate dispersion of harvest throughout the suitable acres, and for in-stream recovery to occur it is assumed that 15% disturbance in 30 years can be tolerated beginning in the third decade (5% / decade X 17,019 tent. suitable acres = 850 acres harvest per decade).

Minimal harvest activities of not more than 100 acres/decade for the first two decades may be possible provided that all watershed restoration measures are completed, the decline in watershed condition is halted, and the following best management practices are strictly adhered to: 1) harvest will be distributed throughout the watershed and not concentrated in any one sub-basin, 2) new long-term road construction will be restricted to gentle stable ground, 3) management activities must be no closer than 1/8 mile from unstable soil areas, 4) all materials will be yarded using full suspension methods, 5) there will be no harvest allowed in Class I, II, III and IV stream riparian areas, 6) all disturbed areas (including but not limited to temporary roads, skid trails, landings, fire lines) will be revegetated and drained prior to the current year fall/winter storm period, 7) all short-term roads must meet the preceding criteria, 8) emphasis will be placed on using KV generated dollars for watershed/fish restoration work, and 9) emphasis will be placed on using timber sale road reconstruction dollars for road drainage restoration.

It is assumed that by the 3rd decade (year 2010) the watershed (channel recovery, canopy closure, root strength) should be recovered sufficiently to allow a harvest rate of 850 acres/decade for the next two decades.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS:_ _ACCEPTABLE _XX_UNACCEPTABLE

1/ MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 100 acres
2: 100 acres
3: 850 acres
4: 850 acres

1/ This expression becomes the watershed constraint to meet water quality and riparian MR's; it will be considered in all alternatives in the FEIS.

Items Considered:

1. Past Harvest Rate/Condition of Watershed
2. Restoration Needs
3. Effectiveness of BMPs - Overall Watershed
4. Future Harvest/Road Needs - Helicopter v.s. Conventional
5. Acres Harvested/Acres Saw Timber Remaining/Proximity to Unstable Soil
6. Road Density

Summary Sheets for All Watersheds

Illabot Creek - AZ 2
(Includes: Illabot, Bluebell, Iron, Arrow, Otter, and Marten Creeks)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The following discussion of fisheries values are based on various surveys, reports, and observations which include: 1) Seattle City Light reports: "Development of Flow Recommendations for a Proposed Small Hydroelectric Project on Illabot Creek: Using the Instream Flow Incremental Methodology" (K. McDowell, March 1983) and "Skagit Valley Small Hydro Environmental Reconnaissance" (S. Ralph and C Hall, August 1981); 2) Washington Department of Fisheries: "A Catalog of Streams and Salmon Utilization", Volume 1. Puget Sound (R. Williams, R. Laramie and J. Ames, November 1975) including supplements; and 3) field reconnaissance by ID Team members and 4) personal conversations with other resource agency fisheries biologists.

Illabot Creek is an important tributary to the Skagit River with significant anadromous fisheries values throughout at least 10 miles of its length. It also has important resident fisheries values in upper portions of the drainage, including tributaries. The stream descends through a narrow canyon from RM 10 at Illabot Lake to RM 2.5 near the Forest Service boundary. The stream channel within this section contains numerous cascades and falls with large boulders and rubble. The tributaries are precipitous and drop off steep slopes which have been extensively logged in some areas.

Electro-fishing and spawning surveys were conducted in Illabot Creek by Seattle City Light in 1982. Adult steelhead trout were observed as high as RM 7.7 and juvenile rainbow trout (suspected to be the anadromous form) were sampled above Illabot Lakes at RM 10.5. Anadromous fish seen during these surveys included adult chum, coho, chinook salmon, steelhead trout and Dolly varden char. Resident fishes included rainbow trout, cutthroat trout, mountain whitefish and Dolly varden char. Major tributaries to Illabot Creek and their respective anadromous barrier RM include: Iron (RM .25), Bluebell (RM .25), Arrow (RM .25), Otter (RM .25).

Illabot Creek has a high level of natural instability that has been aggravated by past management activities. New activities that add more sediment or increase channel instability would reduce the amount of valuable anadromous fisheries and resident trout resources in Illabot Creek and its tributaries.

In channel stability in all channels is fair to good. Streambank stability is fair. Much of fragile stability in the watershed is due to the natural soil and geologic conditions. Pools are relatively medium to high in quality and quantity in most of the channels. Moderate amounts of LWD exist in most channels and the recruitment potential from adjacent riparian areas is moderate. This results in an acceptable watershed condition at the present time.

Allocation Zone 2 on Forest Service land consists of 13,134 acres in Illabot Creek, 2,147 acres in Jordan Creek and 241 acres in the middle Skagit River drainages. The Illabot Creek watershed also contains 13,703 acres in the Glacier Peak Wilderness, State and private lands. Over 35% of the tentatively suitable acres (3,088 acres) are in a pole-sized or clearcut stand condition which reduces harvest dispersion opportunities during the next 4 decades. Most of the remaining mature timber is on steep, marginally productive sites that are more difficult to access Consequently most of the future harvest would occur on the more sensitive areas.

Review of aerial photography (1956 to 1983) revealed that past harvest activities up to 1986 have generally been concentrated in the Iron Creek and upper reaches of Illabot Creek. The harvest rate over the last 3 decades has been approximately 620 acres/decade. This rate of timber harvest combined with the natural background instability of the channel have had some negative impacts on the Illabot Creek system. There have also been several road/harvest related failures in the past which have contributed sediment to the Illabot Creek system.

The ID team concluded that the watershed is in a delicate balance at this time considering the past rate of concentrated harvest and natural instability conditions. Based on the preceding factors, and assuming there is good dispersion of harvest, the ID Team recommends that the watershed could withstand a 425 acre (5% of 8466 acres tentatively suitable) harvest level *without sustaining adverse cumulative effects to the watershed and ultimately* to the fisheries resources.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 425 acres
2: 425 acres
3: 425 acres
4: 425 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Chilliwack - AZ 3

(Includes drainages: Liumchen, Quartz, and Damfino Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Review of aerial photography revealed that past harvest activities up to 1986 had minimal impacts to the upslope and in-channel areas in the AZ except in Liumchen Creek. Plans have existed since 1982 to develop the Liumchen Creek Watershed as a main domestic water source for the City of Chilliwack, B.C.,

Canada (correspondence with Mike Currie, Hydrological Engineer, B.C. Ministry of Environment, Lower Mainland Region, Surrey, B.C., Canada). Plans are still on the books for construction 3 to 5 years in the future. The rest of the AZ (ie., Damfino and Quartz Creeks) has had to harvest activity. The AZ has been rated as acceptable because of the following:

Channel scouring due to management activity only evident in Liumchen Cr. Other scouring in 1st&2nd order channels due to natural causes. Overall channel stability is good.

Pool frequency in 1st&2nd order channels is at least 50/50 except in Liumchen Cr. Pools in 3rd & 4th order channels are of moderate to high quality.

Majority of 1st&2nd order channels exhibit some degree of exposed banks, most due to natural processes Bank stability along 3rd&4th channels is fair to good.

Large Woody Debris is in moderate to high abundance in all channels. High potential for LWD recruitment from adjacent riparian stands along all channels.

Adequate dispersion of future harvest is possible with helicopter logging which would keep the road density at a low level and would avoid the unstable soil areas. Since the past harvest rate has been low, about 230 acres (2%) of NF land, the upper watershed and instream conditions have not been significantly impacted by management activities. Therefore, the ID team concluded that the harvest could be increased somewhat without adverse impacts. The team recommends that 250 acres (10% of tentatively suitable) could be harvested per decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: XX ACCEPTABLE __ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 acres
2: 250 acres
3: 250 acres
4: 250 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Canyon Creek - AZ 4

(Includes: Whistler, Kidney and mainstem Canyon Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Anadromous fish can access Canyon Creek up to a cascades barrier formed by large boulders and LWD, located at RM 4.4 within the National Forest Boundary

(Roger Nichols personal observation, 1987). Anadromous fish that inhabit Canyon Creek include: spring chinook, coho, pink and chum salmon and steelhead, cutthroat and Dolly Varden trout. Depletion of wild spring chinook stocks in Puget Sound and the Columbia River basins have been a major concern of fisheries resource agencies (US Fish & Wildlife Service, WDF, National Marine Fisheries Service, Nooksack & Lummi Tribes). Since 1980 there has been an intensive effort by these agencies to improve the depleted spring chinook stocks in the Nooksack River basin. Canyon Creek, which is an important tributary to the North Fork Nooksack River, has been an important spawning area for spring chinook. Aggravation of unstable channel conditions in Canyon Creek has increased the concern for any further reduction in fish habitat and has emphasized the need for a stream/watershed rehabilitation program.

Above the barrier there are approximately 7 miles of resident trout (Dolly Varden, cutthroat and brook) habitat (based on FS stream surveys, personal communications with WDW fisheries biologists and conversations with local fishermen) in the mainstem Canyon Creek not including tributaries. There are plans to modify the barrier so that anadromous fish, especially steelhead trout, would then have access to an additional 7+ miles of Canyon Creek. Cooperative (FS, Nooksack Tribe, Fourth Corner Fly Fishers) stream/watershed rehabilitation projects have been completed annually in a number of reaches of Canyon Creek since 1986 (log/boulder/jersey barrier deflector erosion control structures, willow planting/grass seeding) to help reduce stream bank and channel instability.

Review of aerial photos, stream habitat/condition inventories (1982, `83, `84, `85,`86) by Forest Service and/or Lummi Fisheries Dept., and various studies (Lummi fisheries report 1984, USFWS and Lummi Fisheries Dept. report 1987 Cummulative effects Study for AC-1 timber Sale 1986) indicate that a substantial increase in sediment delivery has occurred in the Canyon Creek drainage. Other effects observed include: the inability of the stream to transport sediment, loss of LWD, loss of riparian vegetation, and loss of pools. Stream deposition and scouring was found to correspond to a general loss of pools, spawning gravels and an overall reduction in anadromous fish habitat in Canyon Creek. Timber harvest and road building activities that add to the existing channel instability conditions would reduce the fish habitat Because to these factors, the ID team rated this AZ unacceptable.

During the 1950's, 1960's and 1970's timber was harvested at a rate of 1327 acres per decade(7% of the total watershed per decade). However, this harvest was not dispersed over the entire watershed but was concentrated into an area of about 7000 acres or about a third of the AZ (primarily on the lower slopes adjacent to Canyon Creek). This rate of harvest activity combined with associated road construction and old management practices has resulted in the unacceptable stream conditions described above.

Degradation of the watershed began in the mid 1960s when the average rate of harvest was 1130 acres/decade when considering the portion of the watershed in which harvest was being concentrated, which was primarily that which was accessible by road. Based on this information we feel that a harvest rate of around 420 acres/decade would maintain the watershed at an acceptable level once recovery has occurred.

Ten percent of the remaining mature timber and approximately 700-800 acres of poles which will be mature during the 4th decade (a total of approximately 4200 acres) equates to 420 acres/decade harvest of tentatively suitable land.

Harvest during the first two decades would need to be reduced to allow for the recovery of the watershed. In the first decade harvest would be limited to about 100 acres. In the second decade that would increase to 200 acres. Beginning with decade 3 harvest would reach and be maintained at 420 acres which is 4.8% of the tentatively suitable.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ACCEPTABLE XX UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 100 acres
2: 200 acres
3: 420 acres
4: 420 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lower Reach, North Fork Nooksack - AZ 5
(Includes Cornell, Gallop, Hurst, Coal, Deerhorn, Boyd, Lookout, Fossil, Cascade, and Deadhorse Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

All of the NF Nooksack River (up tod the North Fork Falls) and most of the major tributaries (Cornell, Gallop, Boyd, Deadhorse Creeks) contain anadromous fish species including 5 species of salmon and 3 species of anadromous trout. Anadromous fish utilize portions of these streams for adult holding, spawning and juvenile rearing habitat in areas where stable channels, LWD and pools are located. Many of these streams, especially in reaches above barriers to anadromous fish, contain resident trout (including rainbow, cutthroat and Dolly varden).

Some unstable watershed conditions occur in areas of past concentrated disturbance (i.e., private land in the Cornell/Gallop Creek subwatersheds and *the National Forest land east of Deadhorse Creek, and Little Mountain. On the* remainder of the National Forest land, past harvest activities have been well dispersed throughout the tentatively suitable acres. The AZ was rated acceptable because of lower watershed conditions of very little downcutting, medium quantity and quality of pools, and moderate LWD. Past harvest rate has been variable over the past 4 decades but has averaged about 400 acres/decade. The team concluded that continuation of this rate through dispersion, helicopter, and BMPs will allow hydrological recovery to continue in those disturbed subwatersheds. The ID team concluded that this 400 acres/decade rate

(4.2% of tentatively suitable) can be sustained while maintaining an acceptable watershed condition. Any increased harvest rate will not sustain this condition considering the condition of private inholdings, and the need to sustain the anadromous and resident fisheries habitat described above.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 400 acres
2: 400 acres
3: 400 acres
4: 400 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Glacier Creek/M.F. Nooksack, North - AZ 6

(Includes: Upper Clearwater Creek, Upper Rocky Creek, Thompson, Coal, Deep, Little, Davis, Smith, Balls and Glacier Creek.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Based on stream survey data (Forest Service stream habitat surveys (1983), small hydro proposals. Nooksack Tribe Fisheries Dept., Lummi Fisheries Dept.) anadromous fish have been documented in Thompson Creek and Glacier Creek upstream to a cascade/barrier falls at R.M. 3.6. It is possible that steelhead and salmon can access upper portions of Glacier Creek depending upon stream flow conditions at the falls. Stream surveys indicate that the portion of Glacier Creek above the falls contain resident trout (rainbow and Dolly Varden trout).

It is suspected that resident trout utilize the National Forest portions of the Clearwater and Rocky Creek drainages as well as upper tributaries of Glacier Creek based on information from studies of adjacent drainages.

The ID team rated the AZ as marginally acceptable due to little downcutting, but loss of storage and transport capacity, and reduced pool quantity and quality.

Based on aerial photo review of past management activities it was determined that the rate of occurrence of landslide activity significantly increased after harvest and road building activities in the 1960's. This rate of harvest was 16% in the Rocky/Clearwater Creek part of the AZ, and 2% in the Glacier /Thompson Creek partion; these two rates involved approximately 860 acres of harvest in the 1960's. Harvest rate significantly decreased in the 1970's and 1980's. This decrease in management activity, coupled with a reasonable rate

of harvest with adequate dispersion, has been effective in maintaining a marginally acceptable upper watershed and instream condition.

Past harvesting over the last 3 decades has been very variable in the AZ; for example from 190 acres in Glacier/Thompson Creek area during the 1980's to 1528 acres in the Clearwater/Rocky Creek area during the 1960's. It was the judgement of the ID team that 1528 acres harvest rate in the 1960's was a rate that could not maintain an acceptable watershed condition because (1) past harvest activities on private lands, (2) reduced opportunity for harvest dispersion throughout the AZ, (3) concerns for water quality protection in the Middle Fork Nooksack River Municipal Watershed (ie., Rocky/Clearwater Creek watershed), (4) high anadromous fish habitat concerns in Thompson Creek, (5) concern for protection of domestic water use of Thompson Creek tributaries and (6) unstable soils evenly distributed throughout the remaining mature timber acres. Based on these factors it is recommended that a maximum of 280 acres or 4% of the tentatively suitable acres can be harvested per decade over the next 4 decades and still maintain an acceptable watershed condition.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 280 acres
2: 280 acres
3: 280 acres
4: 280 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Middle Fork Nooksack - AZ 8

(Includes tributaries that drain into the Middle Fork Nooksack River: Clearwater,
Rocky and Warm Creek.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photography revealed that past harvest activities up to 1986 had some negative impacts on soil and water resources in the headwaters of Rocky and Clearwater Creeks, which are outside the AZ. There have not been any harvest activities in the AZ. The streams are in an acceptable condition because of relatively little downcutting, a high pool quality, and moderate amounts of LWD. All of the AZ is within the Middle Fork Nooksack River municipal watershed (City of Bellingham). A significant portion of the tentatively suitable acres are comprised of steep, rocky and wet soils of low productivity. Most streams in the area have not been surveyed or sampled to determine fish populations present. There are cutthroat trout in Warm Creek.

There is good opportunity to disperse harvest throughout the AZ. Harvest has not yet occurred within the Warm Creek headwaters on National Forest lands. Approximately 1/4 of the remaining mature timber in the AZ would be helicopter logged. Only 14 miles of new road construction (ie., mostly within the Warm Creek drainage) would be needed in the future, bringing the road density to 2.1 miles/sq. mile. Based on these factors, along with consideration of the impacts of the previously harvested areas upstream, it is recommended that a maximum of 250 acres/decade (4.4% of the tentatively suitable) could be harvested while maintaining an acceptable watershed condition.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 acres
2: 250 acres
3: 250 acres
4: 250 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach, North Fork Nooksack - AZ 9

(Includes: mainstem NF Nooksack River and Wells, Barometer, Anderson, Swamp, Ruth,
Bagley, Razorhone, and White Salmon Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Based on stream surveys and creel census information (small hydro and conversations with WDW biologists and local flyfishermen) there are healthy populations of resident trout (rainbow, cutthroat, brook) in many tributaries of the NF Nooksack River above Nooksack Falls at Wells Creek Trout habitat is below optimum levels in some areas including the mainstem NF Nooksack R. above Silver Fir Campground and in White Salmon Creek due to channel aggrayation, stability problems, and corresponding loss of habitat.

Review of aerial photography revealed that past harvest activities up to 1986 have generally been well distributed throughout the AZ. However, there are unstable watershed conditions in areas of past concentrated disturbance (ie., mainstem NF Nooksack R. above Silver Fir Campground, White Salmon, Wells and Anderson Creek areas). Overall, the distribution conditions, along with current BMP's, have been effective in maintaining acceptable upper watershed and instream conditions.

The watershed presently is in a acceptable hydrologic condition due to:

In-channel conditions: channel scouring in 1st and 2nd order channels due to management activities is evident in 2 tributaries (Wells & White Salmon Creeks), other scouring due to natural causes. Channel stability in the 3rd-4th order channels is fair to good.

Pool Condition: pools are usually less than 50% of the surface area in many 1st & 2nd order channels, but greater than 50% in the fish bearing 3rd-4th order channels.

Streambank Stability: over 30% of the 1st&2nd order channels exhibit exposed banks, most due to natural causes. Banks along 3rd&4th order channels are in stable condition.

LWD: adequate to moderate amounts of LWD in both 1st&2nd and 3rd&4th order channels. Moderate potential for recruitment of wood into these channels from the adjacent riparian areas.

Due to the relatively low amount of unstable soils in the National Forest portion of the watershed, the high percentage of helicopter logging in the future, and the low future road needs (ie., 7.5 miles) it is recommended that the past harvest rate of 500 acres/decade on Forest land , averaged over the 50's, 60's, 70's, and 80's, could be increased to 980 acres/decade (7% of tent suit). This increase would not change the present overall acceptable upper watershed and instream conditions provided that BMP's are strictly adhered to and dispersion of harvest continues. Increasing the harvest rate to above 980 acres/decade on National Forest land would result in concentrating harvest activities in the more sensitive areas.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: XX ACCEPTABLE ___ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 980 acres
2: 980 acres
3: 980 acres
4: 980 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Middle Fork Nooksack, South - AZ 10

(Includes un-named trib. in Sec. 35, Sisters, Hildebrand, Ridley Creeks, main Middle Fork Nooksack River, Rankin and Wallace Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors *Together and Logically Leads to Watershed Constraint*

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The City of Bellingham water supply diversion dam located at RM 7.2 prevents anadromous fish migration upstream into the AZ. However, there are plans being

considered to build fish passage structures at the diversion so that anadromous fish may access the upper Middle Fork Nooksack in the future. Presently there are resident trout species (rainbow, cutthroat and Dolly Varden trout) in most tributaries in the AZ.

Based on aerial photo review and on-the-ground observations, it is determined that past management activities in the Rankin Creek area on the north side of the Middle Fork Nooksack River have resulted in an unacceptable watershed condition for that portion of the AZ, although the overall condition of the AZ was rated as acceptable. Much of the AZ is in a less than desirable condition but this is due to a large degree to natural conditions. However, further degradation should not be allowed to occur. The most significant amount of this disturbance occurred in the early 1960s (primarily due to the salvage of extensive blowdown from a single storm event). Vegetative recovery is relatively good at this time.

Past harvest of NF acres in the AZ has varied from approximately 800 acres in the 60's to a total of 145 in the 70's and 80's. Although some soil instability exists east of Green Creek and in the Hildebrand Creek area, where some residual impacts are still left from the 60s, there is good opportunity to disperse harvest over the mature timber acres remaining in the tentatively suitable ground. Approximately one half of this mature timber would be harvested by helicopter. Because of this, the amount of future road construction needed for harvest activities would be quite low (i.e., about 7 miles of new system road). Also, the existing road density of 1.6 miles/sq. mi. is relatively low in comparison to other areas of the District. Even though this AZ is within the Middle Fork Nooksack Municipal Supply Watershed for the City of Bellingham, future harvest dispersion combined with strict attention to BMPs could increase harvest (increased compared to harvest rate during 70s and 80s) from 145 acres to 200 acres. This 200 acres/decade is also less than the 800 harvest rate of the 1960s, a rate that demonstrated unacceptable in-channel damage in certain parts of the AZ. This 200 acres/decade over the next four decades will maintain an acceptable watershed condition.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ **ACCEPTABLE** ___ **UNACCEPTABLE**

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 200 acres
2: 200 acres
3: 200 acres
4: 200 acres

South Fork Nooksack - AZ 11
(This includes the following streams: Loomis Creek, Wanlick Creek, Bell Creek, Pine Creek, Heart Creek and the upper mainstem SF Nooksack.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photos (1940, 1956, 1964, 1972, 1979, 1983 & 1986), on-site observations (personal observations by certain team members over past 20 years) and stream/fish habitat condition inventories (1983, 1986 & 1988 Forest Service and U.S. Fish & Wildlife Service) indicate that the upper watershed and instream conditions are unacceptable and in a declining condition in the South Fork Nooksack River and in the Wanlick Creek portion of this AZ. The yreceding information indicates that there is high background instability in the South Fork Nooksack River and Wanlick Creek drainages which contributed to the unstable instream conditions as described. Timber harvest and road construction have accelerated these in-channel processes, particularly in the Wanlick Creek drainage, resulting in an increase in sediment delivery to the South Fork Nooksack R./Wanlick Creek drainages. Other effects observed include: the inability of the stream to transport sediment, loss of LWD, loss of riparian vegetation, and loss of pools. Stream aggradation was found to correspond to a general increase in stream temperature, in-filling of pools and an overall reduction in anadromous and resident fish habitat. All of the above observations led to the determination of an overall rating of the AZ as unacceptable.

The U.S. Fish & Wildlife Service, Lummi and Nooksack Tribes report (Schuett-Hames, Wampler and Doughty October 1988. "An assessment of the availability and quality of spring chinook holding and spawning habitat in the South Fork Nooksack River", 1986) concludes that "The major freshwater limiting factors for South Fork spring chinook appear to be: adult mortality from poaching; predation and stress during holding due to lack of woody cover; lack of cool water temperatures and inadequate pool depth; and loss of eggs due to stream channel instability." Water quality surveys conducted by the U S. Fish & Wildlife Service as well as the Lummi and Nooksack Tribal Fisheries Departments since 1985 indicate that the South Fork Nooksack River frequently reaches water temperatures in the high 60's in late summer. High water temperatures (> 65 degrees F) can stress salmonids and increase their susceptibility to disease and even result in mortality. Based on data presented in the U.S. Fish & Wildlife Service, Lummi and Nooksack Tribe Report there were 10 days between August 7 and August 27, 1986 when the maximum daily water temperature was equal to or exceeded the 65 degrees F.

Stream surveys conducted by the Forest Service and volunteers during August and September, 1988, in Wanlick and Heart Creeks indicate that populations of rainbow and Dolly varden trout are in these streams. Although there are a series of 4 falls on the mainstem South Fork Nooksack River located between river miles (RM) 30 and 31, approximately 2 miles below the Forest Service Boundary, it is suspected that the rainbow trout in Wanlick Creek are juvenile steelhead trout based on available evidence (discussions with WDW and Nooksack Tribal fisheries biologists indicating that these barriers are only partial barriers to steelhead trout and surveys by the Nooksack Tribe that found adult steelhead above RM 33). Conversations with Washington Department of Wildlife

fisheries biologists and fishermen indicate that the Forest Service portion of the South Fork Nooksack River, particularly between RM 33 and 37, is an important trout fishing area. Resident trout in this area include rainbow, cutthroat and Dolly Varden trout. Anadromous fish species that potentially could be in the river include spring chinook, coho, chum, pink and sockeye salmon, summer and winter steelhead, cutthroat and Dolly Varden trout.

During the analysis of this AZ, the I.D.Team observed that past harvest took place, almost exclusively, on those acres that are being classed as tentatively suitable in the Forest Plan. Therefore, for this discussion all past harvest is expressed in terms of a percentage of tent. suitable in an effort to arrive at an equatable number to be used as as MR and expressed in terms of acres of harvest/decade.

Harvest began in the Wanlick Creek drainage in the 1960's and by 1964 significant stream channel impacts had occurred after approximately 322 acres of the watershed had been harvested (review of 1964 aerial photos). A rate of harvest of 373 acres occurred in the 1970's and 1180 acres in the 1980's. Wanlick Creek was analyzed separately and these rates of harvest apply to just that drainage which is only a part of the total AZ. Of the 1180 acres , approximately 1000 acres occurred on private land within the headwaters of a tributary to Wanlick Creek. This is a unique situation in that the drainage in which the heavy harvest took place has its headwaters on private land outside the N.F. boundary and then drains in a direction that flows inside the N.F. boundary before it joins main Wanlick Creek. The I.D.Team felt the impact of this past harvest activity on the entire Wanlick drainage was so significant that it was necessary to assess that impact when establishing the MR for the AZ. Presently, there is a high risk that continued harvest in the Wanlick Creek portion of the AZ will increase stream instability. Excessive sedimentation would further reduce habitat for the already tenuous summer steelhead populations. It is deemed necessary that the Wanlick drainage be allowed a recovery period (2 decades) before additional harvest take place just to protect the hydrologic integrity. The disturbance level in Wanlick Creek should not exceed 375 acres in 30 years (recovery based on canopy closure, channel stability, root strength, etc.) or an average of 125 acres/decade and watershed recovery should be complete before new harvesting begins. By 2015 some harvesting could occur in the 2nd half of decade 3. The full 125 acres could be harvested in decade 4.

Stream conditions in the South Fork Nooksack River are dominated by high natural sediment inputs from Pine and Heart Creeks and the headwaters of upper SF Nooksack River which drain the flanks of the Twin Sisters Mtn. (aerial photo review).

Past management activities were concentrated along the mainstem of the South Fork Nooksack River and have impacted watershed conditions (aerial photo review) The past harvest rate in the SF drainage, exclusive of Wanlick Creek was 260 acres in the 1960's, 801 acres in the 1970's and 63 acres in the 1980's. Approximately 2000 acres of the remaining mature timber would be helicopter logged and 4 miles of new road construction would be required in the future for the portion of the AZ exclusive of Wanlick Creek. This would allow for better dispersion of future harvest units throughout the AZ. However, there are significant fisheries habitat concerns (see above) as well as significant impacts from mining activities (olivine). Much of the remaining mature timber occurs on upper slope ground that is marginally stable (ie.,

steep, shallow, wet soils) and has a moderate to low productivity. Based on these conditions it is recommended that the harvest rate on tentatively suitable acres should be set at 325 acres.(5% x 6472 tent. suitable acres)

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ _ACCEPTABLE _XX_UNACCEPTABLE

Swift-Park Creeks Watershed - AZ 14
(Includes Swift Cr., Rainbow Cr., Shuksan Cr., Morovitz Cr., and Park Cr.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The lower reaches of Swift and Park Creeks, below barriers located at RM 2 and RM 1.8, respectively, are utilized by chinook, coho and sockeye salmon and anadromous from Baker Lake and resident trout. Rainbow, Shuksan and Morovitz Creeks are all tributaries of Swift Creek and most likely contain resident trout. Morovitz Creek has been documented to contain coho salmon up to RM 1.75 (Beak Study for Puget Power & Light). There is a lack of LWD in many of these streams. Most pools are formed by boulders, bedrock outcrops and undercut banks. The pools are of medium quality and there is a moderate amount of them in these streams. There are extensive beaver pond areas in the Morovitz Creek area that are utilized by juvenile coho salmon. Reduction in LWD, and sedimentation that fills in pools or impacts spawning gravels would reduce the amount of available habitat for fish in these streams.

The AZ was rated acceptable because of lower watershed conditions of very little downcutting, moderate ability to store sediment, good ability to transport sediment, medium quantity and quality of pools, and moderate amount of LWD throughout.

Past harvest has been well distributed throughout the AZ. Although unstable soils have been generally avoided, there are two specific areas where watershed conditions have been impacted by management activities: 1) the Morovitz/Marten Lake area, and 2) the upper Shuksan Creek drainage. The past harvest rate on NF lands has been variable but has averaged about 410 acres per decade over the past 4 decades.

Even though future harvest could be dispersed, current road density is moderate (3.0 miles/sq. mi.), little new road construction would be required (approx. 2.0 miles), and some of the mature timber (roughly 200 acres) would be helicopter logged, it is concluded by the I.D. team that the 410 acres per decade rate could not be sustained and still maintain an acceptable watershed condition. While past harvest activities generally avoided unstable soil areas, much of the remaining mature timber is located in marginally stable, steep, shallow, and wet soil areas. There is a high risk that harvest activities could trigger mass wasting and stream sedimentation in these areas which would impact existing fish habitat. For these reasons the I.D. team recommends a harvest rate of 250 acres per decade (4.25% per decade) of the tentatively suitable acres over the next 4 decades.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 acres
2: 250 acres
3: 250 acres
4: 250 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the Final Forest Plan.

Baker Lake - AZ 15 & 16

(Includes Dillard, Sandy, Little Sandy, Boulder, Little Park, Shannon, Baker River,
Hidden, Lake, Noisy, Ermine, Silver, Four Mile, Welker, and Anderson Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Based on various surveys and reports (WDF Stream Catalog, 1975, WDF and FS Stream Surveys, Beak & Assoc., Puget Power & Light Co.) chinook, sockeye and pink salmon utilize the Baker Lake basin Anadromous and resident forms of rainbow (steelhead), cutthroat and Dolly Varden trout also utilize the basin based on records of fish collected at the Puget Power & Light Co. fish collection facility at Concrete on lower Baker River. Important streams in the AZ that are utilized by anadromous fish and the river mile (RM) location of the barrier to anadromous fish include: Baker River (RM 9), Sandy (RM .75), Little Sandy (RM 1), Little Park (RM 1), Shannon (RM .5), Hidden (.25), Blum (.25), Lake (.25) Creeks. The upper reaches of these streams and most of the remaining streams in the AZ contain resident trout.

Overall pool quality and quantity is low in most streams. Exceptions are portions of Sandy, Noisy and Little Sandy Creeks. Much of the pool habitat is formed by boulders and bedrock outcrops. The majority of LWD has been removed from Anderson, Welker, and portions of Sandy Creeks. There are moderate

amounts of LWD remaining in portions of most of the other streams (ie., upper reaches of Welker, Silver, Noisy and Lake Creeks) in the AZ. Baker River and Boulder Creek, two of the largest streams in the basin are lacking in LWD due to natural conditions. Activities that reduce LWD, fill in pools or impact spawning habitat would further reduce the available fish habitat in the AZ.

To a large degree, past harvest has been well distributed throughout AZ #15. However, while unstable soils have generally been avoided, the following specific areas have been impacted from concentration of past harvest activities (Ref. 1964 & 1983 aerial photos): 1) the Sandy/Dillard Creek area, 2) Anderson Creek, and 3) Boulder Ridge. Effectiveness of new BMPs will be limited to the immediate area of application and will not be effective in improving upper watershed and in-stream conditions in the first decade in these impacted areas. For this reason and considering the fisheries resource in the Baker Lake basin the I.D. team recommends no harvest for the first decade in the three impacted areas described above.

Over the past four decades the harvest rate in AZ #15 on the west side of Baker Lake has been variable: 2061 acres in the '50s,452 acres in the '60s, 571 acres in the '70s, and 1026 acres in the '80s. The average rate overall has been 1278 acres over the past four decades. No harvesting has occurred in AZ #16 on the east side of Baker Lake. However, the average rate of past harvest for the eastside is 237 acres considering the past harvest in the Anderson Creek Drainage (AZ15).

A significant portion of the remaining mature saw timber in AZ #16 (approx. 1000 acres) is located in marginally stable, steep, wet soil areas along the east side of Baker Lake. Harvesting in these areas would create an unacceptable high risk of mass wasting and stream sedimentation.

The IDT concluded the overall rating for this watershed and these allocation zones should be acceptable. Even though the team felt pool quality in this drainage could be better and LWD is only available in moderate amounts, the condition of the stream channel and banks are generally satisfactory when considered with overall pool conditions and availablity of LWD.

Future Harvest Rate in AZ #15: Of the 16,102 acres of tentatively suitable land on the west side of Baker Lake, approximately 10,800 acres are located outside of the Sandy/Dillard Creek and Boulder Ridge areas. It is felt that these acres (10,800) could be harvested at the rate of 650 acres per decade starting in the first decade. Translating that average to the remaining suitable timber the IDT felt the harvest rate could be increased to 650 acres and maintain the acceptable hydrologic condition of the watershed. Therefore, by eliminating harvest in the first decade in the Sandy/Dillard Creek and Boulder Ridge areas on the west side, and the Anderson Creek Road area on the east side, the first decade harvest level would be 650 acres. When the tentatively suitable acres for Sandy/Dillard, Boulder Ridge, and Anderson Creek are added back in for decades two through four the total tentatively suitable in the AZ is 17,357 acres. For this period it is felt a harvest rate of 1025 acres/decade is sustainable in the AZ while maintaining an acceptable watershed condition.

Future Harvest Rate in AZ #16: In this AZ, it is felt that 4870 acres of the total 5870 acres of tentatively suitable is actually available for future harvest management after the 1000 acres of marginal ground mentioned above is

removed from consideration. It is felt this remaining 4870 acres could be harvested in decades one through 4 at a rate of 350 acres/decade, while maintaining an acceptable watershed condition in this AZ. A higher percentage for this AZ seems appropriate because of the large portion of the AZ that will undoubtedly be helicopter logged.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

	AZ #15	AZ #16

3:	1025 acres	350
4:	1025 acres	350

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lake Shannon - AZ 17

(Includes Rocky, Part Time, and Sulphur Creeks)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Rocky and Sulphur Creeks are major tributaries to Lake Shannon, a large reservoir located on Baker River north of Concrete, Washington. The following discussion of fish and fish habitat is based on information from various fish and aquatic habitat reports and surveys that have been completed on Rocky and Sulphur Creeks. Many are related to small hydro project proposals by Puget Power & Light Co. and other companies in these drainages (Koma Kulshan, Beak & Assoc., Washington Department of Fisheries etc.).

The lower portions of Sulphur and Rocky Creek, below RM .5 and RM 1.3, respectively, are suspected as being utilized by coho and sockeye/kokanee salmon (WDF Stream Catalogue, R.W. Williams and others, 1975) and anadromous and resident trout. Fish surveys (snorkel and electro-fishing) conducted related to the Koma Kulshan Small Hydro Project found some resident trout in intermediate reaches of both Sulphur and Rocky Creeks. These surveys indicate that there is habitat to support small resident trout populations. Pool quality and quantity in these streams is fair to good with most pools formed by boulders and bedrock outcrops; with few formed by LWD. Management activities that result in the filling in of these pools and/or scouring or burying spawning gravels would reduce this habitat being available to fish in these streams.

Some unstable watershed conditions occur in areas of past concentrated disturbance (i.e., Schrieber's Meadow and upper Rocky Creek areas).

Overall, the in-channel conditions are poor to fair in the 1st&2nd order channels, scouring is widespread in tributaries to Rocky and Sulphur Creeks, in the 3rd&4th order channels conditions are fair to good due in part to the armoring and bedrock nature of many of these channels. Streambank stability in the 1st&2nd order channels is only fair, half due to natural causes and the remaining related to land management activities. Bank stability in 3rd&4th order channels is generally good Large Woody Debris is generally lacking in the 1st&2nd order channels, but good in the 3th&4th order channels. The stability and distribution of LWD in these channels is only fair.

The past harvest rate (over past 40 years) on commercial Forest land within this AZ has averaged 8% per decade. The existing road density is high, at 4.0 miles/sqmi and the anticipated new road construction over the next decade (7.0 miles) would increase this density to 4.8 mi/sqmi. A moderate amount of unstable soil (14%) exists in the tentatively suitable acres. Steep sideslopes and shallow soils remain on most of the remaining suitable acres. Only 16% of the tentatively suitable acres can be helicopter logged.

For these reasons, the I.D. Team felt the past harvest rate of 8% per decade could not be sustained in the future while maintaining acceptable in-channel and fish habitat conditions.

A rate of 5% per decade of tentatively suitable acres is recommended for each of the next 4 decades; this would result in 300 acres per decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 300 acres
2: 300 acres
3: 300 acres
4: 300 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lake Shannon - AZ 18

(Includes Thunder, Watson & Survey Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The Thunder-Shannon Allocation Zone (AZ #18) includes the drainages that flow into Lake Shannon from the east, i.e. Thunder Creek. The Thunder Creek drainage includes Watson and Survey Creeks. Based on surveys and reports (WDF Stream Catalog, 1975; Thunder Creek Small Hydro Projects, Scott Paper Co. & Puget Power & Light Co.) anadromous fish (primarily coho salmon and sockeye)

utilize Thunder Creek up to RM 3.3 The upper reaches of Thunder, including the tributaries, Watson and Survey Creeks, would be expected to contain resident trout. Due to past timber harvest and road construction practices, primarily on private land within the Forest Service boundary, fish habitat is in poor condition due to the high channel instability which has resulted in most pools being filled in with sediment and spawning areas impacted due to scouring and aggradation. Activities that add more instability and consequently more sediment to the streams will further impact fish habitat.

Review of aerial photography revealed harvest activity began in the mid 1940's with road building and harvest on the private land adjacent to Thunder Creek. Within a period of 5 years a contiguous area that included about 1000 acres of private and 600 acres Forest Service was harvested on the north side of Thunder Creek (much of this was on steep sensitive soils). This intensive harvest and poor road construction caused massive soil movement into lower Thunder Creek and resulted in tremendous damage to the stream and fish habitat. Most of the 1st-2nd order channels exhibit evidence of channel scour in harvested portions of the watershed. Pool frequency in these small channels is less than 50%, especially in and downstream of harvest areas. Over 50% of these channels have exposed and unstable banks, again these are located in and downstream of harvest areas. LWD is lacking in these channels also, and there is little or no potential for LWD recruitment from the adjacent riparian areas. Heavy deposition has occurred in the lower channel areas (Thunder and Watson Creeks). This has resulted in little or no pools in these channels. These channels have little or no LWD. Because of these factors, the team rated the condition of the AZ an unacceptable. Much of this channel is still in a recovery mode. Harvest continued on private land through the 1950's in the lower watershed Only a minor amount of harvest (mainly Forest Service) has occurred since the 1950's The upper 2/3 of the Thunder Creek drainage has remained unroaded and unharvested. Some of this area, mainly in the stream draws, contains sensitive soils similar to those harvested in the lower watershed.

Past harvest is certainly not indicative of what future harvest will bring using BMP's in the upper 2/3 of Thunder creek but there is similarity in soil types that lead us to exercise caution when determining the harvest rate in this area. As we have observed, concentration of harvest can result in serious consequences in this drainage. Because past harvest was so intense and the effects significant, it is difficult to determine what harvest level the watershed could withstand based on this information alone. Information on other similar watersheds indicate that harvest levels of about 7-10% of the remaining suitable area is the rate of harvest that can be sustained while maintaining an overall acceptable watershed condition. The amount and location of sensitive soils in this area would lead us to use the low end of this range.

With the extent of negative effects and the nature of the in-channel recovery at the present time, the ID team recommends that harvest in the first two decades be 200 acres in the first decade and 300 acres in the 2nd decade to allow for further recovery of the stream's in-channel condition. By decade 3 and 4, the rate of cut could be increased to 400 tentatively suitable acres being harvest each decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ____ACCEPTABLE _XX_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 200 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Jackson Creek - AZ 20
(Includes Jackman and Webber Creeks)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Fish habitat information is based on the following surveys and reports: WDF 1975 Stream Catalog, including Supplements; T. Williams-channel condition report for lower Jackman Creek, 1960's?; Jackman Creek small hydro project proposals-Puget Power & Light Co. and Scott Paper Co. Jackman Creek has a barrier to anadromous fish located at RM 1.5 below the Forest Service boundary. Upper reaches of Jackman Creek contain resident trout and receive some fishing pressure.

Reaches in Jackman Creek that have received heavy timber harvest and road construction activity have significant channel instability problems which have contributed to poor fish habitat conditions. Pool quantity and quality are poor in these reaches from sediment filling in pools and scouring and aggrading spawning gravels. In the harvested areas, streambank stability is unstable and the LWD is lacking and there is little or no potential existing for recruitment from the adjacent riparian areas. Generally these in-channel conditions exist for both 1st and 2nd order as well as for 3rd and 4th order channels Because of these in-channel impacts, the watershed is presently in an unacceptable condition. The headwater reaches of Jackman Creek, where no harvest activities have occurred, are in good condition except where natural avalanche conditions have contributed to unstable channel conditions. Activities that add more sediment to the channel could impact fish habitat. Jackman Creek has the potential to become good anadromous fish habitat (especially steelhead trout) providing upstream sediment sources are reduced, channel stability is increased and debris jam barriers are removed.

Limited harvest began in the Allocation Zone in the 1950's. The main harvest began in the 1960's when the road was built along the south side of Jackman Creek. 1722 acres of the private land and 230 acres of the Forest Service land was cut in the 1960's. It is no coincidence that this is the time period that we saw the most dramatic increase in sediment to Jackman Creek and a corresponding decrease in fish habitat. Sediment sources included road sidecast failures, stream debris torrents, and in unit slumping. Harvest continued in the 1970's and 1980's at the reduced rate of 370 acres/decade on private and

about 732 acres/decade on National Forest Land. Since the Forest Service cut has been concentrated on 2/3 of the total allocation zone the effective harvest rate has been about 490 acres. Some sedimentation has occurred even at these reduced rates which indicates that an acceptable harvest rate would be lower than 490 acres.

Based on past harvest rates the ID team feels that a harvest rate of about 325 acres/decade (7% of tentatively suitable) could be sustainable in this allocation zone without effecting the recovery of the watershed.

Harvest in the 1960's was so high that effects of it are still present in the Jackman stream system and fish habitat is being limited. It will take additional time for these effects to subside and for the upslope in-channel recovery to take place. Therefore, the ID team recommends that harvest be reduced in the first decade to 200 acres and limited to the previously uncut upper Jackman area

OVERALL MANAGEMENT REQUIREMENT RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ _ACCEPTABLE _XX_UNACCEPTABLE

MAXIMUM HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 200 acres (assumes harvest will be in upper Jackman Creek)

3: 325 acres
4: 325 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Middle Reach, Skagit - AZ 22

(Includes drainages: Barr (Bark), Sutter, Rocky, Patent, Corkindale, Backus Creeks)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Based on the following information [Forest Service Stream surveys (1983), WDF Stream Catalogue (1975) with new supplements, Percy Washington report "Fishery Enhancement Survey of Upper Skagit River Tributaries" (1984), and the Rocky Creek small hydro project proposal], Rocky Creek contains anadromous fish in the lower 2 miles and probably contains resident trout populations in the upper reaches. The lower 1/4-1/2 miles of Bark, Sutter and Corkindale Creeks are utilized by anadromous fish from the Skagit River. These streams contain adequate spawning habitat but are limited in rearing habitat for anadromous fish. Patent (a tributary to Rocky Creek) and Backus Creeks contain populations of resident trout. Lower Backus Creek has a significant population of cutthroat trout that is providing an excellent fishing opportunity.

Review of aerial photography revealed that past harvest activities up to 1986 had some negative impacts on soil and water resources in portions of the AZ. The generally southerly aspect of the several drainages that flow south and east to the Skagit River are subject to rain-on-snow events and debris torrent activity (Ref. Buggy and Olson timber sale EA's and analysis files).

The ID team rated the AZ as acceptable due to lower channel conditions of some downcutting, moderate to high ability to store and transport sediment, high pool quality and quantity, and moderate amounts of LWD. However, activities that contribute additional sediment to these streams would increase channel instability, fill in pools, scour or aggrade spawning gravels and result in a further reduction in fish habitat.

Only a minimal amount of timber harvest and road construction activity has occurred to date in this AZ, as indicated by the 0.3 miles/sq. mile road density and 21 acres harvest on National Forest land in the past 3 decades. Good opportunity would exist for future harvest dispersal except that only 2829 acres of mature timber exist out of 7,959 acres of tentatively suitable land. The remaining approximately 5000 acres are in pole-sized timber, which may not be available for harvest until after the 4th decade. As a result, harvest dispersion opportunities may be limited within the remaining 2829 acres of mature timber.

Much of the 5000 acres of pole-sized timber in the tentatively suitable land occurs on marginally stable and/or marginally productive land where soils are shallow, droughty and located on steep slopes. It is doubtful that some of these acres will ever be harvested. Based on the preceding factors, the ID Team recommends that about 625 acres per decade (approximately 8% of the tentatively suitable) could be harvested and still maintain acceptable upper watershed, instream and fish habitat conditions in drainages within this AZ.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ **ACCEPTABLE** ___ **UNACCEPTABLE**

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1. 625 acres
2. 625 acres
3. 625 acres
4. 625 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach Skagit River - AZ 23
(Includes Olson, Diobsud, Falls, Bacon, Jumbo, Steelhead and Oakes Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The following discussion of fish and fish habitat is based on various surveys and reports (WDF 1975 Stream Catalog, including supplements, WDF (annual spawner/redd counts) and FS Stream Surveys (1983), and the Percy Washington report (Fishery enhancement survey of upper Skagit River tributaries, 1984 for Univ. of Washington).
Chinook, coho, chum, sockeye and pink salmon and anadromous and resident forms of rainbow (steelhead), cutthroat and Dolly Varden trout utilize Bacon (up to RM 6) and Diobsud Creeks (up to RM 1.8) two of the most important tributaries to the Skagit River. Lower portions of Olson (RM 1.5), Falls, Jumbo, Steelhead and Oakes Creeks also are utilized by most species of salmon and anadromous trout.

Bacon Creek is a powerful stream that has a moderate to high amount of channel instability which has reduced pool and spawning habitat quality and quantity. Pools important for adult holding and juvenile rearing habitat have a moderate amount of filling in and spawning gravels are impacted at some times due to scouring and aggrading. This instability is primarily due to a combination of erratic stream flows and high bedload movement, primarily from natural conditions. Timber harvest and road construction activities have also contributed to this instability (ie., Jumbo, Steelhead and Oakes Creeks). Activities that increase sediment to the Bacon Creek drainage could further reduce fish habitat.

Diobsud Creek has an excellent pool/riffle ratio and spawning habitat up to the impassable falls. The stream channel is generally in a delicate balance with the natural instability contributing an adequate level of spawning gravel replacement but not too much that pool habitat is impacted.

Olson Creek has a high sediment load, primarily due to natural conditions, that has been contributing to a certain amount of instability and reduction in fish habitat.

Pool quantity and quality is decreasing and in a declining watershed condition in Bacon and Olson Creeks due mainly to natural conditions. Diobsud Creek upstream of the east Diobsud main tributary is in good condition but overall fish habitat is in a delicate balance. Any additional sediment entering the Diobsud, Bacon and Olson Creek drainages could reduce the available fish habitat as a result of moderate to high amounts of LWD existing in a majority of the 1st-2nd order channels and the recruitment potential from the adjacent riparian stands is good. In the 3th-4th order channels, moderate amounts of LWD is well anchored and distributed in the upper sections of these channels but is limiting in the lower portion of most of these channels especially in Bacon, Diobsud, and Olsen Creeks. After analysis of these factors, the ID team rated the AZs as acceptable.

AZ #23 occupies the roaded portions of the Bacon, east Diobsud and Olson Creek drainages. While unstable soils have generally been avoided during harvest and

road construction activities in these areas, three locations (i.e., east Diobsud, Oaks Peak and the lower Falls Creek areas) have been impacted from concentrated harvest activities. Effects of BMPs, during future harvest within and downslope of these areas, will be limited to the immediate area of application until more vegetation recovery occurs. Future harvest dispersion opportunities appear good in AZ 23, considering 1600 acres is helicopter logging. AZ #24 occupies the upper watershed, unroaded portions of Bacon (i.e., upper Falls Creek drainage on west side of watershed), Diobsud and Olson Creeks. Unstable soils are scattered throughout these areas, usually associated with 1st and 2nd order channels. 12 miles of road will be needed for future harvest.

Approximately 5500 acres of pole size timber occurs in these AZs, which may limit the opportunity for dispersion during the first 4 decades.

For purposes of looking at these two allocation zones on a watershed basis, the ID team combined them to assess the in-channel and upslope conditions, and then split them out into three watershed areas to determine the maximum acres available for harvest. The 3 watershed areas are: 1) the Bacon Creek drainage, 2) the Diobsud Creek drainage, and 3) the Olson Creek drainage.

In the Bacon Creek watershed area, the past harvest rate has averaged about 370 acres, since the 1950's The I.D. team determined this rate has been to high in this watershed and recommends a reduced harvest rate to 295 acres per decade to maintain acceptable upper watershed, instream and fish habitat conditions.

Of the remaining tentatively suitable acres (5,291) in the watershed, approximately half of the acres occur in the Diobsud watershed, and half in the Olson Creek watershed.

Since the Diobsud Creek channel is in a delicate balance, due primarily to natural conditions, and sustains a significant anadromous fisheries resource, the I.D. team has determined the Diobsud Creek watershed portion of the AZ's can only sustain a 50 acre harvest rate per decade.

The I.D. team concludes that the Olson Creek drainage can sustain a 210 acre harvest rate per decade and maintain an acceptable upper watershed and instream condition.

To maintain a acceptable in-channel condition, a 2% harvest rate in Diobsud, combined with a 4% harvest rate for Bacon creek and a 8% rate for Olsen Creek should bot be exceeded. AZ 23's share of this harvest would be 330 acres per decade and should be dispersed among the subwatersheds as follows:

Watersheds:	Olson Watershed	Diobsud Watershed	Bacon Watershed	AZ Total
AZ 23 Future harvest Per decade	70 ac.	15 ac.	245 ac.	330 ac.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 330 acres
2: 330 acres
3: 330 acres
4: 330 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Cascade River - AZ 26

(Includes: mainstem, South Fork and North Fork Cascade R., Day, Lookout, Monogram,
Marble, Irene, Sibley, East Fork Sibley, Hard, Swamp, Pincer, Sonny Boy, Barrett,
Kindy, Vee and Found Creeks)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The following fisheries discussion is based on various surveys, reports and observations including: Forest Service 1983 Stream Surveys, WDF 1975 Stream Catalog (including supplements), conversations with WDF and tribal fish biologists, fish electro-fishing associated with fish habitat improvement and timber sale related KV projects, and annual interagency salmon spawner/redd counts.

A wide variety of fish utilize the mainstem of the Cascade River. Chinook, coho, pink, and chum salmon and steelhead trout reportedly use the mainstem and the lower portions of many tributaries for transportation, spawning and rearing up to RM 16, however, there apparently is unrestricted access for anadromous fish up to RM 22.5. Anadromous forms of rainbow, cutthroat and Dolly Varden trout use the upper reaches of the mainstem Cascade River and many tributaries for transportation, spawning and rearing habitat. Above anadromous barriers many of the streams in the drainage contain resident trout. The mainstem Cascade River between Marble and Sibley Creeks has been described as providing excellent spawning and rearing habitat for salmon. Important tributaries for anadromous fish and their respective barriers (RM) include: Marble (RM .9), Sibley (RM .5), Found (RM .5), Kindy (RM .5), Sonny Boy (RM .25), and the North (RM .5) and South Forks (RM 4) of the Cascade River.

The Cascade River is a large tributary to the Skagit River. The channel capacity is inadequate, the lower banks are in poor shape, the upper banks are in fair shape and the channel is in good to excellent shape except in certain areas. Channel instability ratings are high for a specific reach starting immediately below Found Creek upstream in the mainstem to the South Fork. These conditions are due primarily to natural factors but management activities

have aggravated problems in a few specific locations (e.g., Vee Creek). Activities that aggravate the existing channel instability in those specific locations in the Cascade River and its tributaries could negatively impact existing fish habitat conditions. Pool/riffle ratios are less than 50/50 in the upper watershed but this is more a function of the natural gradient. Pool quality and quantity are good in the lower watershed. LWD exists in moderately good amounts. In-place debris is relatively stable and recruitment opportunities s are good. Upon summing up these conditions, the ID team concluded that the AZ condition was acceptable.

Allocation Zone 26 consists of 23,713 acres of National Forest in the Cascade River drainage. The watershed also contains 70,000 in Glacier Peak Wilderness and North Cascades National Park. There is an additional 25,000 acres of State and private for a total of 118,000 acres.

Review of aerial photography revealed that past harvest activities up to 1986 have generally been concentrated in the lowland portions of the Cascade River. There has been some dispersion upslope into Sibley and Irene Creeks. The past harvest rate over the last 4 decades has averaged about 530 acres/decade (including wildfire acres). This rate has impacted watershed and fish habitat conditions in heavily harvested areas which include: Sibley, Found, lower Kindy Creeks. There have been some road/harvest related failures in the past and a few of these have been significant contributors of sediment (particularly Kindy and Vee Creeks).

The Cascade River is a relatively stable watershed where dispersed harvest activity can occur (tentatively suitable). Past harvest has had little effect overall on watershed and fish habitat conditions except where mentioned above. The ID team concludes that harvest can occur, assuming good dispersion of harvest and new BMPs. An estimated 1100 acres (8% of the tentatively suitable)) acres could be harvested per decade without adverse cumulative effects.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ **ACCEPTABLE** ___ **UNACCEPTABLE**

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 1100 acres
2: 1100 acres
3: 1100 acres
4: 1100 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lower Reach, Skagit River - AZ 27
(Includes Cumberland, Texas, and Wild Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This allocation zone is made up of 4 small drainages: Texas Creek and Wild Creek (that flow into Cumberland Creek), upper Cumberland Creek, and an area that drains into the Skagit River to the north. No fish sampling has occurred in these streams on National Forest land.

Approximately 80% of the 1st and 2nd order channels are in an unstable condition, widespread channel scouring is evident, and most of these channels have unstable streambanks. Also,little or no LWD exist in these channels and there is little or no potential for recruitment of LWD from the adjacent riparian areas. Because to this the ID team rated the AZ as unacceptable.

Since 1960, 1620 acres of National Forest land (or approximately 45% of the AZ acres) has been harvested. This is an average of 15%/decade when considering the entire allocation zone. However, most of the harvest during that period was not dispersed over the entire allocation zone but was concentrated into only 60% (2130 acres) of this area. Therefore,the effective rate of harvest in this area was 540 acres/decade. It is these areas (namely Texas Creek and in general the north end of the allocation zone) that have experienced the greatest amount of stream debris torrents. Harvest at this rate of 540 acres/decade has led to unacceptable stream conditions.

Since past, heavy harvest in the Texas creek area has caused unacceptable stream conditions in that and other streams, the ID team concluded that this area needs a period of recovery of 20 years before any further harvest is scheduled. After that time the remaining 100+ acres of mature saw timber should be harvested in two entries, about 50 acres per entry with a recovery of 2 decades between entries.

Approximately 900 of the 1050 acres of mature saw timber is located in the southern end of the allocation zone in the Wild Creek and upper Cumberland creek areas.

The upper Cumberland Creek area has received considerable, recent harvest (200+ acres in 1980's). It too should be allowed to recover for a 20 year period before rescheduling harvest. After that period harvest could resume in that area at a rate of about 60 acres/decade.

The ID team concluded that since there has been little past harvest in Wild Creek, harvest could begin in that area and maintain adequate dispersion at the rate of 75 acres/decade. 6

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _XX_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 75 acres
2: 75 acres
3: 185 acres
4: 135 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lower Reach, Skagit - AZ 28
(Includes: O'Toole, Boyd, Mill, and Pressentin Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The streams in this area on National Forest land have not been sampled to determine fish populations present but based on available information form adjacent drainages resident trout species (rainbow, cutthroat and Dolly Varden) would be expected to occur in portions of these streams. Anadromous fish populations do occur in downstream areas off National Forest.

The ID team has rated the AZ as acceptable because of lower watershed conditions of some downcutting and deposition, moderate to high ability to store and transport sediment, high quantity and quality of pools, and moderate amount of LWD.

Review of aerial photography revealed that past harvest activities up to 1983,292 acres per decade on National Forest Land had little apparent impact on stream condition. Most of the harvest has been near ridge top locations except for some of the O'TOOLE SKYLINE T. S. harvest units. These units are adjacent to O'Toole Creek and unstable soils. Full suspension of yarded materials provided adequate protection of riparian areas and unstable soils in these areas

Many of the remaining mature timber areas (ie., 2200 acres) would be helicopter logged. This would allow better dispersion of harvest units throughout the tentatively suitable areas and lessen the risk of potential adverse impacts from road construction. The roads that would be required for future harvest would be on or near ridge tops. BMP's have been and would continue to be effective in protecting the soil and water resources in these areas.

Since past harvest in the AZ has been low and channels have not been adversely impacted it is recommended that a harvest rate of 550 acres/decade (8% of tentatively suitable acres) would maintain acceptable upslope and instream watershed conditions.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 550 acres
2: 550 acres
3: 550 acres
4: 550 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Deer Creek, Northwest - AZ 29
(Includes Little Deer, Day, and DeForest Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Review of aerial photos, stream habitat/condition inventories, and the DeShazo Study has shown a substantial increase in sediment delivery to the Little Deer Creek drainage. Other effects observed include: the inability of the stream to transport sediment, loss of LWD, loss of riparian vegetation, and loss of pools due to timber harvest and road building activities. Stream aggradation was found to correspond to a general increase in stream temperature, filling in of pools and an overall reduction in anadromous fish habitat in Little Deer Creek. Stream temperature monitoring since 1983 has shown that temperatures frequently exceed 60 degrees F during the summer (Forest Service and Tulalip Tribe temperature monitoring) and indications are that Little Deer Creek has become temperature sensitive. Because of these conditions, the drainage condition is rated unacceptable.

An average timber harvest rate of 1070 acres per decade in the Little Deer Creek drainage during the 1950's, 1960's,and 1970's including FS and Private land. This combined with associated road construction and old management practices has resulted in these unacceptable stream conditions (poor future storage capacity, poor pool quality and quantity, and very little LWD). The major portions of past timber harvest activity in the drainage occurred by 1975. Dispersion of harvest was not provided for. It is estimated that these areas will have recovered in 30 years.

In Little Deer Creek in the first decade, there would be a high risk that additional timber harvest activities would continue the current degradation in watershed condition (even considering the use of current BMP's) and contribute to a worsening of instream conditions. These recommendations are based on the following factors: (1) the remaining tentatively suitable area is interspersed with many existing clearcuts, unidentified sensitive soils and steep, unproductive sites and (2) any additional sedimentation would further channel degradation and reduce habitat for the tenuous summer steelhead and salmon

populations in Little Deer Creek If no further harvest activities occur before 2005, it is expected that the watershed condition would become acceptable.

In the first decade 100 acres of timber is recommended in the Day Creek portion of the AZ without further degrading instream conditions. This is based on the following factors: (1) a substantial amount (approximately 345 acres) of mature timber is left in the upper elevations, (2) much of the area would be helicopter logged which has less impact on soils, and (3) there is very little road stacking.

Considering in-stream recovery in 2005 in the Little Deer and DeForest Creek drainages and adequate dispersion of harvest throughout the suitable acres the ID team concluded that 400 acres (3rd & 4th decade) can be harvested per decade with little or no risk of further stream degradation. This equates to 5% of the tentatively suitable acres. Since 2005 occurs in the middle of decade 2, 200 acres can be harvested in this decade. The ID team recommends that no harvest occur in the Little Deer Creek watershed in the first decade. Harvest of the full 400 acres in the AZ would occur in the third and fourth decades. This rate would allow for adequate dispersion of harvest throughout the suitable acres, and would still allow for instream recovery.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _XX_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 100 acres
2: 200 acres
3: 400 acres
4: 400 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Finney Creek - AZ 30

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photography revealed that past harvest activities up to 1975 (29% of N.F. lands in the watershed) had little apparent impact on stream condition. Between 1976 and 1988 additional heavy harvesting in the upper watershed (20% of N.F. lands), coupled with rain-on-snow flood events (1975,77,79, & 80) caused a large increase in sediment yield and transport through debris torrents & landslides. Dispersion of harvest was not provided for. Upper watershed, in-channel streambed and bank conditions are highly disturbed where debris torrents have occurred. This has affected 75% of the major 1st and 2nd order streams. Sediment from these events and other landslides has been deposited in the mainstem of Finney Cr. The ability to

retain sediment in the side channels has been greatly reduced. Pools have been filled in and/or scoured which has severely impacted the resident trout habitat. The main channel of Finney Creek has been scoured, widened, and straightened. Woody debris has been re-distributed and/or lost from the system. Because of these factors the ID team rated the condition of the AZ as unacceptable.

The average harvest rate in the 1960's, 70's and 80's was 3137 acres per decade on the AZ. This rate resulted in an unacceptable watershed condition. The Finney Creek watershed is still in an unacceptable condition. This condition will not change until natural recovery and watershed restoration measures are completed in the first decade. The decline in watershed condition must be halted before any timber harvest and road construction activities can take place.

Watershed condition in 1976 was determined to be unacceptable based on observation of stream conditions in the lower WS. Considering that rooting strength deteriorated for 8 years, it is assumed this condition was triggered at the 1968 harvest level. This rate was 16% on NF land. In order to provide for adequate dispersion of harvest throughout the suitable acres, and for in-stream recovery to occur it is assumed that 15% disturbance in 30 years can be tolerated beginning in the third decade (5% / decade X 17,019 tent. suitable acres = 850 acres harvest per decade). Minimal harvest activities of not more than 100 acres/decade for the first two decades may be possible provided that all watershed restoration measures are completed, the decline in watershed condition is halted, and the following best management practices are strictly adhered to: 1) harvest will be distributed throughout the watershed and not concentrated in any one sub-basin, 2) new long-term road construction will be restricted to gentle stable ground, 3) management activities must be no closer than 1/8 mile from unstable soil areas, 4) all materials will be yarded using full suspension methods, 5) there will be no harvest allowed in Class I, II, III and IV stream riparian areas, 6) all disturbed areas (including but not limited to temporary roads, skid trails, landings, fire lines) will be revegetated and drained prior to the current year fall/winter storm period, 7) all short-term roads must meet the preceding criteria, 8) emphasis will be placed on using KV generated dollars for watershed/fish restoration work, and 9) emphasis will be placed on using timber sale road reconstruction dollars for road drainage restoration

It is assumed that by the 3rd decade (year 2010) the watershed (channel recovery, canopy closure, root strength) should be recovered sufficiently to allow a harvest rate of 850 acres/decade for the next two decades.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ __ACCEPTABLE _XX_UNACCEPTABLE
MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 100 acres
2: 100 acres
3: 850 acres
4: 850 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Deer Creek, Southeast - AZ 31 & 32
(Includes Deer and Higgins Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photos, stream habitat/condition inventories, and the DeShazo Study has shown a substantial increase in sediment delivery to the Deer Creek drainage. Other effects observed include: the inability of the stream to transport sediment, loss of LWD, loss of riparian vegetation, and loss of pools due to timber harvest and road building activities. Stream deposition and widening was found to correspond to a general increase in stream temperature, filling in of pools and an overall reduction in anadromous fish habitat. Based on stream temperature monitoring conducted by the Forest Service and Tulalip Tribe since 1983 temperatures frequently have exceeded 60 degrees F. Deer Creek is considered a temperature sensitive stream, a condition that is limiting to fish. Because of these factors, the AZ has been rated as unacceptable.

Since the 1960's approximately 2950 acres of AZs 31 and 32 have been harvested. This is an average harvest rate of 985 acres per decade for the 13,453 acre watershed. However, this harvest was not dispersed over the entire area but rather was concentrated into only about 5300 acres of AZ 31 (largely along Deer Creek and Higgins Creek). The effective rate of harvest in these concentrated areas was about 19% per decade overall (985 acres/5300 acres). This rate of harvest has led to serious degradation of Deer Creek and Higgins Creek and is unacceptable.

The ID team concludes that harvest in AZ 31 should be deferred for at least two decades to allow instream recovery. After that time harvest could continue at a rate of 262 acres/decade (5% of the tentatively suitable acres). Harvesting at this rate will maintain an overall disturbance level of 15% (Based on a 30 year stream channel recovery period). The ID team concludes a maximum 15% disturbance level in 30 years is appropriate for this area because of the inherent instability of the soils.

The 262 acres/decade rate (based on tentatively suitable lands) would also apply to AZ 32 due to the instability of the soils in this area. 5% of 4391 tentatively suitable acres is 220 acres/decade. However the first two decades would be reduced to 110 acres/decade to enable a quicker recovery of Deer Creek and Higgins Creek channel conditions.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ ACCEPTABLE _XX_ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

	AZ 31	AZ 32
1:	0 acres	110
2:	0 acres	110
3:	262 acres	220
4:	262 acres	220

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Middle Reach, N. F. Stillaguamish - AZ 34
(Includes: Segelson and Swede Creeks)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Fish habitat is poor to fair overall in the confined channels of Swede and Segelson Creeks. Pools are generally shallow and small, and local areas of heavy deposition are common for both main channels. Habitat deficiencies are the result of extensive streamside logging on upper Segelson Creek, and unsupervised mining operations and road building in upper Swede Creek. Removal of LWD throughout accessible channel reaches both on and off-Forest have further deteriorated the ability of the watersheds to store sediments and alter stream power.

The ID team has concluded that this AZ is in an unacceptable condition. This rating is supported by upslope factors of numerous slides, heavy road stacking, channel scouring, raw stream banks, and minimal LWD. In the lower watershed channels there is heavy deposition, shallow and infrequent pools, inadequate and unstable LWD.

The harvest rate in this AZ over the last 3 decades has been 536 acres/decade on National Forest land. There is currently an estimated 1625 acres of mature saw timber on 3123 acres of tentatively suitable land. When evaluating the distribution of the available timber, the ID team concluded that in order to provide the dispersion necessary to provide adequate recovery and protect sensitive areas, the harvest should not exceed 200 acres per decade over the next 4 decades. This will be 6.4 percent of the tentatively suitable lands per decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1 200 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's to be considered in all alternatives in the FEIS.

Middle Reach, N. F. Stillaguamish South - AZ 35
(Includes Boulder River, French and Squire Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Fish habitat is in good condition for the lower watersheds of Boulder River and Squire Creeks, and only fair for French Creek. This is based on the size and number of pools, stream bank stabilities, and amount, size and stability of LWD. Condition of fish habitat in the upper basins is not well documented, but appears to have been altered to a moderate degree in upper French Creek. LWD has been removed from upper French Creek and streambanks are severely disturbed. French Creek also has a marked reduction in pool capacity in the upper watershed. Upper Boulder River is pristine, and upper Squire Creek appears to have mostly recovered from streambank logging. The majority of sediment and mass movement in this allocation zone is the result of natural instability. The ID team concluded the overall watershed condition for this AZ is marginally acceptable

The majority of the management caused slides in this allocation zone occurred in the upper reaches of French and Squire Creeks as a result of intensive harvest (553 ac.) in the upper watershed in the 1960's. Average harvest rate in the AZ over the past 4 decades was 240 ac. per decade including both private and National Forest lands. In-stream conditions have slightly improved since intensive logging in the 1960's.

Future harvest activities can be well dispersed throughout the tentatively suitable acres due to the 500 acres of helicopter logging areas located primarily in the Jumbo Mtn and Whitehorse Ridge areas. Heavily impacted areas of the French Creek drainage have no mature timber that will be harvested in the 1st four decades. A large acreage of second growth poles occurs along the lower, generally stable slopes of Whitehorse Mtn. that silvicultural examinations indicate will be available for harvest in the 1st decade. For these reasons, the ID team concludes that 500 acres (9.5% of the tentatively suitable acres) can be harvested in decades 1 through 4.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach, N. F. Stillaguamish - AZ 37

(Includes: mainstem North fork Stillaguamish River, North, South, and Middle Branches, Crevice Creek, and the headwaters of a few drainages into the Sauk River)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Fish habitat in the North Fork Stillaguamish River is in an unacceptable condition, based on the widespread aggrading evident in the lower gradient reaches both on and off National Forest lands. The basin is also sensitive to increased summer temperatures some years. Heavy deposits of sand have reduced volume of pools, adversely affected spawning gravels, and diminished rearing habitat quality along the margins of the larger channels.

The North Fork Stillaguamish River System was in acceptable condition until the late 1970's and early 1980's. From the mid 1980's unacceptable watershed damage started to occur. The damage coincided with dramatic increases in harvest levels in the late 1970's and early 1980's to up to three times the prior rate.

The unacceptable rating of this watershed is supported by upslope factors of downcut or scoured streams on nearly half of the upslope area, numerous raw stream banks, unstable LWD, older failing roads on unstable soils, and many stacked roads. The lower watershed has heavy sediment deposition and poor quality pools.

The deteriorated condition of this watershed has resulted from an average harvest rate of 3296 acres per decade (11% based on 4 decades harvest). In order to provide for recovery and proper dispersion, a maximum rate of harvest of 1000 acres per decade is recommended. This rate will be 3.6% of the tentatively suitable acres. This harvest level can be accomplished by restricting harvest on sensitive ground, using BMP's, and good harvest dispersion.

This level of harvest over the next 40 years will provide for satisfactory watershed recovery. After the 4th decade, the previous harvest level of 2200 acres per decade that had maintained an acceptable watershed condition, could be re-established. (The 2200 acres was the harvest level prior to the '80's that had maintained an acceptable watershed condition.)

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 1000 ACRES
2: 1000 ACRES
3: 1000 ACRES
4: 1000 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sauk River, Northeast - AZ 38
(Includes White and Hilt Creeks.)
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The following fish habitat description is based on the WDF Stream Catalog (1975 including supplements). Allocation Zone #38 consists of the Hilt and White Creek drainages. White Creek and Hilt Creek are tributaries to the lower Sauk River. White Creek has a falls that block anadromous fish at RM 0.65 and the upper 5 miles are on Forest Service land with the FS boundary located at RM 1.8. Hilt Creek has a falls located at RM .7 that block anadromous fish and the upper 2 miles are on FS land with the FS boundary located at RM 3.5. Based on knowledge of similar streams in adjacent drainages it is expected that resident trout inhabit the upper reaches of White and Hilt Creeks above the anadromous barriers.

Past harvest in the Hilt Creek portion of the AZ, over the past 4 decades has removed 96% of the mature timber, leaving only 50 acres of the 930 acres of tentatively suitable. This has resulted in degraded in-channel condition and an unacceptable watershed condition. This has caused significant impacts to resident fish habitat in the Hilt Creek portion of the AZ. Based on the preceding factors the I.D. team recommends that no further harvesting should occur in the Hilt Creek drainage over the next 4 decades.

In the White Creek portion of the AZ, 1770 acres have been harvested in the past 3 decades (an average of 590 acres per decade). This harvest has been concentrated within the drainage causing unacceptable upper watershed, instream and resident fish habitat conditions. There are limited dispersion opportunities during future harvest in White Creek and much of the remaining mature timber is located on steep, marginally stable ground. For these reasons, the I.D. team recommends that the White Creek drainage can sustain a 200 acre per decade harvest rate and still maintain acceptable watershed, instream and fish habitat conditions. For the first 2 decades this watershed will require additional recovery time to return to an acceptable condition. Therefore, we recommend that the 200 acre/decade harvest rate be cut in half during the first 2 decades. This is 100 acres per decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _XX_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 100 acres
2: 100 acres
3: 200 acres
4: 200 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sauk River - AZ 39

(Includes: The mainstem Sauk River RM 25 to RM 40, and lower Clear, Falls and Helena Creeks, Murphy, Goodman, Dans, Decline, Conn, Gravel, Peek-a-boo, Brown, Burns, Skull, Lyle, Dutch, and Dubor Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The analysis area for this AZ includes the Sauk (off National Forest lands) to the confluence with Prairie Cr. at RM 15.5. The lower gradient section of the river downstream of the NF lands shows the cumulative effects of sediment aggrading, which are not as evident in the moderate gradient reaches on NF lands. Much of the sediments come from the Sauk River and Dans Creek on NF lands.

Fish habitat in this AZ is moderately productive on NF lands, but appears to have been degraded down-river by widespread channel shifts, filled in pools and overall aggrading. Valley bottom tributaries and river side-channels provide most of the high quality anadromous fish habitat on NF land. Examples of streams which have maintained stable and productive fish habitat are Tiny Kitsutch Cr., Hyakchuck Cr., Dutch Cr., Falls Cr., and Early Coho Cr.

Historical cutting and road building in this watershed have resulted in degradation of individual drainages: Dans Cr. & Murphy Cr. in particular. The dispersed nature of activities geographically and over time, have resulted in marginally acceptable water quality and fish habitat in the anadromous zone in the Sauk River valley. Dans Creek and the Sauk downstream from the NF lands, however, are in an unacceptable condition at this time due to the Dec. 1980 flood that removed most of the LWD and removed the pool structure. There are also numerous slope failures along the Dans Cr. channel and its tributaries (Conn and Decline Creeks).

Average past harvest per decade over the past 4 decades in the AZ was 330 ac. on private land and 4513 ac. on National Forest. All private lands have been harvested at least once except for approximately 40 ac. of mining claims on Gold Hill. Due to current instream conditions and the reduced ability to disperse harvest, the ID team concluded that 1700 ac. could be harvested in the 1st decade, (5% of the tentatively suitable acres) while maintaining an acceptable watershed condition. Beginning with the 2nd decade, this harvest rate could be increased to 2500 acres/decade because of hydrologic recovery taking place, use of state-of-the-art BMP's, and the amount of helicopter logging. By the 3rd decade, some of the 2nd growth area cutover during the 1930's will become available for harvest. Some instream recovery will also have occurred by the start of the 3rd decade. By the 3rd and 4th decade, nearly all of the old cutover area will become available for harvest. (This is 3000 acres/decade, or 8% of the tentatively suitable area.) This increased harvest base will provide improved opportunities for harvest dispersion.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

Unacceptable conditions in Dans Creek

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 1700 ACRES
2: 2500 ACRES
3: 3000 ACRES
4: 3000 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Suiattle River - AZ 40

(Includes: The mainstem Suiattle River RM 12.3 to 26.5, Tenas, Big, Grade, All, Conrad, Black, and Straight Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Because of the large size of the Suiattle River watershed, the instream condition of the main river channel has not been adversely impacted by management activities. The lower channel reaches of Straight and Big Creeks have been impacted, however, and anadromous fish habitat has been slightly degraded. Pools are shallow and fewer in number; channels have become braided (resulting in upstream adult fish passage difficulties at low water), and some LWD has been washed out by flood flows.

Although some unacceptable watershed conditions exist within local areas (i.e., Straight, Tenas, and Big Creek drainages), the ID team concluded that the overall condition of the AZ is acceptable. In general, pool condition, sediment storage, and LWD supply and distribution are adequate for good fisheries habitat and other beneficial downstream water uses.

Past timber harvest within the AZ has been concentrated within the Straight, Tenas and Grade Creek drainages. Unacceptable upper watershed and instream conditions occur in these areas due to these harvest activities.

The past harvest rate since the 1950's in the entire AZ was 1709 acres per decade including both National Forest and private lands. The ID team has concluded that the harvest in the 1st decade can be increased to 2500 acres because: (1)Most of the unstable soil areas (6% of the tent. suitable acres in the AZ) can be avoided, (2)A previously unroaded area (i.e., Huckleberry Mtn.) will be entered, (3) Most of this unroaded area is stable, (4)BMP's will be effectively employed for better stream protection, and avoidance of unstable and marginally unstable areas in road construction and logging. These BMP's will maintain an acceptable watershed condition. The planned 2000 acres of helicopter harvest will also provide excellent harvest dispersion opportunities.

The ID team concluded that the 1st decade harvest rate of 2500 ac. (9% of the tentatively suitable) should be reduced in decades 2-4 to the historic rate of 1700 ac/decade (6% of the tent. suitable area). After the initial entry is

made into the large Huckleberry Mtn. unroaded area, harvest dispersion opportunities will be reduced.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _x_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 2500 ACRES
2: 1700 ACRES
3: 1700 ACRES
4: 1700 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Suiattle River - AZ 41

(Includes: Circle, Harriet, and Lime Creeks, and north facing tributaries to the upper Suiattle River.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Fish habitat in this AZ is confined to streams in 3 upper basins: Circle, Lime, and Danny Boy Creeks. Resident trout habitat quality has diminished in the former two streams by excessive amounts of introduced sediment and little LWD remaining after floods. Anadromous fish habitat, located entirely within the downstream AZ, has been altered by aggrading, alluvial fans and new channels cut by floods on Circle and Lime Creeks. About 40% of the area of this AZ drains into 1st and 2nd order tributaries of the Suiattle River that have not been intensively logged.

Instream conditions are marginally acceptable along the entire lengths of Circle and Lime Creeks. Conditions in Danny Boy Creek and other tributaries and side channels of the Suiattle River, RM 18.4 to 27.6, are fully acceptable. Therefore, the ID team concluded that the overall condition of the AZ is acceptable

The past harvest rate has averaged 509 acres per decade for the last 3 decades. Most of this harvest has occurred in Circle and Lime Creek drainages.

Proposed future harvest is planned for a large block of stable unroaded area that drains north to the Suiattle River. The majority of the mature timber in the AZ occurs on these slopes. For these reasons, the ID team concluded that 750 ac. (13% of the tentatively suitable) can be harvested in the AZ in the 1st decade and provide adequate dispersion. In decades 2-4, harvest levels will be reduced to 350 acres (6% of the tentatively suitable). This harvest level will provide adequate dispersion and watershed protection while continuing to defer harvest in the heavily impacted portions of Lime and Circle Creeks.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 750 ACRES
2. 350 ACRES

4: 350 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

White Chuck River - AZ 42

(Includes: The Whitechuck River, Black Oak, Rat Trap, Crystal, Meadow, Owl, Dead Duck, and Stujack Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Anadromous fish habitat appears to be in nearly pristine condition in most of the AZ. This habitat is limited to mainly side channels and the short low gradient mouths of tributaries. The ample supply of woody debris and high quality pools are reasons for the good condition of this watershed. There are exceptions in Black Oak Creek and Rat Trap Creek. In Black Oak Creek the alluvial fan does not provide a single low flow channel for adult salmon passage upstream, and much of the instream LWD has been washed out of the active channel. Rat Trap Creek is another sub-basin that has been heavily impacted by road building and to a lesser extent by timber harvest. These exceptions account for less than 10% of the AZ. Due to the overall good instream conditions, the ID team concluded that the AZ should be rated as acceptable.

Past harvest rate has averaged 519 acres/decade over the past 4 decades. Due to the relatively low percentage (11%) of unstable soils in the AZ, the 500 acres of helicopter areas, harvest dispersion opportunities will be good. The ID team concluded that 650 acres (6% of the tentatively suitable acres) can be harvested in the decades 1-4 while maintaining an adequate watershed condition. In addition, fish habitat improvement and some watershed restoration work will be implemented on Black Oak Creek and on Rat Trap Creek subwatersheds. Harvesting will be deferred in already heavily impacted areas in Black Oak Cr. and Rat Trap Cr.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 650 ACRES

3: 650 ACRES
4: 650 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Canyon Creek - AZ 44

(Includes: The mainstem Canyon Creek, the North and South Forks Canyon Creek, Meadow, Camp, Boundary, Saddle, and Sevenmile Creeks. A small portion of Jim Creek is also included.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Review of aerial photos, various studies, and on-ground observations show that this AZ has been heavily impacted from previous management activities. Conditions upslope include scoured channels, some heavily stacked and failing roads, landslides throughout, and nearly half the tentatively suitable is in unstable soils. The lower watershed area is characterized by high sediment loads, unstable spawning gravels, poor pool conditions, sparse and unstable LWD, and a diminishing number of returning anadromous fish within recent decades. Because of these factors the ID team has rated the AZ as unacceptable.

Early 1960 photos show that a 1950's harvest rates of 553 ac./decade on NF lands in Canyon Cr. caused slight impacts to Canyon Cr. The impacts began to rapidly accumulate in the 60's when 2727 acres were harvested. In the last 3 decades, the harvest rate has been 1,887 acres/decade, with heavy impacts resulting.

The remaining mature timber in the AZ is located in the lower North Fork, the South Fork, and the portion of National Forest that is below the forks. The South Fork has already been heavily cutover and impacted in the 1980's. These conditions severely limit dispersion opportunities.

During the past 3 decades, the average harvest was 2097 acres/decade from National Forest lands. The ID team evaluated the effects of the 1950's rate of harvest, the effects of the accelerated harvest rate in the last 3 decades, the present condition of the drainage, recovery potential, and the limited options for dispersion , and concluded that the future harvest rates should be no more than 250 acres per decade (2.2% of the tentatively suitable land).

This harvest rate represents the amount that the Interdisciplinary Team believes can be harvested from the more stable areas that provide opportunities to implement Best Management Practices. This should result in a reduction in

harvest related failures and provided for improvement in watershed conditions by the end of the 4th decade.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 ACRES
2: 250 ACRES

4: 250 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sauk River - AZ 45

(Includes: upper portions of Helena, Goodman, Falls, Murphy, Shake and Swift Creeks, and tributaries to Clear Creek.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Anadromous fish habitat is generally in fair to poor condition. This assessment is based on the lack of high quality pools, high percentage of fine silt within many of the spawning gravels on the river and tributaries, and overall lack of stable LWD. Suspended sediment and bedload deposition has increased within the South Fork Stillaguamish basin in about the past two decades. This river has a naturally high bedload transport rate.

In this allocation zone, 30% of the tentatively suitable mature timber is located within unstable soil areas. Previous timber harvest and road construction in this area have resulted in degradation of the watershed resources - particularly Wiley Creek, Benson Creek, and their tributaries. There will continue to be problems associated with older road construction and timber harvest for some time

Based on the above identified conditions the ID team concludes that the watershed is in an unacceptable condition.

The past harvest rate on National Forest land and private land within the AZ is 1726 ac./decade for the last 4 decades. The proposed harvest rate of 350 acres per decade (3.9 % of the tentatively suitable) is below the historical average in order to allow the watershed to recover from the effects of previous management activity. Objectives of future management in this AZ are to maintain the ability to disperse harvest, to avoid additional watershed effects above the high natural rate, and to develop and implement a comprehensive watershed rehabilitation plan.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 350 ACRES

4: 350 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sultan River - AZ 47

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Washington State Biologist Kramer has written that the lower reach of Williamson Creek is the primary spawning habitat for native cutthroat trout in the Spada system. This reach is downstream from the AZ. Habitat within the AZ is limited primarily by lack of pools and stable LWD. This is due to the sediment and bedload deposition that is occurring.

Williamson Creek is currently in a degraded condition and is gradually recovering. Large quantities of bedload have been transported into and deposited within the main reach of Williamson Creek. Channel widening has also occurred. The channel has also been redirected down the county road as a result of a debris jam. Bedload transport occurs within this drainage at relatively high levels from undisturbed areas, but the landslides from the 70's harvest on private lands also contributed significant quantities of bedload to the system.

Management activities, particularly the harvest on unstable soils in the 70's on private lands and lack of maintenance of the county road, have contributed to the current condition Timber harvest on all ownerships has occurred at moderate rates in previous decades Approximately 221 acres was harvested in the 50's, 814 acres in the 60's, and 571 acres in the 70's. The average rate of harvest for these three decades was 535 acres per decade.

The ID team considered this AZ to be in a marginally acceptable condition. The watershed is gradually recovering and restoration work would assist the recovery process. Much of the future harvest on National Forest lands will occur with the use of helicopter which will reduce further damage. Very little additional harvest on private lands is expected for several decades. In order to continue the recovery process, the ID team concluded that the harvest rate should be reduced from previous levels The team recommends a harvest level of 150 acres within the AZ during the first decade. 150 acres represents 20% of the tentatively suitable lands. The team recommends an increase in the harvest rates in the following decades to 200 acres per decade (27% of tentatively

suitable) due to expected recovery over the 2 decades of reduced activity. (includes the 80's decade when no activity occurred).

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 150 ACRES
2: 200 ACRES
3: 200 ACRES
4: 200 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach, S. F. Stillaguamish - AZ 48

(Includes: mainstem South Fork Stillaguamish River RM 53.3 to RM 70, Palmer, Perry, Coal, Beaver, Deer, Marten, Boardman, Mallardy, and Blackjack Creeks.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The upper part of the AZ is characterized by shallow residual and colluvial soils on steep slopes particularly in the upstream reaches of Perry, Palmer, Coal, *Deer Creeks and the upper South Fork Stillaguamish. The lower reaches of* the AZ in the Blackjack, Mallardy and Boardman Creek areas are characterized by deep, generally unstable glacial terrace deposits.

The upper 1/3 of the South Fork Stillaguamish channel in the AZ, upstream of Perry Creek (and including the lower reaches of Palmer Creek), contains the best spawning habitat in the AZ. High quality pools are common, spawning gravels have a low percentage of fines, and LWD is abundant in these sections.

The instream conditions of the S.F. channel in the lower 2/3 of the AZ are much more unstable. High bedload deposition, few and shallow pools, and extensive raw stream banks occur below the confluence of Perry Creek. These conditions are the result of both timber harvest activities and failures of the unstable glacio-lacustrine materials. Based on instream conditions in the lower S.F. channel, the ID team recommends an overall unacceptable rating for the AZ.

Average timber harvest rate over the past 4 decades is 1575 acres/decade (all ownerships). The remaining mature saw timber is in areas characterized by irregular terrain and contains numerous small 1st and 2nd order streams. The ability to leave buffer strips on these streams may be difficult. Future harvesting should incorporate BMP's including helicopter and multispan logging

systems. In order to change the present unacceptable in-channel conditions to acceptable, the ID team recommends a future harvest rate of 500 acres per decade (3.7% of the tentatively suitable). This rate will allow hydrologic recovery, though both natural and management rehab activities. As with AZ 46, this AZ will require developing and implementing a comprehensive watershed rehabilitation plan.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 500 ACRES
2: 500 ACRES
3: 500 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sauk River Forks - AZ 49

(Includes the North and South Forks Sauk River, Sloan, Elliot, and Cadet Creeks, and other tributaries to the upper Sauk River.)

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

Anadromous fish habitat in the South Fork Sauk appears to have partly recovered from the December 1980 flood, although the river channel below Monte Cristo Lake is still deficient in high quality pools, stable LWD, and side channels with spawning gravels that are stable for only several months at a time. These conditions will be expected to improve slowly over several decades, barring additional major debris torrents from Bedal Creek or other tributaries.

The ID team concluded that the South Fork was in an unacceptable condition for fish habitat because of extensive channel braiding, few and shallow pools, channel bank failures, high sedimentation levels and recurrent debris torrents and debris flows from Bedal and Chokwich Creeks. These conditions are partially the result of the December 1980 flood. The major slide on the South Fork across from Bedal Creek continues to adversely affect spawning conditions in the downstream river system.

The ID team concluded that the North Fork and Sloan Creek were in an acceptable condition based on the number of high quality pools, minimal past harvest rate, and virtually undisturbed conditions in many tributaries.

The ID team concluded that the overall rating for the AZ was marginally acceptable.

The average harvest rate since the 1960's was 712 acres per decade in the AZ. Considering the unacceptable condition of the South Fork, the ID team concluded that the MR for the AZ should be reduced to 250 ac/decade, (3.8 % of tentatively suitable). Harvest in the 1st decade will primarily be in the North Fork drainage. This harvest level will allow adequate dispersion throughout the tentatively suitable acres in time and space and should provide for adequate recovery and maintenance of instream watershed conditions in the South Fork.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: X ACCEPTABLE __UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 ACRES
2: 250 ACRES
3: 250 ACRES
4: 250 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sultan River - AZ 51

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

In this AZ, all the streams are either 1st or 2nd order channels. These channels support only a resident trout population, there is no anadromous fish habitat. Little current information exists on the resident trout population, but based on similar 1st - 2nd order channels in other Forest watersheds, the populations are probably small and sparsely located. The majority of fish are probably found in the upper S.F. and N. F. Sultan River and upper Elk Creek. The existing habitat is probably capable of supporting this existing population.

Even though most of the channels have scoured to bedrock, enough pools, formed by large boulders and LWD, exist to support these small fish populations. Adjacent riparian areas along these channels offer a moderate LWD potential to these channels. Based on these in-channel attributes, the ID team concluded that the AZ was in an acceptable watershed condition.

There has been no past timber harvesting in the AZ However, the ID team concluded that about 300 acres per decade (50% of the tentatively suited area) should be the maximum allowable acres for harvest.

Cause/effect relationships, in regards to timber harvest and road building, for establishing the watershed MR within this AZ are unavailable due to the lack of management activity within the area. Most of the timber is in the stream bottoms or near to riparian areas and avalanche chutes or the lower slopes. The removal of large blocks of timber would have a high localized impact on the streams. This would be kept within acceptable limits by cutting less than half of what is available within a decade. The team estimated that about 300 acres could be harvested without experiencing a significant decline in the watershed condition assuming that units were kept small and riparian areas would be protected, preserved, and state-of-the-art BMPs were applied.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 300 Acres
2: 300 Acres
3: 300 Acres
4: 300 Acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Sultan River - AZ 52

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

In this AZ, all the streams are either 1st or 2nd order channels. These channels support only a resident trout population, there is no anadromous fish habitat. Little or no current information exists on this resident trout population, but based on similar 1st and 2nd order channels in other Forest watersheds, the populations are probably small and sparsely located. The majority of fish are probably found in upper S.F. and N.F. Sultan River and upper Elk Creek. The existing habitat is probably capable of supporting this existing population. The Sultan Basin is used as a municipal water supply for the City of Everett and other communities.

Even though most of the channels have scoured to bedrock, enough pools, formed by large boulders and LWD, exist to support these small fish populations. Sediment from upslope areas and the unstable soils surrounding the reservoir have degraded many of these pools. In addition, the sediment has degraded water quality of the municipal watershed. Adjacent riparian areas along these channels offer a fair LWD potential to these channels. Because of the sediment input to the channels it is not considered stable. Based on these in-channel attributes, the ID team concluded that the AZ was presently rated as acceptable but only marginally.

Previous timber harvest on all ownerships within this AZ has averaged 1,970 acres/decade. Harvest was very high in the 1960's and 1970's in preparation for construction of the dam which created the reservoir. Harvest in the 80's was reduced to about 500 acres. About 550 acres of mature tentatively suitable acres remain on NF lands within this AZ. This remaining suitable acreage is either very difficult to access or relatively unstable. Considering the location of the remaining timber and the potential impacts on the Sultan Basin, the ID team determined that a maximum rate of 100 acres per decade (3% of the tentatively suitable) could be harvested within this AZ without substantially degrading the present watershed condition

North Fork Skykomish River - AZ 53, 54, 55, 56
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The North Fork Skykomish River basin encompasses a large watershed area. The basin encompasses all the acres in AZ 43, 54, 55, and 56. The North Fork Skykomish River contains significant populations of coho and pink salmon as well as sea-run trout (steelhead, cutthroat, and Dolly Varden). Smaller numbers of spring and fall Chinook Salmon are also found. All of this anadromous fish production in the river is by natural means. Anadromous fish are known to migrate up to RM 18 on the river to spawn and rear. Many of the major tributary streams to the NF also contain valuable anadromous fish habitat in the lower gradient sections (West Cady, Goblin, Silver, Salmon, Howard, Trout, and Lost Creeks). Besides the anadromous fish presence and utilization of the North Fork, a substantial resident trout population exists in this large river system.

The upper watershed area which encompasses most of AZ 53, 54 and 56, contain many 1st and 2nd order channels that are either avalanche chutes or steep runoff channels that have scoured to bedrock. This scouring has resulted over recent time from numerous high flow storm events especially in the 1970,s and 1980,s. In addition, early railroad logging in the 1920-1930 period harvested both sides of the N.F. Skykomish. Harvesting involved yarding logs across the river in the riparian areas. This had additional impact on the river channel and banks. What pools exist in these channels are formed mainly by rocks and

boulders and little LWD. Potential recruitment of LWD from the adjacent riparian areas is fair. Overall, these channels are slowly recovering from past flood events. In the lower 3rd and 4th order channels, past high flow and flood events (70s and 80s) caused large amounts of in-channel and streambank instability. Additional in-channel and fish habitat impacts occurred following the massive flood repair and cleanup work within the main North Fork channel. Old aerial photos (1940 - 1970) show that most of these channels had moderate in-channel and bank stability. Presently, many of these channels and the fish habitat is recovering from the natural and management caused impacts of the 1970s and 1980s. Natural recovery is presently being supplemented with habitat improvement activities. In-channel and stream bank stability is improving, the quality and quantity of pools is increasing and recruitment of LWD is occurring from the adjacent riparian areas. Because of these improving conditions with the N.F. Skykomish River system, the ID team determined the watershed in an acceptable condition.

The past harvest rate on NF land in the four AZs has been variable. The harvest rate on 53 has averaged 25 acres/decade from 1950 through the 1970's. AZ 54 has averaged 103 acres/decade for the two cutting history decades of 1950's and 60's. AZ 55 has been heavily harvested int the 20's and 30's with an average of 3900 acres/decade. In subsequent decades, starting with the 1940's, the harvest has averaged 430 acres/decade. AZ 56 had 63 acres harvested in the 1960's.

Allowable harvest levels for the individual AZ's within the North Fork Drainage were determined based on specific site characteristics within each AZ and the probable resulting response of management on the watershed as a whole. The majority of available timber and, consequently, future harvest will occur along the lower slopes of side channels to the North Fork. New road construction will be needed to access many of these areas. Historical harvest levels have varied substantially within each AZ, but recent levels appear to be lower than necessary to continue the recovery and maintenance of a stable watershed condition.

Based on the observed condition resulting from past activity and the probable location of future harvest, the ID team determined that 12% of the tentatively suitable lands within each AZ would be maximum harvest rate that the North Fork could tolerate without adversely affecting the watershed condition.

Skykomish River - AZ 57
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

In this AZ, all the streams are either 1st or 2nd order channels. These channels support only a resident trout population; there is no anadromous fish habitat. Little or no current information exists on this resident trout populations, but based on similar 1st and 2nd order channels in other similar Forest watersheds, the populations are probably small and sparsely located. The majority of fish are probably found in the upper Wallace Creek and May Creek areas. The existing habitat is probably capable of supporting this existing population.

Even though most of the channels have scoured to bedrock, enough pools, formed by large boulders and some LWD, exist to support these small fish populations. Adjacent riparian areas along these channels offer a moderate recruitment of LWD to these channels. In addition, these in-channel conditions on Wallace Creek provide for high water quality for use in a downstream (outside AZ) state salmon hatchery. Based on these in-channel attributes, the ID team concluded that the AZ is presently in an acceptable condition.

The ID team determined that a maximum of 350 acres (17% of tentatively suitable) could be logged within this AZ and retain acceptable stream channel conditions. No significant impact was observed as a result of approximately 75 acres harvested each decade in the 1950's and 60's. Substantial damage was noted as a result of railroad logging of 1,000 acres in the 1930's. The remaining tentatively suitable timber is located primarily along perennial streams and lower slopes. The lower slopes are highly dissected by avalanche chutes. The ID team also determined that the removal of the tentatively suitable in four decades (460 acres/decade) along with construction of the required transportation system to accommodate the harvest represented a significant risk to the watershed condition. 350 acres would be satisfactory if distributed with 230 acres in the Wallace drainage and 120 acres in the May Creek Drainage.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ ACCEPTABLE _ _ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 350 acres

3: 350 acres
4: 350 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Tye River - AZ 59

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This small AZ is composed of the Martin Creek and Kelly Creek systems. No anadromous fish utilize these stream systems The streams do contain resident populations of cutthrout and rainbow trout. Martin and Kelly Creek probably support self-sustaining, small populations of both these trout species. Over time, these stream systems have developed habitat features to support these small populations. Channel and bank stability has been fair to moderate, the quantity and quality of the pools has been good, and the recruitment of LWD to these channels has been in balance. But recent heavy harvesting on the private land and the less intense harvesting on NF land has, and continues to have, impact on the channels and the fish habitat. These are fragile channels due to their location and elevation, and future timber harvesting will require that no further degradation or losses occur in channel stability or in the fish habitat capability. Presently the ID team determined the AZ to be in an acceptable condition.

Prior to the 1980's, only 219 acres of NF land had been harvested and none on private lands. As stated previously, the fragile channels within this AZ were not substantially altered with this level of activity.

Harvest rates in the 80's increased dramatically. An additional 283 acres were harvested on National Forest lands and 1,250 acres on private lands. This rate of harvest and the location of harvest (riparian areas and avalanche chutes) has resulted in degradation of stream channels and an accelerated rate of sedimentation. Due to the short time period since harvest, it is difficult to predict what the full impact will be of the recent activity. Monitoring activities are planned for further evaluation. Considering the observed existing condition, the anticipated harvest of an additional 350 acres of private land during the rest of 1989, and the uncertainty of future impacts, the ID team concluded that future harvest rates, at least for the short term, should be reduced from previous levels. The team proposed 100 acres for the for the 1st decade which represents 9% of the remaining mature tentatively suitable within the AZ. This harvest should occur within the Kelly Creek and West Fork of Martin Creek Only limited salvage harvest will be scheduled for Martin Creek due to little expected harvest on other ownerships and anticipated gradual recovery, the team increased the rate in future decades to 150 acres/decade. (about 12% of the tentatively suitable).

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: ~100 ACRES
2: ~150 ACRES
3: ~150 ACRES
4: ~150 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Beckler-Rapid Rivers - AZ 60
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The Beckler River contains more than 13 mainstem river miles plus 28 tributaries that total about 167 linear stream miles. The Beckler River is the major tributary of the S.F. Skykomish River. The Beckler River contains significant populations of coho and pink salmon as well as sea run trout (steelhead, cutthrout, Dolly Varden). Smaller, but important runs of spring chinook and chum salmon also can be found in the mainstem Beckler River. All of the anadromous fish production is natural production except for the steelhead trout that are outplanted from nearby hatchery production. Natural production in the Beckler River is possible due to fair to moderate amounts of spawning habitat existing, but only fair quality and quantity of rearing habitat is present. Much of the high quality rearing habitat in the Beckler and Rapid Rivers was lost or displaced following the floods in the late 70's and 80,s. In addition, the extensive flood control and prevention work following the floods (LWD removal and channelization) further damaged or destroyed this rearing habitat. Since the mid 80's to the present, natural channel recovery and fish habitat restoration management activities have steadily improved this rearing habitat capability. Rearing habitat capability is improving because the channels have become more stable, the number, size, and location of pools is increasing, and the recruitment of LWD is occurring. The present conditions of the 1st and 2nd order channels and the downstream 3rd and 4th order channels support viable populations of salmon and trout therefore the ID team determined that the Beckler River AZ is in an acceptable condition.

The past harvest rate (for past 2 decades) on both National Forest land and private land has averaged about 3500 acres per decade. The Rapid and lower Beckler River areas are in a process of recovery from past heavy harvest rates that employed poor management practices, and had roads constructed in unstable soil areas. In addition, this portion of the watershed is recovering from past wildfires like the Evergreen Mtn burn. Examination of aerial photos over the past 2 decades shows that hydrologic recovery is occurring on National Forest lands. This recovery is taking place in the watershed despite the presence of large, contiguous acres of harvesting on the upper slopes and in the riparian areas on private land.

The ID team concluded that the implementation of state-of-the-art BMPs and the amount of helicopter logging possible (which would decrease new road needs) in this AZ would allow the District to maintain and slightly increase the past 2 harvest rate of 3500 acres/decade. The ID team determined a slight increase of 100 acres to total 3600 acres could be the maximum harvested in the 1st decade. Hydrologic recovery is taking place on National Forest land as well as private land. Five of the seven parcels of other ownerships in the second growth along the bottomlands of Beckler River have been recently acquired as National Forest lands. These parcels will not be subject to extensive harvesting as they would have if they had remained in private ownership. The potential future impacts to the watershed from management activities, under N.F. administration, will be decreased. Upon consideration of the previous discussed factors, the ID team determined that the harvest rate could be increased on the AZ to 4000 acres/decade for decades 2,3, and 4. These rates, along with state-of-the-art BMPs, are expected to maintain the present acceptable watershed condition in this AZ.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __X__ACCEPTABLE ____UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: _3,600 Acres
2: _4,000 Acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

South Fork Skykomish River - AZ 61

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This small AZ contains only resident fish habitat. The major stream system in the AZ is the upper sections of Barclay Creek and Barclay Lake. Resident rainbow or cutthroat trout populations in this creek are probably small and vulnerable to being depleted with any additional recreational fishing pressure. Creating additional access to upper Barclay Creek with more roads could lead to increased fishing pressure on these small populations. Presently, the habitat is supporting these populations. Channel and bank stability in most channels is fair to good, the pools are small, but still are providing food and cover; and Barclay Creek has a good supply of LWD along its entire channel length. Recruitment possibilities are also good. Because of these conditions, the ID team concluded the AZ to be in an acceptable condition.

Lacking previous cutting history in the immediate area to draw from for background information, the tentatively suitable lands were analyzed in three categories which are:

1. The avalanche chute area of about 600 acres
2. The upper basin area of 600 acres
3. The area below the end of the road of about 600 acres.

The avalanche chute area contains numerous, deeply incised chutes that highly dissect the area. Roading would not be economically feasible. Logging of the timber should leave buffer strips to protect the chutes from sedimentation. Because of the closeness of the chutes, there is very little, if any, timber that could be logged without incurring impacts on the watershed.

The area above the end of the road into the upper basin has many, small feeder streams that are 1st and 2nd order channels. Natural sedimentation of Barclay Lake is occurring. The harvest of more than a minor amount of timber would increase this sedimentation rate. Therefore, the ID team determined that the maximum rate of 60 acres per decade should be established when considering a slow rate of vegetation growth and a relatively long period for hydrologic recovery after impacts occur.

The area south of the end of the road has no severe problems. The private land adjacent to this area has been clear cut but has not full revegetated.

The ID team determined that 180 acres per decade could be harvested and still maintain the acceptable condition of the watershed.

The total harvest that can be harvested from this AZ is 240 acres/decade (about 14% of the tentatively suitable) and still maintain an acceptable watershed condition. Helicopter logging may be employed to harvest up to 2/3 of the area.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ ACCEPTABLE ___ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 240 ACRES
2: 240 ACRES
3: 240 ACRES
4: 240 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

South Fork Skykomish River - AZ 62
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Barclay Creek is a major tributary that enters the S.F.Skykomish River in this AZ. Barclay Creek contains about 1/2 mile of spawning and rearing habitat for coho salmon and steelhead trout. The remaining portion of Barclay Creek contains good quality resident trout habitat. The S.F. Skykomish River channel that flows within this AZ serves as a migration area for salmon and sea-run trout moving upstream to spawn and rear. This channel area in addition has moderate amounts of spawning and rearing habitat. This habitat is in good condition at present. In-channel stability is moderate and streambank stability is moderate. In addition, a fair number of high quality pools exist in both Barclay Crek and the S.F. Skykomish River channel within this AZ. A moderate amount of LWD exists in almost all the channels. Based on these factors, the ID team determined that the present in-channel conditions in this AZ are acceptable.

Based on a past harvest rate of 364 acres of NF and private lands per decade over the past 4 decades, and the fact that the old railroad logging of the 1930's has hydrologically recovered, the ID team concluded that a maximum of 270 acres/decade (12% of tentatively suitable) rate of clearcutting could be conducted and still maintain the AZ in an acceptable watershed condition. This rate of future allowable harvest was influenced by the bulk of the area being in the scenic corridor along US highway 2. This requirement of meeting visual quality objectives places restrictions on timber management activities. The lower elevations of this AZ contains extensive acreage of second growth timber that is about 50 to 60 years old. Management of these stands will be by thinning to meet the visual quality management objectives. The maximum harvest acreage would be significantly increased in this situation. The exact figure would have to be evaluated on an individual project basis.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ ACCEPTABLE ___ UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 270 ACRES
2: 270 ACRES
3: 270 ACRES
4: 270 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Skykomish and Tolt Rivers - AZ 63
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The majority of the land in this AZ is in private ownership. Only 2195 acres out of 20,825 acres are NF land. This AZ also includes the Deer Creek subwatershed, on the north side of the S.F. Skykomish River, and the Proctor Creek subwatershed on the south side. In addition, this AZ straddles the ridge line separating the Skykomish and North Bend Ranger Districts. Many of the 1st and 2nd order channels in the south portion of this AZ are tributaries that feed into the N.F. Tolt River which is in a North Bend District AZ. In the middle portion of the AZ, Lake Cavanaugh drains both north to the S.F. Skykomish River and south to the N.F. Tolt River. In this AZ, only a resident trout fishery exists. The following description of the in-channel conditions apply to all channels in the AZ especially Proctor, Deer, and the N.F.Tolt. These channels contain populations of resident cutthroat and rainbow trout. In addition, the lower 1 mile channel sections of Proctor, and Deer Creek areas outside the NF boundary, contain anadromous fish habitat. Coho and pink salmon utilize these channel sections for spawning and rearing. Presently these channels (outside the AZ) contain only fair quality habitat for these salmon species. Bedload and sediment deposition, transported from upslope areas (inside the AZ) has displaced or degraded rearing and spawning habitat. The in-channel conditions of Proctor, Deer and the N.F. Tolt presently are in fair to good condition The 1st and 2nd order channels have only a fair ability to control the heavy bedload transport and deposition process that occurs in the downstream 3rd and 4th order channels. These 3rd and 4th order channels have fair stability, but only a small number of adequate size pools exist. With the future recruitment of LWD from the adjacent riparian stands, the number of high quality pools should increase. Based on the present in-channel conditions, the ID team rated this AZ in an acceptable condition.

The large areas of railroad logging in the watershed have made full hydrologic recovery. These stands are now second growth timber. On private lands they are being placed under intensive management. The DNR lands are being commercially thinned. On private lands these stands are being clearcut. This is expected to continue for the next few years until these stands have been all regenerated. The thinned stands will be regenerated in the next decade.

The ID team concluded that the maximum acreage that could be harvested and still maintain the current acceptable in-channel conditions is about 300 acres per decade. This amounts to about 14% of the tentatively suitable. No recent cutting records are available. This acreage is about what was cut in the last decade and this rate has maintained the AZ in an acceptable condition. With implementation of BMPs and the restrictions of TFW on private lands, the 300 acres should be an acceptable rate of harvest.

In the second decade the impacts of the present high level of private cutting will begin. The level of maximum acreage of NF lands should be reduced to about 200 acres to reduce the potential impact on the watershed. This should hold for the third decade and then increase in the fourth decade to 300 acres (same as decade 1). This is dependant upon the recovery of the private lands that are being cutover.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 300 ACRES
2: 200 ACRES
3: 200 ACRES
4: 300 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

South Fork Skykomish River - AZ 65
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ has 3 main subwatershed areas that were analyzed for their in-channel conditions. Maloney and Money Creeks each have less than 1 mile of anadromous fish habitat. In this lower mile section, both creeks have spawning and rearing habitat for coho and pink salmon as well as for steelhead trout. The present habitat conditions in these channel areas are in fair to good shape. In-channel stability is fair, a fair number of high quality pools exists, and moderate amounts of LWD exist to contribute to pool formation in these channels. The S.F.Skykomish River channel contains moderate amounts of spawning and rearing habitat for coho, pink, and chum salmon. This habitat is in relatively good shape. In the upper sections of the Maloney and Money Creek channels, resident trout habitat exist. On Money Creek, little or no resident fish have been found in recent years. This is probably due to leaching from nearby mine tailings of toxic heavy metals (copper sulfate, arsenic, etc). Other smaller streams in the AZ (Index,Anderson Creeks) probably contain small isolated, self-sustaining populations of resident trout. Habitat conditions are probably capable of supporting these populations. Because of these current in-channel conditions throughout the AZ, the ID team rated the AZ in an acceptable condition.

Maloney Creek has three different situations. The west side of the upper 2/3 of the drainage has no history of timber harvesting. The land allocation is Dispersed Recreation. Therefore, there will be no timber management in the area. The east side of the upper drainage is in the General Forest Allocation. This area has had numerous entries for harvesting over the last two decades. The older cutting areas have nearly reached hydrologic recovery. The lower part of the drainage was clearcut in the early 30's and has revegetated with dense stands of conifers or hardwoods. This part of the drainage has completed its hydrologic recover. The ID team determined that the upper part of the drainage is the restrictive part of the drainage. The maximum level of harvest is low and is estimated at about 60 acres. This may be increased to about 100 acres if cutting is in the lower drainage.

The lands suitable for timber harvest in Money Creek are along the stream bottom and the lower slopes of the drainage. The land allocation is Scenic Forest for this timber. About 600 acres has been cutover in the last 4 decades in this watershed. Because of the natural instability of the stream and because of the location of the timber, the rate of cutting should not be significantly increased. The estimated maximum is 175 acres per decade on the long term basis. The restrictions that the partial retention objective poses makes this maximum practically unattainable.

The main south fork of the Skykomish in this AZ has about 2,000 acres of timber that is suitable and available for management. The lower parts were logged in the 30's and 40's. These areas have fully reached hydrologic recovery. The second growth timber is nearing or has reached culmination of mean annual increment and should be placed under management. This area is in the Scenic Corridor along US 2 and is subject to restrictions to meet the Retention and Partial Retention Objectives.

The background areas are allocated to General Forest and to Dispersed Recreation. The tentatively suitable NF land in the General Forest Allocation is about 2,000 acres. Only a minor amount of cutting has occurred in this area in recent decades. The impacts on hydrologic issues are none to insignificant. Private lands on the upper slopes have been clearcut within the last two decades. The ID team estimated that 200 acres/decade of clearcutting would be the maximum harvest that could be obtained without serious impacts on the hydrologic aspects of the areas.

The area from the north side of Money Creek north through the Lake serene and Anderson Creek drainage is allocated to the Mt Index Scenic Area. The Visual Quality Management is Preservation. No timber harvest is foreseen in this special area.

The total for the AZ is a maximum of 430 acres/decade (4% of tentatively suitable) that could be cut through a regeneration system such as clearcutting. The second growth stands along the bottoms may be managed through commercial thinnings to obtain the Retention and Partial Retention Objectives. The maximum acres cutover then would be significantly increased. The exact amount would be dependant upon many factors and would have to be evaluated on an individual project basis.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: _430 ACRES
2: _430 ACRES
3: _430 ACRES
4: _430 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Tye and Beckler Rivers - AZ 67
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The main watershed in this AZ is the Tye River. It also includes in their entirety the Tunnel, Sawyer, Carroll, Alpine, Anthracite, Bolt Creek subwatersheds. The lower reaches of the Beckler River, Foss River,and Deception Creek drainages are also included. The South Fork Skykomish from its junction with the Tye River to its junction with Beckler River is also included.

Anadromous fish utilize the SF Skykomish River up to Alpine Falls. Chinook, coho, and pink Salmon along with sea-run trout (steelhead and cutthroat) spawn and rear in the main-stem and the side channels. The present habitat conditions in this portion of the SF Skykomish River channel are capable of supporting these populations. Above Alpine Falls, the river becomes the Tye River and only supports a resident fish population for rainbow, cutthroaty and eastern brook trout. These trout populations exist in smaller numbers in the major tributaries to the Tye River. The habitat conditions in these tributaries are probably only in a fair condition given the amount of natural instability, and the amount of timber harvesting (past and present) on the private lands. The habitat conditions of NF lands are also only in fair condition. Future timber harvesting in the AZ will need to maintain or improve these habitat conditions. At this time the ID team determined this AZ to be in an acceptable condition.

The lower slopes along the main SF Skykomish and Tye Rivers were railroad logged in the 1910 -1930 period. Large areas on the adjoining slopes were also burned during this period. These areas have revegetated with conifer or hardwood stands. The hydrologic recovery is completed. These areas have hydrologically recovered.

Most of these lower lands are in private ownership, and second growth timber harvesting has begun. These private lands are either holdings within the AZ or on the AZ boundary. The recent harvesting started in the 50's and a large acreage was harvested in the 60' and 70's. 1306 acres were harvested in the 1960's and about 1194 acres were cut in the 70's. Presently, the areas harvested in the 1950's and 1960's have hydrologically recovered. Harvest areas from the 1970's are near almost full recovery.

About 3600 acres have been harvested on NF lands over the past 4 decades, or an average of 900 acres/decade. The Alpine and Carroll Creek Watersheds have been heavily cut. Alpine Creek has naturally unstable soils along its riparian area and lower slopes. Cutting has not been done in these unstable areas. Therefore, not much in-channel impacts have been noted on this stream or downstream in the Tye River channel.

Carroll Creek has had the heaviest harvesting,but most of the riparian areas have been left uncut. This is a steep gradient stream and the channel transports sediment quickly downstream. Sediment deposition downstream to the Tye River has not caused much impact, but any additional sediment deposition could lead to unacceptable levels of channel damage. This stream is in a delicate balance at the present time.

The remaining sub-watersheds in this AZ are in good condition. The potential harvesting of large tracts on private lands on the lower border of the AZ or adjacent to the AZ creates a potential for impacts to these sub-watersheds.

The ID team concluded that the AZ should be able to withstand a 1500 acres/decade. However, because of the potential impacts on several small watersheds and the forthcoming private land harvesting, this rate should be reduced until the recent and new cutover lands have recovered. Based on a past average harvest rate of 900 acres/decade, the ID concluded that during the 1st decade while hydrologic recovery is underway in the AZ, the harvest rate should be about 75% of the past harvest rate, or about 700 acres/ decade. the ID Team then determined that in the second decade, the rate could be increased to 1000 acres. This level could be held for another decade to compensate for the recovery of the large parcels of private lands that will be harvested. This 1000 acres is 10% of the tentatively suitable NF lands. In the following decade the maximum level of 1500 acres could be obtainable without impacting the watershed values. This represents 14% of the tentatively suitable NF lands.

The Alpine Lakes Land Management Plan provides allocation of land to all of this AZ. The Scenic Corridor along US Highway 2 follows the center of the AZ along the SF Skykomish River and The Tye River. This allocation requires the Visual Resource Management Objective of Retention be met for all the foreground area VRM Objective for middle ground area as Partial Retention. These allocations restrict the methods of cutting, sized of units and indirectly the amount of area that can be cut at one time. This has the overall effect of reducing the impacts on the watershed

Foss River - AZ 68

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

The AZ encompasses the entire Foss River watershed, a major tributary to the SF Skykomish River About 7 miles of the mainstem serves as habitat for chinook, pink and coho salmon a well as for sea-run trout (steelhead, cutthroat, and

Dolly Varden). The river contains significant areas of high quality spawning gravels and has many high quality rearing pools formed by LWD and boulders. Overall, the habitat conditions are capable of supporting the existing anadromous fish utilization. In addition, this section of the Foss River as well as in the upper, steeper gradient sections of the West and East Forks contain moderate populations of resident trout. The habitat in these channels also is in good condition. Overall the in-channel conditions in the Foss River *are presently in good shape. Because of this, the ID team rated this AZ in an* acceptable condition.

Timber harvest and associated activities that have occurred in recent decades within this AZ have not resulted in an observable deterioration in the condition of the watershed. Very few landslides have occurred and those that have are the result of sidecast construction and/or inadequate culvert side.

Harvest rates within this AZ have averaged about 350 acres/decade during the last 4 decades. This 350 acres represents 5% of the total AZ acreage. Decade harvest rates during the 4 decade period have ranged from 245 acres in the 70's to 553 acres in the 60's.

Considering the existing watershed condition and its apparent ability to absorb *the level of activity that has occurred during previous decades, the ID team* concluded that a harvest level of 500 acres could be sustained in future decades without deteriorating the watershed condition. No harvest is expected on other ownerships for several decades due to the lack of mature timber. This rate of harvest represents a 43% increase over the historic level. The 500 acre/decade harvest rate also represents 10% of the remaining tentatively suitable lands.

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Miller River - AZ 69

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ includes the entire Miller River watershed outside of wilderness. Six miles of the mainstem and almost 1 1/2 miles of the West Fork Miller contain spawning and rearing habitat for spring chinook, coho, and pink salmon. In addition, these channel sections are also habitat for steelhead trout and Dolly

Varden. The upper Miller River also contains habitat for resident trout populations. The majority of the resident and anadromous fish habitat is in good condition. The habitat is capable of supporting the existing salmon and trout populations.

In-channel and bank stability is fair to good, the number and quality of the pools is good, and the amount of LWD in the channel is fair. An exception to these good in-channel conditions, is the lower mile of the Miller River Channel. This section is experiencing substantial bedload deposition, causing pools to fill in and become unusable to salmon or trout. LWD is also either buried under this sediment or has been washed downstream. Overall, the Miller system is in good shape, and the ID team determined it to be in an acceptable condition.

Timber harvest activity within this AZ has averaged 214 acres per decade for the past 6 decades. Decade harvest has ranged from a high of 543 acres in the 30's to a low of 46 acres in the 80's. With the exception of the lower mile of the Miller in which deposition is filling some pools, relatively stable conditions exist within the drainage as a result of this harvest level. The remaining tentatively suitable acres are expected to have a greater impact on the watershed than previous harvest. This is because the remaining acres are located in steeper, less stable topography.

The ID team considered this AZ to be in an acceptable condition, and considered the historical average harvest rate as a reasonable rate to continue. The team recommends 200 acres of harvest per decade which represents 6% of the tentatively suitable land.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 200 ACRES
2: 200 ACRES

4: 200 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Tolt River - AZ 70

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This cumulative effects analysis has determined that a separate acceptance ratings, one for the South Tolt, and one for the North Fork, was essential to determine the future harvest prescription for the AZ. The logic for this decision was based on past forest management activities in the South Fork

drainage, while the entire North Fork system within the AZ remained unroaded and uncut.

A harvest rate of 452 acres/decade (NF and private) for 2 decades resulted in an unacceptable watershed condition for the South Fork Tolt. Excessive harvesting along the main channel and associated upstream tributaries led to an observed reduction in the quantity and quality of fish habitat. Declining amounts of LWD with inadequate recruitment, lack of riparian cover, channel scouring, and evidence of excessive peak flows were the observed conditions in this analysis. The present channel configurations suggests that fisheries habitat is continuing to deteriorate. Because of these attributes, the South Fork Tolt was rated unacceptable.

The North Fork was rated acceptable. No management activities have occurred within the North Fork Drainage. Fish habitat is fair to good according to onsite observations from district personnel. Pools are of moderate depth and adequate amounts of LWD exist along the North Fork Tolt channel. This LWD is stable and the adjacent riparian stands represent a good potential for future recruitment.

When considering the summation of the conditions throughout the AZ, the ID team concluded that the overall rating was marginally acceptable.

Based on the findings of this assessment, the harvest of 250 acres per decade (11% of tentatively suitable) could be harvested without experiencing unacceptable impacts to North Fork. This is assumed that BMP's will be implemented, particularly retention of riparian areas and minimal road construction. In addition, this rate of harvest will allow for recovery in the South Fork.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 acres

North Fork Snoqualmie River - AZ 71

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ comprises the upper watershed area of the North Fork Snoqualmie River and a major tributary, Lennox Creek. As with river systems in the Snoqualmie

River basin within the NF boundary, this AZ only supports populations of resident trout. These populations include rainbow, cutthroat, and eastern brook trout. Not much is known about the status of these populations but it is suspected that the current habitat conditions support these trout populations.

Overall the stream channels do not provide high quality fish habitat due to the frequency of high flows and steep channel gradients. Past management practices have not affected the stream characteristics nor has fish habitat decreased as a result of past activities. Because of the above conditions the ID team rated this AZ as acceptable.

Harvest rates over the past 4 decades has ranged from 412 to 1000 acres/decade. No significant hydrologic in-channel impacts were observed after examination of the aerial photos and using District knowledge about these channels. But because of the history of flash flows and peak runoff in this AZ and with on-going hydrologic recovery, the ID team determined that 70% of the maximum historic harvest rate could be harvested in this AZ without altering the current acceptable in-channel conditions. In addition, roughly 2900 acres have been identified in the timber sale planning process as being feasible for helicopter logging. In conclusion the ID team determined that 700 acres/decade would be the MR (This is 14% of the tentatively suitable area).

700 acres/decade of harvest is acceptable, based on past management activities. No significant hydrologic impacts occurred as a result of the 595 acres which were harvested in the 1960's. The extremely flashy flows that are characteristic of this drainage could be increased to an unacceptable rate which would create flooding and unstable channel conditions. 700 acres/decade is believed to be the maximum rate that can be harvested before flows are altered to this unacceptable degree.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ **ACCEPTABLE** ___ **UNACCEPTABLE**

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 700 acres
2: 700 acres
3: 700 acres
4: 700 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Taylor River - AZ 72
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This small AZ includes the 3rd and 4th order channels of the Taylor River and Quartz Creek. These stream systems support resident trout populations of rainbow and cutthroat. Habitat conditions in both systems probably are capable of supporting the existing populations. In-channel stability is fair, the quantity and quality of pools is moderate and the presence and stability of LWD is fair to good, especially in the upper reaches of these two systems. Based on these in-channel conditions, the ID team determined the watershed conditions in this AZ to be acceptable.

Management activities, beginning in the 1940's and continuing intermittently into the 1970's has resulted in 2700 acres of the total acreage within the AZ being harvested. Approximately 2000 acres were harvested during the 1940's for which associated effects are hard to detect at the present time.

A comprehensive comparison of aerial photos taken in 1970, 79, and 84, and comments gathered from district personnel with onsite observations of the AZ, suggests that the effects of road building, falling and yarding timber produced minimal changes to local and downstream conditions. Examination of the entire length of the Taylor River and Quartz Creek failed to show significant differences in channel patterns from upslope disturbances between a 14 year span observed from aerial photos. Two district personnel corroborate this assessment, in part, by commenting on the presence of quality pool habitat on the upper reaches of both channels.

It should be noted that regeneration problems have been experienced in at least two upslope units north of Quartz Creek. Hydrologic response (peak discharge) could be influenced if substantial additional acreage experiences revegetation difficulties after harvest.

Due to the lack of management activity during the past 15 years in Quartz Creek and 50 years in Taylor Creek, direct cause/effect watershed relationships are not available for this AZ. Until these relationships can be established, through monitoring of future activities, observed cause/effect relationships in adjacent drainages which have similar geologic and watershed characteristics have been used to assist in establishing an acceptable maximum rate of harvest for AZ 72.

The maximum decade harvest rate which was established for AZ 70 and AZ 71 represented 3.4% and 7.4% of the total AZ acreages respectively. The consideration of the existing conditions within AZ 72 in conjunction with the cause and effect relationships observed within adjacent drainages (AZ 70 & 71) led the ID team to conclude that a harvest level of 520 acres per decade would be a reasonable maximum harvest rate for this area.

Alpine Lakes Management Plans dispersed recreation category will concentrate future harvest into the Quartz Creek drainage area which contains approximately 3200 acres of the total AZ acreage. Harvest of the entire 520 acres/decade in Quartz Creek would increase stream discharge, soil erosion, bedload deposition,

and eventually decrease existing rearing habitat in the lower reaches of Quartz Creek. In order to avoid the anticipated effects of this level of concentrated harvest, the ID team concluded that a maximum harvest level of 250 acres should be established for AZ 72. Future monitoring of management activities and associated watershed response will provide the information necessary to adjust the harvest levels in future decades.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 acres

3: 250 acres
4: 250 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Middle Fork Snoqualmie River - AZ 73

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This small AZ encompasses a portion of the Middle Fork Snoqualmie River. This river supports low to moderate levels of resident trout populations (rainbow and cutthroat). Present habitat conditions to support these populations are fair. As the AZ further recovers, the in-channel conditions will also improve and habitat quality and quantity should increase. Presently what pools exist in the Middle Fork are moderate in quality. Quantity of such pools is lacking. Presence of LWD is lacking, but the recruitment from the adjacent riparian areas is good. Overall the ID team rated this AZ as in an acceptable condition, especially in light of the on-going hydrologic recovery.

Approximately 1750 acres of the AZ was harvested in the 1930's and 40's. These harvested areas have revegetated and are providing stable conditions within the AZ. Subsequent harvest in the 1970's and 80's has been negligible (approximately 400 acres). While these acres are not hydrologically recovered, their impact on the AZ as a whole is minimal due to the location of harvest in relation to the tributary and main stream channels within the AZ.

Unstable soils are minimal within the AZ, although extensive areas of clay textured soils exist throughout the valley bottom. This results in some turbidity reaching the Middle Fork.

350 acres of harvest per decade within this AZ has been determined to be an acceptable rate. This conclusion is based on the following observations:

Watershed conditions were not substantially impacted by harvesting 330 acres in the 1970's.

Landforms similar to that which was harvested in the 70's and 80's is available for the first decade at a harvest rate of 350 acres/decade.

2600 acres of helicopter logging would lessen ground disturbance from reduced road construction.

Harvest levels in the 2nd and future decades may be influence by inventories that are currently being conducted in order to update suitability information for several areas in this AZ.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 350 acres
2: 350 acres
3: 350 acres
4: 350 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach, M.F. Snoqualmie River - AZ 74
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ includes most of the Middle Fork of the Snoqualmie River. The State of Washington has designated the Middle Fork as quality water for management of resident fish populations. These resident trout populations include cutthroat, rainbow, and smaller populations of eastern brook trout. Fair to moderate fishing pressure presently exists on this special catch-and-release sport fishery. The habitat in the Middle Fork channel presently is capable of supporting fair to moderate numbers of cutthroat and rainbow trout. The channel is relatively stable. Overall pool quality and the quantity is good and there is moderate, stable amounts of LWD in the channel. Because of these attributes, the ID team concluded that the AZ is in an acceptable condition.

The majority of timber harvest (2000 acres) occurred in this AZ in the 1930's and 1940's. Harvest areas and stream channels associated with those harvested areas have fully recovered hydrologically. 255 acres of timber harvest occurred on private lands in the 1970's. This acreage is not fully reforested and minor accelerated discharge and associated scouring has occurred.

The Middle Fork Snoqualmie River transports large quantities of sediment and bedload Transport occurs primarily during peak flow events. Peak flows are

very flashy events (rapid discharge response to storm events) due to extensive areas of rock outcrops and ice fields.

Due to the lack of recent management activity within the area, direct cause/effect watershed relationships are not available. Until these relationships can be established, through monitoring of future activities, observed cause/effect relationships in adjacent drainages which have similar geologic and watershed characteristics have been used to assist in establishing an acceptable maximum rate of harvest for AZ 74.

The maximum decade harvest rate which was established for AZ 70 and AZ 71 represented 3.4% and 7.4% of the total AZ acreages respectively. The consideration of the existing conditions within AZ 74 in conjunction with the cause and effect relationships observed within adjacent drainages (AZ 70 & 71) led the ID team to conclude that a harvest level of 800 acres per decade (11% of tentatively suitable) would be a reasonable maximum harvest rate for this area. Approximately 90% of this harvest acreage will employ helicopter yarding which will substantially reduce access roading needs and associated ground disturbance and accelerated erosion. Unit size, dispersion, and silviculture treatments are prescribed within the scenic Forest component of the ALMP was considered during the development of the MR. Future monitoring of management activities and associated watershed response will provide the information necessary to adjust the harvest levels in future decades, if necessary.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: **_XX_ACCEPTABLE** **_ _UNACCEPTABLE**

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 800 acres
2: 800 acres
3: 800 acres
4: 800 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Pratt River - AZ 75

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ comprises most of the Pratt River system, which is a major tributary to the Middle Fork Snoqualmie River. The habitat within the Pratt supports fair to moderate populations of cutthroat and rainbow trout. The upper channel sections are moderately stable, but in the lower 1/4 mile reach area the channel stability is poor to fair, due to the sediment deposition and excessive channel braiding. Pool quality and quantity is moderate in the upper reaches but limiting in the lower reach area. LWD is limiting along the entire channel

length. Except for this lower 1/4 mile reach, the Pratt River Channel and the smaller 1st and 2nd channels are considered to be in an acceptable condition.

Approximately 3,500 acres of timber were harvested within this AZ by railroad logging in the 1930's and 1940's. Evidence of impacts to the Pratt River from this harvest activity is difficult to identify do to very successful vegetative recovery. Pre-harvest photo's are not available, but the main channel of the Pratt appears to be unusually wide for a stream of its size and may have experienced widening as a result of harvest.

The Alpine Lakes Management Plan has designated approximately 1,700 acres of dispersed recreation within this AZ. Dispersed recreation acreage is located along the upper slope positions in the upper half of drainage. Approximately 2,400 acres of tentatively mature acres remain in the AZ if dispersed recreation acres are considered.

Available mature acres (2,400) are located in mid-slope positions (above 2,400 feet) and it extends from the Wilderness boundary down to the confluence of the Pratt with the Middle Fork Snoqualmie River. Immature stands occupy the main channel and lower slope areas.

Maximizing harvest levels during the initial entries will result in the need for extensive road construction. Mature stands of timber are distributed in blocks and narrow bands the entire length of the drainage. In order to disperse cutting units throughout these areas, significant road construction will be required. Potential impacts of both activities need to be considered, particularly during the initial entry.

Cause/effect relationships, in regards to timber harvest and road building, for establishing the watershed MR within this AZ are not available. Considering the extent of road building that will be necessary during the first entries (preliminary planning estimates approximately 15 miles), 650 acres per decade 10% of tentatively suitable) is believed to be a maximum rate of harvest that can be tolerated within each of the first two decades and retain acceptable channel conditions.

Road construction is expected to be substantially less and helicopter logging opportunities increased in the 3rd and 4th decades. This would allow an increase of harvest acreage to 800 acres and 1,000 acres for those decades respectively while providing for maintenance of acceptable in-channel conditions. These acres represent 12 and 15% of the tentatively suitable.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _XX_ACCEPTABLE _ _UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 650 acres
2: 650 acres
3: 800 acres
4: 1,000 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

South Fork Snoqualmie River - AZ 77
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ comprises most of the SF Snoqualmie River system. Resident fish populations of rainbow and cutthroat trout can be found in the SF Snoqualmie is presently managed as a high quality sport fishery by the State of Washington. The present capability of the habitat in this AZ to support these fish populations is in doubt.

Channel scouring and the frequency of debris torrents in many 1st and 2nd order channels plus the amount of sediment and bedload deposition in the lower 3rd and 4th order channels (mouths of tributaries and the SF Snoqualmie) have caused fish habitat degradation in these channel areas. This sediment and bedload deposition has caused a loss of pool quality and quantity. Much of the sedimentation presently seen on the South Fork channel may be attributed to forest fires that removed vegetation and consequently exposed soil surfaces. Because of these conditions, the ID team rated the AZ as unacceptable.

Since the 1930's approximately 14,000 acres of the AZ has been harvested and/or burned. In the last 3 decades an average of 1800 acres per decade were logged. As a result of these activities the South Fork channel and the majority of its southern tributaries have been impacted.

200 acres of harvest on National Forest in conjunction with approximately 440 acres of harvest on private ownerships in considered to be the maximum harvest that the AZ could accommodate within further deterioration of channel conditions.

Based on observed watershed conditions, the ID team concluded that this AZ is currently in an unacceptable condition. The concentration of mature NF timber within drainages which have been heavily impacted during past decades reduces the options of dispersing future harvest activity for mitigation purposes. The ID team concluded that a 60% reduction in the average historic harvest levels would be necessary in order to facilitate recovery of the watershed condition. 640 acres/decade is considered to be the maximum total allowable harvest rate. Considering the anticipated harvest of about 440 acres/decade on private ownership, the ID team concluded that 200 acres/decade (2% of tentatively suitable) would be the maximum harvest level on NF lands which would permit the desired recovery.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 200 ACRES
2: 200 ACRES
3: 200 ACRES
4: 200 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Upper Reach, Green River - AZ 81
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

High road density (4.53 mi./sq.mi.) in conjunction with intense timber harvest activity over the past 20 years has adversely impacted stream channels within this AZ due to increased erosion, sediment transport, and sediment deposition in fish rearing and spawning habitat. Stream surveys conducted in 1982 indicated poor pool/riffle ratios. The surveys also reported sediment deposition along stream channels which aerial photo examination supports. Deposition of sediments and bedload along lower reaches of channels has resulted in channel changes and braiding, particularly in the Green River. Because of these in-channel conditions, the ID team concluded that this AZ to be in unacceptable condition.

Approximately 49% of this AZ has been harvested within the past 3 decades. Harvest activity has been most intense within the upper two thirds of the AZ, extending from Tacoma and Pioneer Creeks in the south to the headwaters of Sunday and Snow Creeks in the north. The upper reaches of the Green River and the Twin Camps drainage have seen the least harvest activity. Average harvest rates over the last three decades have been approximately 1,250 acres/decade on National Forest lands and 4100 acres/decade on private land (5,320 acres/decade overall).

Presently 8,447 acres of mature timber is available for harvest on Forest Service lands and approximately 6,300 acres of mature timber remains on private lands. Based on recent harvest rates and stand age, we estimate that mature timber on private lands will be harvested within the next two decades. 3,500 acres of harvest on private lands is estimated for the first decade with the remaining acreage (2,800 acres) being harvested the following decade.

In order to initiate hydrologic recovery that is considered necessary within this AZ, a lower total harvest acreage/decade will be necessary. Harvest of private lands is expected to continue for at least the first decade at or near the historic average.

A reduced rate of 500 acres/decade during the first 2 decades on National Forest rather than the 3 decade (60's, 70's, & 80's) average of 1,250 acres would help promote the hydrologic recovery in the AZ. The remaining mature

timber on private land in the AZ will probably be completely harvested by the 3rd-4th decades. As these harvested private lands begin to become reforested and the in-channel conditions within the AZ gradually change from unacceptable to acceptable (through natural hydrologic recovery plus watershed rehabilitation activities), harvest rates on NF lands could be increased in the 3rd-4th decades. The ID Team determined that 1000 acres in the 3rd decade and 1500 acres in the 4th decade could be harvested.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: __ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 500 ACRES
2: 500 ACRES
3: 1,000 ACRES
4: 1,500 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Green River - AZ 82

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ is one of the three that comprise the upper Green River system. The in-channel conditions for the 1st and 2nd order channels on the north side of the Green River are only poor to fair in stability, pool frequency and the presence of LWD. The channel conditions in the Green River are generally in fair condition. Sediment storage is occurring and is affecting some of the pool quality and quantity. There is moderate channel braiding existing in this section of the Green. LWD is present for lacking in sufficient quantity and stability. These overall in-channel conditions probably have the ability to support the existing cutthroat trout populations. These populations are self sustaining populations that receive little or no recreational sport fishing harvest due to the limited access into the Green River Watershed. Because of these conditions, the ID team concluded that the AZ was in an acceptable condition at the present time.

Based on aerial photo examination and field observations, the harvest of 19,000 acres on the total AZ in the last 40 years in conjunction with extensive burned acreage has contributed to increased peak flows, erosion, and sediment transport within the majority of the drainages interior to this AZ. Riparian vegetation is becoming established in some 1st, 2nd, and upper 3rd order streams which had been scoured. This indicates that recovery of degraded channels may be relatively rapid in the area.

Based on current harvest activity and the age class of stands adjacent to that activity, approximately 5,000 acres of harvest/decade is projected within the AZ on other ownerships. Harvest is also occurring immediately adjacent the Green River (just outside the AZ boundary) at an extensive rate. This rate exceeds the 4 decade average harvest of 4750 acres.

1,921 acres of mature tentatively suitable are available. These acres are concentrated in the eastern portion of the AZ. The majority is located in two small tributaries to the Green River (McCain Cr. and Friday Cr.). Very little harvest is expected on private ownerships in this immediate area due to previous harvest.

Due to the concentration of mature timber and the evidence of damage sustained in adjacent stream channels from higher rates of harvest, the ID team concluded that 300 acres/decade (5% of tentatively suitable) is considered to be a maximum harvest rate during decades 1 and 2 that this AZ could tolerate while retaining acceptable watershed conditions.

2,106 acres are currently listed as tentatively suitable poles. Most of these "pole" stands will be available for harvest within two decades. As a result the ID team concluded that 800 acres (14% of tentatively suitable) could be harvested in decades 3 and 4 while protecting watershed integrity and fisheries habitat. The additional available acreage will be dispersed along the southern portion of the AZ in areas other than McCain and Friday Creeks.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE _ _UNACCEPTABLE

Green River - AZ 83
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

Stream surveys were conducted in 1982-83 in Rock Cr., Champion Cr., and Wolfe Cr. According to the surveys, steep stream gradients and other associated channel conditions are the principal factors regulating fish density and distribution in these systems. Due to these naturally occurring conditions, good fish density and distribution was only observed in Rock Creek. Few small

fish were observed in Champion Creek and no fish were observed in Wolf Creek. The past harvest levels in the last 3 decades and associated activities has not substantially reduced fish numbers in Rock Creek and it is doubtful that activities had much influence on fish numbers in the other two streams surveyed.

Observed watershed conditions suggest that natural limiting factors have determined the overall fish habitat conditions existing within the AZ. Therefore, past forest management activities have produced marginal downstream effects to the watershed and fisheries habitat. Because of the above in-channel conditions, the ID team concluded the AZ is presently in an acceptable condition.

Harvest within this AZ has increased substantially within the last two decades. Total harvest in the 70's was 4,400 acres and approximately 3,500 acres in the 80's. Harvest in the next decade on other ownerships is expected to continue at near the 1980's rate of 3300 acres and decline there after.

Within the past 3 decades, harvest has been well distributed across approximately 10 varying sized tributary drainage areas within the AZ. Harvest has generally occurred in the more stable lower reaches of these drainages. Most headwater areas (1st order streams) are National Forest and have not been harvested.

The harvest level in the last two decades has averaged approximately 4000 acres in the AZ. The cumulative effects analysis suggests that future projected harvest could continue at this rate while maintaining quality fish habitat. Improved BMP's, particularly road location, design, and reduced road density, and retention of riparian vegetation, will further reduce potential harvest related impacts.

Approximately 1000 acres (10% of tentatively suitable) of harvest on National Forest land during the first decade is considered and acceptable rate, considering the projected harvest of 3000 acres of mature timber on private ownership during the same period. Harvest on other ownership is expected to liquidate the remaining mature stands of timber in the second decade, with an expected harvest of approximately 2500 acres. This would allow an increase in harvest on National Forest lands to 1500 acres per decade.

Reduced harvest rates in the 3rd and 4th decades on private ownerships offers an opportunity for an increased rate of channel recovery for the main reach of the Green River during this period. The proposed harvest of 2500 acres in the 3rd decade and 3000 acres (30% of the tentatively suitable) in the 4th decade on National Forest would be below the previous average harvest levels for all ownerships. Maintaining lower harvest rates during this period will assist in restoring stable channel conditions to the Green River.

Greenwater - AZ 84

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

The current conditions have caused a severe reduction in quantity and quality of anadromous fish habitat. Lack of adequate holding water for adult fish is common along with an associated lack of rearing pools for juvenile fish. The heavy braiding causes isolated pockets of water in low flow which trap fish and increase mortality. Spawning success is limited due to the constant scour and deposition of gravel during each storm event.

Using the four primary criteria for evaluating watershed condition, the following summarizes the in-stream conditions in the AZ. The main channel of the Greenwater has been heavily aggraded from significant upstream materials being flushed downstream. Pools are described as poor in quantity and quality. They are regularly being filled in. Whenever there is high runoff, a significant amount of bank erosion takes place throughout the watershed because of existing instability. LWD has been almost absent in the main river channel until recently. A level of stable debris is being reintroduced artificially through cooperative habitat improvement projects in the AZ.

Heavy aggradation and braiding are present in all portions of the mainstem with the worst problems existing in those sections where the riparian zone was completely harvested. Past heavy roading and harvesting on Private and NF lands have contributed to this condition along with two major floods and the subsequent cleanout. Based on these factors the ID Team concluded that the Greenwater River and associated tributaries in the AZ are in an unacceptable condition.

POTENTIAL FUTURE IMPACTS:

A recovery process is underway but this will take at least 2 decades. Natural landslide and bank erosion will continue. Road failures and sedimentation will continue but at a reduced rate. Some of the timber remaining to be harvested and the few roads remaining to build are in very steep, unstable areas and hold a greater risk.

Instream structure work will continue. Most of the available private lands have been harvested so that these impacts will be reduced over time. Several roads will be put to bed and revegetation will occur. Several slides will be proposed for rehab work.

The recommended harvest level was developed after considering past harvest rates and current stream conditions. During the 1960's, 2400 acres of the private and NF land were harvested. Considering the effect of this harvest level on the mainstem, it was apparent the even at this level of harvest there was a detrimental effect on the Greenwater River. In addition, the factors mentioned above are still affecting the stream condition. For this reason, the ID team established an MR level at approximately one-half of the 60's historic level of harvest to provide for a recovery period, including the effects of significant private land harvest. This is approximately 650 acres or 4.4% of the tentatively suitable area. This is an appropriate level to project for the first decade because of the need for recovery.

The MR level can be increased after the 1st decade based on the assumption that private harvest is basically finished for the next 30 years in the drainage and the impact will be minimum. The only impact still to be realized from private logging could be from two units harvested in 1988 along the Greenwater River and in the upper watershed of Pyramid Creek, both of which are sensitive areas. We expect that there will be a partial recovery (within the overall Greenwater system) in the 1990's that would allow for some increase in harvest beginning in the second decade, because of using improved BMPs (such as no riparian area harvest), natural recovery, and stream rehabilitation. Based on these factor the ID team concluded that the 2nd decade harvest level of 880 acres could be sustained without resource damage.

Assuming that the recovery will be complete by the end of the second decade, the ID team concluded that harvest could be increased to 1320 (Approx. 9% of tentatively suitable) for the 3rd and 4th decades

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE _X_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 650 ACRES
2: 880 ACRES
3: 1320 ACRES
4: 1320 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Lower Reach, White River - AZ 85
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

A small resident population of cutthroat trout resides in the lower reaches of the 2nd order stream channels in this AZ. Downstream, outside the AZ, Slippery Creek is the water supply for a small, private "u-fish" trout pond enterprise. The in-channel stability of the 1st and 2nd order channels of Slippery and East Twin Creeks is poor. There is a low number of pools present and only a few isolated pieces of LWD exist in these channels. These channels are unstable due to sediment and bedload deposition. At present, the ID Team concludes that Slippery and East Twin Creeks are in an unacceptable watershed condition. Past heavy roading and harvesting on Private and NF lands have contributed to this condition.

POTENTIAL FUTURE IMPACTS:

A recovery process is underway but is expected to be lengthy. The natural erosional processes will continue. Road failures and sedimentation will also continue, but at a reduced rate. Timber remaining to be harvested and the few roads remaining to build are in very steep, unstable areas and hold a greater risk of impact.

Instream structure work and watershed rehabilitation will be planned, but funding is not approved at this time. Most of the available private lands have been harvested so that these impacts will be reduced over time. Private roads will continue to recover and revegetation will occur, but at a very slow rate since active rehabilitation efforts are not anticipated.

During the 1960's, 100 acres of the AZ was harvested, (all private). No observable watershed impacts were apparent at this level of harvest. In the 1970's, the harvest rate increased to approximately 1100 acres on NF and private lands. This amounts to 25% of the entire AZ. It was apparent that this level of harvest had a severe detrimental effect on in-channel conditions in the AZ. Most of this observable impact came from roading. During the 1980's, the harvest rate increased to over 1600 acres which caused additional resource damage to occur. In consideration of these factors and the unacceptable rating of the AZ, the ID team recommends a NF harvest rate of 250 acres per decade (11.6% of the tentatively suitable) for the 4 decade period as the MR. To sustain this harvest level will require strict adherence to BMP's (for streamside protection and road construction), natural recovery, and continuation of instream structure work and watershed rehabilitation until the time that the AZ has reached a fully acceptable condition.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: ___ACCEPTABLE XX_UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 250 ACRES
2: 250 ACRES
3: 250 ACRES
4: 250 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Clearwater - AZ 86

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This small AZ covers the upper half of Milky Creek. Presently, this stream supports a small population of cutthroat trout. Due to the remoteness and access to this stream system, there is very little or no sport fishing pressure. The present habitat conditions support this existing population.

A chronology of events within the watershed was analyzed using a series of aerial photos starting in 1950 through 1985. The analysis weighs the impacts of past activities such as roads, timber cutting, naturally occurring debris avalanches and earth flows, on water quality within the planning area and downstream. Unstable areas which were observable on the 1952 aerial photos were monitored for change through time. Since this drainage was entered for the initial harvest in the late 1960's, it is possible to compare pre and post harvest photos in terms of impact from roads, and clearcut units. None of the observable slides or unstable areas have changed in size since activity began in the drainage. None of the roads or clearcuts units within the drainage are actively impacting the stream at this time and no evidence of historic impact is present.

There has been obvious downcutting and scouring in the past and it continues to present. However, this seems to be significant in short sections only. Quality of pools generally seems to be good. Frequency could be improved, but pool/riffle ratios can be rated as moderate. There are some serious streambank stability problems in certain areas such as reaches of Milky Creek. However, large amounts of woody debris exist throughout the system with almost all channels having ability for recruitment. The LWD that is in place is relatively stable. For these reasons, the ID team concluded that the AZ is in an acceptable condition.

The ID team wishes to qualify this acceptable rating. The main stem of Milky Creek has been severely degraded by natural events in the past but still maintains some habitat for resident fisheries. Therefore, we have given this AZ an acceptable rating because the impact of man's activities to the watershed seem to be minimal. However, this would require the practice of stringent protection measures along the streamside zones.

Four hundred and seven acres (12.3% of the AZ) were harvested on National Forest land during the 1960's in the AZ. This historic rate of harvest did not

have any detectable long-term impacts to the watershed. Private lands outside of the Forest boundary was harvested at a 20 to 30% rate per decade which has had a significant impact on the downstream sections of Milky Cr. and the Clearwater R. The ID team concluded that by using state-of-the-art BMP's, the harvest rate of 407 acres per decade can be sustained without degrading the acceptable level of the AZ.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 407 ACRES

3: 407 ACRES
4: 407 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Huckleberry Creek - AZ 90

Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This drainage has had very little impact from road building and harvest efforts. Stability in general is fairly high even on steep slopes. Areas that are still to be harvested may have higher levels of unstable soil inclusions but are still stable overall. Future impacts are anticipated to be similar to past impacts and relatively insignificant. The major impact to Huckleberry Creek was the massive cleanout effort that occurred in the late 1970's after two major floods. This activity reduced the LWD in the system to almost nil. This in turn caused an initial aggradation in certain reaches and then an armoring of the substrate. The resultant habitat was and still is low in pool quantity and quality, backwater and quiet areas for juvenile rearing and a very limited amount of quality spawning gravels.

Since this flood cleanout work in the late 1970's, natural channel recovery in addition to intensive stream rehab and fish habitat improvement work has begun to restore the former high quality anadromous and resident fish habitat.

The past harvest levels ranged from 54 acres in the 1940's to 1257 acres in the 1980's. The effects of the 1960's harvest level of 1091 acres was not judged to have negatively impacted the watershed by the ID team. We made the assumption that the 1257 acres of harvest will not have a negative impact either. Because of these reasons plus the continued application of new BMPs, and additional emphasis on channel rehabilitation and fish habitat improvement, the ID team recommended a MR of 1300 acres/decade (14% of the tentatively suitable) as the

harvest rate and still maintain the acceptable watershed condition in the AZ. This would suffice through Decade 4.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 1300 ACRES

4: 1300 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

West Fork White River - AZ 91
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS IOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINI:

The West Fork of the White River and the lower reaches of a few of the tributaries serve as current or potential habitat for chinook, coho salmon, and steelhead trout. These channel areas also support populations of resident trout (rainbow/cutthroat). The habitat conditions to support these populations are improving from the past damage done by flood events and follow-up flood cleanup work. Natural recovery combined with past and future fish habitat rehabilitation work is restoring high quality pools, installing LWD structures, and stabilizing streambanks. Based on these improving in-channel conditions, the ID team determined the AZ to be in an acceptable condition.

Most of the roads exist that will be needed in this drainage although some of the future roads may be located in more unstable locations. Impacts from past harvest activities have been low with some exceptions. Heavy harvesting of the flood plain appears to have contributed to channel widening. The active channel width has been increasing as a percentage of the total floodplain width since 1970. The harvest rates of 2061 acres in the 1960's and 2242 acres in the 1970's seemed to be at or slightly above the level at which impacts to the watershed were discernible. Some of the impacts were due to a higher rate of harvesting in sub-basins such as, Jim Creek and Dinner Creek. For these reasons, the ID team concluded that the average harvest rate for the past 4 decades would be the MR for this AZ. The average per decade harvest since 1940 has been approximately 2000 ac. per decade, (13% of the tentatively suitable).

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 2000 ACRES
2: 2000 ACRES
3: 2000 ACRES
4: 2000 ACRES

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Carbon and Puyallup Rivers - AZ 93
Summary Statement That Ties the Evaluation of Instream and Upslope Factors Together and Logically Leads to Watershed Constraint

SUMMARY STATEMENT THAT TIES THE EVALUATION OF INSTREAM AND UPSLOPE FACTORS TOGETHER AND LOGICALLY LEADS TO WATERSHED CONSTRAINT:

This AZ includes a portion of the Carbon River and its major tributaries of Tolmie, Evans, Chenuis, and Cayada Creeks. The AZ also includes portions of South Prairie Creek. Anadromous fish habitat is only found within the Carbon River. The remaining streams in this AZ contain only resident trout. Fair to moderate numbers of rainbow and/or cutthroat trout exist in these streams. The present habitat is capable of supporting these populations. These trout populations receive only a low amount of recreational fishing pressure. The existing in-channel conditions in these streams, except for Tolmie Creek, have set up fair habitat conditions. Overall, a fair amount of pools exist in most streams and there are moderate amounts of LWD. Bedload deposition is fairly stable in some of these systems.

South Prairie, Evans, Cayada, and Tolmie Creeks have been severely impacted in the past. A large percentage of these areas were railroad logged and have recovered at least to the point of stream bank vegetation and having the potential for LWD input. At present, only Tolmie Cr. drainage would be considered unacceptable. Within 10 years, this area should be recovered to a point where it is also considered acceptable.

Only 30+ % of the remaining area has tentatively suitable mature sawtimber. The past levels of harvest within this AZ ranges from approximately 525 acres (3%) to 3862 acres (18%) per decade including private harvest. The impacts were primarily from railroad logging although subsequent harvest in the 1960's slowed down the recovery process.

The average harvest per decade since 1960 is 1210 acres (NF and Private). Based on past harvest and the overall acceptable conditions of the AZ, the ID team concluded that 1150 acres per decade (8% of tentatively suitable) would maintain the acceptable watershed condition and allow recovery to take place in Tolmie Creek.

OVERALL RATING OF ALLOCATION ZONE BASED ON INSTREAM, UPSLOPE, AND ANY OTHER CONSIDERATIONS: _X_ ACCEPTABLE ___UNACCEPTABLE

MAXIMUM TENTATIVELY SUITABLE HARVEST OF NATIONAL FOREST ACRES FOR DECADES:

1: 1150 acres

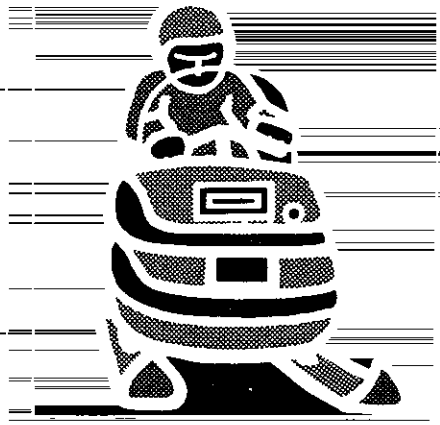
4: 1150 acres

This expression becomes the watershed constraint to meet water quality and riparian MR's, to be considered in all alternatives in the FEIS.

Appendix



APPENDIX I

BEST MANAGEMENT PRACTICES (BMP's) FOR SOIL AND WATER PROTECTION

Soil and water are protected through the use of Best Management Practices (BMP's). **Best Management Practices** are defined as:

> "methods, measures, or practices selected by an agency to meet its nonpoint source control needs. BMP's include, but are not limited to, structural and nonstructural controls, operations, and maintenance procedures. BMP's can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters." (40 CFR 130.2, EPA Water Quality Standards Regulation).

Usually BMP's are applied as a system of practices rather than as a single practice. BMP's are selected on the basis of site-specific conditions that reflect natural background conditions and political, social, economic, and technical feasibility. (EPA Interagency Nonpoint Task Force, 1985).

BMP's are basically a preventative rather than an enforcement system. BMP's are a whole management and planning system in relation to sound water quality goals, including both broad policy and site-specific prescriptions.

Best Management Practices are the primary mechanism to enable the achievement of water quality standards (Environmental Protection Agency 1987). BMP's will be selected and tailored for site-specific conditions to arrive at the project level BMP's for the protection of water quality. The process for determining appropriate BMP's and for ensuring their implementation at both the Forest Plan and Project level is described. Following is a description of the methods and procedures that will be used to control or prevent nonpoint sources of pollution from resource management activities and to ensure compliance with the·

> **Clean Water Act of 1972, as amended (1977 and 1987). Section 319 of the Clean Water Act Amendments of 1987 requires that the States determine those waters that will not meet the goals of the Act. to determine those nonpoint source activities that are contributing pollution, and to develop a process of determining BMP's to reduce such pollution to the "maximum extent practicable." This Appendix is designed to fulfill the intent of the requirements of Section 319.**
>
> **Washington Administrative Code** (Chapter 173-201 and 202). Department of Ecology (DOE). Washington's Administrative code contains water requirements for protection of various classes of surface waters.
>
> > **Memorandum of Understanding:** The Washington Department of Ecology and U.S. Department of Agriculture, Forest Service (7/79), and "Attachment A" referred to in the MOU (Implementation Plan for Water Quality Planning on National Forest Lands in the Pacific Northwest 12/78).

The EPA has certified the Washington Forest Practices Rules and Regulations as BMP's. The State of Washington compared Forest Service practices with these State practices and concluded that Forest Service practices meet or exceed State requirements. As State practices change, comparisons are made to ascertain that Forest Service practices meet or exceed these changes. Monitoring and evaluation will determine the need for changes in BMP's and/or State standards.

Forest Service management practices will meet, as a minimum, the substantive State BMP requirements, and other considerations required by the National Forest Management Act (NFMA), and other authorities, for the protection of the soil and water.

The general BMP's described herein are action initiating mechanisms which call for the development of detailed, site-specific BMP prescriptions to protect beneficial uses and meet water quality objectives. They are developed as part of the NEPA process, with interdisciplinary involvement by a team of individuals that represent several areas of professional knowledge, learning, and/or skill appropriate for the issues and concerns identified. BMP's also include such requirements as Forest Service manual direction, contract provisions, environmental documents, and Forest Plan Standards and Guidelines. Inherent in prescribing project-level management requirements is recognition of specific water quality objectives which BMP's are designed to achieve.

BMP IMPLEMENTATION PROCESS

In cooperation with the State, the primary strategy for the prevention and control of nonpoint sources is based on the implementation of BMP's determined necessary for the protection of the identified beneficial uses.

The objective is to identify the most practical means of attaining water quality objectives Water quality objectives include water quality measures that adequately reflect the needs of identified beneficial uses.

The Forest Service Nonpoint Source Management System consists of:

1. Selection and design of BMP's that are based on site-specific conditions, technical, economic and institutional feasibility, and the water quality standards of those waters potentially impacted.

2. Implementation and enforcement of BMP's.

3. *Monitoring to ensure that practices are correctly applied as designed.*

4. Monitoring to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards

5. Evaluation of monitoring results and mitigation where necessary to minimize impacts from activities where BMP's do not perform as expected.

6. Adjustment of BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluation of the appropriateness of water quality criteria to reasonably assure protection of beneficial uses. Consideration of recommending adjustment of water quality standards.

BMP Selection and Design - Step 1

Scoping: Potential concerns are identified, e g , water quality, as part of the NEPA process for environmental analysis. Public notices are dispersed inviting comment and participation in the process. Alternatives

are developed to address potential problems and to accomplish project objectives.

Environmental Analysis: Each alternative is evaluated for its potential effect on different resources, including water. From this analysis, a preferred alternative is identified, along with the measures (BMP's) needed to reduce risk and increase the potential for success.

Documentation: An Environmental Assessment (EA) or Environmental Impact Statement (EIS) is developed with a decision notice or Record of Decision and includes required measures (BMP's).

Water quality standards are used as objectives towards which practices are designed to protect beneficial uses

Appropriate BMP's are selected for each project by an interdisciplinary team BMP selection and design are dictated by water quality objectives, soils, topography, geology, vegetation, climate, economics, institutional constraints, etc. Environmental effects and water quality protection options are evaluated and a range of practices is considered. A final set of practices is selected that not only protect benefical uses, but meet other resource needs. These final selected practices constitute the BMP's.

The selected BMP's, an estimate of their effectiveness, and a plan for monitoring them is included in the project EA or EIS. The site-specific BMP prescriptions are normally included in project implementation plans, but may also be included in the body or appendix of a project environmental document

BMP Implementation and Enforcement - Steps 2 and 3

The site-specific BMP prescriptions are taken from plan-to-ground by appropriate contract language and a combination of project layout and resource specialists (hydrology, fisheries, soil, geology, etc.). Final adjustments to fit the BMP prescriptions to the site are made before implementing the resource activity.

When the resource activity (e.g., timber harvest or road construction) begins, timber sale administrators, engineering representatives, resource specialists, and others ensure that the BMP's are implemented according to plan. A similar implementation process is used for other resource activities (range management, mining, etc) on National Forests.

BMP implementation monitoring is done before, during, and after resource activity implementation. This monitoring answers the question: Did we do what we said we were going to do? Some examples of implementation monitoring for a streamside management unit BMP prescription may be:

1. **Before project:** Checking Stream Management Units (SMUs) along streams to see if layout meets the objectives of the BMP prescription, or if the road crossing of a stream is properly located and designed per estimates made during the environmental analysis.

2. **During project:** During timber felling, the timber sale administrator checks to see if the timber fallers understand marking prescription for timber to be felled in the SMU. The timber sale administrator also observes on-going harvest operations to see if the activity meets the objectives defined in the project plan.

3. **After project:** Measuring canopy stream shading to see if the amount specified in the BMP prescription was retained, or monitoring a beneficial use of the water to determine a change or trend in use.

Enforcement is carried out primarily through internal project reviews and contractual enforcement e.g., timber sale contract, grazing or special use permit, etc.

Contract enforcement is a more formal method used to achieve desired results Normally, each project is assigned a person as a contracting officer. For timber sales, that person is called a timber sale administrator. The project is routinely monitored to ensure that practices are being carried out in the manner and method prescribed in the contract, permit, etc. When a contractor or permittee is not in compliance, they can be held in breech with penalties (e.g., bond forfeiture) until remedies are implemented.

Often during the course of an activity, adjustments are made if it is determined that unsatisfactory results are currently resulting or may occur. This can often mean that a contract modification may be necessary (as in the case of a timber sale)

BMP Monitoring - Step 4

Once BMP's have been implemented, further monitoring may be done to evaluate their effectiveness. BMP "effectiveness monitoring" answers the question· Are BMP's effectively meeting management objectives for protection of water quality?

Water quality standards are the "yardstick" against which the effectiveness is tested. If, through objective monitoring, BMP's do not meet prescribed objectives, then information is available to modify either the BMP's for future management, or the objectives, or both.

The natural variability of water quality under unmanaged conditions is an important factor that will be considered during the monitoring and evaluation. Additionally, effectiveness monitoring will include measurement against land management objectives as well as water quality objectives.

Some examples of the types of BMP effectiveness monitoring to be conducted are:

1. Measuring stream temperatures to see if the riparian prescriptions in a watershed are maintaining water temperature.

2. Storm period surveillance monitoring of a road system to see if road rocking is effectively preventing road surface erosion.

The monitoring and evaluation section of the Forest Plan, (Chapter 5), provides that monitoring of BMP's will be accomplished on an appropriate sample basis. Once a specific project is designed, a site-specific monitoring plan may be developed.

Results of monitoring should be shared with State and local agencies as well as available to the public. Monitoring design, sampling, and laboratory analyses will be coordinated.

BMP Evaluation and Adjustment - Step 5 and 6

The technical evaluation/monitoring described above will determine how effectively BMP's protect and/or improve water quality. If the evaluation indicates that water quality objectives are not being met and/or beneficial uses do not appear to be receiving adequate protection, corrective action will consider the following three components:

1. **The BMP:** Is it technically sound? Is it really best, or is there a better practice which is technically sound and feasible to implement?

2. **The implementation program or processes:** Was the BMP applied entirely as designed? Was it only partially implemented? Were personnel, equipment, funds, or training lacking which resulted in inadequate or incomplete implementation?

3. **The water quality standards:** The water quality standards are established to protect the beneficial uses of water. They include numeric and narrative criteria that, when exceeded, are assumed to indicate detrimental impacts on beneficial uses. They are intended to provide a benchmark for evaluating harm to beneficial uses.

Assessing the applicability of the standards is a responsibility of the State. The Forest Service will provide information to the State to address the following types of questions.

Do the standards describe the conditions necessary for protecting beneficial uses?

Are standards higher or lower than that necessary for protecting beneficial uses?

Do the standards reflect the natural variability occurring within the natural and human-affected ecosystem?

Do the parameters and criteria that constitute water quality standards adequately reflect (are they sensitive enough) human-induced changes to water quality and beneficial uses?

"Validation" monitoring may be needed to make this assessment. The purpose of validation monitoring is to answer the question whether standards, coefficients, requirements, and guidelines are appropriate to meet objectives, e.g., protect beneficial uses.

Examples: (1) Did the change in water temperature impact the fish population?

(2) Did the soil compaction effect tree growth?

Validation Monitoring will need to be closely coordinated with or, in some cases, conducted by research. It may require the establishment of permanent plots or administrative studies. This kind of monitoring will be very limited and will require coordination to select projects with broad application and to prevent duplication. Only those coefficients and standards that are not reasonably validated by existing research or documentation should be candidates for this monitoring.

Corrective action may be initiated once the reason for failing to achieve the management objectives is determined. The management practice may have to be changed, the water quality objectives modified, or both.

Training

National Forest personnel involved with project location, design, layout, administration, and maintenance activities will receive BMP training. The training will consist of BMP awareness, as well as on the more technical aspects such as planning, implementation, monitoring, and evaluation.

General Best Management Practices and Examples

Individual, general Best Management Practices are described in General Water Quality Best Management Practices, Pacific Northwest Region, 11/88 This provides guidance, but is not a direction document. Also included in this document is a description of the process, and limitations and use of these BMP's. Each BMP listed includes the Title, Objectives, Explanation, Implementation and Responsibility, and Monitoring. Evaluations of ability to implement and estimated effectiveness are made at the project level.

Not all of the general BMP's listed will normally apply to a given project, and there may be specific BMP's which are not represented by a general BMP in this document.

The sensitivity of the project determines whether the site-specific BMP prescriptions are included in the EA/EIS, or in the sale/project plan, or in the analysis files.

Following is an example of a general BMP, as described in this document, along with an example of a site-specific BMP which is developed at the project level.

GENERAL BMP EXAMPLE

T-5. Title: Limiting the Operating Period of Timber Sale Activities

Objective: To ensure that the Purchaser conducts operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC).

Explanation: The TSC specifies a normal operating season, during which operations may be generally proceed without resource damage. Operations are permitted outside the normal operating season only when they can be conducted without damage to soil, water, and other resources. Where determined to be necessary through the environmental analysis, the TSC will limit operations to specific periods or weather conditions. Operations are not permitted to continue if damage will occur.

Implementation and Responsibility: Limited operating periods are identified and recommended during the Timber Sale Planning Process by the interdisciplinary team and followed through the life of the timber sale primarily by the Sale Administrator.

Ability to implement: Add at project level.

Effectiveness: Add at project level

Monitoring: During implementation of timber sale activities by the Sale Administrator, Forest Service Representatives (FSR), Engineers, and Watershed Specialists. Also see Forest Plan monitoring plan, Chapter V, monitoring plan item: Water Resource Monitoring

SPECIFIC MAP EXAMPLE

PT-5. Title: Limiting the Operating Period of Timber Sale Activities

Objective: To ensure that the Purchaser conducts operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC).

Explanation: The Ship Mountain Timber Sale contains sensitive soils that are subject to soil compaction during tractor skidding, and a non-surfaced road that is not suitable for wet weather haul.

The normal operating season for the Forest will be enforced for the Ship Mountain Timber Sale. All operations off road FR 10 (non-surfaced) will be halted at the onset of wet weather to prevent erosion and damage to the road. Tractor skidding on units 1-5 will be restricted if soil moisture is above the level established by the soil scientist. Other operations can continue outside the normal operating season if they can be conducted without damage to soil, water, and other resources.

Implementation and Responsibility: For the Ship Mountain Timber Sale the normal operating season for the Forest will be enforced. All operations off or road FR 10 (non-surfaced) will be halted at the onset of wet weather to prevent erosion and damage to the road. Other operations can continue outside of the normal operating season if they can be conducted without damage to soil, water, and other resources. The forest watershed specialists will work with the timber sale administrators to evaluate the potential for resource damage if operating outside of the normal operating season.

Ability to implement: High.

Effectiveness: High.

Monitoring: During implementation of timber sale activities by the Sale Administrator, Forest Service Representatives (FSR), Engineers, and Watershed Specialists. Also see Forest Plan monitoring plan, Chapter V, monitoring plan item: Water Resource Monitoring

APPENDIX J
FOREST SERVICE RESPONSE TO COMMENTS

This appendix documents the efforts of the Mt Baker-Snoqualmie National Forest to involve and consult with the public during the review of its Proposed Forest Plan and Draft Environmental Impact Statement. Supplemented by Appendix A - which identifies the development of issues, concerns, and opportunities and the public involvement up to December, 1987 - this Appendix presents public participation activities since release of the draft plan. The sections of Appendix J are:

- a description of post-DEIS public participation activities;
- a summary of the analysis of public comments;
- a list of all those who commented on the draft plan and DEIS;
- the substantive comments received and the corresponding Forest Service responses;
- copies of the letters from elected officials and agencies.

SUMMARY OF PUBLIC PARTICIPATION ACTIVITIES

Availability Announcements - News Releases

The Forest began setting the stage for the release of the DEIS and Proposed Forest Plan in December, 1987 There were six separate news releases; the first (12/23/87) included notification of 11 open houses, to be held throughout the Puget Sound area. This was sent to our entire media distribution - about 300. Following the major media briefing on January 4, 1988 (see below), additional news releases were made prior to each Open House (also discussed below).

Three sets of Public Service Announcements were written, produced, and distributed to about eight radio stations prior to the open houses

Two "Forest Plan" reports, distributed to the entire mailing list (over 5,000), discussed the availability of the DEIS. Three additional announcements were mailed to 80 to 100 people.

Federal Register Notice

Published January 8, 1988 The original 90-day review period was extended to May 2, 1988 by the Regional Forester, for a total review period of 115 days.

Distribution of Documents

The complete set of documents included the Draft Environmental Impact Statement, Appendices, Proposed Land and Resource Management Plan, and Public Summary with a packet of Alternative Maps and Resource Maps. Additional packets consisting of only the 65-page Public Summary of the DEIS plus alternative and resource maps were printed. In January, 1988, an Execuyive Summary was prepared for Congressional staff and Forest Service in-service briefings A small brochure, "Forest Planning...A Blueprint for the Future" was also produced. This brochure was used as a handout at the reception offices at all Ranger Districts and the Supervisor's Office, and was also distributed to all employees.

Public Participation

Mailing List

The mailing list for Forest Planning grew from an initial 5,000+ names to 12,484 after the public review period.

Public Meetings

Eleven Open House meetings were held: February 1, 1988 in Everett, 2/3/99 in North Bend, 2/4/88 in Seattle, 2/5/88 in Olympia, 2/10 in Bellevue, 2/11 in Sedro Woolley, 2/12 in Bellingham, 2/17 in Skykomish, 2/18 in Enumclaw, 2/23 in Tacoma, and 2/26 in Darrington All were double sessions, running from 3:00 to 5:00 p.m. and from 6:00 to 9 00 p.m. Forest Service planning team members plus the District Ranger and/or Forest Supervisor, plus additional interdisciplinary team members (such as the wildlife biologist, minerals specialist, etc) were available for questions. There were large displays of the alternatives presented in the DEIS, with documents available to all attendees. The total attendance was over 1,000 people.

Employee Briefings

The Planning Team and Forest Management Team met with all employees, either at the Ranger District or Supervisor's Office during January, 1988. The Forest Management Team met for two full days to discuss the DEIS and Proposed Plan.

Media Briefings

On January 4, 1988, immediately following release of the DEIS, major news media were briefed in Seattle. On that same day, the following groups were briefed in separate meetings: local Congressional Staffs, members of the Liaison Groups (including environmental group leaders, timber industry representatives, and recreation liaison representatives), and Indian Tribal leaders.

During the month of January, one-to-one or small group briefings were held with the Seattle Post-Intelligencer, Seattle Times, Everett Herald, Skagit Valley Herald, Bellingham Herald, Tacoma News-Tribune, and the Daily Olympian.

For background information, a number of fact sheets were prepared, including "Background Facts About the Mt. Baker-Snoqualmie National Forest" and "Old Growth Timber Totals " These were distributed to the media and other key contacts.

Contacts and Presentations to Individuals, Government, and Organizations

Immediately following release of the DEIS, over 200 phone contacts were made

Congressional delegation staffers were briefed in Washington, D.C. January 11-15, 1988. Contacts were made with USDA Forest Service, Washington Office Planning and Legislative Affairs Staffs

Presentations were made to the national offices of the American Forestry Association, Society of American Foresters, and to representatives from the Wilderness Society, Sierra Club, and Natural Resource Defense Council in

Washington, D.C. at this same time. Draft documents, the Executive Summary and "Blueprint for the Future" brochures were distributed to these groups.

The Forest Supervisor and staff briefed representatives from the following State agencies in Olympia, February 5, 1988: Department of Ecology, Department of Natural Resources, the Governor's office, Department of Wildlife, Interagency Commission for Outdoor Recreation, Washington State Parks, Department of Commercial Development, and Department of Fisheries.

The Forest Supervisor and staff briefed several British Columbia (Canada) Provincial ministers and staffs in early March, 1988. Presentations were also made to faculty and campus representatives from University of British Columbia and Simon Fraser University, and to representatives from the Outdoor Recreation Council of B.C., March 1988.

During the course of mailing DEIS information, we used NW Indian Fisheries Commission contacts and mailing lists to directly distribute material for tribal groups.

Throughout 1988 and into 1989, numerous individual or small group meetings (formal and drop-in) were held. Persons briefed included foresters and scientists from the Soviet Union and Japan.

Information Distributed by Others

Flyers were printed and distributed by several organizations, including Washington Trails Association, Earth First!, Public Land Users' Society (a response form), and an 8-page news alert, sponsored by 24 organizations. Copies of these are available in the planning records.

Working Meetings, Post-Release of the DEIS

Working meetings were held with timber industry representatives regarding a series of technical issues raised in their response to the draft documents Meetings started in May, 1988 and were continued into 1989. The Regional Forester and his staff, the Forest Supervisor, Management Team members and the planning team from the MBS, and representatives from industry were involved in the efforts to resolve these timber technical issues. Refer to "Changes Between Draft and Final" in Chapter II, FEIS, FS responses to substantive comments later in this appendix, and to the planning records.

Meetings and presentations were made to Public Land Users Society, including a series of working meetings (February-March, 1989), where board members and specialists in trails, motorized recreation, timber, and wildlife worked to map management areas and identify tradeoffs. This information resulted in a mapped alternative, presented in this FEIS as Alternative I.

Another set of meetings were held with representatives of the Conservation Liaison Group, to clarify their comments to the DEIS and their suggested modifications to Alternative G, now displayed in this FEIS as Alternative G-Modified

In response to public and agency comments on wild and scenic rivers, especially the suitability and eligibility process, the Forest Management Team formed a committee, including representatives from the FS, river rafters, Washington

Public Participation

State Department of Fisheries, Washington Department of Parks and Recreation, and a retired timber industry representative. The committee redefined the eligibility criteria and then reviewed 51 potential rivers, finding 47 eligible. The group then identified the "outstandingly remarkable" values for each of the 47 rivers, and classified into wild, scenic, and recreational segments. More documentation of this work is noted in the planning records

Additional Meetings, Prior to Release of Final Documents

As the analysis for the FEIS neared completion, meetings were held with representatives of timber industry groups to explain the hydrologic cumulative effects analysis, developed as a method to meet water quality and riparian management requirements. Industry was given access to all documents related to the process and its application and feedback was requested. On this same issue, the Forest briefed various officials of the Washington State Department of Natural Resources, including Public Lands Commissioner Brian Boyle

The Forest also met with members of the scientific community and university faculty regarding our hydrologic cumulative effects analysis, in an effort to obtain their ideas on how the process used could be improved. The Center for Streamside Studies, University of Washington have shown a keen interest and generally support the concept.

In early 1990, the Forest also participated in two meetings sponsored by Pilchuck Audubon, discussing Forest Plan issues, the hydrologoic cumulative effects analysis, and Plan implementation.

A SUMMARY OF THE ANALYSIS OF PUBLIC COMMENTS RECEIVED

The Mt. Baker-Snoqualmie received a total of 11,718 inputs (letters, response forms, postcards, reports, etc.) commenting on the proposed plan and DEIS, signed by 12,827 people. This response to the draft plan came from a non-representative, self-selected sample of the public, primarily from five-county area in which the Forest lies.

All written input postmarked by May 2, 1988 was included in the in-depth analysis. The 68 responses received after that date were read and considered by the planning team, though those number are not reflected here.

This summary is taken from the 340-page "Analysis of Public Comment, Mt. Baker-Snoqualmie National Forest, January, 1989 " The larger document is available in the planning records, or as loaner copies, by request In addition, all original letters etc. are maintained in the planning files, Forest Supervisor's office in Seattle.

The Forest used a detailed content analysis process for coding and analyzing the input received. This allowed the team to report what the public said, in their words, using a systematic, objective, traceable, and retrieveable method of analyzing very large numbers of public response

The Forest team "coded" or reported what was said about all issues along with the reasons **why** the respondents felt that way; what people said about the DEIS alternatives and why; and how respondents wanted specific geographic sites (rivers, trails, areas) on the Forest managed.

The results of this analysis were very useful in moving from a draft to final plan and most of the major changes between the DEIS and FEIS are in response to public comment.

Two important points: analysis is not evaluation of public response The decision maker weighs the various comments; it is not a vote-counting process Secondly, public comment is only one factor to be considered in the final decision, along with resource capability, legal, technological, and fiscal considerations.

WHO RESPONDED	# of Inputs	% of Total
Individuals, Families	11,514	98.3 %
Federal Agencies	6	-
State Agencies	3	-
County, City, Local Agencies	4	-
Elected Officials	6	-
Indian Tribes	9	0.1
Environmental Organizations	31	0.3
Timber Industry Organizations	36	0.3
Motorized Recreation Organizations	5	-
Other Recreation Organizations	38	0.3
Chambers of Commerce, Other Groups	17	0.1
Unknown	49	0.4
TOTAL	11,718	99 8%

FORM OF RESPONSE	# Inputs	% of Total	# Signatures
Personal Letter, Postcard	3,484	29 7 %	3,989
Petition	22	0.2	562
Resolution	1	-	1
PLUS Response Form	7,831	66 8	7,883
"Mini" PLUS Form	85	0.7	85
Recreational Mining Questionnaire	43	0.4	39
Other Form Letters	252	2.2	268
TOTAL	11,718	100.0%	12,827

The emergence of the Public Land Users Society (PLUS) had a significant impact on the nature of the input received, especially compared to public involvement efforts of the past (where the majority of input was personal letters.) Nearly 67% of the input received were PLUS response forms. The PLUS form had boxes to check on over a dozen issues with space for comments after many of them

ORIGIN OF RESPONSE	# Inputs	% of Total
King County		
Seattle Metro Area	2,857	24 4%
Rest of County	976	8 3
Snohomish County		
Everett, Edmonds, Lynnwood Area	1,437	12.3
Rest of County (Darrington etc.)	1,220	10 4
Pierce County		
Tacoma Metro Area	619	5.3
Rest of County	620	5.3
Skagit County		
Mount Vernon, Burlington	234	2.0
Rest of County	368	3 1
Whatcom County		
Bellingham Area	536	4.6
Rest of County	205	1.7
Subtotal: I-5/Metro, 5-County Area	**5,683**	**48.6%**
Subtotal: Rural, 5-County Area	**3,389**	**28.8%**
Vancouver, BC	7	-
Rest of Western Washington	1,531	13.1
Eastern Washington	566	4.8
Oregon	277	2.4
Other States	163	1.4
Rest of Canada, Other Countries	4	-
Unknown	98	0.8
TOTAL	11,718	99 9%

Over 50% of the personal letters originated from the Seattle metropolitan area. PLUS response forms came primarily from from the I-5, metropolitan area (39%), the rural 5-county area (35%), and the rest of western Washington (16%).

The Alternatives

A majority of those responding had an opinion about the alternative plans for management of the Mt. Baker-Snoqualmie National Forest. Only 1,436 of the 11,718 inputs did not speak to at least one alternative.

Three alternatives generated the most comment: support for the PLUS Alternative, as outlined on the PLUS response form [and described in more detail in the PLUS organization response]; support for Alternative G [as presented in the DEIS, and also as modified by the conservation groups in a published flyer]; and opposition to Alternative H, the Forest Service preferred alternative in the DEIS. A number of people also supported Alternative C.

The PLUS response form included a box labeled "another alternative" which, although not defined, was supported by nearly 400 people. [The other alternative choices presented on the PLUS response form were the PLUS Alternative and Alternative H.] Few people commented on Alternatives NC (No Change), B (the RPA alternative), D, E, E-Departure, F, or H-Departure.

In developing a Preferred Alternative for the FEIS, the Forest Management Team was interested in why people felt the way they did - what their major concerns and desires were, rather than "counting votes." Refer to the January 1989 document.

As respondents often discussed more than one alternative, nothing can be tallied from the figures presented in the following table

OPINION ABOUT THE ALTERNATIVES

Alternative	Like, Support	Dislike	Needs Modification	2nd Choice	No Clear Opinion
NC (No Change)	12	11	0	1	6
A (No Action)	41	15	2	2	4
B (RPA)	18	11	6	0	2
C	264	8	68	14	4
D	9	15	4	3	5
E	7	8	3	0	1
E-Departure	4	6	0	0	1
F	6	11	2	0	1
G	1,711	18	120	28	7

Combine H & PLUS	16	0	1	0	0
"Another" Alt	382	0	2	0	1
A New Alt.	10	0	1	0	0

Summary of Analysis of Comments

The Major Issues

The heart of the analysis effort was coding and analyzing public opinion about issues and the reasons they felt that way. Comments such as "Build more roads" or "Protect the old growth" are opinions; reasons might be "for recreation" or "for wildlife habitat."

Recreation and trails generated the greatest volume of comments· over 68,000 comments. There were 15,000 comments in the general area of timber/vegetation, 14,000 on owls and wildlife; and 4,000 on old growth. The numbers for types of comments reflect, in part, the design of the PLUS response form. The "Recreation Opportunities" section of the form had boxes to check for "more" "less" or "the same amount" of various recreation activities However, even without these comments, there were over 32,000 comments on recreation and trails

Other issues generating considerable response included: roads, roadless areas, wild and scenic rivers; the Backcountry Area proposal; old growth, owl habitat, and wildlife; timber harvest level and jobs; deficit sales; log exports; and a wide variety of technical planning process comments.

Areas of Consensus

From the written comment received, two areas of general agreement stood out. first, recreation is a vitally important function of the Mt Baker-Snoqualmie National Forest. Second, we need more trails; opinion varied on who should use those trails.

Substantive Comments

An important note: the reader should review the substantive comments as well as the following list of opinions on major issues For example, cumulative effects of management activities and fisheries both appear as issues of major concern from State and Federal agencies and Indian Tribes. In addition, timber supply and technical issues have been raised as a major concern among timber industry and other respondents. The numbers reported below do not necessarily include the comments identified as substantive and responded to by the Forest Service.

A substantive comment, as defined in FSH 1909 15, is "factual information, professional opinion, or informed judgement " Every letter was screened for substantive comments prior to coding; additional comments were identified during coding/checking The substantive comments were entered, verbatim, into a separate data base - organized by issues or topics. Refer to the last section of this appendix for the substantive comments and Forest Service responses

Public Comment on the Issues

Included below are all of the comments made about issues, concerns, and other topics. The wording for each comment is that used by the respondents; if more than one way to stating an opinion was coded, it was included Refer to the January, 1989 document for selected reasons to support opinions.

GENERAL	Number of Inputs Mentioning This Opinion
Must preserve and protect the Mt Baker-Snoqualmie. Preserve forest for the sake of the earth itself. Preserve NF for non-consumptive uses. Preserve our remaining forest land.	793
Preserve and protect the scenery of the state.	118
Must change policies, natural resources are finite.	105
Stop over-development of public lands.	25
Tired of mismanagement of national forests. Forests don't need to be managed; do well on their own	98
Coordinate ecosystem mgt. between Park land and NF land. Consider the proximity of National Parks.	20
Management should be along ecosystems approach. Main focus of plan must be on ecological integrity of forest If delicate balance of forest disturbed, will set off a chain reaction that ultimately affects man. We don't own the earth!	250
Time to manage forest in a balanced way.	158
Manage forest using a balanced mix of conservation and recreation	129
Time to set an example of aggressive forest preservation for the world.	55
Moved here/live here for the scenic beauty, and the environment; don't destroy it	260
Forest vital to the state as a tourist attraction. Most important future values of this region are recreation, wildlife habitat, high water quality, and fisheries.	89
Leave land open to all of the people. Don't restrict access. Leave public lands open Let all people use the forest.	339
There is plenty of acreage set aside for the enjoyment of everyone.	18
Manage for the most benefit for the most people. Give priority to whatever uses benefit the most for the long run.	37
GENERAL - MULTIPLE USE	
Manage via the multiple use concept.	144
Make it all multiple use (timber emphasis).	26

GENERAL - MULTIPLE USE, continued	Number of Inputs Mentioning This Opinion
Save public land for multiple use; let timber companies rely on their own land.	12
FS doesn't know the meaning of multiple use-only timber harvest. Forest Service has lost sight of the true meaning of multiple use. Return to original mandate of multiple use of public lands - need to address the imbalance of budget, staff, & resources for timber/rds.	61
Nonwilderness lands should be released for multiple use	76
Nonwilderness lands should NOT be released for multiple use.	8
1984 Wilderness Act released these lands for multiple use; timber and mining companies are concerned nondevelopment will limit commodity production, have adverse effect on local communities, and lead to future wilderness.	51
Disagree with above statement.	12
Multiple use is OK but not all uses on every acre - segregate users. Not all sites are suitable for all mgt. activities; select best use for individual sites.	6
Timber harvest & recreation are of equal importance.	7
GENERAL USE	
17% of the Forest open to recreation use and full commodity production is not enough.	6,604
17% of the Forest open is enough.	723
17% *open is too much.*	29
25% open to recreation and full commodity production is (or should be) enough.	35
50% open to both is (should be) enough.	22
At least 50% should be open to both recreation and commodity production.	463
Keep 100% of the Forest open to recreation use, commodity production	50
Full commodity production destroys forests.	2
More emphasis on commodity production, less on recreation.	19
Leave 70% untouched, develop easiest 30% for access to areas of interest.	4
"VALUES"	
Values for resources other than timber are not considered Forest is more than timber.	146

"VALUES", continued	Number of Inputs Mentioning This Opinion
I understand the economy of the area depends somewhat on timber, but for most people, the value of the forest is greater if left intact.	
Recreation offsets loss of harvest.	16
Recreation value is undervalued. Recreation is a commodity too; treat it as such. Don't sacrifice recreation values to logging.	48
Roadless area values far outweigh commodity values.	7
What about fishing, why all the emphasis on timber? Fishing values have been overlooked. Commercial fishing is important to the NW economy. Fisheries should be a major ICO.	46
Don't road and log lands that are steep, expensive to road and have old growth, roadless recreation, wildlife, and Indian values just to log small areas that may be suitable.	1
Comparing tables of costs, the value of municipal water exceeds that of the timber sold.	1
RECREATION	
Recreation is an issue of concern to me (PLUS).	5,012
Focus of forest should be on recreation.	136
Consider recreation assets first, not timber More emphasis on recreation, less on commodity production.	202
Manage forest using a balanced mix of conservation & recreation	129
Recreation use is increasing greatly.	57
More dispersed recreation. Need backcountry recreation.	53
More recreation opportunities needed.	126
More motorized recreation opportunities needed. Not enough roaded recreation.	89
Enough roaded recreation already.	23
Enough recreation	14
Don't restrict recreational development. Keep roads, trails, and campgrounds open.	53
Don't need new campgrounds - maintain present ones. Angered and disgusted by the deterioration of recreation facilities Restore old campgrounds.	36

RECREATION, continued	Number of Inputs Mentioning This Opinion
More campgrounds needed. More developed recreation opportunities are needed.	159
Campsites along main roads with walk-in access only	7
Need greater areas for recreation in natural areas, primitive forest.	47
Disagree that there is enough roaded recreation lands to meet demand, but not enough land for unroaded, nonwilderness recreation.	44
Agree that there is enough roaded recreation lands to meet demand, but not enough land for unroaded, nonwilderness recreation.	26
Demand for roaded recreation will exceed capacity within 10 years.	48
Demand for roaded recreation will not exceeded capacity.	17
Willing to pay user fee to gain access to all NF lands.	37
Hikers should pay user fees, pay for use of trails.	18
Oppose a permit system for outdoor recreation	13
Favor use of permits for recreation.	9
Assess a stumpage surtax to fund recreation management.	1
Emphasize importance of education. Our kids need to see how the forest works on it's own.	42
FS should have a continuing program of public education for hiking, camping, etc.	18
Favor use of volunteers (or youths) for trails construction, fish and game projects, etc Expand the "adopt a _____" program.	66
More fishing	4,195
Less fishing.	118
Same amount of fishing.	2,321
More hunting.	3,291
Less hunting	443
Same amount of hunting.	2,652
No hunting.	6
More camping.	5,196
Less camping.	68

RECREATION, continued	Number of Inputs Mentioning This Opinion
Same amount camping.	1,525
More hiking.	4,174
Less hiking	229
Same amount hiking.	1,997
More skiing.	32
Enough ski areas. Amount of skiing available is fine.	3
More X-C skiing.	36
More trapping opportunities.	6
Favor (more) rockhounding opportunities.	66
More mountain bike opportunities.	23
Less mountain bikes/opportunities.	10
More climbing opportunities. Want climbing opportunities.	3
Recognize that winter recreation differs from summer recreation. Note that snowmobiling is different from ORV use	14
Provide and develop more opportunities for winter recreation.	30
More private recreation facilities/opportunities.	7
Discourage establishment of private resorts, organization camps.	5
Allow seaplane landings in high-elevation lakes.	1
Support signposts at trail junctions, trail mileages and registry at trailheads.	12
Support parking (at trails)	5
Preserve all existing fire lookouts	3
Maintain current opportunity levels for boating/rafting.	2
Manage campgrounds for "primitive" settings - lots of big trees.	6
Focus of Forest should be 85-90% on hiking because there are more hikers than people who use vehicles for recreation	4

Summary of Analysis of Comments

ORV's, MOTORBIKES or TRAIL BIKES, SNOWMOBILES	Number of Inputs Mentioning This Opinion
No ORV use. Ban ORV use on public land.	124
No ORV's on trails.	519
Support limiting motorized use on trails.	45
Less ORV use in general. Minimize ORV use.	758
No ORV's off paved roads.	12
Keep logging roads open after harvest for ORV use.	5
Restrict size and type of motorbikes.	3
Ban snowmobiles.	7
Segregate all users.	47
Build areas just for ORV's, away from hikers and environmentally sensitive areas.	59
Manage primitive travelways over 40" wide for 4WD.	4
Set up a few well-deliniated areas.	21
More areas for ORV's. More ORV use in general. ORV trails for 4 x 4.	3,389
Keep existing areas open to ORV's. Same amount ORV use.	1,773
Don't cut trail mileage for motorcycles.	9
More areas for motorbikes.	64
Less areas for motorbikes.	9
More snowmobile opportunities.	3,056
Less snowmobile opportunities.	485
Same snowmobile opportunities.	2,117
Draft Plan not consistent with existing snowmobile agreements.	40
Need effective controls on ORV use.	21
If ORV and 4x4 clubs want more facilities, they should bear the cost of construction and maintenance.	8
Permit snowmobile use in Mgt. Area 1B, semi-primitive nonmotorized.	6

ORV's, etc., continued	Number of Inputs Mentioning This Opinion
No ORV's in unroaded areas, RNA's, Botanical Areas.	2
No ORV's on trails leading to wilderness.	2
TRAILS	
More trails in general More areas need trail access	269
By the year 2000, restore the trail milage of the 1940's. 2000 miles of trails by the year 2000	15
More trails, not logging roads.	23
New trails should be developed and the old ones upgraded (to give access to greater number of people).	6,995
More non-wilderness trails.	17
More wilderness trails.	55
Need more low-elevation trails. High priority to the construction of lowland trails More close-in trails	38
Allow llamas on trails; their impact is minimal.	1
More trails for hikers only	80
More trails for horse use (hikers too) More horse / hiking trail access MOre horse use/ packing.	149
More multi-use trails. Don't limit trail use to only one group.	110
More trails, fewer roads.	27
High priority for maintaining present trail system. More maintenance of existing system.	117
Protect all existing trail miles/corridors.	35
No new trails, just maintain the existing system.	176
No new trails needed	735
Too many trails	1
Timber sales shouldn't obliterate trails. Detest hiking through clearcuts. Wouldn't need such a large trails program (spending taxpayer money) if if old trails weren't wiped out by logging and roads.	264

TRAILS, continued	Number of Inputs Mentioning This Opinion
More close-in, easily accessible trails for nonmotorized use only.	9
Use road money for trail building Transfer money from road building to trail development.	16
Willing to pay (like the sno-park system) for maintenance of trails and construction of new trails	8
Add to interpretive trails, to educate our young.	5
More trails in old growth.	12
Restore trails that are now roads Close roads and restore the trails that were there before.	11
No livestock on trails.	3
Less horse use on trails. Fewer trails open to horses.	3
Don't want any access to wilderness.	6
Reopen abandoned trails.	17
Build more primitive backcountry/roadless area trails.	2
ROADS, MOTORIZED ACCESS	
Build more roads. Not enough roads yet. More access Don't have too many roads	4,266
Fire roads essential	15
More motorized access should be provided to roadless areas to encourage recreation	6,324
Don't close roads, keep open.	111
Access developed through timber harvest allows more people to enjoy recreation	208
Build more roads, but no timber harvest	5
Build more roads, but use more road closures.	9
General: oppose roads.	43
Same [number of miles] roads.	14
No new roads. Already enough roads Already enough motorized access.	213

ROADS, MOTORIZED USE, continued	Number of Inputs Mentioning This Opinion
Too many roads. Fewer roads.	1,117
Must limit density of roads open to the public [to lessen impacts on wildlife.]	2
Road density of 2 5 miles/sq mile is too high; should be closer to 1 mile of road/sq. mile.	2
Greatly reduce the number of roads being built Reduce road building.	90
No new arterial or collector roads in roadless areas.	17
No motorized access to roadless areas to encourage recreation.	1,337
No new roads, just maintain the existing ones for cars and ORV's.	34
Spur road construction phased out after 15 yr. logging phase out.	2
Expansion of road system should be carefully controlled.	44
Less access to roadless areas.	9
Ban on new roads in roadless areas.	34
Put roads in the roadless areas as soon as possible: will spread out load on other roads, better for water quality	3
Roads/road construction contribute to siltation, stream degradation.	77
Existing roads need to be upgraded/maintained Reopen roads, logging roads.	59
Close/bar/remove logging roads upon completion of harvest, and revegetate the roadbed.	48
More pullouts on existing and new roads for camping, viewing, etc More loop roads with scenic opportunities, pull-outs for viewing, etc.	16
Close roads [for areas endangered by overuse - or to prevent wildlife harrassment.]	39
No new roads in riparian areas Consider closing roads in excellent riparian areas.	3
ROADLESS AREAS	
Save the roadless areas. Preserve existing roadless areas.	562
More wild areas needed. Expand roadless areas.	33

ROADLESS AREAS, continued	Number of Inputs Mentioning This Opinion
Want large contiguous blocks of roadless area.	17
Add these areas to wilderness.	11
Develop the existing roadless areas.	42
Too much roadless area now.	14
Roading backcountry areas increases pressure on wilderness, causing its deterioration.	39
Oppose any plan to reduce areas suitable for wilderness recreation to to such an extent that a permit system is needed. Don't restrict visitor access in backcountry.	32
I support the 16 roadless areas in Alternative G.	3
Don't enter any roadless area until complete study of old-growth dependent systems and future recreation demand/use is complete.	2
SPECIAL INTEREST AREAS	
More special interest areas. More special areas.	13
Protect special interest areas	23
Full acreage of all special use areas should be designated as such.	40
Protect botanically fragile areas/unique flora.	8
RESEARCH NATURAL AREAS	
All five potential RNA's should be recommended for designation	26
Full acreage of all RNA's should be designated as such	54
More RNA's.	13
RNA's are an important link to biological diversity	2
Keep present RNA's.	3
RNA's are not compatible with nonmotorized recreation	2
No timber harvest/salvage of any type in RNA; much can be gained studying natural regeneration following catastrophe.	2
WILDERNESS	
No more wilderness. No more wilderness additions. Have enough wilderness. Amount of wilderness should remain the same.	254

WILDERNESS, continued	Number of Inputs Mentioning This Opinion
Abandon wilderness areas. Repeal 1964 Wilderness Act.	7
Less wilderness. Too much wilderness	24
More wilderness. Keep more in wilderness. More sections of the National Forests should be placed in Wilderness.	88
Demand [for wilderness] will exceed capacity within 10 years.	37
Demand won't exceed capacity	18
More wilderness reduces rockhounding activities	62
More wilderness does not reduce rockhounding activities.	5
Preserve/maintain wilderness.	141
Wilderness capacity levels are way too low; let capacity expand or contract with demand	3
Dedicated Trailless areas are not needed. Dedicated trailless seems too restrictive. Zero disturbance seems unachieveable.	7
Capacity coefficients are in error. especially General Trailless.	4
Expand Dedicated Trailless. Protect/maintain Dedicated Trailless	15
Areas designated wilderness should be totally restricted from human use or entry.	3
Oppose Supplement 81. More development of wilderness for recreation (trails, roaded access, etc.)	7
Wilderness areas on the Forest are incomplete, they need low-elevation old growth forests to make them complete recreational experiences and ecological units.	10
Wilderness permit system needed	6
Allow way trails. Don't obliterate user-made trails.	8
Don't expand any of the adjacent national parks.	2
Keep wilderness group size at 12; any smaller will compromise safety Party size of 12 should be the maximum.	2
Limit visitors as a last resort - more/improved trails, advertise less-impacted areas, and employ user education instead	3

WILDERNESS, continued	Number of Inputs Mentioning This Opinion
Exclude outfitter guides/commercial use from off-trail areas. Tighten regulations on outfitter guides.	3
WILD AND SCENIC RIVERS	
Add more wild and scenic rivers in general. Too few rivers	151
Forest Service has mixed up eligibility and suitability process resulting in too few rivers eligible Suitability criteria used in making eligibility determination results in too few rivers	13
Add the wild and scenic rivers of Alt. G. Add to W & S the 47 rivers of the conservation alternative.	336
Designate all rivers with over 450 cfs. as wild and scenic.	2
Amount of land allocated to W&S rivers should remain the same.	69
No logging adjacent to wild and scenic rivers.	15
No more additions to W & S rivers - there are enough protected	23
No Wild and Scenic Rivers	2
All rivers of Alternative G should at least be studied, drop later if need be. All potential rivers should at least be studied	6
Don't break river systems up, tributary streams should be considered with the mainstream.	5
RIVERS, GENERAL	
Protect river systems	132
Reallocate more water to instream uses	1
WATER, WATERSHEDS	
Protect vital watersheds, is important, especially in times of drought	90
Timber, energy, mining development can occur and any adverse impacts to water supply/quality or fisheries can be mitigated	54
Disagree that the impacts on water from timber, mining, and energy can be mitigated.	10
Rockhounding is not detrimental to water quality.	8
Increased wildlife populations in watersheds will increase the risk to water quality	2

WATER, WATERSHEDS, continued	Number of Inputs Mentioning This Opinion
Maintain water quality above present levels.	5
Maintain current management direction of municipal watersheds.	4
Replace "other" municipal sources with subsurface systems (wells).	1
More emphasis on the value of water to the State and region	6
No new restrictions, just maintain what we're doing today.	3
Support limited recreation opportunities in watersheds.	1
SOIL, SOIL EROSION	
Increase efforts to control soil erosion.	28
Avoid roadbuilding and logging in areas with unstable soils, steep slopes	50
Roads/road construction contribute to siltation, stream degradation.	77
Harvesting depletes soil nutrients.	17
Protection of soil/topsoil and site productivity is of top importance.	3
OLD GROWTH	
Save the old growth Leave the old growth alone. Don't sacrifice the old growth. Prefer to see some old growth left in our forests	1,087
Stop all old growth logging. Save all remaining old growth Total ban on harvest of old growth	755
Need a moratorium on harvest of old growth.	62
Protect low-elevation old growth	332
No old growth harvest, harvest second growth instead. Retool mills to use second growth	81
Preserve old growth in sizeable, contiguous chunks. Manage for forests with large, high quality trees (long rotations, diversity of species)	145
Need to manage to increase the amount of old growth.	20
Continue the harvest of old growth.	44
Need to retain corridors of old growth Should be linked areas of old growth. Leave old growth areas connected to each other.	452

OLD GROWTH, continued	Number of Inputs Mentioning This Opinion
Need a valid definition of old growth. Old growth definition shouldn't be tied to tree size. Old growth needs 32" trees not 21" trees.	338
Don't change the definition of old growth'	1
Need an updated mapping of the old growth with field verification Old growth map is 10-15 years out of date.	258
Old growth inventory is flawed; less than 1/2 the acres are truly old growth. Acres of old growth are over-estimated. There is far less old growth than FS claims, FS acre figures include much that is not in old growth ecotype. Forest Service included much second growth as old growth, so public doesn't know just how little true old growth there is.	88
Less old growth harvesting will increase utilization and production of small woodlots.	5
Don't harvest old growth cedar.	4
We like 2nd growth: it provides oxygen, wildlife habitat, is pretty.	20
There is plenty of old growth in wilderness; we're not harvesting it all.	9
Need buffers around old growth stands to protect from blowdown.	4
All old growth and mature forest areas should be designated wilderness.	4
SPOTTED OWLS	
Less emphasis on owls. Less acres for owls. Don't lock up more areas for owls	68
More emphasis on owls and owl habitat. Protect spotted owl habitat. [No timber harvest in SOHA's.]	350
Same amount of emphasis on owls.	6
Enlarge SOHA's.	53
Enlarge SOHA's to at least 4,000 acres.	84
SOHA's should be at least 2200 acres in size, maybe up to 4000 acres	1
Should be 3800 acres in size	1
SOHA's should be enlarged to between 3,800-4,500 acres.	3
Enlarge SOHA's to 4,500 acres.	449

SPOTTED OWLS, continued	Number of Inputs Mentioning This Opinion
SOHA's should be larger than 4500 acres.	12
Increase number of spotted owl pairs.	12
More areas for old-growth dependent wildlife, above the MMR level; estimate 30% more needed for replacement areas (for falldown, fire loss etc.)	1
Continue studies, continue harvest until studies are conclusive. Study owls before deciding on a land allocation.	23
Current spotted owl MMR's are inadequate. SOHA's are inadequate due to location and elevation. SOHA's are misplaced.	77
Protect known SOHA's (currently occupied). Protect areas with nesting owls. Conserve trees with nesting owls.	72
Add spotted owl to the T&E list.	10
SOHA's need to be located below 4,000' but below timberline. Emphasize low-elevation SOHA's.	19
High elevation areas with no snags, downed logs, broken tops etc. and isolated areas of large trees can't qualify as habitat.	22
Designate 142 SOHA's averaging 2200 acres each.	2
SOHA's of about 220 acres, and a network of 82 SOHA's.	1
Should protect owl habitat using "managed" prescriptions rather than the dedicated area approach.	2
Be conservative in management, with current lack of knowledge, it is foolish to back any plan based on unfounded techniques like "managed old growth." Pleased to see the MBS used dedicated MMR habitats.	7
No livestock or ORV's in MA's 11 & 12.	1
WILDLIFE	
National Forest management should focus on wildlife. Manage the National Forest for all species Emphasis on wildlife protection. Maintain a high level of wildlife habitat.	330
Increase potential population levels for cavity nesters to at least 40-60%.	10
Need dedicated snags in every timber sale.	3
More emphasis on non-game species such as owls and woodpeckers.	1,190

WILDLIFE, continued	Number of Inputs Mentioning This Opinion
Less emphasis on non-game species such as owls and woodpeckers.	5,108
Same amount of emphasis on non-game species.	34
Need more game and fish enhancement projects. Work on habitat rehabilitation.	4,897
Need less game and fish enhancement projects.	647
Fish and game programs are adequate. Present wildlife programs are adequate.	27
Fish and game programs inadequate.	4
Fish and game enhancement benefits non-game species too.	2
Plan only pays lip-service to protecting/preserving grizzly habitat	9
Would like to see MMR's for grizzly, wolf, wolverine, bald eagle, fish	9
Reintroduce native species Manage to encourage recovery of all native plant and animal species to historic levels.	50
Encourage study of grizzly bear and wolf; don't preclude reintroduction.	1
Reintroduce wolves.	16
Reintroduce grizzly bear.	13
Do not reintroduce the grizzly bear.	2
Protect any areas that may be habitat for indicator species. More indicator species needed. Not enough indicator species.	16
There are no indicator species for wetland/riparian sites	11
Plenty of land's set aside to protect endangered wildlife, habitat.	13
Give more protection to T & E species. *Recover T & E populations.*	16
Timber harvest generates better game and wildlife habitat.	41
Timber harvest generates better game habitat only for a few years.	2
More management indicator species for management of wetlands, riparian areas.	3
Monitor species to ensure man's impact does not endanger their existence.	4
Don't kill bears to protect trees; Smokey will be angry!	3

WILDLIFE, continued	Number of Inputs Mentioning This Opinion
Manage wildlife for maximum biological potential.	23
Wildlife populations should be managed for maximum natural populations instead of reduced to MMR status to over-emphasize timber.	3
No trapping, predator control.	25
Trapping is an important sport but also a big income generator.	2
Deer and elk may prefer thermal cover, but research shows it is not a requirement. Extensive acres of old growth not needed to maintain viable populations for most species.	7
The pileated woodpecker is not an appropriate indicator species for old growth/mature forest dependent wildlife.	1
There is no biological justification for using owl, piliated woodpecker, marten, deer, elk, mountain goat, and primary cavity excavators for indicator species.	2
Protect winter habitat.	21
No harvest in mountain goat habitat.	2
Revegetate/improve habitat with native plants species, not exotics.	8
Use should not be restricted if an area is suspected mountain goat habitat, but no goats are present.	3
FISH, RIPARIAN HABITAT	
Increase natural salmon runs. Conserve and improve migratory fish populations.	32
More fish hatcheries.	10
No more hatchery fish!	3
Protect fisheries!	74
Potential value of in-stream fishing not recognized.	5
Impacts on sea-run trout and steelhead, which are considerable, are not addressed.	3
Nearly all salmon produced in Puget Sound are affected by water from the National Forest, not just 50%	6
Work on aquatic habitat rehabilitation.	17
More emphasis on non-degradation of habitat rather than restoration.	12

FISH, RIPARIAN HABITAT, continued	Number of Inputs Mentioning This Opinion
Rehabilitate all streams for natural anadromous fish passage.	15
Fully mitigate for wildlife and fisheries losses due to logging.	5
Phase out all logging, especially in sensitive areas (such as stream, creek drainages.)	15
In logging areas, leave a 200' buffer, or more, along trails and streams.	71
Timber, energy, mining development can occur and any adverse impacts to water supply and quality, and to fisheries, can be mitigated.	54
Protect, don't destroy riparian habitat.	82
More fish stocking.	20
Less fish stocking.	6
Existing fisheries data is too broad, out-of-date, inaccurate, doesn't tie to individual river systems. It is hard to draw conclusions from the Plan.	14
Plan does not take into account the effect of timber harvest level on fish populations.	13
More emphasis on resident fish.	3
More emphasis on wild fish.	4
There is no discussion of HOW fish habitat restoration and enhancement will be accomplished. Production is not simply a function of the amount of money spent. It is assumed that use of mitigation will offset fish habitat losses from forest activities This belief is contrary to commonly-held opinion among fisheries-management agencies. Disturbed that there is so much emphasis on artificial spawning techniques and habitat manipulation for anadromous fish - these are unproven methods.	18
No ORV's, livestock in riparian areas. Livestock has serious effects in riparian/wetlands.	1
SCENERY, VISUALS	
Give up scenery in viewsheds to protect larger old growth blocks.	11
Important to pay attention to both foreground and middleground of visually sensitive landscapes. More control must be exerted to prevent clearcutting in the view areas. Be extra-sensitive to visual quality in major travel corridors.	52
Eliminate harvest reductions based on visual classifications.	3

SCENERY, VISUALS, continued	Number of Inputs Mentioning This Opinion
Scenic viewsheds/visual corridors (2AB) seem designed to hide what's going on over the 1st ridge (a flattened moonscape).	28
Visual management only in foreground of major travel routes.	10
No created openings larger than 60 ac. without public consent, Regional Forester OK.	1
PLANTS	
Make more thorough inventory of plant communities/rare plant habitats.	19
Assess the real effects of Plan on sensitive native plant communities.	44
Develop a management and recovery plan for sensitive species.	1
More strict guidelines for commercial plant and mushroom gathering Document impacts of mushroom gathering, provide guidelines and limits before fungi become endangered.	14
Manage for undergrowth and trees. Manage for diverse plant communities (mushrooms,etc.).	29
Need more cedar. Plant cedar.	4
Preserve, don't cut/convert to conifers all significant stands of hardwoods.	1
Protect native plant species.	10
Protection of highly unique and important native plant communities and wild ecosystems of the MBS is an issue of national significance.	1
TIMBER	
More timber harvest.	153
Don't cut back on harvest levels. Harvest level has shrunk enough. Keep level as it is. Don't reduce ASQ.	207
Older forests are no longer growing; should be cut and replaced.	4
Timber harvest level is an issue of concern to me.	3,712
Realistic timber harvest levels provide and maintain jobs and recreation opportunities.	615
No declining flow on the Forest!	1

TIMBER, continued	Number of Inputs Mentioning This Opinion
NF are meant to be working forest. Resource producing lands should be utilized to the fullest. Timber is a crop, should be harvested when ripe.	75
More cedar sales needed.	4
Increase harvest in proportion to population growth. Set harvest level commensurate with anticipated demand.	12
Logging important to NW economy. Timber harvest important.	144
Keep harvest level the same; keep things as they are.	41
Concentrate on replanting. Land should be reforested.	176
Harvesting and replanting will provide for the needs of the future. Reforestation, cleaning up will provide forests for our children and their children	51
Less timber harvest. Timber is almost gone, must slow down harvesting. Current logging practices diminished.	427
No timber harvest	109
Phase out all timber harvest after 10-15 years	15
Keep logging in areas that are already developed. Limit harvest to tree farms and areas grown for harvest. Better utilization of existing harvest areas.	131
Reduce harvest by 30%.	3
Reduce harvest by 40-50%.	1
No logging on mountains, hill or ridge tops or within 1/2 mile of these areas. No logging on ridges.	23
Restrict all harvest in the high country.	18
Avoid intensive logging.	11
Intensively manage all suitable lands for timber production, maximum productivity.	1
Timber companies should not be allowed to take their land out of production for subdivisions or residential development.	17
Let the market determine the harvest level. Let demand determine timber supply.	54

TIMBER, continued	Number of Inputs Mentioning This Opinion
Demand exists and will be worse in coming years as private timber production declines. Demand for MBS timber will increase as other NF propose reductions.	6
Reduce harvest level to at least as low as 128 MMBF. Reduce ASQ to level of Alternative G: 128 MMBF.	504
Support ASQ of 140 MMBF.	3
Timber harvest at 200 MMBF	25
Timber harvest at 220 MMBF.	4,589
Timber harvest at 253 MMBF. (TSPQ)	2,273
Timber harvest at "179 MMBF, Forest Service's Alternative H, adjusted for spotted owl impacts" (PLUS)	428
Timber harvest level as in Alternative H.	2
Timber harvest below 120 MMBF.	14
Support an ASQ of 88 MMBF (Alternative C).	*14*
ASQ of 70 MMBF.	1
Gradually decrease the timber harvest (over 80 years) to 100 MMBF.	1
Oppose clearcutting when so poorly planned, causing damage to area. No clearcutting.	404
Use selective logging as much as possible Supportive selective harvest, leading to multi-species, and a multi-generation forest.	95
Favor selective logging by helicopter to reduce impacts on resources.	8
Oppose even-aged monoculture. More emphasis on planting mixed species, not exclusively Douglas fir.	36
Favor sustained yield. Harvest level should be based on sustained yield concept. Use FS idea of sustained yield - it's still good.	176
Forest should be managed on the "sustained yield" principle, unlike Forest Service's past practices of overharvesting. Industry has been greedy, could have had true sustained yield at one time with sustained industry and jobs.	60
Timber harvest more efficient in South & SE; should get timber there.	9
Limit logging adjacent to National Parks/wilderness.	2

TIMBER, continued	Number of Inputs Mentioning This Opinion
No logging adjacent to National Parks/wilderness.	47
No logging adjacent to wild and scenic rivers.	15
Need a sensible amount of timber harvest, not a radical position on either side.	34
Use timber harvest practices that are less wasteful.	37
Do more thinning.	2
Harvest level at the timber industry's last 10-year average rate.	3
Harvest as little timber as possible. Minimize timber harvest.	82
Harvest rotation must be no less than 125 years. Use longer rotations.	21
Avoid logging where upstream flooding is likely to occur.	6
Timber companies should bear the cost and responsibility for rehabilitation of logged areas: stream cleanout, erosion control, etc.	10
Areas for recreation and areas for timber should be larger and fewer rather than smaller and scattered throughout the Forest	4
Preserve lowlands, rivers, river valleys, and lakes for recreation; harvest sides and tops of surrounding hillsides.	3
Suitability of this Forest to produce timber is minimal at best. Too much non-suitable included in the "tentatively suitable" base. Plan assumes acres that have been cut are being returned to a condition suitable for future harvest - doesn't take into account poor past management.	29
More timber sale inspection to ensure compliance with environmental protection requirements and prescribed sale practices, requirements	17
Educate people on positive aspects of timber harvest; look past obvious visuals and promote positive attitudes.	9
Educate people about the environmental costs of wood products consumption.	1
MOUNTAIN HEMLOCK	
No logging in Mtn. Hemlock zone. Remove the Mtn. Hemlock zone from the suitable land base.	28
Stop the Mtn. Hemlock study.	19
Include mountain hemlock zone in the suitable land base.	14

MTN. HEMLOCK, continued	Number of Inputs Mentioning This Opinion
The environmental impacts of this study have not been analyzed under NEPA; need a full EIS.	2
Mtn. Hemlock study is a good idea.	3
RESIDUE, WOOD UTILIZATION	
Favor more effective use of wood. Recycle.	42
Encourage cellulose-bearing plants other than wood (trees) for pulp.	2
No PUM piles; leave it for soil erosion protection, wildlife. Maintain critical amounts of snags & course woody debris in clearcuts.	16
Don't limit activities outside wilderness to protect Class I airsheds; law says no buffers outside wilderness.	2
Chip logs and residue and leave it in place.	2
FIREWOOD	
More firewood cutting.	2,967
Less firewood cutting.	371
Same firewood cutting opportunities.	2,871
VEGETATION MANAGEMENT	
Oppose use of pesticides, herbicides, and other poisons.	35
See no problem with limited use of pesticides.	3
LOG EXPORTS	
Stop exporting of logs. Oppose exporting logs, adds little to the State economy. TOTAL ban on *exportation of raw lumber.*	235
Less exporting. Limit exporting of logs and lumber.	60
Exporting allows too many jobs to go overseas. Feel ill when I see logs and jobs being shipped to Japan. Mills are being shut down due to overseas shipments.	56
When logs are sold directly to other nations without first being milled and finished, it's economic suicide. Keep logs here to be processed by our mills.	109
Export fewer logs and save the large ones for home use, or leave them in the natural habitat.	13

LOG EXPORTS, continued	Number of Inputs Mentioning This Opinion
If demand for NW lumber is so great, why are we exporting logs?	25
Create tree farms with a tax on exported wood or logs.	3
Favor exporting of logs. It's one of the few exports we have left.	9
JOBS, THE ECONOMY	
Jobs are an issue of concern to me.	4,376
Emphasize creation of recreation jobs over timber jobs. Timber industry is dying out, consider recreation more important Importance of logging to economy is vastly overstated, give recreation jobs fair treatment. Recreation supports non-polluting non-destructive workforce State will be more positively affected by recreation than timber industry.	142
Recreation income exceeds timber income	34
Short-term sustenance of local timber companies and communities can't compare to long-term protection and survival of the earth.	95
Industries have come and gone, employees had to find other jobs. It isn't unique to the timber industry.	62
Balance timber jobs and recreation jobs. Logging, recreation and wilderness can all work together.	138
Consider jobs over all other values. Keep our jobs. Jobs depend on logging. Keep permanent logging jobs Jobs are most important.	152
Jobs are more important than owls.	9
Disappearing sawmill job have no relation to the timber supply; more jobs have vanished due to increased technology, mill efficiency Jobs have vanished due to lost surpluses, low demand, low cost, and overseas processing.	53
Find alternate resources for wood - technology can do it!	12
Use economics to make management decisions	14
Find other revenues for supporting schools	17
Wood should be more expensive. Old growth is valuable; price of wood should reflect this - willing to pay more for timber products	22
Create jobs by repairing/cleaning up forest environment.	12

JOBS, THE ECONOMY, continued	Number of Inputs Mentioning This Opinion
Small, local loggers and mills should get the first shot at what logging is allowed.	2
Recognize that the Forest supports a large number of non-timber industry jobs.	16
Many mills have already made the conversion to 2nd growth, are not dependent on old growth.	2
AMERICAN INDIAN RELIGIOUS AND CULTURAL USE	
It is wrong to disturb the scared sites of Native Americans	17
Complete protection for all spirit quest and legend sites, cedar areas, ceremonial flora, cemeteries. Complete protection to all remaining sites.	40
Protect all nondegraded spirit quest sites, cedar areas, flora area and cemeteries.	5
Protect all spirit quest sites.	1
Protect legendary sites.	1
Protect cedar areas.	5
Protect ceremonial flora areas.	2
Protect cemetery/archaeological sites.	1
Less emphasis on Indian cultural sites.	3
Indians allowed to over-harvest fish/game. Unfair advantage to Indians. Concerned that Indians are excluded from the law, can do anything on NF land.	37
Need to differentiate between Indian and non-Indian cultural uses and sites; SHPO doesn't always take into account Indian uses	1
Religious, Cultural Use Inventory is incomplete, out of date.	2
In suggesting 1 site is as good as another site, the FS fails to comprehend the meaning tribes attach to specific sites, can't mitigate loss by moving to another place.	2
Consider Native Americans foremost in the management of the forest; they are culturally and economically dependent upon the forest. It as theirs to begin with...	1
Protection of tribal treaty rights is law - don't lose sight of this in the concern for local citizens.	3

AMERICAN INDIAN RELIGIOUS USE, continued	Number of Inputs Mentioning This Opinion
Don't reduce amount of timber available due to Indian religious practices.	1
ARCHAEOLOGICAL AND HISTORIC RESOURCES	
Don't destroy any historic sites without full public involvement.	2
ENERGY, SMALL HYDROELECTRIC DEVELOPMENT	
No more dams.	38
Remove all dams on NF lands.	5
Oppose dams that will create only a small amount of power.	1
Need a better policy statement on hydro. project application process, and restrictions/environmental safeguards for these projects.	2
No geothermal drilling/facilities in roadless areas.	1
Carefully sited hydro, projects provide energy, recreation opportunities without adverse effects.	2
FIRE	
Pro let-burn policy. Fire is a natural part of ecosystem; leave natural fires to burn.	10
Man-made fires should be controlled.	1
More emphasis on fire protection.	6
No dangerous slash burns. No slash burning.	35
Scaling back on the amount of slash burning is OK; it's a useful tool, but don't overuse. Support reducing smoke from prescribed burning to reduce air contaminants.	5
MINERALS AND ROCKHOUNDING	
Recreational mining should be defined , used in the plan	67
Recreational mining should not be defined and used in the plan.	1
Rockhounding should be defined and used in the plan.	73
Rockhounding should not be defined and used in the plan	1
Implementation of some alternatives could make mineral access very difficult; Alt. NC and A are least restrictive, Alt. C is the most restrictive.	42

MINERALS AND ROCKHOUNDING, continued	Number of Inputs Mentioning This Opinion
I disagree that implementing some alternatives could make mineral access difficult.	10
Agree with Alpine Lakes Management Plan definition of recreational mining and rockhounding.	42
Disagree with ALPS definition of the above.	2
More prospecting opportunities	2,771
Less prospecting opportunities.	255
Same prospecting opportunities.	2,483
More mineral development.	7
No mining. No mining in wilderness/ roadless areas.	30
My rights as a miner are infringed upon.	6
Mining/prospecting is an issue of concern to me.	55
Favor (more) rockhounding opportunities.	66
More access for rockhounding (not necessarily any more for commercial mining.)	33
Include in the Plan "..Recreational mining preserves mineral *specimens from natural degradation.*"	8
Regulation of prospecting, rockhounding, and recreational mining is overly restrictive. Access is critical.	8
No further withdrawals from mineral entry (except for needed roads.)	1
Adopt stringent regulations on recreation mining.	1
LAND USES	
No permits for military use, over-flights of NF land.	9
Federal land adjacent to private development should be maintained for the good of the environment.	8
Intensify land acquisition/trading efforts for more contiguous National Forest land.	8
No land exchanges that would result in lessened quality/quantity of timber cut.	6
Retain all mineral rights in any land exchange.	6

Summary of Analysis of Comments

LAND USES, continued	Number of Inputs Mentioning This Opinion
Acquire more public timber lands.	1
Don't stop use of rock pits.	2
GRAZING	
Eliminate cows. Eliminate subsidized grazing on NF lands. Eliminate grazing.	18
Low level grazing OK if secondary to needs of native species.	1
No grazing in wilderness.	1
BUDGET, COSTS	
Forest budget needs changes; phase out timber sale planning, no more direct allocations for road building, increase budget for stream habitat rehabilitation. Budget has been predominately for lumber; this must change. While Reagan administration has cut funds for recreation and closed campgrounds, it spared funds for roads and decreased roadless areas; this must change.	69
Logging should pay costs of all roads, bridges, etc.	29
No deficit sales. Re-evaluate the role of timber production financially - nationwide, nearly half the sales lose money. Harvesting timber in a manner that doesn't cover costs is a criminal waste of resources Tired of hearing that the FS is selling timber below market costs.	132
Money for road building, timber admin. should be shunted to programs to assist affected communities with economic diversification and support schools	14
Use timber receipts to maintain existing trails and build new ones.	7
Increase trail construction/reconstruction and have logging contracts set aside money for this.	5
PLANNING PROCESS	
Why do we need a plan anyway?	4
Based on past action, I feel that regardless of what the public says, the FS will do as it damn well pleases.	6
Little publicity given; meetings not well advertised. Public unaware of impact of the plans until it's too late.	3
Method of getting public input is very limited.	8

PLANNING PROCESS, continued	Number of Inputs Mentioning This Opinion
Commend Forest Service for efforts to date. Awesome task, commend your efforts.	139
Appreciate soliciting public comments.	294
I feel poorly educated about forest management and PLUS. PLUS form is vague.	5
Not information to make a decision. I'm making a decision with very little information.	80
Not enough information on the current status of water quality.	2
Don't feel the FS should conduct polls as to best useage of the Forest.	8
Have a public referendum on the Plan - let the public decide by voting.	8
I need more time to study the plan/alternatives/ etc.	8
I don't like the FS consulting with special interest groups while drafting the plan	2
More hearings needed with loggers, timber folks represented to discuss the issues.	2
FS should work with conservation groups, Indian tribes, & fisheries folks to develop a measurable set of criteria to protect the environment while allowing some timber harvest.	4
Maps are exceptional! Readable and I like the use of color.	6
The documents are confusing, disorganized, and full of contradicting statements.	7
Range of alternatives is inadequate.	17
Range of alternatives in questionnaire is inadequate.	1
Consider alternatives suggested in "Weekly" article.	5
Serious flaws in analysis.	16
The true effects of timber harvesting/road building not disclosed.	10
Document ignores potential public health issues in watersheds.	1
Impacts of recreation in the watersheds are not discussed.	2
Include some discussion of the effects/cumulative effects on RNA's.	2
Effects of management activities on wilderness are not discussed.	1

PLANNING PROCESS, continued	Number of Inputs Mentioning This Opinion
Economic impacts aren't clearly addressed.	15
Economic costs and values are outdated, incorrectly derived.	2
Can't compare timber and recreation values because the use of "willingness to pay" reflects final value to customer.	2
Little discussion of employment/income effects/impacts on communities.	6
Plan doesn't consider impact a reduced ASQ will have on pulp/paper mills.	1
Not enough information on FORPLAN inputs & constraints.	3
Timber (and other) inventories are outdated.	10
Timber supply information inadequate; need a complete analysis.	4
There's no meaningful timber demand analysis.	2
Information Needs (Chap. 2, Plan) are top priority; make sure they're funded.	1
Should prepare an analysis based on different levels of funding.	7
Should look carefully at budgets for each alternative; I can't believe they'd decline as shown, based on the real world.	1
You have seriously underestimated the money it will take to enhance, rehabilitate, mitigate all streams on the Forest.	2
Benefits not clearly stated.	5
Do an honest cost/benefit analysis, taking into account all values, not just wood.	10
There is a lack of biological information in the documents.	3
Where is the data to back up your claims that the timber cut you say will be achieved can actually be done, with the environmental safeguards you say you will employ. Don't believe you have the data	12
Plan ignores proximity of NCNP (or National Parks in general).	7
Cooperation is mandated by law. Agency cooperation is needed to achieve wildlife/fish protection.	17
All landowners (including State) should cooperate to help timber-dependent communities.	7
City (of Seattle) looks forward to cooperating with the FS as it reevaluates its watershed management goals, including more emphasis on wildlife (old growth) habitat.	1
Cumulative effects analysis is done in generalities.	4

PLANNING PROCESS, continued	Number of Inputs Mentioning This Opinion
Plan doesn't coordinate with other landowners to examine cumulative effects of clearcutting in NW.	14
Cumulative effects on wildlife are not discussed nor is fragmentation of ecosystems.	3
Cumulative effects analysis for fish is inadequate.	7
Cumulative effects of forest activities on watersheds and water resources are NOT addressed.	10
Supplement must be issued to address Alpine Lakes Mgt. Unit, which was unfairly excluded from this study. Include some alternatives with differing management for Alpine Lakes.	11
MA prescriptions are not very specific; need at least a minimal level of specific guidance.	1
Need a more thorough, written prescription for educational concerns and enforcement of conservation practices	2
Vandalism is a problem - not mentioned in the DEIS.	3
Forest Service has mixed up Wild and Scenic River eligibility and suitability process resulting in too few rivers eligible. Suitability criteria used in making eligibility determination results in too few rivers	2
Need to evaluate supply/demand for trails occasionally.	3
Ignore/don't correct any technical flaws discovered by forestry consultants.	1
Correct technical flaws discovered by forestry consultants [to enable a sustainable volume of 220 MMBF]	20
Don't issue a FEIS until the discrepancies in timber supply base are resolved	1
Too many acres excluded from harvest consideration (excluded from the suitable land base); other valuable tree-growing property severely restricted. Plan should retain the largest possible suitable land base.	7
American Indian religious and cultural use issues not fully addressed.	6
Create a more meaningful and effective Indian consultation process.	6
Plan needs a more valid monitoring plan.	18
Plan must contain automatic revisions in land allocations to protect fish, other resources, if fish runs begin to be affected by roads/harvesting.	5

PLANNING PROCESS, continued	Number of Inputs Mentioning This Opinion
If final plan doesn't work in 5 years, it should be modified before irreversible damage occurs.	3
More MMR's for soils, watershed, recreation, wildlife.	3
Replace BMP's with MMR's for fish habitat & riparian; will provide better protection. BMP's are not adequate to protect fish habitat. Need to specifically discuss mitigation measures for fish.	5
Disagree with the MMR process; no public comment allowed, no discussion of how they should be developed.	7
MMR's should be eliminated and alternative resource protection methods developed.	4
MMR's are over-emphasized, too big; slack back if species found outside habitat. MMR's were applied in a way that far exceeds the intent of NFMA.	5
Water/riparian MMR's exceed the law.	2
Do not agree that deer and elk can maintain viability without MMR's.	2
EIS fails to reveal how MMR's affect resources such as timber.	3
Put MMR's where they won't impact the suitable land base.	2
Wildlife standards and guidelines are good - don't weaken them	1
Too much reliance on unproven/suspect mitigation measures.	19
Mitigation measure discussion for water is too general.	5
There's no worst case analysis; should do one	10
Management horizon of Plan is too short; should be managing for 50-100 yrs.	1
Question the validity of the indicator species approach to wildlife.	7
Need indicator species for larger, predatory mammals.	1
Roadless area evaluation is no better than RARE II.	2
Boundaries of MA 1AB seem to be located so as to minimize commercial forest lands, especially old growth.	2

Trails 2000

Support Trails 2000	529 Inputs
"2,000 miles of trails by the year 2000."	15 Inputs
Dislike Trails 2000	6 Inputs

In addition, the Alternative G-Modified included, as an integral part of the adjusted alternative, the Trails 2000 proposal. A total of 265 respondents supported Alt. G-Modified but did not specifically mention the Trails 2000 proposal (77 inputs did mention both)

Those 265 inputs have not been included in the above totals, although it could be assumed that they also supported Trails 2000.

Selected Reasons for Supporting Trails 2000:	**Number of Inputs**
Population of local area is exploding, recreation use is increasing.	61
Relieve overcrowding on trails.	19
I strongly support this proposal.	18
Provides interconnecting, loop trails.	10
Increases variety, quality of hiking experience.	9

Backcountry Areas

Support Backcountry Area Proposal (no sites named)	158 Inputs

Site Specific Comments (These figures are also reported in the Sites Section.)

Helen Butte	89 Inputs
Jackman Creek	87
Mt. Dickerman	97
Eagle Rock	27
Pratt River	95

In addition, Alternative G-Modified included this proposal. Respondents supporting Alt. G-Modified, but not specifically mentioning the Backcountry Areas are not included in the above figures.

Selected Reasons for Supporting Backcountry Area Proposal	**Number of Inputs**
Population of local area is exploding, recreation use is increasing. Population is increasing while recreation opportunities are decreasing.	14
Use roadless areas to relieve pressure on wilderness, National Parks.	8
I strongly support this proposal.	7

Site Specific Comments

The Forest also received comments about the management of specific, geographic sites on the MBS. The detailed analysis, by Ranger District, is available in the January, 1989 document, in the planning records.

A total of 1,977 inputs out of the 11,718 received mentioned specific geographic sites (or just under 17% of the total input.)

Form of input mentioning specific sites:		
	Personal Letters	1,804
	Petitions	9
	PLUS Response Forms	57
	"Mini" PLUS	1
	Other Form Letters	106

The majority of comments about specific sites stated that the respondent wanted the area protected from development, timber harvest, roads, etc. Very few site-specific comments favored development or timber harvesting. Protecting old-growth ecosystems, wildlife habitat, and recommendations for wild and scenic river status were also frequently mentioned.

The areas highlighted below are those mentioned most frequently:

Pratt River - 1,309
Monte Cristo - 981
Illabot Creek - 766
N.F. Nooksack River - 732
Cascade River - 700
Jackman Creek - 652
M.F. Snoqualmie River - 621
Canyon Creek (Mt. Baker RD) - 555
Rapid River - 535
Dickerman Mtn. - 529
White Chuck River - 516
Naches Pass - 506
White River - 501
Damfino Creek - 496
Taylor River - 494
Baker Lake - 471
Noisy Diobsud Roadless Area - 468
Greenwater River - 458
Foss River - 452
Cedar River - 451
Miller River - 436
Diobsud Creek - 435
Skykomish River - 420
Noisy Creek - 420
Baker River - 405
Mt Rainier Adjacent Areas - 402
Chenuis Creek - 401
Stillaguamish River - 397
S.F. Nooksack River - 394
Helen Butte - 390
S F Stillaguamish River - 379
Huckleberry Creek - 379
Higgins Mtn. - 373
M.F. Nooksack River - 371

What the Public Said About Specific Sites

In the following pages, we have highlighted some of the opinions given about management of specific, geographic sites. While this list looks huge, it is only about half of what everyone said!

The number of inputs mentioning specific sites: 1,977 (out of a total of 11,718) This is just under 17% of the total input received.

Form of input mentioned specific sites:		
	Personal Letters	1,804
	Petitions	9
	PLUS Response Forms	57
	"Mini" PLUS	1
	Other Form Letters	106

Not surprisingly, very few response forms mentioned specific sites. A number of form letters were prepared by snowmobile and horse clubs (and these groups are very interested in specific trails/sites.) The PLUS response form told folks that "A written, personal letter is the best way to comment.. " and a few did attach letters to their forms. Inputs from some of the major timber and motorized recreation organizations did give site-specific comments. But, most of the site specific comments came in letters, and from people who spoke - sometimes passionately - about their personal experiences on the trails of the Forest.

Most respondents speaking to specific sites can be characterized as environmentally-oriented, as opposed to commodity-oriented. This is typical of public response on past planning efforts. Accordingly, the most-often mentioned comments are "protect....." rather than "build a road here." The rivers and sites discussed in the flyer prepared by the coalition of environmental groups (and REI) generally got the most comment. Refer to the computer printouts for the complete list of site-specific comments.

How To Read The Numbers: After each site is the number of times it was mentioned. This is the **total** times an area was mentioned for some type of management. Thus, one person could want the Pratt River designated a wild and scenic river, a trail built there, and the area protected for its fisheries. This would be tallied as "3" in the times mentioned. HOWEVER, the majority of respondents mentioned only one "action" for each site.

While the actual numbers are a bit meaningless, they DO tell us the intensity of interest in an area. The areas highlighted below are those of most concern:

The Pratt River (mentioned 1,405 times - the highest amount of concern)

Monte Cristo - 976	Greenwater River - 458
Illabot Creek - 765	Cedar River - 452
N.F. Nooksack River - 732	Foss River - 452
Cascade River - 700	M.F. Nooksack River - 448
Jackman Creek - 651	Diobsud Creek - 435
M.F. Snoqualmie River - 621	Skykomish River - 419
Canyon Creek (Mt. Baker RD) - 556	Noisy Creek - 418
Rapid River - 535	Baker River -404
Dickerman Mtn. - 529	Chenius Creek - 401
White Chuck River - 517	Mt. Rainier Adjacent Areas - 401
Naches Pass - 505	Stillaguamish River - 396
White River - 502	S.F. Nooksack River - 394
Damfino Creek - 494	Helen Butte - 390

Summary of Analysis of Comments

Taylor River - 494
Baker Lake - 470
Noisy Diobsud Roadless Area - 467
S.F. Stillaguamish River - 379
Huckleberry Creek - 379
Higgens Mtn. - 373

List of Agencies, Organizations, and Individuals Responding to the DEIS

The number preceeding each name is the "input" number assigned to each letter, form, or report received. The original letters etc. are on file in the planning records.

Input #	Federal Agencies
427	Dept. of the Air Force, Regional Civil Engineer
10685	USDA Forest Service, Mt. Baker Ranger District
10664	U.S Environmental Protection Agency
453	USDA Forest Service, Forestry Sciences Laboratory
11934	USDI, Office of Environmental Project Review
9	USDT, Federal Highway Administration
	State, Regional, Local Agencies
258	Puget Sound Air Pollution Control Agency
10935	State of Washington, Office of the Governor
1410	Washington State Department of Transportation
10934	City of Seattle
11842	Tacoma Public Utilities
10668	Whatcom County Courthouse
	Elected Officials
10924	Tim Douglas, Mayor, City Of Bellingham
285	Rod Chandler, U.S. Congress, House of Representatives
1737	Brock Adams, U.S. Senator
11902	Mike Lowry, U.S. Congress, House of Representatives
2609	Grace Cole, State of Washington, House of Representatives
1078	Jolene Unsoeld, State of Washington, House of Representatives
11900	Lois North, Cynthia Sullivan, Audrey Gruger, King County Council
	Indian Tribes
10178	Lummi Tribal Fisheries Department
4842	Lummi Indian Business Council
10183	Lummi Indian Tribe
10700	Muckleshoot Indian Tribe
10707	Nooksack Indian Tribe
10844	Nooksack Indian Tribe
10669	Samish Indian Tribe
11806	Skagit System Cooperative
10191	Tulalip Tribes
	Other Organizations
1540	A-1 Builders
1536	Allen Logging Co
10663	Alpine Lakes Protection Society
11112	American Alpine Club

FOREST SERVICE RESPONSES TO SUBSTANTIVE COMMENTS

A substantive comment is defined as "A comment that provides factual information, professional opinion, or informed judgement germane to the action proposed." (Forest Service Handbook for implementing NEPA 1909.15) This section of Appendix J contains of the substantive comments received, along with our response.

The Council of Environmental Quality Regulations for implementing NEPA (40 CFR 1503.1) give five possible ways to respond to comments:

- Modify alternatives, including the proposed action;
- Develop and evaluate alternatives not previously given serious consideration by the agency,
- Supplement, improve, or modify the analyses;
- Make factual corrections;
- Explain why the rationale, authorities, and sources were used in the DEIS and why the Forest's position is maintained in the FEIS.

Organization

Comments are grouped by general subject matter. There is a brief table of contents on the following page. Each comment (or set of comments) has a title, in bold capital letters, followed by the comment(s), and then the response.

We used the respondents own words to record the comment, although some were edited for length or clarity. When two or more comments were made on the same general topic, they were grouped together, with one response. Where possible, a reference is made in the response to the location in the final documents wherein the reader may find changes and/or supporting information. As abbreviations are used throughout this section of the appendix, refer to the Glossary, FEIS.

SOIL PROTECTION SHOULD BE GIVEN MAJOR CONSIDERATION

You would not be amiss to come out and say that, above all, the soil, being the most important of all the resources is the underlying reason for all the management and that any successful management will hinge upon protection of the soils

Serious soil erosion problems aggravated by logging and road; building must be identified by local area and given primary credence in any pertinent plan There is too much emphasis on production and too little on protection.

Response: Agreed. The Land Suitability for Timber Production process includes removal of 95,500 acres of forested lands with unstable soils (the S-8 soils - see Glossary for definition) from the tentatively suitable land base Refer to FEIS, Chapter III, Commercial Timber section and Appendix B. In addition, Forest-wide Standards and Guidelines, Items 7. and 8. under the Soil Resource, Chapter 4 of the Forest Plan, include special prescriptions for activities in soils that are unstable, but do not fall into the S-8 category Soil protection is also addressed at the project-planning level, in the NEPA analysis.

THE SOIL RESOURCE MR's ARE TOO GENERAL

In light of these disturbing characteristics of the northern half of the Forest, the staff opinions regarding timber harvest impacts to fish and fish habitat, and the legal requirements of the NFMA, the Forest Service must implement management practices which protect against these impacts. The MMR's described for the soil resource are extremely general and do not appear adequate to prevent significant damage to aquatic resources (DEIS page IV-160). How do these MMR's differ from current and recent practices?

Response: Only a very brief synopsis of the MR's are presented in IV-160 of the DEIS, there is discussion in greater detail in Chapter 4, Forest-wide Standards and Guidelines for the soil resource, in the Forest Plan The MR's are similar to current protection, but offer considerably more protection than they did several years ago. A major difference is the removal from harvest and road building those lands which contain severely unstable soils; refer to the response above.

DESCRIBE IN MORE DETAIL HOW ADVERSE ENVIRONMENTAL IMPACTS WILL BE PREVENTED

It is stated that mitigation measures, proper construction, and timely maintenance can help negate these effects from runoff and major sedimentation from road systems The extent to which the adverse environmental impacts will be prevented, the mechanisms for doing so, and the commitments toward protection needed to be described.

Response: Adverse environmental impacts will be prevented to the extent possible by using road locations that are compatible with the topography, construction practices that will assure road integrity, and mitigation measures such as proper drainage, grass seeding and other erosion control measures to assure that soil movement will not occur. This is accomplished at the project level by an interdisciplinary team consisting of knowledgeable specialists who determine needs and practices that are

implemented through contractual requirements. Refer to Forest-wide Standards and Guidelines for soil, Chapter 4, Forest Plan.

HOW ARE SOIL AND WATER OBJECTIVES AND STANDARDS MET?

The statement that says that the FS will "Plan and accomplish rehabilitation projects as necessary to meet soil and water objectives and standards" needs to contain specific information to be meaningful Again, criteria, commitments, etc need to be included

Response: New Plan Appendix I details the first phases of the Watershed Rehabilitatio Program. These implementation schedules constitute specific, scheduled projects that will be completed Also refer to the monitoring plan, Chapter 5, Plan In addition, site-specific requirements are determined at the project planning level

DESCRIBE THE PROCESS USED TO DETERMINE SEDIMENT LEVELS

Were sediment levels based on sampling, extrapolations of data from other studies, or what?

It would be helpful for our analysis of the planning efforts if a discussion on the methodology used for determining erosion and sedimentation rates was included in the final EIS. Moreover, drawbacks and limitations of the methodology should also be discussed Tables IV-1 and IV-6 present soil erosion and sedimentation in tons of material over time Such a statement should be made with supporting rationale and documentation, as appropriate.

The Forest Service does not identify in the DEIS the techniques used to quantify sediment yields Rather, the documents simply list the total sediment *expected to come off the entire forest, per year, as a result of any of the* alternatives. This discussion is insufficient under NEPA.

Response: Sediment is that part of erosion that has been redeposited To estimate sediment it is first necessary to estimate the amount of erosion that is occurring The procedures used to estimate erosion and more discussion of the sediment tables developed for Chapter IV are presented in the FEIS

EVALUATE SEDIMENT LEVELS BY WATERSHED

Sediment yields are developed and averaged for the entire forest, which make it impossible to assess the impacts of proposed timber sales and road building to specific basins It would be beneficial to breakdown background sediment inputs and proposed harvest/road sediment inputs by watershed This would facilitate a watershed by watershed analysis and offer greater protection for those basins already severely impacted

Sediment yield is not distributed evenly throughout the Forest. The Forest Service must look at each proposed timber sale, one by one as they effect each watershed or drainage. It is the Tribe's position that such generalizations are merely a means for the Forest Service to rationalize cuts without looking *at the impacts of that cut on a site specific basis.*

Response: You are correct in your statement that sediment yield is not distributed evenly throughout the Forest. In fact it varies greatly, as does the stability of the soils To develop sediment levels for each watershed is beyond the scope of the Forest Plan. This can best be developed at a basin planning level when specific soil types along with locations of roads and harvest units are known. However, since the DEIS was released, the Forest has continued our efforts to develop a method of meeting water quality and riparian management requirements. Refer to new Appendix H for a discussion of the hydrologic cumulative effects analysis procedure, and the method developed to meet these MR's - a maximum number of acres available for final harvest in each watershed, by decade.

CLARIFY SEDIMENT OUTPUTS

For the estimated soil sediment outputs to be meaningful, the current sediment outputs need to be stated, including a breakdown of what fraction is activity generated and what is natural background.

Response: A series of tables in Chapter IV, Soils, FEIS, show sediment broken out by background, from roads, new harvest acres, etc by alternative The current output is similar to Alternative NC (No Change).

CONFUSION ON SOIL EROSION TABLE IV-1

For Table IV-1 (DEIS), does this mean that the preferred alternative will contribute 67,000 new tons of erosion/year? Is this in addition to the existing 72,000 tons per year above natural rates? Are all these caused by human activity?

The second paragraph appears to conflict with previous descriptions of the sediment index The two components should be (1) natural and (2) activity-produced. The latter should include both old and new sources The quantified analysis will be of little value unless this distinction is made.

There are some apparent inconsistencies within Table IV-1 which need to be explained or corrected For example, the background tons of soil per year are higher for Alternative G than they are for Alternative C, and yet this is reversed under new tons of soil per year Also, the ratio of background tons of soil per year to new tons of soil per year appears to be higher for Alternative G than for the other Alternatives. Further, it could be expected that the background tons of soil per year should be roughly the same for all of the alternatives; but the table shows wide variations in soil loss between the alternatives

Response: The background erosion is actually different among the various alternatives This is due to the differences in the amount of restoration (grass seeding, waterbarring, etc) planned on old existing roads in the various alternatives. Alternatives with the most restoration on old roads can be expected to have the least background erosion. The referenced table has been redone for Chapter IV, FEIS, and a more complete narrative added. Note that this table shows erosion, which is not the same as sediment. Erosion is simply movement downslope from point A to point B; it does not become sediment until it enters water

SEDIMENT LEVELS AND WATER YIELD DATA SHOULD BE DISPLAYED DIFFERENTLY

Table B-66a: Compare to minimum management alternative and average last decade Show sediment produced over background (due to activity). Your water outputs indicate something is wrong with your modeling.

In this and subsequent tables, it would be much more useful to show sediments as they increase over natural levels, not the total for natural plus activity-produced sediment. In addition, the water yield numbers should be omitted since their display indicates that this factor will show no change. In reality, the question is not resolved and the numbers simply reflect a lack of quantified data. The constant numbers imply that there will also be no changes in peak or minimum flow values (both of which could be detrimental to fish production).

Response: Sediment levels at best are only an index, useful for relative comparisons among the various alternatives. Water yield remains the same through Decade 5, due to lack of quantitative data in which to base a change.

WHAT IS THE APPROPRIATENESS OF USING FORPLAN TO MANIPULATE RAW EROSION DATA?

There is no discussion on the appropriateness of using the FORPLAN model to manipulate raw data from the erosion and sedimentation study. Such a discussion should be included in detail in the final EIS.

Response: We consider it appropriate since FORPLAN is the model used for all other aspects of the Forest Plan. Refer to the discussion on FORPLAN in Chapter III of Appendix B, FEIS

THE DISTURBANCE RATE FOR SOILS IS EXCESSIVE

We understand that when 12% of an activity site is left in a severely burned, compacted, puddled, etc state, that long-term resource damage is sustained and productivity lost We consider the 20% allowance to be excessive, and to exceed the amount other Forests are using as a limit.

Response: There appears to be some misunderstanding regarding your implied meaning of 12% disturbance, and that it is a disturbance threshold beyond which watershed degradation occurs This 12% stems from work done by Harr (1976), when he found that when a watershed in western Oregon had at least 12 percent of its area heavily compacted by road building, tractor skidding, or tractor windsowing of slash, peak flows were increased. This infers a potential for some damage but there is no tie to watershed degradation or productivity loss. The 20% disturbance allowances you refer to in the Plan are those contained in Regional Direction Supplement # 45 and are used by all Forests in Washington and Oregon.

NOT ENOUGH DISCUSSION OF SOIL FERTILITY

The presentation on timber harvest levels fails to significantly discuss the limits of soil fertility on the suitability of the proposal for long term sustained yield. The statement that the soil on the MBS can generally absorb the effects of management activities with little or no productivity loss is not

substantiated by recent research. Reference is made to the publications of J F Franklin, L D Harris and C Maser.

The statements in the effects of implementation regarding maintenance of site productivity are unsubstantiated. The ability of a large block of land that has been clearcut, intensively harvested, and in places burned, to continue to function with diversity, is questionable. Mike Amaranthus' work has highlighted the importance of site specific soil microbiologic constituents. In fact, different mycorrhizae may be important at different stages in the rotation How has the forest plan evaluated site productivity? It has been essentially been dismissed as a non-problem on this forest

I don't think there is enough data to fully assess the long-term impacts of replacing the self-sustaining old-growth habitat with tree farms than are managed by man. Can we continue to remove large quantities of organic materials from the forest ecosystem without affecting the productivity of the soil?

Response: Soil productivity is addressed in Chapters III and IV in the FEIS. New Forest-wide Standards and Guidelines on Diversity and Long-Term Productivity have been added to Chapter 4, Forest Plan Monitoring soil productivity is also included in the Monitoring Plan, Chapter 5, Forest Plan. Our analysis is based on current observations and measurements of soils and regeneration growth, and when considering future harvest rates and the BMP's that will be utilized. Conclusive research that would support a change in direction is lacking at this time As new knowledge is gained, we will incorporate the findings into Plan direction, standards, and guidelines.

SOIL STABILITY SHOULD INFLUENCE MANAGEMENT ACTIVITIES MORE THAN STEEPNESS OF SLOPE

"Steepness of slope affects other management activities to a greater degree than does soil stability " Please! Nothing should influence management activities more than soil stability or instability, regardless of other factors.

Response: The above sentence gives an erroneous impression and is deleted in the FEIS.

ON WHAT BASIS WERE LANDS WITHDRAWN FROM TIMBER PRODUCTION FOR UNSTABLE SOILS?

Regarding the 95,500 acres were withdrawn from timber harvest because of unstable soil conditions: no management process or criteria are described which show how the Forest Service decided which acres to withdraw Is there a process which the Forest Service uses to review timber sales to determine their impact to soils? Can other acreage be added to that already withdrawn if negative impacts to soils are discovered?

Response: This process, part of the Determination of Land Suitability for Timber Production, is explained briefly in Chapter III, Commercial Timber section in the FEIS; addition detail is included in Appendix B. Also, see the Chapter III, FEIS section on soils. Addition acres can be withdrawn at the project planning level when they are discovered and verified in the field During project planning, an environmental analysis is conducted for

each project. At this time, the potential impacts to soils are determined, along with appropriate mitigation. See the Forest-wide Standards and Guidelines for soils, Items 7. and 8. for discussion on the special treatment prescribed for fairly unstable soils (those not in the S-8 highly unstable category)

INCLUDE A TABLE SHOWING ACRES OF UNSTABLE SOILS IN MA 17

There is need for a table showing the amount of land that has unstable soil conditions in the acres allocated to Management Area 17, by alternative Presentation of such a table would improve our ability to assess the effects of a large allowable timber harvest on important fish and wildlife resources

Response: Generally, there should be no acres of highly unstable soils (S-8 soils) within acres allocated to MA 17. The lands with identified highly unstable soils (95,500 acres) have been removed from the tentatively suitable land base. While small areas or pockets of unstable to fairly unstable soils will be found within MA 17, generally lands allocated to the Timber Management Emphasis prescription are tentatively suitable for timber harvest Therefore, such a table would not likely provide the information you desire.

Since the DEIS was released, the Forest has continued our efforts to develop a method of meeting water quality and riparian management requirements. Refer to new Appendix H for a discussion of the hydrologic cumulative effects analysis, and the method developed to meet these MR's - a maximum number of acres available for final harvest acres in each watershed, by decade Also, see Plan, Forest-wide Standards and Guidelines for soils, Items 7. and 8. for special protection of fairly unstable soils.

NORTH HALF OF FOREST IS UNSTABLE AND SHOULD RECEIVE SPECIAL CONSIDERATION

The narrative under soils for the "North Half of the Forest" should also state that this area is one of the most unstable in the entire Pacific Northwest region. There seems to be plenty of evidence to justify special protection measures in this area, particularly with respect to degree of riparian area protection. While some of this extra protection will come through routine but site-specific application of management requirements, alternatives such as a 100-foot anadromous fish riparian zone merit serious consideration.

Response: The narrative has been modified to include the suggested wording Timber harvest will be limited on the unstable drainages (based on the hydrologic cumulative effects analysis, which resulted in this method to meet water quality and riparian management requirements - see Appendix H). The areas containing the most highly unstable are withdrawn from timber harvest. Additional protection is provided in Forest-wide Standards and Guidelines, and site-specific measures will be provided during project planning and implementation through rigorous application of BMP's.

DEBRIS TORRENTS IN OLD GROWTH

We have only rarely witnessed debris torrents in old growth areas. However, they are relatively common in cut-over areas, especially where small (even seasonal) streams have had their banks denuded by timber practices.

In large standing timber, debris slides (flows) usually "hang up" after only a short distance and become debris "jams."

Response: Agreed; this is reflected in the document text (both DEIS and FEIS).

MORE EVALUATION NEEDED RE: SEDIMENT OFF ROADS AS ROAD DENSITY INCREASES

If the accumulations of sediment in streambeds become significant when the roaded portion of a sub-basin area exceeds 2-3%, and the average road density on the MBS is between 3 percent and "somewhat less than 3%," it appears that the accumulations are or are about to become significant. Therefore, the assumption that road construction will not contribute a critical level of sediment is tentative. This needs to be evaluated much more thoroughly. In addition, how the percentages are calculated, and how the percentages will change over the next decades should also be discussed.

Response: This section (the direct effects of the alternatives on water) has been re-written in the FEIS.

THE EFFECTS OF BURNING ON SOILS HAS BEEN MISREPRESENTED

The effects of burning on soils is misrepresented in this section of Chapter IV, DEIS. There are studies which indicate significant negative effects of burning to long-term soil fertility, soil flora and fauna, and soil organic matter. Paragraph 5 on page IV-6 is particularly misleading, as you have not cited any of the literature which may show negative impacts. Other sentences in this section are contradictory

Response: Burning can have negative impacts on soils with the level of impact depending upon the intensity of the burn. This section has been rewritten in the FEIS for clarity. Also, note in the text on prescribed fire activities in Chapters III and IV, FEIS and in the Plan document· the MBS continues to decrease the acres of broadcast burning prescribed each year.

WHAT ARE THE VARIOUS COURSES OF SEDIMENTATION AFFECTING FISHERIES AND HOW CAN THEY BE AVOIDED?

The DEIS states that "Changes in soil which increase surface erosion and/or mass wasting can have a major effect on fish spawning and rearing, when the material reaches stream channels and is deposited as sediment..." The various causes of sedimentation affecting fisheries and how they can be avoided should be discussed.

Response: Some additions have been made to this text in Chapter IV, FEIS to explain some of the techniques that can be used to hold human-caused sedimentation to a low level These may include: using road locations

where soils are stable and risk of failure is low, construction practices that will assure road integrity, and mitigation measures such as proper drainage, grass seeding, and other erosion control measures to assure that soil movement will not occur.

IMPACTS OF SOIL ON WATER ARE MISLEADING

Having a section on the impacts of soil on water may be misleading because soil itself does not have the impact on water; rather, it is the soil disturbances that cause erosion, sedimentation, and mass wasting The crucial elements are how the soil gets to the water, how much, and whether this affects beneficial uses.

Response: Agreed. We believe this is clarified in the opening statement this section in the FEIS; it is the changes in soils from impacts which promote surface erosion and/or mass wasting can strongly affect water quality, specifically sedimentation.

UPDATE SOIL INFORMATION

The Forest Service conducted a soil survey in 1972. The soil survey techniques are not described in the DEIS. While soil composition may not have changed since the survey was conducted, new information regarding impacts of various activities should be available to update the generalizations made from the survey

Response: The characteristics on which the soil survey was based (ie, soil and geologic properties) have not changed. However, knowledge of how soils respond to various management activities has greatly increased since the survey was made Soil input to current projects always utilizes the most recent knowledge

CONDUCT A SOIL SURVEY AND TAILOR HARVEST MANAGEMENT PRACTICES ACCORDINGLY

The FS is obligated to prevent harvest impacts to fish habitat under NFMA. You must insure that timber is harvested from the Forest only where "soil, slope or other watershed conditions will not be irreversibly damaged. (or) protection is provided other bodies of water from detrimental changes in water temperatures, blockages of water courses and deposits of sediments where harvests are likely to seriously and adversely affect water conditions of fish habitat..." 16 U.S C. 1604 (g). In order to comply with the legal mandate, the FS must conduct a soil survey and tailor harvest management practices accordingly

Response: The MBS has a soil survey in place that identifies the degree of risk of landslides and other impacts to water and fishery values. In addition, soils that are sufficiently unstable so as to incur irreversible damage from management activities have been classified as not suited for timber harvest; refer to Chapter III, Vegetation and Timber, of the FEIS.

TIMBER HARVEST CAUSES NO ADVERSE EFFECTS

We believe that a well-designed timber management program will impose very little risk at all of significant adverse effects, especially relative to the tremendous adverse impacts resulting from natural erosion and catastrophic events. Many forest hydrologists have reached the same conclusion. Dr. David Wooldridge recently wrote that the environmental consequences of current best management practices in forest management are "inconsequential compared to past epidemics." He noted that year-to-year variations in erosion rates due to random natural processes are "the dominant factor in long-term sediment transport processes" and concluded that "in general, amount of erosion caused by man's activities in the forest are insignificant."

Response: This opinion is not shared by the watershed specialists, fisheries biologists, and other specialists on the Forest, especially those with 10-20 or more years of professional experience on the MBS Observation over time, both on-the-ground and from aerial photos, has shown some dramatic changes after significant harvest has occurred Examples are Deer Creek, Finney Creek, and Canyon Creek. These streams were stable prior to logging and supported healthy fish populations. Now, after having been heavily logged, landslides abound, roads are failing, streams are sediment-choked and unstable, and fish runs are absent or seriously depleted. Refer to new material in Chapter III, Appendix H, and text in Chapter IV, FEIS, on the condition of watersheds on the Forest and the method developed to meet water quality and riparian MR's.

MONITOR ROADS TO DETERMINE SEDIMENT LOSS, ETC. AND BUILD NEW ROADS TO SPREAD OUT THE IMPACT ON THE EXISTING SYSTEM

We encourage the Forest to establish a monitoring system on all major drainages to determine sediment load and temperature change on the streams before and after timber harvesting has taken place The Forest should consider road closures when necessary or at least limit the road use to essential management activities during the time of the year when topsoil may be lost. Consider road building in the roadless areas as soon as possible; building access road into new drainages would have a tendency to improve water quality by reducing the work load on existing road systems, thereby reducing the sediment load moving into our streams

Response: Monitoring is discussed in Chapter 5 of the Forest Plan. The impacts of roads are discussed in Chapter IV of the FEIS It has been our experience that roads open to use, but adequately maintained and monitored have relatively little impact on water values. Some problems are caused by failure on old, unused roads that have not been "put to bed." The most severe impacts occur from new construction within the steep, relatively unstable drainages, where cuts and fills are prone to failure.

DOLLAR VALUE OF WATER

In the Plan, the value of the water is listed at $51,876,000 per year. Where did this value come from? Does it include the value of fish produced in the water? Was this based on municipal and industrial or domestic use, or agriculture, or some mysterious combination of uses? Does it include the value of the land? Is recreation value included?

I am concerned about the validity of the $52 million figure given as the dollar value of the water that flows from the Forest. Surely this is only value to those that then sell this resource to others. It is only a proxy value given as a result of not being able to quantify the value of this resource. How was this figure reached? The potential exists for this figure to be balanced against the quantifiable value of some other forest commodity, such as timber, leading to the dilemma of whether the timber is worth more that the water.

Response: As stated in Chapter III, Water, FEIS, the figure shown is based on the value of water for municipal and industrial uses, plus the value of the water from the Forest used for power generation. It does not include values for fish, land, or recreation

CUMULATIVE EFFECTS NEED MORE DISCUSSION

The reference to cumulative impacts needs to be supported by further discussion

Response: The discussion on hydrologic cumulative effects, Chapter IV, has been expanded in the FEIS. In addition, between the draft and final plans, a hydrological cumulative effects analysis was completed by this Forest. It resulted in a method to meet water quality and riparian management requirements; refer to new Management Requirement Appendix H, and the documentation of the analysis process in Appendix B.

FEIS NEEDS MORE DISCUSSION OF CURRENT WATER QUALITY, CONDITION OF STREAMS, ETC.

Headwater streams on the forest are naturally almost sediment free. It would be useful to identify the ones that are not, identify the causes for this, and what is being done to prevent sedimentation, and differentiate between natural and man-induced causes. While the DEIS elaborates on mitigation processes (for removal of streamside vegetation) it should be concentrating on current conditions within the Forest. Again, where are conditions unacceptable, what are their causes, and what things are being done to rectify the problem?

Additional detail on the current status of water quality is needed. There is no organized summary presented which covers the whole Forest. A watershed inventory would be a logical place to present information documenting water quality conditions. It is difficult to evaluate effects on water quality which would result from implementing the various options without documentation on the current status.

Response: Due to the vast number of headwater streams on the MBS, data on their condition is limited. The need to update such inventories, especially as we implement the Geographic Information System (GIS) in 1992, is noted in the Information Needs section of Chapter 2, Forest Plan. Most headwater streams that are in a natural state are sediment free, except

where influenced by landslides or glaciation. The conditions of large basins are know and documented All major watersheds on the Forest were re-evaluated between draft and final Forest Plan, as to their present condition - acceptable or unacceptable - as part of a hydrologic cumulative effects analysis. To meet water quality and riparian MR's, a maximum number of acres available for final harvest, per decade, by watershed, was set These harvest levels set the limits of the drainage to absorb impacts without causing watershed degradation, and allow watersheds in unacceptable condition to recover Refer to new text in Chapter IV, Water, FEIS, and discussion in Appendix B and the new MR Appendix H. In addition, all future timber harvest and road construction will follow Best Management Practices (see new Appendix I, BMP's) and the prescribed standards and guidelines.

ADDITION TO DISCUSSION RELATIVE TO FERC PROJECTS

The discussion relative to FERC projects should note that full mitigation is legally required for any adverse impacts on fish and wildlife resources (although the practical result may be something less). The FERC process also allows for enhancement

Response: This has been incorporated into the discussion in the FEIS Chapter IV, Environmental Consequences

DISCUSSION OF WATER RIGHTS

The State of Washington is responsible for the granting of water rights The Forest Service needs to address the matter of federal reserved water rights as part of their planning process, so that the State can more efficiently allocate, protect, and adjudicate its water resources.

Response: Water rights have not been a significant issue in the past on the MBS, and were not identified as a major issue, concern, or opportunity in the Forest Planning process This is primarily due to the abundance of water on Forest Service Lands.

NEED BETTER INDICATORS OF RESPONSE FOR THE WATER QUALITY ISSUE

For the water quality issue: better indicators of response would include temperature, suspended sediments, BOD, and fish production

Response: This ICO has been refocused between DEIS and FEIS, refer to Chapter I, FEIS and Appendix A (pages A-16 to 19). Water quality is addressed as a facet of the Effects of Timber Management and Related Activities ICO. In response to this comment, we have added "sediment produced from all sources" as an indicator of responsiveness. See Table I-1, FEIS Other indicators to measure responsiveness to water quality include timber harvest levels (acres) and miles of road construction, as they allow direct comparison among alternatives. It is assumed that the alternatives with the highest harvest level and miles of new road construction/reconstruction will have the greatest impact on stream temperature, sediment level, and other water quality indicators. Existing data for stream temperature, etc. is not available at levels necessary to allow projective and comparison at the Forest Plan Level. Fish production

is included as an indicator for the Old Growth Ecosystems and Fish/Wildlife/Plant Diversity issue.

GOAL STATEMENT FOR WATER DOESN'T CONSIDER MUNICIPALITIES

Regarding the Forest-wide Standards and Guidelines, goal statement for water: the Washington State Department of Social and Health Services rules and regulations and the new EPA drinking water regulations are not mentioned with regard to water quality, nor are the desires and concerns of the municipalities expressed in this section.

Response: The goal statement and Forest-wide Standards and Guidelines for water speak to meeting or exceeding State Water Quality regulations. The Forest is not required to supply pure drinking water to municipal watersheds. We are required to supply high quality water that is treatable (FSM 2542.03); this is not affected by the EPA standards.

DELETE CONCLUSIONS ON DISCUSSION OF WATER

Most of the conclusions beginning at the bottom of page IV-14 should be deleted. For example, one conclusion states, "Water yields will not be noticeably different from one alternative to another or from the present situation "

Response: You do not state why you believe the conclusions are not appropriate. After reviewing the pages in question, we believe that the conclusions provide information needed to clarify our discussion. In addition, this section has been updated to reflect the alternatives displayed in the FEIS.

ADD AND CLARIFY THE RAIN-ON-SNOW INFORMATION

Page III-3, DEIS: the description of the climate should include a statement about rain-on-snow, as it is a dominant climate-related hydrologic process on the MBS It is involved in numerous management problems including road failures, debris avalanches and torrents, quantity and quality of fish habitat, and management of riparian areas. There are also some indications that harvesting can affect rate of water delivery to soils during rain-on-snow events *I suggest the following wording be incorporated: [not reproduced in* this appendix.]

Response: These comments have been incorporated, where appropriate, into Chapters III, IV, and the References section of the FEIS

THE EFFECTS OF CLEARCUTTING IN THE RAIN-ON-SNOW AREA ARE NOT DISCUSSED

The analysis in the plan did not address the effects of clearcut logging on stream hydrology and channel stability . Increases in peak flows can result from accelerated snow melt during the rain-on-snow events. This can result in increased mass wasting, erosion of streambanks, changes in channel stability, and downstream flooding, all of which affect the productivity of fish habitat and the survival of eggs and fry. We would suggest that the amount of timber

harvest in the rain-on-snow zone under each alternative be used as an indicator of the potential for changes in hydrology and downstream flooding.

I was very surprised that the report did not address the obvious watershed problem that occurred this last fall. In fact, many if not all of the alternatives seem hell-bent on clearcutting the municipal watersheds as quickly as possible. Isn't it apparent that the greater the clearcut area, the faster the snowmelt and rainwater runoff thus leaving lower reservoir levels following the summer/fall dry season.

I didn't see any mention within the report of increased water needs from national forest municipal watersheds for the ever-increasing Puget Sound population. Additional clearcuting wouldn't seem an appropriate solution for that need

Response: Water runoff from rain-on-snow events on clearcuts has a major influence on erosion and is discussed in Chapter III, FEIS The effects of harvesting and other activities on water yield have been expanded, Chapter IV Soils and Water In addition, a new section on groundwater recharge and aquifers has been added to Chapter III, page II-14.

FUTURE WATER QUANTITY AND SUPPLY HAVE NOT BEEN ADEQUATELY ADDRESSED

I don't think water quantity and water supply for the future has been adequately addressed. Great emphasis is on high quality, but the real problem of the future will be quantity and the Forest Service must face this as the principal resource holder.

The discussion indicates that changes in water yields (at least for smaller areas) can be expected even though they are not quantified in the planning process

Water, a major and vital product of the forest, is recognized in the Plan as to quality but not as to quantity. Protection of watersheds is well covered, but what about increasing water yield and planning for additional storage capacity?

Response: Management activitives on national forests on the west side of the Cascade Mountains do not appear to have significant effect on water quantity There have been a number of small watershed studies, typically 100 acres in size or less, where changes in stream flow - before and after timber harvest - have been measured. The general conclusion is that temporary on-site increases in annual and summer flow normally occur. Effects on peak flows are inconclusive. While initial on-site increases may be substantiated, they are too small (less than 5%) to be measurable in large watersheds, where only one or two percent are the area is harvested annually. This is due to vegetation re-growth in harvested areas. See the previous response for additional sections to refer to in the FEIS.

INADEQUATE DISCUSSION OF WATER QUALITY IN MANAGEMENT AREA DESCRIPTIONS

There is inadequate discussion of water quality in general over the forest, Forest Plan management prescriptions. Comments are too dispersed.

Response: It is not our intent to discuss water quality in the management area prescriptions in the Forest Plan The MA standards and guidelines

include the direction for water and watersheds applicable to a specific MA. Refer to Chapters III and IV, FEIS for more discussion of water quality.

DRAINAGE INVENTORIES NEEDED FOR BASELINE DATA

It is essential that drainage by drainage inventories of both the fisheries and the water quality of the 66 major watersheds be determined and used as a baseline for future evaluation Monitoring of the streams and the fisheries should be made frequently throughout the life of the Plan and compared with the baseline studies. A "triggering mechanism" needs to be in place which would force cutbacks in roading and logging activities once acceptable levels have been exceeded.

Response: Drainage inventories will be done on representative drainages to establish baseline data. Refer to the Information Needs, Fish-Water-Riparian, Forest Plan, Chapter 2. Monitoring will be done to determine changes. When changes exceed established standards, the information will be cycled back into the planning and operational process. Refer to Chapter 5, Monitoring Plan, Forest Plan.

ADDITIONAL RESEARCH NEEDS

There are some research needs that could be included in the list of information needs, Chapter 2 of the Plan I suggest adding some statements similar to the following: determine the extent of the transient snow zone and the probability of occurrence of rate of water delivery to soil during rain-on-snow conditions; study the effects of different types of forest cover (new clearcut, mature forest, 15-year-old unthinned plantation, etc.) on rate of water delivery to soil during rain-on-snow conditons; determine under what site conditions forest roads collect and redirect subsurface water, determine the relative importance of sediment from valley glaciolacustrine deposits reworked by streams in adversely affecting spawning gravels of anadromous fish.

Response: These have been added to the Chapter 2, Information Needs section of the Forest Plan; refer to Fish-Water-Riparian Items 15, 16, 17, and 18.

HOW ARE WATERSHED RESTORATION TECHNIQUES SELECTED?

DEIS, Chapter IV, page IV-28 states "There are some...restoration techniques that will occassionally be used." What does this mean? How many, where, and how many dollars? Are problems in Class II or only Class III addressed? Who decides this?

Response: This paragraph, on mitigation that may be used for water resources, has been reworded in the FEIS to better explain the following: specialized restoration techniques include such items as stabilization of landslide areas, installation of check dams in steep drainage areas, and permanent and temporary water barring of road prisms. They will be used on a case-by-case basis at the project level, when determined by District personnel. A seriously damaged area will likely be repaired, regardless of watershed class, provided that repair is necessary to protect resource values and funds are available.

PLAN ONLY CONSIDERS LIMITED WATERSHED IMPROVEMENT, LIMITED FUNDING

The Plan only identifies 35 acres of watershed improvement projects per year. The data base is at least 6 years old. There is limited funding for field personnel and there is very limited validation of existing conditions. Is the intent to say that only 350 acres of the Forest needs restoration or improvement in the next 10 years? Why is this effort confined to the north part of the Forest? What data base was used to determine the acres in need of restoration?

> **Response:** Refer to the new Plan Appendix I, Watershed Restoration Program. The 350 acres per shown in the Draft Forest Plan was an error; the figures have been corrected in the Forest Plan. The restoration efforts are concentrated in those portions of the Forest with the most severe damage (and conditions). Inventories were conducted in the most critical watersheds.

DISCUSS HOW THE LEVEL OF INVOLVEMENT WILL VARY WITH PROJECT COMPLEXITY

Referring to the Resource Summary for watersheds, Forest Plan: we support the concept whereby the level of involvement will vary commensurate with project complexity. However, this needs additional discussion. The criteria for determining what levels of involvement are appropriate, the monitoring to confirm predictions, the contingency plans, the responsible parties, the level of environmental analysis, etc., all need to be tied into this procedure for it to be meaningful.

> **Response:** It is beyond the scope of the Forest Plan to define the precise nature of the involvement that may be required at the project level. The appropriate level of involvement is determined during the Scoping process, when a project is conceived.

MEETING TIMBER PRODUCTION GOALS WILL DEGRADE CLASS I WATERSHEDS TO CLASS III

The plan further assumes that by dispersing harvest activities from Class III to Class I drainages, the impact of harvest activities will be reduced. It does not address the scenario wherein these watersheds will also be degraded to Class III, because in meeting timber production goals, they will be as heavily cutover as current degraded watersheds.

> **Response:** The harvest rate for Class I watersheds will be limited by the Size and Dispersal of Openings and State of Vegetation Standard and Guideline, Pacific Northwest Regional Guide (1984b), dispersion management requirement, which states that adjacent, cut-over stands must reach at least 4-1/2 feet prior to harvest of the adjacent stand. The Class I watersheds, by definition, are able to absorb this level of harvest without becoming degraded. In addition, to meet water quality and riparian MR's, a maximum number of acres available for final harvest, in each watershed per decade, has been set. Refer to new Appendix H.

DEGRADATION OF SMALL WATERSHEDS CAUSES IMPACTS TO LARGER WATERSHEDS DOWNSTREAM

The degradation of these smaller watersheds also results in downstream impacts on larger watersheds which they are tributary to. According to the Plan, there

are no planned restoration activities in drainages without local anadromous fish populations, despite the fact that they are tributary to larger fish-bearing streams. In fact, it is stated that watershed restoration work is expensive and will only be done on a very limited basis.

Response: The development of a method to meet water quality and riparian MR's, through the hydrologic cumulative effects analysis procedure, will allow dispersion of timber harvest and limiting entry in watersheds that are in an unacceptable condition. See new Appendix H. Meeting the MR's, along with use of Best Management Practices, will allow recovery in the smaller, degraded watersheds. Recovery will be hastened, in high priority areas, with watersheds restoration, as funding allows. Refer to new Forest Plan Appendix I, the Watershed Rehabilitation Program.

HARVEST RATE IS TOO HIGH TO PREVENT WATERSHED DAMAGE

I still do not see watersheds being assessed as entities, specifically with regards to timber harvest I believe that the maximum harvested area percentage for watersheds is still to high to prevent resource damage. It appears short sighted to put so much energy into anadromous fishery improvements when sediment from timber harvest areas degrade the resource perhaps more than any other single factor.

Response: The development of a method to meet water quality and riparian management requirements should help address this. The Category II and III watersheds were evaluated and a maximum number of acres available for final timber harvest, per decade, was established for each watershed This is the harvest rate that the watershed can withstand without incurring soil and water degradation. Refer to the discussion in Chapter IV, FEIS and the new Appendix H.

NEED MORE DETAIL ON PESTICIDES, CHEMICALS THAT MAY BE USED, EFFECTS ON WATER

While the Forest is still enjoined from use of herbicides, the plan should describe those elements of pesticide use that are site-specific to the MBS, but only generally described in the programmatic vegetation management EIS.

Chemicals can enter surface water if applied without proper care. As they destroy forbs and woody vegetation, they may limit large areas of regenerated forestland from contributing to the appropriate forage/cover quota In areas of wildlife habitat, chemicals should be strictly limited, or areas adjacent to hiding cover should be seeded with alternative food sources.

The effect of biocides and fertilizers on aquatic systems need to be addressed in more detail.

Response: The court injunction was lifted in May, 1989; however, the Forest Service is under an administrative stay, imposed by the Chief of the Forest Service, not to use herbicides. Until this stay is lifted, vegetation management will continue to be accomplished using other methods. When it is lifted, we will follow the Pacific Northwest Region, FEIS on Managing Competing and Unwanted Vegetation, the Record of Decision, and the provisions of the Mediated Agreement. Refer to the updated discussion in Chapter III, FEIS, Vegetation. Any proposed herbicide use

will be analyzed in a site-specific environmental analysis, with public involvement and a NEPA document that will discuss effects in detail.

Also note that the prescription for MA 13D, Forest Plan Chapter 4 states: integrated pest management is permitted except where the use of pesticides conflicts with riparian values."

HOW WILL IMPACTS FROM MINING BE INSURED?

It is not sufficient to "insure" that impacts to water resources from mining will not be significant because of the regulatory controls available for water resources. The mechanisms and processes for carrying out the regulations need to be presented.

For mineral extraction, a statement of protection of riparian values is not sufficient. How will this be determined or ensured?

Response: Mining impacts on water quality are addressed in FEIS, Chapter IV. State agencies (Departments of Ecology and Environmental Quality) set applicable water quality standards and permit requirements. The Forest Service may add additional requirements Refer to the Best Management Practices, new Appendix I. Water quality protection methods will be addressed on a project basis, and will include applicable Forest Plan Standards and Guidelines. The removal of tailing ponds, which are a threat to water quality, as well as other needed restoration projects, are inventoried. Restoration will occur if and when funding is provided for this.

Cumulative effects of mining will be evaluated on a project-by-project basis, because mining activities are normally unscheduled. Mining activities depend on economic conditions, technology available to extract minerals, and mineral location. None of these factors are predictable.

CORRECT DISCUSSION ON EFFECTS ON WATER

In Chapter IV, DEIS this section states that increased populations of animals can be expected in our watersheds because of various reasons. Another statement says that there are no known effects in watersheds with uncontrolled access, indicating that having uncontrolled access must be good for water quality. This is completely against the thinking of the vast majority of public health officials and experts in the field

Response: These sections have been rewritten and corrected in the FEIS.

HAVE THERE BEEN INSTANCES OF WATERBORNE DISEASE?

For the comprehensive list of municipal watersheds listed in Table III-2, have there been instances of waterborne disease? Any significant source related water quality problems should be summarized.

Response: There has been no record of waterborne disease in the municipal watersheds.

ERROR IN DISCUSSION OF ROAD 54 IN THE GREEN RIVER WATERSHED

Forest Plan, Appendix G: The closure point on this road is approximately 4 miles west of Lester, as of March, 1988. The closure point will be moved to Lester after a land exchange is completed. You could point out that the FS is still the controller of road 54 and retains full administrative/contractor/ permittee rights to use the road at any time without hindrance. It is only general public use (recreational) that has been given up.

Response: This section of the Plan Appendix H has been re-written.

MODIFY DISCUSSION ON CLEARWATER RIVER

The discussion after Table IV-6, DEIS, needs to be modified regarding the Clearwater River There are substantial numbers of pink salmon here, a species much more prone to be limited by sediments during its critical life history stages (spawning/incubation) It is also probable that the average stream gradient in the Clearwater study area is significantly greater than the the norm on the Forest

Response: The discussion has been modified in the FEIS.

ERROR IN NUMBER OF PEOPLE SERVED BY FOREST MUNICIPAL WATERSHEDS

There was an earlier statement that indicated 1 2 million people were served by the 136,400 acres of the forest supplying municipal water On page S-10, it indicates that 2 million people were served.

Response: Both statements have been corrected to show that the Forest supplies approximately 1.4 million people.

DESCRIBE THE HISTORY OF THE CEDAR AND GREEN RIVER WATERSHEDS IN THE FEIS

It would be helpful if the history of both watershed were described so that a historical perspective could be developed, and one could see the long-term relationship that has existed between the Forest Service and these municipal watersheds.

Response: We feel the length of the discussions on the Cedar and Green River watersheds in the Chapter III, Affected Environment, FEIS are adequate for this level of planning We have added references to current agreements; see References section, FEIS To include a history, especially in the Cedar River, would not meet CEQ's directive to limit lengthy descriptions of the affected environment and avoid including material not specifically germane to the issues and concerns

WHAT IS THE EFFECT OF CITY'S SECONDARY USE POLICIES ON TIMBER SUPPLY AND NFS MANAGEMENT?

The City has put a moratorium on timber harvesting on the 70,000 acres of City-owned lands in the watershed until they complete a secondary use analysis, which appears to be moving rapidly away from further harvesting of City-owned lands there. How will this affect the regional timber supply? What bearing might it have on the management of NF lands in the same area?

Response: On August 7, 1989, the Seattle City Council adopted Ordinance 114632, which embodies the new Secondary Use Policies for the Cedar River Watershed. The City will set aside approximately 50% of its lands in a reserve precluding timber harvest. They will prepare a long-range timber harvest plan for second-growth lands outside that reserve. In addition, the policies call for acquiring 4,000-6,000 acres of old-growth forest that are currently NFS lands, to be maintained as old-growth habitat.

Theoretically, there will be no effect on NFS land management in the area, as the City cannot dictate land management for NF system lands, any more than the Forest Service can dictate management for City lands. However, the intent of the policies is to acquire at least a portion of the existing NF lands with old growth intact. Whether this will result in an overall decrease in NF timber harvest over the next several decades will not be known until the City and the Forest Service negotiate a land exchange. If the City trades mature timberlands for the NF old growth, there would be little or no immediate decrease in harvest If cutover lands are traded for old growth, there would be a net decrease in timber harvest until the cutover lands once again have timber of harvesting age. However, the lands the FS would acquire may be located elsewhere in the State of Washington, or even out-of State.

It is also not really possible to tell what the effects will be on the regional timber supply until the City finishes its inventory, prepares its long-range timber harvest plan, and completes the land exchange with the Forest Service. Even under the scenario that would withdraw the maximum amount of mature timber from the region's harvestable base, the net effect would be very small for the region as a whole (defined, say, as Western Washington). There could possibly be some minor local displacement in the immediate area of the watershed, but most likely local mills would make up at least some of the volume by going further afield. Any decrease would contribute to the overall shrinkage of the available timber base, but its contribution, strictly by itself, would be almost immeasurable.

ASSURE NFS MANAGEMENT IS COMPATIBLE AND COORDINATED WITH NEW CITY POLICIES

We urge you to use the overlap in City and Forest Service planning to assure the creation of compatible and coordinated policies by the two major landowners of the largest single source of drinking water in the State of Washington.

Response: The Preferred Alternative includes a new management prescription for the Cedar River Watershed: 20D Negotiate a New Cooperative Agreement. The MBS has proposed to the City that we begin a renegotiation of the 1962 Cooperative Agreement. A new agreement would to recognize (and incorporate into our working relationships) the many changes that have occurred since 1962, both in the natural and social environments in which we operate, and in the policies guiding the City and the Forest Service. It is our intent to continue to the degree possible the cooperative relationships of the past, within the context of changing demands and management direction.

MANAGEMENT IN THE WATERSHED NEEDS TO BE CONSISTENT WITH NEPA, NFMA, ETC.

The 1962 agreement is nonbinding in that in predates NEPA, NFMA, etc. Activities in the watershed need to be completely revised to bring them in as part of the NEPA process.

Response: Forest Service management activities in the watershed will be governed by the approved Forest Plan, which meets the requirements of NEPA, NFMA, etc.

REQUIRE FAIR MARKET VALUE FOR NFS OLD GROWTH ACQUIRED BY THE CITY

Prescription 20B does not specifically state if the City would be required to pay for the old growth timber at fair market value. This timber is a public asset. It should not be "given" to the City. Also, to do so would set a dangerous precedent for timber stands in other municipal watersheds

Response: By law, the Forest Service cannot sell land to the City (or any other party). Rather, land must be traded on a value-for-value basis (although there is allowance for a value differential of up to 25% to be settled by cash). If the City is to acquire NFS lands in the watershed that have standing old growth, it will have to either find comparable old growth lands somewhere outside the watershed to trade on an acre-for-acre basis, or it will have to acquire sufficient additional acres of land that will be equivalent in total value to the NFS lands in the watershed

WATER PRESCRIPTIONS DO NOT PROVIDE SAFE WATER; FILTRATION NOT ADDRESSED

Management prescriptions 20A, 20B and 20C, Cedar River Watershed, do not provide a commitment to preservation of high quality water so that it can be safely used in municipal system without filtration. Uncontrolled and dispersed human recreational activities on National Forest lands within the watershed present the greatest single health risk to the 1.1 million people who use and depend upon this water supply. Accordingly, the Indicators of Response in your otherwise excellent discussion of Water Quality and Municipal Watersheds, should also include a quantitative evaluation of the level of dispersed, unsupervised public use of the Forest Service lands in the Watershed.

The provisions in intensity 20C, which would result in an increase in dispersed recreation in the Watershed, would present significant problems for the City in complying with the new regulations and other expected changes to these regulations. The City, therefore, opposes intensity 20C. We also recommend that an appropriate management intensity (rather than 20A, 20B, or 20C) be developed cooperatively by the City and the Forest Service.

Our concern for the biological, chemical, and physical characteristics of the streams is not mentioned nor is our prior request that the economics of filter plant be compared to the trade-offs of recreational uses of the watershed.

The City of Seattle is committed to producing high quality water without filtration; we urge that MA 20A, 20B, and 20C explicitly address filtration.

> **Response:** The Forest Service is not required to supply pure drinking water to municipal watersheds, we are required to supply high-quality water that is treatable. Forest Service Manual 2542.03 states, in part: "Encourage municipalities to adequate and appropriate water treatment. Do not rely on management practices to provide pure drinking water". We feel the goal statement for MA 20D Cedar River Watershed meets this intent. An analysis of the economics of filtration is currently outside the scope of the Forest Plan.
>
> The Preferred Alternative management area prescription for the Cedar River Watershed is 20D, Negotiate a New Cooperative Agreement, developed since the DEIS was released The Forest Service will initiate new discussions with the City of Seattle, in light of the 1989 Secondary Use Policies. The FS will not enter into any new land exchanges affecting national forest lands within the watershed until a new agreement is negotiated. Until such time, the 1962 Agreement will remain in effect. See Forest Plan, prescription for MA 20D

UPPER MIDDLE AND S.F. NOOKSACK IMPORTANT FOR MUNICIPAL USE; SHOULD BE W & S

The DEIS recommended logging roads, and ultimately logging, in the North Fork Valley and the Bellingham Municipal Watershed in the Upper Middle Nooksack Valley. These areas are especially important to Whatcom County for domestic water, plus important wildlife habitat. The County feels the Middle and South Forks of the Nooksack should be considered for Wild and Scenic River status, to help protect the scenery and ensure water quality essential to native fish runs.

> **Response:** In the Preferred Alternative, the South Fork of the Nooksack is recommended for inclusion in the Wild and Scenic Rivers system; refer to

Table 4-14, Forest Plan for the classification of various segments. A total of 6.6 miles are recommended. The upper Middle Fork is allocated to a combination of MA 23A, Other Municipal Watershed, MA 14 Deer and Elk Enhancement, and MA 15A Mountain Goat Habitat. There is no scheduled harvest in mountain goat habitat and no new road construction. Refer to standards and guidelines for the management area, Plan Chapter 4. Timber harvest activities will take place in MA 23A; the intensity applied is 17B - natural regeneration, pre-commerical thinning, and final harvest. All Forest-wide standards and guidelines to protect or enhance water quality will apply, and watershed improvement and maintenance activities are permitted. Again, refer to the MA standards and guidelines. Harvest is at less-than-full yield in MA 14, the allocation that is located along the river. Units are designed to achieve optimal thermal cover acreage requirements first, then meet forage requirements. Old-growth as well as second growth stands and clearcuts will occur. Refer to the map for Alternative J (Preferred).

WHO HAS USE OF WATERSHED ADJACENT TO CRYSTAL MOUNTAIN?

Is the entire MA 23A area adjacent to Crystal Mountain a watershed for another municipal facility? If so, which municipal area, what rights do they have, and what impacts might this have on Crystal's development?

Response: The watershed is for the use of Crystal Mountain and the Silver Springs area.

NOT ALL RIPARIAN AREAS AND WETLANDS ARE RECEIVING ADEQUATE CONSIDERATION

Riparian zones are defined to include all wetlands However, discussion of management and environmental effects to riparian zones elsewhere in this section and throughout most of this document only include those areas adjacent to streams, and then are only concerned with fish-bearing reaches of streams.

Management of other wetland areas - around lakes, ponds, springs and non-fish bearing streams, wet meadows, bogs, marshes and swamps - needs to be discussed.

Maintaining wildlife habitat and conditions for fish is not sufficient to maintain native riparian wetland and aquatic system. Native plant communities, nutrient levels, non-fish aquatic species of animals and plants, and food webs all need to be considered.

Management plans for protection of wetland (including streamside) plant communities and native ecosystems are needed, including buffer zones to protect them. Equipment, motorized vehicles, livestock, and in many cases people, need to be kept out of wetlands.

> **Response:** The protection of riparian areas of wetlands (fish and non-fish) is included in the Forest-wide Standards and Guidelines for Water Resources and Riparian Areas (Item 5), Forest Plan. These standards and guidelines speak to lands adjacent to perennial and intermittent streams, lakes, bodies of water of all sizes, wetlands, ponds, seeps, floodplains, and other wet areas. Also, refer to the specific guidelines for MA 13, Riparian As noted, in the Desired Future Condition for MA 13, diversity of vegetation is also addressed; there is no domestic livestock grazing.
>
> A new Appendix I, Best Management Practices for Soil and Water Protection, has been added to the FEIS. This appendix discusses the application of BMP's as a preventative system, including· selection of management practices and evaluation in an environmental document (either EA or EIS, for site-specific projects), implementation and enforcement, monitoring, and evaluation and adjustment.

MAP RIPARIAN ZONES TO ESTABLISH A BASELINE FOR MONITORING

Riparian zones are our most sensitive hydrologic zones and the point of initiation of most large scale mass wasting. By comparing changes in riparian vegetation and channel configuration over time, accurate and efficient assessment of conditions relative to Forest Plan Standards can be obtained. The draft Plan states that Riparian Areas will be mapped during project design; the problem with the above standards is there is no current baseline to measure against. Riparian zones and Class I, II, and III streams need to be identified and the vegetation mapped.

> **Response:** We agree. Refer to Forest-wide Standard and Guideline for Water Resources and Riparian Areas, Item 11. Riparian zone mapping will be conducted as funds allow and has already been started. Approximately 18 miles of aquatic/riparian mapping was done in 1989.

MORE DISCUSSION, GUIDANCE RE: INVENTORY AND MAPPING RIPARIAN AREAS

We support the decision to inventory and map riparian areas for the Forest-wide data base, but discussion of this needs to be much broader It should include the data that the Forest will be collecting - very useful for cumulative effects. Specific guidance is needed so that data collection will be consistent across the forest. How will the information gathered here be used to address the information needs identified on page 2-19? How will decisions affecting riparian area be handled without this inventory?

> **Response:** Several guidelines are given in the Information Needs section of the Plan. In addition, as the MBS implements a Geographic Information System, more information on how to map riparian areas may be developed. Prior to the inventory development, decisions affecting riparian areas will be made on-ground at project site after evaluating pertinent factors of the riparian area.

WHAT SIZE WETLANDS WILL BE PROTECTED?

In MA 13 Standards and Guidelines, Item C 1 e , for managing wetlands, is it meant that wetlands will only be protected if threatened and endangered species are involved or if the wetland is at least several acres in size. It appears that this may unnecessarily neglect some important wetlands How is the "several acres in size" to be interpreted?

> **Response:** In the Plan, MA 13, C.1.e has been changed to read "...Manage wetlands to protect all bogs, swamps, and beaver ponds."

WHAT TYPE OF STREAMS ARE INCLUDED IN RIPARIAN AREAS? HOW IS THE BOUNDARY DETERMINED FOR OTHER RIPARIAN AREAS, INCLUDING WETLANDS?

Does the width of riparian areas (100 feet from the water's edge on both sides of all perennial streams) include intermittent streams that do not directly supply domestic water, are not used by fish, or contain enough water to be a major contributor to streams that contain these characteristics? How and when is the boundary determined for protecting all other riparian areas, including wetlands?

> **Response:** The area included for the purposes of Forest planning is defined in Chapter III, FEIS. Actual riparian boundaries for streams and other riparian areas are determined during site-specific, project level planning, based on topographic and vegetative conditions. Refer to Forest-wide Standard and Guideline, Plan Chapter 4, Water and Riparian Items 4 and 11

WHAT ARE THE CHARACTERISTICS OF RIPARIAN AREAS?

It is stated that "Geographical boundaries of riparian areas are determined by on-site characteristics." What are these characteristics? How much of the area around the riparian area is included within the area to protected?

> **Response:** There are several on-site characteristics that are evaluated to determine the geographical boundary These are topography, vegetation, soil stability etc. Usually all the unique riparian vegetation is included within the boundary. The most common topographic boundary occurs at a

natural slope break, such as the top of the inner gorge. Also, refer to the discussion in Forest-wide Standards and Guidelines, Chapter 4, Plan.

INFORMATION ON WETLANDS IS INSUFFICIENT

There is insufficient information in the EIS with regard to impacts on wetlands. How many wetlands are in the National Forest, and where are they? How can they be characterized? What benefits do they provide, and how do the alternatives differ in terms of their impacts on wetlands?

Response: As discussed in Chapter III, Riparian Zones, there are thousands of wetlands on the MBS, located on valley bottoms and within topographic depressions. They range in size from a few yards square to several acres. The actual number of wetlands is unknown, as many of the smaller wetlands, and those located in undeveloped or wilderness areas, are too small be seen on aerial photos. The characteristics of wetlands are defined in Chapter III, FEIS and in the glossary. Also, see Chapter III, Riparian, FEIS for a discussion of the benefits. Chapter IV, Environmental Consequences, includes the impacts of implementing each alternative on wetlands - see Water, Chapter IV.

LIST ALL STREAMS ON THE MBS, ALONG WITH PROPOSED BUFFERS.

I would like a list of all the streams, even if they do not run the entire 12 months of the year, along with the minimum proposed buffer for each stream, for protection from logging near a riparian zone. Since only a small amount of all the timber harvest comes from the riparian areas, the actual increased cost of maintaining buffers or entire undisturbed riparian zones could not be a large contributing factor to overall timber production costs.

The Forest needs to complete a full stream survey before the next planning period.

Response: The prescription for MA 13, Riparian and Fish Habitat Emphasis, includes the specific standards and guidelines to be used for all Class I, II, and deeply incised Class III streams, and lakes, wetlands, ponds, seeps, floodplains. In addition, refer to the Forest-wide Standards and Guidelines for Water Resources and Riparian Areas, Chapter 4, Plan. In part, MA 13 calls for meeting or exceeding water quality; extended rotations for some harvesting (some areas will not be harvested and some will be managed on a normal rotation - to be determined at the project level, environmental analysis); maintenance of streamside vegetation; soil protection; fish habitat improvement; and maintaining or improving the diversity of tree and animal species.

A list of **all** Forest streams is beyond the current scope of the Forest Plan. Such information, along with the site-specific riparian prescription, is developed at the project level. The MBS is in the process of implementing a Geographic Information System (installation to be completed by 1992). With the aid of this computerized technology, we should be able to generate a mapped layer of all streams before the next round of Forest planning.

AVOID ANY MORE LOSS OF WETLANDS; DISCUSS THEIR REHABILITATION

Wetlands are fast becoming rare and unique habitats because so much has been lost; further losses should be avoided entirely. How are the wetland areas rehabilitated:

Response: The Forest-wide Standards and Guidelines and standards and guidelines for MA 13 (Forest Plan, Chapter 4) speak to wetlands and riparian areas In addition, we are required to follow the direction of Executive Order 11990 - Protection of Wetlands (1977). It requires agencies to take action to minimize the destruction, loss, or degradation of wetlands, to preserve and enhance their benefits, and avoid construction in wetlands unless there is no practical alternative and the action is designed to minimize impacts. Because the Forest Service is a multiple-use agency, it is not possible to limit entirely activities in wetlands. However, the objectives are to minimize disturbance and maintain the integrity of the wetlands. Where disturbance does occur, rehabilitation will be done by re-establishing vegetation on disturbed areas.

BETTER RIPARIAN PROTECTION NEEDED

The forest needs better riparian protection. A 100-foot buffer should be provided for all sizes and classes of streams. This would also provide potential wildlife corridors and restrict erosion and siltation.
It is stated that "Emphasis will be placed on the protection of riparian areas so that their integrity is maintained " Riparian integrity needs to be clearly defined. Under such an approach, what level of impact still preserves the integrity of the area?

The Forest-wide Standards and Guidelines for riparian areas are extremely vague, with far too much qualifying language. They need to reflect a more greater level of protection for the vital riparian ecosystem

Maintenance of buffer strips should be clearly mandated for all riparian types, and enforcement of timber harvest regulations near buffer strips should be strictly enforced.

It appears that Class I, II, and heavily incised Class III aquatic/riparian areas may not be given the quality of protection that is required for conservation of fish and wildlife resources. There is simply too much flexibility in the Plan, which could result in intensive logging and road building within these areas.

Response: Riparian integrity means that the quality of the area will be maintained to meet the riparian objectives that are defined for a specific riparian area during project analysis. At the time of project proposal, the boundaries of the riparian area are set, depending upon specific topographic variation: see Forest-wide Standards and Guidelines. Refer to the specific management prescription for MA 13, Chapter 4, Forest Plan; specifically note that timber harvesting is on an extended rotation, and is permitted only when riparian objectives can be accomplished. MA 13 L.2.a. states that roads should avoid riparian areas when possible and that they may be located in a riparian area only if riparian values are protected. There is discussion in Appendix B on the FORPLAN modeling done for MA 13.

Note that buffer strip is an outdated term. The present concept (and the one used in this planning process) centers around managed vegetation in the riparian zone. Trees are left in sufficient numbers to achieve desired objectives, such as: shade over the stream, future large woody material recruitment, etc. Site-specific requirement are determined during project design.

CLASS III AND IV STREAMS IGNORED

The width of the "buffer" seems to be fixed by stream class rather than site specific conditions. Other problems· without any inventories of Class III and IV streams, how can the plan propose narrow "buffer" widths? The implication, again, is that the Class III and IV streams are unimportant to fish production. This doesn't fit with commonly accepted ideas about ecosystems and food chains.

The preferred way to mitigate impacts to the riparian zone is to give full protection to that zone for all stream Classes This would require that logging and road building occur well outside of the riparian zone.

Standards and guidelines for riparian zones may be inadequate to protect important fish and wildlife resources such as anadromous fish, amphibians, cavity nesting waterfowl, other waterfowl, and mammals. It appears that lightly incised Class III streams and all Class IV streams can be heavily logged. Consequently, the management guidance preserved here should be re-evaluated and changed to meet fish and wildlife requirements. It should be noted that what happens in these small headwater streams has a disproportionate effect on downstream biological activity.

In the smaller, lightly incised or intermittent streams, the plan allows for a ten foot buffer which is totally inadequate for fish and wildlife protection. Studies have shown that wildlife and fish species diversity is reduced significantly as streamside zones are decreased. Since riparian habitats are so critical for wildlife and fish, they merit special protections and the State recommends a riparian zone as wide as the potential height of the tallest trees in the zone. This prescription should apply to all waters bearing fish as well as smaller Class III streams featuring key wildlife habitats.

Response: The streams side management unit (SMU) discussed in the Appendix B (including the 10-foot width for Class IV streams) are widths that were used **only** for modeling timber harvesting constraints in FORPLAN. They have no tie to the width of the riparian area on the ground. For project level, or timber sale planning, a District ID Team will determine the actual riparian area boundaries for all steams. At a minimum, riparian areas are maintained as per the Forest-wide Standards and Guidelines. Actual on-the-ground project planning will determine the riparian widths along all stream channels. Note Item 6, maintaining riparian areas in accordance with FSM 2526, which states, in part, "Give special attention to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes, and other bodies of water. This distance shall correspond to at least the recognizable area dominated by the riparian vegetation." (FSM, as amended 3/86) Timber harvesting in this 100 foot zone can only be planned and developed it the riparian area dependant resources of soil, water, fish and wildlife can be protected or adequately mitigated. MA 13C will be applied to all Class I, II, and deeply incised Class III streams.

The Forest-wide Standards and Guidelines also speak to lightly incised Class III streams with existing fish useage. Refer to Item 9.b..

CLASS IV STREAMS NOT PROTECTED IN THE PLAN

The ramifications of the series of assumptions documented in Appendix B (page B-150) ends with the following "the SMU prescription does not apply to Class IV streams." Thus, the following appears to have occurred:

Stream Class	Current Actual Protection	Planned Protection
I & II	225 feet width	200 feet
III deeply incised	125 feet (average)	100 feet
III lightly incised	125 feet (average)	10 feet
IV	125 feet (average)	None

We realize that this only applies to the planning process and that each case will be examined on its own individual merit. However, changes of this magnitude must significantly impact implementation or the planning process is deliberately flawed. We cannot see how even existing levels of fish production (which are already admittedly far below potential natural levels) can be maintained with this type or reduced habitat protection.

Response: These widths were used only in FORPLAN modeling to determine a Forest-wide timber harvest constraint Actual riparian area widths will be determined on a project level bases During project level planning, at least 100 on each side of a channel must be considered. This situation is similar to the current actual protection column

"DEEPLY" AND "LIGHTLY" INCISED ARE SPECIAL TERMS

The basic stream classification system described is common to National Forests in general. However, "deeply incised" and "lightly incised" is a special adaptation unique to Mt. Baker-Snoqualmie

Response: These characteristics, which do describe the physical situation on the MBS, are defined in the Glossary

MITIGATION IS LIKELY TO BE COSTLY, AND FUNDS PLANNED FOR FISHERY ENHANCEMENT ARE LIKELY TO BE DIVERTED TO MITIGATION

The narrative discussion under "Water and Riparian Resources" consistently points to a direct relationship between expensive mitigation measures and levels of management activities (timber harvest, roading relationship. For example, Alternative D - which has a high level of timber harvesting, etc. would require "intensive mitigation measures" while Alternative C has "least mitigation required". However, none of this is quantified. A realistic expectation it that mitigation would be a significant cost, particularly for management activities in the riparian area. It is also probable that funds planned for fishery enhancement will actually be diverted to mitigation in most of the alternatives involving moderate to high levels of forest management activities.

Response: The actual cost of either fisheries or watershed mitigation is difficult to narrate, and the scale and/or scope of the mitigation is highly variable over the Forest. Difference between fishery mitigation (rehabilitation or restoration) and enhancement (improvement) for this Forest is this: mitigation is correcting a situation in order to restore fishery production or capability to a previous desired state, while enhancement is improving or making better an exiting acceptable fishery production or capability level. Watershed Rehabilitation and Fish Habitat Improvement schedules for the first decade of the Plan are included in Plan Appendices I and C

IDENTIFY RIPARIAN AREA MITIGATION STANDARDS MORE FULLY

The standards for riparian area mitigation that have been developed need to be identified more specifically. By stating that special attention will be given to activities in riparian areas, there are no assurances that the riparian areas will be adequately protected and that potential impacts will be properly mitigated. For example, what will and will not be allowed in riparian areas should be discussed

Response: Mitigation measures applicable to all alternatives are discussed in Chapter II, FEIS. Also, refer to Forest-wide Standards and Guidelines for riparian areas, and the standards and guidelines for MA 13, both in Chapter 4, Forest Plan. Together, and with the mitigation measures and application of Best Management Practices (determined at the site-specific project level), these provide a great deal of detail regarding what will and will not be allowed in riparian areas. Additionally, each proposed project - from timber sales to trail reconstruction - will involve an environmental analysis, following the NEPA process, with site-specific mitigation measures for each alternative.

DISTURBING SOILS PROVIDES HABITAT FOR NON-NATIVE AND WEED PLANT SPECIES

Disturbing soils provides habitat for non-native and weed plant species. Their establishment can change the species composition and succession of plant communities. They can alter food webs by displacing native species. This is particularly true of wetland and riparian systems, but also applies to uplands.

Soil erosion can lead to sedimentation of wetlands and riparian areas altering the native vegetation (killing vegetation, altering the hydrology, soils and aeration of the areas).

Response: It has been our experience that native vegetation, almost without exception, comes back on disturbed soil on the MBS. The re-establishment of native species will be delayed a few years if the determination (at the project level) is made to plant non-native grass species in order to provide erosion control (and the sedimentation that can occur in wetlands if erosion is left unchecked.) After a few years, the area is unusually invaded by native species and the grass disappears.

Forest-wide Standards and Guidelines for Diversity and Long-Term Productivity speak to a goal of maintaining native (and desirable introduced) plant species. (Plan, Chapter 4). Big game preferred seed will be used for reseeding in identified winter range (Wildlife Forest-wide Standards and Guidelines) And the Forest-wide Standards and Guidelines

for Wilderness state that non-native plants should not be introduced. Also required in wilderness is the use of weed-free hay or grain for pack and saddle stock, to minimize the accidental introduction of non-native species.

DISCUSS SOIL IN RIPARIAN AREAS AND EFFECTS OF TIMBER HARVEST, ROAD CONSTRUCTION ON THEM

Soils in riparian areas (all wetlands) are not discussed in much detail, contrary to what is stated in this paragraph. Effects of road building and timber harvest on these soils especially need to be discussed.

Response: Soils - Forest-wide - are discussed in Chapter III, FEIS; the effects of road construction and timber harvest on soils are discussed in Chapter IV More site-specific analysis of proposed activities on soils in riparian areas will be done in project-level environmental analysis. Refer to Chapter 4, Forest Plan, Forest-wide Standards and Guidelines for the soil resource for practices, standards, etc that will be met in all management areas to maintain and enhance soil and land productivity.

HOW IS IT DETERMINED WHEN WATER TEMPERATURE IS AN ISSUE?

How will it be determined where and whether water temperature is an issue? And doesn't it usually become an issue until after the shading requirement goes below 80%, and it is to late?

Response: If water temperatures is likely to be an issue in a ground-disturbing project, it is first identified by District personnel during the scoping process for an environmental analysis Once identified as a concern, an analyses or evaluation is made to determine the significance or magnitude of the problem. Under Forest-wide Standards and Guidelines, Water Resources Item 10, we have cited additional information to quantify "acceptable limits" for water temperature.

GIVE MORE ATTENTION TO VARIOUS MANAGEMENT CONCEPTS IN RIPARIAN AREAS

Greater attention should be given to clarifying riparian zone management concepts, such as providing for recruitment of large woody debris to a stream. For this example, information is needed on the recruitment potential (to the stream) of large woody debris under an unlogged condition as compared with the logged condition. Further, management concepts (e g., stream classes, timber management intensities, structural erosion control, forest-wide standards and guidelines and riparian prescription for fish and wildlife) should be presented in such a way as to form an integrated whole

Response: Beyond the Forest-wide Standards and Guidelines (Chapter 4, Plan), and those of MA 13, this level of detail - such as potential to recruit large woody material - must be described and identified at the project level, when site-specific analysis can be done, and the riparian area identified and mapped. The specific aquatic/riparian inventory of the potentially affected stream system will determine the desired future large, woody material level and recruitment condition.

INSUFFICIENT COMMITMENT TO WATER QUALITY AND RIPARIAN AREAS

The Forest-wide Standards and Guidelines lack the specific commitments to water quality and riparian areas needed to ensure adequate protection.

> **Response:** These are the Standard and Guideline Statements that apply Forest Wide. More specific and intensive watershed protection measures are utilized in various management areas, in sensitive areas, etc. Also refer to the new Appendix I, on application of Best Management Practices. In addition, we have included specific monitoring (Plan, Chapter 5) activities with the objective of measuring how effective our prescriptions, standards, guidelines, and mitigation measures are in meeting the stated objectives and desired future condition for riparian areas. If we find, as each activity and output is measured, that adjustments need to be made, the Plan will be amended.

FOR SILVICULTURAL TREATMENT, HOW ARE RIPARIAN OBJECTIVES DEFINED?

Under MA 13, Item E., silvicultural treatments will be permitted only when riparian objectives can be met How are the riparian objectives determined, and who makes the decision whether or not the treatments are consistent with the objectives? A reference to another section of the EIS may be in order. There should also be inclusion of BMP's for mitigation, as well as contract conditions.

> **Response:** The riparian objectives are discussed in the Forest Plan, Forest-wide Standards and Guidelines. Specialists on each project-level ID team will be involved in the selection of various silvicultural treatments to insure that stated riparian objectives are obtained. In addition, the application of BMP's (refer to new Appendix I) plus stated monitoring (Chapter 5, Forest Plan) all help insure that the objectives are met.

CLARIFY MA 13C STANDARDS AND GUIDELINES FOR ROAD CONSTRUCTION IN RIPARIAN ZONES

MA 13C, (L) (2) (c) states that water quality/anadromous fisheries habitat problems caused by road construction will be given "high priority for corrective action " There should be a high priority for protection above and beyond correction. Further, how does "high priority" translate into management reality?

13C (L) (1) says: "Locating roads in riparian areas can only be done if riparian values are protected." You need to explain **how** values are to be protected. Under (L) (2) (a), what are the "stated riparian area objectives"?

> **Response:** Riparian area objectives are site-specific and are defined at the project level. The objectives may vary, depending upon topographic, geologic, and vegetative conditions, and habitat requirements at that site. Roads will be located in riparian areas only if the objectives which have been defined for that site can still be met. Should damage inadvertently occur, it will be given high priority for correction. Priorities for watershed rehabilitation are defined in new Appendix I, Forest Plan.

CLARIFY ITEMS E. AND F. UNDER STANDARDS AND GUIDELINES FOR MA 13

(E) (2) (b), the purpose of the reference to F1 is unclear.
(E) (2) (b), what happens if more than 10% of the area is damaged, and what defines the area? How is this enforced and monitored?
(F) (1) (a), what does it mean to permit watershed improvements and maintenance? Should they not be required? We suggest that a more active, rather than passive, approach be taken.
(F) (2) (a) how is no more than 10% soil exposure ensured?
(F) (2) (b), how are disturbance, widely distributed, and project area to be interpreted?

Response: Reference to F1 is an error; it should be F2 and has been corrected in the Plan. The project area will vary in size depending upon the particular project The BMP's that will be used should limit soil exposure to no more than 10% of the area. Monitoring will be done to verify that this standard is met, if the limits are exceeded, the BMP's will be revised so as to accomplish the desired objective in future projects.

CORRECT STATEMENT ON WATER LEVEL IN WETLANDS

Referring to the effects section, Chapter IV: changing water levels can have major effect on wetlands, causing them to dry up and change to other vegetation or habitats, or flooding and killing wetland vegetation.

Response: This has been incorporated into Chapter IV of the FEIS.

SUGGEST MODIFICATIONS TO WORDING IN MA 13 STANDARDS AND GUIDELINES

Do not feel the language in MA 13C, program element Recreation Planning is appropriate. Specifically, we are concerned about the wording ".. conflicts will be resolved in favor of riparian and anadromous fish values." The NEPA standards govern, but a progressive, creative, and flexible approach to resolving conflicts must be used.

Under the title "Descriptions of Lands..." for MA 13: the second paragraph says riparian areas contain a variety of resources. The Forest completely left out timber, these lands are, in many cases, the most productive timber lands.

The guidelines for riparian areas focus primarily on the protection of water quality. These habitats are also of very high value to wildlife; attention should be given to protecting riparian habitats for wildlife habitat.

Response: The wording of this standard comes directly from FSM 2526 03 as amended 3/86, and which states in item 2. "Manage riparian areas under the principles of multiple-use and sustained-yield, while emphasizing protection and improvement of soil, water, vegetation, and fish and wildlife resources. Give preferential consideration to riparian dependent resources when conflicts among land use activities occur." The wording of this portion of the MA 13C prescription has been modified slightly since the Draft Plan, it now reads "...conflict will be resolved in favor of the dependent riparian resources and values (soil, water, fish, and wildlife.). *This better meets the national direction. The value of timber in these* areas is recognized, as harvest is permitted when riparian area objectives can be met.

CORRECT WORDING IN THE RIPARIAN STANDARDS AND GUIDELINES

Forest-wide Standards and Guidelines, page 4-97, Item 4: strike the word "large" from the first sentence.

MA 13, J 4 a: the second sentence should read, "...amount of mature riparian habitat."

MA 13C, L.2.c: must be full mitigated in kind, on site.

> **Response:** The suggested changes have been made in the Forest Plan, Chapter 4.

WHICH TREES ARE RETAINED IN MA 13?

MA 13C, C.1.b.: which trees are not planned to be harvested? How will it be determined which trees are needed for slope stability or future wood debris?

> **Response:** This will be determined by a project-level ID Team, with specialists from at least timber, hydrology, and fisheries.

CLARIFY SHADE REQUIREMENTS FOR MA 13

MA 13C, C.1.c.: for monitoring streamside vegetation, it is not clear whether 80% shade is 80% of the existing total watershed.

> **Response:** The 80% figure refers to all the fish bearing streams within the planning area or the drainage (watershed).

IDENTIFY CURRENT HABITAT CAPABILITY AND VEGETATION DIVERSITY IN RIPARIAN AREAS

Under MA 13C C.1.d: current levels of habitat capability and riparian vegetation diversity need to be identified. Discussion needs to be given to what criteria will be used for determining which places are selected for improvement.

> **Response:** Levels of habitat capability and riparian vegetation are varied across the Forest. As noted in Item 10. Forest-wide Standards and Guidelines for Water and Riparian, and the Information Needs in Chapter 2 of the Plan, much of the exact mapping (and thus identification of both habitat capability and diversity of existing vegetation) will be done, site-specifically, on each watershed. New Appendix I in the Plan shows the Watershed Rehabilitation Program for the first 10 years of Plan implementation As inventory, site-specific projects, and watershed or area assessments are completed, this program may be adjusted

WHAT DOES "EMPHASIZE" MEAN FOR FISH AND WILDLIFE HABITAT IN MA 13?

Under Habitat Improvement (MA 13 C 2) fish and wildlife habitat to be emphasized. How is this emphasis to be realized, i.e., what does emphasize mean and what specific activities will be encouraged and actually carried out?

Response: Emphasis in this case means given highest priority for management consideration and action at a watershed or project level. The standards and guidelines included in the MA prescription discuss some methods for habitat improvement; also, refer to Mitigation Measures for fish, Chapter IV, FEIS.

I DO NOT UNDERSTAND "STRATEGY" IN MA 13

In the "Description of Lands Where Prescription Applicable" for MA 13, there is also reference made to "this strategy" - what strategy? There is no strategy discussed or presented.

Response: The wording in this paragraph has been modified for clarity in the Forest Plan; the words "this strategy" have also been deleted.

CORRECTION IN FEIS, CHAPTER III

On page III-19, paragraph 1, last sentence, Riparian Zones and Planning: Possible typographic error: this sentence probably should have said "or do not contain enough water to be a major..."

Response: The suggested change has been made in the FEIS, Chapter III.

NO RIPARIAN PROTECTION FOR STATE WILD AND SCENIC RIVER

No comprehensive riparian protection has been implemented for this State designated scenic river and its 64 tributaries.

Response: The Washington State Scenic Rivers Program does not require specific riparian protection. In the Preferred Alternative, the Skykomish River and a number of it's tributaries are is recommended for designation as part of the National Wild and Scenic River System. Refer to Alternative Descriptions, Chapter II, FEIS and Appendix E, which discusses each river in detail

"FULL RANGE" OF TIMBER ACTIVITIES NOT APPROPRIATE IN MA 13

Page B-43 states "A full range of silvicultural activities.. " - this is not appropriate for riparian areas, i.e. thinning, fertilization, brush control. Please modify this in Appendix B.

Response: We have substituted "limited range" in this sentence in the FEIS, Appendix B

CORRECT WORDING RIPARIAN MR IN APPENDIX B

Appendix B, page B-42: the third paragraph under "Riparian Minimum Management Requirements" has a critical assumption. Basically, "within an acceptable level of disturbance" means "while still protection streambanks, maintaining stream shading, and providing a buffer against sediment moving into the stream." This should be so stated.

Response: This clarification has been added.

ARE MAPS TOO SMALL IN SCALE TO SHOW RIPARIAN AREAS?

The accompanying maps do not show the management areas for riparian and fish habitat emphasis. Page 4-98, #10, implies that these areas area not known If the resolution of the maps is such that the riparian and fish habitat areas cannot be shown on the maps, they still need to be identified somehow.

Response: The riparian standards and guidelines apply to lands meeting the characteristics identified in the Forest Plan Standards and Guidelines They are too small to be mapped for the FEIS and, as stated in Item 10., exact boundaries will be mapped during the planned inventory.

THE RIPARIAN AREA DISCUSSIONS ARE POORLY ORGANIZED

The monitoring and evaluation of riparian areas is covered in several sections of the Plan; all of this material should be pulled together under one heading titled Riparian Areas.

Response: In the preparation of any document, especially one as complex as the Forest Plan, there are many different ways that information can be organized. The organization of information, monitoring, standards and guidelines for riparian resources is handed in the same way as other resources. The format of this document is determined 1) by direction (national and Pacific Northwest Region) and 2) for ease of use by managers on the ground. Riparian resources are discussed together with soil and water resources in the Forest Management goals and Forest-wide Standards and Guidelines sections of Chapter 4 of the Forest Plan. The monitoring plan (Chapter 5) contains a separate heading for riparian resources.

REGIONAL AND FOREST DIRECTION FOR RIPARIAN MANAGEMENT NOT INCLUDED IN PLAN

You refer to Riparian management guidelines from a memo released in the early 1980's, yet you fail to print these guidelines in your forest plan. Why?

Response: These documents are available in the Planning Records, and only referenced in the plan documents, to meet requirements of 40 CFR Parts 1500 to 1508 (the CEQ Regulations for Implementing NEPA) to reduce paperwork by incorporation by reference.

ANY ROADS IN RIPARIAN AREAS SHOULD CROSS STREAMS AT RIGHT ANGLE

To discussion in MA 13C, L.1.a: add "No new roads should be constructed unless necessary to cross; these should be constructed at right angles to the stream channel."

Response: *The prescription, as written, is designed to first, protect the* dependent riparian resources. Adding this level of detail to the MA standards and guidelines is beyond the intent of the Forest Plan and, on a site-specific basis, may restrict project design so that the objectives of the MA cannot be met.

LIVESTOCK ALSO DAMAGES RIPARIAN AREAS

Livestock use also has a serious effect on riparian zones (all wetlands).

Response: There is no domestic livestock use in riparian zones on the MBS; refer to MA 13, Item D. Range (Plan, Chapter 4), which reads "No practice."

PROHIBIT MINERAL EXTRACTION IN RIPARIAN AREAS

Mineral extraction and processing "material sites" should be prohibited in riparian zone.

Response: As described in Chapter III, Minerals, locatable minerals can be acquired under the General Mining Laws of 1872 (as amended); their removal cannot be precluded by Forest Plan standards and guidelines. Salable minerals (common varieties of sand, gravel, etc) are disposed of under the Materials Act of 1947 (as amended); disposal of salable minerals is at the discretion of the FS. As stated in MA 13. G.a., extraction of common variety minerals may be conducted provided riparian values can be protected. Any activity will be analyzed in an environmental document.

NO LOGGING, ROADS, BROADCAST BURNING IN RIPARIAN AREAS

There should be no logging in wetland and riparian areas, no vehicle use, or road construction. Trails should be routed around the area. Avoid broadcast burning except where clearly necessary

Response: Detailed management prescriptions for the management of riparian areas are included in Chapter 4 of the Forest Plan; also, refer to Forest-wide Standards and Guidelines There are been some updates between draft and final plans MBS use of broadcast burning is/has been very limited; we will continually decrease our use of broadcast burning as a management tool. Refer to Chapter III, Fire, FEIS.

NO ORV's IN RIPARIAN AREAS

There should be no use of ORV's in any of the riparian area types, on or off trails. The use of ATVs in streambeds is particularly destructive and their use should be specifically prohibited in the Forest.

Response: ORV use is permitted on existing roads or ORV trails (MA 13C); new Item A 5 b. regarding new ORV trail construction/reconstruction states that these activities will be permitted only when state riparian objectives can be accomplished. The use of ORV's in the aquatic portion of the riparian zone is not permitted (MA 13C, A.2.a.)

MAINTAIN NATURAL SPRINGS

Natural springs should be maintained for the use of wildlife, and livestock should not be allowed to degrade these vulnerable habitats.

Response: Natural springs have been added to Forest-wide Standards and Guidelines for Water and Riparian Areas, Chapter 4, Forest Plan.

THE FOREST SERVICE PLACES TOO MUCH FAITH IN THE USE OF BMP's

The Forest Service seems to place much too much faith in the use of BMP's. The use of BMP's does not ensure State Water Quality Standards will be met or exceeded A BMP is "the most effective, practicable (including technological, economic and institutional considerations) means of preventing or reducing the amount" of nonpoint pollution to a level compatible with water quality goals. Just because you say you will use the "best" management practices doesn't imply the best for the resource, as BMP's can be diluted by economic considerations.

The DEIS states that water quality standards for the State are met through application of Best Management Practices (BMP's). The process for how this will be carried out should be explained further.

With reference to BMP's and water quality standards: the Plan and EIS must be consistent and accurate on the relationship between the two throughout the documents.

> **Response:** The material in new Appendix I, FEIS includes more detailed discussion of the implementation process for BMP's, plus samples of general and specific BMP's. Best Management Practices are the primary mechanism to enable the achievement of water quality regulations. BMP's are selected and tailored for each site-specific project, and the selection process is part of the NEPA process. Monitoring and evaluation are key steps in the BMP process; as these steps proceed, the BMP may be changed if it fails to achieve the desired objective.

THE TIMBER-FISH-WILDLIFE AGREEMENT STANDARDS SHOULD REPLACE THE RIPARIAN MMR

The new Washington State Forest Practices Regulations (TFW Agreement) meet the needs of the FS and allow harvest scheduling in all classes of riparian areas. The TFW regulations have been reviewed by the public and passed the State of Washington Environmental review process. They should replace the MMR riparian constraints. The MMR's go way beyond the BMP requirements and should be dropped.

We insist, as a minimum, that the FS address the Timber/Fish/Wildlife process and the Best Management Practices (BMP's) set forth in the rules and regulations affecting water quality. This process would provide assurance the State needs to approve the forest plans for water quality compliance.

We think that the new Washington State Forest Practices Regulations meet the needs of the Forest Service and allow harvest scheduling in all classes of riparian areas. These new state regulation have been developed by the State Departments of Natural Resources, the Department of Wildlife, the Department of Ecology, and several environmental organizations and Indian tribes. The new regulations have been reviewed by the public and passed the State of Washington Environmental review process. The TFW agreement standards should replace the MMR riparian constraints The MMR's go way beyond the BMP requirements and should be dropped

> **Response:** The Forest Service is a multiple-use agency which is required by various laws to protect many resources. Some of these laws which are binding include: the Organic Administration Act, 1987; National Environmental Policy Act, 1969; and the National Forest Management Act, 1976. The Washington State Forest Practices Regulations do not provide all

the resource protection sufficient to meet these federal laws The State Forest Practices Act Rules have been certified as Best Management Practices for silviculture activities. An initial comparison has been made of Forest Service practices; it was determined that they meet or exceed the State's BMP's.

Section 208 of the Clean Water Act and Section 319 of the Water Quality Act of 1987 are the legal precedents that most affect forest management because they address nonpoint source pollution. It has been determined that even with the use of BMP's, a number of drainages on the MBS have become severely degraded as the result of past activities. Examples are Deer Creek, Finney Creek, and Canyon Creek. Landslides, failing roads, unstable streams, and degraded fish habitat are becoming common. Because of these conditions, we completed a hydrologic cumulative analysis; this procedure resulted in a method to meet water quality and riparian managements. Refer to more detailed discussion in new Appendix H, in Chapter II and IV, FEIS, Appendix B, and Forest-wide Standards and Guidelines for Soil, Air, Water, and Riparian Areas, Chapter 4, Forest Plan.

RIPARIAN AND WATER QUALITY MMR'S WERE DEVELOPED WITHOUT PUBLIC COMMENT

The riparian and water quality MMR's are developed differently by each forest; the process used did not involve the public and in several cases, was not interdisciplinary. Each water quality MMR was applied to all alternatives and each forest claims their approach is required by law, even though the MMR's differ for identical stream classes.

Response: Each National Forest has its own set of climatic, topographic, soil, and geologic conditions. Stream classes are based only on size and broad use. Identical classes can have very different conditions among National Forests; therefore, what may be appropriate for a stream on one forest may not be appropriate for the same class of stream on another forest. In addition, National Forest lands have a much different character that do State and private lands.

In the DEIS, documentation in Appendix B, Appendix J, and Chapter II, DEIS explained how the MR's were developed. These documents provided reviewers with the information needed to comment on the development of management requirements. Comments received during the 115-day review period were considered in preparation of the FEIS.

In response to public and agency comment on the draft plan, more analysis was done to develop a method to meet water quality and riparian MR's. The process used, and the extensive meetings with both the scientific and academic communities and timber industry representatives are summarized in new Appendix H, and explained in detail in the planning records.

THE CONTEXT OF THE STATEMENT ON BMP's AND THE EPA IS NOT CLEAR

The context of the statement on BMP's and the EPA is not clear. The purposes for which the reports are prepared and are carried out needs to be discussed, as well as how they affect Forest Service management activities.

Response: Refer to new Appendix I, FEIS, for more discussion on Forest Service BMP's. A determination is made periodically determine if Forest

Service BMP's meet or exceed State requirements. This is included in the report submitted to the EPA.

WHAT ARE BMP'S? WHAT FEEDBACK MECHANISMS EXIST TO REPORT TO THE STATE?

What are BMP's? What guarantees that they are adequate? What feedback mechanism has been designed to report water quality conditions in the Forest to the State Department of Ecology?

Response: BMP's are defined as "methods, measures, or practices selected by an agency to meet nonpoint source control needs. Refer to discussion added in new FEIS Appendix I, that addresses the question of adequacy for meeting State water quality regulations. The feedback mechanism is contained in the process to implement the State Water Quality Plan on lands administered by the FS, as described in a Memorandum of Understanding between the Department of Ecology and USDA Forest Service (7/79), and "Attachment A" - referenced in the MOU - "Implementation Plan for Water Quality Planning on National Forest Lands in the Pacific Northwest" 12/78.

REQUIRE BMP'S, MONITORING FOR PROJECT ACTIVITIES

The MBS should consider requiring BMP's, site monitoring, and tracking cumulative effects before, during, and after project activity.

Response: These will be monitored. Refer to the Monitoring Plan, in Chapter 5 of the Plan. Also, refer to new Appendix I, on BMP's.

INCLUDE DEVELOPMENT, VERIFICATION OF BMP'S IN MA 17

under MA 17 standards and guidelines, Timber element, Item 25: Timber Harvest Administration should include development, implementation, and verification of BMP's; this will help determine that BMP's are doing what they are supposed to do - monitoring is needed. Under Item 29 or 30, the FS should ensure that the environmental components of the sale have been satisfactorily done.

Response: The reference to BMP's suggested is covered under Item F.1. Water, Soil, and Air Planning, which states "meet Forest-wide Standards and Guidelines " Refer to Chapter 4, Forest-wide Standards and Guidelines for Water Resources and Riparian Areas. Items E. 19, 21, and 24, Timber Harvest Administration, have been reworded to reflect this comment.

NEED MORE DISCUSSION ON CUMULATIVE EFFECTS

The reference to cumulative impacts on page 4-98 of the draft plan needs to be supported by further discussion.

Response: Considerable new discussion on hydrologic cumulative effects has been added to Chapter IV, FEIS, new Appendix H, and Appendix B.

MORE PROTECTION FOR MODERATELY UNSTABLE SOILS, PREVENT "DEER CREEK" EVENTS

The narrative under "Special Conditions" describes protection for soils with "a 75 percent probability of a doubling of mass soils movement." The problem is that "risk" is really a gradually diminishing series of values over a range, from highly unstable to very stable soils. The draft plan does not adequately address soil types with a moderately high degree of risk (for example, with a 50 to 75 percent probability of a doubling of mass soil movement). A table of special measures by risk category would be useful. In addition, the draft plan's discussion of the Deer Creek situation is very superficial. This is the "best known" example of forest environmental damage in the entire Pacific Northwest region. The case merits detailed discussion at several points in the plan, including cumulative effects. The planning process needs to present in detail how it will prevent a new "Deer Creek" in the future

Response: We have specific direction to remove lands with soils that are susceptible to irreversible damage from the tentatively suitable for timber production land base (reference, Land Suitability for Timber Production, 36 CFR.219.14 and Regional Planning Direction 1920, November 10, 1983). The level of risk is defined as a "75 percent probability of a doubling of mass movement."

Soils that are unstable but are not sufficiently unstable to be in the above category are protected in several ways. Refer to updated Forest-wide Standard and Guidelines for Soils, Chapter 4, Plan, new Item 8, which states "Other soils that are known to be unstable, but which are not sufficiently unstable to be classified as S-8, will require special transportation planning, design, layout, preconstruction, construction, and maintenance techniques." All unstable soils are investigated during project planning, and the appropriate BMP's are recommended. These would include specific road location and construction requirements, rehabilitation measures, harvest methods, where harvested, timing and size of units.

In addition, refer to Appendix H for discussion of the hydrologic cumulative effects analysis procedure to meet water quality and riparian management requirements. Watersheds in unacceptable conditions (and one criterion for determining watershed condition was streambank stability) will be subject to a set maximum number of acres available for final harvest, by decade

Some additional discussion has been added to the "special conditions" section of Soils, Chapter III, FEIS. There is no guarantee that a "Deer Creek" type of event will never happen in the future. However, meeting management requirements and management area and Forest-wide Standards and Guidelines, plus use of appropriate BMP's will minimize the chance of this occurring.

PLAN DOESN'T ADDRESS EFFECTS OCCURRING OUTSIDE THE FOREST BOUNDARY

Snohomish County is currently attempting to identify and eliminate nonpoint sources of pollution. Logging practices have been identifed as a major source of pollution and silt in the lower Stillaguamish, affecting many recreational uses and destroying salmon runs. Yet the plan does not even address the problem of watershed impact on streams and rivers outside of the Forest.

The Forest's habitat is critical is Puget Sound natural salmon production and there are large amounts of private land within the National Forest boundary. These two factors justify a greatly expanded planning treatment for cumulative effects, particularly with respect to riparian areas. The draft plan only has a few vague statements; specific criteria for future decision-making are needed.

Because of the checkerboard ownership pattern in the lower Greenwater, the FS has the obligation to mitigate poor land practices (abuse and over-cutting) on private lands.

Response: The analysis presented in the DEIS, Chapter IV did include some discussion on the cumulative and indirect effects of implementing alternatives on national forest land on other lands, including a section on conflicts between the effects of the alternatives and the plans and policies of other agencies and landowners Refer to each resource section in the DEIS. Forest Service policy directs each Forest to consider the effects of adjacent and intermingled activities. There is no legal mandate that requires the Forest Service to adjust management in National Forest lands to offset the effects of adjacent activities.

In response to public comments about the cumulative effects of harvest and road construction in watershed, between DEIS and FEIS, the Forest developed a procedure to meet water quality and riparian management requirements. A *set maximum number of acres available for final harvest, by watershed, by* decade was the result of this analysis, which should also result in hydrologic recovery in watersheds currently in an unacceptable condition. See Appendix H, FEIS.

We will continue to assess the cumulative effects of all activities on all land ownerships (national forest and all other) during site-specific project planning activities. Case-by-case decisions will be made at the project level as to what, if any, adjustments of National Forest projects are necessary to offset other land owner's activities.

ADD CUMULATIVE EFFECTS ANALYSIS AND EFFECTS ON EACH WATERSHED TO TABLE IV-4

The text with DEIS Table IV-4 states: "These percents will give a very rough estimate of the effects of harvest activities on water." There should be a narrative describing the relationship between the two. A table of anticipated impacts to water for each watershed should be included. This could be part of a comprehensive cumulative impacts analysis.

Table IV-4 would be much more useful if modified to consider cumulative effects. In this case, the proportion of each watershed outside of Forest Service control (if any) could be shown.

Response: Table IV-4, Chapter IV FEIS, has been replaced, based on the results of the hydrologic cumulative effects analysis procedure, to meet water quality and riparian management requirements. The table now shows the maximum number of acres of final harvest available, by watershed, to meet these MR's. In most cases, the harvest level is reduced for the first two decades, increasing in the third and fourth. Refer to Appendix H.

Watershed condition is a key item in the monitoring plan; see Chapter 5, Forest Plan. As we monitor the effects of implementing the plan, by

watershed, the information you asked for can be collected. At this time however, the final documents do not show the anticipated impacts to each watershed. A table of anticipated impacts to water for each watershed would be appropriate at watershed or project-level planning, but is beyond the scope of the Forest Plan.

DEFINITION OF OLD GROWTH USED IN THE PLAN IS INADEQUATE

You should use the more restrictive definition of old growth that was formulated by your own Pacific Northwest Research Station.

The 297,000 acres that meet most scientist's definition of old growth are less than half of the 667,000 acres referred to in the draft plan. Your totals include mature, large sawtimber; the DEIS explains this, but nevertheless calls it all old growth.

The FS use of the single criterion of 21 inch diameter at breast height (DBH) is not a valid method for identifying old growth stands, 21 inch DBH trees are generally about 125 years old, substantially younger than the criteria by Franklin et al (1981). In addition, old-growth structural features are not used as part of the definition.

The FEIS should re-evaluate the consequences of the alternatives on old growth and old-growth dependent wildlife in light of a more accurate and scientifically valid definition of old growth, that put forth by the agency's own team of experts: "Interim Definitions for Old-growth Douglas-fir...in the Pacific Northwest," J Franklin et al , PNW Research Station, 1986.

By including mature secondary growth in the overall inventory, the loss of the most sensitive areas of primary old growth is obscured. This aspect of the plan needs much clarification.

The text defines old growth as "mature, large sawtimber, at least 21 inches DBH." The glossary definition (page V-46) is different.

Response: Four primary definitions have been proposed for old growth in the Pacific Northwest: 1) the definition used in the Region 6, 1984 Regional Guide, 2) the definition proposed by the Society of American Foresters in 1984, 3) the interim definition proposed by the interagency Old-growth Development Committee (Franklin et al., 1986), and 4) a series of old growth definitions developed by Peter Morrison for the Wilderness Society.

For this planning process, we used the definition of old growth as developed in the R-6 Regional Guide; this definition was developed as part of the EIS for the Regional Guide, and had considerable public review. It was assumed that further refinement of the definition was needed, that Forest Plans were due to be produced soon, and the the refined definition could be used in the next round of planning. The refined definition was published by Franklin et al., Research Note PNW-447, but the Region has continued to use the definition established in the Regional Guide. The definition used by the Wilderness Society in "End of Ancient Forests" closely resembles the definition from Franklin et al. and Research Note PNW-447 (developed as an objective of future inventories, not to amend the Regional Guide).

All four definitions are based on ecological stand conditions. Each includes provisions for multi-species, multi-canopy conditions, large woody debris standing as well as on the forest floor, and trees that are old. But the definitions also contain significant differences.

As stated above, the old growth definition used in the Glossary for the MBS DEIS and FEIS is that established by the Regional Guide. However, in both

the DEIS and Final EIS and Plan, the MBS has been limited in our ability to generate more accurate old growth acreages from our existing inventories. The most recent timber inventory for this Forest (1976) was not based on ecological conditions, but on tree classes such as seedlings, saplings, poles, mature small sawtimber, and mature large sawtimber

It was necessary to interpret the existing inventory data (along with some additional stand mapping) to generate acres of old growth. This is explained in Chapter III of the DEIS/FEIS. Trees classed as mature, large sawtimber (trees 21" or more in diameter and averaging about 250 years of age) were considered old growth. The old growth figures used by the Wilderness Society were also generated through interpretation of our existing inventories, or in some cases, inventories that were designed for other purposes. As the Society's definition of old growth is more restrictive, the acres are different.

All west-side Forests in the Region are now starting an accelerated inventory of all potential old growth; mapping should be completed by the fall of 1990. The old growth inventory is part of the new Integrated Resource Inventory, which replaces the old, timber-only inventories. The old growth inventory is designed to measure physical and biological attributes of stands, not just size and class. This will enable us to respond to various definition of old growth in the future.

The text in various chapters of the FEIS has been revised to reflect the above information. Also, the Information Needs section, Chapter 2 of the Forest Plan has been updated.

WHAT ABOUT VIRGIN TIMBER THAT DOES NOT MEET "21 INCHES DBH" DEFINITION?

Does your definition of old growth - large sawtimber, 21 inches DBH - cause any confusion in roadless areas that may have virgin growth not meeting this definition?

Response: This may cause some confusion. Older trees that did not meet the mature, large sawtimber criterion were not considered old growth for this round of planning. Once the new Integrated Resource Inventory is completed, we will have the ability to respond to many different definitions of old growth. See above response.

UPDATE THE OLD GROWTH INVENTORY; IT SHOULD BE FIELD VERIFIED

Old growth inventories done by the Forest Service are inadequate. They do not make a distinction between true old growth and "mature" forests and much of the data is not field checked.

It is unclear what proportion of the inventoried old growth has actually been field inventoried. With all of these problems and sources of error in the Draft documents, we must request that the Forest completely re-evaluate and update its inventory of existing old growth, using up-to-date definitions and accurate, field-verified data. A complete moratorium on old growth harvest should be instituted until an accurate inventory has been obtained.

I urge the FS to re-evaluate and update its inventory of old growth. The data in the plan is based on a 1976 inventory which has been updated, in a manner

which is not clear to me, to reflect cutting through 1983. In speaking to FS personnel, there seemed to be some confusion regarding the updating of the data base. The total acreage of "old growth" remaining does not seem to reflect the amount of cutting has taken place.

Response: Refer to the responses for previous comments. For the FEIS, the acres of old growth and the old growth resource map has been updated to reflect additional acres of old growth harvested through 1988, but no new inventory has been completed, as explained above. On-the-ground information, provided by the District specialists, was used to update this map. The scale of the FEIS old growth map has been increased, to 3/8" to the mile, compared to 1/4" to the mile in the draft plan.

OLD GROWTH MAPS ARE INACCURATE

There are obvious discrepancies between Audubon's maps and the FS old growth map. The data base and map should at least be updated to the present.

The old growth resource map does not reflect present, on-the-ground conditions. Comparing it to a 1977 Darrington map, and with my personal knowledge, the resource map it is off in many drainages on this district. Forest-wide, there must be an immense amount of acreage that is misrepresented and has already been cutover.

Response: As mentioned above, the old growth resource map for the FEIS has been updated to reflect all harvested acres through 1988. Once the old growth/potential old growth inventory is completed in the fall of 1990, more accurate maps can be produced.

ACRES OF OLD GROWTH AVAILABLE FOR HARVEST ARE CONFUSING

I question the analysis of old growth timber availability. The final result was 667,000 acres of old growth, but this figure includes trees over 4,000 feet in elevation and stands located in preserved areas. The plan implies that over 600,00 acres of old growth are potentially loggable, in actuality, only about 300,000 acres are available.

Response: As explained in the DEIS (III-27), and updated in the FEIS, 232,500 acres of the 643,500 acres (FEIS) of old growth are located within wilderness; 134,400 acres are considered unsuitable for timber harvest because of unstable soils, high elevation areas that are difficult to regenerate, or because they have been withdrawn (such as Research Natural Areas.) The remaining 276,600 acres (FEIS) of the total old growth are tentatively suitable for timber harvest. See Chapter III, Diversity and Old Growth section, FEIS.

Land is not suitable for timber production until it is assigned to a management prescription, in an alternative, that includes timber harvest In the Preferred Alternative, 140,817 acres of old growth are suitable, at the start of the first decade. At the end of Decade 1, the old growth remaining on suitable lands will be about 121,900 acres - along with all the unsuitable/wilderness acres of old growth.

MAPS, DISPLAYS, DATA SHOULD SHOW OLD GROWTH BELOW 2500 FEET ELEVATION

A low-elevation old growth stratification should also be considered in evaluating the alternatives and shown on the maps. The data base includes a 2500 foot stratification, but this is not made available in the plan or used in the evaluation of alternatives. This low-elevation old growth has characteristics and values which are very different than the higher elevation old growth.

High-elevation old growth forest was lumped together with low-elevation old growth forest in setting aside areas for the spotted owl, despite the fact that high-elevation forest is of little use to the spotted owl. This mistake should be corrected.

The DEIS fails to document the quantitative and qualitative differences between low-valley old growth stands and higher elevation, steep slope old growth stands. The DEIS fails to identify those old growth stands that are essential for the survival of either big game or non-big game wildlife.

At the Open Houses, after the DEIS was released, one display had a bar graph showing the percent of old growth remaining in each alternative. However, this pattern would appear quite tame if shown against a bar graph showing percent of old-growth under 2,000 feet elevation remaining.

> **Response:** The old growth resource maps for the FEIS has been modified to show old growth located below 2,500 feet, between 2,501 and 4,000 feet, and above 4,000 feet in elevation. We have also revised a number of sections of the final documents to show acres of old growth, by management area (wilderness, dispersed recreation, timber emphasis, etc.) by the three elevation ranges

DEIS OVER-ESTIMATES THE ACRES OF OLD GROWTH, LOW-ELEVATION OLD GROWTH

The DEIS significantly overstates the amount of remaining old growth. Using the FS definition, Peter Morrison (Wilderness Society consultant) found only about 297,000 acres of true old growth remain, with less than 20,000 acres of classic old growth below 2500 feet, where the greatest species diversity is found.

I estimated that only about 56,000 acres of old growth exist below 2500 feet, whereas the Forest Service numbers provided to me indicate there are 166,665 acres of old growth below 2500 feet. This discrepancy needs to be sorted out.

> **Response:** An expanded discussion of the acres of old growth (as defined for this round of planning - see response to the first old growth comment), has been added to Chapters II (see Table II-91 and text), III (Old Growth and Diversity section), and IV in the FEIS. In summary, in the Preferred Alternative, a total of 502,721 acres of old growth (mature, large sawtimber, 21" and larger DBH) will remain in management areas will no timber harvest. There are 32,860 acres of old growth below 2,500 feet within wilderness, and an additional 131,292 acres in wilderness located at 2,500 to 4,000 feet in elevation. In the Preferred Alternative, there are approximately 84,000 total acres of old growth under 2,500 feet that are unsuited for timber harvest.

STANDARDS AND GUIDELINES FOR OLD GROWTH HABITAT ARE WEAK

Standards and guidelines for MA 11 and 12 are far too weak and non-specific, with too many poorly-defined exceptions. Either these areas should be left alone, so that they can retain natural old growth community process, or they should specifically prohibit entry and/or use of these areas by ORV's and livestock or for any form of timber management, road construction, or firewood cutting

Response: Management Areas 11 and 12 are dedicated old growth habitats for the primary old growth indicator species on the Forest As written, the standards and guidelines for these MA's prohibit management activities such as timber management, road construction, new trail construction, ORV use, and livestock use except under stringent controls and restrictions, to maintain the integrity of the old growth habitat component. Restrictions on the timing of certain activities, such as trail reconstruction, are also included.

ACRES OF OLD GROWTH MENTIONED IN THE DEIS ARE INCONSISTENT

The acres of old growth mentioned in Chapter III, Wildlife conflict with statements elsewhere in the documents

I'm confused about some information presented on old-growth acres. The summary states there are about 667,000 acres of old growth within the MBS. The figures, however, show that at the end of Decade 1, all alternatives result in 667,000 acres of old growth remaining. This seems inconsistent with discussions elsewhere that state nearly all harvesting will be in old growth (Draft Plan, page 4-7).

Response: The acres of old growth throughout the documents have been updated to reflect harvesting that has occurred through 1988.

The bar graphs in the summary were incorrectly labeled in the DEIS. The figures shown represent the **beginning** of Decade 1, where all alternatives will have the same starting acreage This has been corrected in the Final.

TABLE OF ACRES OF REMAINING OLD GROWTH IS MISLEADING

DEIS Table IV-12 indicates hardly any difference in the effective old growth habitat area between Alternatives G and H. 426,000 and 471,000 acres in Decade 5, respectively. This kind of comparison is wildly misleading, since most of the difference is the extremely rare low-elevation, classic old growth forest.

Response: This table (Chapter IV, Wildlife, FEIS) has been revised and now shows acres of old growth habitat, by alternative, based on updated inventories of suitable owl habitat (completed between draft and final plans) In all alternatives, there are a total of 232,500 acres of old growth in wilderness: 32,860 acres below 2,500 feet, and 131,292 acres located between 2,500 and 4,000 feet.

PROTECT MORE LOW-ELEVATION OLD GROWTH, IN LARGER TRACTS

It is extremely important to protect the few remaining lowland (below 2,500) tracts of old-growth forest. Recent studies by forest ecologists at the University of Washington indicate that over 90% of the Pacific Northwest's original old-growth forest has been logged, and that several of the important lowland communities are virtually extinct.

Those roadless areas lying at lower elevations (below 2500 feet) and containing old growth should be considered "critical sensitive areas" because this habitat type is usually limiting. There is relatively little of this habitat remaining in the Puget trough.

From the map, it appears that half or more of the remaining old growth in the southern end of the Forest is mountain hemlock/silver fir, which generally grows above 4000, is not of great commercial value and slow to reforest. Including this type in all old growth calculations obscures the probability that all low-elevation old growth will be cut.

Despite your assertions that old growth will be largely preserved under Alternative H, it is obvious from the maps and documents that low-elevation habitat will be largely eliminated.

> **Response:** In the Preferred Alternative, 32,860 acres of low-elevation old growth (under 2,500 feet elevation) will remain in wilderness Of the approximately 19,000 of old growth harvested in Decade 1 in the Preferred Alternative, about 61% will be old growth under 3,000 feet in elevation. See Chapter II, output tables, and Chapter III, FEIS for more information. These discussions have been updated and expanded, in response to these and other comments on the DEIS.

PROPOSED PLAN WILL REDUCE DIVERSITY AND CREATE ADDITIONAL HABITAT FRAGMENTATION

Any plan which results in scattered and small areas of old growth will have a negative impact on a variety of organisms; the small areas of old growth will be like "biological islands".

Much of the old growth that does remain is so fragmented an punctuated by roads as to have lost most of its biological value. Refer to the Wilderness Society study. The FS should consider not only total acreage of old growth, but also the fragmentation and isolation of patches.

It is imperative to retain extensive coherent stands of old growth, not only for the well known indicator species such as the spotted owl, but also as a reservoir for a diverse flora and fauna, especially mycorrhizae and invertebrates, for which there is as yet negligible data. We simply do not fully know the roles played by the diversity of species associated with forest stands, from youth to maturity, on a long-term basis Proposed stands are inadequate in size, fragmented and subject to deterioration at their margins

We must systematically save a greater portion of our remaining old growth forest, now, while it is still distributed fairly evenly throughout most of the major drainages on the MBS. Roughly 10% of each major drainage should be old growth, including stands at all elevations.

The treatment of old growth in the DEIS is by far the most seriously flawed

portion of those documents. With the principles of island and old growth ecosystem ecology, a viable old growth forest system can only be maintained if 10-15% of each drainage is retained in old growth. That old growth must be well-distributed over the given land base, with corridors of mature forest linking the old growth reserves.

We suggest that any one drainage has a total of at least 5 percent old growth and, where larger blocks occur, they should be favored for protection over the fragmented and isolated stands. This will provide both sufficient habitat and travel corridors to help ensure population viability.

According to Jerry Franklin, uninterrupted forest patches should be at least 500-600 acres in size to remain ecologically viable units. It is most sensible ecologically to retain entire drainage basins intact in order to ensure that viable forest patches (especially old growth patches) remain. How do the alternatives respond to this concern?

For long-term survival of old growth species, they must be assured a good interconnected network of old growth forest, both within the MBS and with nearby old growth areas in Canada, North Cascades National Park, Wenatchee NF, and Mt. Rainier National Park.

Diversity is a complex concept In order to maintain the regional or global species diversity, it is necessary to maintain large areas of some relatively homogeneous habitats, such as old-growth forests. This may mean that the local diversity is low. But without maintaining these large homogeneous areas, species which are dependent on these habitats or species which are widely spaced throughout the environment may not survive, reducing the regional and global species diversity.

Increasing the "edge effect or creating a relatively small scale patchwork of different habitats may increase the number of species which can occupy and area, but these species tend to be cosmopolitan and often weedy species (species which can take advantage of disturbed habitats). Species which are specific to native ecosystems or are intolerant to disturbance decrease or are eliminated from many managed, patchwork areas.

Isolated pockets of old growth do not provide habitat corridors. For species that require more resources than are available in a single area, a network of refuges connected by corridors would allow travel between areas of old growth (Simberloff and Cox, 1987). The DEIS does not include an alternative that would provide habitat corridors.

A systematic policy of logging the last remaining old growth forests (and the resulting loss of biological diversity) violates 16 USC 1604(g)(3)(8) which requires the Forest Plan to "provide for diversity of plant and animal communities." Such a policy also violates 36 CFR 219.27 (g) which states that "reductions in ..existing diversity...may be prescribed only where needed to meet overall multiple use objectives."

The Forest Plan must recognize the importance of old growth and state explicitly how the FS plans to protect this irreplaceable resource.

Of concern is the fragmentation of the remaining old growth. More than 60,000 acres of the remaining 297,000 is so fragmented as to be of little use to old-growth dependent species. New information on forest fragmentation reveals the importance of forest patch size, shape, and distribution as key factors in

wildlife population viability and dispersal. For instance, "interior" species, such as the spotted owl, pileated woodpecker, and fisher, avoid edges and therefore need large contiguous blocks of habitat. The draft plan fails to address the effect of fragmentation on wildlife populations and the amount of increased fragmentation to be expected from logging.

Fragmentation also exposes small remaining patches to windthrow. Consequently, harvesting will result in a greater reduction of old growth than is estimated in the plan's calculations. It appears that little consideration was given to information about minimum stand sizes to avoid the problem of blowdown.

Harris suggests the use of core conservation areas, with old growth islands surrounded by outward-fanning layers of increasingly intensive management. (Harris, 161) This concept of planning does not separate conservation and development, but integrates them. Biogeographic theory suggests that management strategies be applied to much larger areas which can provide sustained use.

Response: The alternatives in the DEIS provided for diversity of forest types (and seral stages within those types) and of non-forest vegetative types. The alternatives in the FEIS provide for similar diversity through varying amounts and distribution of different seral stages, including old growth. Changes between the release of the DEIS and this FEIS include: a revised network of SOHA's, larger in size, to meet the direction of the Supplemental FEIS to the Regional Guide; a revised network for the indicator species for mature/old growth - the pine marten and pileated woodpecker; additional discussion and analysis of the existing situation and effects of implementing the alternatives on diversity (see Chapter II, expecially Table II-91), Chapter III, and Chapter IV, FEIS); and Forest-wide Standards and Guidelines for Diversity and Long-Term Site Productivity have been added to Chapter 4, Forest Plan.

The component of the ecosystem that is of particular concern, as it relates to habitat fragmentation, is old growth. For any alternative in the FEIS, 276,600 acres of old growth have been identified as tentatively suitable for timber harvest. Each alternative will retain a different amount of this old growth component. The total acres of tentatively suitable land are fairly well distributed across the Forest and occur at various elevations. In the first decade, in the Preferred Alternative, about 61% of the 19,000 acres of old growth that will be harvested are located below 3,000 feet elevation.

PRESERVE OLD GROWTH UNTIL MORE MONITORING, RESEARCH IS DONE

The evaluation of the draft preferred alternative on old-growth dependent wildlife and plant species is woefully inadequate, as are the monitoring and mitigation programs. What species of plants and animals are dependent on old growth ?

The Forest Service should initiate a system for on-the-ground monitoring and assessment of the old growth portions of the forest.

At this time we do not know that old growth ecosystems can be managed at all and still maintain the integrity of the ecosystem. There is much research on the subject and with the uncertainty, it is best to leave stands undisturbed until more information is gathered The best available information suggests

that to maintain old growth ecosystems, 5-15% of the forest in each major plant community be dedicated to old growth ecosystems and should be well distributed by slope, aspect and elevation.

A goal should be preservation of original old growth until biological research determines that old-growth dependent species can, with certainty, survive in the *now aging second growth.*

Research done by the Old Growth research team in Olympia has not been incorporated into the draft plan; it should be included in the FEIS.

Too little research has been done to determine to what extent the health of younf forests depend on adjacent old growth stands as reservoirs for disease and pest control species (fungi, etc.)

Response: According to USDA, Forest Service publication "Wildlife of the Pacific Northwest: Occurrence and Distribution by Habitat, BLM District, and National Forest" by Keith Guenther and Thomas Kucera, October 1978, only two species occurring on the MBS are dependent upon old growth for their survival· the Northern spotted owl and the bald eagle A significant number of species occurring here use old growth habitat for a portion of their habitat requirements. We have no documentation of any plant species occurring on this Forest that is totally dependent upon old growth habitat for its existence.

As recent as July/August, 1988, researchers presented papers at various symposia on old growth and related wildlife species. Results of these studies suggest there are 11 individual species and 2 groups of species in the Northwest that are closely associated with old growth Douglas fir or with features of old growth habitats: Olympic salamander, Oregon slender salamander, northwestern salamander, spotted owl, Vaux's swift, red crossbill, pine siskin, northern flying squirrel, and red tree vole. The species groups are cavity nesting birds and Myotis bats. These species are among the group of 75 species which we knew were closely associated with old growth. The degree of association varies by season and physiographic province. For a number of species, the studies were not conclusive and further work is needed.

We will continue to incorporate the latest research findings and results of our monitoring, through periodic reviews of our Forest Plan, as it is implemented If any of the findings indicate a significant change in management direction, the Plan can be amended to incorporate that change.

We plan to monitor several species that depend upon and use old growth habitats. Refer to the monitoring plan, Chapter 5, Forest Plan.

SUPPORT THE CONCEPT OF DEDICATED OLD GROWTH

We object to the assertion that old growth can be "managed for." Old growth is not simply old or large trees, but a complex ecosystem of plants and animals that has evolved over hundreds of years. The characteristics and diversity of a true old-growth ecosystem cannot be duplicated by timber management practices. We support the concept of dedicated old growth.

Response: As discussed in Appendices B and J of the DEIS, the MBS conducted an efficiency analysis during the establishment of management

requirements for wildlife (to provide for viable populations of native vertebrates, as required by NFMA). The results of this analysis indicated that, in terms of effect on timber outputs, it was more efficient to "dedicate" existing old growth for those species which use old growth as an indicator habitat, as opposed to a implementing a "managed" old growth concept. Also see Appendix H, FEIS.

LITTLE OLD GROWTH PROTECTION IN ALPINE LAKES MANAGEMENT AREA

The Alpine Lakes Management Area plan did not address old growth either as a resource or wildlife habitat. The draft Forest Plan indicates little additional old growth protection over the Alpine Lakes plan. A significant old growth resource exists in the Pratt drainage, particularly the "bridge" of old growth across the river between the valley side slopes This is some of the lowest elevation stands remaining on the Forest (below 1500 feet).

Response: The issue of old growth is addressed in several sections of the the Alpine Lakes Land Management Plan FEIS, see short versus long term effects (page 88) and the response to public comments, page 118.

As stated on page 118 of that FEIS· "Low elevation old growth forest were considered when the Alpine Lakes Wilderness boundary was drawn in 1976. There are over 950 acres below 2000 feet elevation and over 21,211 acres between 2000 and 3000 feet elevation in the Wilderness .In addition to the wilderness, the management unit contains over 3,300 acres below 2000 feet elevation and 5,252 acres between 2000 and 3000 feet elevation in the Dispersed Recreation Allocation Asahel Curtis Area at 2,400 feet elevation is dedicated to remain old growth forest. This topic will be addressed further in the Wenatchee and Mt. Baker-Snoqualmie Forest Plans..."

The "bridge" of old growth (mentioned in the comment) was actually logged (by railroad) in the 1940's. Most of the old growth was removed, but scattered old growth trees were left. Since that time, the area has regenerated to a dense stand of understory hemlock with scattered old growth above it. This stand is partially located within the General Forest allocation of the Alpine Lakes FEIS, and can be considered for timber harvest. However, any value of the stand as a "bridge" for old-growth dependent wildlife would have to be considered in the project environmental analysis, with full opportunity for public input.

There are no old growth stands (below 1500 feet) at the lower end of the Pratt. The stand often referred to is actually less than 160 years old. The old growth overstory was removed from this area in the 1940's when it was railroad logged. There are about two dozen very large, old trees scattered over several hundred acres, left after the original logging There are no plans to remove these large trees.

MANGE THE FOREST FOR DIVERSITY

Forest needs to be managed to maintain diversity.

The various alternative management proposals boil down to a basic management principle. Maintenance or enhancement of complexity - genetic, structural, and spatial, whenever possible. Foresters must develop an appreciation of nature's complexity, the merit of that apparent disorder, and must conserve it

Response: Agree. NFMA requires that "management prescriptions...preserve and enhance the diversity of plant and animal species so that it is at least as great as that which would be expected in a natural forest." The discussion of diversity has been expanded to include a Forest-wide goal statement and Standards and Guidelines, Plan, Chapter 4, with added discussions in Chapters III and IV, FEIS.

The substantive means by which vegetative diversity is maintained is through the management requirements (MR's) for fish and wildlife. By maintaining "viable populations of existing native and desired non-native vertebrate species in the planning area," the Forest maintains at least the diversity of the natural forest by maintaining the populations of vertebrate species and the habitats they depend upon Refer to Appendix H, Chapter II, and Appendix B for discussion on MR's and to Chapter IV, FEIS for the effects of implementing the alternatives.

NEED TO MANAGE FOR PREMIUM DENSE-GRAINED TIMBER, PLANT OTHER SPECIES

None of the plans provide for sustained yield of dense-grained timbers, nor has consideration been given to sustained yield of premium long-aged species, especially western redcedar. Virtually only Douglas-fir is being replanted, ignoring valuable other species

There is no planning for premium, dense grain timbers after the existing old growth has been cut. I believe we have a moral and economic imperative to replace other premium species on a sustained-yield basis, particularly western redcedar.

What quality can we expect from 60-100 year rotations? It's already on the markets: poorer quality, wide-grained, narrow diameter logs yielding decreasing design stresses, and best suited for small dimensional studs and wood fiber/pulp uses. What about those of us dependent on the aesthetic and structural characteristics of dense grained timbers, shingle stock, and door and window stock?

Not managing for high-quality timber will insure that none exists, which will insure that no industries exist which can use it, which insures that no demand will exist for high quality wood Managing for forests of uniform size, quality, and species will allow for greater mechanization, larger mills and fewer mills, less competition, less employment, lower revenues, less product diversity, lower timber harvests, and less economic stability

Managing for high quality timber or longer rotations is more ecologically stable. The forests in the Pacific Northwest are composed of conifers with long lifespans The ecology of these forests developed around the multi-storied, multispecies stands with large old trees dominating. The best way to maintain a healthy ecosystem and harvest trees, is to try to duplicate

some of the structure of the ecosystem. This can be done using long rotation quality wood management regimes. If we do not maintain the health if the forest, we will lose its productivity which will decrease timber harvests and revenues

Planners can use forecasting in two ways. The passive way currently used by the FS timber planners is leading toward disaster. The forest which will result from the proposed forest plans will be composed of small trees averaging less than 10 inches in diameter, timber harvest will be dominated by knotty, low quality wood with a very high percentage of juvenile wood fiber, and the forest will be dominated by clearcuts. The alternative is to identify our goals for timber management, which are produce high revenues, high employment, and high timber volumes. The forest we all want is one managed for larger, older, higher quality trees and a wide diversity of species.

Response· The various management prescriptions include a wide range of timber prescription from no harvest, old growth management areas (MA's 11 and 12), to longer rotations, and also short rotations that emphasize timber production (MA 17). In those management areas where timber harvest is allowed, a variety of products are produced, based on the objectives of the management area and the timber prescription selected.

In MA 17, where short rotation predominate, the diameter at breast height (DBH) of final-harvested trees will average 14 to 16 inches. These DBH's will become greater the longer final harvest is delayed after culmination of mean annual increment Larger trees are also produced in stands which are managed with longer rotations, to meet a number of objectives; included are MA's 1, 2, 5, 6, 7, 13, 14, 15, 17, 20, 21, 22, and parts of 27 (FEIS Chapter II). In these stands, final harvest DBH'S could reach 40 plus inches in 200 years

In the Preferred Alternative, there are approximately 346,000 acres of land suitable for timber production. Approximately 150,000 acres of suitable lands will have extended rotations of 200 years or more. The result large diameter trees (up to 40" DBH) with slower growth rates and thus dense grained wood.

MANAGING FOR A WIDE VARIETY OF SPECIES PROVIDES MORE JOBS

Managing for a wide variety of species provides more jobs *Every tree species* has unique wood properties. As industry becomes more sophisticated, it takes better advantage of the unique properties of each species. While one industry may want the entire forest planted with the species it prefers, the best policy for the region is to manage for a variety of species This adds diversity to the economy, stability, and the highest level of employment.

Managing for quality and diversity provides economic stability The depressed housing market in 1982 had the most impact on those communities most dependent on producing dimensional lumber for home construction. The wood furniture industry expanded during that time. The mills supplying quality wood to overseas markets never shut down. The ponderosa pine mills east of the Cascades were much less affected. So were the cedar, hardwood, paper and firewood producers less affected.

Response. Agree. In the Forest Plan, the MBS will provide a variety of tree species for commercial sale. They include Douglas-fir, pacific silver

fir, western hemlock, western white pine, western redcedar, red alder, mountain hemlock, grand fir, white fir, englemann spruce, and subalpine fir Actual species selection will be based on a site-specific analysis, with interdisciplinary planning. (Forest Plan, Chapter 4). In addition, the Preferred Alternative produces a variety of market and non-market goods, services, and opportunities, to contribute to the diversity of the economic base of the area, (FEIS Chapters II and VI, Forest Plan Chapter 4).

SIGNIFICANT STANDS OF HARDWOODS SHOULD BE PRESERVED

All significant stands of hardwoods should be preserved uncut and should not be "converted" to conifer stands. A thorough analysis of the inherent values, distributional significance, and values to wildlife of these groves should be completed before any development is permitted in these unique and valuable habitats.

Response: The MBS is currently inventorying its resources. By the end of 1990, the Forest will have a good indication of the distribution of the hardwood stands. Not all hardwood stands will be harvested in the Forest Plan; some will follow a natural course to climax, in management areas where timber harvest is not allowed. In MA's where timber harvest is allowed, hardwood stands will be managed But even here, some hardwood stands will be allowed to regenerate, while others will be converted to conifer species. The management for each stand will be determined at the project level, after a site specific analysis by an interdisciplinary team, in an environmental analysis (NEPA document). A "no action" alternative will be considered in each case. See Forest Plan, Chapter 4.

WHAT SPECIES ARE USED TO REGENERATE HARDWOOD STANDS?

When hardwood stands are harvested, what species are used for regeneration.

Response: We have added to Appendix B, Chapter III, E, the information regarding regeneration of hardwoods We will plant red alder and may use coppicing (letting sprouts regenerate from the cut stumps) for red alder, black cottonwood, and big leaf maple.

REPLANT CEDAR

Cedar makes up 9.4% of commercial tree species, yet only 1% of tree species planted is cedar. No Western redcedar superior trees were selected for genetically improved stock. Alternative H preserves only 31% of present old growth cedar Over the years, we have commented to the Skykomish District about the lack of commitment to replanting cedar, especially in riparian areas and clearcut cedar groves above Garland Mineral Springs.

Consider modifying silviculture practices to allow a minimum of 250-year rotations in prime sites for western redcedar. This would accommodate long-term needs of American Indians and will benefit all people. Cedar is still fairly inexpensive, but where we we get it in 100 or 200 years? We need to start promoting its growth now

Response: In response to these comments, we have added a Forest-wide Standard and Guideline for cedar, Forest Plan, Chapter 4. It reads: "Favor the regeneration and management of western redcedar on those sites where it now occurs and on sites where environmental conditions are such that successful establishment and management would occur." Actual rotation lengths will be determined by the specific site and management area. See discussion in the last comment of this Diversity/Cedar section.

The reason western redcedar is not replanted more often is that it is a prolific seeder and where it is established, it exhibits excellent survival and growth. These same characteristics are the reasons that western redcedar was not included in the genetics program.

AREA OF ALASKA YELLOWCEDAR SHOULD NOT BE HARVESTED

The old trail out of Rattrap Pass to Skarr Pass (T.31 N., R.11 E.) went through a solid stand of small **Chamaecyparis nootkatensis** (Alaska yellowcedar) along the ridgetop and south side of the ridge. Alternative H proposed cutting this. It should be left uncut, as the timber is small (probably because it is in an old burn) and the site is probably abysmal. This is a good research area: will yellowcedar regenerate in a burn or in the mountain hemlock zone? As *yellowcedar is valuable lumber ($900 per MBF), it may warrant management rather* than planting noble fir in this zone.

Response: In the Preferred Alternative, this area is allocated primarily to MA 1D Roaded Natural (harvesting permitted with longer rotations) and MA 19 Mountain Hemlock Zone (a study area - any timber harvested is non-chargable). Only a small portion of the area is allocated to MA 17, Timber Management Emphasis.

The vast majority of the Alaska yellowcedar stands on the Forest are found in mountain hemlock areas. In the Preferred Alternative, the overall inventory of Alaska yellowcedar will be reduced only slightly because of the species location in the mountain hemlock type.

WESTERN REDCEDAR SHOULD BE MANAGED FOR ALL PEOPLE

On IV-81, the possibility of modifying silvicultural practices to allow a minimum of 250 year rotation in prime sites for western redcedar growth to accommodate the long-term needs of American Indians for cedar strikes me as something that should be done on a large scale for the benefit of all peoples. Cedar is still fairly inexpensive now while there is old growth to be logged here and in British Columbia, but where will people get it in 100 years? or in 200 *years? We need to start now to develop ways to promote the growth of* western redcedar.

Response: A new Forest-wide Standard and Guideline has been written to address western redcedar. It directs "favoring" redcedar on those sites where it now occurs and on sites where conditions are such that the species can grow and be managed See Chapter 4, Forest Plan, Forest-wide Standards and Guidelines for timber. At the project level, timber management activities will be designed to meet the management objectives of the particular site. The actual selection of species to be grown on those sites will be determined by a certified silviculturist taking in to account the physical properties of the site, e.g. elevation, rain fall, plant

community present now and what can be anticipated in the future. In those areas were western redcedar is present, it will very likely again be part of the regenerated stand. Actual rotation lengths will be determined by the specific site condition and MA objectives.

CEDAR IS NOT A LOW-VALUE SPECIES

In Appendix F, page F-6, cedar is lumped with hemlock and silver fir as a species of low commercial value. Cedar is the material of choice for shake, shingles, siding, and other weather-exposed uses for wood products.

Response: This paragraph in Appendix F (page F-6) has been rewritten in response to this comment.

"RICHNESS" DOES NOT FOLLOW AFTER TIMBER HARVEST

Referring to Table II-8, Diversity of Plant Communities: we disagree that richness increases following timber harvest and reforestation. Intensive timber management is oriented towards producing a monoculture. There is a short-term increase in plant diversity for 5-10 years, followed by a much lower diversity than occurred during the pre-harvest condition, which lasts for the next 60-80 years when harvest occurs again. The net result is less diversity, not more.

Response: In the FEIS, Table II-8 and Chapter IV, Effects on Vegetation have been modified, with references to "richness" and "evenness" removed. These discussions now focus on the changes in age class of timber stands, by alternative. In addition, more discussion on the concept of plant and animal diversity has been added to Chapters III and IV, FEIS.

NO ALTERNATIVE HARVESTS THE OLD GROWTH FAST ENOUGH

None of the alternatives harvest the remaining old growth quickly enough, doesn't harvest enough old growth in the first decade Need to harvest old growth as quickly as possible to convert decadent stands to young, fast growing stands

Response: The MBS is a deficit-inventory forest, meaning that old-growth trees available for harvest must be metered out for 70-80 years before the second growth on the Forest is ready for harvest. If the harvest of old growth is accelerated in the early decades, future harvest levels must decline until the younger stands are ready for harvest. This option of departing from the non-declining flow policy was evaluated in the departure alternatives (E-Departure, H-Departure) in the DEIS.

THE FOREST IS LIQUIDATING ALL OLD GROWTH IN THE FIRST TWO DECADES

In reviewing Table S-2 of the Summary in the DEIS, it appears there will be a sharp decline in the annual timber sale volume after the second decade. Does this mean that the Forest intends to liquidate the mature stands and old growth within the first two decades? Alternative C is the only alternative that appears to provide for non-declining even flow of timber volume offered for sale.

Response: Refer to Chapter II, Table II-9a in the FEIS. The Timber Sale Program Quantity increases from Decade 1 to 2, and from 2 to 5 for all alternatives displayed in the FEIS, except Alternative NC (No Change). As discussed in Chapter IV, FEIS, the direct effects of implementing the alternatives on the various resources, all timber harvest activities in all alternatives in the first decade will occur primarily in old growth stands.

PERCENTAGE OF SALE QUANTITY FROM OLD GROWTH VERSUS SECOND GROWTH SHOULD BE DISPLAYED

I find nothing to indicate what percentage of timber production derives from regrowth areas and what percentage derives from old-growth presently being cut.

Response: Table 4-1, Chapter 4, Forest Plan displays the acres/year cutover. The portion clearcut comes from mature stands. The portion coming from commercial thinning is from second growth stands. In the first decade, about 2,865 acres per year will be clearcut and 200 acres annually commercial thinned (from second growth stands).

NO ALTERNATIVE INCREASES THE AMOUNT OF OLD GROWTH

The range of alternatives is inadequate in that no alternative proposes an increase in the amount of old growth Forest Why not allow some previously harvested areas to revert to old growth ?

Response: The intent of Alternative C is to allow some of the acreage that is presently in an ROS class of Roaded Natural to revert to an ROS class of Primitive. This would be accomplished by road closures and allocations to non-harvest prescriptions. Over time, through the natural process of vegetative succession, these areas could eventually revert to "old growth."

OLD GROWTH ACREAGE DISCREPANCY

On the maps I found the "Starting Inventory of Old Growth" acreage to be stated as 667,000 in the Comparison of Alternatives growth to be "about half" of 599,000 acres. I hope this isn't an example of the "New Math "

Response: In the final documents, the starting inventory for old growth has been corrected and updated through 1988.

NOT ALL OLD GROWTH ACRES CAN PRODUCE HIGH VOLUMES; OLD GROWTH HAS A HIGHER VALUE FROM A PRODUCT STANDPOINT

In Chapter III, page III-27, the DEIS states that old growth stands with a net growth of less than 20 cubic feet per acre per year could be replaced with young stands that could potentially produce in excess of 170 cubic feet/acre/year. The DEIS fails to point out that: (1) Not all of the suitable old growth sites are capable of producing these volumes Note the forest-wide average productivity of 114 cu ft/acre/year; (2) Second growth wood fiber is far less valuable than the old growth, from a product value standpoint, (3) It may not be economically efficient to apply intensive management to many of the old growth stands The DEIS tends to place the greatest value upon the management regime that produces the greatest wood fiber growth rates.

Response: The text in Chapter III has been modified to reflect your first point The text states that 170 CF per acre per year could **potentially** be produced in an intensive management regime Not all suitable acres allocated to a timber harvest prescription will be scheduled for intensive management. For example, western hemlock, Pacific silver fir, noble fir types are not scheduled for intensive management. The management intensities scheduled for the Preferred Alternative are discussed in the Timber Resource Summary section, Chapter 4, Forest Plan.

OLD GROWTH STANDS SHOULD BE CATEGORIZED BY A WIDE VARIETY OF CHARACTERISTICS

It would be helpful in analyzing the various alternatives if old growth was broadly categorized into dominant, co-dominant, and subdominant tree species, age of dominant and co-dominant tree species; and elevation. If the Forest Service data base is sufficient, it would also be helpful to give the number of sub-canopies and snag characteristics for these old growth stands All of this information should be displayed in table form. This information should then be keyed into a large-scale map(s) and displayed by acreage as well as location. Further, the old growth information should be allocated, as appropriate, across the various Plan alternatives and presented in appropriate places in the DEIS. An initial attempt to provide the botanical detail that is necessary for an adequate analysis of the Plan impacts on old-growth animal communities.

The Forest Service should define old growth in terms of the entire component, not just in terms of some indicator species.

> **Response:** This information, while desirable, is not currently available. The MBS, along with other Forests in the Region, is in the process of a new Integrated Resource Inventory, which replaces the old timber-only inventory. The old growth component of the inventory is on an accelerated schedule, it should be completed in 1991. The inventory is designed to measure physical and biological attributes of stands, not just size and class. This will allow more detailed analysis of impacts on old growth communities during plan implementation and updates.

SELECT OLD GROWTH STANDS FOR PROTECTION BASED ON ECOLOGICAL FACTORS

The selection of old growth for protection should be based on an ecological classification of these habitats, and should be independent of the economic status or wilderness classification of these forests. If old growth of no commercial value or in wilderness areas does not meet the habitat quality thresholds established in the habitat evaluation, it should not be counted in the inventory of this habitat for the indicator species, although it may have other substantial value, such as for recreation or scenery.

> **Response:** The process used to establish the habitat network for the northern spotted owl (indicator species for the old-growth habitat type) is documented in the planning records While suitable habitat does exist within wilderness, areas were selected based on habitat needs, distribution requirements, and sightings/confirmations of nesting and breeding pairs of owls. Refer to Appendix H.

DON'T USE STAND AGE TO DEFINE OLD GROWTH IN NATURAL STANDS

Referring to Appendix B, page B-107: the stand age is probably appropriate for natural stands, but should not be used for managed stands, which will likely take closer to 250 years to develop old-growth characteristics

> **Response:** As stated later in that paragraph, the definition we did use in the DEIS (and FEIS) for tracking acres of old growth remaining, is the mature large sawtimber definition. The MBS, along with other Forests in the Region, is in the process of a new Integrated Resource Inventory; the old growth component of the inventory is on an accelerated schedule, due to be completed in 1991. The inventory is designed to measure physical and

biological attributes of stands, not just size and class. This will allow more detailed analysis of acres of remaining old growth, based on any of a number of definitions.

LAST REMNANTS OF IN-LAND RAIN FOREST SHOULD BE PROTECTED

It is the understanding of the National Park Service that the last remnants of natural rain forest in the contiguous forty-eight states exists in the MBS, due west of the Carbon River entrance to Mt. Rainier National Park We believe that this remnant should be preserved; the DEIS Preferred Alternative does not afford adequate protection of this very significant resource.

Response: In the Preferred Alternative, the section of national forest land immediately south of the Carbon River has been allocated to MA 1D, Roaded Natural. The remainder of the area is in MA 17, Timber Management Emphasis. All proposed projects will have a site-specific environmental analysis, with NEPA document, at the project level.

NEED TO MANAGE OLD GROWTH TIMBER ON A SUSTAINED YIELD BASIS

There presently is no Forest Service, or BLM policy of managing our National Forests for old growth timber on a sustained yield basis. Not only must we preserve as much old growth as possible for future commercial use, but we also must ensure its future commercial use, and we also must ensure its future availability on a sustained yield basis. To accomplish this, significant areas of site 1 and 2 land must be selectively logged, leaving behind many middle aged and older trees (50-160 years old or older) to become the new stand of old trees in a relatively short time. We are not suggesting that a short-term rotation be abolished; we are simply saying we need something in addition.

Response: For lands allocated to MA 17, timber management emphasis, the goal is to provide for the production of timber; other multiple-use objectives are also met, see Chapter 4, Plan. On these acres, we will produce trees of small diameters on short rotations. This does not mean that larger trees will not be produced and eventually harvested. This will occur in management areas where timber harvest is not the primary objective (Forest Plan - Chapter 4), with trees grown and harvested on a longer rotation. In addition, the Preferred Alternative has allocated more acres to management areas with extended rotations: acres allocated to MA 2A and B equalled 106,000 acres in the DEIS, and 119,000 in the Preferred Alternative; also, the Preferred Alternative allocates 21,000 acres to Potential Wild and Scenic River, compared to 9,000 in the draft plan.

OLD GROWTH IS MORE VALUABLE

A Washington Department of Natural Resources study found that Douglas fir aged 160 years and older was worth $125 more per thousand board feet (MBF) than Douglas fir less than 100 years old. Old growth western hemlock and white fir were worth $98 more per MBF than second growth.

Response: Agree. At the present time, higher prices are paid for logs with few defects and higher grades. Trees that produce these logs are usually of large diameter and over 160 years of age. Research conducted by the Pacific Northwest Forest and Range Experiment Station indicates that

high grade material can be produced from second growth trees with diameters starting at 16 inches (reference: Ponderosa Pine Symposium Proceedings).

In Management Areas 1D, 2A, 2B, 4, 5, 6, 13, 14 and 27, there will substantial amount of acreage where trees will be grown on rotations exceeding 160 years

SECOND GROWTH TREES HAVE MORE JUVENILE WOOD, WHICH HAS LESS STRENGTH, ETC.

Large, old trees make less juvenile wood. Juvenile wood is the wood within the first twenty rings of the center of trees. All conifers in the Pacific northwest have a long cone-shaped care of juvenile wood. In large, old trees this cone of juvenile wood is less than 5% of the total tree volume, most of the wood is mature wood. But, in small, rapidly grown second growth trees, juvenile wood may comprise most of the tree's volume. Juvenile wood has lower than average strength and specific gravity; shorter fiber length; and higher than average longitudinal shrinkage, tendency to warp, and fibril angles. Timber harvests comprised mostly of juvenile wood will adversely affect all segments of the forest products industry.

Response: Agree. The amount of wood in any tree that meets juvenile wood criteria will vary, depending upon when that tree is harvested. The volume coming from the forest will consist of trees averaging 23+ inches DBH in Decade 1 of implementation; see the analysis done on the Final Preferred Alternative. This analysis also indicated that even in the regulated forest, harvest diameters would vary from 13 to 19 inch in DBH at 70 plus years of age. In both instances, 50+ years of growth would be mature wood, or approximately 5 to 11 inches.

OLDER STANDS OF TIMBER HAVE A LOWER FIRE RISK

Long rotation, high quality timber management regimes have a lower fire risk. The FS plans will create vast expanses of forest where the largest trees are only 17 inches in diameter. These forests are far more susceptible to fire than old growth forests. The research done for the Bull Run Watershed on the Mount Hood National Forest revealed that the most fire resistant timbered stands are old growth stands (with thick bark, which withstands fire, and canopies that are not as thick or close to the ground, so fire does not race through).

Response: Fire has always been a part of the natural cycle affecting the structure of plant communities. Stand replacement fires have occurred at intervals of approximately 150 years at lower elevations and 300 to 1,000 years at higher elevations, based on local ecological studies. These fires were limited in size by natural factors such as weather conditions, topographic feature drainage patterns and natural barriers. Experience on the forest indicates that the fire ratio of Natural to man caused is 45 55 respectively. Fires are usually 10 acres or less in size, and are slow spreading fires, of low intensity that do little damage (Chapter III, FEIS). Management objectives for each MA should keep loss to wild fire at the same level as in the past or less, with the exception of those areas with approved prescribed fire plans, where natural events will take their course (FEIS Chapter III, IV and Forest Plan, Chapter 4).

LARGE TREES PROMOTE TOURISM

Long rotation timber management regimes are better for tourism. The forests in the Pacific Northwest are proposing long rotation management on a small portion of the forests along highways, as this is more visually pleasing to visitors. Practicing the long-rotation management across the entire forest would also be more aesthetic. The tourism divisions in Oregon and Washington are trying to get visitors to get off the main highways and travel the back roads. More and more people are doing so; what will they find when they leave the curtain of big trees along the highways?

Response· Agree In response to the visual quality and recreation concerns voiced in response to the DEIS, in the Preferred Alternative, more acres were allocated to those management areas which feature large trees with no harvest occurring or longer rotations when harvest is allowed. Refer to Table II-8, FEIS, Chapters II and IV, and Forest Plan, Chapter 4.

TIMBER INVENTORY IS OVER 12 YEARS OLD

Accurate land surveys and reliable inventories of all forest resources are essential We are concerned that the MBS is using a timber inventory that is over 12 years old.

Response: As discussed in Appendix B, Chapter II, the timber resource was inventoried and mapped in 1976. In addition, we have updated the condition class inventory to 1989 with inventory volume grown to 1995. The statistical accuracy has been validated for the degree of precision and reliability needed at the Forest Plan level of resolution. (Forest-wide volume estimates are within 10% at the 67% confidence interval.)

The MBS has already started on the new Integrated Resource Inventory, which will replace the old, timber-only inventory. Potential old growth will be re-inventoried by fall, 1990. Physical and biological attributes of stands, not only size and class, will be measured. The rest of the Inventory is scheduled to be completed by 1995.

FORPLAN outputs for the Forest Plan will be reanalyzed with these new data as part of the Monitoring Plan. The need for any adjustments will be considered in light of this analysis See Plan, Chapter 5, Monitoring Plan

TIMBER MANAGEMENT PLAN SHOULD HAVE BEEN UPDATED IN 1981

Why was the timber management plan not revised in 1981 to account for the effects of the Alpine Lakes Management Plan? This Plan directed fewer CFL acres to be available for harvest, resulting in a cut reduction of up to 9 MMBF per year for both the Wenatchee and MBS. This translates to some reduction on the MBS that clearly was not implemented, or it would have shown in Table III-8.

Response: The following direction from NFMA regulations and the Alpine Lakes Management Plan made it unnecessary to revise the TM plan in 1981 36 CFR 219.4(b)(3) states "Each Forest Supervisor shall develop a Forest Plan for administrative units of the National Forest System One Forest Plan may be prepared of all lands for which a Forest Supervisor has responsibility." Alpine Lakes FEIS, page 3: "Calculating programmed harvest levels and scheduling is not the subject of the EIS. This information will be addressed in the Forest Plans currently under development"; and page 153, Plan Revision: "A programmed harvest calculation for each Forest will include the Alpine Lakes Management Unit

TIMBER MANAGEMENT PLAN HISTORY IS CONFUSING

Table III-8 in the DEIS, Timber Management Plan History, makes no sense. The 1968 North Cascade Act would have resulted in a Potential Yield reduction of 36.3 MMBF. Remember, the north unit of the Park had been part of the North Cascades Primitive Area since 1935

Response: Early inventories included all federal forested acres that were considered commercial (CFL) and administered by the Forest Service. Forested acres were not removed from the CFL base until they were transferred to another jurisdiction (such as the National Park Service) or

were removed through special designation, such as wilderness or Research Natural Area. Thus, the acres you refer to remained as part of the PY until transferred to the Park. A brief note has been added to the text of this table, which will hopefully clarify the display.

TIMBER RESOURCE SUMMARY IN THE PLAN IS POORLY ORGANIZED

The organization of this [timber] section of the resource summaries is very poor. The wildlife resource summary better describes the objectives of the program, and should be used as a model. The tables of numbers are fine, but it is difficult to wade through them without an explanation of why they are there and how they related to the objectives of the timber program.

Response: The resource summaries have been substantially rewritten since the DEIS; the discussion under the timber resource summary is hopefully better organized.

GENERAL ENVIRONMENTAL EFFECTS ARE UNCLEAR

Under "Cutting Vegetation" as a general effect of management activities on the environment, we suggest adding that cutting vegetation also changes the timing and flow peaks (page IV-2, DEIS).

On page IV-3, delete item that says burning vegetation is less costly..., this is not an effect.

It is not clear how Planting Vegetation increases noise from motors, logging whistles, and people. Further the significance of these impacts and how they can be avoided should be discussed

Consider wildlife production potential in the direct effects of timber management upon wildlife.

Response: Regarding the first two comments: these corrections have been made in the FEIS.

The second referenced impacts have been moved from "General Effects of Planting Vegetation" to "General Effects of Road and Landing Construction." The effects of noise, etc and their significance are discussed in Chapter IV, FEIS, under "Air and Noise - The Direct Effects of Each Alternative."

The effects of timber management on wildlife habitat and population levels for management indicator species are discussed in Chapter IV, Direct Effects, FEIS.

PLANS ARE NOT DETAILED ENOUGH FOR FULL EVALUATION OF EFFECTS

I have serious concerns that road and timber plans are not detailed enough to ensure full evaluation. Do the roads proposed fully serve all users well over the long pull; or is timber harvest (expedient) alone paramount? What about stability of the soils for road construction? Are these rivers or streams important to anadromous fish, which could be damaged seriously by soil runoff? *Is the timber volume to be harvested in line with overall costs-economic* evaluation?

Response: The Forest Plan does provide direction for all resource programs, practices, uses, and protection measures through establishment of both Forest-wide and management area specific standards and guidelines. The miles of roads, etc proposed in the Preferred Alternative are an integral part of the design of the alternative, and needed to meet the overall objective and goal of the alternative. The environmental consequences of implementing the Preferred Alternative are fully documented in this FEIS, which meets National Environmental Policy Act requirements. The Forest Plan does **not** provide **all** the detailed information needed to evaluate all projects that will proposed. As discussed in Chapter 5, Implementation, Forest Plan, site-specific project proposals will be subject to an environmental analysis, evaluation, and documentation in a NEPA document.

THE FOREST PLAN IS NOT AN "INTEGRATED PLAN" BECAUSE ALL OTHER USES ARE SATISFIED BEFORE TIMBER

The MBS Plan first subtracted huge areas for all other non-timber resource uses and only then allows some of the remaining acres to be managed for timber emphasis. As a result, all other uses are satisfied many times over and the ASQ drops 17%. Such "balkanization" of the forest followed by isolation of the productive timber resource from the forest as a whole is not in any sense an "integrated plan."

Under legislative direction, the Secretary of Agriculture must provide for a high level of timber products on a sustained yield basis and set harvesting levels/management practices consistent therewith. Why, then, in the MBS plan is the renewable timber resource subordinated to all other resource uses?

Response: "Integrated Plan" refers to the NFMA requirement that Forest Plan coordinate all the resources and land uses into a single plan and not separate resource plans such as timber, wildlife, recreation etc. This was discussed in the DEIS, Appendix B, Chapter I. Also see the FEIS, same appendix and chapter. Requirements for integrating individual Forest resource planning into the Forest Plan (36 CFR 219.13) were followed throughout the planning process. The process for development of the various alternatives, including the consideration given for defining the timber resource base, is included in the DEIS, Chapter II, part B.

As noted in Appendix H, Management Requirements, the Forest made a concerted effort to locate habitat areas for the pine marten, pileated woodpecker, and spotted owl in areas that were not suited for timber production (wilderness, research natural areas, areas with inoperable soils or regeneration difficulty).

DON'T RELEASE A FEIS UNTIL DISCREPANCIES WITH TIMBER INDUSTRY ARE RESOLVED

The State has met with timber industry representatives and has been advised of their numerous questions regarding the accuracy and validity of the Forest's timber supply figures. We feel there is merit to at least some of the issues raised. The substantial discrepancy between the industry and the FS over the timber supply base is a major concern; relative agreement on this issue is a most critical element. We do not believe a final EIS should be released until the discrepancies have been resolved.

Response: In response to these (and other of the timber technical issues raised in commenting on the DEIS), the Forest Supervisor and staff from the MBS and the Regional Forester held extensive meetings with representatives from the Northwest Forest Resource Council's technical committee, the Governor's office, PLUS, and others. After a course of action was agreed upon by these parties (see Appendix J and the planning records for documentation of meetings held, attendance, etc.), the following modifications were made in our analysis: recalculation of board foot ASQ volumes for the first decade, development of new site index values for the Douglas-fir and Pacific silver fir/hemlock species groups, adjustment of regeneration time-lags downward for artificial and natural regeneration, updated the number of acres by age class, development of new managed yield tables; development of new empirical yield tables; adjustment of board foot/cubic foot ratios.

With this information and based on the public comment we received, a new alternative, Alternative I, was developed to respond to the objectives of PLUS. Again, refer to Appendix J for a summary of these working meetings.

CORRECT THE BOARD FOOT/CUBIC FOOT RATIO TO INCREASE ASQ

The draft plan uses a factor of 4.89 to convert FORPLAN cubic foot output to board feet. Based on the Forest Service's inventory plot data, the expected factor for the stands to be cut during Decade 1 is 5.10. Correction of this error will increase ASQ by 4.3%.

The BF/CF ratio was recalculated in response to public comment, for Decade 1 only. The results are displayed in the FEIS, Chapter II, timber output tables. (Both ratios are shown.) The conversion ratio is calculated based on a weighted average of the ratios for the stand type and model components actually scheduled during the first decade Program development and target attainment will be based on the cubic feet calculated for planned sale activity during each program year, and appropriate conversion factors calculated at that time.

WHY WEREN'T UNEVEN-AGED MANAGEMENT PRACTICES CONSIDERED?

Even-aged timber management will be assumed for all alternatives. As the MBS is not a lodgepole monoculture, why weren't other kinds of management more seriously considered?

PCT and CT are options in uneven-aged management, just not as cost-effective. However, a management objective would be significantly enhanced through utilization of uneven-aged regimes, it should be the preferred option, such as in riparian areas, and modeled as such.

The series of arguments used in Appendix F show a strong bias toward even-aged management. None of the alternatives present a model of the Forest as is would appear using uneven-aged management. The MBS has chosen to ignore an important local and national issue and has presented us with alternatives that allow no choice.

Appendix F is an apologist's rationale for clearcutting. Wildlife, fish, and old growth values are not discussed. If dwarf mistletoe thrives by increased sunlight, how are the edges of clearcuts different from selective harvesting?

If bole rot is concomitant to selective cutting, is research rethinking harvest practices? In the Appendix, uneven-aged management is given to appear as a cause of root disease.

The rationale for producing even-aged stands is flawed. The DEIS states that uneven-aged stands are more susceptible to pest infestations. In fact, the reverse is true, as evidenced by the mountain pine beetle infestation in Idaho.

If root rot and mistletoe are not such a problem in Pacific fir (see Appendix F, Selection of Harvest Cutting Methods), why automatically go for clearcutting?

Response: Appendix F reviews the rational for selection of a harvest cutting method, either an even-aged or uneven-aged silviculture system, by species zone and management area. NFMA state that "Clearcutting may be prescribed only where it is found to be the optimum method of regeneration to meet multiple-use objectives." This will usually not be known until project planning, when the best method to meet specific management objectives will be addressed on a site-specific basis, when costs, timber values, and harvest systems are determined. While in Appendix F, clearcutting is found to be the appropriate method for a number of species and management areas, the MA prescriptions in the Forest Plan do not preclude selection of an uneven-aged silvicultural system, in most cases. Refer back to Appendix F and see Chapter 4, Forest Plan for more detail.

Although dwarf mistletoe is not as serious a problem in the Pacific silver fir zone as in lower elevations, it still is a problem. With less reliance on prescribed burning - one method of removing mistletoe - clearcutting is the next best tool for removal. Uneven-aged management (such as selection cutting) creates another problem: in harvesting selected trees, those left standing are often damaged by the logging cable. Damaged trees are then more susceptible to bole and root rots, and also to dwarf mistletoe. Refer to FEIS, Appendix F.

UNEVEN-AGED MANAGEMENT

"Uneven-aged methods may require artificial regeneration to maintain the appropriate species composition...". Please explain appropriate species composition Doesn't that depend on the management area objective?

Same comment as above regarding "appropriate species composition". "Uneven-aged management may favor growth of hardwoods and prevent regeneration of tall growing conifer..." In riparian areas, hardwoods are commonly succeeded by conifers; the mix is good for fish and wildlife. "...so that shading is reduced on larger streams." We are not concerned that the mix of hardwood and conifer that would accompany uneven-aged management would in any way contribute to increases in temperature significantly impacting to fish streams, especially as compared to complete removal as in clearcutting regimes.

Response: The "appropriate mix" is that prescribed during the site-specific, environmental analysis by an interdisciplinary team And yes, species selected depends upon the exact objectives for the management area. The standards and guidelines for MA 13 - Watershed, Wildlife, and Fisheries Emphasis in Riparian Areas, give further direction; see Chapter 4, Forest Plan.

Vegetation - Timber

APPENDIX F DOES NOT DISPLAY THE IMPACTS OF THE DIFFERENT HARVEST METHODS

Erosion potential is not mentioned in the selection of harvest cutting method section for mountain hemlock zone. It should be addressed as it was in Chapter IV of the DEIS, in the Effects of Recreation on Soils section

There is no reference to potential impacts to water yield, water quality, channel stability, fish habitat, or insect production in Appendix F.

> **Response:** Resource concerns for each zone were not identified in Appendix F. The criteria used in determining which cutting method to employ takes into account those identified resource concerns. Chapter IV of the FEIS also discusses the effects of harvest activities on the other resources.

SHELTERWOOD HARVEST METHOD SHOULD BE USED ON AREAS WITH EXTENDED ROTATIONS

There is an opportunity to increase timber production on areas where very long rotation ages are specified through the use of shelterwood harvest that would be compatible with the management emphasis on the areas.

> **Response:** As outlined in Appendix F of the FEIS, shelterwood system is one of the even-aged methods available. All or portions of Management Areas 1D, 2, 4, 5, 6, 13, 14 and 27 have extended rotations planned as part of the timber program element (Forest Plan, Chapter 4). The even-aged method of cutting is available to be used in these areas when appropriate. An environmental analysis will be prepared for each project; as part of this site-specific analysis, the harvest method will be selected.

QUESTION ASSUMPTION RE: GENE POOL FOR SEEDLINGS

We question the assumption (Appendix F, page F-6 DEIS) that the selected genetically superior seedlings have a broader gene pool than seedlings produced in natural stands. Large openings are generally planted with stock and are not dependent on distant, less closely related trees for seedlings.

> **Response:** Agreed. This section of Appendix F has been rewritten to reflect your concerns

INTRODUCE GENETICALLY ENGINEERED TREE SPECIES

What is the policy regarding the introduction of genetically engineered tree species? Would any public-owned forest be opened for exploratory scientific research, either by public researchers or private timber companies?

> **Response:** Genetic engineering is not yet a perfected method for forest trees, and is still in the Research and Development phase. As new information becomes available, we will re-analyze Forest conditions. Changes may be made to the Forest Plan, either as amendments or as part of the planned revision (at least every 10-15 years)

HOW WAS THE AVERAGE GROWTH GAIN FOR GENETICALLY IMPROVED SEEDLINGS CALCULATED?

Was the average growth gain because of genetically improved seedlings based on the percentage of timber types on suitable land?

Response: The average was based on tentatively suitable acres. All tentatively suitable acres are entered into the FORPLAN model, the model then selects from various attributes and produces suitable acres based on the allocations for each alternatives. Appendix B of the FEIS has been rewritten to better reflect the process used.

YIELD IS UNDERSTATED DUE TO ERROR IN DETERMINING SITE PRODUCTIVITY

An erroneous procedure for determining productivity on hemlock and Pacific silver fir lands was used in the draft plan. Soil land productivity (site) was adjusted downward to reflect current understocked conditions. Site index is independent of current understocked conditions. The impact of this is to understate future yields by about 30% on these lands

Response: As explained in Appendix B, no adjustments are needed on these issues to proceed in the FEIS. For example, although site quality is used to assess the growth potential of forest land, it is not always a statistically significant predictor of volume per acre in wild stands. It appears that additional clarification will help in understanding the issue of species not being taken into account in determining site indexes and the perception of understating site indexes.

While site index may be a good predictor of initial volume per acre, it will influence growth rates even in an empirical yield. For a given plot, each tree species will generally have a different site index

OTHER RESEARCH HAS FOUND HIGHER YIELDS

I'm enclosing a copy of Newton and Cole's Oregon State University Study, indicating a sustained-yield management scheme with both quality old-growth timber and near old-growth habitat. They've found that the annual volume growth continues to accelerate, producing substantially greater than 100,000 thousand board feet per acre, per year at ages 170-190.

Response: *Arney's Stand Projection System (SPS) provides more realistic* simulations of growth and yield in areas managed for western hemlock and Pacific silver fir, we will continue to use this model in these areas. However, we will continue to use the volumes from the empirical yield tables for poles and small saw timber as an upper limit for naturally regenerated hemlock stands without management. We have used the Douglas fir model (DP-DFSIM) in areas managed for Douglas-fir. In the FEIS and Forest Plan, our yield tables reflect the revised site indices and stockability adjustments, made in response to public comment.

GROWTH ON EMPIRICAL YIELDS

FORPLAN is a model that works in ten-year increments. Each decade's total harvest is assumed to occur in the middle of the decade. Thus, empirical yields must be grown to the middle of the first decade prior to being input

into FORPLAN. The MBS planners grew empirical yields to 1990, but the first decade is likely to run from 1989 through 1998. Thus, the empirical yields should have been growth through 1993.

Response: The initial empirical tables were developed utilizing an estimated beginning time period. This time period did not materialize, therefore the time period for the beginning of the period of the empirical tables has been adjusted to reflect the new start period.

WESTERN HEMLOCK AREAS THAT WILL RECEIVE PLANTING ON 25% OF THE AREA SHOULD HAVE HIGHER YIELDS

Yields for western hemlock areas that will be naturally regenerated were arbitrarily reduced to be no higher than existing stands. The Plan assumes inter-planting of up to 25% of these areas to achieve full stocking, so it is erroneous to assume these areas will have lower yields.

Response: In response to public comment on the DEIS, new managed yield tables were constructed. Refer to Appendix B, FEIS The revised tables for western hemlock and Pacific silver fir were constructed using the Stand Projection System. At this time, there is only a very slight increase in yield with planting genetically superior stock/final harvest, compared to natural regeneration/final harvest. The planting in western hemlock areas will occur in small areas (up to 25% of the area), primarily on temporary roads, landings, and areas where natural regeneration will not be sufficient.

REGENERATION ASSURANCE STANDARD OF 125 TREES PER ACRE IS BELOW STATE MINIMUM

The Proposed Plan indicates that FS Regeneration Assurance standard requires a minimum of "125 well-established trees per acre." This level is less than the Washington State Forest Practices Act minimum of 190 trees per acre.

Response: This figure has been corrected in the Forest Plan. Refer to Chapter 4 Prescriptions require a range of between about 250 to 500 seedlings per acres When the number of seedlings falls below 300, an analysis is made to determine if additional seedlings should be planted.

MORE ACRES SHOULD BE REFORESTED BY PLANTING

According to Table 4-5 in the proposed plan, about 72% of the area reforested after final harvest, in the first decade, would be accomplished by relying on natural regeneration, and only 28% of the area would be planted after final harvest. More acreage should be reforested by planting than is called for in the proposed plan. A heavy reliance on natural regeneration could result in a shift in species composition, to more prolific, lower-valued species such as Western hemlock, and fewer less prolific high valued species such as Douglas-fir

Response: In the Forest Plan, for the first decade, approximately 2,800 acres will be harvested per year and 2,200 of those will be regenerated by planting, rather than neutral regeneration. This change is discussed in detail in Plan, Chapter 4, Timber Resource Summary; also, refer again to Table 4-5 in the Forest Plan

WHAT IS THE VOLUME PER ACRE FOR STANDS YOUNGER THAN OLD GROWTH?

Old growth growth rate is less than 20 cubic feet per year, versus 170 CF/Year fro young trees. However, what is the cubic feet of wood fiber in reserve on young forests for future generations? For 10 year-old trees? 50 year-old trees? No figures are given on volumes available per acre for even-aged forests.

Response: This information can be developed from two tables presented in Chapter 4 of the Plan (both Draft and Final). The acres of various age classes are shown in Table 4-9 (for tentatively suitable acres that come into solution as suitable acres). Acres of suitable timber by productivity classification are shown in Table 4-8. The weighted average potential productivity on suitable lands (from Table 4-8) for the Forest = 115 62 CF per acre per year. Applying this to a stand, for example, of 70 years: 115.62 CF/AC/YR x 70 years x 17,560 acres [number of acres of 70 year old stands, from Table 4-9] = a standing volume for that age class of 142 12 million cubic feet.

THERE IS A PROBLEM WITH DETERMINATION OF SITE PRODUCTIVITY

There appears to be a problem with your classification of site productivity. You seem to be classifying each site based on its current, rather than, potential stocking ability. This can easily be remedied and changed to meet standard forestry practices.

Response. Between the Draft and Final, we changed the process for developing managed yield tables and determination of site indices, primarily in response to public comment. In general, two growth and yield simulators were used to develop projected yields, DFSIM for Douglas-fir and stand projection system for hemlock and true firs Site indices were based on site trees found on existing forest inventory plot's on suitable lands, by species, with site trees determining the group in which the inventory plot would be placed. Once plots were grouped and the model completed, an average site index was calculated. The most current research and methodology was used to convert raw filed site index into final format for use in growth and yield simulators. See Appendix B and the August 1989 MBS documenting development of managed yield intensities.

GROWTH RATES SEEM LOW

The law says that management should not impair productivity. It does not say that you cannot increase productivity. There are many ways to do this which are not addressed.

Present timber productivity in terms of net growth at 34 ft 3/a/yr is extremely low. Someone should express more concern about this. On areas managed for timber as a major use, the potential should be more than 90 ft 3/a/yr. There are many ways to improve this but these are not discussed in any way.

Response: Chapter III of the Forest Plan states the average growth rate of mountain hemlock stands is 35 cu ft/ac/yr. This is due to the harsh sites where mountain hemlock is found. Overall for the Forest, the average productivity is 114 cu ft/ac/yr.

Cubic foot outputs vary widely depending on the management objective of the area. Some areas managed for timber emphasis will have outputs exceeding 120 cu ft/ac/yr, while areas managed for resources other than timber will produce as low as 40 cu ft/ac/yr. Throughout the life of the plan, growth rates will improve as more stands are managed intensively and genetically improved stock is used.

NEED A BETTER EXPLANATION OF "NOT RESTOCKABLE WITHIN 5 YEARS" LANDS

We have an uneasy feeling about the description in the draft Plan regarding land "not restockable within five years." As forestland managers, we feel that unless these sites are talus slope, rock outcrops, or slide areas etc., an extra effort to reforest difficult sites is prudent and can be economically justified. The plan was unclear about the physical characteristics of these 159,739 acres, making it difficult to judge the adequacy of the classification.

Response: In this FEIS, a better explanation of the identification of suitable lands has been added to Appendix B, Chapter II, Land Suitability for Timber Production. A reference to this new discussion has been added to FEIS, Chapter III, Commercial Timber.

DISCUSS THE STANDARD REFERRED TO UNDER REGENERATION ASSURANCE

In the Forest-wide mitigation measures (end of Chapter IV in the DEIS), the standard referred to under Regeneration Assurance needs to be discussed, including what it is, who applies it, and where it can be found.

Response: A reference to the discussion on regeneration difficulty lands in Chapter III, FEIS has been added to this mitigation measure. In addition, the reference to 36 CFR 219.14(A)(3) has been added, and a definition of "reasonable assurance" (from the Chief's letter of 7/15/83 and Pacific Northwest Regional direction 8/23/83) added to the Glossary.

ADDRESS REDUCTION OF SOIL FERTILITY

The Forest Service should address the problem of reduction of soil fertility that results from its silvicultural methods. Specifically, the removal or destruction of the duff layer reduces the number and kinds of microorganisms and fungi in the regenerating stands and these have been shown to be important contributors to tree growth and health

Response: Soil productivity was addressed in the DEIS on pages 111-53 and 54, IV-5 and 6.

RECOMMEND USE OF FERTILIZERS

Suggest that the Forest Service increase the intensity of timber management practices on suitable lands in all the proposed Alternatives contained in the Plan The concept would identify the suitable lands for timber production and mandate that their management emphasize maximum productivity, utilizing silvicultural and economical practices including commercial thinning. Added to the above planned regime, we would recommend the application of nitrogen

fertilizer to Douglas-fir stands occupying lands with site categories IV to II.

Weyerhaeuser has demonstrated fertilization to be cost effective when applied at five year intervals beginning 25 years before rotation age, but not beyond 45 years of age.

We do not understand the conservative view taken today by the Forest Service relative to the application of fertilizers. The narrative in the Plan indicating more research is needed (4-29) seems to have overlooked the many credible studies already completed on suitable lands and extensive use among private forest landowners and Washington State Department of Natural Resources. Rotation ages of North and South Conifer can be shortened by 25 to 20 years, respectively, with the application of fertilizer

Despite the fact that the plan assumes nearly 40% of suitable lands will be replanted in Douglas-fir, it was assumed that only 2% of suitable lands met the criteria for fertilizing. PLUS yield tables incorporating fertilizer response should be used for predicting future yields.

Response· The use of fertilizers was discussed on page 4-29 of the Proposed Forest Plan, and page B-85 of Appendix B: "Analysis determined that only about 2% of tentatively suitable acres may meet criteria and feasibility for this practice..." In addition, the growth simulators used to build yield tables do not appear to predict reasonable response to multiple applications of fertilizers. One MBS silviculturist analyzed yields from the DFSIM model, using multiple applications of fertilizer. The growth due to one application appeared to be consistent with field data, but the multiple applications showed a synergistic effect which, in our judgement, was unreasonably high. Unofficial comments from Bob Curtis, the developer of DFSIM, have substantiated this observation.

PLANTING STOCK SHOULD NOT BE INNOCULATED WITH NITROGEN FERTILIZER

Planting stock used for reforestation on the MBS should not be innoculated with nitrogen fertilizer. Instead, planting stock should be treated with mycorrhizal fungi to insure good growth and to overcome the loss of important mycorrhizal fungi populations through silvicultural methods that include clearcutting and slash burning.

Response: Planting stock used to reforest harvested areas are grown under proper conditions to produce acceptable seedlings at the nursery. At the present time the forest does not innoculate seedlings directly with nitrogen. Nitrogen is applied to the soil during normal nursery operations to promote desired plant growth. When the seedling is transferred to the actual growing site nitrogen fertilizer has been applied in the past to specific sites to promote growth and can be applied under the Forest Plan on specific sites (see Forest Plan Standard and Guidelines).

Mycorrhizal fungi are an ever-present part of soil, under all but the most unusual circumstances, and form their symbiotic relationship with plants at an early age, i.e. in the nursery. The relationship continues when the seedling is planted on the growing site where already present mycorrhizal fungi add to the relationship on new root growth. Current observations, measurement of soils and regeneration growth, on clearcut and burned areas do not lend themselves to great concern for the loss of mycorrhizal i.e.

long term productivity. These facts combined with anticipated future harvest levels and application of BMP's utilized strengthen this conclusion. Conclusive research that would support a change in direction is being conducted at this time. If this research indicates a change in direction is need to insure sufficient levels of mycorrhizal to maintain site productivity it will be incorporated into management activities.

WHAT IS THE RATIONALE BEHIND THE COMMERCIAL THINNING STANDARDS?

What is the rationale behind restricting commercial thinning in management intensities C and E to stands that are "accessible by roads in which 50% or more of the crop trees are Douglas-fir" (Draft Plan, page 4-190)? The assumption that roading is automatically non economical when associated with commercial thinning is not necessarily true. There is a very large body of experience and study that proves that Douglas-fir stands are not the only ones that can be successfully thinned commercially. The MBS very little experience with commercial thinning and seems to have written a standard that is not necessary when compared with work done elsewhere

Response: This standard has been changed in the FEIS and Forest Plan; commercial thinning is allowed in any stand which meets the criteria See Forest Plan, MA 17 standards and guidelines

ARBITRARY TIMING CONSTRAINTS APPLIED

Arbitrary harvest timing constraints are being applied to more than 50,000 acres of unroaded lands containing mature sawtimber and currently classified as economically in accessible. These constraints force the areas to be harvested within the first 5 decades or not at all; the result is only 4,000 acres are harvested and the remaining 46,000 acres effectively become de facto wilderness

Response: The Forest has tested and reanalyzed the effects of changing the constraints designed to avoid concentrating final harvest in the later decades. There does not appear to be a significant effect on ASQ; economics rather than the timing are the major constraint. No changes have been made for the FEIS. However, as we monitor the plan, both economics and the harvest timing constraints will be re-visited.

ALTERNATIVE H FAILS TO ADEQUATELY RESTORE AND RESTOCK CUT-OVER LANDS

The Management Plan does not adequately describe specific management practices for restocking cut-over forest lands for future production. Many areas within the Forest which were harvested 40 to 50 years ago should have nearly-harvestable timber, but in fact have only crowded and dwarfed trees of no commercial value.

In determining total acres suitable for timber production, the Plan assumes that all acres which have been harvested are being returned to a condition suitable for future harvest. It does not take into account previous poor management decisions, conversions to hardwoods, acres lost to landings and slash, and most important, inadequate reforestation at higher elevations.

Response The discussion of reforestation and timber stand improvement in Chapter III, Commercial Timber, in the FEIS has been expanded For the period 1980 through 1988, on the Mt. Baker-Snoqualmie, survival of first-year tree plantings averaged 79%; third year survival was 89% of the trees from first year plantings. The average number of trees per acre was 308, which is generally within acceptable limits of the prescription (Reforestation Survival and Growth Annual Report). Since October of 1981, the Forest has been successful at reforesting all cut-over lands. Also refer to the discussion in Chapter III, FEIS on lands identified as not suitable for timber production due to reforestation difficulty

Since 1982, there has been an average of 2,600 acres per year that have been pre-commercially thinned or released. Whereas, in the same time period, the Forest has reforested over 4,600 acres per year on the average. The Forest is actively seeking funding to treat all plantations in need of thinning or release. It is anticipated that these funds will be received and the additional acres will be treated as part of the timber stand improvement program Goals for management in this type of area can be found in Chapter III in the FEIS, Chapter 4 and 5 of the Forest Plan.

At the present time, stands that were harvested 40 to 50 years ago and have received proper stocking level control activities are generally not ready to receive a commercial thinning In management areas where this prescription was chosen, the stand won't be ready for a final harvest for 20 to 30 additional years when they reach at least 95% of their culmination of mean annual increment. See Chapter II in the FEIS, Appendix B and Chapter 4 in the plan for additional information.

MAINTAIN A LARGE SUITABLE LAND BASE

Because of RARE I and RARE II analysis and other administrative action over the past decade, harvesting has been restricted to an artificially reduced land base creation potential future conflicts with other resources. In order to maintain the highest possible sale level, it will be essential for the final plan to include the largest suitable land base possible, even if every acre is not immediately needed to meet timber production targets. PLUS believes that a final plan based on the largest possible suitable land base, intensive monitoring, and effective mitigation measures can produce timber needed to maintain viable local economies without excessive impact on other resource values and management objectives.

Response: Over the years there have been many changes to the suitable land Base (commercial forest lands); see FEIS Chapter III) These changes have resulted in a reduction in Potential Yield. NFMA and it's implementing regulation, CFR 219.14, required a review of all all National Forest Acres to determine their availability for timber production. This has been accomplished by following a set of criteria (see Appendix B, Chapter II) to determine **tentatively suitable** forested lands - those capable of producing a continual supply of trees on a given acre. The total **tentatively suitable** acres are 597,000 acres. Alternatives are then developed to respond to the issues in various ways. The number of acres actually considered **suitable** for an alternative depends upon the acres assigned to various management prescriptions. In the FEIS, the range of suitable acres in the alternatives is 546,500 in Alternative NC to 247,091 in Alternative G-Modified. See Chapter II, FEIS Output levels will vary depending on

the intensity of management and amount of suitable acres available in the alternative.

In response to comments from PLUS, the Forest developed and displayed in detail a new alternative to meet the goals and objectives stated. Alternative I has 386,512 suitable acres (compared to the Preferred Alternative with 346,411 suitable acres. Refer to FEIS, Chapter II, Alternatives Considered in Detail, for more information.

USE ALTERNATIVE'S D SUITABLE LAND BASE - PRODUCE 220 MMBF PER YEAR

WFIA has determined that the suitable acres existing on both the North and South ends of the Forest actually resembles the suitable acreage as displayed in Alternative D, with the following exceptions: manage the 3,899 acres of MA 1A Primitive for timber production. Also, the difference between acres of MA 1B in Alternative H (244,095 acres) and D (197,095 acres) should be managed for timber harvesting. If these two categories of land classification were brought back into timber management, the forest should be capable of producing approximately 220 MMBF per year.

Response: The range of alternatives considered in the FEIS include alternatives that assign a high percent of the tentatively suitable acres to a timber harvest prescription (Alternatives NC, A, B, and I). See Alternatives Described in Detail, Chapter II, FEIS. Alternative I was developed in response to public comment on the draft EIS, with a goal of producing of 220 MMBF annually, providing increased numbers of big game animals, more trails, and more roaded recreation opportunities. In this alternative, no acres were allocated to MA 1A (primitive dispersed recreation) or MA 1B (semi-primitive nonmotorized recreation). Refer to the output tables (Table II-9a though II-9o), Chapter II, FEIS. As a result, the ASQ for Alternative I is 129 MMBF, Decade 1

Refer to Chapter III and Appendix B, FEIS for a discussion of the process used to determine acres tentatively suitable for timber production.

NEED A DISCUSSION OF HOW LANDS ARE EVALUATED FOR CLASSIFICATION

There needs to be a discussion of how the evaluation of land for classification takes place. This would include discussions of the accuracy of methods and identification of the responsible officials.

Response: The DEIS, Appendix B described the process and the general criteria used to determine which lands are suitable for timber management More detailed information is available in the planning records. The suitability process is also summarized in Chapter III, FEIS

THE SUSTAINED YIELD CONCEPT IS NOT DISCUSSED IN THE DOCUMENTS

Previous documents and discussions with Forest Service personnel have indicated that the FS manages resources on a sustained yield basis, yet we found no direct reference to the sustained yield concept in any of the alternative plans or the DEIS.

Response: The concept of sustained yield management was discussed in Chapter I, DEIS, it is first mentioned on page I-1 in this FEIS Also, refer to discussion of long-term sustained yield capacity in Chapter II, Table II-9c and Figures II-17 to II-23

THE FOREST CAN NOT BE MANAGED ON A SUSTAINED YIELD BASIS

The amount of acreage to be harvested is not consistent with a true long run system of sustainable yield The system we envisage will provide sustainable harvest for human use, but still keep a wide variety of age classes, including old growth, in perpetuity. We would suggest developing a harvest scheduling system based on the model presented by Larry Harris in The Fragmented Forest. [complete discussion of model not presented here; area divided into 8 parts, total area is harvested over a 320 year cycle.] A system of this nature can provide protection for wildlife, but also enhance the long run viability of our timber communities.

Response: All alternatives, including the Preferred, reach long-term sustained yield capacity by the 8th decade. Refer to Chapter II, FEIS, narrative for Table II-9c The inclusion of standards and guidelines, management requirements, and mitigation provide for viability of other resources as well as maintenance of a sustainable yield of commercial timber

STATE WHETHER TIMBER WILL BE SOLD ABOVE THE SUSTAINED YIELD LEVEL

NFMA forbids selling timber above the sustained yield level. How do the alternatives respond to this requirement? This should be stated explicitly in the comparison of alternatives section.

Response: It is discussed in Chapter II of the FEIS, specifically in the narrative for Table II-9c.

IS A TIMBER HARVEST OF 170 MMBF A SUSTAINABLE YIELD?

I question whether 170 million board feet represents a sustainable yield. The fact that roadless areas are being slated for cutting indicates that the USFS sustained yield calculation includes more land than is currently used for logging.

Response: While the roadless area acres were unavailable for harvest during the RARE process (1972 to 1984), the commercial forest land within the roadless areas was used to calculate the annual allowable timber harvest In the Forest Plan, the harvest level is based on the lands available for timber harvest, the productivity of those lands over time, the management emphasis of those lands, plus constraints to spread timber management activities across the suitable land base to meet basic soil and water requirements, wildlife requirements, visual quality objectives, etc and supply a steady flow of wood products. The FORPLAN model schedules harvest levels based on these constraints and determines a sustainable Allowable Sale Quantity (ASQ). Refer to Tables II in Chapter II of the FEIS, Chapter IV in the FEIS and Appendixes B and C for more explanation.

WHY ARE PROPOSED TIMBER SALES FAR IN EXCESS OF THE 60-ACRE LIMIT?

A size restriction of 60 acres for created openings seems reasonable, but well over half of the proposed timber sales in Appendix A are far in excess of 60 acres. One example is Goodman Ridge at 259 acres.

Response: The acres you are referring to are the total acres in the timber sale. Note - in the remarks section of Table A-1 - that each sale is comprised of a number of units. The sale will meet the Forest-wide standards and guidelines for created openings (Chapter 4, Forest Plan). Each actual harvest unit will be 60 acres or less in size. We have clarified this in the introduction to Appendix A of the Forest Plan.

MINIMUM CLEARCUT SIZE SHOULD BE STATED IN THE FOREST PLAN

The minimum clearcut size as stated in Chapter 4 of Draft Plan is ambiguous. Specific guidelines should be adopted rather than using such undefined terms such as "net public benefit".

Response· The language in the Forest-wide Standards and Guidelines for created openings is correct as written; there is no minimum clearcut sizes, only maximum sizes for openings, as stated in this chapter of the Plan For information on net public benefits, refer to the discussion in Chapter II, page II-2 and the glossary.

CREATED OPENINGS SHOULD BE CONSIDERED NO LONGER AN OPENING AT END OF 3RD SEASON

The MBS has paraphrased the Regional Guide, indicating that an area with prescribed tree stocking that is at least 4-1/2 feet high and free to grow is then no longer considered an opening. Our recommendation is that it would no longer be considered an opening when it is adequately stocked at the end of the third growing season. Also, departures from the 4-1/2 feet height are buried in the Plan, such as on page 4-93, Forest-wide Standards and Guidelines. The FS should list these.

Response: The NFMA regulations (36 CFR 219 27(d)(1)) provides a minimum: "openings in forest stands are no longer considered openings once a new forest is established." The regulations then state that Forest Plans may set forth variations to that minimum based on site-specific requirements to meet multiple-use objectives, and that regional guides shall provide guidance for determining variations.

The MBS Plan follows the direction of the Pacific Northwest Regional Guide (1984) regarding when a cutover area is no longer considered an opening The example in Chapter 4, Plan, Forest-wide Standards and Guidelines regarding objectives for big game winter range has been deleted in the Forest Plan; it was taken directly from the Regional Guide, but does not apply to this Forest. This should remove some of the confusion. We did not, however, include a list of MA's which vary from the 4-1/2 foot standard.

GUIDANCE ON CREATED OPENINGS SHOULD BE PRESENTED

The reference for guidance on created openings should be presented. For example, how was it decided that a clearing is considered closed when the tree is 4.5 feet high? Is this from other Forest Service documents? Further, what does "when other resources management considerations prevail" mean, and where in the Plan are the "particular management objectives" to be found?

Response: The reference for the 4.5 foot standard - the Pacific Northwest Regional Guide (USDA 1984b) has been added to this section. "When other resources management considerations prevail" means if other resources such as wildlife, watershed, etc. require a standard more restrictive than the created opening standard, the standard for that resource shall apply. These are found in the specific management area standards and guidelines, such as 2A Scenic Viewshed, Foreground, Item E 2.d.: "Created openings shall no longer be considered openings in sensitivity level 1 areas when trees reach 20 feet in height." See Chapter 4, Forest Plan.

36 CFR 221 SHOULD BE IDENTIFIED AS AN AUTHORIZING REGULATION

It is noted that the Forest Service no longer cites 36 CFR 221 as part of their authorization, although these regulations have not been superseded. Perhaps an acknowledgement would strengthen their emphasis on a continuous supply of timber, stabilization of communities, and opportunities for employment.

Response: The Forest Plan was developed in compliance with all applicable laws and regulations To meet 40 CFR Parts 1500 to 1508 (CEQ regulations) direction to reduce paper, not all applicable laws and regulations were listed in the documents.

HOW LONG WILL THE DISPERSION CONSTRAINT BE IMPOSED AND WHERE?

The sensitivity analysis in the DEIS does not contain information on how long the dispersion constraint will be imposed and the extent of the geographic area to which dispersion should apply. How long does a harvest unit remain open? Why cannot the dispersion constraint be limited to the five decade RPA planning horizon as some forests do, and why must it be applied by allocation zone?

Response: The dispersion constraint will be in effect throughout the life of the Plan. The dispersion constraint applies to all Management Areas that have timber harvesting activity. On a project by project basis, the dispersion constraint is governed by the specifics of the Forest-wide Standards and Guidelines, Timber, for created openings, Chapter 4, Forest Plan. The dispersion constraint is not applied by allocation zone, it is applied by management area and it is modeled by the constraints.

IF TREES ARE A RENEWABLE RESOURCE, WHY DO WE NEED TO LOG NEW AREAS?

You have promoted timber as a renewable resource, so why not farm previously logged low-elevation, fast-regeneration forests rather than logging more virgin forest?

If trees are so renewable, why are we cutting new areas?

Response: Heavy timber management activities did not begin until the late 1950's. This makes the majority of the second growth stands on the Mt. Baker-Snoqualmie 30 years or younger and not ready for commercial harvest for another 20 to 30 years. Final harvest can not occur until stands reach culmination of mean annual increment, or 95% there of, which will not occur until 40 or 50 years at the earliest. See Appendix B, yield tables. Until these stands reach that point, existing stands will be supplying the bulk of the allowable sale quantity. Analysis indicates that reliance on second growth stands to provide the majority of the harvest volume will not occur until the 7th decade. See Chapter II, FEIS and Chapter 4, Forest Plan for additional information.

SHOULD DISCUSS THAT NON-NATIONAL FOREST LANDS ARE THE MOST PRODUCTIVE

The DEIS should have pointed out (in Chapter III, timber base) that the 2,628,000 acres of commercial timber land in the 5-county Puget Sound area that are non-National Forest lands are substantially more productive than those lands on the MBS. Our greatest opportunities to increase the timber supply lie outside the Forest.

Response: The discussion on timber supply (FEIS, Chapter III) has been updated.

MEETING RPA TARGETS FOR TIMBER

It is very apparent from comparison of RPA Program outputs assigned in the 1984 Regional Guide with the outputs for various plan alternatives that the MBS is capable of and intends to meet all targets except timber. Since the RO and the Forest collaborated in setting targets, it is evident that there has been a subsequent, significant change in attitude toward timber production. It is not explainable by any new information.

We strongly urge the Forest Supervisor to fight hard against the RPA timber harvest targets. It is well known that harvest levels in the state far exceed the long term sustainability of the forests

Response: As explained in Chapter I of the EIS, the RPA targets are based on present and anticipated supply and demand for various resources. The 1984 Regional Guide presented a "tentative distribution of its portion of the national resource objectives to each National Forest." The analysis of Forest outputs and their effects is, in turn, incorporated into the National RPA Program.

As discussed in Chapter II (DEIS and FEIS), in "Alternatives Considered But Eliminated From Detailed Study," we were unable to formulate an alternative that could simultaneously meet all of the 1980 RPA targets. There are several reasons, including· a decrease in available land base since the 1980 RPA Program was developed and NFMA resource integration requirements and land suitability classification. See discussion in Chapter II, FEIS.

The analyses and information from this Plan will be used in future updates of the RPA Program, which should result in program targets that are more consistent with the current physical and biological capability of the MBS.

IF THE BUDGET IS REDUCED, ALL PROGRAMS - EXCEPT TIMBER - WILL BE REDUCED

In days of tight budgets, the only part of the program that will not be reduced will be the allowable cut The removal will continue but the replacement will not Neither will there be replacement in kind - there will never be old growth forests again.

Response: Of the 1,303,100 acres of forest lands on the Mt. Baker-Snoqualmie National Forest only 597,000 acres are tentatively suitable for timber production. Thus 706,100 acres will continue to remain in their national conditions, ie. old growth or advancing to an old growth condition, as only natural events would occur here. Refer to the new discussion on Diversity and Succession, Chapter III, FEIS. Since October 1981, the Forest has been successful at reforesting all cut-over land, see Chapter III FEIS. Actual budget allocations will have an effect on all management activities. If funding is not received in amounts sufficient to accomplish the timber management portion of the Forest Plan, it will most likely result in a reduction in the allowable sale quantity. See Chapter I and V of the Forest Plan for more information.

PRIMARY LOGGING SYSTEM ON THE FOREST SHOULD BE BY HELICOPTER

I would like to see the forest service adopt the helicopter as the preferred method of tree removal; nothing is more intrusive upon the outdoor experience than a road. Not only do roads disrupt the feeling of solitude and the view, but they also decrease the amount of viable habitat for the big game. Therefore, I would be less disposed to opposing to logging operations if I knew that at least some of the remoteness of the area would be retained.

Response: Timber harvest activities on the Forest are designed to meet specific resource objectives. As a result, the harvest method used will vary depending upon the resource objective for the area. Helicopter logging is generally used in visually sensitive areas and areas where soil and water are sensitive resources. The Preferred Alternative increases the acres assigned to a Visual Quality Objective of Retention, Partial Retention, or preservation and Acres Assigned to Scenic Corridor, so the helicopter logging system will be used more than in the past.

DO NOT MAINTAIN ARTIFICIALLY HIGH TIMBER SELL LEVELS TO MAINTAIN EMPLOYMENT

Between 1979 and 1986, jobs in the wood products industry in Oregon and Washington plummeted from more than 13,400 to fewer than 101,600 while lumber production increased from 11.15 billion board feet to 12.28 billion board feet - 25% fewer workers produced 10% more lumber. It is clear that sawmill jobs are disappearing in the Northwest, and it is just as clear that the disappearance has no relation to the timber supply. The main immediate cause of the job fall-off was a vast increase in mill efficiency, a result of the 1979-82 recession. The problem won't be solved by cutting all the old growth.

Response: Your observation on industry becoming more efficient is correct. You are also correct in stating that more lumber is being produced in Oregon and Washington These trends of more efficient mills and higher demands for lumber (wood) will most likely continue (refer to Chapter III, FEIS). Timber grown on NF lands is part of the supply base needed to meet anticipated demand for wood products in the United States.

It is the policy of the Forest Service to provide timber on a sustained yield level on an even flow basis with few exceptions (36 CFR 219.16). The Forest Plan does provide for a sustained yield of timber over time, while meeting resource objectives (Chapter II, FEIS and Forest Plan)

In the Preferred Alternative, more acres have been allocated to prescriptions with an extended rotation, in a number of site-specific areas, lands have been allocated to non-development, including no scheduled timber harvest. See Chapter II, the output tables, and refer to the Preferred Alternative map.

PROVIDE A RELIABLE FLOW OF TIMBER TO HELP STATEWIDE INDUSTRY

Policy Number: the National Forest should provide a reliable flow of raw material to help support the viability of the Statewide forest products industry

Response: We agree that the national forests should provide a reliable flow of raw materials. One of the things Forest planning is designed to do is to determine what level of raw material can be counted upon from NF lands. The level of Allowable Sale Quantity (ASQ) set by the Preferred Alternative is lower than historic levels, but it will provide a reliable flow of raw material while achieving a balance with the many nonmarket values desired by the public. Refer to Chapter I, FEIS and "Forest Management Goals" in Chapter 4, Plan.

TIMBER HARVEST REDUCTION WILL RESULT IN MORE HARVESTING FROM OTHER LANDS

The Forest Service's proposed reductions will increase pressure in the State, Simpson, and other landowners with available inventory to accelerate their harvests to satisfy demand for forest products. For every acre of National Forest not harvested, two acres of State or private land must be logged to produce an equivalent volume. It is not clear whether FS harvest reduction lessens or heightens environmental effects associated with timber production.

In considering an annual timber harvest, the Forest Service must consider the supply impacts of the timber harvest reductions presently proposed for almost all national forests

Response The level of harvest on National Forest lands is determined by its capability and the objectives of the Preferred Alternative (FEIS Chapter II and Forest Plan Chapters 3-4). Changes made between draft and final have resulted in a lowering of both ASQ and TSPQ This results in an even larger gap between supply and anticipated demand for timber from National Forest lands

It is anticipated this shortfall will probably be made up from non-industrial forest landowners or imports from outside the region or outside the country It is estimated that private forest landowners will not be able to make up the shortfall

GREATER COOPERATION AMONG ALL TIMBER LANDOWNERS WOULD BENEFIT LOCAL COMMUNITIES

The State does believe that timber-dependent, local communities would benefit from a greater cooperative relationship among all timber landowners in the area, regardless of the harvest level. With the majority of timber harvest occurring on non-federal lands in the MBS area-of-influence, a coordinated strategy to address current and future economic, possibly environmental and resource, problems would be very beneficial We would be willing to work with the MBS and others in exploring this idea.

Response: We agree Our commitment is stated as a Forest-wide Standard and Guideline under General Procedures, Chapter 4 of the Forest Plan: Item 4 states that it is our intent to coordinate management of forest system lands, resources, and activities with appropriate local, State, and Federal agencies, private landowners, Indian Tribes, and interest and user groups.

TIMBER SELL LEVEL IS NOT JUSTIFIED

I strongly urge that the Forest Service's mandate, to insure the sustained yield of National Forests, be used to set an absolute ceiling for future quotas

The MBS's attempt to develop a balanced forest plan that both provides timber needed to maintain viable local economies and protects important non-timber resources, has fallen short We do not believe the Forest has justified the need for a 13% reduction in timber sale level in the first decade We are concerned that the timber sale program described in the plan may not be sufficient to avoid significant adverse impacts on the timber industry and general economy of the Puget Sound area.

Response: The level of harvest, ASQ or TSPQ, is based on the capability of the land and the objectives of a given alterative. As per direction found in 36 CFR 219 27, each alterative will have some level of sustained yield calculated. Forest Service policy also states that Sustained Yield Capacity will be on a non-declining bases with exceptions allowed only when conditions as stated in 36 CFR 219.27-3 are met, i.e. the development of a departure (see Chapter II, FEIS) Long term Sustained Yield Capacity, for any alternative is the upper limit of sustainable production, with the exception of a departure Departures will have production levels fluctuating both above and below the long term sustained Yield Capacity over time, (Ref. FEIS Chapter II).

It is estimated the lower ASQ will have less than 0.1% effect on the income and the employment rates within the five county Puget Sound Basin (FEIS Chapter IV).

A full range of alternatives have been developed during the planning process, Chapter II, FEIS. The alternative chosen as the preferred, Forest Plan, is the alternative that responds to the issues and concerns, and - in the opinion of the Responsible Official - maximizes net public benefits

HARVEST LEVEL IS TOO HIGH; PLAN CANNOT MAINTAIN LEVEL OF PROTECTION STATED

I feel that this EIS does not document the ability to produce the cut level and maintain the level of protection to environment and its elements called out.

So that old-growth habitat and recreational opportunities are not sacrificed, I believe an ASQ of no more than 88 million board feet per year is adequate. The difference in jobs and income is less than four tenths of one percent in the first decade, and the return would be incalculable in saving the ecosystem.

> **Response:** We feel that the level of goods, services, and outputs estimated for the Preferred Alternative are attainable, while still meeting law, regulations, moving towards the desired future condition of the Forest, meeting the Forest-wide and MA standards and guidelines and all management requirements, including all management requirements (See New Appendix H for discussion of the method finalized to meet water quality and riparian MR's). In addition, the mitigation measures common to all alternatives will help avoid, minimize, rectify, reduce, mitigate, or compensate for environmental effects. Importantly - as the plan is implemented and projects are evaluated/activities monitored - if standards and guidelines are not being met, plan amendments will be considered.

LANDS ALLOCATED TO TIMBER EMPHASIS SHOULD BE MANAGED INTENSIVELY

It would appear in reading in reading the "intensities" for management prescription 17 that cost efficiency is the basis for determining which management intensity will be applied. Even though a minimum or low investment level may be more efficient from a strict dollar sense, it could have a drastic effect on the amount and the quality of wood produced from NF lands. I don't believe this is a sound professional approach to timber management, particularly when you consider that profitability is not the only driving force for timber management on NF lands. As low elevation private lands are developed, timber to meet the nation's needs will have to come from a shrinking land base. The National Forests have to be prepared to meet part of this demand. NF lands that are allocated to a timber emphasis should be managed intensively for that purpose.

Why isn't the USFS pushing for intensive timber management in areas already logged?

Intensive forest management practices seem to be largely omitted from the alternatives. Fertilization and stocking control are proven techniques for increasing timber yields. The FS should introduce more intensive forest management as the land base for timber production declines

> **Response**· A full range of timber management prescription were developed for every forested acre, by an interdisciplinary team during the planning process (see Appendix B and Chapter II, FEIS). These prescription were tailored to meet physical and economic consideration of each stand as to its species composition, physical attributes, and location in the forest The final list of prescription were then input into the Forest Planning model (FORPLAN) to calculate a level of outputs for each alternative (and it's varying goals and objectives.) The FORPLAN program selects the most cost-efficient investment level, which may be the Low Investment Level In addition, FORPLAN "runs" were made, varying the objective function, and using both a maximum present net value and/or a maximum timber objective function for development of the Forest Plan; refer to Appendix B. This analysis indicated that timber outputs increased when an objective function of max. timber was used, but the increases were not great. This indicates that, for the most part, the most cost-efficient prescriptions also are the most intensive.

HIGH QUALITY TIMBER IS MORE VALUABLE

High quality timber is more valuable. According to the March 25, 1988 price guides from Random Lengths, the higher quality grades of lumber and veneer are almost always more valuable than the lower grades.

Response: Agree. The Forest Plan did not specifically examine longer rotations to obtain higher quality timber. It was assumed the higher value obtained through a longer rotation would be negated by the higher discounting effect for the increased amount of time it would take to obtain the higher value.

LARGER DIAMETER TIMBER IS MORE VALUABLE

Larger diameter timber is more valuable. The price guides from Random Lengths indicate that higher prices are paid for lumber of the same grade but with larger dimensions. Larger trees are needed to produce this lumber. You can't get 2"x10" boards out of 8" diameter trees.

Response: Agree. Analysis of harvest information in the preferred Alternative, FEIS Chapter II and VI, indicates that the forest will be harvesting trees with an average DBH of 23 inches plus through the 7th decade. Average DBH's being harvested after the 7th decade will range from 13 to 19 inches in DBH. Even with this average, there will be some trees harvested that will exceed 23 inches plus.

In Management Areas 1D, 2A, 2B, 4, 5, 6, 13, 14 and 27 there will be a substantial amount of acreage where trees will be grown on extended rotations. In these areas, the diameters of the trees will be exceed an average of 23 inches.

MANAGING FOR HIGH QUALITY WOOD PROVIDES MORE JOBS

Managing for high quality wood provides more jobs. Ann Hanus, Oregon State Economist, has stated that managing for high quality timber provides more jobs than low quality timber. High quality wood is the foundation of employment for secondary manufacturing in the Northwest. A switch to managing for low quality wood fiber will eliminate the millwork industries, quality door and window manufacturers, and many other industries that rely on high quality wood.

The number of mills in the Northwest is decreasing rapidly The decrease would be faster if we did not need two kinds of mills We now have mills for large diameter timber and high-tech mills for small diameter timber. The small diameter mills require fewer employees to process the same volume of wood. If we continue to manage our forests on short rotations, we will not need the large diameter mills. Managing for large diameter trees will keep both types of mills. Commercial thinnings will supply wood to the small diameter mills if we manage for large diameter trees.

Response: Technology and industries that use large diameter material to produce products are continually changing to remain competitive in the market place. It has been the trend in all industries, as well as in the lumber industries: as older mills become less efficient and competitive they are either closed or modernized to produce saleable products. This usually means more machines and less people to produce a product. Research

has continued to develop methods to use existing and available raw material to meet public needs/demands. They have developed procedures of processing young, small-diameter trees to meet building industry needs as well as management systems that will provide raw material small logs, that will meet the needs of millwork industries. (Reference: Ponderosa Pine Symposium, The Species and its Management.) There will continue to be a supply of older, larger-diameter material from the MBS, under the Preferred Alternative, through the seventh decade; in addition, some large-sized timber will always be available from MA's with extended rotations (riparian and scenic).

MANAGING FOR A WIDE VARIETY OF SPECIES PROVIDES MORE JOBS

Managing for a wide variety of species provides more jobs. Every tree species has unique wood properties. The forest products industry has already taken advantage of some of the unique properties of the species. Douglas-fir makes good dimensional lumber. The pines provide wood for millwork, doors, and windows, etc As industry becomes more sophisticated, it takes better advantage of the unique properties of each species. While one industry may want the entire forest planted with the species it prefers, the best policy for the region is to manage for a variety of species This adds diversity to the economy, stability, and the highest level of employment.

Managing for quality and diversity provides economic stability The depressed housing market in 1982 had the most impact on those communities most dependent on producing dimensional lumber for home construction. The wood furniture industry expanded during that time The mills supplying quality wood to overseas markets never shut down. The ponderosa pine mills east of the Cascades were much less affected So were the cedar, hardwood, paper and firewood producers less affected

Response Agree In the Forest Plan, the MBS will provide a variety of tree species for commercial sale. They include Douglas-fir, pacific silver fir, western hemlock, western white pine, western redcedar, red alder, mountain hemlock, grand fir, white fir, englemann spruce, and subalpine fir. Actual species selection will be based on a site-specific analysis, with interdisciplinary planning. (Forest Plan Chapter 4) In addition, the Preferred Alternative produces a variety of market and non-market goods, services, and opportunities, to contribute to the diversity of the economic base of the area, (FEIS Chapters II and VI, Forest Plan Chapter 4).

MANAGING FOR QUALITY TIMBER WILL PROVIDE HIGHER WATER QUALITY

Managing for quality timber will provide higher water quality Managing for higher quality timber will extend rotation ages, so less clearcutting will be required Managing for high quality timber will allow for construction of higher standard roads and better road maintenance, because the timber provides greater revenues This will decrease sedimentation and debris slides from roads. Long rotations and larger target diameters for harvest will allow large woody debris to enter these streams, benefitting wildlife and fish

Response· One of the major goals/objectives of the Forest Plan is to maintain or enhance water quality. All management activities are designed to accomplish this. Standards and guidelines have also been adjusted to

more adequately address and clarify the role of large woody debris in streams; see Forest-wide Standards and Guidelines, Chapter 4, Plan plus standards and guidelines for MA 13, Forest Plan. Refer to responses in the Water and Fish sections of this appendix for more discussion on this issue.

THE FOREST SHOULD EXAMINE IT'S ROLE AS A "TREE FARM"

The plan should examine the role of the federal government as a "tree farmer" - an activity more properly in the hands of private industry. The plan should also include recommendations for any needed State laws to assure proper and coordinated resource management among private and public landowners. The MBS has arrived at a point where a major change in goals and management policy is due.

The plan should contemplate the phasing out of general timber harvest and tree farming operations on public land at elevations above about 2000 feet. Mill owners and other buyers need to be told that supply from this source is not going to be available and that they should plan accordingly. The remaining lower-elevation FS lands should then be subject to planned resource management coordinated with adjacent public and private landowners. Industry should be encouraged to grow their own raw materials, with consideration given to land exchanges and sales

Response: Changes in the FEIS and Plan, in response to these comments include recommendation of a Preferred Alternative with an increased trail mileage, increased number of rivers recommended for addition to the National Wild and Scenic Rivers System, emphasis on unroaded recreation and greater protection of scenic values. Timber production is emphasized on suitable acres assigned to a timber harvest prescription. First decade allowable sale quantity will be 110 MMBF annually; most harvesting will occur under 3,000 feet in elevation. Coordination with other agencies is addressed in various Forest-wide Standards and Guidelines; see Chapter 4, Forest Plan

THE TEN-YEAR TIMBER SALE ACTION PLAN IS INADEQUATE UNDER NEPA

In Appendix A to the Plan, the Forest Service presents a ten year action plan, sales it anticipates will go forward in the next decade This appendix is not sufficient under NEPA to provide the needed information for an environmental review here. Such generalizations are legally inadequate and fully unjustified when the agency actually knows where, when and how it intends to cut. See e.g. California vs. Block, 690 F. 2d 753 (9th Cir. 1982). It is unclear from the information provided by the Forest Service whether the little analysis the Forest Service does perform has a significant relationship to the actual sale plans it prescribes The Tribe is unclear whether the preferred alternative "H" generated by the FORPLAN model has anything to do with the ten year action plan. The Tribe therefore requests clarification on the correlation between FORPLAN models and the 10 year action plan.

Response: It is not the intention of this Appendix to perform the environmental review at this time. This appendix is intended to identify projects that probably will be worked on in the future. Chapter 1 of the Plan explains that the Forest Plan provides the framework within which project planning will take place Before any projects are developed, they

will have to comply with all National Environmental Policy Act (NEPA) requirements.

STATE THAT ASQ WILL LAST AT LEAST 10 YEARS; OUTPUTS DRIVE THE PLAN

In the Plan, Resource Summary for timber· this section should include a statement that the Plan's ASQ will be at least 10 years in duration, and that the outputs are what drives Plan, not the standards and guidelines. The Forest Service does not guarantee anywhere in the Plan that the ASQ will remain the same for the plan period

Response: As stated in Chapter 5, Implementation of the Forest Plan, projects (including proposed timber sales) are scheduled in response to the management direction in the Plan, planned outputs of goods and services, near-term management needs and opportunities, and the budgeting process. "If there is a conflict between standards and guidelines and program outputs, projects will be in full compliance with standards and guidelines set forth in this Forest Plan." This comes from Chief's 1920 memo, dated February 23, 1990.

CLARIFY REFERENCE TO NEPA REGULATIONS

In Chapter 3 of the Plan, response to the Effects of Timber Management ICO: we suggest referencing the NEPA regulations, to clarify the nature of environmental analysis that will be done. Also, explain "other resources."

Response: *These suggested changes have been made, see* Chapter 3, *Forest* Plan.

SCOPING IS NECESSARY FOR POSITION STATEMENTS

In MA 17 standards and guidelines: you must include under (E) (21), a reference to NEPA. It is part of the scoping process and contributes to the decision-making for determining the addition of a sale project to the Forest's Sale Program

Response: A reference to environmental analysis under NEPA has been added to section sections of element E. in MA 17, see Forest Plan, Chapter 4.

MONITORING SHOULD CORRESPOND DIRECTLY WITH MANAGEMENT INTENSITY

Under Management Practices for Timber Management, it is stated that "Management intensities will vary with site productivity, timber species, other resource management objectives, and timing of implementation." In the same way, the Forest Service should ensure that monitoring intensities correspond directly with management intensities and site sensitivities.

Response: *Agree; the Monitoring Plan has been updated in the Forest Plan* (Chapter 5) to better track management activities and their effects.

NEED REGIONAL PLANS TO COVER LOG EXPORTS, DEVELOPMENT OF FOREST LAND

We need a Pacific Northwest Plan to achieve regional planning to stop the export of logs (let our local saw mills process it), and to create state-wide zoning laws to insure that prime timber-producing lands, whether federal, state, or privately owned, will remain forested and used for tree-growing, not for shopping centers.

Response: Much of what you want is outside the scope of the Forest Plan. We are required, by law, to address impacts on prime forestlands. This is discussed in Chapter IV, FEIS, Environmental Conditions Unchanged by Alternatives, near the end of the chapter.

NOT ENOUGH EMPHASIS IS PLACED ON THE IMPORTANCE OF WOOD RESIDUE IN THE ECOSYSTEM

The Draft Plan did not place enough emphasis on the value of wood residue to the environment. It does not address the effects of removing the organic matter on site productivity, wildlife, soils, etc.

Response: Between DEIS and FEIS, in response to this and other comments, additional Forest-wide Standards and Guidelines were developed to address "Diversity and Long-Term Productivity " See Chapter 4, Forest Plan. This subject also receives more extensive treatment in Chapter III, in the Wood Residue section. Refer to Chapter IV for the effects of implementing the alternatives on this resource.

IMPLEMENTATION OF TIMBER ELEMENTS FOR THE MANAGEMENT AREAS

How are the Timber elements for each of the Management Areas monitored and who implements them?

What criteria will be used to determine the prevention of degradation?

Response Chapter 5, Forest Plan, Monitoring Plan identifies how the different elements will be monitored, who will monitor, how often etc. The responsibility for most of the monitoring in the timber resource lies with the District Ranger.

The actual implementation of the Timber Elements is done at the Ranger District level with review by the Forest Supervisor's Office personnel. Completing environmental analysis, with appropriate NEPA documentation (such as an EIS or environmental assessment, with decision documents) is a very important part of the implementation process.

THERE SHOULD BE AN EVALUATION OF ENVIRONMENTAL RESULTS OF PAST ACTIVITIES

Under mitigation measures: there should be an evaluation of the environmental results of past activities for use in future decision making.

Response: The results of past activities were used, between DEIS and FEIS, to develop a process to meet water quality and riparian management requirements (watersheds were rated on current condition - see Appendix H). Past experience was also a factor in determining land suitability;

refer to Chapter III, FEIS and Appendix B In addition, the information gathered the Monitoring Plan (Chapter 5, Forest Plan) will be used as a source of information in making future decisions.

HOW WILL STANDARDS AND GUIDELINES FOR SOIL, AIR, WATER AND RIPARIAN AREAS BE MET?

To meet the Forest-wide standards and guidelines for soil, air, water, and riparian areas, what are the Forest Service's responsibilities over and against those of the state and private contractors? What kinds of arrangements are made with the contracted harvester, mineral lessees, special use permit holders, etc.? What does the contract include?

Response: The Regional Office has a Memorandum of Understanding with the Washington State Department of Ecology (DOE) regarding administration of Clean Air and Water Quality Act. This agreement essentially says the Forest Service, through its best management practices, will meet or exceed the standards set by the DOE. The Forest's Standards and Guidelines are designed to meet or exceed the State's standards. See Appendix I

On a project by project basis for timber sales, mining operations, special use permits, etc., the appropriate document (Timber Sale Contract, Mining Plan of Operation, Special Use Permit) has provisions to insure the Forest's Standards and Guidelines are met. The needs for the individual project are determined through the development of an environmental document (Environmental Analysis, EIS, etc.)

IMPLEMENT A PRUNING PROGRAM

Pruning limbs from young trees allows them to produce clear wood at a much earlier age. If the FS implemented such a program, over 3,000 new jobs could be created in Oregon and Washington. Pruning young stands will make future thinnings more profitable; very little clear lumber will come from intensively managed stands without pruning

Response: We agree; however, analysis on the MBS to date indicates that pruning of young trees is not an economical practice at this time When conditions change, this cultural treatment will again be reviewed for application on this Forest. Refer to the discussion on timber stand improvement, Chapter III, Commercial Timber, FEIS

A SEPARATE EIS IS REQUIRED FOR THE MOUNTAIN HEMLOCK STUDY

A full EIS must be completed before this project may even be considered. The Study Plan is just that; it does not attempt even a cursory analysis of environmental effects and nowhere are they compared by alternative.

Neither the Mountain Hemlock Study Plan nor the Forest Plan consider the environmental effects of logging, as required by NEPA. The 2,500 acres planned for harvest for research purposes are only mentioned in passing.

Considering the limited quantity of mountain hemlock on the Forest and the extreme conditions under which it occurs, the plan to study logging in this zone represents a major federal action; a full EIS is warranted.

> **Response:** The Mountain Hemlock study plan is part of the Forest Plan and will follow standard and guidelines set forth in the Forest Plan and Management Area 19, Plan Chapter 4. Clarifying language has been inserted regarding the total acres proposed for harvest under the study plan and approximate unit size. 25 sale units of approximately 6 to 12 acres each Refer to Chapter 4, Plan, Resource Summaries and MA 19.

A WORST CASE ANALYSIS SHOULD BE HAVE DONE FOR THE MOUNTAIN HEMLOCK ZONE

The Regional Forester's decision on productivity and suitability [for mountain hemlock acres] is chiefly based on a final analysis report for the Mountain Hemlock Zone study dated February 14, 1983. This report made a number of admissions which show that the degree of "research and experience" at that time could not be used to justify an unsuitability decision.

Such admissions include: 1) all plots contain western hemlock and Pacific silver fir as co-dominants, 2) concerns about regeneration of the Mountain Hemlock Zone did not result in a consensus; 3) the data used to test regeneration came from silvicultural regimes involving Douglas-fir; 4) regeneration success varies significantly by habitat types and environmental factors; 5) general success was found using the shelterwood system; and 6) there is an absolute lack of published literature on managing the Mountain Hemlock Zone on the MBS.

Where incomplete or unavailable information exists which is "relevant to reasonably foreseeable significant adverse impacts," such information shall be obtained and included in the DEIS, unless the costs are exorbitant or the means to obtain it are unknown Your DEIS is legally inadequate, as you failed to perform a worst case analysis, as required by 40 CFR 1502.22.

> **Response:** The mountain hemlock areas were identified as part of meeting 36 CFR 219.14, NFMA implementing regulations, to determine land suitability for timber production. These are lands for which there was not reasonable assurance that, given current technology, the land could be restocked within five years of cutting (Chapter III, EIS) The mountain hemlock study is designed specifically to determine whether - under conditions of a complete scientific study - these lands can be reforested, using a variety of techniques, and possibly returned to the tentatively suitable land base in the future See "Study Plan for the Determination of Suitability for Mountain Hemlock Zone on the Mt. Baker-Snoqualmie National Forest.

We recognize that the information needed is not available, and thus have designed this study to develop it. A worst case analysis is not applicable. The actual acres within MA 19 that could be classified as suitable - do not have unstable soils etc. - are fewer that the total 31,965 acres in MA 19 in the Preferred Alternative, and would have a relatively small contribution to first decade allowable sale quantity. Additionally, the 31,965 acres comprise only 5 percent of the total tentatively suitable acres on the entire Forest Refer to Chapter 4, MA standards and guidelines for MA 19, Forest Plan We feel we are in compliance with 40 CFR 1502.22.

76,000 ACRES OF MOUNTAIN HEMLOCK ZONE HAVE BEEN ERRONEOUSLY CLASSIFIED UNSUITABLE

About 76,000 acres of silver fir land in the so-called Mountain Hemlock Zone were misclassified as unsuitable. The average net green volume per acre on these lands is 6% higher than for the overall large sawtimber class. The real productivity of these lands is more than twice that estimated by the Forest Service, they are capable of producing over 100 cubic feet per year.

A total of 76,000 acres have been incorrectly withdrawn. By changing your management and not burning slash, these acres can easily be added back into the timber-growing land base If private industry can grow and harvest trees on adjacent lands, you can and should do the same

The majority of ground plots taken in the Mountain Hemlock Zone have Pacific silver fir as a cover type, not mountain hemlock. If in fact we do have a problem, it most likely is over-stocking in the Pacific silver fir. The area classified as mountain hemlock should be returned to the suitable forest land base and harvesting techniques modified to suit the terrain and to accomplish the regeneration necessary.

Response: The current unsuitable classification for this land will be continued; there is not reasonable assurance that these lands can be reforested. However, the regeneration study of the zone, as described in the draft Forest Plan, will test the opportunity to change the suitability determination of a portion of this zone The plan calls for the selection of 250 acres of land for harvest in the zone, consisting of 25 parcels ranging in size from 6 to 12 acres each The standards and guidelines for MA 19 have been clarified, see Chapter 4, Forest Plan.

STUDY PLAN NEEDS FULL PUBLIC REVIEW

The study plan to be developed for the mountain hemlock plant association silvicultural practices must be subject to full public review, since many of the MA 19 parcels are located in environmentally sensitive places

Response: Harvest activities will be done in accordance with objectives stated in Chapter II of the FEIS for Management Area 19 and the standards and guidelines found in Chapter 4 of the Forest Plan. An environmental analysis will also be prepared for the study units; any volume will not contribute to allowable sale quantity, but will be part of the timber sale program quantity.

IS 2,500 ACRES EXCESSIVE FOR THE MOUNTAIN HEMLOCK STUDY?

Is 2,500 acres an excessive amount for the study?

I'm opposed to the Mountain Hemlock study, as I don't think "the field" knows any more about the management of these species than we did and 2,500 acres is a lot of failed acreage to attempt to re-establish.

Response: The wording has been clarified in Chapter II of the FEIS and Chapter 4 of the Forest Plan. The actual number of acres to be harvested are 250, in 25 sale units of 6 to 12 acres each.

WHERE ARE THE 25 MOUNTAIN HEMLOCK STUDY UNITS LOCATED?

Why did you not show the specific places on the Alternative H map where the experimental logging is to take place?

Where are the "25 units" mentioned in the Plan (page 4-202)? The location of these must be subject to public review. The 10 Year Timber Sale Action Plan lists only three sales (60 acres) on the Skykomish District.

Response: Mountain Hemlock study units will vary between 6 to 12 acres in size, too small to show on the maps published with the draft and final EIS. In addition, the exact location for five of the study units have not been determined. Along with those already proposed, these units will be identified in the ten year sale program or amendment to that sale program, Forest Plan Appendix A.

CLARIFY ROAD CONSTRUCTION STANDARDS IN MOUNTAIN HEMLOCK ZONE

We are encouraged that your management area [for mountain hemlock study] does not allow for the construction of new roads in these areas.

Under Item L. MA 19 says "no system roads would be constructed..." It is our understanding that this applies to the Study Plan, but it is also our understanding that system road construction is allowed to pass through areas of MA 19 to access other suitable lands for harvest. This point needs to be clarified.

Response: The wording for Item L. Facilities, MA 19 has been clarified. No system roads would be built; temporary roads may be built to meet study plan objectives or to access adjacent management areas.

WHERE ARE MOUNTAIN HEMLOCK ACRES IN THE LAND SUITABILITY TABLE?

Where in the land suitability table (page III-24 DEIS) are the commercial forest land acres in the Mountain Hemlock Zone accounted for? Are they included in III, D. Regeneration Difficulty?

Response: The mountain hemlock acres are included in the 159,700 acres of forested land with regeneration difficulty (part III, D. of the land suitability table). Refer to Chapter III of the FEIS.

IF MA 19 CONTAINS NON-MOUNTAIN HEMLOCK, CAN THE ACRES BE RE-ALLOCATED?

Is it not true that if portions of areas currently allocated to MA 19 are found to not be mountain hemlock, they will be re-classed and available for timber harvest at the project planning level? If so, a statement should be included in the introduction for MA 19.

Response: As stated in part D. Amendment and Revision of Chapter 5, Forest Plan, the boundaries of management areas other than those legally established (such as wilderness) are not firm. They represent a transition from one set of opportunities and constraints to another. Field verification, during project design, may indicate that a mapped MA boundary should be changed to reflect the environmental conditions the MA was intended to include. This section of Chapter 5 explains the process used to amend the Plan, if necessary. If the Forest Supervisor determines the change is significant, the same procedure used to develop and approve the Forest Plan will be followed. If the change resulting from the amendment is determined not to be significant for the purposes of the planning process, the amendment may be implemented after appropriate public notification and meeting NEPA requirements. This process applies to MA 19.

CONSIDER ECONOMIC RETURNS FOR HARVESTING MOUNTAIN HEMLOCK; MARKET FOR THIS MATERIAL IS UNCERTAIN

Consider the full costs of the mountain hemlock study. This economic analysis should emphasize that CMAI for trees in the mountain hemlock zone is 240 years (DEIS, page III-29). This necessitates a very long rotation time and, therefore, a very low present net value for any investment in forest management in this zone.

We object to the current mountain hemlock study, since it appears that mountain hemlock do not regenerate quickly, that the cost for harvest would be very high, that the market for mountain hemlock is uncertain, and that the entire ecosystem could be lost.

I question the need to establish a market for mountain hemlock where no market presently exists. I question the ability of the material to pay its way and return a reasonable amount to the government.

Response: Past management activities indicate that there is a market for this material. Additionally, if after this study it is determined that the mountain hemlock lands can be regenerated within five years, and, thus returned to the tentatively suitable land base, timber management prescriptions would be applied only after an economic analysis. (Refer to Timber Sale Program Information Reporting System (TSPIRS), 1989.) The over all cost of the study will most likely exceed the value of the trees removed from the 250 acres of study plots, but the study will help gain solid research information on future suitability in this zone.

INCLUDE NORTH BEND, WHITE RIVER R.D. IN MOUNTAIN HEMLOCK STUDY; ADJUST CRITERIA

Two changes: the North Bend and White River Ranger Districts should be included in the mountain hemlock acres with regeneration difficulties. In addition, if an area - because of lack of adequate soils and short growing season - cannot produce an adequate-sized stand in 150 years, it should be

unsuitable for timber production (ie. less than 80 cubic feet, per acre, per year).

Response: Enough empirical information is known about Mt. Hemlock stands that occur on the North Bend and White River Ranger Districts to make a determination of suitability using the standard suitability analysis (FEIS Chapter III and Forest Plan Records).

TIMBER SUPPLY ANALYSIS IS INADEQUATE

Timber supply information presented in the DEIS and draft Plan, while better than most reviewed, is inadequate as a basis for final decisions in the forest planning process. An adequate analysis must be completed before publication of the FEIS and the results fully discussed in the planning documents.

Response: We have reviewed and updated the timber supply information, where applicable and where newer information is available. It is impossible to put precise numbers on timber supply for two reasons.

First, private ownerships (and to a lesser degree, public ownerships) respond to market conditions. Reduced prices resulting from any of a number of causes - e.g., a slowdown in the economy, increased supply on the market from other sources, or increased substitution of other materials - will elicit a lower supply response from private ownerships Conversely, increased demand will bring about a higher supply response, within the biological and technological capability of the owners to produce timber. While the biological capability is relatively fixed in the short run, technological changes continue to add to the economic supply by making wood previously uneconomic to bring to market economic to do so now.

Second, industrial forest owners tend to keep confidential both inventory data and production plans to the extent possible. Nonindustrial owners, on the other hand, are a very difficult group from which to extract data of this type because of the diversity and fragmentation of the ownerships. Therefore, it is difficult to get a good handle on available inventory, current plans for production, and future plans for production given various market scenarios from the private sector. This creates a significant problem for supply projections in the Puget Sound area, as the private sector in total accounts for roughly 65%-75% of the regional market.

Changes that have taken place since the original timber supply analysis was prepared for the DEIS indicate these problems In the DEIS, it was stated that, based on best information available at the time, production from industrial forest lands would remain near current levels up through the fourth decade, then decline as an age gap in inventory was experienced Current data now indicate that the gap in industrial inventory will be encountered in the early 1990's and last through about 2010. Thereafter, industrial inventories and production will once again begin to rise (D Adams and R.Haynes, "Future of the Douglas-fir Region Forest Economy," CINTRAFOR Working Paper #26, Univ. of Washington, Dec 1989). On the other hand, production from private nonindustrial forest lands has increased in both relative and absolute terms over the past five years. Speculation is that if prices continue to remain high, production from that sector will continue to stay up. But there is no way to attest to that with any certainty, as the sector is too fragmented to be able to elicit an indication of future production plans given various market scenarios. However, we do know that the inventory exists to maintain as high, or higher, production levels from the nonindustrial private ownerships

In the FEIS, we have laid out the timber supply situation in narrative form with the latest information available; see Chapter III, FEIS. In summary - **given no major changes in levels of economic activity in the economy, either up or down** - timber supply in the region will continue to tighten over the next two decades as all ownerships, except perhaps for nonindustrial private, face declining production capabilities. In the

private industrial sector, that decline is from lack of inventory of merchantable age. In the public sector, both State and Federal, the decline is from less old growth available for harvest as a result of increased requirements for protection of other resource values. In those public sectors as well, it will be at least two decades before current young stands are of merchantable size. The result will be increasing prices until about 2010, when new inventory from all sectors, including the international, will become available, sharply tempering prices. In the interim, the market and consumers may have several choices for coping. Substitution of other materials, technological changes in wood utilization and building techniques, changes in building codes, increased imports from other regions of the U.S. and from Canada, and restrictions on log exports are all possible market and political responses to tightened timber supply.

The timber supply analysis in the FEIS lays out the timber supply situation as best we know it today. Because of the difficulties in attaching numbers to the supply scenarios that have any meaning, in the FEIS we have chosen to utilize a narrative describing the situation and the direction of expected changes in supply by the various ownerships, and have not used specific numbers. The historic-to-date harvests by ownership in the region provide the reference point for that narrative

It is important to examine the current and expected future timber supply situation. It is also important to know that, in the Mt. Baker-Snoqualmie National Forest's area of influence, National Forest timber makes up somewhere between 10%-20% of the market, depending on circumstances in any given year. The Forest is a major supplier, but nowhere near a majority supplier. The Forest has an obligation to meet other resource protection and maintenance requirements and to meet demands for other resource uses. Some of these actions are being adopted at a difficult time from a timber supply standpoint. But the Forest's position in the timber market makes those actions less costly than they would be if the Forest were the majority supplier in the area

EFFECTS OF REDUCTION IN TIMBER SUPPLY ON PULP & PAPER INDUSTRY NOT CONSIDERED

Changes in timber sale levels on the MBS and other National Forests in Washington have a major impact on Washington's pulp and paper industry. We were unable to locate any consideration of this fact in the Plan and DEIS.

The MBS has not fully considered the impact of any reduction in timber supply to the pulp and paper industry, either accumulative throughout the region or to the pulp and paper mills within the MBS zone of economic influence.

Response: Discussion of the pulp and paper industry has been added to the FEIS, Chapter III The situation of the pulp and paper industry in the Puget Sound region is discussed along with the rest of the timber supply and demand information.

Effects of changes in timber sale levels on the pulp and paper industry are not shown directly in terms of reductions in employment and income. This information is included as part of the total estimated change in jobs and income (Chapter II, Table II-9n) . Information on individual sector changes as projected through IMPLAN is in the planning records.

CUMULATIVE REGIONAL ASSESSMENT SHOULD BE MADE OF CHANGES IN NAT'L FOREST ASQ'S

The DEIS contains absolutely no indication that the Forest made any attempt to assess future timber program levels on adjoining National Forests. The final Plan must recognize that proposed reductions on adjoining National Forests will lead to increase competition for MBS timber

Response: The Regional Office in Portland has published an analysis of the cumulative economic effects of the aggregate changes in timber to be supplied from the National Forests, as reflected in Draft Plans, on the regional timber market (USDA Forest Service, "Timber Supply in the Pacific Northwest: Aggregate Implications of Forest Plans," Pacific Northwest Region, June, 1989). The effects for Western Washington indicate that harvest level changes on the MBS, Olympic, and Gifford Pinchot National Forests will not have a major effect on the overall timber supply picture. What does change much more significantly over the next 2-3 decades is harvest from private industrial lands. Any increase in competition for logs from any of the Forests caused by declining harvests will come primarily as a result of these declining harvests from private industrial lands. (Of course, as total available supply shrinks, the changes in National Forest timber harvest levels become relatively more important until supplies once again expand)

The Wenatchee National Forest's Plan calls for only a slight reduction in harvest levels over the next decade. Therefore, the amount of timber available for import into the Puget Sound area from the Wenatchee for processing will not change significantly. And, according to the Washington Mill Survey (Wash DNR, 1988), little if any timber flows from the Mt. Baker-Snoqualmie to the east side of the Cascades for processing.

APPEARS TO BE DOUBLE COUNTING IN LOCAL VS. REGIONAL TIMBER SUPPLY

There appears to be a case of double counting in the Forest Plan, with the Forest claiming a portion of the supply from other regions as part of its total supply picture for its own region. The State's concern is that this is a misleading supply figure and, in fact, the industry in this region may have less timber available than projected.

Response: Defining "supply" and "demand" for a subregion within a regional market is very tricky, particularly as data are relatively limited. Use of ownership origin of "logs consumed" in the Puget Sound area as a measure of supply from that ownership may indeed count the production of logs produced outside the area and imported into the area for processing. Not shown, on the other side of that coin, are logs produced within the Puget Sound region and exported to areas outside the region for processing.

Because supply and demand, as used here, are economic concepts and respond to economic forces, the quantity of logs produced and consumed within a subregion of a market area can change from year to year with changes in relative prices, changes in levels of imports from other regions, or simply because one or two mills close down or open up in any given year. Biological capabilities, of course, are limiting factors for maximum potential supply. But relative prices and available substitutes within and outside a region elicit the actual economic supply from the biological potential. For these reasons, it is definitely of interest to look at the market region (e.g., westside Cascades) as a whole, rather than try to make

precise predictions of economic supply levels on a subregional basis. The Regional Office in Portland produced such a study in 1989 that looks at effects of changes in National Forest timber harvest levels for Washington and Oregon as a whole, and by region within that area, given assumptions about current and expected economic supply from other ownerships. We support the additional work being done in this area by the State through the Department of Trade and Economic Development, and the University of Washington Northwest Policy Center.

In the FEIS, we have dropped specific numbers for supply predictions in favor of a narrative description of the expected magnitude and direction of changes in economic supply of timber by various ownerships over the next three to four decades. This approach, when taken in conjunction with the aggregate study done by the Regional Office, gives a better picture of the overall current and expected timber supply situation in the region.

ABILITY TO MEET INDUSTRY'S "CRITICAL MINIMUM LOG REQUIREMENT" NOT ANALYZED

Timber from the Forest has historically played a vital role in the region's economy and should not be compromised during the current planning process. It is important that the sufficiency of the MBS timber sale program be based on four factors; these four factors will determine whether the existing industry's critical minimum log requirement will be met or not, and must be adequately analyzed in the forest planning process and considered in the decision.

PLUS believes the timber sale program described in the draft Forest Plan will not be adequate to meet the timber industry's minimum raw material needs over the next decades.

Response: There is no statutory or regulatory requirement for the Forest to meet "industry's raw material needs" or "critical minimum log requirement," however they might be defined. The Forest is required to assess and consider the current and expected future conditions of supply and demand for timber, as well as for other resources, as part of the disclosure of the estimated environmental effects of actions stemming from the Forest planning process. Based on that assessment, estimates of effects of alternative land management proposals on the economic and social environments -- including the timber industry -- are made. That has been done in the planning documents, and is discussed in more detail as well in responses to questions about the adequacy of the timber supply analysis earlier in this section.

Timber harvest goals are set according to the physical and biological capability of the land, protection requirements for other resources, demands for other resources as well as timber, and in concert with goals and objectives for the overall management of the Forest. We acknowledge that the projected harvest levels for the Forest Plan are not as high as the industry would like. However, our supply assessment states that timber will still be available in adequate amounts from all ownerships within the region for the industry to keep operating During the next two decades, prices are expected to rise because of a supply squeeze coming as a result of inadequate merchantable inventory on private lands, high levels of demand, and reduced harvest levels on public lands. While the National Forests are major, though not by any means majority, contributors to the timber market in the westside Cascades region, our first priority is to protection and maintenance of the sustainability of all resources on the

Forest. The tradeoffs of doing so versus maintaining higher levels of timber harvest are detailed in the planning documents.

OTHER SOURCES OUTSIDE OF NAT'L FORESTS AVAILABLE FOR AUGMENTING TIMBER SUPPLY

There are ways to offset any reduction in timber sales on the Forest that might result from protection of old growth and other values. A much greater emphasis on State and private lands and processing more logs, rather than exporting them could be made. The FS has responsibilities in these areas through the State and Private Forestry programs and RPA. It is incumbent upon you to make clear to the public that these options are there.

Response: The DEIS discussed the historic and expected contributions to the timber supply by the major land ownerships in Chapter III, FEIS. In addition, it has been pointed out in the same section in the FEIS that private nonindustrial forest lands have increased their share of harvest in both relative and absolute terms over the past five years; that those lands have sufficient inventory to maintain current or higher levels of production over the next two decade; but, that it is difficult to predict or elicit supply response from that ownership because of its fragmentation and diversity

The FS, State, and Private Forestry branch is involved in a number of programs to provide knowledge, assistance and encouragement to non-federal timber land owners, particularly the small private nonindustrial owner. That role is all the FS can play in this arena. The agency also has responsibilities under the RPA of 1974 to assess the past, current and future timber supply situation in the United States over all ownerships, and to discuss the potential National Forest contribution to that supply picture. Again, the agency has no role beyond assessment regarding non-National Forest ownerships, other than perhaps those just discussed under State and Private Forestry programs.

DOCUMENT EXPECTED CHANGES IN CANADIAN TIMBER SUPPLY OVER NEXT SEVERAL YEARS

The Forest should document the expected change in Canadian timber supplies in the future (6-15 years hence) with hard data There is some disagreement as to the timing of a Canadian timber supply decline.

Response: There are no "hard data" than can be used to predict what the Canadian timber supply situation will be in the future. However, indications are that the Canadian exports to the United States are decreasing somewhat, will continue to do so, and will be higher priced than was experienced during the late 1970's and early 1980's. The reasons are fairly straightforward and have parallels in the U.S. experience. Canadians (particularly British Columbia) are beginning to see that there is not an unlimited supply of old growth that can be harvested at rapid rates. Concern is rising in Canada over environmental issues related to timber harvest. This means that more restrictions have been and will be applied to timber harvesting; the result will be a reduction in available timber from Canada, and a corresponding increase in price. (D.Adams and R.Haynes, op. cit., 1989).

TIMBER DEMAND ANALYSIS INADEQUATE (DEMAND IS UNDERSTATED)

The lack of a meaningful timber demand analysis further challenges the validity of the Plan, particularly when the Forest is proposing a reduction in sale levels. Presumably, if proper demand analysis were conducted, the Forest would realize that a reduction in total harvestable volume would have devastating effects on the local industry, its employees and communities.

A thorough demand analysis should be completed and specific curves be used in development of alternatives.

The years 1987 and 1988 have seen record removal of forest products from State and Federal lands. Home construction and commercial uses of lumber products are at a record all time high. Stumpage rates on public lands are reaching records set in 1979 and 1980 The latest available figures indicate that the forest products industry will have removed 253 MMBF of timber from the MBS in 1987.

Response: The demand analysis has been updated, along with the supply analysis, for the FEIS. Three critical factors stand out: demographics, relative prices, and the business cycle.

Demographics indicate that new residential construction will not return to the high levels of the late 1970's. This will provide a damper on the demand for wood products from that end use. On the other hand, "repair and replacement" of residential units is expected to increase over the next several decades, which will at least partially offset the decline in new construction. However, the amount of wood used in repair and replacement is significantly less than that used in new construction, so the offset is not likely to be total

As long as demand for wood products stays at current levels, prices over the next two decades will continue to rise until new inventory comes on line from all ownerships around 2010 (see supply discussion earlier). As prices continue to rise, it is very likely that more supply will be elicited from both nonindustrial private ownerships and from regions outside the Pacific Northwest, which will dampen the price increases Also, increases in relative prices tends to stimulate both technological advances in wood utilization, as well as increased use of substitutes (e.g., metal studs in framing).

The economy has a decades long history of growth and recession periods. The wood products industry is highly sensitive in general to these business cycles History tells us that it is imprudent to base projections for planning that covers several decades on the current slope of the business cycle.

In our revised demand analysis, we recognize the current level of demand for wood products and the effects that demand, in combination with the tightening timber supply over the next 20 years, will have on prices (assuming current business conditions continue and that log exports are not restricted to any major extent). While dropping specific predictions of numbers for wood products demand, we have provided a narrative description of the current and expected future status of demand for wood products from the region.

The decision-making process took into account the expected supply and demand situation over the next several decades and allowed for as much timber harvest as possible while meeting other resource protection requirements, demands for other resource uses, and the overall goals and objectives for managing the Forest. Again, as discussed above under timber supply questions, the Forest has a responsibility to consider the demand and supply situation, and to consider the effects of its planning and management decisions within that context on affected economic sectors and communities. That has been done.

TIMBER DEMAND ANALYSIS INADEQUATE (DEMAND IS OVERSTATED)

While the DEIS states that timber demand will "grow slowly" over the next ten *years, the Northwest Power Planning Council study noted above [Northwest* Conservation and Electric Power Plan, Volume II, 1986] disagrees with this self-serving conclusion Because of the forest products industry's influence on electrical power demands, it is not in the best interest of the Council to overestimate the need for wood products.

No adequate discussion is presented on the likely future for the national economy with respect to the long term demand for housing This lack of substantive discussion is difficult to understand since new housing demand accounts for 40% of the market for lumber and wood products (NWPPC, 1986, cited above).

The Power Planning Council has provided estimates for the future of the national economy that relate to wood products demands. The following factors should be noted: high real mortgage rates; reduction in single family residence share of total new residential construction, with correspondingly less wood used; decrease in average size of new housing units; and relatively constant rate of new housing starts through 2005. The above information clearly shows a high potential for a reduced domestic market for wood products.

Response: Any projection of economic demand for a good or service is necessarily bounded by a number of assumptions. Changes in one or more of those assumptions can change the magnitude and direction of the demand forecasts. The Northwest Power Planning Council recognizes this fact in its forecasting process. The Council forecasts a **range** of demand for electricity with five possible paths - high, medium-high, medium, medium-low, and low - based on different sets of assumptions about levels of *economic and population growth, demand for major products from the Pacific* Northwest such as aluminum, lumber and airplanes, and related national economic trends. The Council has a good track record for pulling together the best possible forecasts, using professional consulting organizations, in-house expertise, and feedback from other knowledgeable parties. The 1986 Power Plan, however, did not foresee the rapid and sustained economic recovery from the recession of the early 1980's. It did not foresee the high levels of log exports currently experienced. And it did not foresee the decline in available timber supply currently expected to last over the next two decades, partly as a result of declining merchantable inventories on private industrial forest lands, and partly as a result of increasing requirements for protection and enhancement of non-timber resources on public lands - e.g., significantly large spotted owl habitat areas are required now compared to even 1986.

While an economic slowdown could certainly reduce the demand for timber from the area, the general tightening of timber supply in the Pacific Northwest (see discussion earlier under timber supply questions) would still keep prices from falling much over the next two decades. At most, the expected real price increases of at least 2.5% per year over the next 20 year (D.Adams and R.Haynes, op. cit., 1989) would be modified somewhat while the economy was in a recession

Other factors keeping demand at least constant, if not growing slowly, are the continued demands for fiber by the pulp and paper industry, continued export demand for logs, reduction in imports and/or price increases of Canadian lumber, and growing housing remodeling and replacement activities that will offset to some degree lower levels of housing starts.

Economic supply and demand estimates must be considered in the broad context of national and regional economic trends, relative prices of competing wood products and substitutes, and international supply and demand They must also be considered in relation to each other; each has no economic meaning in isolation from the other. For the MBS, the main question to be answered from the demand analysis is whether the Forest can sell the timber it has available for harvest without significantly affecting prices If the Forest were to sell all its available timber, but prices declined with each successive unit sold; or, conversely, if the Forest were unable to sell all its scheduled sales for lack of interested buyers at the minimum bid price; then one could say that demand for timber was overestimated, and at least a portion of the lands allocated to timber production could be used more productively in some other allocation. On the average, over the next 20 years, it does not appear that either of these scenarios will occur Barring a major economic downturn, all sales will be sold. And real prices for the region will probably continue to rise. Thus, we reject the notion that demand for timber has been overestimated in the Forest planning process.

(The same question could be asked from the supply analysis, as well -- can the Forest sell the timber it has available without significantly affecting prices? We have seen earlier that real stumpage prices are expected to rise over the next 20 years until young inventories, both domestic and international, reach merchantable age. This indicates that demand is expected to exceed supply, resulting in price increases to balance the market. All other things being equal, if the Forest were to sell more timber, price increases should be moderated somewhat, leading to lower prices for consumers [but perhaps to less revenue for the Treasury as well - a distributional decision that would have to be made politically]. However, all other things are not equal. The Forest has only a very small number of acres that are not suitable for timber harvest under current or expected future prices. Other lands potentially suitable for timber harvest are allocated to less-than-full yield or to no-yield prescriptions to meet resource and environmental protection and enhancement requirements, to meet demands for other resource uses, and to meet overall goals and objectives of management for the National Forest. Therefore, while we recognize a tightening of supply over the next two decades, the Forest does not have additional lands available for allocation to timber production that would not result in even higher opportunity costs than the gains made in moderating timber price increases.)

DEMAND FOR LUMBER AND WOOD PRODUCTS WILL DECREASE DURING 1985-2005

The Northwest Power Planning Council has estimated that the demand for Pacific Northwest lumber and wood products will decrease during the period 1985-2005, with lumber production decreasing by 17% and plywood production decreasing by 25%.

Response: The 1989 Supplement to the 1986 Power Plan has revised this estimate in light of unexpectedly strong economic recovery and growth since the mid-1980's. The Supplement does not make specific projections of demand in absolute numbers. It does expect changes in **production** over the next 25 years (14% and 13% declines in lumber and plywood, respectively), but that is only partly related to a drop in demand from declining housing starts and competition from outside the reason. Up through 2010, a decline in lumber and plywood production in the Pacific Northwest will be related as much or more to a tightening of the supply of input for production rather than to a decrease in demand for wood products. Any decrease in demand for wood products **manufactured in the Pacific Northwest** will be related mostly to increased production costs caused by higher labor and raw material prices, causing a shift in comparative advantage to other domestic and international producing regions.

SHOW THAT WOOD USED FOR STRUCTURES REPLACEMENT WILL BE SIGNIFICANT

If there is any potential for long term growth in regional domestic demands for lumber and wood products....if structures replacement, rather than new construction, will characterize the market of the future. ..the Forest needs to show either that new housing construction will increase in the future or that structure replacement demands can offset reductions in new construction.

Response: We recognize that housing starts will remain at lower levels than the highs of the late 1970's because of demographic factors. Measurements of wood used in repair and replacement are not yet common, but best estimates are that use of wood products for repair and replacement is increasing as the housing stock ages, and as higher housing prices encourage people to stay in place and remodel rather than moving to new housing. We do not expect demand from that sector to offset fully the reductions in demand from lower housing starts. However, demand from all end uses is expected to keep total demand near to slightly above current levels, barring major economic recessions.

TIMBER DEMAND PROJECTIONS OF OTHERS SHOULD BE RECOGNIZED

The Forest should recognize the [timber demand] projections of other agencies and respected entities such as the Northwest Power Planning Council and Wharton Econometric Forecasting Associates.

Response: The Forest used RPA projections as the basis for discussion of timber supply and demand in the Forest planning documents. This work is done by some of the most expert and respected individuals in the field. NWPPC, Wharton (now the WEFA Group), Data Resources Institute and others also do expert and credible jobs of supply and demand forecasting. Forecasting is an inexact science at best, and forecasts of timber supply and demand can be found both higher and lower than those used in the

planning documents because of different forecasting techniques and different underlying assumptions.

NEED INVENTORIES OF RARE PLANTS AND OF PLANT COMMUNITIES

A thorough inventory of rare plant habitats must be made.

Present inventories of rare plant habitats are far from adequate.

Impacted in the higher elevations are botanical areas that have not adequately been surveyed. Only the actual sightings of sensitive plants have been recorded There is not adequate staffing or funding to survey areas for sensitive plants in a manner that allows for the contemplated level of harvest in these areas

Although it is essential to conduct field search and inventory for occurrences of T, E and S plants prior to ground disturbing activities, as the DEIS states the Forest does, it is important to conduct these inventories in the earliest stages of planning and at times of year when the identification of these plants can be confirmed. This may mean several field surveys for each site. A single or poorly timed search of a potential project site will not provide reliable data on all plant species present The Forest should provide for this level of inventory.

A serious omission is the absence of an inventory effort for endangered, threatened and sensitive plants We urge the forest to conduct such an inventory and recognize its importance in the Plan.

To reduce the possibility of irreversible loss of certain populations and habitats, the inventory should be completed relatively quickly (midpoint of the first decade) and give first priority to locations outside of wilderness.

Is the Forest's rare plant data base really adequate to the task of identifying the presence of sensitive species on all portions of the Forest where potential developments will occur? We seriously doubt that this is the case, yet the overall effectiveness of the entire sensitive species standard and guideline process is completely dependent on the accuracy and comprehensiveness of this initial step in the following process If the data base indicates no potential for the presence of the species, then no field inventory is done. But if the data base is incomplete, the system breaks down. We suggest that project level field inventories receive a high priority, at least until the rare plant data base is complete in all areas of the Forest subject to ground-disturbing management activities, including livestock grazing.

How will project level inventories be carried out and by whom? Who will prepare the species management guides for plant species? Will they be trained field botanists? How often will the guides be reviewed and updated? How many trained field botanists does the Forest now employ or intent to employ for such inventories? Are there plans to hire additional botanists to adequately implement the proposed plan? These are critically important questions that need answers before the public can evaluate the adequacy of your listed species management program.

The Forest must conduct a more thorough inventory of the plant communities, with the intention of locating and designating additional RNA's and Botanical Areas

Since, as we know, a number of native plant species and communities are in decline, a new and more thorough botanical inventory of the forest should be made with the goal of establishing additional RNA's and Botanical Areas

Response: Forest-wide Standards and Guidelines have been added for Diversity and Long-Term Productivity; the standards and Guidelines for Threatened, Endangered, and Sensitive Species have been revised to better reflect the intended management of sensitive plants. Proposed project areas will be assessed for suitable habitat for sensitive plants. In most cases, field inventory of the areas will also be needed. As funding is available, inventories for sensitive plants will also be initiated in no-timber-harvest areas, such as wilderness.

During the life of this Plan, the Forest will be developing a data base for rare plants, staffed by professional Botanists and Ecologists. A number of plant inventories already started or beginning in 1990 will also provide information on occurrence of rare plants, as well as inventories of plant communities. These include the Ecology Program Inventory, which began in 1980, and to date includes over 3000 plots throughout the Forest, plus other inventories of old-growth areas, of spotted owl habitat, ground-truthing of areas in various successional stages to calibrate satellite vegetation interpretation, and stand examinations. The Plan does not provide the detail on who will do surveys and how. Surveying will be done to professional standards.

PLANT INDICATOR SPECIES

We suggest the use of plant species are indicators if such specialized habitat types as seeps, bogs, and wet meadows, talus slopes and forest wetlands, all of which should have their own indicator species and MMR's.

Response: The Ecology Program has sampled seeps, bogs, wet meadows, talus slopes, forested wetlands, as well as other types of non-forest and forested communities as part of the ecological inventory, and has the information needed to select indicators of these environments This inventory is ongoing, and will be completed during the life of the Forest Plan. Standards and guidelines for managing riparian and adjacent areas, special habitat types (such as cliffs, caves, and talus slopes), and using monitoring to ensure that these standards and guidelines are met and effective is the method in the Forest Plan for protecting fragile or uncommon plant communities. All threatened, endangered, and sensitive plant and animal species are included on the indicator species list. Management guides will be prepared for threatened, endangered, and sensitive plants on the Forest, with the highest priority given to developing guides for species most likely to be impacted detrimentally by human uses

BETTER INFORMATION ON EFFECTS ON SENSITIVE PLANTS

I request that you present a more comprehensive and realistic assessment of the effects of the Forest Plan on the health and viability of sensitive plant species.

The discussion needs to include the possibility on non-ground disturbing activities that could increase the rarity of plants, this the probably listing of species. Non-ground disturbing activities include prolonged moderate grazing, trampling, hiking and cropping.

Although many of the sensitive plants occur in areas not directly impacted by timber harvest, there are still a number of potential threats to the plants. These include road and trail construction, impacts from recreational use, particularly within "over-used" wilderness area sites, small hydro projects, grazing, campground development, etc. Sensitive plant populations are often quite localized and even small projects have the potential for significant negative impacts. The statement in this section tends to suggest that threats to sensitive plants are minimal because they do not occur in harvest areas. Concern for sensitive plants should be expressed under the other categories (e.g. roads, recreation, etc.) as well.

We are especially concerned with the effects of the Plan on sensitive species occurring in old growth forests, particularly Pleuricospora fimbriolata. It may well be old growth dependent. Its reproductive biology and life cycle are still incompletely understood.

Please show for each individual endangered plant or animal that your forest plan will not adversely affect populations of said endangered plant or animals.

We are concern with some aspects of the treatment in the DEIS of the environmental effects of the proposed plan on native plants, especially sensitive plant species. Effects analysis should include a thorough discussion of the role of livestock and ORV's in the degradation of native plant communities by direct impacts and as vectors for the spread of noxious and invasive weed species. Sensitive plant species on the MBS are presently vulnerable to a number of existing threats to one or more of the listed species, including road construction, timber harvest, livestock grazing, ORV activities, commercial plant and seed collectors and recreational hiking. These impacts should be more completely covered in the DEIS.

We are concerned with the lack of a thorough treatment in the DEIS of the environmental effects of the proposed plan on native plants, especially sensitive species.

The DEIS Ch. 4 contains virtually no discussion of the Alternatives' effects on sensitive plants, only the statement that "activities will be modified to protect them". This is not good enough. We need to know how activities will be modified, what mitigation measures will be used, who will monitor the Forest-wide Standards and Guidelines.

By suggesting that most rare plants occur at higher elevations and are not in conflict with planned timber harvest, this discussion incorrectly minimizes the potential threats to plants by Forest activities. The Plan needs to address threats to plants from recreation, construction, grazing, and alteration of riparian, wetland or aquatic habitats.

Response: Standards and guidelines for managing for diversity have been added to the FEIS and Plan, and sections on threatened, endangered and sensitive plants have been revised. Your comments were considered in those revisions. Chapter IV of the Plan has been revised to better discuss the effects of alternatives on plant community diversity and effects on sensitive plants. The Ecology Program has collected some information on sensitive plants, beginning in 1980. Also, the Forest has initiated a Botany Program specifically to inventory sensitive plants and their habitat.

THE SENSITIVE PLANT LIST

We would like to note that it is at least as likely that a species will be added to the sensitive list, due to the actions of the plan and other reasons, as that they will be deleted.

The Forest Service's sensitive species list should be updated to reflect changes in the State's list.

The complete list of sensitive species, their habitats and recognized threats to these species should be clearly listed in the FEIS

Which plants are on the National Endangered Species List?

The appendices should list the sensitive species occurring on or adjacent to the Forest.

> **Response:** A list of all sensitive, threatened and endangered plant and animal species has been included in the FEIS; refer to the Diversity, Vegetation and the Wildlife sections of Chapter III. These lists are updated each year, considering input from the State. Additions, deletions, and changes in listing categories can occur in these revisions

STANDARDS AND GUIDELINES FOR MANAGING SENSITIVE PLANTS

The development of species management guides for sensitive species is required and important. The Forest's intention to develop these guides should be stated as a separate goal, such as "The Forest will develop and implement a species management guide for all sensitive plant and animal species occurring on the Forest".

The Final Plan should include more specific and enforceable Forest-wide standards and guidelines for protecting listed species Implementation of Region 6 guidelines and FSM directives in this regard should be specifically detailed and explained rather than merely implied.

Management and recovery plans should be developed for all listed sensitive species on a species-specific basis. Provide clearly defined protections for the habitats of each listed species. Under the Plan, which species will receive management plans? What will the effects be on species not chosen? Who will decide? Who will develop the plans? How will the species be managed until the plans are in place?

> **Response:** In Chapter 4, Forest Plan, the standards and guidelines for Threatened, Endangered and Sensitive Species have been revised to better reflect the intended management of sensitive plants Proposed project areas will be assessed for suitable habitat for sensitive plants. In most cases, field inventory of the areas will also be needed.
>
> Management guides will be prepared first for species for which the need is greatest, i.e., those for which there is an apparent threat to viability. As species vary considerably in their habitat requirements, population sizes and distributions, and vulnerability to the range of human activities which occur on the Forest, a unique plan must be developed for each sensitive plant species. These plans will be done to professional standards, under the guidance of qualified botanists.

ADD REVIEW AND INVOLVEMENT OF THE WASHINGTON NATURAL HERITAGE PROGRAM

In the Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive Species, sensitive plants should receive the advice and review of the Washington Natural Heritage Program.

Response: Consultation with this Program is included in the standards and guidelines; refer to Chapter 4, Forest Plan

SPECIAL PLANT HABITATS

Fragile plant habitats, such as bogs, wet meadows, talus and cliff slopes, marshes, seeps, and springs should receive specific management protection across the range of land use prescriptions. While the MBS has taken a highly commendable initial step in this direction in the standards and guidelines, more specific protective guidelines should be enumerated and a Forest-wide database inventory should be developed to catalog and exclude such sites from development activities

Response: Revisions have been made to the standards and guidelines for riparian areas and standards and guidelines for diversity have been added to the Forest-wide section, to better address management of fragile and uncommon habitat types such as these. A variety of vegetation inventories will increase our data base on plant communities

VIABLE POPULATIONS OF NATIVE PLANTS

Nowhere is it mentioned that the Forest will maintain viable populations of native plant species. Forest Service policy includes the maintenance of viable populations of native plants, so should the Forest Plan.

Response: This has been added to the Forest-wide Standards and Guidelines for diversity

DIVERSITY OF NATIVE PLANT COMMUNITIES

NFMA requires the preservation and enhancement of diversity yet many of the prescriptions in the draft plan will have exactly the opposite effects.

Large, viable examples of the different plant zones and communities need to be set aside--not just old growth.

Forest-wide standards and guidelines should protect the diversity of native plant communities.

We are concerned that you retain the original mix of native plant species over the entire forest and that you not plant non-native species. Type conversion is not allowed by NFMA (36 CFR 219.26) without extensive justification - which appears nowhere in the DEIS.

Response: These concerns have not been addressed at this Forest Plan level; we have, however, added this as an information need,

NOXIOUS WEEDS

Discuss the effects of noxious weed introductions on native plants, including the role of domestic livestock, ORVs, and other recreational activities in such introductions.

Response: Tansy ragwort is the only "noxious" weed of significance on the MBS, and it is rare, mostly occurring along lower roads. Canada thistle, and some others occur rarely. Refer to the implementation schedule in Forest Plan, Appendix J for the planned control of noxious weeds.

SEEDING WITH NATIVE PLANT SPECIES

It is important to state that natural seeding will be used to eliminate any issues of introducing new species and problems in these areas.

Response: There is an increase in the use of native plant species for seeding for erosion control and wildlife forage enhancement. The introduction of exotic plant species is a concern. In many areas, exotic and non-endemic species were introduced in earlier decades (from horses, homesteaders, and later, brought in on car tires) and have become a common component of the plant community. It would be difficult or impossible to eradicate these, and some have value as forage or erosion control. The Forest-wide standards and guidelines for diversity clarify that the overall goal is to maintain viable populations of all native species, and to maintain adequate representation of all natural plant communities. Site-specific prescriptions for areas will take this, and the area's total management objectives into consideration

NEEDS TITLE

We disagree that noble fir and tansy ragwort (page IV-33 DEIS) increase the value of the forest, as implied by your constricted use of the term "richness." They instead imply an alteration of a native ecosystem; richness does not describe the alterations wrought upon native ecosystems by introduced species, either "desirable" or "undesirable" species.

Response: Noble fior is a native species in the southern part of the Forest, maintained there historically by wildfires. As such, it does contribute to the diversity of the forest The discussion on the effects of the alternatives on vegetation, etc. have been rewritten considerably since the draft plan, in response to this and other comments.

COMMERCIAL COLLECTION OF PLANTS AND FUNGI

What are the impacts of commercial plant and fungus collecting on the Forest and set up stringent guidelines protecting these resources

Permits are given for the harvesting of salal for use across the U.S. and Europe. Washington State is the largest supplier in the world.

The effects of long-term harvesting of bear grass and other plants needs to be researched.

Mushroom harvesting is becoming a concern because of the size of operations that are for commercial purposes. Research is necessary before allowing large-scale operations.

Fungi are a commercially harvestable resource of growing importance in the Pacific Northwest. The conditions required for a sustainable yield of commercially harvested wild mushrooms are not known. This resource has not been considered in this plan and related management practices are not covered.

An inventory of populations of fungi with commercial value and the habitats they occupy could be started.

Commercial collection of native plants and fungi and their seeds and parts is rapidly becoming a matter of resource concern on the MBS, as commercial seed companies now offer high prices for wild-collected mushrooms, plants and seeds. Networks of plant and seed collectors even publish newsletters and pricelists for many species, some as businesses and some as "underground" or informal networks. Washington has become a national center for such operations. The Draft Plan makes no attempt to offer a plan to deal with this growing commercial exploitation of public resources.

What effects will this trade have on sensitive and endemic species? The Plan should provide a clear and specific set of prescriptions for monitoring and regulating expanding commercial ventures on public lands.

A more comprehensive inventory should be made because of the progressively increasing commercial harvest of so-called "minor forest products" for floral supply, gourmet mushroom eaters etc.

> **Response:** We have little knowledge of the harvest of secondary forest products, such as mushrooms, mosses, brush, etc The distribution, growth, and ecology of these ecosystem elements needs research to help determine the effects of harvesting these products. The Forest's Ecology Program will be collecting field data on many of these products in the future.

NO EVALUATION OF THE FUNGAL FLORA

There has been no evaluation in the DEIS of the fungal flora and the effect the different management alternatives will have on it. Maintaining a healthy fungal flora is important for maintaining the angiosperm flora.

> **Response:** The distribution, growth, and ecology of these ecosystem elements needs research to help determine the effects of harvesting these products. The Forest's Ecology Program will be collecting field data on many of these products in the future. Refer to Chapter 2, Forest Plan, Information Needs.

PROTECT BOTANICAL VALUES AROUND TWIN SISTERS

The west side of the Sisters is a spectacular landscape; botanic values there deserve special recognition. There is critical mountain goat habitat (DEIS Appendix C); Bell Creek has a dramatic hanging valley.

Response: In the Preferred Alternative, the west side of Twin Sisters is allocated to MA 1A, Primitive Recreation. The area to the east, between Sisters and Bell Creek is allocated to MA 17 Timber Management Emphasis, MA 14 Deer and Elk Winter Range, and - to the east and north - to MA 5, Proposed Wild and Scenic River. Bell Creek is allocated to MA 11 SOHA and MA 5, Proposed Wild and Scenic River (Recreation River).

DISAPPOINTED THAT THERE ARE NO BOTANIC AREAS IN THE PLAN

We are dissatisfied with the lack of any Botanical Special Interest Areas in the Plan, despite a number of well-known and highly qualified sites.

Response: In the FEIS and Forest Plan, a botanic area at Sulphur Creek (located near the Mt. Baker National Recreation Area, on Mt. Baker Ranger District) has been allocated. Refer to MA 8, Chapter 4 Forest Plan and the map for Alternative J (Preferred)

ACREAGES FOR RNA'S IN TABLE S-1 ARE CONFUSING

In the Summary, Table S-1, the acreages for RNA's are a little confusing. It is a somewhat minor point, but five of the alternatives have acreages that are between 5,238 and 5,240 Shouldn't they all be the same?

Response: The differences in acres result from the rounding of acres in R2MAP On the ground the areas would all be the same size.

ATOMIC ENERGY COMMISSION DOESN'T HAVE RNA'S

In the list of agencies with established RNA's, the Department of Energy could be included, but the Atomic Energy Commission (currently the Nuclear Regulatory Commission), which does not have any RNA's, should be removed.

Response: This has been corrected in the FEIS, Chapter III.

CORRECT NUMBER OF RNA'S TO 102

In the fourth paragraph (P.III-144) a 1972 figure of 48 RNA's in Washington and Oregon is used. That figure is way out of date, in fact as of 1986, there are 102 established RNA's in Washington and Oregon, 39 of which are on Forest Service land.

Response: This has been corrected, in response to this comment.

CLIMAX RED ALDER FOREST LEFT OUT OF LONG CREEK RNA DESCRIPTION

The Long Creek RNA should include "climax red alder forest" as a principal feature (Table III-61 and elsewhere in the planning documents)

Response: This information has been added in the Forest Plan and related documents.

NATURAL HERITAGE PLAN SHOULD BE USED INSTEAD OF RESEARCH NATURAL AREA NEEDS IN THE PACIFIC NORTHWEST

I realize that Regional Office direction is to use the Yellow Book (Research Natural Area Needs in the Pacific Northwest 1975). This document is way out of date. The Washington Natural Heritage Plan is the logical update to to the Yellow Book and deserves mention in that context. The implication is also made that the other agencies use the Yellow Book, when, in fact, the Forest Service is the only agency using it. The other federal agencies all use the updated Natural Heritage Plans.

Response: Regional direction continues to require use of the Yellow Book and cannot be ignored in the Plan. The FEIS has been reworded to eliminate the implication that other agencies use the Yellow Book.

ADDITIONS NEEDED IN THE EFFECTS SECTION OF RNA'S

I believe there are environmental consequences to RNA's, and do not agree that no effects are expected from changes in vegetative plant diversity to RNA's. In fact there are numerous ways effects might occur. The normal process of succession will cause changes. Adjacent land management, that is management practices next to RNA boundaries, can cause changes in vegetative plant diversity. Adjacent clearcuts can cause wind throw, cause changes in microclimate along edges, provide corridors for introduced species, all three of which can cause changes in vegetative plant diversity Recreation use can cause changes. I realize that it is difficult to array these kinds of effects throughout alternatives, yet some mention of them seems important. Otherwise RNA's appear to be preserves that have no real connection to the surrounding landscape and that are "protected" from change once established.

Response: The cited text refers to changes in vegetative plant diversity outside of RNA's, specifically those caused by timber harvest. Thus, the comment about normal succession is misdirected. However, comments about the effects of timber harvest adjacent to RNA's are valid, and the FEIS has been revised to reflect this

NON-RECOMMENDATION OF RNA'S WOULD LEAD TO A LOSS OF BIOLOGICAL DIVERSITY

We disagree with the statement under RNA - Cumulative Effects. Non-recommendation of RNA's not only will reduce the landbase for study of natural processes, but it also threatens biological diversity. The loss of these areas would definitely reduce biological diversity on the Forest.

Response: Text in Chapter IV of the FEIS has been revised to reflect this comment. Also, refer to new text on Diversity, Chapter IV, FEIS.

THESE TIMBER SALES MAY HAVE ADVERSE IMPACTS ON ADJACENT RNA'S

Appendix A lists proposed timber sales for the next ten years. Four of these proposals may have adverse effects on adjacent RNA's, and I hope the District Ranger will coordinate with the RNA scientist in planning the sales.

1. 1988 West Boundary Buyback - Lake Twenty-Two RNA
2. 1991 Betwixt - Lake Twenty-Two RNA
3. 1991 Stalwart - Perry Creek proposed RNA (appears that it may even be in it)
4. 1993 Black Creek Buyback - Lake Twenty-Two

Response :No timber harvest is scheduled contiguous to the Lake Twenty-Two RNA. Land allocated to Management Areas 1B and 11, which are not scheduled for harvest, lie between the RNA and the proposed sales. The appearance that the Stalwart Sale is located in the Perry Creek RNA results from the legal description, which is an approximation of the specific location. The timber will be harvested from Management Areas 2A, 2B, 5B, not the RNA.

RNA'S ARE IMPORTANT FOR BIOLOGICAL DIVERSITY

The protection of biological diversity is mandated by law and the Forest Service is committed to this concept. There is very little in the plan that

links RNA's to biological diversity, and that link is important. RNA's do and will play an important role in protecting various plant communities, aquatic species, and terrestrial species, all part of biological diversity. In some cases RNA's will be the only vehicle for that protection, especially as more of the forest comes under intensive management. The plan seems to equate diversity only with the old-growth issue.

Response: Text in the FEIS and Plan has been revised to reflect this comment, although this concept was recognized in the second paragraph at page III-142 of the Draft EIS and IV-196 of the Draft Plan, which discuss the influence of RNA's on gene pools. The proposed RNA's include a wide array of subalpine lake communities, aquatic communities, a unique assemblage of rare fern species, subalpine parkland mosaic, heather-huckleberry communities, subalpine lush herbaceous communities, and alpine community mosaic with Krummholz, in addition to terrestrial old-growth forest communities.

PERRY CREEK AND CHOWDER RIDGE SHOULD BE RNA'S

The Forest should continue seeking potential RNA's and Botanical Areas. Our Natural Areas Committee has identified several in the past which, as yet, have not been officially recognized. Perry Creek (in the S. Fk. Stillaguamish drainage), Chowder Ridge (N. slope of Mt. Baker) are examples.

Response: Both RNA's were considered in the Draft and are recommended as potential RNA's in the FEIS Preferred Alternative.

LOW-ELEVATION OLD GROWTH RNA IS NEEDED

A low-elevation old-growth RNA is desperately needed to permit continued study of low-elevation forests of Douglas fir and western red cedar.

Response: Several existing RNA's represent these ecosystems on the forest. THe North Fork Nooksack RNA represents Douglas fir and Lake Twenty-two represents Western red cedar Additions are recommended to the North Fork Nooksack RNA in the Forest Plan.

LILY LAKE SHOULD NOT BE PLACED IN RNA STATUS

Lily Lake has been historically stocked with trout by the State Game Department and should be maintained as a backcountry fishing recreational resource and not placed in RNA status.

Response: Stocking would devalue Lily Lake as a typical subalpine lake and would be prohibited except for the re-introduction of former native species with Regional Forester approval. The area represents a mountain hemlock/Pacific silver fir forest, an ecosystem currently not represented in the RNA system. Backcountry fishing opportunities are quite common throughout the Cascades.

SNOQUERA FALLS AREA SHOULD BE RNA TO PROTECT PACIFIC YEW

We wish to propose the Snoquera Falls area as an RNA to protect a unique population of **Taxus brevifolia**, the Pacific yew, as well as other interesting and uncommon plant species. The yew is coming under increasing management pressures in recent years, due to its biochemical properties, and it is essential that the Forest retain some high quality groves to serve as baseline monitoring populations to assess the effects of rapid harvesting elsewhere on the Forest.

Response: The Pacific yew is neither federally threatened, endangered nor sensitive. Snoquera Falls is within the Mather Memorial Parkway and is allocated to Special Area (MA 8). This allocation prohibits timber harvest.

ADD GAMMA HOT SPRINGS OR SULPHUR HOT SPRINGS AS AN RNA

The need for inclusion of natural hot spring communities in the RNA system could be met with designation of either Gamma Hot Springs or Sulphur Hot Springs as RNA's. Either site would be suitable.

Response: Gamma Hot Springs and Sulphur Hot Springs are within the Glacier Peak Wilderness, and will receive a high level of protection regardless of RNA designation. Sulphur Hot Springs is allocated to Management Area 10B, Trailed, and currently receives recreational use. Designation of Sulphur Hot Springs has the potential to create conflicts with established recreation use.

TWIN SISTER AREA SHOULD BE AN RNA

We recommend that the Twin Sisters area, proposed as a Special Interest Area by Alt. G but ignored by the Preferred Alternative, would most appropriately be added to the RNA system. Uncommon geological substrates and an isolated location combine to give the Twin Sisters area an interesting and special flora. This area would greatly enrich the RNA program, and we urge its inclusion in the final Plan

Response: The Preferred Alternative allocates the Twin Sisters area to Management Area 1A, Primitive Recreation The allocation to areas with an emphasis on no timber harvest or developed recreation will substantially protect the unique biological and geological features.

KELCEMA LAKE SHOULD BE AN RNA

We recommend that the Kelcema Lake area be given RNA status for the preservation of an extant population of the sensitive and very easily disturbed Sensitive Plant species, **Fritillaria camchatcensis** The MBSNF has a special responsibility for preserving populations of this species, as a well-known population near the Big Four visitor area has apparently been wiped out by Forest Service development in the area.

Response: Populations of this species are not currently listed as federally threatened or endangered. Sensitive plants are managed so as to avoid listing. Sensitive species will be inventoried and identified

through the regular environmental analysis for every ground disturbing activity. Populations of sensitive species will be managed to protect that species and avoid the need of federal listing.

Kelcema Lake is located within the Boulder River Wilderness. This allocation provides a high degree of protection for the species.

STRICTER STANDARDS NEEDED FOR THE MANAGEMENT OF RNA'S

We recommend a more specific set of guidelines for restricting recreational and commercial exploitation of RNA's. In general, recreational activities that cause any amount of resource degradation are not appropriate in RNA's. Camping and open fires should be specifically prohibited to prevent vegetative destruction. The collection of native plants and their seeds and parts without a scientifically based collection permit should be specifically prohibited. Construction of additional permanent trails in RNA's should be prohibited. Hunting and trapping should be prohibited, not merely discouraged. Use of mountain bikes should also be prohibited on trails through RNA's.

The Plan needs to state that overnight camping is prohibited rather than, "shall be discouraged." FSM 4063.3 directs the forest to prohibit all forms of recreational use if such use threatens RNA values. Overnight camping alters natural conditions and is inappropriate and unacceptable within RNA's. Eliminating established overnight camping use of RNA's and prohibiting the establishment of new recreational patterns within RNA's should be the Forest's goal.

Response: Forest Service policy is to prohibit any form of recreational use if such use interferes with the purposes for which the Research Natural Area was established. The purposes of an RNA are defined in the Establishment Record, which also includes a management prescription that amends the Land Management Plan. Specific guidelines for recreational use are created by the management prescription, and are implemented through orders pursuant to 36 CFR 261. The Land Management Plan contains a more generic set of guidelines, which must allow for the existence of some RNA's with established recreational uses that would be impossible to change.

The Standards and Guidelines state that recreational use or activities will not be encouraged within RNA's. Camping and fires maybe prohibited, as is new trail construction. Hunting and fishing will not be encouraged.

PROHIBIT VEGETATIVE MANIPULATION IN RNA'S

We request that you prohibit any type of timber salvage or "vegetative manipulation" activity in RNA's, as well as scheduled or programmed harvest. Catastrophic events within an RNA do not mean that the research value of the RNA has been destroyed. Much valuable knowledge can be gained by studying the regeneration of particular habitats following catastrophe, and salvage operations of any kind would severely alter the natural regenerative processes.

Response: Standards and guidelines for RNA's prohibit scheduled timber harvest, which also state that natural regeneration following fire, windthrow, insect attack or disease is preferred. Logging may be permitted following catastrophes which threaten the RNA or adjacent values, subject to the approval of the Regional Forester and the Research Station

Director. Substitution of logging for natural regeneration would be *contingent on conformance to the RNA objectives as defined in the* Establishment Record. The Forest Service Manual requires that "Standards for protection and management of a research natural area must support and promote the basic objectives and purposes of establishing the area .... make sure that the establishment record clearly states the objectives for establishing the area and identifies the special values for which the area is being recognized." (FSM 4063.3) Further, "Use only tried and reliable vegetation management techniques and then apply them only where the vegetative type would be lost without management. The criterion here is that management practices must provide a closer approximation of the naturally occurring vegetation and the natural processes governing the vegetation than would be possible without management. Unless the manager is certain that the management practice will meet this criterion, do nothing." (FSM 4063.34) In virtually all cases, this will result in no vegetation management.

NO NEW RIGHT-OF-WAYS SHOULD BE GRANTED IN RNA'S

We request that guideline J-2-c be deleted. No new right-of-ways should be granted in either designated or proposed RNA's, as such activities would clearly degrade the resource values of the RNA's in question.

Response: Roads may be authorized if they contribute to the purposes of the RNA. This is expected to be rare. Road prohibitions may be incorporated in the management prescription included in the Establishment Record

IS RECREATIONAL USE COMPATIBLE WITH RNA'S?

Figure II-2 (page II-47) shows, "the *general type of land uses permitted* within each management area" It incorrectly indicates that RNA's (MA 18) are compatible with Roadless Nonmotorized Recreation. Recreation is prohibited or, at best, discouraged within RNA's. Some RNA's do receive recreational use as a result of historic recreation patterns that are difficult to change. The Forest should make every effort to discourage and avoid any increase in this use. The Figure should indicate that RNA's and recreation have no management compatibility. To show that RNA's and recreation is compatible is misleading to the public and to managers and will encourage rather than discourage recreational use.

Response: Within RNA's, the recreation Standards and Guidelines for Management Area 18 will be applied. These state recreational use is to be discouraged, through the use of permits or closures Forest Service direction (Forest Service Manual 4063.3[5]) calls for recreational use to be prohibited if it threatens the purposes for which the RNA was established, but does not presume that recreation and RNA's are always incompatible. Figure II-2 has been removed to avoid further confusion.

REVISE STANDARDS AND GUIDELINES TO SHOW WHICH OFFICER IS RESPONSIBLE FOR APPROVING SCIENTIFIC USE OF RNA'S

Management Area 18, RNA's (page II-58), incorrectly states that, "Only authorized (by the Chief of the Forest Service) scientific research and

educational uses allowed" In contrast, the FSM ... states that this responsibility lies with the Station Director (FSM 4063.33). Elsewhere (4063.04) the manual states, in consultation with Forest Supervisors and District Rangers, Station Directors are responsible for approving management implementation plans and for overseeing and coordinating approved research on all research natural areas, except those research natural areas in Congressionally-designated areas. Regional Foresters shall approve plans and shall oversee and coordinate approved research on all research natural areas in Congressionally designated areas.

Response: Text in the FEIS has been revised to reflect this comment.

DEIS GIVES INADEQUATE ANALYSIS OF EFFECTS OF HARVEST ON RNA'S

The DEIS gives an inadequate analysis of the effects of harvest on RNA's. Timber harvest adjacent to an RNA can have a variety of potentially serious indirect effects. It is for this reason that the Forest Service Manual (4063.04.6) directs District Rangers to, among other things, "report through the Forest Supervisor to the Station Director any planned activities on, or immediately adjacent to, research natural areas". These effects should be recognized and discussed. In addition, timber harvest activities may have the irreversible effect of destroying an area that will qualify but has not yet been identified as a potential RNA.

Response: Text in Chapter IV of the FEIS has been revised to discuss the effects of timber harvest adjacent to RNA's.

CORRECT GLOSSARY DESCRIPTION OF RNA'S

In the glossary, Research Natural Area is incorrectly defined as an area established by public or private agency. Although private organizations such as The Nature Conservancy cooperate with state and federal agencies to identify and establish dedicated natural areas, Research Natural Area is a federal designation and RNA's are only established on federal lands.

Response: Text in the FEIS has been revised to reflect this comment.

RNA'S NOT COVERED IN THE MONITORING PLAN

Table 5-1, Monitoring Plan, should include monitoring of the Forest's RNA program management and goals, including: a) protecting RNA attributes, and b) identification and establishment of additional RNA's required to fill RNA cell (element) needs. For example, RNA's receiving recreational use will require monitoring and evaluation to determine the need for greater restriction.

For the RNA resource area, the monitoring plan could be as follows:
Action/Effort Monitored: Effectiveness at meeting RNA management objectives.
Objective of Monitoring: Assure the RNA attributes and unmodified conditions are maintained.
Method of Monitoring: Visual site inspection, evaluation of impacts from a)adjacent activities (recreation, timber harvest, etc.) and b) on-site activities that are detrimental to RNA qualities (recreation), Evaluate Forest compliance with standards and guidelines/coordination with Station

Director; Evaluate implementation and effectiveness of individual RNA Management Prescriptions.
Unit of Measure: RNA sites.
Frequency: Annual
Reporting Period: Annual
Precision: M M
Data Storage: District, S.O., and PNW Research Station.
Responsibility: District Ranger
Variability Threshold: When standards are not being met or downward trend is indicated.
Cost: Determine

Response: Table 5-1, Forest Plan has been revised to reflect this comment.

KENDALL PEAK LAKES SHOULD BE AN RNA

I would recommend Kendall Peak Lakes on the North Bend Ranger District as either an RNA or designated Botanical Area. Each lake has a slightly different vegetation type. And the lower lake has an unusual diversity of wildflowers due to meadow/bog shoreline habitats.

Response: The comment is not definite as to whether a terrestrial or aquatic ecosystem is recommended for RNA status, but implies an aquatic ecosystem. Without additional information, it is not possible to assess how the Kendall Peak Lakes might fill one of the ecosystem cells identified in "Research Natural Area Needs of the Pacific Northwest" (Dyrness and others, 1975). However, marsh and bog cells are represented in the existing RNA system.

RNA MANAGEMENT SHOULD BE MORE RESTRICTIVE THAN WILDERNESS

We support the establishment of the proposed RNA's and urge the Forest to continue to inventory for RNA needs, especially in those parts of the forest outside of the wilderness areas. RNA's in the wilderness areas should have more restrictive management than the rest of the wilderness.

Response: When RNA's (Management Area 18) are designated in Wilderness (Management Area 10), the more restrictive of the two sets of Standards and Guidelines (generally, those for RNA's) are implemented.

RNA'S IN ALTERNATIVE G ARE IN ERROR

There seems to be a discrepancy in RNA's for Alternative G - Page II-43 indicates two additional RNA's will be established under this alternative (as opposed to Alternatives C, D, E, F, and H which each proposed five additional RNA's), but the table on page II-49 indicates 6,161 acres of existing and potential RNA's, the highest figure for any Alternative.

Response: This discrepancy has been corrected in the FEIS. Alternative G-Modified has 5 Proposed RNA's.

NEED TO UPDATE THE 1975 LIST OF "NEEDS FOR EXAMPLE ECOSYSTEMS" TO THE PRESENT

Research Natural Areas: Either this section of the Plan or the section on RNA's (4-196) needs to state or clarify the overall goal or objective of RNA designation. How many RNA's are needed? Or what range of variation of natural ecosystems is required for adequate development of an RNA system? Page III-143 lists "... need for examples of ecosystems.. " from the RNA "yellow book" (Dyrness & Franklin 1975). These 1975 cell needs were established based on the state-of-knowledge at that time. Since, the U.S Forest Service, through the work of their own ecologists, has further defined the range of forest ecosystems on the Forest's land. The needs section should, therefore, be updated to reflect this increased knowledge by including major forest associations defined by Henderson, et. al. 1981-1984 in the State of Washington Natural Heritage Plan. If the purpose of the RNA system is to be fully recognized, the Forest should attempt to establish baseline areas in the low elevation hemlock or red cedar community types where an opportunity to plan for designation exists now, rather than later being forced through public pressure to set aside an area that may conflict with future management concerns.

Response: The objectives of establishing Research Natural Areas are stated in the Forest Service Manual (FSM 4063.02), and need not be repeated in their entirety in the Plan. A summary statement has been inserted in Chapter III of the FEIS, however, regional direction is to use "Research Natural Area Needs in the Pacific Northwest" (Dyrness and others 1975) as the basis for assessing RNA needs. A low-elevation hemlock RNA is needed, but these forests are found in the Puget Trough Province, primarily in state and private ownership. Western red cedar forest, without western hemlock or Pacific silver fir dominance, is found in North Cascades National Park

ELIMINATE THE LONG CREEK RNA

Eliminate the Long Creek Natural Area classification. If you can add a natural area at Perry Creek, you should be able to eliminate one which is totally unjustified. Long Creek is simply a timbered slope, nothing unique. It probably had a potential value when it was set aside, but to my knowledge it has never been used. In addition, a vast wilderness has recently been designated on contiguous land What do we need such a Natural Area for, when we now have roughly 100,000 acres set aside in its natural state immediately adjacent to it?

Response: Research Natural Areas are designated to preserve pristine areas that represent widespread ecological areas, as is the case at Long Creek. Management objectives for RNA's and Wilderness are different and not necessarily compatible. Thus, it may be necessary to designate both, in different portions of the same ecological area.

QUESTION THE CONCEPT OF INDICATOR SPECIES

The concept of indicator species is of questionable value.

The management indicator concept, as applied by the Forest, is probably in error.

If no management activities occur in these mini-wildlife preserves, how will these critters help you determine the effects of management on them?

Response: NFMA (36 CFR 219.19) called for the use of management indicator species. Use of this approach has generated much discussion, both favorable and not, plus discussion on other, alternative approaches. Concepts for use in managing for viable populations of native species and monitoring appropriateness of the management methods chosen continue to evolve. However, the current direction is that provided by NFMA. Management requirement habitat areas must maintain the qualities required by the entire group of species dependent on such areas, and not just the habitat characteristics used specifically by the indicator species. As information increases on both the species to which these areas are important and the habitat qualities which they need, additional or different and management prescriptions may be developed.

TO WHAT EXTENT WERE SITES FOR INDICATOR SPECIES INVENTORIED?

What was the Forest's attempt to identify the known sites of indicator species. Are there inventories for these species?

Response: The degree of inventory for various indicator species varies from 80% to 0%, depending upon the species.

Northern spotted owl: habitat areas are approximately 80% inventoried.
Pileated woodpecker and pine marten: no in-place inventory.
Bald eagle: have inventory of known nest sites and much of the roosting areas
Grizzly bear and peregrine falcon no in-place inventory
Black-tail deer and Roosevelt elk: rely on Washington Department of Wildlife inventories and estimates.
Mountain goat: have cooperated with State on an inventory on north end of Forest. Regularly up-dating of wintering habitat inventory
Primary cavity excavators: Have not attempted to inventory these species as of yet.

Also, refer to Chapter 2, Information Needs (Forest Plan) and the Monitoring Plan, Chapter 5 for planned inventories.

PILEATED WOODPECKER IS NOT A GOOD INDICATOR SPECIES FOR OLD GROWTH

Despite the significant amount of research that has been conducted in Eastern Oregon on the pileated woodpecker in particular, the evidence is not compelling that this bird is an appropriate indicator for old growth or mature forest dependent wildlife. With all due respect to the Forest's obligation to follow regional standards and guidelines, it has yet to be demonstrated that the Forest Service model for pileated woodpecker habitat requirements is

sufficiently valid to justify the prescribed limited use of land as applied in this instance.

It is not unusual for pileated woodpecker to adapt to suburban and rural habitats where trees such as cottonwood and alder are growing along water courses in the total absence of seral stages V and VI. The unlikely assumption of the Forest Service model for pileated woodpecker habitat that maintaining viable populations of this species required extensive areas and networks of snags and down logs is not supported by substantial evidence that justifies the provisions for such limited use.

The proposed plan by definition strongly relies upon a dependent relationship between pileated woodpecker and old growth and mature forest habitat in Management Area Prescription 12. The plan apparently provides for this presumed habitat need without taking into account an overlap with riparian Management Area Prescription 13C, which probably provides more suitable pileated woodpecker habitat than MA 12 does.

In regards to the pileated woodpecker, which uses a similar habitat as the pine marten, I would suggest that the forest planners read the recently published thesis at Oregon State University about pileated woodpeckers.

Response: The intensive process of selecting management indicator species was completed with involvement of many of the Forest Service biologists in Oregon and Washington. The Regional Forester insisted on consistency in those species selected, at least by geographical province. For most westside forests, the pileated woodpecker and pine marten were deemed the most suitable to represent species who can utilize both mature and old growth habitats, based on existing literature findings. Guidelines developed in "Management of Wildlife and Fish Habitat in Forests of Western Oregon and Washington" indicate habitat for pileated woodpecker needs to contain 25"+ DBH snags. On the MBS, snags of that size are only found in mature or old growth stands of timber

Most of the land allocations that provide for some level of timber management will not provide for 25"+ DBH snags. We are estimating that 75% of the riparian acres on this forest could have some timber harvest, at full and partial yields, extended rotations, which will make it difficult to maintain pileated woodpecker habitat. Many of these areas will provide suitable habitat for other cavity excavators, but the requirements of pileated woodpecker are unique.

The identification of mature and old growth habitat for pileated woodpecker involved determining habitat requirements from what was known from current literature and mapping a mosaic of habitat areas on the forest, in an effort to maintain viability across the entire forest. In many cases, the requirements were met in a land allocation that would assure this habitat without reducing management activities (ie., wilderness, research natural areas, semi-primitive nonmotorized recreation, spotted owl habitat areas). Pileated woodpecker habitat areas were established in-between other existing habitats to assure adequate distribution.

We feel this concept has validity and will maintain it in the Final Plan. If, through monitoring, additional information is gained about pileated woodpecker or other indicator species, changes will be made in the Plan to adjust habitat requirements of selected species or, in some cases, change species to what will be a more appropriate indicator.

QUESTION USING THE PINE MARTEN AS AN INDICATOR SPECIES

The forest products industry has a great deal of difficulty with the indicator species concept when it comes to animals like the pine marten. This species is found in a variety of habitats throughout the mountainous areas of Washington and Oregon. In both states, a yearly trapping season is set. In Oregon, in 1085, 82 individuals were trapped, with their pelts selling for an average of $22.78 per pelt. Although the 5,000 acres of land set aside is not excessive, additional efforts should be made to locate pine marten habitat in areas that are already restricted from timber harvesting. In areas where pine marten habitat exists in the commercial forests base, timber harvesting should be allowed to continue. Soutiere (1979) recaptured resident pine marten, found in the same area for three months, an area after which partial harvest operations had ceased. Steventon and Major (1982) captured one male in the same area before and after timber harvest activities. His home range included some of the new clearcut, but his use of this habitat was less than expected from its availability. In contrast to clearcutting, selective cutting (57% of harvestable trees removed) as employed in Campbell's (1979) study, and partial cutting (16%-43% of the base areas removed, canopy density of 18-95% as implemented in Soutiere's 1979 did not appear to curtail marten use. Important prey species were not affected by these logging practices and potential nesting sites were noted in selectively-cut areas. Also partial cutting did not significantly reduce marten population densities. Our recommendation is to allow limiting timber harvest in marten areas, and in addition, study closely the ideal of using an indicator that is regularly trapped within the state.

> **Response:** The intensive process of selecting management indicator species was completed with involvement of many of the Forest Service biologists in Oregon and Washington The Regional Forester insisted on consistency in those species selected, at least by geographical province. For most westside forests, the pileated woodpecker and pine marten were deemed the most suitable to represent species who can utilize both mature and old growth habitats, based on existing literature findings. Guidelines developed in "Management of Wildlife and Fish Habitat in Forests of Western Oregon and Washington" indicate habitat for pileated woodpecker needs to contain 25"+dbh snags. On the MBS, snags of that size are only found in mature or old growth stands of timber. See above response for more discussion.

INDICATOR SPECIES LIST INADEQUATE OR INCOMPLETE

Appropriate wildlife or plant indicator species should be designated for hardwood communities.

The need for riparian indicators is especially great.

At least one plant species, and preferably an association of plant species, as well as a vertebrate animal, must be selected as indicator species for riparian habitat.

The indicator species chosen arguably will not achieve the objective of indicating the health of forest habitats. For example, the pine marten is a solitary creature that is rarely found at low elevations. It is unclear how the Forest will monitor the species.

There is no biological justification for using northern spotted owl, pileated woodpecker, marten, mountain goat, roosevelt elk, blacktailed deer, primary cavity excavators as indicator species

We suggest that large, predatory species, such as the wolverine, cougar and bobcat be added to the list of indicator species and allocated MMR areas and standards. As top predators and furbearing animals, these species are numerically rare and environmentally sensitive to any large scale modifications to their habitat As such, they are perfectly suited to indicator species status

An adequate range of appropriate indicator species has not been selected. The most serious of these cases is that there are no proposed indicators for riparian/wetland community types. Each type should have a valid indicator species. (The yellow warbler, willow flycatcher, yellow-breasted chat, wood duck, ruffed grouse and bald eagle are suggested for various riparian types.)

Indicator species should be selected for the special habitats of caves, cliffs, and talus as well as for riparian zones.

There should be MR's for the grizzly bear, wolves, spotted owl, wolverine, bald eagles and fisher.

It seems that at least two other species should have been added to the list of management indicator species· the goshawk and the Pacific giant salamander.

Response: The wildlife sections of Chapter 2, Forest Plan and Chapter III, DEIS, have been revised to clarify the definition and purpose of the indicator species. Appendix H has been rewritten; it documents the process for establishing MR's for certain indicator species.

The establishment of indicator species was a long and difficult process for all Forests in Region Six. The Regional Forester established a policy to aim for a level of consistency among Forests with similar geographic, ecological, and biological settings Many different species were discussed to determine the most representative indicator of a particular habitat type; final selections were made after much deliberation. Refer to discussions in the above responses.

For some habitats, such as the various kinds of riparian areas and special habitats, such as cliffs, caves, and talus slopes, good indicator species were not found. These habitats can best be monitored directly at this time, to ensure that they, and all of their components, are maintained during this planning period.

On-going research and monitoring of the Forest Plan may result in changes in which indicator species are selected, or in standards and guidelines for the MR areas. The concept of indicator species may be replaced with other approaches to maintaining viability of species and the full range of existing habitats on the Forest. Refer to Chapter 2, Forest Plan for the list of Information Needs regarding wildlife species, and Chapter 5, Monitoring Plan.

PLAN IS LACKING IN ON ADEQUATE RIPARIAN INDICATOR SPECIES, OTHER THAN FISH

Your plan is totally lacking in Indicator Species for wetland and riparian lands.

It is incorrect for the Forest to assume that the spawning and rearing habitat requirements of selected fish species adequately represent the biological and physical needs of all the Forest's aquatic animal species. Animal species using riparian and aquatic habitats whose habitat requirements differ from those of fish include beaver, muskrat, mink, river otter, and amphibians. Managing for selected fish species also does not specifically address the habitat requirements of native aquatic and wetland plants. Indicator species should be native species and include other species in addition to fish.

Response: We agree that we are lacking in a terrestrial species for an indicator of riparian health. The biologists for western Washington National Forests met and discussed potential good indicator for riparian, other than fish Some of the species mentioned were beaver, mink, other golden eye, great blue heron, and some species of amphibians. Agreement could not be reached on a particular species. In addition, there were no know monitoring techniques available. One of the future challenges we will have is the monitoring of the species we have selected as indicator species. As we proceed with the implementing and monitoring of the Forest Plan, we will be willing to consider adding another species which can be used as a riparian indicator, if these is a technique available to monitor the species.

We have made some revisions in the goal statement for MA 13 Watershed, Wildlife, and Fisheries Emphasis in Riparian Areas, and placed more emphasis on protection of riparian dependent resources - water quality, fish and wildlife habitat, and soil productivity (Chapter 4, Forest Plan) Also refer to Appendix H, which documents the procedure used to develop a method to meet water quality and riparian MR's.

MMR'S WERE DEVELOPED WITHOUT PUBLIC INVOLVEMENT

Minimum Management Requirements (MMR's) were developed and implemented without public comment, as required by NEPA and NFMA. The true opportunity costs of the MMR's were bypassed.

The public should be involved in the establishment of habitat requirements for the indicator species and the selection of their habitats.

The public should have been involved in the selection of indicator species. The reliance on wildlife biologists as the sole participants in the key decisions about selecting indicator species violates the interdisciplinary planning requirements of NFMA.

The MRs were developed without public input or formal rule making as required by the Administrative Procedures Act.

Response: The National Forest Management Act (NFMA) set legal guidelines for management of the National Forests. The guidelines were interpreted by the Secretary of Agriculture, in cooperation with a Committee of Scientists and with public and professional involvement, to develop regulations. Direction from the Chief of the Forest Service and Region 6 resulted in MR's which reflect the requirements of the laws and regulations in NFMA. The MR direction ensures that minimum legal requirements are applied to all alternatives in Forest Plans consistently across all National Forests. MR's exist for dispersal of created openings, water quality, riparian and wildlife habitat as required by NFMA.

The general concept of management requirements was presented and questions entertained during a series of Liaison Group meetings held in 1984. Refer to the planning records.

In the DEIS, documentation in Appendix B, Appendix J, and Chapter II of the DEIS explained how the MR's were developed. These documents provided reviewers with the information needed to comment on the development of Management Requirements. Comments received on the draft documents were considered in preparation of the FEIS.

Appendix J - now called Appendix H - has been revised in the FEIS and now includes some of the information from Appendix B related to the selection of the most efficient methods of meeting the necessary requirements. The hydrologic cumulative effects analysis was completed, in response to agency, tribal, and public comments. The resulting method to meet water quality and riparian management requirements is documented in new Appendix H. Also, see Chapter II, FEIS, Appendix B, and the Forest Plan, Forest-wide Standards and Guidelines for Water Resources and Riparian Areas, Chapter 4.

DISAGREE WITH PROCESS FOR DEVELOPING AND APPLYING MR REQUIREMENTS

The MR constraints should not have been applied to all alternatives.

The MMR's are not disclosed and discussed in the comprehensive manner required by NEPA

The criterion focusing on the most restrictive habitat requirements is contrary to the Multiple-Use Sustained Yield Act and NFMA. The wildlife requirements must be developed in concert with other multiple use objectives.

The primary effect of using three wildlife species, rather than one, is not improved monitoring of limiting habitat but increased restriction of other forest uses in mature/old growth habitat.

Neither NFMA nor the regulations required the specific sizes or habitat elements of your MR areas.

The consequences of the Forest Service's failure to comply with proper procedures is the artificial narrowing of the range of alternatives and resource outputs.

The MMR analysis fails to describe how the selected method meets the legal requirement.

The Chief's direction does not meet legal requirements for developing MMR's.

RPA program goals must be a factor considered in developing MMR's, and your MMR's preclude meeting the RPA timber goal This violates NFMA.

The EIS fails to highlight MMR decisions.

Nowhere does the EIS discuss the discretionary decisions made relative to the establishment of MMR's.

The MMR analysis does not evaluate alternative methods to meet legal requirements

Resource protection measures must be determined as a result of interdisciplinary analysis and varied among the alternatives of the Forest Plan. This would provide a high level of output of renewable resources.

The MR analysis does not disclose scientific information which supports a different conclusion.

The entire MMR system is fraught with arbitrariness or "best professional judgments."

Some discussion of working with other land management agencies to meet MMR's should be provided.

It appears that access to areas suitable to timber harvesting may have to pass through the MMR's. It is not clear if this is allowed or, if so, what precautions would be necessary.

Response: The MR Appendix has been revised to clarify many of these points. The National Forest Management Act (NFMA) set legal guidelines for management of the National Forests. The guidelines were interpreted by the Secretary of Agriculture, in cooperation with the Committee of Scientists and with public and professional involvement, to develop regulations. Direction from the Chief of the Forest Service and Region 6 resulted in management requirements (MR's) which reflect the requirements of the laws and regulations in NFMA. The MR direction ensures that minimum legal requirements are applied to all alternatives in Forest plans consistently

across all National Forests. MR's exist for dispersal of created openings, water quality, riparian, and wildlife habitat, as required by NFMA (Refer to 36 CFR 219.27.) The Forest management team strove to select the most efficient prescriptions to meet the management requirements. The explanation of MR's and their development has been expanded; see new Appendix H, FEIS.

EFFECTS OF MR's ON OTHER RESOURCE OUTPUTS

The resource trade-offs section of the EIS Summary is silent about MMR's.

The MMR sensitivity analysis does not comply with the Secretary of Agriculture's decision on the MMR appeal.

The Appendix does not reveal how MMR's affect timber production.

You absolutely must change your arbitrary reduction of 3% net green volume for *all cavity excavators*.

Your MMR analysis is totally inadequate and grossly underestimates the impacts of the MMR's. It should be redone

Response: The MR Appendix has been rewritten, better explaining the process used for developing MR's. This Appendix complies with requirements for the MR analysis and documentation. Where opportunity costs are high, alternative ways of managing to meet MR's are examined.

DON'T DROP DEER AND ELK AS A WINTER RANGE MR

We do not agree with dropping the deer and elk winter range MR. You must evaluate viability of individual herds.

Response: MR's were to be developed wherever there was a risk of populations falling below the viability level during the current planning period. Direction from the Chief of the Forest Service (letter to Regional Forester, March 11, 1988) provided that there may be instances where standards and guidelines are not necessary to meet management requirements during the planning period, and sufficient opportunities will remain to impose standards and guidelines needed to meet management requirements beyond that period. A viable population level may be very different than a desired population level, especially in a game species. All alternatives provide for deer and elk populations well above a level which would risk extinction of the species, without needing MR areas set aside to accomplish this.

It is correct that attention must be given to population levels of individual herds, especially if there is any question of viability This issue must be addressed through a combination of species management decisions by the State (e.g. hunting regulations set by the Wildlife Commission and population goals set by the State) and area-specific analyses of habitat capability in the environmental analyses of proposed activities on the Forest. As noted in the monitoring plan, Chapter 5, Forest Plan, we will continue to monitor deer and elk populations, as they are still Management Indicator Species for this Forest.

MR AREAS FOR DEER AND ELK THERMAL COVER ARE NOT NEEDED.

Response: The MR for deer and elk has been dropped from the FEIS. This was discussed in Appendix J, DEIS.

MR's INADEQUATE PROTECTION, OVERLY CONSTRAINING, OR NOT NEEDED AT ALL

MMR levels were intended for use as benchmarks The loss of one habitat or pair at MMR levels provides a risk of non-viability. We recommend the Forest meet level 8 or 9 on the Salwasser Scale, as intended by regulatory language Moderate assurance of viability for 50 years on the planning area does not meet this intent.

The management direction in the preferred alternative precludes viable populations for many of the lowland old-aged forest obligate species.

Many people think your plan will not meet the criterion of protecting at least minimum viable populations of all native wildlife species.

It appears that the spotted owl, peregrine falcon, and possibly the grizzly bear may no longer be viable under your present preferred alternative.

Your prescriptions in the preferred alternative are inadequate in total area, distribution, and quality of habitat maintained for indicator species. Your final plan must include more reasonable protection for old-growth habitat, and that protection must drive the allowable sale quantity, not the other way around.

No constraints to FORPLAN appear to be justified to meet MR requirements. Active forest management will provide more than substantial contribution to meeting habitat requirements for spotted owls, pine marten, pileated woodpeckers,, other cavity excavators, deer, elk and goats

Your constraints incorporated in the Plan to achieve wildlife population goals are excessive. Extensive old growth areas are not required for most wildlife species, and you have ignored the benefits of managed forests with a mosaic of successional stages. Directed silviculture should be included to meet wildlife objectives.

The discussion and documentation falls far short of justifying the proposed constraints on suitable land productivity.

There is no need for MMR's, and in your plan tHE MMR's are over-emphasized and too big. Your requirements are maximum requirements. The number and size of areas should be dropped.

More of the MR's should be placed in areas already restricted from timber harvest.

MMR's must be eliminated. Protection measures which involve the same or more risk of ensuring viability but provide higher timber yields must be examined.

Especially when dealing with the ridiculously low numbers of some of the indicator species, the Forest should err on the side of conservatism by setting aside "too much" habitat, rather than run the risk of setting aside too little, with potentially disasterous results to the wildlife.

The MMR's should be increased to provide for productive and healthy populations of wildlife in perpetuity.

There is a need for MMR's, but in your Plan they are overemphasized and too big.

Response: The process used for developing MR's is described in Appendix H. Research and monitoring needed to permit a full evaluation of the MR standards and guidelines are also described. The implementing regulations for NFMA must be sufficient to meet management requirements and designed to minimize reductions in the achievement of multiple use goals. Where scientific evidence of the effects of management on complex ecosystems was insufficient to provide the entire basis for selecting standards and guidelines, field experience and professional judgment were used to best meet these goals. Monitoring and research will be used to determine the need for changes in MR requirements. Particular focus has been placed on ensuring that management actions during this planning period will not violate management requirements of species whose viability could be at risk during this period

CONCERN ABOUT OCCUPANCY OF MR AREAS

MMR levels were intended for use as benchmarks. The loss of one habitat or pair at MMR levels provides a risk of non-viability. We recommend the Forest meet level 8 or 9 on the Salwasser Scale, as intended by regulatory language. Moderate assurance of viability for 50 years on the planning area does not meet this intent.

MR levels were intended for use as benchmarks The loss of one habitat or pair at MMR levels provides a risk of non-viability. We recommend the Forest meet level 8 or 9 on the Salwasser Scale, as intended by regulatory language. Moderate assurance of viability for 50 years on the planning area does not meet this intent.

Response: The development of MR requirements did not assume occupancy of all MR habitat areas at all times. Allowances for this were made in determining numbers and distribution of habitat areas. Please see Appendix H for a description of the development of the MR requirements.

Additionally, at this time, and through the 10 to 15 year planning period, habitat beyond the MR habitat areas will remain for these species, in wilderness, no-harvest management areas, and areas available for timber harvest but not cut during this planning period.

VERIFICATION AND UPDATES TO MR AREAS

MR's need extensive on-the-ground verification.

The plan must be flexible enough to change the MMR to correspond with new findings. More study must be done to determine what is necessary to keep viable populations.

It seems risky that occupancy of designated pine marten and pileated woodpecker areas is unknown At least some representative areas ought to have been sampled.

Response: Changes are likely to occur as research and monitoring produce new and better information. The monitoring planned for MR areas calls for verification on-the-ground of the suitability of the area as an MR site, monitoring to ensure that areas remain suitable. Monitoring and research (see Chapters 5 and 2, Forest Plan) will test the appropriateness of the indicator species selected and how well MR areas represent the species group for which they were set aside.

PLAN DOES NOT ADDRESS EFFECTS ON THREATENED, ENDANGERED, SENSITIVE SPECIES

The DEIS does not adequately address the impacts of each alternative on threatened, endangered and sensitive species. The Plan does not adequately protect these species. The Plan should include a proposal to reestablish gray wolves and grizzly bears

The Forest should incorporate into the Plan decisive steps toward encouraging re-establishment of the gray wolf population and grizzly bears on the Forest and should insure maintenance of wolf habitat and the prey base.

The grizzly bear and the gray wolf require large tracts of undeveloped land.

Suspected activities of grizzly bear, peregrine falcons and gray wolves must be pursued with fervor and, if appropriate, their natural reintroduction into the Forest and adjacent areas encouraged.

A major flaw in the draft plan is the attention given to endangered species like the wolf and grizzly bear. Do you propose to continue logging and road building while the studies are being done?

The FEIS needs to pay more attention to the effects of road building and logging on threatened and endangered and sensitive species Regardless of the recovery plans for these species, what will be the impacts of each alternative on these species? The destruction of their habitat will drive them closer to extinction.

Maintenance of wolf and grizzly bear habitat includes no further road incursion, extensive road closures, and no logging of ungulate winter range

The Forest Service has done an inadequate assessment of the impacts of road-building and logging on rare animals such as the grizzly bear, the peregrine falcon, and the gray wolf.

Road-building and logging activity will be going into the heart of the remote places needed by these species for survival, and this has been inadequately assessed.

Your statement that grizzly bears will be protected only on a site specific basis is not sufficient. Grizzly bear management must be considered in every timber sale in the North Cascades Ecosystem Road closures should be enacted when conflicts occur to enhance the possibilities of grizzly bear recovery.

The plan does not identify the effects of alternatives on sensitive species.

Activities should be restricted within 1/4 mile of suspected bald eagle habitat, as well as known bald eagle habitat.

> **Response:** Depending on the species present, the type of time of year of the species' use, and human uses of a specific area, needed protection measures for threatened, endangered and sensitive species vary. Refer to Chapter 4, Forest Plan; additions have been made to the Forest-wide Standards and Guidelines since the proposed plan was released, in response to comments from the public, agencies, and organizations. Forest Plan standards and guidelines address typical protection measures which will be employed, but they will be adapted to each site.

A careful analysis must be made of the potential effects of proposed projects on T&E&S species. Whenever a proposed project may affect a federally-listed species in a detrimental way, we will confer with the U. S. Fish and Wildlife Service, the agency responsible for their management, on measures to be taken. Whenever a sensitive species could be affected negatively, an analysis must be made to determine whether the action could affect viability of the species or contribute to a need for Federal listing. Projects are frequently modified and mitigation measures employed.

Recovery plans for federally-listed threatened and endangered species are the charge of the U.S. Fish and Wildlife Service, and are developed with the participation of other Federal and State agencies and extensive public input. They determine measure which will be taken to aid in the recovery of viable populations of a federally-listed species.

There is an existing Bald Eagle Recovery Plan. Standards and guidelines in the Forest Plan meet or exceed those in the Recovery Plan. It is Forest Service policy that project areas will be assessed to determine whether they contain suitable habitat for threatened, endangered and sensitive species, and, if so, whether these species are present. Suspected habitat would be surveyed for use. Surveys for bald eagles are occurring each year, in cooperation with the U. S. Fish and Wildlife Service, the State, the Nature Conservancy, and the National Park Service. These surveys involve a number of members of the public who volunteer to help accomplish this valuable but time-consuming and often cold and arduous work.

The North Cascades Ecosystem is currently being evaluated as a grizzly bear recovery area Members of the public tend to feel strongly one way or the other on the subject of the area being designated as a recovery zone. There will be additional opportunities for public input before a recommendation is made on this subject. If a decision is made for grizzly bear recovery, the methods employed must be addressed in a plan

Wolves and grizzly bears have been sighted occasionally in the North Cascades, and occurred here historically. Both use extensive areas of habitat and cover large areas in the course of their daily lives. This makes them difficult to locate. John Almack, the grizzly bear researcher for the Washington Department of Wildlife, investigates reports of grizzly sightings. One track and one cache site in the ecosystem have been verified as grizzly sites. Neither was on the Forest, but they were close enough to be within the range of bears using the Forest. The habitat throughout the ecosystem is being evaluated and classified according to types of use. This is due to be completed at the end of 1990. Extensive efforts are being made to trap a grizzly bear to study its habitat use through telemetry (and prove its presence) and to photograph grizzly bears at baited camera sites. Habitat use in the North Cascades may be different than in other ecosystems with grizzly bears Any bear that should occur on the Forest is protected from harm under the Endangered Species Act

Both the wolf and the grizzly bear are most likely to be affected by human use of areas. In other areas of their occurrence, it has been found that it is not the removal or timber or building or roads per se which is harmful to these species, but, rather, it is the human activity which results. Road closures are likely to be a tool for their habitat management, and areas such as wilderness, semi-primitive unroaded areas, spotted owl habitat areas, and other areas where human activities are

discouraged or limited will likely be important habitat areas to these species if they are to recover.

Healthy populations of big game are important to the wolf, and one of the Forest Plan's objectives is to maintain a stable population at a fairly high level.

A formal consideration of wolf recovery in the North Cascades has not been started at present. As with the grizzly bear, consideration of recovery would have to consider habitat quality, and would involve balancing human uses with wolf requirements. Laufer and Jenkins (1989), from a study funded by the Washington Department of Wildlife, recently published a compendium of the history and current status of the gray wolf in the Cascade Mountains of Washington. They recommend further research to determine whether any wolf packs exist in this ecosystem, and to evaluate habitat suitability. They conclude that recolonization of wolves may occur in the future, if it has not already.

STATE LISTED SPECIES NOT IDENTIFIED

The plan does not identify which sensitive animal species and species of state concern occur on the Forest. The status of the spotted owl in Washington State has been upgraded to Endangered. The pileated woodpecker has been listed as sensitive by Washington State.

Response: The list of State threatened and endangered species has been updated and included in the documents. The Forest Service Sensitive Species List is revised each year, based on input from the State. Species which are listed as threatened or endangered by the State, but which are not federally listed, are customarily placed on the Forest Service Sensitive Species List. The State of Washington's sensitive list is a category of a lower degree of present concern than is the Forest Service Sensitive List. Species listed by the State as sensitive are ones about which we share information and welcome State input, but they do not fall under policies for managing Sensitive species. Refer to Forest-wide Standards and Guidelines, Threatened, Endangered, and Sensitive Species, Chapter 4, Forest Plan.

NEED ADDITIONAL STUDIES REGARDING THE REQUIREMENTS FOR T, E, AND S SPECIES

Studies are needed of the requirements of threatened, endangered and sensitive species, to ensure the effectiveness of management guidelines and monitoring programs.

Additional research is required to understand the life cycle and habitat requirements of threatened and endangered species. Little data is available to ensure that the planned management will be effective.

Response: This is correct. Surveys and research will continue on these species and their habitat requirements, and adjustments will be made to standards and guidelines for their management as data give us a better understanding of their needs, and of effective protection measures. Refer to the Information Needs section, Chapter 2, Forest Plan.

CONFLICTING STATEMENT ON SITES BEING PROTECTED FOR BALD EAGLES

The statement " . one existing and two potential nest sites..." conflicts with other document statements indicating 4 sites identified for bald eagle recovery. We again ask that the recovery plan specifics be identified in the plan and implemented in the preferred alternative.

Add that the Forest will meet the levels specified in the recovery plan and the recommended locations. The Forest should also provide for alternative nests sites within 1/4 mile of selected recovery sites. Roosts should also be discussed.

Change to read, "Roads within 1/4 mile of nests, in feeding and/or roost areas will have time-of-year restriction on maintenance and use.

Response: This has been corrected in the FEIS; there is one active nest site and three potential, at this writing. Also see Forest Plan, Chapter 4, Resource Summary for Wildlife Management.

USE GRIZZLY BEAR RECOVERY PLAN

Use grizzly bear recovery plan in the MBS plans.

Response: As of yet, there is no approved recovery plan for grizzly bear in the North Cascades. When that plan is developed and approved, we will comply with the intent. Refer to the Forest-wide Standards and Guidelines, Chapter 4, Forest Plan.

PROTECTION AND MANAGEMENT OF GRAY WOLF

Grey Wolf-Gray Wolves historically used National Forest habitat on the MBS but were killed or driven off by humans. There should be no question that the habitat does exist. And while there is little evidence to indicate that wolves are moving in from Canada to re-establish themselves, such as with grizzly bears, there have been numerous sightings of a pack of wolves in the Ashland Lakes are administered by the DNR and adjacent to National Forest. Perhaps it's time to take a look at how to manage for these critters, instead of pretending they don't exist.

Response: Our coordination with the Washington Department of Wildlife and U.S. Fish and Wildlife Service on gray wolf indicated that at this time habitat inventory and evaluation for gray wolf is not a high management priority also, the Fish and Wildlife Service is not actively pursuing a recovery plan for wolf in the worth Cascade, at the present time.

We will continue to be aware of the species and recognizing the need to protect them and their habitat, which we will do when the species is encountered. Refer to our Forest-wide Standards and Guidelines, Chapter 4, Forest Plan.

ERROR IN LISTING OF SPOTTED OWL

The northern spotted owl is a Washington State-listed endangered species, please correct page III-61 in the DEIS.

Response: The error has been corrected in the FEIS.

MANAGEMENT FOR SPOTTED OWLS NOT ADEQUATE TO MAINTAIN A VIABLE POPULATION

The following should be added "SOHA's shall be located and sized to provide sufficient habitat to sustain existing sites and additional habitats as needed for recovery."

We disagree that populations of northern spotted owls will remain viable over the next 50 years in the planning area under the management proposed in the Plan.

State data indicate that the size and dispersal of your protected owl habitat areas is inadequate to maintain the numbers you project.

The EIS should disclose the acreages known to be used by spotted owls.

Response: Management of spotted owls in the Forest Plan follows current direction as set forth in the Spotted Owl Supplement EIS to the Regional Guide (1987). More information regarding areas used by the owl has been added to Chapter III, FEIS. Several processes are underway which may result in changes in the management direction for spotted owls. An interagency committee of scientists is reviewing spotted owl requirements and will make recommendations on needed management in March, 1990. Also, the U.S. Fish and Wildlife Service is considering the proposal to list the spotted owl on the Federal list of threatened and endangered species, with a decision expected in the summer of 1990 Spotted owl management requirements will be updated based on the results of these two processes in the fall of 1990. This is likely to result in amendments to the Forest Plan.

CLARIFY WHAT IS ALLOWED TO OCCUR IN SOHA'S

The prohibition of salvaging blowndown or dead timber should allow for an exception for catastrophic events

"No new road construction shall be permitted in core area" should be changed to "should."

If new roads must be located in spotted owl foraging areas, the acreage of habitat lost should be replaced

Are new motorized trails authorized outside of the core area?

Response: These items have been clarified in the standards and guidelines for MA 11, Old Growth Habitat, Chapter 4, Forest Plan. The emphasis is on not allowing activities which might degrade habitat or disturb owls within the core area (300 acres around the nest site or likely nest site) and minimizing disturbances in the remainder of the habitat area. Unavoidable habitat losses will be replaced with suitable habitat whenever possible.

HOW MANY SOHA'S ARE OCCUPIED BY SPOTTED OWLS?

The final EIS should discuss the results of surveys, including how many of the sites are occupied by spotted owls.

The Forest's SOHA's do not occur where many of your owls occur.

Response: The documents (Chapter III, FEIS) have been updated to include current information on the number of spotted owl pairs known to occur on the Forest. Occupancy, preferably by a breeding pair of spotted owls, is an important criterion for locating spotted owl habitat sites. However, the distribution of habitat sites over the Forest and maintaining dispersal corridors between sites is also important. Sometimes, in order to maintain well-distributed spotted owl habitat over time, a habitat area is located in a portion of the Forest not currently known to be occupied by spotted owls. The MBS does not yet have an extensive history of surveying spotted owl areas for reproductive sites; just because a site is not occupied for one or two years does not mean that it might not be occupied in another year. Spotted owls do not appear to breed every year. Some spotted owls do not respond to the imitations of their calls used for surveying. Because reproduction is relatively low in this part of the spotted owl's range, occupancy by breeding paris is very important, and adjustments to the network will continue to be made in the next few years to improve the network's viability. Refer to Information Needs section (Chapter 2, Forest Plan) and also the monitoring plan, in Chapter 5.

PLAN DOES NOT ADEQUATELY ADDRESS TREAT OF BARRED OWLS DISPLACING SPOTTED OWLS

The public should know of the problem of incursions of the barred owl into spotted owl habitat.

The final EIS should discuss how many of the SOHA's are occupied by barred owls.

Response: The spotted owl SEIS to the Regional Guide addressed the concern that, as barred owls continue to extend their range into and through spotted owl habitat, competition between the two species will reduce the viability of spotted owls. Additional language regarding the relationship between the two species (not yet well understood) has been added to FEIS, Chapter III, Wildlife. Studies are on-going which seek to determine the effects of interaction between the species At the present time, it is not known whether actions are needed to protect spotted owls from barred owl incursion. We also do not know what measures would be effective Barred owls can use a relatively wide range of habitats, including spotted owl habitat. Fragmenting of previously large old growth areas is believed by many to be a factor in the increase of barred owls. However, there are few areas, even deep into unbroken old-growth areas, which do not have barred owls.

PROTECT MORE OLD GROWTH HABITAT IN THE PRATT, ETC. WHERE HABITAT FRAGMENTED

Most of the Pratt Valley should be designated as a Roadless Area to provide suitable habitat for spotted owls and other old growth species. Spotted owls are known to exist in the Pratt, which provides a critical old growth bridge or

travel corridor connecting the east and west sides of the drainage and connecting the northern and southern areas of the Forest.

The Alpine Lakes Plan, which was drafted many years ago, does not adequately consider new information on Spotted Owl Habitat Areas which has been developed since the Plan was adopted.

The area in T22N R10E NE 1/4 of S24, along the lower part of Annette Lake Trail, is about 500 years old, and should be included in a SOHA. Old growth in Sec. 16, T.21 N., R.10.E. is small, but used extensively by a spotted owl pair. Sections 16, 19 and remaining old growth in T 21 N., R.10 E. and R.11 E. Sec. 18 should be preserved.

Existing spotted owl habitat in the Cedar River Watershed should be retained in National Forest ownership and managed as old growth.

Section 14, T.21 N., R.9 E. should be designated as SOHA. It is prime habitat with documented owl habitation. This stand is perhaps the oldest remaining in the watershed and should not be logged.

Owls have not been sighted in the Findley Lake Basin, which is designated SOHA under Alternative G.

Response: Revisions in the spotted owl network in this part of the Forest have been made since the Draft Forest Plan, based on direction for the spotted owl SEIS to the Regional Guide. The Forest Plan proposes a large SOHA centered in the Meadow Creek area of the Cedar River Watershed. It would total about 3200 acres, including certain acres of habitat which the City of Seattle proposes to maintain as spotted owl habitat. This SOHA is a known spotted owl use area. There are five additional SOHA's in this area (see wildlife map, FEIS). The SEIS identified this area as a "Corridor of Concern", where movement of spotted owls through the area might be hampered. As discussed above, spotted owl management needs are being reassessed by an Interagency Scientific Advisory Board, whose recommendations will be used to revise spotted owl management plans on the Forests. It is expected that their recommendations will address this and other areas of special concern.

WOULD LIKE TO WORK WITH THE FOREST ON THE SPOTTED OWL ISSUE

The forest products industry would like an opportunity to work with the MBS, not only on the issue of whether the spotted owl is an adequate indicator species, but, if this is necessary, we would like to work out ways to minimize timber impacts by locating more of the owls in currently reserved areas.

Response: Management of spotted owls in the Forest Plan follows current direction as set forth in the Spotted Owl Supplement EIS to the Regional Guide (1987). Several processes are underway which may result in changes in the management direction for spotted owls. An interagency committee of scientists is reviewing spotted owl requirements and will make recommendations on needed management in March, 1990. Also, the U.S. Fish and Wildlife Service is considering the proposal to list the spotted owl on the Federal list of threatened and endangered species, with a decision expected in the summer of 1990. Spotted owl management requirements will be updated based on the results of these two processes in the fall of 1990. This is likely to result in amendments to the Forest Plan.

THERE IS NO NEED TO SET ASIDE LAND FOR CAVITY EXCAVATOR HABITAT

The preferred alternative deducts 3% of net green volume from all empirical and managerial tables for cavity excavators; this is excessive. The MMR calls for providing enough habitat for 20% of maximum potential excavators. The 3% reduction provides for 40% of potential. PLUS believes that there is no need to set aside habitat or excavators on suitable timber lands, as there is adequate habitat in wilderness and other forested lands not suitable for timber production, such as stream-side buffer areas, etc

An examination of the distribution of acres for each decade over the next 150 years shows that there will always be enough suitable mature forest habitat to provide for a higher percentage of the maximum potential population of cavity excavators that the 40% sought in the preferred alternative It's 3% reduction in all existing and regenerated yield tables is, therefore, totally unnecessary.

Response: We have reviewed the procedures used in relation to compliance with Regional guidelines (Regional Forester letter, August 1988). The MBS is consistent with the interpretation and assumptions used. Refer to the Forest-wide Standards and Guidelines for Diversity and Long-Term Productivity and also for Wildlife, Chapter 4, Forest Plan.

A July 1986 document, under the name of the Regional Forester, "A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region" indicated a 20% population level to maintain viability of cavity excavators would probably not be desirable, but adequate. However, existing Regional policy indicates that we will not drop below 40% population levels on any lands, even those managed for intensive timber emphasis. This 40% population level can not be met by clumping all the habitat in one corner of a watershed and completely eliminating the habitat on other portions of a drainage Distribution is an important issue and population levels have to be managed on a stand-by-stand basis.

The process used to estimate snag and wildlife trees requirements and the effect on timber yield was described in Appendix J, page J-10, in the DEIS. As stated in that section, there is some uncertainty in our estimates. The effect will be monitored and adjustments, if necessary can be made through a Forest Plan amendment. Refer to the Monitoring Plan, Chapter 5, Plan

NEED MORE DETAIL IN STANDARDS AND GUIDELINES FOR SNAGS, DEAD AND DOWN LOGS

The Forest-wide Standards and Guidelines, Items 1. and 2 need to be more specific for determining dead & down snags.

Response: Additional Forest-wide Standards and Guidelines for Diversity and Long-Term Productivity have been added to the Forest Plan; refer to Chapter 4. More detail and specifics as to size and number of snags and logs is found in "Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington " We chose not to include all the detail in these sources, they are included by reference in the standards and guidelines.

PROVIDE FOR 100% OF THE POPULATION POTENTIAL FOR CAVITY EXCAVATORS

It may be a poor assumption that forested areas with timber management will provide 100% of the potential population of cavity excavators. Much of the areas set aside are high elevation where trees are smaller and, therefore, less suitable to all cavity excavators and dwellers.

Maintain 100% of the potential population of snag-dependent species.

Add (in MA prescriptions): "Maintain sufficient dead and down wood for 100% wildlife population potential."

> **Response:** In the Preferred Alternative, there are 346,411 acres suitable for timber harvest, although not all are allocated to full yield harvest prescriptions (see Table II-9c, Chapter II, FEIS). Forest-wide standards and guidelines state we will maintain a minimum of 40% of population potentials on lands where management will take place. In other allocations, such as riparian areas, semi-primitive nonmotorized dispersed recreation, scenic viewsheds and areas set aside for old growth indicator species, plus lands such as wilderness, RNA, etc., habitat will be maintained at a much higher level than the 40% minimum. Allocations such as semi-primitive nonmotorized and motorized, research natural areas, Mt. Baker National Scenic Recreation Area, and Primitive have no scheduled harvest and cavity excavator habitat will be managed to 100% of population potential.

MAINTAIN 40% OF POTENTIAL POPULATIONS

Use 40% level on lands managed intensively for timber, higher elsewhere. Provide for recruitment trees to ensure future snags.

> **Response:** This correction has been made.

MEET 60% WILDLIFE NEEDS

Add to Item 6 , page 4-151 in the Plan: maintain standing dead and down wood to meet 60 percent potential wildlife needs.

> **Response:** The intent of the management prescription for a potential Scenic River allocation is to manage any activity such as timber harvest to provide for near-natural conditions within view of the river. Design shall achieve visual quality objectives We feel that this level of management will produce a population level for cavity excavators greater than the Forest minimum of 40% and probably closer to 60 - 80%.

IN MA 11, MEET 100% OF SNAG-DEPENDENT NEEDS

In MA 11, meet 100 percent of the needs of cavity nesters.

> **Response:** This allocation consists of natural, existing stands of old growth and suitable habitat for Northern spotted owl. Timber harvest is not permitted, so population levels will be maintained at the 100% level.

HABITAT FOR PRIMARY CAVITY EXCAVATORS WON'T ENSURE NEEDS FOR ALL SPECIES

The assumption that managing for primary cavity excavators ensures the needs of all snag dependent wildlife remains unproven for the long term. Some secondary cavity nesting birds and animals dependent on bark sloughing may fall through the cracks on MA 17 lands.

Response: On all lands, including MA 17, at least the MR level of habitat will be provided, with snags and logs in various stages maintained throughout the timber harvest rotation. Snags with sloughing bark, for example, will be provided, both in MA 17 lands and in other allocations with partial yield and no scheduled timber harvest. Also, refer to the discussion under substantive comments/response for Management Indicator Species for wildlife.

USE OF REFERENCES FROM THE BLUE MOUNTAINS IS NOT APPROPRIATE FOR THIS FOREST

The use of the Blue Mountain material for the Mt. Baker-Snoqualmie is questionable, in that this material was developed for a far eastside area. The MBS has many more riparian habitats and much more moisture than the eastside forest. The selection of the common flicker, hairy woodpecker and downy woodpecker as the primary cavity nesters seems appropriate. These species are quite adaptable to a variety of tree sizes and can be managed for in the managed forest The application of providing habitat throughout the managed forest, though, is questionable, in that much of the nesting habitat, and particularly structures for providing holes for these and secondary cavity nesters, are found along waterways

Response: We agree that "Wildlife Habitats in Managed Forests of the Blue Mountains of Oregon and Washington" should not be the primary source of literature for managing cavity excavator habitat on the MBS in Washington. The standards and guidelines for Management Area 12, Mature and Old Growth Wildlife Habitat (pine marten, pileated woodpecker) were developed primarily from the guidelines developed in "Management of Wildlife and Fish Habitat in Forests of Western Oregon and Washington.

INCORRECT ASSUMPTIONS USED FOR STANDARDS ON PILEATED WOODPECKER

This is a prescriptive standard and guideline for pileated woodpeckers It is based on incorrect biological assumptions and should not be included in Forest-wide or MA standards and guidelines.

Response: We feel that this particular standard and guide is based on the best information we are aware of, related to management of pileated woodpecker on the Washington Cascades. The discussion of habitat requirements for the pileated woodpecker were discussed on pages J-7 and J-8 of Appendix J, DEIS. That discussion also included literature references which were used to develop on standards and guidelines.

THE FOREST SHOULD PROHIBIT CUTTING OF SNAGS FOR FIREWOOD

We strongly urge you to adopt a forest-wide prohibition on the cutting of snags for fuelwood by private or commercial harvesters and to see that it is strictly enforced. This should be written into the Forest-wide Standards and

Guidelines. The MBS should also take action to regenerate snags on portions of the Forest that do not contain adequate numbers of snags. Required per acre snag density standards should be established in consultation with the Washington Department of Wildlife and should be implemented Forest-wide. Snags are so critical as wildlife habitat for a wealth of species, that all snags should be preserved as a general Forest Service policy. Any additional loss of habitat for cavity nesters is an "unacceptable loss".

Response: The cutting of fuelwood on this Forest is done in a "controlled environment." Refer to Chapter III, FEIS for an updated discussion on firewood cutting; its use has decreased in the past years. Most permits are issued for use in a designated area of closed timber sales. This area is usually controlled by a central access. The wood available to the public is leftover material from previous harvesting operations, and is on-the-ground and stacked at a landing. The cutting of any standing dead tree is in violation of the issued permit, and subject to fines.

The standards and guidelines provide for management of wildlife trees and habitat for cavity excavating species.

HOW WERE CALCULATIONS MADE FOR EFFECTS ON TIMBER YIELD?

Referring to effects on timber yields to maintain habitat for cavity excavators (page B-97, DEIS Appendix B)· how was this calculated? What does this represent in numbers and sizes? A normal rotation will not produce the larger size snags required by particular species. How many green recruitment trees are available in this method?

Response: A more detailed description of the process used was found in pages J-10 and J-11 of the Appendix to the DEIS. This process is again discussed in Appendix H, Management Requirements, FEIS.

DEIS FAILS TO DISCUSS HARVEST PATTERN EFFECTS ON SNAG-DEPENDENT WILDLIFE

The DEIS fails to identify and discuss timber harvest patterns as important impacts on population viability and dispersal of snag-dependent wildlife. The size, shape, and distribution of forest patches within the large habitat areas are determining factors for population viability This could conceivably affect harvest operations in the first 15 years of the plan.

Response: The discussion in the Plan referred to projects that will be implemented as part of the Forest Plan All projects are subject to analysis under the NEPA process Population viability, if the area includes habitat for snag-dependent wildlife, will be included as an issue in the project-level analysis, and potential impacts evaluated at that time. This type of detailed analysis is beyond the scope of the Forest Plan.

MEET 100% OF SNAG-DEPENDENT WILDLIFE NEEDS

Maintain 100% of the population potential for snag dependent wildlife

Response: This has been changed to 100% in the Forest Plan.

GOAT WINTER RANGE/POPULATIONS NEED MORE PROTECTION

The Preferred Alternative is expected to result in a decline of 13% of goat numbers over five decades. This decline, however, is the opposite effect that many forest users, including environmental groups, hunters, and the Washington State Department of Wildlife The projected decline is really part of the cost of logging old growth. We feel the cost, as documented in the DEIS, is too high and represents a significant unbalance in the Plan. Goat winter range must receive greater protection than is proposed in the Preferred Alternative.

Response: In the FEIS, the management requirement (MR) size for goats has been increased from 45 acres per family group (assumed to be 13 animals) to 585 acres per family group where possible. Where this is not possible, the amount of optimal thermal cover now present in the family group's area is allocated. MR's are a larger size in wilderness or research natural areas (about 45 acres per individual goat) This proposed change was documented and the trade-offs analyzed in Appendix I - Modifications of Minimum Management Requirements for Wildlife, in the DEIS.

Current goat populations are estimated to be about 1,300 individuals, which is below habitat capability, based on vegetative conditions. Habitat capability will remain above current population numbers in the Preferred Alternative. The Forest, along with the Department of Wildlife, will continue to examine goat harvest levels, parasites, and disturbance from road use and recreational activities - all as possible causes for the current goat population number.

In the Preferred Alternative, 17,110 acres are allocated to 15A, the MR intensity, with no scheduled timber harvest; MA 15B Habitat Improvement is not used. This compares to 781 acres allocated to MR (no harvest) in the draft preferred alternative, plus 4,338 acres allocated to 15B, Habitat Improvement. Refer to Table II-7k for trends of mountain goat populations over the five decades. Goat MR areas will continue to be updated as information on important goat use areas is gained.

REVISE MOUNTAIN GOAT PRESCRIPTION TO 45 ACRES PER ANIMAL

Please revise the mountain goat prescription to provide for a minimum of 45 acres per goat on winter range in seral stages V and VI. These may be managed stands, but on a minimum of a 200-year rotation, removed at no more than 5 percent per decade

Response: The prescription for MA 15A, Mountain Goat Management Requirement, has been revised to provide 45 acres of habitat per individual. There is no scheduled timber harvest. Refer to Forest Plan, Chapter 4, MA Standards and Guidelines.

REWORD STANDARDS AND GUIDELINES FOR MOUNTAIN GOATS

The last word, page 4-89 Item 10, should be changed to "avoided" rather than "mitigated." On page 4-178, MA 15, Item 4.a. - change "has been identified" to "may be expected "

Response: While "avoided" would be appropriate for winter range, we feel the wording as is - "activities that adversely affect mountain goats on

their spring and summer range shall be identified and mitigated." - is appropriate for managing spring and summer range.

Referring to restricting road use in goat winter range: we feel the wording "where harassment has been identified" is more appropriate, rather than where harassment "may be expected " We feel it is important to allow for the situation where goats may not be using a portion of identified winter range in a particular year. In that case, harassment wouldn't be an issue. However, if we have identified the harassment, we will restrict use of roads on those parts of the winter range. Mitiation may involve seasonal restriction on road use or recreation use.

MANAGE ALL MOUNTAIN GOAT HABITAT AT THE IMPROVEMENT INTENSITY

All mountain goat habitat should be managed at Intensity 15B, with emphasis that only 5 percent of the acres in this prescription can be harvested per decade.

Response: As discussed above, acres in the Preferred Alternative are allocated to 15A. Alternatives B (RPA) and C in the FEIS include allocations to MA 15B Refer to the discussion and analysis that was included in DEIS Appendix I, with subsequent discussion in the MR Appendix H, FEIS, for the necessity of an MR for mountain goat The MR level, with no scheduled timber harvest, was determined to be necessary to maintain viability of the mountain goat across the MBS

CLARIFY WHERE MOUNTAIN GOAT MA 15 WILL APPLY

The statement that "Forest-wide Standards and Guidelines require surveys for possible goat winter range during project design" is clear enough, as is the statement that, when winter range is identified, the MA 15 standards will apply (Draft Plan, page 4-88). It is not immediately clear when and where the MMR intensity (15A) will be used and what limitations, if any, are intended by the phrase "selected acres of.. mountain goat habitat " (page 4-177)

We are concerned that District Rangers will interpret the ambiguous direction [discussed in the paragraph above] so as to maximize timber harvest.

Response: *The phrase "selected acres ..of mountain goat habitat" applies* to acres of winter range assigned to MA 15. The Forest-wide Standards and Guidelines for wildlife, Item 9 on mountain goats have been clarified. As the inventory for this species is not complete, it is the intent of the Plan to continually update the identified mountain goat winter habitat and, following a Plan amendment, allocated those areas to MA 15. Also, see Information Needs section , Chapter 2, Forest Plan

NO NEW ROADS TO ACCESS MOUNTAIN GOAT HABITAT

MA 15 states that "No new roads will be constructed to access winter range" (Page 4-177). It is critical that roads not be constructed to access any goat habitat (all intensities). Furthermore, access from existing roads must be restricted.

Response: In response to this, and other comments, changes made to this management prescription in the Forest Plan include new wording of Item L.1. which states "No new roads permitted which access winter goat range." Additional clarification has been added to Item 4.1. to restrict use on existing roads when harassment to mountain goats has been identified; and to Item 4.2. prohibiting motorized use (not just ORV use) on goat winter range from October 31 through June 15th.

MBS SHOULD HAVE USED DEPARTMENT OF WILDLIFE'S LANDSAT INVENTORY FOR GOATS

I noted the use of the Washington State Department of Wildlife's brand-new LANDSAT inventory of mountain goat habitat for the MBS draft plan was omitted This was complemented by on-the-ground work by 122 volunteers in 1985. I understand that the State made these data available to the MBS; were they used?

Response: The MBS cooperated with the State on the 1985 inventory; however, the inventory only covered the north end of the Forest. To the extent possible, the inventory was used to remap goat habitat between draft and final plans. Chapter 2, Plan notes that one of the Information Needs is refinement of the mountain goat inventory.

IT IS UNCERTAIN HOW MUCH THERMAL OVER GOATS NEED - MA 15 TOO RESTRICTIVE

To what extent goats require thermal cover is still an unanswered question. In the DEIS, Appendix B, the MBS admits that there is limited information on the location of winter range utilized by goats Because of the limited information, not only of the winter range, but also of the life cycles of mountain goats, it appears to me that close monitoring of the current population is essential, but the reduction of timber harvest or the policy of no new roads is questionable.

The plan overemphasizes the need for winter cover for mountain goats. They do not need so much old growth; any kind of closed cover will do. Riparian zones will work good in most areas. It is very possible that mountain goat populations have grown because clear cutting has been beneficial to their food source.

The MBS has not identified any of the mountain goat winter habitat by an inventory process. They have precluded timber harvest but, on the other hand, state "If timber management activities are conducted, practices applied shall be for the primary purpose of maintaining mountain goat winter habitat." It appears that "shall" should be changed to "should," both here and in Item L. 1.

MA 15: there is no justification for the 5% restriction on suitable lands for timber harvest.

Response: Mountain goats were selected as an indicator species on the Forest because of their status as a hunted species and as a representative of a unique habitat type. Monitoring populations will give an indication of the effects of management activities on that habitat. Refer to Chapter 5, Forest Plan.

Under NFMA, a management requirement (MR) is provided for indicator species for which viability could be a concern if habitat is not provided in sufficient quantities and quality Our consultation with the Washington

State Department of Wildlife (which is responsible for managing the species), indicated goat populations in the Cascade Mountains of Washington were declining. The State concluded that the decline was due to several factors: too much hunting pressure, loss of winter range cover due to timber harvest; and an above-average loading of intestinal parasites.

These deliberations, in concert with the State, indicated to us that significant cover reduction on National Forest land could jeopardize viability of the species. We could not under law take the risk that our management activities might contribute to threatening the viability of this species.

We then needed to establish a management requirement (MR) for assuring a viable population level, while we gathered additional knowledge of habitat needs, and located and inventoried those winter ranges being used by mountain goats.

In DEIS Appendix J (page J-12), we indicated that specific locations of occupied goat winter range are not well known. The areas identified in the DEIS represent the best information available, gathered in conjunction with the State agencies and others. This information will continue to be up dated. Likewise, the required acres to maintain a goat through the winter are not perfectly established. However, because of the viability issue, establishing a management requirement (MR) that dictated constraints and other management activities was deemed appropriate; it is included in the Forest Plan.

As discussed in Appendix I, DEIS, mountain goat MR's have been revised to include a dispersal requirement and the size of the winter range modified to maintain a viable population. In the FEIS, see Appendix H.

DEDICATING ACRES TO MOUNTAIN GOATS IS EXCESSIVE AND UNSUBSTANTIATED

The recommendation of the MBS to have 33,568 acres of timber land dedicated to mountain goats is excessive and unsubstantiated.

Response: We are unable to determine the source of your acre figure. Refer to the above answer for a discussion of the mountain goat MR.

PRATT RIVER AREA HAS IMPORTANT MOUNTAIN GOAT HABITAT

A specific example of goat winter range that could be impacted by logging and road construction is the lower end of the Pratt Valley (Sections 31 and 32 T.24.N., R.10 E). Mountain goats are regularly seen here during the winter months, on the low elevation ledges of Preacher Mountain. A State Department of Wildlife biologist rated this area as excellent goat winter habitat. The area is also a very important elk and deer winter range. The wildlife productivity of this area is very high and as such, should be managed not for timber, but for big game. This data was not known in 1981, when the Alpine Lakes Management Plan was implemented.

Response: There are 4 mountain goat MR's designated in the Pratt River drainage. One is located on the south/southwest sides of Preacher Mountain. These areas will be monitored for adequacy of the size and locations once the Plan is implemented. The lower elevations of the Pratt

River drainage have been identified as Deer/Elk winter range and allocated to MA 14 (which was 14B in the DEIS - the MR for deer and elk has been dropped, as discussed in Appendix J in the DEIS.) Refer to the map for Alternative J (Preferred).

The Pratt River drainage will be managed for big game as well as a variety of other resources, including timber and recreation. The prescriptions and Management Areas for Mountain Goats and Deer/Elk will ensure viability of the wildlife populations that occur in this area.

MOUNTAIN GOAT PROTECTION NEEDED IN LONESOME LAKE AREA

The Lonesome Lake Roadless Area parcel is sort of a way-station for both elk and mountain goats in their annual migrations to and from higher ranges in Mt. Rainier National Park and the lower ranges on Huckleberry Ridge. The goats winter predominately in Section 14, T.18 N., R.9 E. and Section 10. A pileated woodpecker MMR is proposed for Section 14 in most alternatives; this will be of value for many species. The maintenance or preservation of an old-growth timber "migration corridor" in this area is of vital importance for mountain goats.

Response: The Lonesome Lake area is allocated to the following Management Areas in the Preferred Alternative: Scenic Foreground and middleground for the area within Huckleberry drainage, from the ridge in Sections 34, 27, 22, and 15 to the east; MA 1B, Semi-primitive nonmotorized dispersed recreation surrounds Lonesome Lake and Mule Lake. There is a mountain goat MR (MA 15A) in portions of Section 32 and 33. Within the Lonesome Lake area, there is a small portion of MA 12, mature and old growth habitat.

We recognize the value of the migration route and have been able to avoid it in the past five year-period. No sales are planned in the Huckleberry drainage that affects this area in the next five years. As noted in the Forest-wide Standards and Guidelines for mountain goats, Item 9., we intend to survey to determine the presence or absence of mountain goat winter range as part of project design. Refer to Chapter 4, Plan

ALTERNATIVES UNNECESSARILY RESTRICT BOTH TIMBER HARVEST AND DEER AND ELK

The DEIS Preferred Alternative and the other alternatives unnecessarily restrict timber harvest and deer and elk production, when both could be increased by harvesting more timber.

It appears that the Forest Service has purposely left out any habitat improvement in Alternative D, which is unfortunate. Overall outputs can be better if the land base is maintained at a high level where harvest occurs and habitat improvement on winter range is done.

> **Response:** In the FEIS, we developed and evaluated a new alternative, Alternative I. It replaces Alternative D, from the DEIS. The goal of Alternative I is similar to D, but it better responds to public support for an alternative with a high timber harvest, more emphasis on big game, and access for recreation. The goals for Alternative I include: emphasize resources with an established market price, such as timber production, developed recreation, and minerals; and emphasize enhancement of big game habitat and the development and maintenance of an extensive trail system. The outputs and effects of Alternative I are displayed in the tables in Chapter II, FEIS.

HOW WERE WILDLIFE POPULATION NUMBERS DETERMINED?

Your current level estimates for deer and elk are approximately half what the Department of Wildlife would estimate. Do your figures include the effects on habitat usability due to roads? Is your model forage based? Your figures bear little relationship to harvest level; is this due to investments in habitat improvement?

The Forest should put the same effort into developing realistic wildlife and fish population and habitat estimates as you do for timber.

We understand the State Department of Wildlife has data available on elk, goats, deer, and elk on Forest lands that is not being utilized in this planning process.

> **Response:** The population estimates used in the DEIS were obtained through consultation between Forest Service and Washington Department of Wildlife biologists. The State has made population estimates for only a few of the species for which we have attempted to show populations. State population estimates are made for species an a State-wide basis. Using State estimates and pro-rating them to National Forest lands results in a gross estimate, at best. Even though we have indicated these are population estimates for certain species based on individuals, the numbers are really more of an "index" - not actual populations - and should be interpreted that way. They are valid, however, for showing relative changes in population - up or down - due to different management proposed in a particular alternative, and for comparing alternatives.
>
> In the FEIS, Chapter II output tables, we have clarified the text to make interpreting these tables easier.

QUESTION THERMAL COVER REQUIREMENTS FOR DEER AND ELK WINTER RANGE

The proposed prescriptions have no consideration for the forage/cover interrelationships - they are very questionable technically and wasteful in terms of timber productivity Research information does not support the hypothesis that deer and elk require thermal cover for survival. (cites L.L. Irwin and Merril et al)

New data found in the Mount St. Helens blast area make the standards and guidelines for big game too restrictive. It has been proven and used on other Forests that a 20-foot tall, closed canopy stand is all that is needed for deer and elk winter range.

We do not agree that "thermal cover is considered to be the most critical component of big game winter range " Later research studies have shown that the quality of available forage is an equal, if not more, critical component.

The MBS doesn't have the heavy snowfalls on low elevation lands that were anticipated when the optimal elk habitat definition was written.

The distribution of cover/forage in the DEIS, that is 10% forage and as much as 90% cover, is a sure prescription for starvation of wild unglates. It seems intended to save old growth, not deer and elk.

The DEIS would have us conclude that only the "Winter Range" of deer and elk is critical in the selection of a management plan alternative. There is no evidence presented in the DEIS that establishes the necessary habitat requirements for any forms of wildlife. It is imperative the Final EIS does so.

Response: Habitat requirements and relationships for deer and elk on the Nt. Baker-Snoqualmie N.F. are based on Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington, USDA, Forest Service, Pacific Northwest Region, June 1935

Those areas that have been mapped as deer and elk winter range are identified as the most critical and necessary areas to assure maintenance of viability of both species within the planning areas Brown et al, in Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington, find that deer would usually leave foraging areas for thermal cover when temperature dropped below 20 degrees F or rise above 60 degrees F Additionally, elk were observed in the Cedar River leaving clearcuts for thermal cover when solar radiation exceeded 50% of maximum, or about 10.A.M. on clear days, especially during the hot summer months. In these conditions, the elk sought out the thermal protection offered by old growth stands over that of second growth stands.

In order to provide the best opportunity for deer and elk on their winter range, the Forest inventoried areas of optimal thermal cover. "Optimal thermal cover is defined as a forest stand with:

1) Four layers (overstory canopy, sub-canopy, shrub layer, and herbaceous layer),
2) An Overstory canopy which can intercept and hold a substantive amount of snow yet has dispersed, small (<1/8 acre) openings.

These criteria are generally achieved when the dominant trees average 21" DBH or greater, have 70% or greater crown closure, and are in the large saw timber or old-growth stand condition.

Our understanding of the research done after the Mount St. Helen's eruption indicated that if human disturbance was restricted (such as "no hunting"), and nutritious forage was available, these conditions tended to partially compensate for lack of cover. The converse also seemed to be true: good cover may partially compensate for poor quality forage.

It appears inconclusive about whether animals in an extensively-open area, such as the blast zone, can survive a severe winter without good cover. In addition, as human disturbance or hunting pressure is increased, the need for hiding cover may become more of a factor. In any case, as forage areas over time are replaced with young forests, deer and elk use will decrease. Our objective with MA 14, Deer and Elk Winter Range, is to provide a balance of high quality forage and high quality cover to assure viability of the species and a more stable population trend, rather than a "boom or bust" situation.

As we monitor deer and elk populations, the cover/forage ratio is one unit of measure (see Chapter 5, Forest Plan). If we find different ratios can be used to achieve the balance desired, the guidelines will be changed through an amendment to the Plan

DISAGREE WITH DEFINITION OF OPTIMAL COVER

We do not agree that the defined cover will provide "snow intercept, thermal cover, and maintenance forage" necessary to sustain wildlife. We recommend a definition given in Brown 1985, page 229.

Response: The definition shown in the Glossary of the DEIS was meant to be an edited version of that taken from "Management of Wildlife and Fish Habitat, in Forests of Western Oregon and Washington," Brown 1985. In the FEIS, we have added addition wording from Brown, 1985. In addition, and more importantly, the acres identified and mapped as optimal thermal cover are, in fact, those large saw timber or old growth stands that contain the characteristics suggested in the Brown 1985 publication.

MAINTAIN HABITAT IN CRITICAL WINTER RANGE SMALLER THAN 2000 ACRES

All deer and elk critical winter range should be managed under Intensity B [MA 14]. Element C 1.d. should also read the same range of habitat types shall be maintained on winter ranges less than 2,000 acres.

Response: These suggestions and the wording provided have been added to the standards and guidelines for MA 14 (14B in the DEIS). This includes provision for providing habitat in areas smaller than 2,000 acres.

CONTIGUOUS HABITAT AND TRAVEL CORRIDORS ARE IMPORTANT

Item 6. of the Forest-wide Standards and Guidelines for wildlife should also discuss the importance of contiguous habitat management. It should refer to

winter, transition, and summer range and the importance of maintaining travel corridors with continuity between them.

Habitat corridors should be dedicated in every watershed to provide a migration corridor for wildlife. We have discussed this concept with your planning team for the last decade and nothing has been included in the draft forest plan. This failing must be corrected in the final plan, especially in the North Bend and White River Districts.

Response: This concept is a concern. We have added a new Forest-wide Standard and Guideline in the Plan to address this issue See Wildlife, new Item 13. In addition, allocations in the Preferred Alternative increase the acres providing corridors for wildlife: 30 wild and scenic rivers are recommended. A SOHA has been added in the Cedar River Watershed, providing a better owl network on the North Bend Ranger District. Also, the Forest-wide, revised SOHA network better responds to the concern for evenly dispersed habitat for wildlife.

CONSIDER CUMULATIVE EFFECTS OF MANAGEMENT ON OTHER LANDS

Your assessment does not appear to consider the cumulative effects of timber management on intermingled lands and their depressing affect on population numbers of deer and elk due to lack of cover.

The Forest should analyze impacts of adjacent land management on wildlife, in the final plan.

Response: The assessment in our DEIS did not account for effects of management activities on adjacent and intermingled lands Regional Forest Service policy directs each Forest to consider the effects of adjacent and intermingled activities. There is no legal mandate that requires the Forest Service to adjust management in National Forest lands to offset the effects of adjacent activities.

We will continue to assess the cumulative effects of all activities on all land ownerships (national forest and all other) during site-specific project planning activities. Case-by-case decisions will be made (in the environmental document) as to what, if any, adjustments of National Forest management are necessary to offset other land owner's activities.

ACRES OF DEER AND ELK WINTER RANGE INADEQUATE

The Preferred Alternative does not provide adequate winter range for deer and elk, due to extensive clear-cutting, especially in a number of drainages. *Adequate old growth forest needs to be retained for winter range, especially* below 3,000 feet elevation.

Response: We have inventoried 173,300 acres of suitable deer and elk winter range on the Forest. Approximately 33,600 acres have been allocated to MA 14, and will be managed for enhanced winter range in the Preferred Alternative. Vegetation manipulation (timber harvesting) in MA 14 will be prescribed to meet the objective of improving winter range habitat for deer and elk. Most of the area identified as MA 14 is located at elevations below 2,200 feet.

Additional acreage of the remaining, suitable deer and elk winter range will be managed with other management prescription, but generally compatible to the objectives of MA 14.

Our analyses indicates that the acres allocated to MA 14, coupled with other Forest-wide standards and guidelines, will, over time: improve deer and elk winter range habitat; be adequate to maintain populations for deer and elk well above their viability levels; and will assure population levels reasonably close to current populations Refer to the outputs listed in Table II-9k, Chapter II, FEIS

DEIS FAILS TO INCORPORATE STATE WILDLIFE GOALS IN ANY ALTERNATIVE; COVER WILL BECOME LIMITING TO BIG GAME

None of the alternatives presented provide the wildlife and fish habitat protection at levels necessary to achieve State management goals.

Our specific concern is that the FS proposed plan indicates losses for wildlife populations (except for the bald eagle) across all alternatives To protect existing populations, the FS needs to establish a clear policy to protect existing habitat from degradation and to provide for mitigation for areas degraded as a result of management activities, by replacement in kind, on or off site, or other replacement agreed upon by State agencies

Trends across alternatives would indicate that harvesting more timber and building roads creates more capacity for wildlife use; we do not agree Cover is, or will become limiting to big game.

Response: We interpret State wildlife goals to apply to what can be accomplished on all lands in the State of Washington, including National Forest lands The goals articulated by the State in their comments on the proposed Plan inferred that an established set of State goals were specifically translatable to the lands within the MBS.

The two documents we are aware of and referenced for State goals were 1) A Statewide Comprehensive Plan for Fish and Wildlife on the National Forests in the State of Washington, and 2) Strategies for Washington's Wildlife, 1982

The first document made some habitat capability projections for species, by National Forests, by planning area. The planning area for the MBS also includes the Olympic and Gifford Pinchot National Forests. Those projections were a joint task by Forest Service and State biologists.

The second document was prepared by the State and did not express habitat capability in terms of percent of increase for individual species It stated that the goal for species such as deer, elk, and goats was to increase populations over current levels.

Forest Service projections of the effects of proposed management on deer and elk, and other wildlife populations are displayed and discussed in detail in Table II-9k, Chapter II, FEIS.

DEER, ELK, AND GOAT WINTER RANGE SHOULD BE LANDOWNERSHIP GROUP II: RETAIN

Inventoried goat, deer, and elk winter range should be Group II: retain National Forest ownership and acquire private land as the opportunity and/or need occurs.

Response: These lands will remain Group III in the management prescription for MA 14 and 15. Past experience on the MBS shows that maintaining critical lands in a Group III Landownership Classification (available for land adjustment through exchange) provides more flexibility in accomplishing long-term management objectives. Examples are lands located in the Sultan and the Greenwater Basins; active exchange proposals currently involve deer and elk winter range. However, in both cases we will exchange for more acres of important habitat than those Federal lands exchanged.

The Forest Service is interested in retaining management of important habitat types, as part of the Forest-wide goal of maintaining viable populations of all native and non-native species and improving habitat of management indicator species, such as black-tailed deer and Roosevelt elk. (See Forest Plan, Forest-wide Standards and Guidelines.) A Group III classification does not automatically mean the lands will be exchanged. However, if there is an opportunity to improve an ownership problem and improve a habitat management situation, we are interested in maintaining those options.

ROAD DENSITY

The road density should be 2 miles per square mile

Response: Acres identified in MA 14A in the draft Plan have been combined with MA 14B in the FEIS as Management Area 14, Deer and Elk Winter Range Habitat Improvement. The prescription for MA 14 calls for an average open road density of 2 miles per square mile. Refer to Forest Plan, Chapter 4, MA 14, Item C.1.a..

"SHOULD" NEEDS TO REPLACE "SHALL" IN MA 14

Change the wording in MA 14A and 14B, Item L.2.a and g. from "shall" to "should" so that road construction and reconstruction timing constraints are permissive rather than mandatory The use of "shall" throughout this prescription is a restriction beyond the legal requirements.

Response: There are a number of revisions, including minor "wordsmithing" based on public response, in the Forest Plan Standards and Guidelines However, we did not feel that changing the intent and meaning of several of the standards and guidelines from "shall" to "should" was appropriate. With State Department of Wildlife input, the Regional Forester made the decision that the status of deer and elk populations in the States of Oregon and Washington is healthy and that viability is not an issue; therefore, no management requirement (MR) was needed. Refer to DEIS, Appendix I.

KEEP DEER AND ELK AS MANAGEMENT INDICATOR SPECIES; USE INTENSITY 14B

We recognize that the Region has eliminated deer and elk as a management requirement. We recommend their inclusion as a Management Indicator Species and the use of Intensity 14B; it should be retitled Critical Winter Range

Response: Black-tailed deer and Roosevelt elk remain as Management Indicator species. Between the draft and final plans, deer and elk winter range was re-inventoried All of the acres identified as MA 14A [DEIS] and within the updated inventory, have been added to the 14B acres, to form one management area (14) The standards and guidelines shown in the proposed *Plan for MA 14B are the standards and guidelines for* MA 14, *Forest* Plan. There are some revisions included, based on public response. The title of MA 14 is "Deer and Elk Winter Range."

ADDITION TO CHAPTER III, AFFECTED ENVIRONMENT

Add "elevation" to paragraph 4, page III-60 in the DEIS.

Response: This has been added in the FEIS.

ADD TO LIST OF SPECIES IN THE PUBLIC SUMMARY; CORRECT ERRORS

The northern spotted owl has been listed as endangered by the State of Washington since your document was published. Eagles also winter on the Stillaquamish, White, and Nisqually Rivers. In addition, there are eight species of resident game fish in Forest waters, and at least five other fish species.

Response: This has been corrected in this FEIS and Summary.

USE NATIVE SEED IN BIG GAME HABITAT

Any seeding done to improve game habitat should utilize native seed only.

Response: A new Forest-wide Standard and Guideline has been added to the Plan which states seeding in deer and elk winter range will be done with big game-preferred seed. MA 14 also includes provisions for habitat improvement using desirable forage species planting.

CONSULT WITH THE STATE ON SENSITIVE SPECIES, OTHER SPECIAL NEEDS

The Washington State Department of Wildlife should be consulted on all sensitive species Include coordination with the Department on State-listed threatened, endangered, and sensitive species.

Please consult with Department of Wildlife during the planning and development phases, per the new coordination process endorsed by IAC.

Response: Forest-wide Standards and Guidelines for threatened, endangered, and sensitive species prescribe that the MBS will consult specifically with the Washington Department of Wildlife on guidelines for sensitive species. We have added wording to Item 5. of this standard and guideline to clarify that this also includes coordination regarding unique habitats and species of special concern.

MAINTAIN EXISTING AVAILABLE HABITAT RATHER THAN USING ARTIFICIAL TECHNIQUES

Maintaining available habitat is a far surer method of providing for the needs of wildlife. Constructing and maintaining artificial structures to support the wildlife base relies on funds which may or may not be available in the future; it's expensive and dependent on techniques which are not well tested in some cases.

Improvements for fish and wildlife can be quite destructive locally and all should be evaluated on a case-by-case basis, whether they were in existence prior to wilderness designation or not. For example, salting for certain species of wildlife can cause tremendous damage to the plant communities in the area of the salt blocks.

Response: The mandate for management of the National Forest dictates multiple resource objectives, in a balanced mix, to respond to public issues and concerns as determined through the Forest Planning process. Maintenance of critical habitats for wildlife is accomplished through

allocating acres to Management Areas with prescriptions that will assure protection of that specific habitat.

In other MA's, the goals may be to supply one resource output in concert with another. THis would provide for some level of output for several resources but may not be the highest level for any one. Vegetative manipulation on some acres may provide the opportunity for habitat improvement for some animal species. The decision of what can be used to improve the habitat will be made on a site by site basis. It would not be our intent to waste investment on something that will not work. Monitoring the effectiveness of all habitat improvement projects is an item in the Monitoring Plan; refer to Chapter 5 of the Forest Plan. Coordination with the appropriate State agency is standard procedure.

PRIORITIZE PROJECTS IN THE SCHEDULE OF HABITAT IMPROVEMENT

We suggest the proposed projects be re-prioritized to enhance threatened, endangered, or sensitive species first, then those whose populations are declining, followed by those that are of economic significance.

If the experimental black bear forage project is intended to provide silvicultural protection for trees, we suggest it be funded by that department, in consultation with wildlife

For the wildlife habitat improvement schedule of Table C-1, the activity for wetland forage and habitat improvement is not specific, but should be, to be consistent with the rest of the table

Response: This schedule has been updated; refer to the Forest Plan. These Plan appendices will be amended and revised frequently, as projects are accomplished and others are identified.

HOW WERE GOALS AND PRIORITIES SELECTED?

Referring to Appendix C, Forest Plan, the Wildlife and Fish Habitat Improvement Schedules, how were the goals and priorities selected?

Response: Every effort is made to coordinate goals for the program and the five-year habitat improvement schedule with all involved parties, including State agencies, Indian Tribes, and other potential cooperators, such as fish or wildlife organizations. We realize this is a dynamic process. Inventory data and various species needs may change over time The schedule is meant to be revised and updated, as appropriate, to reflect agreed-upon goals and priorities We have encouraged involvement of the Washington Department of Wildlife at the local level and will continue to do so during project planning, NEPA analysis, implementation and evaluation and monitoring.

ADD WORDING CHANGES TO MA STANDARDS AND GUIDELINES

State of Washington recommends the following wording changes to Standards and Guidelines, Chapter 4, Plan: page 4-170, A.1.a. - should read "...fish and wildlife values"; C.1.e. - change "small..." to read "all"; page 4-215, E.1. - add d. "Seed areas in identified winter ranges with big game preferred forage";

add "and other agency" to Forest-wide Standard and Guideline 1. for Recreation; and page 4-73 - eliminate the words "attempt to..." from paragraph 8.

Response: The suggested changes have been made; a new Forest-wide Standard and Guideline address using game-preferred seed (Wildlife, new Item 12).

WE DISAGREE WITH YOUR DEFINITION OF VIABLE POPULATIONS

Referring to page 4-2, Forest Plan: we cannot agree with your definition of viable populations. In some cases, population levels above those currently found on Forest land will be necessary to meet this definition.

Response: The definition of viable populations stated as a goal for Fish and Wildlife come directly from the language used to implement the National Forest Management Act (CFR 219.19). The goal is to maintain viable populations. This is a key item to be monitored, as directed by the Monitoring Plan, Chapter 5, Forest Plan. If existing populations of a species are below a viable population level, it will be our responsibility to coordinate with the State agencies and define what options are available to improve the viability of that species. It will be necessary to differentiate between viable levels and levels established as State goals for certain species.

CHANGE THE INDICATOR OF RESPONSE FOR WILDLIFE

Old growth left over time is not a good indicator of response for the wildlife ICO. If areas are too small, located at the wrong elevation, or too far apart, they may not provide useable habitat. Some model to measure "usability" of old growth by wildlife would better measure success.

Response: Old growth remaining over time is only one of several indicators used to measure how the alternatives respond to the issues and concerns. For the Old Growth Ecosystems and Fish/Wildlife/Plant Diversity ICO, there is an indicator entitled "habitat for old-growth wildlife management indicator species (under 4,000 feet)" which should meet your concerns. Refer to Table I-1, Chapter I, FEIS for a complete list of indicators of response.

MAINTAIN NEST SITES

Nest sites are required to be maintained by law, whether in active use or not. In the Forest-wide Standard and guideline, change the last sentence: change "should" to "shall", and add consultation with Department of Wildlife.

Response: There is no Federal law that requires maintenance. The referenced standard and guideline has been retained in the Forest Plan. Because the State of Washington does have a law providing some protection, the MBS will coordinate with State biologists on activities in the vicinity of habitat for species of special concern.

ADEQUATE PILEATED WOODPECKER HABITAT

Recent studies in western Oregon indicate that 540 acres is the average amount of old growth used by pileated woodpeckers for breeding purposes.

Response: Research Staff with the Old Growth Project in Olympia (RWU 4203 Wildlife Habitat Relationships in Western Washington and Oregon) presented papers at two symposia in 1988. The papers presented the early results of studies that were done to determine which species of wildlife are closely associated with old-growth Douglas fir. For a number of species, the studies were not conclusive and further work is needed. These include Douglas' squirrel, pileated woodpecker, northern goshawk, pine marten, and seed-eating winter resident birds. As additional information becomes available (or is scheduled, as part of Plan implementation) we will include it in the Plan, or write a Plan amendment if conditions change so that an amendment is necessary.

HIGH-ELEVATION OLD GROWTH HAS LITTLE VALUE FOR WILDLIFE

Thirty-five percent of old growth is in wilderness. Much of this old growth is at a relatively high elevation and, in many cases, has only marginal wildlife value.

Response: Approximately one-third of the 232,500 acres of old growth within wilderness are located above 4,000 feet in elevation. About 56% (131,300 acres) are located between 2,500 and 4,000 feet, and the remaining 14% (32,800 acres) are located below 2,500 feet in elevation. (Note. these are R2MAP acres and may differ from others throughout the documents.) MR acres for the northern spotted owl and the pine marten and pileated woodpecker only include acres that have been inventoried as suitable habitat for the species. Refer to FEIS Chapter III, Wildlife.

CONFLICTS WITH DOMESTIC WILDLIFE NOT DOCUMENTED

Conflicts between domestic livestock and wildlife are not fully documented or evaluated. Cattle and sheep can transmit diseases to deer, bighorn sheep and mountain goats. How will allotments be modified or reduced to avoid disease contamination of wildlife species?

Response: As discussed in Chapter III of the DEIS, there is limited available domestic range on the Forest. In the past, little grazing has occurred on the Forest, with available range being transitory, occurring in timber harvest units. There are no currently active allotments.

PLAN CONFLICTS WITH STATE PLAN FOR FISH AND WILDLIFE

Plan appears to be in conflict with the statewide comprehensive Plan for Fish and Wildlife.

Response: This was mentioned in Appendix G of the DEIS. While the Statewide Plan does mention goals for population levels of certain species (ie. Mountain Goat, Roosevelt Elk) it is neither site nor area specific, so the degree of conflict is debatable.

NO EVIDENCE IN DEIS FOR NECESSARY HABITAT REQUIREMENTS FOR WILDLIFE

The DEIS would have us conclude that only the winter range of deer and elk is critical in the selection of a management plan. There is no evidence presented in the DEIS that establishes the necessary habitat requirements for any forms of wildlife. It is imperative the final EIS does so.

Response: The MBS, as well as all Forests in Region Six, used the management indicator species concept (reference: 36 CFR 219.19). It was discussed in the DEIS, and is discussed in more detail in Chapter 2, Plan and Chapter III, FEIS. By identifying a species that is a good indicator of a habitat found on the Forest, we are predicting we will be able to determine the effects of management activities and relate them to population levels or indices to assure viability of the MIS species, as well as others who utilize the same habitat type.

Habitat needs have been identified for the northern spotted owl, pileated woodpecker, pine marten, bald eagle, blacktailed deer, Roosevelt elk, cavity excavator species, and anadromous fish (riparian habitat). We have identified and dedicated specific habitats for some of these species with a management prescription. Others, such as cavity excavators, will be maintained through application of standards and guidelines throughout the Forest, unless otherwise noted in an individual MA prescription.

CHANGE DATES TO MINIMIZE DISTURBANCE IN MA 12

In MA 12, for pine marten and pileated woodpecker: change the timing restriction dates from April 1 to September 31 to April 1 to June 15, in response to our District wildlife biologist's response.

Response: These changes have been made in the prescription for MA 12, Forest Plan.

ADD TO MA 13 PRESCRIPTION

Under Facilities, for MA 13 Riparian: add to 2.a. "calving or fawning and raptor nesting."

Response: These specific changes were not made, as the wording of this standard in the Forest Plan states road construction and reconstruction will be permitted in riparian areas only when riparian values are protected. Wildlife is included - in the MA 13 Goal Statement and elsewhere - as one of values of riparian areas.

CONFUSION OVER NON-CONSUMPTIVE WILDLIFE USE

In Chapter III, page III-60, the figure of 33% ("non-consumptive use of wildlife exceeds consumptive use by 33% ..") conflicts with table figures in the Plan which attribute only 6% of wildlife recreation to non-consumptive use.

Response: The 33% figure represents non-consumptive uses occurring further than one mile from the users home, on both NF and non-National Forest lands. The 6% figure represents the percent of non-consumptive use we have estimated to occur on the MBS. We recognize this 6% is probably low;

additional data - as the Plan is implemented - will allow better analysis, with amendments if necessary.

PROVIDE ACTUAL ACRES OF HABITAT IMPROVEMENTS, NOT ACRE EQUIVALENTS

To avoid confusion and provide a clear indication of the actual extent of wildlife habitat improvements, we suggest providing actual acreages as well as acre equivalents.

Response: Appendix C, in the Forest Plan, shows the fish and wildlife habitat improvement schedules; the unit of measure is both structures and acres.

NO DESCRIPTION OF WILDLIFE MODEL

We cannot find a description of your wildlife model development or any coefficient development, even though it is stated to be in the appendix volume. Please describe it and whether the loss of use of habitats due to the presence of open roads was used to reduce the population numbers reported.

Response: This description has been clarified in Appendix B, Chapter III. The effects of open roads on wildlife (especially deer and elk) are discussed in Chapter IV, Effects, FEIS.

ADD DISCUSSION REGARDING PROTECTION OF WATERFOWL

The final planning documents should also include a discussion on protection on- and off-Forest waterfowl habitat that could be adversely affected by forest activities.

Response: The MBS has no low-elevation, high waterfowl density areas, but riparian protection (see Chapter 4, Forest Plan, Forest-wide Standards and Guidelines for riparian, plus MA 13) and planned waterfowl habitat improvements (see Appendix C, Forest Plan) will contribute to waterfowl management. See additional discussion on snag protection (Chapter 4, Forest Plan, Forest-wide Standards and Guidelines). The common loon is discussed in Chapter III, FEIS, Wildlife; it is also a sensitive species and is protected by regulation. For the effects of implementing the alternatives, refer to Chapter IV, FEIS, wildlife.

FOREST MUST CONSIDER THE IMPLICATIONS OF THE MIGRATORY BIRD TREATY ACT

The FS should consider the implications of the Migratory Bird Treaty Act for projects on the Forest Standards and guidelines for the Plan give limited indication that the MBS will be managed to specifically conserve migratory birds and their habitat.

Response: The Migratory Bird Treaty Act applies on the Forest. The needs of migratory birds are considered in the Forest-wide Standards and Guidelines and MA prescriptions for MA 11 and 12 (old growth habitat and mature/old growth habitat), scenic viewsheds and wild and scenic rivers (the corridors of MA 2A, 2B, and 5), wilderness, RNA, and in MA 1A and 1B - all provide and maintain habitat for migratory birds.

APPLY A 100 FOOT NO-HARVEST PRESCRIPTION ALONG ANADROMOUS FISH STREAMS

We recommend a 100-foot no harvest prescription along anadromous fish streams, and the prescription applied to other streams as provided in our general comments.

> **Response:** Most of the Forest's anadromous fish habitat falls into either Class I or II stream classes Refer to the standards and guidelines for MA 13D, Chapter 4 Forest Plan. For project level planning purposes, at least 100 feet on each side of all stream classes must be considered as riparian areas. As stated in MA 13, timber harvesting is permitted when riparian objectives can be met, and if the soil, water, fish and wildlife values in these riparian areas can be protected and mitigated. The timber management will be an extended rotation. Other guidelines prescribe specific requirements for the management area.

ENHANCEMENT SHOULD BE AT A HIGH LEVEL; INCLUDE REGULATIONS FOR LEAVE TREES ETC.

I am pleased to note that MMR's with regard to riparian treatments are maintained throughout the process. Stream enhancement expenditures are preferred at a high level, through this has not been defined. It is disturbing to note that no riparian regulations are stated with regard to leave tree, viable condition, stand density and/or composition.

> **Response:** MA 13D is a high investment prescription for enhancement expenditures; this would equate to $250,000 to $400,000 per year, allocated to develop, plan, and implement habitat improvement projects over the Forest. Prescriptions are not stated for leave trees, condition, or stand density because the MBS does not currently have a Forest-wide riparian area data base; without such a data base, it is not possible to state acceptable or unacceptable conditions for these riparian features As stated in the Forest-wide Standards and Guidelines, and noted in the Information Needs section (Chapter 2, Plan), during implementation and continuing through the first planning period, a Forest-wide riparian data base will be collected and evaluated.

LINKS BETWEEN FOREST MANAGEMENT ACTIVITIES AND FISH PRODUCTION NEEDED

Under "Fish-Water-Riparian," modifications are needed. The primary thrust should be development of quantified linkages between forest management practices, environmental changes, and anadromous fish production. In addition, the specific methods proposed need careful review. We have found that (1) summer standing crops in stream study sections are not a good indicator of eventual smolt production; and (2) that smolt production from selected tributaries does not necessarily correlate well with system-wide production levels.

The discussion under "Anadromous Fisheries" seemingly explains the intent of "acceptable level," namely: The approach was taken to incur investment costs that, at a minimum, would maintain existing levels of anadromous fish runs, which are considered minimal for population viability." It also makes it clear that the draft plan will have no quantified linkage between fish production and levels of environmental manipulation ("were difficult to quantify").

Fish
Effects on Fish

The document contains no quantified statements that show relationships between environmental impacts from forest activities and fish production.

Response: A better discussion of the tie between Forest management activities (including timber harvest and road construction), environmental changes, and fish production has been added to Chapter III, Fish, in response to these and other comments. We have also added discussion in Chapter IV regarding the lack of a model (such as sediment or recovery model) to fit the situation on this forest. To address the concern raised by these and other comments on the DEIS, the Forest completed a Forest-wide hydrologic cumulative effects analysis. For a description of the development of this process, refer to Appendix H. This procedure resulted in a better method of meeting water quality and riparian management requirements (MR's) the result is a set maximum number of acres available for final harvest in 70 of the Forest's 78 allocation zones (or watersheds). Again, for more detail and the literature/research used, and the process developed, refer to new Appendix H.

DISCUSSION OF FISH OUTPUTS BY ALTERNATIVE IS POOR

The analysis of fisheries by the Draft EIS is deeply disappointing It suggests that the available fish harvest should be the same under Alternatives H and G. I have not found in the DEIS or elsewhere in the documents an adequate for the fish outputs between these two alternatives Because Alternative H will involve more road building, more logging, and more general development than Alternative G, it will inevitably degrade the pristine environment more than Alternative G. This is reflected elsewhere in the DEIS, such as the sediment index for alternatives. Such a substantial difference in sedimentation alone must mean a substantial difference in fish outputs. A better analysis of fisheries is necessary, or at least a clearer and better explained one.

Table II-7h, shows that Alternatives D, B, H, H-Departure, G and C will produce identical amount of pounds of fish per year; A, E-Departure, and E will be likewise. This is absurd and highly unrealistic! Not only is no variation indicated between alternatives, but also no variation is expected to take place throughout 5 decades of increased road building, logging, and other development. These figures in this chart are quite suspect, especially in regard to fish populations.

The analysis of impacts from each alternative to fish resources is again erroneous and contrary to any reasonable scientific conclusion.

We are expected to believe that construction of and heavy traffic on logging roads, with resultant erosion and sedimentation, will have no effect on commercial harvest of anadromous fish that spawn in streams in these areas - i.e. that the output will be the same for alternative H as for the preferable alternatives, C and G. This is nonsense.

Response: The discussion in Chapters III and IV in the FEIS have been rewritten and should provide a clearer explanation of the problems in trying to apply a sediment-related or other model to this Forest. In order to address the effects on fisheries, the resource was included as a major component of the hydrologic cumulative effects analysis. The results of this procedure - developed to meet water quality and riparian MR's - is a constraint, by watershed, Forest-wide, on the number of acres available for

final timber harvest, by Decade. Refer to new Appendix H for more discussion. Appendix C, Forest Plan, shows the Fish Habitat Improvement Schedule for the Preferred Alternative, including estimated costs, by project, per year for first years of plan implementation.

NEED TO QUANTIFY EFFECTS OF SEDIMENT ON FISH
ASSUMPTIONS, TIES BETWEEN SEDIMENT PRODUCTION AND FISH NOT SUPPORTED IN DEIS

In the DEIS, it is stated that it is not possible to quantify the effects of sediment on fish production. It should be noted, however, that the Olympic National Forest has used a direct quantified linkage between sediment and fish production in their planning process. In addition, other National Forests in this state have used an "index" for environmental impacts on fish (Gifford Pinchot) and a direct relationship between fish production and riparian area disturbance (Umatilla). These same planning options were available for the MBS, but were rejected for largely unspecified reasons.

Given the lack of reliable data in the area of fisheries and sedimentation, the plan is based on a number of assumptions which are stated at various times in the documents, but are never supported by factual evidence. We believe that many of the assumptions are invalid, consequently the analysis which is based on them is flawed. Some of the invalid assumptions upon which the plan and its analysis are based include: Sedimentation from continued timber harvest and road construction under all alternatives will have no impact on the fisheries resource. This assumption fails to recognize that serious damage has already occurred to the fisheries resource from timber harvest and road building in the past and damage is continuing, despite improvements in techniques and erosion control measures. The Plan admits that these activities will result in sediment production, and no evidence is presented to document that damage to fish habitat and populations will not occur or that preventive and mitigation measures have been effective or successful. Evidence from watersheds such as Canyon Creek indicates that landslides occur even on units logged by helicopter. The statement that riparian buffer strips would prevent sediment from reaching the stream is incorrect. In Canyon Creek, for instance, when mass wasting activity has occurred on steep slopes most of the sediment from landslides has been documented to end up in the stream channels. Therefore we believe this assumption is invalid.

The sedimentation analysis is not tied to effects on fisheries resources and recovery of disturbed fish habitat.

Increasing the sediment input into a stream environment has been shown to have a direct negative effect on the ability of the instream habitat to support fish Sediment-related impacts are side-stepped through the basic assumptions of the Plan that further timber harvest and road building activities will not decrease fish production and that sediment impacts to instream habitat and fish production will be offset by mitigation/enhancement opportunity.

FS studies on other forests have documented the increase of sediment production, debris torrents, and road failures, as well as the resultant decrease in fish production caused by forest management activities The DEIS fails to make any attempts at quantifying these impacts to fish resources. Please provide references for any supporting information you might have on this question.

Fish
Effects on Fish

One of the major shortcomings of the Plan is the lack of any attempt to tie the effects of increased sediment from timber harvest and road construction to degradation of fish habitat and reduced fisheries production. The plan loses its credibility to us due to this failure. There is abundant evidence documenting the damage to fish habitat from landslides which occur when unstable areas such as Canyon Creek are logged. Consequently, the failure of the plan to admit that there will be adverse effects to the fisheries resource from timber harvest and forest roads in unstable areas appears to be a whitewash and cover up. We suggest using the sediment yield calculations, with the improvements suggested below, together with the information on the existing habitat conditions and the timber sale plans, to calculate sediment yield and predict effects to fish habitat and stocks on a sub-watershed basis, i.e. the size of Canyon Creek or the South Fork Nooksack.

Response: The model used by the Olympic NF is a model developed for use in the Idaho Batholith. It only includes fine sediment. On the MBS, the major sediment problem is the large bedload materials. The discussion in Chapters III and IV in the FEIS have been rewritten and should provide a clearer explanation of the problems in trying to apply a sediment-related or other model to this Forest. In order to address the effects on fisheries, the resource was included as a major component of the hydrologic cumulative effects analysis The results of this procedure - developed to meet water quality and riparian MR's - is a constraint, by watershed, Forest-wide, on the number of acres available for final timber harvest, by Decade. Refer to new Appendix H for more discussion. An extensive research and literature search was completed prior to development of the MBS-specific process; this documentation is included in Appendix H.

FISH INCREASES HEAVILY BASED ON UNPROVEN MITIGATION AND ENHANCEMENT TECHNOLOGY

The fish production models contained high rates of increase in fish biomass during the beginning stages of the first decade. These yearly high rates of increase in fish biomass appear to be heavily based on the application of unprove mitigation and enhancement technology.

"There will be no decrease in fish production from the current level in any alternative " This statement needs to be examined. It stems from the belief that mitigation technology can be used to fully offset the adverse effects of logging on fish habitat so that current levels of fish production remain stable. This belief is not shared by the State fisheries agencies or the Fish and Wildlife Service.

Response: In order to address the effects on fisheries, the resource was included as a major component of the hydrologic cumulative effects analysis. The results of this procedure - developed to meet water quality and riparian MR's - is a constraint, by watershed, Forest-wide, on the number of acres available for final timber harvest, by Decade. Refer to new Appendix H for more discussion. Appendix C, Forest Plan, shows the Fish Habitat Improvement Schedule for the Preferred Alternative, including estimated costs, by project, per year for first years of plan implementation.

NOT ENOUGH CONCERN FOCUSED ON DAMAGE TO FISHERIES FROM CLEARCUTTING

We question whether enough concern has been focused on the damaged to fisheries from clearcutting. A recent paper by Ruper Andrews, former director of Alaska Department of Fish and Game's Sport Fishing Division sums the problem up as: "Scientific research has not been accomplished to identify constructive changes in the current harvesting of timber and the overall impact on fisheries or individual stocks and populations of fish. We do not know how to harvest old growth forests and maintain optimum fish yield or enhance fish yield. The second statement we can make is that we aren't doing very much to shed any intelligent light on the first statement." We feel that these data are applicable to the MBS and we feel that forest harvests should proceed in a much more cautious manner until the relationship between timber harvest and fisheries has been more clearly documented and understood.

Our views on the uses to which those forest lands should be put are influenced by some of the things we have seen happen that have hurt the steelhead resource. Years of improper logging and logging-road construction, both on Forest Service lands and other adjacent lands, have resulted in the degradation of virtually all of the rivers flowing into Puget Sound. They muddy up and flood easier and often, their courses have straightened and gradients steepened, and their channels have become more clogged with grit and sand, all to the detriment of the steelhead. More and more we are seeing slides occurring similar to the DeForest Creek Slide that has all but wiped out the world-famous run of summer steelhead in Deer Creek, all because of years of careless logging and logging-road construction on watershed lands that are too steep or unstable for that purpose.

> **Response:** In the FEIS, the future timber harvesting activities will be planned and developed within the Forest's watersheds based on the current and future condition of the in-channel fish habitat. Sediment related impacts and effects on the ability of the habitat to support fish will be identified and acknowledged through the application of management requirements for water quality and riparian areas. Applying the MR includes a timber harvesting constraint of the acres available for final harvest, by decade, on 70 of the Forest's 78 allocation zones (or watersheds). Refer to new Appendix H.

SEDIMENT YIELD CALCULATIONS SHOULD BE FIELD TESTED; DISPLAY BY WATERSHED

The validity of the sediment yield calculations should be tested by field checking to determine if the aerial photo analysis is identifying all the features present in the field. There is also no evidence that erosion from the surface of landslides over time can be equal to the initial failure volume. It needs to be determined whether this volume is being measured in the erosion plot calculations. It is possible that sediment production is several times higher than the figures in the sediment yield calculations. Display sediment yield by watershed and separate out background sediment production from that generated by past management practices.

> **Response:** The Forest does not have the information nor data collected by field sampling to validate the sediment yield calculations. We do acknowledge that in some watersheds, erosion from the surface of landslides over time is equal to or greater than the initial failure, and that landslide occurrence and frequency is greater in the northern portion of the Forest (Chapter III, FEIS). Because of this variation, the risk for,

presence and frequency of landslides, and sedimentation, the MBS has examined the condition of each watershed in the process of a hydrologic cumulative effects analysis. See new Appendix H. We will monitor watershed acceptability, sedimentation, and other activities to determine the effects of sediment production on the Forest's fishery resources. See monitoring plan, Chapter 5, Forest Plan

FISHERIES PRODUCTION CONTINUES TO DECLINE; FUNDING FOR ENHANCEMENT INADEQUATE

Fisheries production is continuing to decline due to habitat degradation from past management practices, especially due to sedimentation from mass wasting and debris flows, as in the cases of Canyon Creek and Finney Creek. The difficulty of repairing damaged habitat is also seriously underestimated. In many cases, restoration of habitat may not be technically or financially feasible. Natural recovery times are slow and the effect of past practices may last for many decades. Past damage to the fisheries resource is not acknowledged, and it is assumed that maintaining the present degraded conditions existing in many of the streams is satisfactory performance for the Plan. We consider the present degraded condition of the habitat in many streams on the Forest to be unacceptable and the habitat improvement program to be unprove and underfunded. Reduced fisheries production caused by past timber harvest is adversely affecting tribal income from fishing and is endangering the viability of valuable fish stocks, such as the Nooksack spring chinook. Funding for the watershed improvement program to reduce sediment production and speed stream recovery is inadequate for the need. Therefore we consider the assumption that current production is stable and adequate to be invalid. We think the Forest Service has ducked management responsibility for the condition of the fish habitat The Plan should recognize the habitat degradation that has occurred and incorporate a plan for restoration of habitat to acceptable levels.

Response: These concerns for existing in-channel and fish habitat conditions for the Forests watersheds were considered and used to evaluate the current acceptability or unacceptability in all watersheds during the Forest's hydrologic cumulative effects analysis. This analysis, in response to public comment, is documented in detail in new Appendix H. A total of 70 out of 78 watersheds on the Forest were examined and rated either acceptable or unacceptable. In order to address the effects on fisheries, the resource was included as a major component of the hydrologic cumulative effects analysis. The results of this procedure - developed to meet water quality and riparian MR's - is a constraint, by watershed, Forest-wide, on the number of acres available for final timber harvest, by Decade. Appendix C, Forest Plan, shows the Fish Habitat Improvement Schedule for the Preferred Alternative, including estimated costs, by project, per year for first years of plan implementation.

WHAT ARE THE THRESHOLD LEVELS FOR FISH?

What are the threshold levels for fish and fish habitat and what will be done if management activities cause a drop below that level? It is not sufficient to say the impacts are adverse and unacceptable; rather, the ways and processes for avoiding, protecting, and mitigating need to be discussed.

Response: Refer to the above response for a brief discussion of the hydrologic cumulative effects analysis; see new Appendix H. The monitoring

plan, Chapter 5, Forest Plan, includes the monitoring that will be done, the activities that will be monitored, the threshold of variability, etc. If, during plan implementation, evaluation, and monitoring, it is found that the standards and guidelines are not moving us towards the desired future condition for a management area/resource, a plan amendment will be considered.

COMPARISON OF CUMULATIVE EFFECTS OF TIMBER VERSUS ROADS ON FISH IS UNCLEAR

It is stated that "timber management activities generally have less cumulative effect on spawning habitat quality than do forest roads." The meaning of this comparative statement is unclear Is it based on habitat monitoring on the MBS? Both have the potential to cause adverse environmental impacts and need to be addressed as such.

The cumulative impact assessment for fish is inadequate.

Response: The statement is based on the literature collected from studied watersheds in the Pacific Northwest and British Columbia. On the MBS, this has been observed and acknowledged for the past 10-15 years. Both management activities (timber harvesting and forest roads) can and do cause adverse environmental impacts to the in-channel beneficial uses of the Forest's watersheds. Much of this impact is cumulative in nature. In addition, we have included the fishery resource as a major component in the Forest-wide hydrologic cumulative analysis, completed to develop a procedure to meet water quality and riparian MR's.

FISH, RIPARIAN, STREAM DATA AND INVENTORIES LACKING

Of primary concern to the Tribes is the impact of harvesting activities to fish and fish habitat. The Plan (Chapter 2) indicates gross data gaps with respect to a section entitled Fish-Water-Riparian. The FS lacks complete stream surveys, an inventory of anadromous streams, instream flow impacts model, *assessment of fish production capability linked to habitat improvements, and* more. These data needs are critical if the FS hopes to achieve its standards and specific management directories of maintaining habitat for viable populations of fish.

Throughout both the Plan and the DEIS, the Forest Service announces its dedication to preserving fish habitat The FS cannot achieve this goal without the information that they acknowledge they lack. The information the Forest Service uses to develop and assess its planning alternatives is in many cases neither unique nor relevant to the MBS. Frequently, supporting data constitutes general literature searches which are not geographically relevant to the MBS.

Response: As stated in Chapter 2 of the Plan, these data and inventory needs are important; many of these information/inventory needs are already built into the Monitoring Plan, Chapter 5, Plan. Each of the 78 allocation zones (watersheds) have been analyzed between draft and final plans, and rated as being in either an acceptable or unacceptable condition. As we implement the Forest Plan and management requirements, one of the items we will be monitoring is the condition of watersheds, and whether they are recovering. Also, refer to the literature used in the MBS hydrologic cumulative effects analysis, Appendix H, FEIS.

Fish
Effects on Fish

NEED A SPECIFIC DISCUSSION OF THE IMPACTS OF ROADS ON FISH

The presentation of the impacts of roads to fish is again a presentation of broad categories of what can occur, and of general events that are known to occur, rather than specific discussions of what is taking place on the MBS.

> **Response:** In the FEIS, the Forest addresses the past, present and future impacts of roads as well as timber harvesting activities. The Monitoring Plan (Chapter 5, Plan) and Information Needs section of Chapter 2, Plan have been updated. Also, refer to new Appendix H.

SHOULD STATE WHAT HAS HAPPENED TO FISHERIES AND PLANS TO REVERSE IMPACTS

Chapter III, DEIS: "Major effects to fisheries resource and habitat come from stream sedimentation resulting from road building, timber harvest activities, and recreation over-use on erodible soils; and from vegetation disturbances along streams, primarily that which removes shading vegetation or leaves excess debris in the streams " This is more a discussion of environmental consequences that affected environment. The DEIS needs to describe what these have done to the MBS environment and what is being done to curtail or reverse impacts.

> **Response:** A number of changes have been made to the fisheries discussion throughout Chapters III and IV, FEIS. The Mitigation section of Chapter II also discusses planned measures included in the standards and guidelines to avoid, minimize, reduce, or compensate for undesirable environmental effects. In addition, the FEIS addresses the past, present and future impacts from sedimentation as a result of timber management and road building activities in the discussion of the development of a hydrologic cumulative effects analysis to develop a procedure to meet water quality and riparian MR's. Refer to new Appendix H.

DOCUMENT DOES NOT ANALYZE BASIN-SPECIFIC EFFECTS OF ACTIVITIES

The document makes no attempt at analyzing basin specific effects of forest management activities on fish runs We are particularly concerned about areas such as the South Fork Stillaguamish, Canyon Creek, and Deer Creek which have a history of severe impacts from logging and road building These areas contain highly unstable soils, steep terrain, and high rainfall. They also contain discrete fish runs which must be managed as such. The runs within these areas are considered depressed, but largely to environmental conditions and often constrain mixed stock fishery management. In addition, substantial, amounts of time and money have been spent in recent years to rehabilitate these runs How were sensitive areas such as these considered and why are they not reflected in the analysis of the impacts of each alternative?

> **Response:** In the FEIS, a much more complete watershed analysis was done as part of the development of a hydrologic cumulative effects management requirement. Refer to new Appendix H (the MR Appendix) and revised text and effects discussion in Chapter IV, FEIS. Note, too, additions made in the Monitoring Plan, Chapter 5, Forest Plan.

HYDRO-POWER DEVELOPMENT: EFFECTS ON FISH RESOURCE

The effects of land uses on fish is a generic statement of the impacts of hydroelectric power plant development on fish and fish habitat. It is important that the criteria for what is acceptable and what is not should be discussed. (The FERC Cluster Impact DEIS on the Snohomish River may be useful here.) Also, the process FS will follow if an applicant wishes to put in a dam needs to be included in the EIS. The FS role is ensuring no unnecessary adverse environmental impacts needs to be explained.

Response: The specific procedures to be followed are explained in Forest Plan, Chapter 4, Forest-wide Standards and Guidelines for Land Uses; also, refer to Item J.3 for MA 13D. All such proposals include environmental analysis (NEPA document), including public involvement, with provisions to protect the land and resources of the Forest.

IMPROVE FISHERY INFORMATION TO MEET REQUIREMENTS OF NFMA

Improvements needed in the planning process to address the requirements of NFMA in regards to the fisheries resource.

To meet requirements of NFMA, the Plan should be based on recent, accurate fishery information including reasonable estimates of fisheries production on the forest, inventory of habitat conditions and productivity, and identification of critical habitat for various fish stocks, including sensitive, and depleted runs Streams where productivity has been impaired should be identified Watersheds containing critical habitat, as well as watersheds which due to the nature of their stability or hydrology are sensitive to disturbance should be identified. Timber harvest should be set at levels which will avoid disturbance of sensitive watersheds, allow recovery of previously disturbed habitat, and prevent future disturbance to critical stocks or habitat that have been identified in conjunction with the tribes and state and federal fisheries agencies.

We request that the USFS not implement alternative H at this time and undertake the development of another alternative which addresses the critical fisheries issues we have identified.

Response: In the FEIS, we have addressed all the management concerns raised in these comments by updating the current fishery resource data base. This was accomplished by requesting data input from the Washington Department of Fisheries and Department of Wildlife, and from the Puget Sound Treaty Tribes. In addition, since the DEIS was released, the forest addressed the effects of past, present and future sedimentation and other ground disturbance (natural and human-caused) to the fishery resources in 70 forest watersheds. See new Appendix H for a discussion of the hydrologic cumulative effects analysis. In this analysis, sensitive populations of fish were acknowledged, along with identification of sensitive watersheds. Applying management requirements for water quality and riparian areas will include a timber harvesting constraint (acres per decade) for the 70 watersheds; it will also provide mitigation of adverse effects of management activities on soil, water, and fisheries values.

Fish
Effects on Fish

INFORMATION NEEDS/HABITAT IMPROVEMENT EFFECTIVENESS

Paragraph #6 on page 4-7 seems incompatible with Information Needs #3, #4, #5, #9, #10, and especially #14 or at least overly optimistic. It's unclear how the MBS could have the view that fish habitat will have improved significantly at the end of ten years if the current situation is not well understood and the effects of various management activities on fish habitat and of habitat improvement techniques are unknown as the information needs suggest. It would seem that there is insufficient time to acquire all the information is ten years to be able to make this statement

Response: The Desired Future Condition for the forest's fishery resources reflects what we feel the MBS will look like at the end of ten years of Plan implementation. Refer to the previous response for a brief discussion of the analysis completed between draft and final plans. With the land allocations, timber harvest level, standards and guidelines of the Preferred Alternative, the rehabilitation and improvements scheduled in Appendix C and I of the Forest Plan, application of site-specific BMP's at the project-level, and meeting management requirements Forest-wide for water quality and riparian areas, we feel this description of the fisheries resoucre is accurate.

HOW WAS THE NEED FOR PROJECTS DETERMINED?

How was the basin-by-basin resource need for these projects determined?

Response: The past and present condition of watersheds Forest-wide was analyzed between draft and final plans; refer to Appendix H. Management activities, and the state of the upslope and in-channel conditions were evaluated This evaluation was done in an ID Team process using empirical data, photo interpretation, and professional experience on this Forest. The watershed and fish rehabilitation and improvement schedules in Appendices C and I, Forest Plan, were developed based on the problems identified.

MANAGING ONLY FOR FISH MAY BE LIMITING

In Chapter III, this sentence is incorrect ("The spawning and rearing habitat requirements of these species represent the the biological and physical needs of the forests aquatic animal species ") Managing for the listed species of fish may not necessarily manage for microbe, insect, amphibian, reptile or herptile species which use the forest's aquatic systems. There is literature which indicates that some aquatic beetles may be much more sensitive to perturbations to riparian and aquatic systems than are fish

By only managing for fish species there may be no management for stream reaches which do not have the listed fish species. Not all of the species of fish listed are native to the forest. Managing for species of fish where they do not naturally exists disrupts the native physical and biological system. Managing for the listed fish species does not necessarily manage for native aquatic and wetland plants which are the foundation of the aquatic ecosystems.

Response: Refer to the discussion in this Appendix regarding Management Indicator Species (in the wildlife section). Also, refer to Forest-wide

Standards and Guidelines for riparian areas and the MA 13D standards and guidelines, which speak to management for riparian-dependent resources.

WATERSHED CONDITION CLASS

The Watershed Condition Class Assessment under Fish/Water needs a whole table and section for itself. Table 5-1 in the Monitoring section of the Plan should contain "Watershed Condition" as an "action/effort to be monitored."

Response: Revisions have been made both to the watershed table in Chapter IV and the monitoring plan, based on the hydrologic cumulative effects analysis.

ADDRESS PROTECTION OF FISH-PRODUCING RIVERS AND ENHANCEMENT OF RUNS

Protection of the salmon and steelhead spawning rivers and enhancement of the fish runs in the MBS also should be addressed in the Land and Resources Management Plan. The salmon and steelhead fishery is within the MBS is a resource every bit as economically valuable as the timber. The Plan must accept this fact, assure that nothing is done to further damage the rivers or the spawning runs, and take steps to remedy the damage that has already taken place

The plan also does not disclose the economic impacts to the fisheries resource from the impacts of the projected sediment yield. It does not discuss the tradeoff that was between the economic benefits of timber harvest and the potential damage to the fisheries resource.

The National Forest Management Act (NFMA) directs the Forest Service to prevent "serious adverse" impacts to fish habitat. It is the Tribe's position that the draft plan does not meet this standard, nor assure that the Tribe's federally guaranteed treaty rights will be protected. Whether those impacts, if revealed, would represent real threats to habitat, is unclear

Response: Protection and enhancement (short and long term) of the salmon and steelhead habitats of the forest has been expanded in the FEIS, through inclusion of the fisheries resource as a major component of the hydrologic cumulative effects analysis This process resulted in a procedure to meet water quality and riparian MR's. More up-to-date data has been incorporated, and more evaluation has been added to Chapters III and IV, FEIS to display or narrate the relationship between upslope conditions and management activities and the impacts generated downstream in fish-bearing stream and river systems. Refer to new Appendix H. Additionally, the Preferred Alternative incorporates a high investment level for anadromous and resident fish habitat enhancement (MA 13D). Refer to the Forest Plan, Appendix C for the Fish Habitat Improvement Schedule.

TIMBER EFFECTS, FISH REHABILITATION ARE NOT DISCUSSED

The Plan and EIS also do not address rehabilitation opportunities or acknowledge that past timber harvest activities have caused a significant decline in fish habitat quality, quantity and production The Plan and EIS essentially sweeps the past under the carpet without accepting responsibility for declining fish production The current level of fish production as stated

earlier, is an unacceptable bench mark by which to evaluate the success and failure or Forest resource management. We therefore strongly recommend that the Plan acknowledge its legal management responsibilities by identifying rehabilitation opportunities, strategies and budget commitments toward this end.

Response: In the FEIS, the text and analyses in Chapters III and IV of the document have been rewritten. Since the DEIS was released, the forest has addressed the effects of past forest management activities and the known or suspected impacts to the beneficial uses of the water, namely, the fish and fish habitat. Refer to previous responses and new Appendix H for discussion of the hydrologic cumulative effects analysis. In the process, sensitive populations of fish were acknowledged, along with identification of sensitive watersheds. Appendix C of the Forest Plan, plus the Mitigation sections of Chapter II (Forest-wide) and Chapter IV, FEIS (Fish section) discuss rehabilitation opportunities and planned improvements. Also, see the Watershed Rehabilitation Schedule, Appendix I, Forest Plan.

NO CLEAR LINK BETWEEN CHANGE AND FISH PRODUCTION

The discussion beginning under "Opportunity Cost Analysis" should be deleted. From the Appendices, it is clear that the planning process did not establish any quantified linkage between environmental change and fish production. Thus, riparian area protection is only a "cost" with respect to fish. There are no calculated economic benefits balanced against this cost

Response: In the FEIS, we have responded to this comment by. adding discussions to Chapters III and IV, FEIS that better explain the situation on the MBS, and why models such as a sediment-related model are not applicable; added more discussion to Appendix B, Chapter III on the relationship between anadromous fish production and forest management activities; and included fisheries resouce as a major component to the hydrologic cumulative effects analysis Linkages between watershed conditions and fish production are made Refer to new Appendix H.

DEIS FAILS TO DISCLOSE LOSS OF FISH PRODUCTION, ESPECIALLY CHINOOK STOCK

The DEIS fails to disclose the potential long term loss of fisheries production due to habitat degradation from factors such as sedimentation, temperature increases, changes in peak flows, and habitat disruption from debris flows. Related to this loss of productivity is the potential for loss of populations of depressed and sensitive fish stocks. An example of this is the Nooksack spring chinook stock in Canyon Creek which is identified as a high priority (Category I) resource by the US Fish and Wildlife Service and is on the verge of being extirpated from the creek.

Response: A better discussion of the tie between Forest management activities (including timber harvest and road construction), environmental changes, and fish production has been added to Chapter III, Fish, in response to this and other comments. Refer to Table III-33 through III-37 for production figures of Nooksack River chinook. We have also added discussion in Chapter IV regarding the lack of a model (such as sediment or recovery model) to fit the situation on this forest. To address the concern raised by these and other comments on the DEIS, the Forest completed a Forest-wide hydrologic cumulative effects analysis. For a

description of the development of this process, refer to Appendix H. This procedure resulted in a better method of meeting water quality and riparian management requirements (MR's): the result is a set maximum number of acres available for final harvest in 70 of the Forest's 78 allocation zones (or watersheds). Canyon Creek is rated Unacceptable; in the first decade, a total of 100 acres are available for timber harvest. Again, for more detail and the literature/research used, and the process developed, refer to new Appendix H and Table 2, the AZ Summary in the Appendix. With the land allocations, timber harvest level, standards and guidelines of the Preferred Alternative, the rehabilitation and improvements scheduled in Appendix C and I of the Forest Plan, application of site-specific BMP's at the project-level, and meeting management requirements Forest-wide for water quality and riparian areas, we feel the production levels for fish will be met.

USE 1982 UPDATED VERSION OF IMPLAN MODEL

The final plan should utilize the newly-developed 1982 version of the IMPLAN I-O model for its social-economic assessments.

The IMPLAN I-O model used to estimate employment and income changes for the various alternatives should be updated.

Response: The 1982 IMPLAN model, which includes an interindustry technical coefficients matrix revised as of 1982, has been used to calculate employment and income changes for the FEIS.

CONSIDER UPDATING THE IMPLAN MODEL TO 1986 OR 1987

The [1982] I-O model should be critically examined for potential distortions prior to use due to the fact that 1982 was a severe recession year for the forest products industries and for the U S. and State economies. Such examination may reveal that the model should be updated to 1986 or 1987 industry relations.

Response: The heart of an input-output model is a matrix of linear relationships that describe for each economic sector the inputs purchased from all other sectors (including itself) for each dollar of output it produces The fact that 1982 was a recession year with low final demand for wood products would, in and of itself, produce little if any change in the interindustry technical coefficients. Therefore, employment per unit of production would show little change between 1982 and a nonrecession year What is probably different, though, is estimation of income by the model. According to the Washington Office LMP staff responsible for the FS IMPLAN model, coefficients for income components other than employee compensation tend to be lower than in a nonrecession year. Therefore, a model updated to 1985, for example, would probably show somewhat higher total income estimates.

On the other hand, a model updated to 1985 or later will probably show some measurable changes in the interindustry technical coefficients because of the restructuring of the industry that took place as a result of the recession of the early 1980's. Marginal mills closed, existing mills modernized with more efficient technology, and workforce reductions took place. As a result, today the same amount of lumber is being produced with roughly 25%-30% fewer workers. A model revised to 1985 or later will likely show lower employment related to the same amount of timber output compared to the figures in the DEIS While stated above that income estimates may come back up, that may be offset to some degree because of the wage cuts that many wood products workers took during the recession.

The Forest Service currently has a contract with the University of Minnesota to provide an IMPLAN model updated as of 1985 The updated version should be available by the latter part of 1990.

It is important to remember that I-O models have limited utility for forecasting specific levels of jobs and income more than a few years into the future. What the IMPLAN model really provides is a means to compare the relative effects of different land and resource management alternatives on the socioeconomic environment Even if the numbers produced are not

exact, they reflect the magnitude and direction of changes in a consistent manner among alternatives.

It will never be possible to monitor the specific changes in jobs resulting from changes in Forest management and compare that to the IMPLAN numbers. IMPLAN computes estimated direct, indirect and induced employment changes. Especially in a large and complex economy such as the one in the Mt. Baker-Snoqualmie area of influence, it would be impossible to track accurately anything but perhaps the direct jobs. Indirect and induced job changes are diffused throughout the economy, and changes are subject to a variety of other factors that are assumed constant in IMPLAN for any given run. Also, IMPLAN does not assess over what time frame the estimated changes would actually take place. So it would not be possible to monitor and compare, as the time frame over which to monitor would be unknown.

In summary, the Forest has used the 1982 updated version of IMPLAN to estimate employment and income effects from the alternatives in the FEIS. While not exact predictions, those figures provide relevant information in terms of the magnitude and direction of change of employment and income for decision-making purposes.

PROVIDE BREAKDOWN OF PROJECTED JOB CHANGES BY ECONOMIC SECTOR

By looking under all the indexed references to employment I could not find a breakdown of what industries would contribute to these presumed jobs.

Response: The IMPLAN model generates the reported job changes by economic sector, as included in the model. The version of IMPLAN used for the DEIS had over 400 economic sectors represented The version used for the FEIS is more aggregated, but still has over 200 sectors. The information on changes in employment and income, by sector, for each alternative can be found in the planning records; it can be provided, on request, in nonaggregated or in aggregated form

PROVIDE TIMBER FOR ECONOMIC STABILITY

One of the first mandates of the FS is to provide timber for economic stability.

The reduction in the annual timber sale program proposed from one of the nation's most productive forests is based upon a flawed supply-demand analysis and is fundamentally inconsistent with the Forest Service's statutory obligation to maintain a continuous and adequate supply of timber for dependent mills and communities.

Response: While the Forest Service has been concerned over the years about the effects of its management activities on local economies (the latest example being the Pacific Northwest Strategy recently set out by the Regional Forester), the agency does not have any statutory requirement to provide timber to assure "community stability" (also referred to as "local economic stability"). The Organic Administration Act of June 4, 1897 (16 U.S.C. 475) provided that: "No national forest shall be established, except ... and to furnish a continuous supply of timber for the use and necessities of the citizens of the United States.. " The Multiple-Use, Sustained Yield Act of 1960 (16 U.S C. 528-531) defines both multiple use

and sustained yield, but does not use the term community, or local economic, stability. Nor is the term found in the National Forest Management Act of 1976 (16 U.S.C. 1601-1614). The only statutory uses of the term relative to forest management are in the Sustained Yield Forest Management Act of 1944 (16 U.S C. 583) which authorized the establishment of public/private sustained yield units (such as the Shelton SYU on the Olympic Peninsula) and in the 1937 legislation providing management direction for revested Oregon and California (O&C) lands under the administration of the Department of Interior (43 U.S.C. 1181).

While Congress has not used the term in legislation, legislative history has shown that Congress has long been interested in local economic or community stability Recognition of that interest has been reflected in the promulgation of regulations by the Forest Service and other agencies over the years. However, none of those regulations **requires** provision of timber for community stability. Rather, they are couched in terms of "so far as feasible," "consider" and "evaluate." Even in the NFMA regulations, community stability is indirectly referred to only in terms of adverse economic impacts on local communities being one of the criteria under which departure alternatives will be evaluated, and in the requirement to estimate and evaluate the physical, biological, economic and social effects of implementing each plan alternative.

See Community Stability in Forest-Based Economies (Proceedings of A Conference in Portland, Oregon, 11/16-18/87, Dennis LeMaster and John Beuter, eds., Timber Press, Portland OR, 1989) for a thorough discussion of community stability concepts and issues. In particular, for the statutory and regulatory history, see "Community Stability: Is There a Statutory Solution?" by James P. Perry, pp 30-35. (For an alternate interpretation of that history, see also "Discussion: Neither Complex Nor Obscure in Meaning" by W. Hugh O'Riordan, pp. 51-53.)

NEW RECREATION-RELATED JOBS NOT ECONOMICALLY EQUAL TO LOST TIMBER JOBS

Recreation job growth should be viewed as an addition to lumber and wood products employment -- not as a substitute for it. This is especially true considering the disparity in average wages -- $25,821 in the forest products industries compared to $12,935 in the recreation-serving industries.

Response: It is true that manufacturing jobs typically pay higher wages than many service jobs associated with the recreation industry -- food service, fuel service, lodging, retail trade, etc. However, the disparity is quite a bit less than that cited by the respondent, according to recent figures. This is at least partly because of a decline (in real terms) during the latter 1980's in lumber and wood products hourly earnings. It is difficult to extract a very precise estimate of average wages paid to recreation-related workers, as that category covers portions of a number of economic sectors. Also, one must recognize that, particularly in the Puget Sound economy, not all recreation-related jobs are service jobs Clothing and equipment sectors exist here, as well as oil refineries. Some of the additional spending by recreationists works its way back to these manufacturing sectors, which pay wages significantly higher than the service jobs noted above.

It is not our intent to imply a direct equality between manufacturing jobs foregone and recreation-related jobs gained. That is why change in

personal income estimates are also shown Employment and income estimates together give a more comprehensive view of the expected changes in the economy, compared to using either by itself. It is also not our intent to imply there will be no individual difficulties as a transition is made from higher to lower timber harvest levels. What we have tried to do is to show as well as possible the relative shifts in employment and income as management alternatives change.

RECOGNIZE SPORT FISHERIES CONTRIBUTIONS TO LOCAL ECONOMIES

It would seen that fish have an indirect value for local economies the same as recreation does. Listing only the market value seems to narrow a view. What about boat and motor sales, fishing gear, lodging, etc.?

Response: The values listed for fish in the DEIS Summary, Affected Environment, incorporated the commercial values of anadromous fish and the assigned (noncash) value of sport-caught anadromous and resident fish. Values to local economies from expenditures on travel, lodging, food, etc. are represented in the employment and income calculations under the section "The Human Community."

EMPLOYMENT EFFECTS FROM WILDERNESS, NONMOTORIZED RECREATION ARE DOUBLE-COUNTED

We also question how it is possible to distinguish between the employment created by dispersed nonmotorized recreation and Wilderness. By separating the two categories you are doubling their employment effects, giving them a value that is likely disproportionate to their actual contribution

Response: RVD's for dispersed nonmotorized recreation and Wilderness recreation are tracked separately. However, for purposes of calculating employment and income effects, they are assigned the same expenditure value, as the types of expenditures required to undertake each type of use are very similar (travel, similar types of equipment and food, etc.). The differentiating factor is the number of RVD's projected for each type of use. Per RVD, the employment/income effects would be the same from the model, because the unit expenditure values and their allocations among sectors are the same. In total, they will differ as the number of RVD's for each type differs. If the end results of the two estimates were summed, the total would be approximately equal to the result that would be obtained if they were treated as one. There is no double-counting taking place in the projection of employment and income effects.

DEVELOP REGIONAL I-O MODEL FOR WASHINGTON AND OREGON

The Forest Service should develop separate IMPLAN models for Washington and Oregon to permit assessment of the overall economic impacts of the 19 National Forest plans being developed

Response: The Regional Office in Portland has published an analysis of the effects of the aggregate changes in timber to be supplied from the National Forests, as reflected in Draft Plans, on the regional timber market (USDA Forest Service, "Timber Supply in the Pacific Northwest: Aggregate Implications of Forest Plans," Pacific Northwest Region, June, 1989). Included in the analysis are estimates of regional employment and income

changes derived from a regional IMPLAN model that includes both Washington and Oregon. Because of the regional nature of the timber market, creating two separate state models would not provide as much useful information as does a regional model with both states included.

USE BUREAU OF ECONOMIC ANALYSIS REGIONAL I-O MODELS RATHER THAN IMPLAN

The Forest Service should consider the cost savings and quality of regionalized input-output models developed by the Bureau of Economic Analysis, Department of Commerce, before any further resources are expended on the IMPLAN I-O approach.

Response: Each Forest was free to choose the tool or tools it felt were best suited for analysis of economic impacts of alternative management plans on its area of economic influence. Unlike the national direction to use FORPLAN for optimization modeling, there was no centralized direction that all Forests use IMPLAN. The BEA input-output models were considered as an alternative to IMPLAN by a number of Forests, including the Mt. Baker-Snoqualmie.

There were a number of reasons for deciding to use IMPLAN over the BEA models IMPLAN is very flexible. Single- and multi-county models can be developed and run to look at economic impacts on different portions of an area of influence To do that with BEA models would require a separate request and purchase for each one. For instance, the MBS can look at its entire five-county area, or at subsections consisting of the more urbanized Snohomish/King/Pierce county group and the more rural Whatcom/Skagit combination, using essentially the same data set. Another reason for choosing IMPLAN was the openness of the series of programs used to construct the actual I-O model and the fact that it had in-house support from people readily available who knew the agency, its problems, and peculiar needs. Third, from the Forest's budgetary standpoint, the cost was low. The software and support were provided to the Forest free of charge. All that was required was analysts' time and computer time, both of which would have had to be paid for under any other circumstances. Finally, IMPLAN was developed to run on the agency's UNIVAC computer system at Fort Collins. There have been many instances in which major problems have been encountered in trying to get computer programs developed on one system moved over and running on another system. A good case in point was the early attempt made to get FORPLAN to run on an IBM mainframe. It simply did not work as hoped because of code and system problems.

The dollars and effort put into developing and improving IMPLAN have appeared to pay off, as more and more non-Forest Service agencies and organizations around the country are using the program for economic impact analysis. The development of the PC-based IMPLAN version (Micro IMPLAN) has further enhanced the flexibility of the program, speeded up turnaround time for runs, and has eliminated mainframe timeshare costs.

TIMBER HARVEST BASE FOR COMPARING EMPLOYMENT/INCOME EFFECTS IS TOO LOW

Rather than using the annual TSPQ of 220.1 MMBF from Alternative NC as the basis for comparison of employment and income changes, the three year (1985-1987) average total timber harvest of 255.3 MMBF per year [should] be used, since this is the average operating level for the forest products industries.

Response: The forest products industry is a cyclic one The latter part of the 1980's have been a period higher demand and production The early 1980's were a period of low demand and production Defining a period in the higher end of the production spectrum does not provide a complete picture of the nature of the industry and does not provide a good base for comparison. For instance, the annual average harvest level for 1979-1986 was 219.1 MMBF, which is much closer to the first decade annual average used for comparison of employment and income effects.

For decision-making purposes, the **relative** changes in employment and income are more important than the **absolute** changes. In reality, absolute changes are very difficult to predict, particularly because of a wide variety of factors that are subject to change which are not under the Forest's, or even the industry's, purview. The projected changes relative to the total employment/income picture for the area of influence, and the differences in projected changes among alternatives under a consistent set of assumptions, are most important for evaluating alternatives and their effect on the *social/economic environment*.

INADEQUATE EXPLANATION OF HOW IMPLAN WORKS

A description of the FORPLAN modeling is found in the Appendix [B] In addition, a description of other modeling procedure used to estimate the employment and income impacts should be made available in this section. Although the plan states that the IMPLAN model was utilized, no mention of how employment and income multipliers are calculated is made.

Response: A discussion of input-output models in general, and of IMPLAN in particular, is found in Appendix B, Chapter V ("Social and Economic Impact Analysis"), Section B. While it is true that the IMPLAN modeling is not discussed in as much detail as is FORPLAN modeling, a basic reference to the details of the IMPLAN model and programs is provided; detailed final demand numbers by sector, population and employment base numbers, allocation of final demand numbers among sectors, etc. is in the planning records.

RECREATION RESPONSE COEFFICIENTS FOR EMPLOYMENT AND INCOME SEEM HIGH

The employment and income response coefficients for the various types of recreation seem high in relation to each other and in relation to t.mber.

Response: Wildlife and fish-related recreation generally have greater economic impact through expenditures than general dispersed recreation because of higher expenditures for equipment, licenses, etc. Many hunters and anglers may also use guide services, motels, etc., especially on multi-day trips. Hunters and anglers also tend to have greater investments in equipment, especially RV's used primarily during the hunting and fishing seasons, than do people engaging in general dispersed recreation not involving consumptive use of wildlife or fish

While timber production definitely supports a significant number of direct, indirect and induced jobs, it is generally easier to see where those jobs are than for recreation-related jobs. The latter are diffused over a wide range of sectors in the economy, but are no less real. The Puget Sound area will also show more jobs generated from recreation spending than would

a more rural area in northeastern Washington or eastern Oregon because there are many recreation-related industries here -- outdoor clothing and equipment manufacturers, petroleum refineries, etc. A greater percentage of the expenditures made for recreation turn over with in the region before leaking out than one would find in a less economically diversified area. Thus, more indirect and induced jobs are supported.

FULL PUBLIC INVOLVEMENT NEEDED BEFORE DESTROYING HISTORIC STRUCTURES

We are concerned about the Forest-wide standard for curtal and historic resources within wilderness that states: "If it is determined, after historical evaluation, that a structure is not of significance, it shall be removed by a practical method compatible with the goals of this plan." This method does not involve the public or give consideration to the value of a structure to local communities. We recommend that no structure be destroyed until a full public involvement process is undertaken which focuses particularly on local communities with possible ties to the structure.

Response: Many stories of destruction originate in events occurring prior to the establishment of a cultural resource management program on the Forest in the mid-1970's. Under current procedures, there is provision for public involvement through environmental and historic preservation procedures. The effects of structure removal are evaluated through environmental analyses, and Wilderness standards and guidelines have been clarified to reflect this. In addition, it the structure is historically significant, removal is an adverse effect under 36 CFR 800 (Protection of Historic Properties). Regulations at 36 CFR 800.5(e)(1) and (3) direct that the public be involved in consultations regarding adverse effects. Again, the Final Forest Plan has been changed to clarify this requirement; see Chapter 4.

ADD "OTHER INTERESTED GROUPS" TO GOAL FOR CULTURAL AND HISTORIC PROPERTIES

Suggest you expand goal #3 on page 4-5 for Cultural and Historic Resources and add coordinate efforts with "other interested groups" as well.

Response: We agree The Forest Plan expands the range of cooperators cited in connection with this goal.

NEED TO INVOLVE INDIAN TRIBES IN CONSULTATION FOR HISTORIC PROPERTIES

Throughout the documents, a distinction is made between "Cultural and Historic Properties" and "American Indian Religious and Cultural Uses". The former deals with archaeological resources, undoubtedly many of these sites are of Indian origin While this is acknowledged in the Plan, the role of the tribes is ignored in the consultation process The tribes must be included.

Response: To avoid possible confusion between the resources under discussion, the Plan documents have been revised to speak of "Archeological and Historic Properties" and "American Indian Religious and Cultural Uses", under an overall heading of "Cultural Resources".

Approximately 25 of 175 recorded Forest archeological and historical properties are archeological sites of Indian origin. When excavation permits are issued under the Archeological Resource Protection Act, 36 CFR 296.7 requires notification to Indian tribes of possible harm to, or destruction of, sites on public lands having religious or cultural importance to the tribes. When consultations occur in compliance with the National Historic Preservation Act, 36 CFR 800 1(c)(2)(iii) requires that if an undertaking affects properties of historic value to an Indian tribe on non-Indian lands, the consulting parties shall afford the tribe the opportunity to participate as interested persons. Traditional cultural

leaders and other Native Americans are considered to be interested persons The Forest-wide Standards and Guidelines, Chapter 4 of the Forest Plan, have been revised to more explicitly recognize these regulations.

LACK OF DETAIL FOR CULTURAL RESOURCE MANAGEMENT

With respect to cultural resources, the Preferred Alternative lacks detail in planning which suggests that cultural resources are being relegated to individual management discretion.

Response: A comprehensive Cultural Resource Overview, which is referenced in the Plan, was prepared as part of the planning effort. It describes specific archeological and historical themes and resources. The Implementation Schedule, Appendix D of the Forest Plan, has been amended to included targets for specific areas and resources.

ADD A SUMMARY OF THE CULTURAL RESOURCE INVENTORY PLAN TO THE FEIS AND PLAN

The Forest's cultural resource inventory plan is apparently still under preparation. A summary of the chief features of the inventory plan should be incorporated in the Forest Plan. It should, to the extent possible, outline both project-related and research-based investigations, excavation, and interpretation.

Response: The cultural resource inventory plan has not been written, therefore a summary cannot be included in the Forest Plan. Currently, inventory strategies and tactics are developed on a project-specific basis. Inventory plan preparation is scheduled for Fiscal Year 1992 (see the Cultural Resource Implementation Schedule, Appendix D). The main features of the inventory plan will include a summary of the Forest environment and cultural history, drawn from the Cultural Resource Overview. These will be used to stratify the Forest into environmental zones; survey tactics will be specified for each zone (e.g., transect types and intervals, extent of post-project monitoring, etc.). An outline of investigations is contained in Plan Appendix D.

AMOUNT OF CULTURAL RESOURCE SURVEY IS DIFFERENT IN THE DEIS VERSUS THE PLAN

The DEIS discusses only project or land transfer-related cultural resource survey (Chapters III and IV) in contrast with the Plan, which states in several places that nearly the same amount of land will be subjected to non-project purposeful survey. These two documents should be reconciled.

Response: The text in the FEIS has been revised to reconcile this document and the Forest Plan The wording in Chapter III of the FEIS has been changed to read, ". .inventories generally have been conducted . .." Text describing future non-project purposeful survey has been added; also see the Cultural Resource Implementation Schedule, Forest Plan, Appendix D. The text in FEIS Chapter IV has not been changed, as this material pertains specifically to the mitigation of project effects

THE PLAN SHOULD STATE WHY SO FEW SITES HAVE BEEN RECORDED

The Plan should address why only 20 prehistoric and 100 historic sites have been adequately recorded out of an inventory of 800 sites and 170,000 acres of survey to date.

> **Response:** The DEIS implicitly addressed this issue for prehistoric sites on page III-95. The Forest Plan addresses this issue explicitly in Chapter III of the FEIS. The figure of 800 sites (currently 973) represents sites reported in a number of sources (e.g. ethnographic reports of villages) that did not include field inventory. It also included sites not on National Forest lands. As of April 1989, 173 historic and 23 prehistoric sites have been adequately recorded, largely through project-related inventory. Many reported sites can no longer be located on the ground. Others are not in the National Forest and may never be recorded. The Cultural Resource Implementation Schedule (Plan, Appendix D) includes the recordation of sites lacking adequate records at a regular rate over the life of the Plan. This will not be tied to project inventories. It will reduce the backlog of reported but unrecorded sites

CULTURAL RESOURCE INVENTORY, ETC. SHOULD BE PRIORITIZED

The Forest should prioritize, or schedule the inventory, recordation protection and interpretation of the numerous referenced historic features, such as the "14 distinct mining areas, 6 transportation, and 8 logging areas." Specific examples include the "Snoqualmie Pass Wagon Road; Northern Pacific Railroad Corridor; the Mt. Baker, Silverton, and Index mining districts; and Stillaguamish and Sauk River drainage logging areas."

The Plan should contain information such as priorities and a schedule of management plans for historic resource management.

> **Response:** The Cultural Resource Implementation Schedule (Plan, Appendix D) has been revised to do so. The earlier a management plan is scheduled, the higher its priority.

MORE EMPHASIS ON PRESERVATION OF CULTURAL, HISTORIC PROPERTIES

In discussing the process goals of the Cultural and Historic Properties element, you state that one of the primary aims is to increase "interpretation of cultural resources." There should be more emphasis on preservation than appears in the Plan goals.

> **Response:** Protection objectives have been added to the Forest Management Objectives for Archaeological and Historic Properties Protection Standards and Guidelines were included in the Draft Plan (page 4-75) and have been retained in the Forest Plan. Specific protection activities are scheduled in the Cultural Resource Implementation Schedule, Plan Appendix D.

WILL THE PLAN CONSIDER LEAVING ARCHAEOLOGICAL AREAS UNDISTURBED?

There has been a long standing and well publicized debate between tribes and archaeologists about how archaeological properties should be treated. Tribes

often favor leaving an area undisturbed; the plan diminishes this alternative. Is this an alternative which will be considered and used by the MBS?

Response: Avoiding disturbance to archeological sites may be suggested by any of the parties to consultations required by 36 CFR 296 or 36 CFR 800 discussed above. Forest-wide Standards and Guidelines have been amended to require consideration of avoidance. Use of this alternative will depend on the issues raised during consultations.

LITTLE RECOGNITION OF THE IMPORTANCE OF THE NACHES PASS WAGON ROAD

There was little recognition in the DEIS of the historic importance of the Naches Pass wagon trail. As the first route over the Cascades, and as it intersects the Pacific Crest National Scenic Trail, it should be spared any more degradation from crisscrossing logging roads and clearcuts.

Response: The Naches Pass area was considered for Special Area designation in Alternative G of the DEIS, on the basis of its historic importance. Its historic value is documented in pages 208 to 212 of **A Cultural Resource Overview: Prehistory, Ethnography and History, Mt. Baker-Snoqualmie National Forest.** The Overview was prepared as background information for the Land Management Plan. The Implementation Schedule (Plan, Appendix D) addresses the need for a detailed inventory and management plan.

ALL REMAINING FIRE LOOKOUTS ARE SIGNIFICANT

Of the many fire lookouts that were once on this forest, only a few remain. All have historic significance, despite their eligibility for the state historic register. They represent a bygone era that intrigues the greater share of the hiking public. Green Mountain and Miner's Ridge Lookouts should be preserved in addition to the lookouts listed in the plan.

Response: In the context of historic preservation law, "significance" is defined as eligibility for the National Register of Historic Places. Normally, resources less than 50 years old are not eligible for the National Register. After a comprehensive evaluation of MBS lookouts, none built within the last 50 years were felt to be of such exceptional importance to justify listing in the National Register. Both the Green Mountain and Miner's Ridge Lookouts are more than 50 years old and are listed in the National Register of Historic Places. The Management Area prescriptions for Areas 10E and 18 have been revised to accept the existence of historic structures in these Areas. With respect to other lookouts less than 50 years old, nothing in the Forest Plan precludes their preservation. However, as historic preservation funds are limited, priority will be given to lookouts qualifying for the National Register of Historic Places.

THE AREA AROUND PARK BUTTE LOOKOUT NEEDS PROTECTION

The Park Butte Lookout will soon join the National Register of Historic Places Inventory; although the lookout itself is adequately protected, the surrounding environment is not. Note that the National Register nomination form says [in part]: "These extant fire lookouts, which remain in pristine mountainous forest environments...[are] part of the comprehensive detection system which

worked...to protect and conserve National Forest lands..." It would be sadly ironic, a half-legacy, to save the lookout but not the surrounding environment.

Response: Timber harvest and extensive burned-over areas are elements of panoramic photographs taken from Mt. Baker-Snoqualmie lookouts in the 1930's, and cut-over areas are visible in the background of the Park Butte panorama. A principal objective of fire detection and suppression in the 1930's was to protect public and private investments in forestland, reducing pressure to recover the investment through immediate harvest. Except in a very few instances, usually in National Parks, preservation of the timber stands in perpetuity was not envisioned.

The Forest Plan allocates the area surrounding the Park Butte Lookout to Management Areas 1B, Semi-Primitive Nonmotorized Recreation; 4, Mt. Baker National Recreation Area; and 10, Wilderness. The area at Schreiber's Meadow has been allocated to MA 2A, Scenic Viewshed. The North Fork Nooksack Drainage has been allocated to 14 and 15A, Deer and Elk Winter Range and Mountain Goat Habitat, and to MA 23A, Other Municipal Watershed. Only the South Fork Nooksack contains allocations to MA 17, Timber Management Emphasis The result of these allocations will be the retention of foreground views and a reduction in the modification of middle-ground and background views, compared to the Draft Plan allocations.

PROTECTION, PRESERVATION OF INDIAN RELIGIOUS USE AREAS HAS NOT BEEN ACCOMPLISHED; PLAN VIOLATES AIRFA.

The Forest Service is in direct violation of its own directive as regards the American Indian Religious Freedom Act (AIRFA) . The Forest Service Report to the Federal Agencies [AIRFA] Task Force specifically embraced the interpretation of AIRFA as requiring it to preserve sacred areas of land when necessary to protect American Indian religious freedom. F S. directive states that when land and sites are determined to need protection and preservation, this will be accomplished in and through the land management plan. Protection and preservation of these documented sites has not been accomplished through this Management Plan!

According to Forest-wide Standards and Guidelines for Indian religious and cultural use, protection measures will be taken only where practical!

Response: These two comments state that the Forest failed to follow agency direction by failing to protect all religious and cultural use sites identified in the 1981 **Inventory of Native American Religious Use, Practices, Localities and Resources (Inventory)**. The direction cited is a 1700 (Civil Rights) memo from Forest Service Deputy Chief Jerome A. Miles to Assistant Secretary of the Interior Forrest J. Gerard, dated May 10, 1979. The memo describes Forest Service implementation of the American Indian Religious Freedom Act (92 Stat. 469). It cited a 1020 (Laws) memo sent to the Regions, Research Stations and Washington Office staff directors by John R. McGuire, Chief of the Forest Service, on November 14, 1979. That memo stated, in part:

> "In the interim until further direction is available the following direction will apply. In the preparatory stages of land management planning native traditional religious leaders will be notified of all public involvement activities and invited to provide input. If an issue concerning Indian religious freedom is identified, the cultural resource overview for the forest plan should provide substantive background on the traditional Indian religious practices within the planning area. When examination and consultation determine a need to protect or preserve certain lands or sites this will be accomplished in and through the land management plan."

Final direction was not issued. The interim direction did not imply that all identified sites would be protected, hence the use of the term "consultation", which indicates a mutual decision. The reasoning is made clearer in the following paragraph, which reads in part:

> "Each application by traditional Native Americans to use National Forest system lands for religious purposes shall be carefully considered.... To the extent the proposed use or activity is considered consistent with existing laws and regulations, a special use permit may be issued."

The key consideration is consistency with other laws and regulations, some of which require production of resources or amenities that may conflict with the preservation of religious or traditional use areas. To the extent that such areas are to be preserved, it must be recognized in the Land

Management Plan, as preservation will in most cases constitute a land allocation.

FOREST SERVICE HAS A MANDATE TO PROTECT, PRESERVE CULTURAL/RELIGIOUS USE AREAS

The DEIS states that "mining, energy development and small hydropower development can result in loss of ritual purity and reduce the old-growth and mixed-age stands. Costs of protection and salvage of archeological artifacts will be borne by the operators of the individual projects... If at all possible the resource will be protected." "If at all possible" implies uncertain protection for these resources. I wish to emphasize - the Forest Service has a mandate to protect and preserve cultural resources and religious and cultural use sites.

Response: Protection and preservation of religious and cultural resources is subject to legal and regulatory mandates in addition to the AIRFA. The General Mining Law of 1872 confers rights to locatable minerals upon those who discover them. FS control of these minerals is limited to minimizing impacts on surface resources, through the review of operating plans. If removal of the minerals will disturb or destroy religious or cultural resources, and the effects cannot be mitigated, the FS does not have the authority to deny removal.

THE PLAN GOAL FOR INDIAN USE IS HOLLOWED OUT BY ACTUAL GUIDELINES IN THE PLAN

The MA 7 goal is a worthy one with respect to Indian Religious use, but it is hollowed out by the actual activities under the preferred alternative (H) It is clear use areas and sites will be heavily impacted. In the consultation section, the Plan states that where mitigation in not possible, the "value (of the site) as a religious or cultural use area will be reduced or lost. ..Sites will be protected....and protective measures will be taken... wherever practical... "

Response: The Preferred Alternative assigns between 35% (cedar areas) and 71% (ceremonial flora) of the inventoried religious use acreage to non-developed areas (Table II-9o and Table IV-24). It is not possible to guarantee 100% protection through the Plan, and this is made clear in the document Also, see the above discussion. Further, the Supreme Court's decision in Lyng v. Northwest Indian Cemeteries Protective Association indicates that neither AIRFA nor the First Amendment guarantee absolute protection of all religious sites against the multiple demands on public lands.

PLAN MAKES ASSUMPTION THAT SITES WILL BE DISTURBED

The Plan states that cemeteries will receive 100% protection, although ceremonial use sites and areas will be subject to disturbance. The informants from the tribe were emphatic that disturbance was both irreversible and unacceptable. It is assumed that sites and areas will be disturbed

Response: In Chapter IV, Environmental Consequences of the Alternatives, the DEIS did not make clear that some effects of management activities are irreversible; this text has been revised in the FEIS. Sites not protected through allocation to non-developed areas may be disturbed. They will be

subject to the consultation process during project-level environmental analysis. Options to avoid or mitigate disturbance will be considered (FEIS, Chapter IV and Forest Plan, Chapter 4). It is inevitable that some current and potential religious use sites will be disturbed, and that mitigation will not be possible, leading to an irreversible commitment of resources.

INCLUDE THE RECOMMENDATIONS, MITIGATION MEASURES SUGGESTED IN THE INVENTORY

The Plan/EIS should incorporate the conclusions and recommendations of the **Inventory**, or explain why different measures have been adopted. For example, it recommends that spirit sites be protected from alteration and that a buffer be established around them. Nowhere in the draft Plan/EIS is this suggestion addressed or considered. Instead of specific measures as recommended in the Inventory, the draft Plan/EIS proposes to protect resources needed for American Indian religious uses "wherever practical".

The Plan/EIS must be more specific in its mitigation and protection measures in order to permit a reasoned analysis of the impacts on Native American religious uses of the National Forest.

Response: The discussion in Chapter IV, FEIS has been augmented to include a discussion of the recommendations of the **Inventory** (pages 532-540). With respect to site management, there is a consistent recommendation for protection and preservation of each of the five site types. It is not feasible to protect each and every inventoried site, as this would violate other legal and regulatory obligations of the Forest.

With respect to resource use, the **Inventory** recommended that environments conducive to the growth of important plant and animal resources be maintained throughout the Forest. It is not possible to address effects on these resources in a meaningful way in the Plan, since no information exists on the distribution of many of these species (for example, camas) outside of localities identified in the **Inventory**. Buffers were not included in the Plan, as the need or size of a buffer varies by tribe and even individual practitioner, making an general standard infeasible. Accordingly, the Forest has considered areas that need protection, as identified in the **Inventory** and planned updates. Chapter II, FEIS and Chapter 4, Forest Plan have been revised to be more explicit in the definition of protection and the measures taken to achieve it.

USE CANNOT BE SHIFTED TO ANOTHER SITE ONCE ONE AREA IS LOST

There are some disturbing indications as to what some of the mitigation measures are. Both the Plan and the DEIS refer to identifying sites which are "best suited" or "most appropriate" for a particular use, and discuss having to shift locations as less area is available for religious and cultural uses.

There is a startling lack of sensitivity on the part of the Forest Service to tribal cultural needs. It is obvious that the Forest Service expects to identify suitable or appropriate alternative locations for tribal members to shift their use to once Forest activities have adversely impacted current use sites. This type of treatment is inappropriate when planning Forest activities around these types of sites.

The suggestion that one site is just as good as another for a particular use make clear that the Forest Service fails to comprehend the meaning tribes attach to these sites. Some locations have been utilized over an historic period of time; sometimes the location being passed from generation to generation. In many cases, the site itself contains many qualities which make it unique and irreplaceable.

Response: We do understand that each site is different because of its spirit associations, the religious experiences of particular individuals, or its place in tribal history. Thus, one site cannot completely substitute for another. But there is also the recognition that religious practices are not static. For example, consultations regarding project activities have produced information leading to the conclusion that religious use of National Forest land is increasing as sites are lost on State and private lands. This suggests that some degree of substitution is possible. Also see page 525 of the **Inventory**. In the Forest Plan, the Information Needs section of Chapter 2 has been revised to indicate that there is a need to identify the changing patterns of religious use of the Forest, and to identify areas that are most critical for protection from a tribal perspective. This will be accomplished through updates to the **Inventory** (Plan, Appendix D, Cultural Resource Implementation Schedule).

SITES ARE USED YEAR-ROUND; DISTURBANCES ARE AN IMPACT YEAR-ROUND

As mentioned repeatedly in the Inventory, sites are used year-round The Plan states that timber harvesting etc will be scheduled from April to September. Disturbing the sites during the time of latency is no less an impact than disturbing them during their season of use.

Response: The Forest Plan revises the management area guideline for these areas to indicate that scheduling is one mitigation measure that can be considered to remove conflicts with timber harvest; refer to Chapter 4, Forest Plan, and Chapters II and IV, FEIS. This mitigation covers circumstances in which a protection or mitigation decision is made in a project-level environmental analysis, for a religious or cultural use area **other** than one allocated to a non-development management area The religious/cultural use areas with high-moderate protection have been allocated to management areas that preclude timber harvest.

DEIS FAILS TO CONSIDER INDIAN USE IN ENVIRONMENTAL CONSEQUENCES CHAPTER

The DEIS fails to consider American Indian religious uses in the sections analyzing the relationship between short-term uses and maintenance and enhancement of long-term productivity (p. IV-151), the irreversible commitment of resources (p. IV-151), and the adverse environmental effects that cannot be avoided. It is surprising that one of the ten highlighted issues, concerns and opportunities is not addressed in these sections, as NEPA requires.

Response: The DEIS, pages IV-73 to 81, recognized the adverse effects of many Forest activities on religious uses. Chapter IV, FEIS has been revised to explicitly recognize the irreversible commitment of resources.

RELIGIOUS AND CULTURAL USE NOT FULLY ADDRESSED IN THE SUMMARY

American Indian Religious and Cultural Use issues were not fully addressed in the Summary document. The document (page 41) is vague as to exactly what and how much protection will be given to these sites. Except cemeteries, only a high of 52% of other sites will be given protection.

Response: The discussion in the draft Public Summary was limited, though there was more detailed discussion in the Plan (pages 2-4, 2-21, 3-4, 4-5, 4-7, 4-8, 4-45, 4-76 & 77, 4-154 to 156 and 5-8) and the DEIS (pages S-4, S-8 & S-9, Table S-4, S-33, I-13 & 14, II-53, II-109, III-92 to 94, and throughout Chapter IV) The 52% figure cited in the comment applies to acreage receiving a high level of protection, not sites. In addition, approximately 15% of the acreage would receive a moderate level of protection, the difference between "high" and "moderate" is the expected frequency of encountering other Forest users, not the level of development. The wording in the Summary has been clarified.

DOCUMENTS DO NOT IDENTIFY USE SITES OR EXPLAIN QUALIFYING CRITERIA; INVENTORY PROCESS NOT MADE AVAILABLE TO THE PUBLIC

Since, for confidentiality, lands are not specifically allocated to Indian Religious use, it is difficult to evaluate the effects of these uses. All forest users, including Indians, would benefit by a better explanation as to how these sites were determined and how their use impacts other forest uses.

The location of any of these sites is not identified, nor are number of acres given, under the claim of confidentiality. Besides failing to explain why confidentiality is legally necessary, the DEIS and Plan do not discuss what criteria were used to qualify each site Since the inventory and inventory process are unavailable to the public, one cannot determine if Indian religious uses are primarily at stake on each site; the public cannot evaluate the environmental impacts of such designation. This failure to provide necessary and significant information to the public undermines the NEPA process.

Response: A full discussion of the inventory process and the criteria used to define sites is contained in the first volume of the **Inventory**, which contains the non-confidential information and is available for public review Loan copies of this volume have been made available to Plan respondents, including an individual representing the organization making this comment. Tabular material in the volume lists the sites and discusses their general use.

Information withheld consists of location data and identities of site users These have been withheld under specific exemptions contained in the Archeological Resource Protection Act (P.L. 96-95, as amended) and National Historic Preservation Act (P.L. 89-665, as amended) where the sites include resources that may be considered historical or archeological, and exemptions to the Freedom of Information Act (P.L. 93-502), where release would impair the Government's ability to obtain information in the future, or invade the privacy of individual practitioners. These references have been added to discussions in Chapter II (Table II-9o) in the FEIS.

As discussed in Chapter III of the DEIS, religious use sites are identified through consultation with Indian tribes and tribal groups. Methods are described in the **Inventory**. The classification of sites is based on

information provided by Tribal representatives and practitioners. The Report that accompanied AIRFA (Report No. 95-709, hereater cited as "AIRFA Report") makes it clear that practitioners are the ultimate authority. Information for individual projects is obtained through inquiries to tribal officials and other tribal representatives undertaken during the preparation of Environmental Assessments.

Chapter II of the FEIS has been revised to better describe the use of Management Area 7. Chapter IV of the DEIS described the effects of religious and cultural use on other resources; in the FEIS, this chapter has been revised to improve the clarity of the discussion and expand the scope of the effects assessment.

PLAN VIOLATES AIRFA, COURT DECISIONS BY PROHIBITING ACTIVITIES BASED ON "ANTICIPATED USE"

In Wilson v. Block,... the court found that development of FS land would not impair Indian tribes' ability to exercise their religious beliefs nor deny them access to any sacred areas... Specifically, the court found that as long as Indian religious freedom was protected, access not prohibited, possession and use of religious objects permitted, religious ceremonies allowed, and consultation takes place with Indians before proposed actions occurred, the Act did no mandate that "native traditional religious considerations always prevail to the exclusion of all else."

The Act does not prohibit agencies from adopting land uses that conflict with traditional Indian religious beliefs and practices. In Northwest Indian Cemetery Protective Association v. Peterson ... planned road building and logging operations would have greatly impaired religious exercises on "the only place where they can be performed." ... None of the 308,000 acres on the MBS have been shown to be "indispensable" to the exercise of any Indian tribes' religion, and it has not been shown that any proposed governmental operations are bound to interfere with that exercise... For these reasons the MBS Plan and DEIS violate the Act when they absolutely prohibit logging and road construction in any alleged "high" and "moderate" [use area where use] has not been verified.

Response: The DEIS and Plan show areas receiving "high" or "moderate" **protection from development**, in various alternatives (Table II-9o), not protection of areas with actual, or anticipated, "high" or "moderate" use. "High" or "moderate" protection is based on allocation to management areas that preclude development. These allocations are based on other resource needs, for example wildlife habitat or semi-primitive nonmotorized recreation. The conclusions of the courts in Wilson v. Block and Northwest Indian Cemetery Protective Association v. Peterson are not directly relevant in this situation.

DEIS AND PLAN DO NOT DISTINGUISH BETWEEN RELIGIOUS AND CULTURAL SITES

The declared policy of AIRFA is "to protect and preserve" the right to express, believe, and worship, for religious reasons and not merely cultural beliefs. The DEIS and Plan do not distinguish what sites involve religious expression and what sites are merely cultural in nature.

The Forest-wide Standards and Guidelines even prohibit land-disturbing activities where there is cultural use, which is contrary to AIRFA. Such inflexibility violates the NFMA and protection is not absolutely warranted for each site by Act or by case law. The standards and guidelines must include substitution of comparable timber if protection of any religious site later occurs and lands otherwise managed for timber are eliminated from future harvest activities.

Response: Although the Inventory originated as a response to the AIRFA, it and the Plan also responded to provisions of the Medicine Creek and Point Elliot Treaties, which guaranteed Tribes the right to collect on the unclaimed lands of the State, in common with other citizens. Religious and cultural use areas, identified by the Tribes, are considered protected if they occur on lands allocated to a non-development management area, based on needs for wildlife habitat, etc. or to meet the goal of the alternative. Management Area 7 Standards and Guidelines will be applied within these areas. As timber harvest is already precluded in these MA's, there is no additional impact on timber harvest. MA 7 Standards and Guidelines may be applied to other areas as a result of consultation during project environmental analysis. Substitution of additional timber is not required as long as any loss in timber volume will not constitute a significant change in the Plan.

CLEARLY STATE THAT NO ALLOCATIONS ARE MADE SOLELY FOR INDIAN USE

Apparently, no land allocations are made solely to protect Indian religious sites, but this is not clearly stated in the plan. One could easily come away with the feeling that 440,000 acres are being "hidden" in other allocations to protect them for Indian use.

Response: The text in Chapter II of the FEIS has been revised for clarity.

WHAT AFFECT WILL RELIGIOUS AND CULTURAL USE CONSTRAINTS HAVE ON TIMBER?

In order to comment on the proposal for religious and cultural use, we need to know the effects of these constraints upon timber production. While we know that site specific areas are not listed, it should be easy to include the impacts on timber volume in the final plan.

Response: *Inventoried use areas shown as protected in the Plan are* protected through allocation to a management area that precludes timber harvest and road construction. The primary basis for these allocations were other resource needs, such as wildlife habitat or semi-primitive nonmotorized recreation. Thus, there are no independent effects on timber volume from the protection of religious and traditional use sites.

WHY IS THE EFFECT OF TIMBER HARVEST "UNKNOWN" - IF IT WERE A PROBLEM, TRIBAL LEADERS WOULD HAVE MENTIONED IT

Why, when timber management will benefit religious customs, is the "effect it will have" unknown? (IV-75) If it were a tremendous problem, tribal leaders would certainly have mentioned it.

Response: The record of tribal input on timber management is clear and consistent - it has adverse effects on traditional religious practices. The comment on page IV-75 reflected an **Inventory** finding that collection of edible and medicinal plants occurs where they are available, since for some groups, traditional areas are no longer available or are so altered as to be unproductive (page 535). Available, but modified, sites may be used. This leaves open the question of how much and what kinds of disturbance can be tolerated for this class of activity. However, users are clear in their expressed preference to collect plants from undisturbed areas.

IS IT POSSIBLE FOR INDIAN TRIBES TO REQUEST HARVEST ACTIVITIES?

Is it possible that harvest activities could occur at the request of Indians? If, for example, religious activities will be enhanced through timber management, will the Indians be able to influence timber sale plans? One could assume so, based on the final paragraph on IV-75.

Response: Harvest at the request of Indian tribes is possible, but is unlikely to occur in practice and any volume from such a request has not been programmed in the Plan Tribal input is clear and consistent in indicating that commercial timber harvest is incompatible with religious and cultural objectives. If such a request were made, it would be accommodated through established timber sale procedures, in conformance with the Plan, and subject to the NEPA process.

DISCUSS UNDEVELOPED ACRES OF INVENTORIED RELIGIOUS/CULTURAL USE

How much of the Inventoried Indian religious and cultural use area is currently developed? Are you planning to perpetuate this development or return the areas to a natural state (despite opposition from Indians)?

Response: Planning data are not available to provide a figure for the number or acres of Inventoried use sites and areas currently developed. In the Preferred Alternative, approximately 25 miles of roads will be closed and the area returned to a more-natural condition. Road miles to be closed are within land allocated to MA 1A and 1B: Primitive and Semi-primitive Nonmotorized Recreation. Otherwise, additional acreage will be developed as the Plan is implemented. Comments received from Indian tribes oppose development.

CONFIDENTIALITY OF SITES MAY ALLOW THEM TO BE MISSED IN SALE PLANNING

The confidentiality of these sites may allow them to go un-recognized during planning and layout of harvest activities

Response: Refer to the Forest-wide Standards and Guidelines, Chapter 4, Forest Plan. These established procedures will result in the recognition of religious and cultural use sites identified in the **Inventory**. The environmental analysis process for each proposed project includes an examination of impacts to listed sites, discussion of mitigation measures, and evaluation of a no action alternative. In addition, the affected tribe(s) will be consulted. Updates of the **Inventory** are scheduled for 1991 and 1996 (see Plan, Appendix D, Cultural Resource Implementation

Schedule). Tribal officials or individual practitioners may come forward at any time and identify additional sites.

WHAT PROTECTION WILL AREAS NOT YET IDENTIFIED HAVE?

What protection will those areas yet to be identified as religious and cultural use sites have, if the identified sites will be roaded and logged?

Response: Areas may be identified at any time by Tribal representatives or religious practitioners. Protection will be considered through consultation and decision-making for project environmental assessments. Areas can be protected if the decision will not require a significant change in the Plan. As discussed above, updates of the **Inventory** are *scheduled in 1991 and 1996. Data will be incorporated in the assessment of* resource conditions and public demands that must occur every five years (Plan, Chapter 5).

IS THERE A PROCESS TO DEAL WITH RELIGIOUS USE SITES DISCOVERED THROUGH FOREST MANAGEMENT ACTIVITIES?

Is there a process for dealing with sites which are discovered through Forest management activities which have not been formally identified in the **Inventory**? Discuss in the EIS and Plan.

Response: This has not occurred to date, however, any discoveries would presumably consist of the identification or artifacts or features used in religious practice. In that case, the procedures specified in 36 CFR 800.11 would be followed, with notification of the tribes which historically used, or currently use, the area In the Forest Plan, the Forest-wide Standards and Guidelines have been revised to incorporate this process.

PLAN HAS NO ESTIMATE FOR FUTURE NEEDS FOR SITES, AREAS, AND CEDAR

There is no indication that the agency attempted to determine the future needs for these sites and areas; also, there is no estimation in the plan of how much cedar would be needed by the tribal community in the future.

We recommend that the agency, along with the tribes, establish a schedule of present and future needs for sites and areas; incorporate these figures into the planning process

Response: *Although the DEIS at III-94 indicated that future use would* increase, the text in the FEIS, Chapters III and IV, has been revised to recognize that religious practitioners are increasingly relying on undeveloped areas of the National Forest, as sites on State and private land are developed. More detailed estimates of future use are not within the scope of the Forest Plan. Practitioners may come forward when environmental analyses are prepared for specific projects in order to identify localities not listed in the **Inventory**. Also, updates of the **Inventory** are scheduled, in the Cultural Resource Implementation Schedule, Appendix D of the Forest Plan. The Information Needs section of Chapter 2, Plan has been revised to show the need for trend data in the updates. Effects on cedar availability were addressed on page IV-74 of the DEIS and

are discussed in Chapter IV of the FEIS. It is likely that demand for cedar will increase in the future and that a shortage of cedar for traditional uses will be experienced

ACCESS MEANS NOTHING IF THE SITE IS DESTROYED; ROADS DIMINISH ACCESS

If the Forest Service allows roading, logging and mining etc. in and around religious use sites, of what value is access? Access to nothing, to destroyed sites? Extirpation of the natural conditions of the sites, means the destruction of the site values

Indian people have found their way through the forest for the last 10,000 years or so without the "facilitation" of U.S. Forest Service roads!!

In Section 2, P.L. 95-341, the Executive Branch reported to Congress that in order to preserve Indian free-exercise rights: "The accommodation of Native religious uses within federal land management programs must take into account their desire for these lands to remain in their natural state." This directive is not followed in the Forest Plan...the plan adopts a restrictive and negative interpretation of access Roads do not increase access; they diminish it. The principles of purity, privacy, isolation, and permanency apply to all types of cultural uses . . to diminish these values is to deny "access" in the context of AIRFA, the First Amendment and, most importantly, in the context of the information in the Inventory. And, it should be noted, AIRFA states that protection and preservation should be construed to mean "including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites." The Forest Service, in the Plan, has narrowed the original intent of the Act, and misinterpreted the meaning of "access" in the process

Response: The term "access" has been problematic. "Access" is used in the American Indian Religious Freedom Act (AIRFA), 92 Stat. 469. The Report which accompanied the Act (Report No. 95-709) states, "The issue is not ownership or protection of the lands involved. Rather, it is a straightforward question of access in order to worship and perform the necessary rites." (p. 3) Notwithstanding this, the responsiveness of the DEIS alternatives to the issue of American Indian Religious and Cultural Use was measured by considering the proportion of inventoried use acres afforded moderate or high protection in each alternative. Moderate or high protection was defined as management that would preclude timber harvest and road construction (DEIS, II-66). This approach [definition of access] was taken because of the emphasis on consultation in AIRFA

> "Because much of the present problem stems from lack of knowledge of what traditional native religions constitute, it is imperative that the evaluation find a source of knowledge if it is to rectify the problem It is the intent that the source be the practitioner of the religion...." (AIRFA Report, p. 5)

Still, "access" was used in its more restricted definition at certain places in the Draft Plan and DEIS. In the FEIS and Plan, to more accurately reflect the issue, the term "availability" has been substituted for "access." Definitions of responsiveness to the issue remain the same. This is necessary "to insure for traditional native religions the same right of free exercise enjoyed by more powerful religions" (AIRFA Report, p. 6).

IF ACCESS IS A GOAL, WHY IS THERE AN EMPHASIS AGAINST ROADS?

The goal for Indian Religious and Cultural Uses is access. Why is there such am emphasis throughout the plan against both road and trail access?

Flora and, to some degree, cedar areas should undergo management activities in order to enhance their usefulness for religious and cultural purposes. Why does the staff plan to exclude timber harvest and roading? It seems as though you are actually reducing access, not encouraging it as your goal and the law insist that you must do.

"Some degree of roading...may be desired to provide easier access for the elderly." (II-109) Yet, those alternatives affording "high or moderate" protection preclude roading altogether. Who has decided that elderly Indians or others wishing easy access will not be served in the plan?

> **Response:** The choice of the term "access" in the Plan was based on the use of the term in the AIRFA, as discussed above. The AIRFA Report (page 5) makes it clear that Indian practitioners must define adequate access. Consultation on the MBS and comments on the Draft Plan make it clear that Indian practitioners do not define "access" as roads and trails. For more on this subject, see the **Inventory** pages 176-177, 209-210, 272, 284-289, 301-307, 386, 309, 438-442, 456, 466. "Protect", "preserve" and "set aside" are repeatedly recommended, rather than "road" or "harvest".

NOTE THAT RIGHT OF ACCESS IS NOT A NEW RIGHT

The Plan/EIS should note that the right of access to sites was passed by Congress not as a new right, but as an implementation of the First Amendment to the United States Constitution. The Plan/EIS should go on to consider the current state of judicial decision making in this unsettled area of law.

> **Response:** The Forest Plan has been revised to indicate that concern with religious and traditional uses arises from treaties and the Constitution in addition to the AIRFA. Broadly speaking, the Plan and FEIS consider the most significant recent development in this area of the law to be the Supreme Court's decision in Lyng Northwest Indian Cemeteries Protective Association v. Block. The decision is interpreted as requiring sensitivity to American Indian religious uses, and as encouraging minimization of impacts on religious uses, but as not requiring protection of each specific use.

ROADS IN UNDEVELOPED AREAS, LOGGING LOW-ELEVATION OLD GROWTH AND THEIR EFFECTS ARE NOT DISCUSSED

A number of factors have not been given adequate consideration in the Forest Service preferred alternative. Road building in previously roadless areas and logging of lower-elevation old growth forest will unquestionably reduce the areas available for religious activities and gathering of traditional materials.

> **Response:** These effects were discussed in the DEIS, Chapter IV, pages IV-74-76; parallel text has been included in the FEIS.

LOGGING CEDAR DOES NOT FACILITATE ENTRY TO CEDAR AREAS

The Plan states that roads will facilitate entry to cedar areas for a brief period after roads are built and before trees are cut. This statement is an affront to the intelligence of the Indian and non-Indian people! The implication that the Forest Service is helping the Indian people by opening roads to cedar areas is absurd! This short-sighted "reasoning" ignores the fact that the cedar will be logged! Cedar is a cultural resource. The values of the cedar sites will be lost forever.

Response: The effects of logging on cedar availability were recognized in the DEIS and also in the FEIS, in Chapter IV The brief availability of cedar between road construction and timber harvest was not considered as a benefit to be derived from the implementation of the Plan; this statement has been reworded in the final EIS.

MANAGEMENT OF WESTERN RED CEDAR IS NOT DISCUSSED

None of the plans address the co-management of western red cedar; we are gravely concerned that the limited old growth cedar is threatened

Response: Changes made since the Draft include addition of a Forest-wide Standard and Guideline that states that western red cedar will be replanted where it currently or historically has existed or where it would be suitable to plant. Refer to Chapter 4, Forest Plan. Tribal input into the environmental analysis process for each project will certainly be considered in deciding whether cedar is included in the planted stock.

The protection afforded to cedar sites identified in the **Inventory** is summarized in Table IV-24, FEIS. Overall, as discussed in Chapter IV, the availability of cedar will be reduced

CHAPTER IV DISCUSSION ON CEDAR IS CONTRADICTORY

The section in the DEIS, Chapter IV on cedar is somewhat contradictory. "Cutting of cedar and particularly old-growth forest is perceived as irreparable." (IV-74) Yet, in the next paragraph the document suggests that "Cedar of a variety of age classes from old-growth to mixed-age stands is the *most valuable* " *In other words, although old-growth cedar* is "*irreparable*" after harvest, it is not necessarily the most valuable

Response: The text of this section of Chapter IV in the FEIS has been revised to indicate that cedar of saw-log size or greater is more valuable than cedar of smaller sizes Within the larger sizes, old growth cedar is more valuable than other size classes, and pure stands are most valuable. That is indicated by the **Inventory**. Conversion of cedar stands to a managed condition (i.e. harvest) irreparably destroys the natural qualities, (that is, the spiritual influences on their condition), that confer religious significance.

NEED A POLICY TO PROHIBIT HARVEST OF CEDAR

Recommend that western red cedar be considered a "sacred object" by the agency, and that the agency adopt a formal management policy that strictly prohibits its' commercial harvest.

Response: Consideration of western red cedar as a sacred object would exceed the scope of the AIRFA. Prohibition of commercial harvest would conflict with the Multiple Use-Sustained Yield Act, NFMA, and other legislation. The AIRFA Report shows that its concern with sacred objects is to remove restrictions on their possession. The Forest Plan now includes a Forest-wide Standard and Guideline for western red cedar; see Plan, Chapter 4.

PLAN SHOULD ADDRESS TAKING OF CEDAR

In the DEIS and draft Plan, no specific provision is made for Seyowin access to cedar and other floral needs The NF should allow for the taking of these materials or explain why it believes it is not within its discretion to do so. Note that the Indians reserved these rights by treaty.

Response: Forest policy on cedar use is governed by a 2400/2360 memo of April 27, 1981 to the Director of Recreation R-6, from Arno Reifenberg, Regional Attorney, and a 2400/2360 memo of July 23, 1981 from Regional Forester Jim Torrence to the Supervisor of the Olympic National Forest. The policy was reaffirmed by a July 19, 1989 memo from Michael E. Trow, Attorney, Office of the General Counsel, to the Supervisor of the MBS. In brief, the policy permits negotiated cedar sales to Native American groups. The effects of various Plan alternatives on cedar availability are shown in FEIS, Chapter II, comparison of alternative outputs and effects.

BETTER INVENTORY DATA NEEDED, ESPECIALLY FOR OLD GROWTH CEDAR

Before the Plan/EIS can adequately evaluate protection of old growth cedar forests, the Inventory of other National Forest timber stand data needs to be refined to identify them. Better inventory information is also needed for most other resources.

Response: As discussed in Chapter III, Vegetation and Timber, DEIS, "old growth" was not specifically inventoried in the most recent timber stand inventory. Chapter 2, Forest Plan, Information Needs has been revised to state the need for additional information on cedar availability. Also refer to the new discussion in Chapter III, FEIS on the integrated resource inventory, the old growth portion of this inventory should be completed by 1991 Amendments after this date (and the next full revision of the Plan) will include this new data. In addition, the complete resource inventory (which includes timber, vegetation, and other resource data) will be completed by 1995. Refer to Chapter 2, Plan for the list of information needs for all resources. Listed data will be gathered as funding becomes available.

DISCUSS SITES USED FOR GATHERING

Gathering is a right secured by treaty. Sites traditionally used for gathering roots, berries, mushrooms, and other flora need particularized consideration by the Forest Service.

Discuss impacts on old growth with regard to the several varieties of flora which are found only in old growth areas and are gathered by tribal members.

> ***Response:*** *Recognized in the DEIS on pages III-92 and IV-75. Sites used* for plant gathering are included in data on sites receiving "high" or "moderate" protection, and will be considered in project-level consultation.

INCLUDE MORE OF THE INVENTORY IN THE FEIS

The Plan/EIS should include a more complete discussion and analysis of the historical, ethnological, and legal bases for American Indian religious use of the National Forest. Entire sections of the **Inventory** could be copied and/or summarized for a more thorough foundation for decision making.

> **Response:** The **Inventory** was used in developing the summaries presented in the Draft and Forest Plans/EIS, and constitutes the overview required by the NFMA. Entire sections were not copied, since the Inventory is quite lengthy (743 pages), and 40 CFR 1502.7 recommends that "The text of final environmental impact statements .. shall normally be less than 150 pages and for proposals of unusual scope or complexity shall normally be less than 300 pages" Copying substantial segments of the Inventory would not guarantee better understanding.

INVENTORY IS INCOMPLETE, OUTDATED; COMMIT TO UPDATING THE INVENTORY

The Tribe is appalled by the Forest Service's current position that the Tribe had better hurry up and inform the agency of all such sites now or forever hold their peace. To inventory such sites, the Tribe's elder population must be involved; a great deal of work is involved The Forest Service must exhibit more understanding of this highly sensitive issue.

There were Tribes which did not participate in the **Inventory** process; it is, therefore, incomplete and efforts to update it should be made.

In addition to incomplete participation, the **Inventory** was completed in 1981; it is is old and probably incomplete even as to those who participated Does the Forest Service intend on updating this Inventory?

The implementing regulations for the NFMA (36 CFR 219 12(d)) require that areas needing further research be incorporated into budget development. The need for extension of the work started during the preparation of the Inventory is acknowledged in the Draft. Now, you should implement this by explicitly committing the resources necessary, include this commitment in the Final Plan.

> **Response:** The **Inventory** identified all Native American groups known to have a direct religious interest in lands administered by the Forest. However, specific tribes varied in their participation, and it is likely that use areas were not included in the **Inventory** Also, additional sites

have come into use. Updates of the **Inventory** are scheduled for 1991 and 1996 (Plan, Appendix D, Cultural Resource Implementation Schedule) This schedule is the basis for developing the program budget. The Forest will contact Native American groups regarding the updates and an appropriate format. Details of the budget will be developed based on tribal response. Also, Tribal representatives or individual practitioners may come forward at any time to identify additional localities.

NEED TO IMPROVE THE CONSULTATION PROCESS

The Plan/EIS should create a more adequate consultation process.

Recommend that the FS and the tribe establish agreed upon management principles which will guide all activities in-or-around potential or actual sites.

The Plan emphasizes the importance of the consultation process and Memorandum of Understanding. Yet, the consultation process has failed to respond to Lummi Tribal concerns. When tribal leaders and elders state that an area must be preserved, they are told that, at best, the forest activity can be adjusted "at the margin", or, the activity can be "delayed". Neither of these choices are real choices for areas with a sacred meaning. In addition, the fact that the FS does not meet in good faith to protect these sites, and now, that the Plan outlines the destruction of identified sites, is not likely to increase confidence in the consultation process.

Response: Inquiries will be made of the tribes to evaluate the consultation process and improve it. Establishment of management principles for religious and cultural use sites, through Memorandum of Understanding, will be undertaken within this context.

The Forest regrets that it is not possible to protect 100% of the inventoried religious use sites, and we regret that this is perceived as bad faith. The nature of most religious use sites is such that decisions must be of an all or nothing nature - a site is protected through non-development, or its religious significance is totally lost. It would not be appropriate to miss opportunities for protection or mitigation by failing to require consultation, hence we will continue to consult. A "no action" alternative is considered in each Environmental Assessment, and other protection or mitigation measures may be considered, however, it is not possible to protect 100% of the identified, or potential, religious use areas within the framework of multiple-use management.

THE CONSULTATION PROCESS NOT ADEQUATELY DESCRIBED IN DOCUMENTS

No planning element adequately describes the consultation process that the Service intends to employ when activities threaten to damage or destroy culturally significant sites.

Response: The existing process was briefly described in the DEIS, page III-93 and the Plan at 4-76. In the Forest Plan, the Forest-wide Standards and Guidelines have been revised to more explicitly describe the process to be employed during consultation. In 1987, the MBS contracted for development of a model consultation process, to be used as a starting point for updating consultation procedures. This will be submitted to local

tribes with the inquiry on **Inventory** updates, and responses will be used to develop consultation processes tailored to the needs of each group.

WHICH TRIBE HAS PRIORITY CONSIDERATION FOR USE, CONSULTATION?

With 15 Tribes in consultation about sites, the conflict between the various Tribes and individuals within those Tribes must be great. Which Tribes get priority consideration? This needs to be discussed in the document.

Response: Inter-tribal competition for the use of specific sites is not present, so it is not necessary to establish priorities among the Tribes.

WHEN DOES THE PUBLIC GET INVOLVED IN CONSULTATION?

We support attempts at mitigation through consultation. At what point, if any, does the public enter the process? We believe that we should be included in the early stages of consultation

According to the Forest Indian specialist, the public enters into the consultation process after the environmental assessment is written, and after Tribes are consulted (if there is an potential impact) - in other words, at the end. Does this violate NEPA?

Response: In fact, the public is involved during the first step of the environmental analysis process: scoping. As part of the scoping process, interested or impacted individuals, agencies, and organizations are consulted and invited to develop the issues and concerns to be addressed in the proposed project. The **Inventory** is consulted during scoping, well before the project is documented (either in an environmental impact statement, an environmental assessment with finding of no significant impact, or in a decision memo). If a religious site is present in the project area, the appropriate tribe is consulted during the data-gathering phase. A range of alternatives is developed, based on the input from the tribe and from other organizations and individuals involved. A preferred alternative is selected based on the decision criteria for the project, and the direction of the Forest Plan

TRIBE SHOULD BE FORMALLY INCLUDED IN ALL TIMBER HARVEST DECISIONS

Include provisions in the final plan to formally include the Tribe in all timber harvest decisions. Such coordination is crucial in order to insure that the Tribe's treaty rights are not interfered with by the Forest Service and contracting loggers.

Can we assume that if an area has cedar and pure water all tribes must be notified of ground-disturbing projects? (III-93) This seems to be an open invitation to control the management of the MBS by one interest group. Your goal is to provide access, not to protect the entire forest for Native American religious practice

Response: Including tribes in timber harvest decisions is provided for under FS NEPA Implementing Regulations (FSM 1950 and FSH 1909.15). The Tribe should make this request of the Rangers of the Districts managing lands of concern to the Tribe. It can be implemented at any time: in the

context of a project environmental analysis or through an agreement to send scoping requests to the Tribe. Subsequent decisions can consider Tribal input to the analysis.

Consultation is undertaken with a tribe if a ground-disturbing project is proposed within an area identified in the **Inventory**, or within an area in which the Forest has subsequently been notified of use. The tribe(s) notified are those with a record of use (historic or present) of the project area The Forest goal is to make areas available, subject to the totality of laws and regulations under which it operates.

LITTLE DISCUSSION OF PLAN IMPACTS ON TRIBAL SOCIETY

There is a lengthy discussion of the impacts of the Plan on the Human Community There is, however, little discussion of the impacts of these activities on the tribal social and community structure.

Response: Chapter IV of the FEIS has been revised to add material on the role of traditional culture in maintaining a sense of personal identity and worth, and in maintaining an ordered and meaningful community structure.

PROVIDE LOCAL LAND MANAGERS MORE DISCRETION TO SET ASIDE AREAS

Recommend that the agency restructure the consultation process, providing local land managers more discretion to permanently set aside identified cultural use sites and areas.

Response: The only authority to allocate cultural use sites and areas to Management Areas providing protection is contained in the National Forest Management Act and Renewable Resource Planning Act, which establish the Land Management Plan as the vehicle for making long-term allocation decisions The current Forest Plan will be updated at least every 10 to 15 years. In addition, during the environmental analysis for each proposed, ground-disturbing project, a "no-action" alternative will be considered.

ALL AREAS WITH CONDITIONS FOR TRADITIONAL/RELIGIOUS USE SHOULD BE SET ASIDE

Recommend that areas which contain environmental conditions necessary for traditional and/or religious use be set aside for traditional religious purposes and that transverse corridors be established between these areas.

Response: Areas containing environmental conditions necessary for religious and traditional uses consist of unpolluted lakes, streams and creeks; old growth and associated habitat, and unique geologic formations, all in an isolated setting We have interpreted this comment to mean a request to set-aside all such areas. That is not feasible within the context of existing Forest Service program legislation (Multiple Use-Sustained Yield Act, National Forest Management Act).

SUSPEND ALL ACTIVITY NEAR FOUR SITES

Recommend that all forest activity be suspended within a one mile radius (minimum) of Lummi sites 1-1, 1-3, 1-9, and 1-10. These sites will be significantly impacted under the current preferred alternative.

Response: The Preferred Alternative assigns areas 1-1 to MA 17, Timber Management Emphasis. Area 1-3 is assigned to MA 1B, managed to retain a semi-primitive character for non-motorized recreational use and to provide natural habitat for wildlife. Area 1-9 is primarily within Management Areas 23A (Other Municipal Watershed), 14 (Deer and Elk Enhancement), and 10, Wilderness. Area 1-10 is partially allocated to MA 5 (Recommended Wild and Scenic River), MA 11 (SOHA), and partially to MA 17, the portion allocated to MA 17 is currently roaded. On an acreage basis, a substantial portion of these areas will remain unroaded and unlogged.

DISCUSS AND IMPLEMENT PROCEDURAL ASPECTS OF AIRFA

The Plan/EIS should also discuss and implement the procedural aspects of the AIRFA. AIRFA not only requires access to sites, it also requires that Federal agencies give special consideration to American Indian Religious activities that affect them.

Response: The provision for consultation was discussed in the draft plan, pages 4-76 to 77, 4-154 to 4-156 and 5-8; it is discussed on page III-93 in the DEIS. Parallel text is included in the Forest Plan; Chapter III of the FEIS has been revised for clarity Local Tribes will be contacted on the need to update the Inventory, and updating has been scheduled Additional protection for sites will be considered in the context of project-level environmental analysis, and will be implemented provided it does not constitute a significant change to the Plan

NEED AN ADVISORY COMMITTEE TO EVALUATE ADEQUACY OF THE PLAN

Recommend that the Regional and National Forest offices, in association with the tribes, convene an Advisory Committee to jointly evaluate the adequacy of the Forest Plan, and the planning process, with respect to Indian Religious Use.

Response: A decision was made not to convene the Committee, since tribal comments on the Plan have shown a high degree of consistency, favoring a cessation of old-growth harvest, and other developments of old-growth areas, and calling for a halt to the decline of western red cedar Comments regarding the consultation process have likewise been consistent, expressing dissatisfaction. It is not clear what the Committee would add to this evaluation

SUGGEST A PROGRAM OF CROSS-CULTURAL EDUCATION

Recommend that the agency undertake a program of cross-cultural education, in association with the tribes, to improve understanding of the value and meaning of cultural use sites, areas, and resources.

Response: This recommendation is accepted, and is not dependent upon implementation of the Plan or any specific alternative.

HARVEST OF OLD GROWTH WILL IMPACT RELIGIOUS AND TRADITIONAL USES

The Forest Service makes harvest projections for cutting almost all of the old growth timber over a period of years; the opportunities for tribal members to practice their religion and gather traditional materials unique to old growth forests will be gone. The prospect of handing down a legacy is very dim given these planning objectives.

Response: Approximately 643,500 acres of old growth timber are present on the MBS. Over one-third are located in wilderness and not available for harvest. Other acres are not suited for timber harvest due to other resource allocations or because of unstable soils. Refer to Table II-91, FEIS. By the end of the first decade, the old growth remaining on suitable lands will be about 122,000 (from a starting point of 140,800); by the end of the fifth decade, old growth on suitable acres will total about 32,400 acres, with a total old growth acreage of about 535,000 acres.

INADEQUATE CONSIDERATION IS GIVEN TO SCENIC QUALITY

The plan only addresses 17 of 55 viewsheds on the forest. This is too much of an urban forest with high recreation use to allow only these few viewsheds to be well done. Add the following viewsheds: Whitechuck River, Suiattle River, French Creek, North Fork Sauk River, Crystal Mountain (it receives 300,000 skiers), Cuyada Creek, and Corral Pass.

Response: Based on public response to the Draft Forest Plan, several viewsheds have been added to the "Scenic Viewshed" management areas 2A and 2B. These include the roads up the Cascade River (FR 23) and Whitechuck River, Crystal Mountain, and the route to Suntop Lookout.

Additionally, there are many other allocations which maintain high standards of scenic quality. These include 1A, 1B, 1C, 3A, 3C, 3D, 5, and 10, among others. More than 75% of the National Forest land base has a high standard for visual quality, either Preservation, Retention, or Partial Retention.

STATEMENT ABOUT VISUAL QUALITY OBJECTIVES FOR ALL NF LANDS IS MISLEADING

"Establish and implement visual quality objectives for all Forest lands." This is very misleading. It implies that the visual management system will be in affect on all lands, when in reality, a few management areas have restrictive visual guidelines, and most just say meet maximum modification.

Response: Modification and Maximum Modification are visual quality objectives which allow management activities to dominate. This does not mean that there is no consideration for the visual resource. Less than 25% of the National Forest land base has this visual quality level

HOW ARE VIEWSHED CORRIDORS AND DISTANCE ZONES DEFINED?

Visual corridors should be limited to a half mile, rather than the two miles that you suggest (III-99).

In none of your summary did I understand the distinction between foreground and middleground scenery

Response: The purpose of designating scenic corridors or "viewsheds" is to provide a recreation setting that meets the public's expectations for scenic quality. Seen areas define the boundary of the area of concern. Distance zones (foreground, middleground) are established to differentiate between importance of detail (close up) and perspective (further away).

Foreground begins at the viewer and extends 1/4 mile to 1/2 mile away. Middleground begins where foreground ends, and extends 3 to 5 miles away. The purpose of having a range is to accommodate variations in terrain without creating arbitrary lines across the landscape. In some cases, parallel viewsheds, i.e. a road and a river, are combined when mapped, producing a wider foreground. A narrower corridor is not sufficient to sustain visual quality over time. These terms are further explained in Agriculture Handbook # 462.

WHAT DETERMINES PRIMARY AND SECONDARY VIEWSHEDS?

Are your primary and secondary classifications of viewsheds based upon the amount of traffic or some subjective criteria (page III-99 in the DEIS)? If there is specific criteria, it should be made available to the public and reaction to it sought during the comment period.

Response: Identifying Primary and Secondary Viewsheds is one step in the process of establishing sensitivity levels, which are a measure of people's *concern for scenic quality in National Forests* Sensitivity levels are determined for areas viewed by people traveling through the Forest on developed roads and trails; using areas (campgrounds, visitor centers); or recreating at lakes, streams, or other water bodies. Some degree of visitor sensitivity is established for the entire land base All travel routes, use areas, and water bodies are identified as being of either primary or secondary importance. The following list provides a general method for determining into which category an area falls:

	Primary Importance	**Secondary Importance**
Travel Route	National importance	Local importance
	High use volume	Low use volume
	Long use duration	Short use duration
	Arterial/Collector	Local/Project roads
Use Areas	National importance	Local importance
	High use volume	Low use volume
	Long use duration	Short use duration
	Large Size	Small Size
Water Bodies	National importance	Local importance
	High fishing, boating, or swimming use.	Low fishing, boating, or swimming use

The Draft Forest Plan allocated some of these viewsheds to management areas providing for protection of the scenic resource. The Forest Plan added several other viewsheds to this category See Chapter II, FEIS, Alternative Descriptions, for further information.

DON'T UNDERSTAND THE HARVEST REDUCTIONS FOR MEETING VISUAL QUALITY OBJECTIVES

I don't see how we can harvest 65% in foreground Retention, and 86% in background Partial Retention if we expect to have any trees in a large size class, and are on a very long rotation

We need more information about the rationale used to determine the length of extended rotation of vegetation; the 65% reduction in timber volume is a rotation twice as long as normal It seems very arbitrary.

Response: These figures have been misinterpreted. Sixty-five percent of full yield does not equal 65% harvest, nor is it a 65% reduction in timber volume. Rather, it means that with an extended rotation (5-6% harvest per decade for foreground Retention), we will only achieve 65% of potential timber yield over a rotation The prescriptions are designed to meet the desired future condition for the management area; refer to Chapter III of Appendix B, FEIS for more information on modeling extended rotations.

MA 2A NEEDS MORE SPECIFIC STANDARDS AND GUIDELINES

In MA 2A Foreground, requiring that 10% of timber stands in foreground areas contain trees 30"-36" in diameter is not very much. Why isn't there an extended rotation age of 120, 200 or 250 years, or a stipulation that only 3-5% of area may be harvested in a decade? There is a minimum 125 year rotation in Roaded Natural, why not in MA 2A?

Response: The model used to predict timber yields to achieve a certain visual condition can be found in Agriculture Handbook #559. In areas managed for foreground retention the model assumes a 195 year rotation. This will vary for different sites, but assumes that approximately 5-6% of the land base will be harvested each decade. The 10% stands with trees of 30-36 inches DBH is a minimum. The amount of disturbance per decade and the rotation length have been added to the prescription for this management area; see Forest Plan, Chapter 4.

SEEN AREAS AND ROTATION LENGTHS ARE NOT SITE SPECIFIC

The length of extended rotations for visual management should be site specific. It is nearly impossible to rationally comment on visual management in this plan, because most was done with computers and topographic maps, rather than by looking at the sites.

We cannot determine the impact that visual management has on other resources on a site-by-site basis. There is no rationale given to explain why an area was dedicated to visual management and/or how many acres will be allocated.

Response: For the purpose of forest planning and the visual resource inventory, seen areas are generated by computer. However, when projects are designed to implement the forest plan, actual viewing conditions are used. General rotation length to meet visual quality objectives are based on guidelines in the "Timber Chapter" of the National Forest Landscape Management series (Agriculture Handbook #559). Project planning will recommend adjustment to this as needed to meet specific area conditions. Rotations are long term management schemes while this plan covers only 10 years.

The acres falling into each VQO class by alternative, are displayed in Chapter II, Table II-9f. The existing visual condition, and the expected visual condition of each viewshed on the forest is described, by alternative, in Chapter IV, Scenery, Direct Effects, in the FEIS.

"FOREGROUND" SHOULD BE ONE-QUARTER MILE WIDE

Foreground must be defined as a strip 1/4 mile wide, not up to two miles.

Response: Foreground is "based upon the distances at which details can be perceived. Normally in foreground views, individual boughs of trees form texture or the detail we perceive. It will usually be limited to areas within 1/4 to 1/2 mile of the observer, but must be determined on a case-by-case basis.. " (page 7, Agriculture Handbook #462) Foreground may have been confused with viewshed, which is the portion of the landscape "seen" by most visitors from roads, trails, and recreation areas. The

viewshed is a corridor 1/4 to about 2 miles wide on either side of a road, trail, or river. (DEIS and FEIS, Chapter III.)

VISUAL QUALITY OBJECTIVES FOR MA 2B MIDDLEGROUND SHOULD INCLUDE RETENTION

In the management prescription for MA 2B Middleground, why is only partial retention required? Why not retention?

Response: Please Refer to page 43 of the Visual Management System Handbook, Agriculture Handbook #462. Typically, those areas in management area 2B which are suitable for timber harvest are in variety class B or C. These variety classes specify Partial Retention or Modification for the visual quality objective.

MIDDLEGROUND SHOULD NOT BE PROTECTED.

We support foreground retention/partial retention in some areas, but oppose the concept of middleground partial retention/modification, as it restricts management activities.

Some consideration should be given to protecting the 1/4 to 1/2 mile (maximum) adjacent to the road, but evidence of multiple use forest management should not be hidden when it occurs "in the distance." The public is infinitely more tolerant than the forest's middleground visual policy intimates.

The use of middle ground is too restrictive. Timber harvest areas should not be restricted if the harvested areas cannot be revegetated in one year; this is also true for landings.

Response: Management of the middleground of viewsheds or seen areas is an integral part of the visual management system. Given the high degree of public concern over scenic quality, it is appropriate to include this intensity in the plan. Considerable public comment was received regarding "paying attention to both foreground and middleground of visually sensitive landscapes."

WHAT LEVEL OF VISUAL QUALITY CAN BE EXPECTED FROM "ROADED NATURAL"?

The plan on page, 4-129 states that in Roaded Natural, "...modifications noticed...however, from sensitive travel routes and use areas, these alterations will appear subordinate to the surrounding areas". What are "sensitive travel routes and areas"? I thought only the 17 selected viewsheds were managed, and nothing was done elsewhere?

Response: When the "roaded natural" allocation overlays a sensitivity level 1 Foreground or Middleground, or a Level 2 Foreground, the visual quality objective will be Partial Retention.

For level 2 Middleground, or level 3, any distance zone, the visual quality objective for roaded natural is Modification.

In the DEIS, the visual quality objectives were met in the 17 viewsheds allocated to management areas 2A and 2B The visual quality objectives for the rest of the forest are still in place, but they are overridden in some

instances by the management allocation. Thus, on some pieces of ground we are exceeding the VQO, and on others we are not meeting the suggested objective. The visual quality objectives are established to meet goals for the management of the visual resource only. To the extent possible, these objectives are met for all areas. In some instances - where resource objectives conflict - we may reduce the VQO for these areas.

WHAT ABOUT VIEWSHEDS FOR TRAILS?

It doesn't seem like there is any consideration to trail viewsheds or smaller scale areas.

Response: Trails take on the Visual Quality Level prescribed for the management area they pass through. Thus, a trail passing through a Research Natural Area (MA 18) would assume a VQL of preservation. Some small scale areas, such as fee campgrounds, are considered sensitivity level 1 areas, and thus, receive foreground retention. Consideration for the scenic quality of a trail corridor should also be a part of planning at the project level

VISUAL IMPACTS SHOULD BE CONSIDERED FROM NATIONAL PARKS

Timber harvest plans along National Park boundaries should be subject to site review to mitigate the visual impact of cuts as viewed from the park. An agreement should be instituted between the Forest and the Park to assess the effects of timber harvest and other development upon the viewshed of the park, and to propose mitigation.

Response: Coordination between the MBS and the National Park Service has been on-going since the Forest planning process began The NEPA process allows for involvement by the Department of Interior during project planning. Consultation is carefully considered in the development of alternatives

HIGHWAY 410 SHOULD HAVE A FOREGROUND SCREEN

The supposed foreground protection screen along Highway 410 east of Enumclaw is inadequate. Consider leaving a 400 foot strip on each side of the road. Within the first 100 feet, mature trees that could be felled or pulled onto the road would be selectively harvested on a 2 to 5 year cycle. Mature timber within 200 feet of the clearcut would be selectively harvested at the time of the clearcut, leaving the remaining 100 foot strip of trees within the corridor untouched. This design would alleviate most of the windfalls due to lack of windbreaks near both the clearcut and the road, and still provide an adequate visual screen for the motoring public.

Response: Highway 410 is largely in private or checkerboard ownership up to the boundary of the Mather Memorial Parkway. There has been little consideration for the visual resource on private lands along the highway, though Mather has had very little disturbance. In the Preferred Alternative, Mather Memorial Parkway is allocated to MA 8, Special Area. No scheduled harvest is proposed, with the management emphasis on enhancement of the scenic and recreational values of the Parkway. (Plan, Chapter 4) The Mather Memorial Parkway will retain its mature forest

character. The 400 foot strip concept proposed here would be inadequate for maintaining visual quality over time.

WHAT IS THE STANDARD FOR VISUAL QUALITY AT CRYSTAL MOUNTAIN?

In your expected visual condition categories, Crystal Mountain has been designated as High for both the 10 and 50-year time frames Does this category result from the normal resort development associated with the ski area, including its trails, or are there other higher impact timber sales planned for the immediate area?

Response: The existing permit area at Crystal Mountain Ski Area is allocated to MA 3C. The standards and guidelines for this area allow no scheduled timber harvest, only that needed to maintain an attractive, safe setting, or to clear new ski runs. Roads and trails are to be developed according to an approved site development plan. Since Crystal Mountain is a sensitivity level 1 recreation area, the VQO's would be foreground Retention and middleground Partial Retention.

Visual Quality Levels for the access road leading up to Crystal Mountain have been revised between draft and final. The expected visual condition for the Crystal Mountain road have also been revised. See Forest Plan, Chapter 4, Visual Resource Summary.

WHAT IS THE VQO FOR THE PACIFIC CREST TRAIL AS IT PASSES THROUGH THE GREEN RIVER WATERSHED?

Referring to the statement on the Green River Watershed: "Manage to maximum modification except in areas seen from the Pacific Crest Trail." What do you manage for on these seen lands?

Response: The standard from the Pacific Crest Trail is foreground retention; refer to element A.1.a. for Management Area 21A, Forest Plan, Chapter 4.

CHANGE THE MANAGEMENT OF THE CASCADE RIVER CORRIDOR

The alternative selected in the final plan should be sensitive to the potential for visual impacts from forest practices along Park access roads and from Park lands along common boundaries. The National Park Service is concerned with the designation of the South side of the Cascade River to MA 17 (timber management). This is a major access route to the park and use is expected to grow in the future. Area should be designated as 1D or 2AB, and the road included as a scenic viewshed. Senate Report No. 700, 90th Congress indicates Congressional concern for scenic viewshed management on this road

Response: We agree. The allocation of the south side of this road has been changed to MA 11 (Spotted Owl Management Area) and MA 2B (Scenic Viewshed) in the Plan.

DID YOU CONSIDER SCORP AND NATIONAL PARK SERVICE PLANS?

In making a cross check between SCORP and the Forest plan, it is quite evident that the plan provisions for recreation did not make use of this information as required in 36 CFR 219.36 CFR 219.21(e).

Response: National Park plans and the Statewide Comprehensive Outdoor Recreation Plan (SCORP) were considered in this planning effort. National Park Service Plans are referenced in Appendix G; we inadvertently neglected to list SCORP in the DEIS. This has been corrected.

SCENIC CORRIDOR ALONG MT. BAKER HIGHWAY MAY BE DIFFICULT TO PROVIDE FOR

I see a dichotomy in Alternative H that could be difficult to deal with. There is a significant commitment to the concept of a scenic corridor along the Mt. Baker Highway. This will, in conjunction with local tourism efforts, act as a magnet for the type of recreation needing more developed recreation services. Alternative H does not adequately provide for the type of service.

Response: The Mt. Baker Highway has been designated as a Scenic Byway by the Chief of the Forest Service. It will be managed primarily for its scenic values. Refer to Forest-wide Standards and Guidelines for Scenic Byways, Chapter 4, Forest Plan Developed recreation services are currently being expanded, as evidenced by the renovation and additional facilities at the Glacier Visitor Information Center and the Heather Meadows Area. Opportunities also exist for recreational facilities on private lands adjacent to the highway.

ALTERNATIVE C SHOULD NOT HAVE THE LOWEST DISCOUNTED RECREATION BENEFITS

I completely dispute the paragraph in the Summary, page S-43, that states "Alternative C has the lowest discounted recreation benefits...but the highest levels of primitive and semi-primitive nonmotorized recreation capacity." The paragraph conclusion is that motorized use is more valuable than non-motorized use. This portrays the ultimate folly of misdirected analysis that derives from ignoring the value of the human spirit.

Response: We believe the paragraph should be retained, as it explains the discounted recreation benefits for each alternative displayed in Table S-3. Within the paragraph, recognition is given that ". primitive and semi-primitive nonmotorized recreation use has a higher value per recreation visitor day than motorized use...."

WHY ARE CUT-OVER AREAS ALLOCATED TO MA 1A IN ALT.C?

In Alternative C, many extensively-harvested areas were allocated to MA 1AB. This seems odd, as the high impact of existing roads, etc. would contradict the given definitions of this category. Why call a cut-over area "primitive"? What primitive recreation can be done in a clearcut?

Response: The goal of Alternative C was to maximize primitive and semi-primitive recreation opportunities. This was done by closing over 300 miles of roads. Closing the roads allowed many of the existing roaded natural/modified areas to be allocated to semi-primitive non-motorized.

While the current conditions of these areas do not meet the semi-primitive criteria, the future conditions would.

DO WE NEED TO LIMIT NUMBER OF OUTFITTER GUIDES?

Do we need a statement about excessive outfitter-guide use in and outside wilderness? How do we determine if there is too much physical or social impact? If too much, do outfitters get booted out before the public is rationed?

Commercial outfitters and their attendant stock animals should be carefully regulated and monitored. Preservation of natural resources should take precedence over such commercial uses .

Response: Commercial outfitting and guide permits should be allowed where there is a demonstrated management and public need compatible with general public use. This use will be permitted if it does not generate unacceptable impacts on wilderness resources or cause changes which approach limits of acceptable change. The number of permits issued and the amount of use allocated to permit holders should be evaluated periodically to assure an appropriate balance of use between the general public and outfitter-guides. Outfitter guides should not be allowed to dominate the use of an area or occupy favored campsites to the point that use by the general public is limited or constrained. This has been clarified in the Forest Plan, Chapter 4, Forest-wide Standards and Guidelines for wilderness

ALLOW NO DEVELOPED SITES IN RIPARIAN AREAS OR CRITICAL WILDLIFE HABITAT

Developed sites should be located outside riparian management area boundaries and provided with developed trails to access water.

Keep developed sites outside of known critical wildlife habitats or riparian management area boundaries.

Response: Standards and Guidelines for Management Area 13 stipulate that activities within riparian areas will be permitted only when riparian objectives can be accomplished. Any conflict between riparian values and recreation use will be resolved in favor of the riparian values.

Developed sites, such as campgrounds and day use areas, are permitted within riparian areas. People are attracted to this type of environment and our experience has shown that riparian values can be better protected when facilities - including sanitation - are provided in a managed setting, compared to unrestricted use with no facilities. Critical wildlife habitat, such as that needed for threatened and endangered species, would preclude any development. Refer to MA 13, Chapter 4, Forest Plan.

ASSUMPTION THAT USE WILL NOT EXCEED ESTIMATED CAPACITY IS FLAWED

The assumption (page II-96, DEIS) that projected recreation use will not exceed the estimated capacity for any activity is strange. If this were valid, no area could experience overcrowding.

Assuming that projected use will not exceed estimated capacity for an activity may be good for modeling but it does not correspond with experience. It is more likely that the "quality" of the experience will simply be reduced. The FS has dealt with this problem for many years, but there are very few instances where overuse has been successfully controlled. Even then, controls have only been imposed as a last ditch resort and only after environmental damage is very evident.

Response: This statement refers to our decision not to value any expressed recreation demand beyond the estimated capacity for a particular zone or activity. For example. if the capacity for developed recreation is x and the demand is 5x, the FORPLAN model is constrained from accruing any value over x, as it is likely that use will be restricted and thus managed at or near this capacity level. This is done to more accurately portray the economic effects of recreational use as limited by capacity, instead of valuing all potential use, even that beyond capacity. Economically, the total value should be about the same - if use significantly exceeds capacity, all users will incur decreases in value because of deteriorating quality of experience. Thus, use greater than capacity times lower unit values should be approximately the same total value as that modeled.

Historically, overuse has been a problem as stated; however, with implementation of this plan, and the standards and guidelines - including monitoring the limits of acceptable change (LAC's) - the Forest is optimistic that site deterioration can be reversed

EXPLAIN TABLE S-1

Table S-1 shows zero potential recreation sites - what does this mean?

Response: Table S-1 shows acres allocated to various management areas, but does not show potential projects All proposed developed site construction are shown in the Forest Plan, Appendix D, Recreation Implementation Schedule. Additional sites will continue to be added to this implementation schedule, through Forest Plan Amendments, as the need arises and funds are available.

PLAN DOESN'T RESPOND TO DEMAND FOR DEVELOPED SITES

The lack of maintenance in many developed areas and associated use impacts has been apparent for at least a decade. This, along with the projected increase in demand for all types of recreation sites should be a primary focus of the plan.

Your figures are not realistic when you say there are ample campgrounds; we have been turned away from too many to believe that.

According to your estimates, population in the Puget Sound area is projected to grow by 16% to 26% from 1980 to 1990, and another 10% to 19% by 2000. While this is mentioned in the DEIS, the proposed plan does not respond to these widely recognized public needs for more sites and developed facilities to accommodate the obvious present and future demand. The plan states that new construction of sites will be needed later - why not now? The Plan also states the Forest has enough developed sites to meet demand in the short term - we disagree.

Response: We recognize that, while we can meet Forest-wide developed site demand over the short-term, some specific sites on the Forest are currently over-used and over-capacity, especially on high-use summer weekends. The priorities in the near future will focus on these areas, with reconstruction, expansion, and increased maintenance of the existing sites. In the next decade we intend to rehabilitate all of our campgrounds that are currently in need of maintenance. Late in the first decade, four new campgrounds, and 8 to 12 new day-use sites, like Heather Meadows and Deception Falls, will be constructed. The decision to construct new sites is dependant on demand and the availability of funding. Developed site construction and reconstruction schedules can be found in Appendix D of the Forest Plan.

DISPLAY OF DEVELOPED CAMPGROUND INFORMATION IS MISLEADING

The draft documents are misleading in portraying the number of campgrounds planned for construction by alternative The misprints in the Public Summary, which conflict directly with the DEIS, will leave people confused and unable to comment on the management of the MBS.

By lumping campgrounds with ski areas, it is difficult to determine the plan's effect on campground development and maintenance.

Response: The errors in the Public Summary has been corrected. Appendix D, Forest Plan shows the program for construction and reconstruction of campgrounds in the Preferred Alternative. Chapter II, FEIS shows the campground construction and reconstruction by alternative.

NEED A LIST OF DEVELOPED SITES

Please include a list of all existing and potential developed sites with their capacities and current experience level, along with desired future capacities and experience levels.

Response: This information has been included in the FEIS, Chapter III, and in the Forest Plan, Chapter 4 (Resource Summary). Future developed recreation construction and reconstruction is found in Appendix D of the Forest Plan.

NEED FOR IMPROVED AND UPDATED FACILITIES, AND A VARIETY OF DEVELOPED SITES

There is a need for more campgrounds with flush toilets, running water, hot showers, etc. However, do not make campgrounds into cities by making them all larger in order to reduce unit costs.

The Forest Service must realize that the demographics of national forest recreation clientele are rapidly changing as the visitor population is aging and changing their activity preference in favor of better facilities and easy access.

I would hate to see Forest Service campgrounds run KOA style, they should offer a more primitive setting.

Response: The FS recognizes there is a demand for a wide diversity of developed camping facilities and experiences. This is addressed in Chapter 4, Forest Management Goals for recreation, Forest Plan. Our goal is to provide a broad spectrum of recreation opportunities which require a natural setting and cannot be provided on non-National Forest Lands. To accomplish this, we will be upgrading some campgrounds and high use sites to include more amenities (like flush toilets) where water and power are economically available.

CAMPGROUND CLOSURES ARE NOT JUSTIFIED

Developed car campgrounds are in great need. Why are only half the original number of campgrounds open? We recommend you begin a program to reopen most of the campgrounds and/or identify future needs.

After closing campgrounds due to lack of funds, you are now proposing to build new ones or enlarge some, while many of the closed campgrounds are still sitting there in their closed condition. It would be judicious to make sure that adequate funding is available before committing to new ones.

Response: The decision to close a campground is not taken lightly. In 1984, a study was conducted of all developed recreational facilities on the Forest, it is described in Chapter III of the DEIS and FEIS. The goal of this study was to better utilize available funding and to identify opportunities for improved campground management. The study recommended altering management on 43 percent of the sites. Twenty-one sites were closed, most with less than 10 units/site, so the overall capacity of the Forest was not impacted. These sites will remain permanently closed as a developed site, but remain available for dispersed camping. New capacity will be added at existing sites and at new, economically efficient, locations.

IT IS A CRIME TO CLOSE FRENCH CREEK CAMPGROUND

I think it was a CRIME to beat up and close the beautiful campgrounds at French Creek. Citizens paid a lot of money to build that, and donated time to care for it. And now you are planning on spending $280,000 plus the cost of the facilities that are in place to destroy our other property.

Response: French Creek Campground had deteriorated to the point that the Forest was unable to effectively maintain and manage the facilities. A quality camping experience was not available there. In 1980, about one-third of the facilities were heavily damaged by flooding; vandalism followed. This destruction, coupled with limited financial resources, lead to the closure decision. The historic shelter and sanitation facilities have been retained for public use.

NEED YEAR-ROUND CAMPGROUNDS

We object to the arbitrary and unrealistically short use-season for developed campgrounds. We believe FS policy limiting use of most campgrounds to between around May 15 to September 15 is inappropriate, unjustifiable and without logical support, especially since the weather during the remaining 9 months is

often good. Especially onerous is the fact that access to the campgrounds is usually blocked by locked gates outside of the use season.

You should rewrite your plan recreational policy to provide unrestricted, year around access to developed campgrounds, except during the snow season, when use will be self-limiting. Year-round use need not include a water supply or garbage service outside the heavy use season.

Response: The Forest Plan does not dictate the season of use for recreation. This has traditionally been a function of the budget. We would be responsive to a longer season of use for developed campgrounds if solutions could be found to the problem of vandalism - and to a lesser extent inadequate funding - experienced during those months when use is down. Gates have been installed to offer some degree of protection of the site from vandals

Darrington Ranger District is currently experimenting with keeping 13 campgrounds along the Mountain Loop Highway open all year at reduced service levels. There is no security, water, or garbage pickup. This policy may be continued if campgrounds remain clean and free from vandalism.

GREATEST DEMAND IS FOR MOTORIZED DISPERSED RECREATION LIKE DRIVING FOR PLEASURE

The Forest has misinterpreted use data and has erroneously shown higher demand for non-motorized dispersed recreation than for motorized dispersed recreation. It must be kept in mind that "driving for pleasure" or "auto travel" is the most popular activity on the forest.

Response: While it is true that motorized dispersed recreation has a greater demand than non-motorized in absolute numbers, motorized recreation also has a greater surplus of capacity (supply) over demand (use). The plan shows that capacity is reached quicker for non-motorized recreation than for motorized dispersed. In part, this is due to the higher per acre carrying capacities for motorized recreation lands

Driving for pleasure can be a misleading statistic and needs clarification For instance, in 1983, 70% of the driving for pleasure RVD's occurred on I-90 over Snoqualmie Pass. This is typical; most of the currently reported auto travel/driving for pleasure RVD's occur on state or federal highways that pass through the national forests, a much smaller amount actually takes place on Forest Service system roads. The 1975-76 Outdoor Recreation Survey for Washington identified driving for pleasure as the number one activity in the state, but did not identify where this activity was occurring.

WHY DOES THE AMOUNT OF DEMAND SATISFIED VARY SO LITTLE AMONG ALTERNATIVES?

Why do tables B-65 and B-74 of the Appendices show the demand satified for non-motorized recreation varying so little among the alternatives when the amount of unroaded lands varies significantly?

Response: The percentages cited in Table B-65 include acres within wilderness as well as unroaded lands. The amount of non-wilderness unroaded lands does not vary greatly across the alternatives because

approximately 60% of these areas are unsuitable for timber harvest. The total acres of unroaded lands plus wilderness vary by only 18% across all alternatives. This table shows that the forest will only be able to satisfy 86% of the demand for these types of recreation at the end of the first decade. The small variance is due to the assumption that we are already at or near capacity for non-motorized dispersed recreation.

NEED TO ADDRESS SITE-SPECIFIC DEMAND

The plan should adequately address site-specific recreation demands and propose alternatives for dealing with those demands. The proposed plan discusses the expected increased demand for recreation but fails to address site specific solutions and impacts.

Response: This is a programmatic Plan that addresses the various resource programs on a forest-wide basis; however, potential site specific projects are identified in the appropriate appendices of the Plan. During the implementation of the Forest Plan, the decision on which site-specific projects will be needed to meet the intent of the forest-wide plan will be determined. The impacts from increased demand for recreation are addressed in Chapter IV of the FEIS.

DISCUSS THE EFFECTS OF RECREATION ON NATIVE ECOSYSTEMS

The effects of recreation on the native ecosystem need to be addressed, both in recreation use conflicts in Chapter III and elsewhere in the documents. Recreation can have a disproportionate impact on some areas/habitats (around lakes, and in alpine and subalpine meadows for instance), and indications are that recreational use will increase.

Response: The effects of recreation on all aspects of the environment are discussed in Chapter IV, FEIS. A specific discussion of the ecological impacts of wildland recreation has been added to the Wilderness section of Chapter IV.

PLAN DOES NOT INCLUDE ANY EDUCATION PROGRAMS

There is not provision for the development of education programs within the National Forest system. Was this an oversight? Just as important as any other topic that is covered here, we feel the Forest Service should integrate a very much needed public education program that would illustrate all the various aspects of multiple use and the National Forest System. Examples are displays in service centers, nature and interpretive walks, programs at campgrounds, etc.

Response: We recognize the importance of education programs and did address these programs in several places in the DEIS. In response to this and other comments, a new goal has been added to the Forest Management Goals, Chapter 4, Forest Plan· "Encourage a sense of ownership through expanded interpretation and education. ." The Forest also has an active program of wilderness education in several of the areas school districts. The Forest has also embarked on a greatly expanded interpretive program. Recent projects include Snoqualmie Pass Visitor Center, Skagit River Wild and Scenic River Interpretive Sites, John Muir Interpretive trail for the

handicapped, new displays at the Glacier Visitor Center, and the Fire and Ice Trail at Heather Meadows.

INCLUDE AN ANALYSIS OF RECREATION NEEDS IN A REGIONAL CONTEXT

The Plan should include an analysis of recreational needs in a regional context including all land management agencies. Some discussion should be given to the need for interpretation and information services.

Response: An analysis of recreational needs in a regional context is addressed in the Forest Service Regional Guide for the Pacific Northwest Region and the Washington Statewide Comprehensive Outdoor Recreation Plan (SCORP). Both of these documents were used in the preparation of this Forest Plan. A new goal was added to the recreation goals section of chapter IV of the plan dealing with increased interpretation and education.

SUGGEST CHANGES IN INDICATORS OF RESPONSE

Indicators of Response Should include an evaluation of actual recreational use rather than just some suitability criteria; i.e , some smaller areas could have good visual qualities, adequate roads, and other amenities, but could be too isolated to provide wildlife recreation or have and insect problem or some other nuisance that would keep people away, but that would not show up in a "qualitative analysis." We recommend that wildlife abundance and diversity be a parameter to judge these areas.

Response: Wildlife abundance and diversity are considered and addressed in the Indicators of Response for the issue of Old Growth Ecosystems and Fish/ Wildlife/Plant Diversity. Note that this issue has been re-titled since the DEIS. The indicators of how the FEIS alternatives respond to the issue of Recreation Opportunities have not been changed from the draft.

NONWILDERNESS PRIMITIVE AND SEMI-PRIMITIVE RECREATION OPPORTUNITIES LACKING

In the Summary, it is stated that the assumption was made that projected nonwilderness primitive and semi-primitive recreation use will not exceed capacity. It sounds like you are speaking of a net displacement of recreationists from the national forest. Since there are few alternatives for this type of use, it will become essentially unavailable to those who can't travel to another, less-developed forest. If the Forest chooses to further reduce the supply of this kind of recreation, people will have little choice but to abandon the activities they value. I don't see this as providing for a wide range of recreation opportunities, as required of NFMA.

Response: We believe a broad range of recreation opportunities has been displayed and analyzed among the various alternatives Due to the greatly increased population of the Puget Sound area, it will not be possible, under any alternative to meet the demand for Primitive and Semi-Primitive recreation. This will lead to a reduced experience level on these lands and displacement to other areas, or to increased regulations on the use of these lands.

JUST ASSUME CAPACITY EXPANDS AND CONTRACTS WITH DEMAND

Instead of making arbitrary judgements, isn't it just as rational to assume that capacity expands and contracts with visitor demands? If an area is too crowded either: 1) people will regulate themselves and not return or 2) the number of people there doesn't impact their experience.

Response: Your assumption that capacity expands and contracts with visitor demands assumes that wilderness was created solely for recreational use, and that use can continue to expand unchecked. This assumption is false. *The over-riding goal of wilderness management* is to protect and preserve the natural environment from human caused change. This is accomplished through the use of the LAC process.

Outside of the wilderness, the ROS system attempts to preserve a broad spectrum of recreational opportunities and experiences. It attempts to stop displacement of users. Displacement is a shift in behavioral patterns of resource users in response to adverse changes. Displacement is presumed to be differential among individuals; as the recreation setting changes such changes may alter the probability of users having desired recreation experiences (Anderson, 1980). Research on river users shows that crowding is the most frequently cited reason for not returning to an area (Dekker, 1976, Nielsen and Endo, 1977, Shelby, 1988.

TOO MUCH LAND ALLOCATED TO WILDERNESS, UNROADED RECREATION

Under the proposed land allocations, wilderness, Alpine Lakes area, and proposed unroaded areas total 1,233,445 acres, or 74.6% of the net forest acres. However, recreation use days for wilderness and unroaded areas constitute only 12.6% of all recreation-user days. PLUS feels that this is clearly an imbalance in land allocation.

There are numerous factual errors and false assumptions in the analysis and proposed management direction for the recreation resource on the forest. The draft plan presents a biased, hard-sell case for retaining non-wilderness roadless areas. There are many examples of the overly-enthusiastic case for roadless area retention

Response: We are unable to duplicate the 1,233,445 acre figure cited. The acres in MA 27, Alpine Lakes Management Area are not assigned solely to *unroaded recreation, but to a variety of uses, including general forest,* scenic forest etc. Refer to the discussion in Chapter II, Alternatives, FEIS.

Land was allocated in the Preferred (and all) alternatives to meet the objectives of the alternative and maximize net public benefits. A new alternative is displayed in the FEIS that was developed to meet to objectives of PLUS - Alternative I.

ADD THE POSITIVE EFFECTS OF BUILDING ROADS IN UNROADED AREAS

The discussion of cumulative effects and indirect effects of building roads in roadless areas (DEIS, page IV-120) is a fictionalized elaboration of the obvious It is interesting that only the perceived negative aspects are mentioned. There will be a change in use, resulting in increased RVD's and

other multiple-use benefits, but whether or not this would affect wilderness use on and off-Forest (negatively or positively)... this is unknown. Please elaborate, including the citation of pertinent research publications.

Response: There are a number of publications that speak directly to the behavior of the recreating public, this information and citations have been added to the FEIS. However, we acknowledge that opportunities would increase for those seeking recreational pursuits in a roaded setting. The cumulative effects on recreation has been revised accordingly (Chapter IV, FEIS).

MINIMIZE PRIVATE DEVELOPMENT ON NF LAND

Private development under special-use permits on the public forest lands should be minimized. The Forest does not have an obligation to provide profits to private industry, nor does it have an obligation to develop its lands for more sophisticated forms of recreation. Developed recreation is better developed by private industry on private lands. Primitive recreation is absolutely unavailable on private lands; this experience should be available for as many people and for as many years as possible.

On page 4-1, Forest Management Goals for recreation are addressed Paragraph 6 talks about encouraging private development under special use permits. This is highly objectionable and evidence of the unfortunate trend to "privatize" national forests.

Resorts and organization camps would constitute an exclusive use by my definition. It is, in a sense, providing "free land" for a very specialized elite user group while taking the land away from use by the general public. Recognizing the FS obligation to existing groups (Camp Shepard, etc.), I oppose additional "permittees" permanently changing the character of national forest land.

Response: The Forest Management Goals for Recreation found in Chapter 4, Forest Plan, have been revised. These goals now focus on providing recreational opportunities through partnerships and providing a broad spectrum of opportunities, with an emphasis on those opportunities which require a natural setting.

STATEMENT THAT THE MBS CANNOT MEET DEMAND FOR SPNM RECREATION IS UNFOUNDED, THE FOREST DOESN'T NEED MORE WILDERNESS-LIKE RECREATION.

According to the North Cascades Complex 1987 General Management Plan, 94% of the total 674,000 acres under Park Service jurisdiction is recommended as suitable for wilderness and will be so managed. This consideration should be weighted heavily in recreation planning on the Forest. It should indicate increasing demand for non-wilderness facilities and road access on the Forest. It should not be construed as a need for "more of the same" wilderness outside the park.

We can find no factual evidence to support the planning assumption that "the Forest cannot meet demand for unroaded, nonwilderness dispersed recreation without seriously altering the expected recreation experience on these lands."

The statement that SPNM demand exceeds supply is illogical and unfounded by any credible evidence presented in the plan documents. We believe the supply/demand analysis and projections for SPNM recreation are biased, erroneous, and skewed beyond reason relative to the supply and demand for accessible, developed and motorized dispersed recreation.

Response: Considerable discussion is offered in the FEIS (Chapters II and III) to substantiate our conclusion that demand for semi-primitive nonmotorized recreation outside of wilderness exceeds the supply. This conclusion generated several comments to our draft planning documents and warrants further explanation.

There may be a misunderstanding of just what lands are included in the ROS classes. *The ROS classes pertain only to those lands outside of* designated wilderness. There is much less primitive and semi-primitive recreation lands available since the 1984 wilderness legislation.

While wilderness can offer a primitive or semi-primitive setting, the management emphasis within wilderness is preserving natural conditions and provide outstanding opportunities for solitude. This contrasts with a management emphasis on recreation in semi-primitive areas outside wilderness, where a higher level of use can be accommodated with greater management flexibility.

The 1985 Washington State SCORP projected a shortage of backpacking, day hiking, camping, four wheel driving, and motorbike opportunities within the two regions of the State which include the Mt. Baker-Snoqualmie. The *national forests and parks have the most suitable lands for those* activities requiring a semi-primitive or primitive setting such as backpacking and day hiking. Those activities requiring a roaded setting are better met elsewhere in the state. Most camping opportunities are provided by the private sector. SCORP shows that state-wide, the demand can be met for roaded settings, but that we are falling farther behind in meeting those opportunities dependant on the unroaded setting. The Draft 1990 SCORP states "Approximately 1,169,000 acres in National Forests are currently designated for semi-primitive recreation. There should be no net loss of these acres". The State of the Environment 2010 report concludes that "overuse by humans currently poses the most serious ecological threat to recreation lands, esp. to primitive lands." The Preferred Alternative reflects these concerns in its allocation of land.

EXCESS ROADED RECREATION SHOULD NOT BE VALUED IN FORPLAN

There appears to be an over-supply of roaded recreation. Roaded recreation should not, therefore, be counted as a benefit in the FORPLAN calculations.

Response: We assume that you mean that the "excess" supply (that supply not currently being used) should not be counted as a benefit in the FORPLAN calculations. This is correct; FORPLAN only places a value on recreation which is currently occurring.

MISSING SPM ACRES

The current total acres of SPM zone is shown in the plan (2-6) as 9,714 acres. In contrast, the Preferred Alternative "H" shows 2,512 acres for SPM recreation. What became of the missing 7,200 acres of SPM zone?

Response: The 9,714 acres in the plan (page 2-6) refer to acres of semi-primitive motorized recreation opportunity located across the forest. The 2,512 acres referred to in Alternative H are acres allocated to management area 1C- Semi-Primitive Motorized. Alternative H actually allocated 1,667 acres of the existing SPM ROS acres to Management Area 1C. The other acres of SPM ROS were allocated as follows: 1,201 to scenic viewshed, 1,836 to semi-primitive non-motorized, 781 to developed recreation, 63 to special area, 1,095 to wildlife habitat, and 2,195 to timber harvest.

DEMAND FOR ROADLESS RECREATION IS NOT RISING

In the DEIS, following a glowing - albeit nonobjective - discourse that "many people feel that the remaining roadless areas should be retained...in recognition of the increasing interest in unroaded recreation and the shrinking land base", there is a statement that interest in this issue is part of a national trend. This statement is false, from the base year of 1980 to the last year of record, 1986. Dispersed, general undeveloped area recreation in the nation has increased only 0.7%. This is not a significant trend. Statewide, there is no such rising demand either, in the backcountry areas of North Cascades National Park recreation use has been steadily declining over the past decade.

Response: Updated recreation supply and demand information presented in the draft 1990 SCORP show that statewide, visits to Park Service sites have increased 24 percent between 1983 and 1988, surpassing the national visitation increase of 16 percent. Additionally, while "backcountry" (managed for primitive recreation) overnight stays have declined 37% nationally during those years, overnight backcountry use of our state's National Parks increased 17%. A significant difference between these Parks and others is their convenient location relative to large population centers. The 1990 SCORP identifies that the demand for primitive recreation is exceeding capacity in National Parks and Forests (Draft Washington Outdoors 1990 Assessment and Policy Plan)

PLANNED NEW AND RECONSTRUCTED TRAIL MILEAGE IS INADEQUATE

The Forest Service has acknowledged the continuing increase in demand for backcountry hiking and horseback recreation. The Draft Plan did not offer enough new/reconstructed trails to replace those lost to timber harvest and lack of maintenance. Planned new miles do not meet the increasing demand.

Response: Alternative J (Preferred) includes a total of 220 miles of new trail construction in Decade 1 and an additional 220 miles of new trail construction in Decade 2, a substantial increase over the DEIS. In the first decade, 493 miles of trail reconstruction will be completed. See FEIS, Chapter II, Table II-9f for a comparison of alternatives. Appendix E of the Forest Plan includes a total system trails inventory with planned year of construction. The MBS will not be able to meet the continued demand for "more recreation" because of the limited land base of the Forest. Other agencies and landowners will need to share in providing opportunities. Even then, there will be a point in time when demand will exceed opportunities.

NEED ADEQUATE MILES OF TRAILS FOR MULTIPLE USES

Is an adequate mileage of trails to serve various modes of travel provided? The Forest should not feel obligated to provide for all types of uses.

The proposed level of trails in primitive and semi-primitive areas is not adequate to meet projected demands. Incorporate the Trails 2000 proposal.

Build more trails throughout the Forest The only way to reduce conflict in a true multiple use system is to provide facilities that encourage natural separation without undue restrictions on one or two kinds of users

The final plan should propose improvement, expansion, and proper administration of trails to accommodate more users and a wider variety of uses.

Response: The Forest does not feel obligated to provide for all types of use. We do, however, seek to provide diverse recreation opportunities when and where that opportunity exists. Each "user type" (or primary objective) may not occur in all areas of the Forest. One area (or Ranger District) may, however, have more opportunities for a particular user type than another. The miles of trails in the Plan have been increased by 350 miles, in response to public comment on the draft plan. The vast majority of new trails are in dispersed recreation lands outside of wilderness. Between DEIS and FEIS, we incorporated many of the ideas and concepts of the Trails 2000 proposal.

Refer to Appendix E of the Plan for a list of trails by user type (primary objective) and level of difficulty. The Capital Investment Program (Table E-2) is a more aggressive program than that proposed in the draft plan.

NO TRAILS EXCEPT THE PCT AND TRAILS WITHIN WILDERNESS SHOULD BE RESTRICTED TO USER TYPES

No trail except the Pacific Crest Trail and those trails in Congressionally designated Wilderness should be restricted to certain types of users, unless preceded by a specific evaluation to determine that unacceptable and

irreversible resource damage is occurring. Even then, restrictions should involve closure of the whole area, not just restricting certain users

Response: It is our objective to provide trails designed for 1) Primary Objective (user type) and 2) Difficulty Level, within those user types. It is also our intent to NOT restrict any other uses unless resource damage is occurring or conflicts arise. This has been clarified in the Plan, Appendix E, Objectives

SHOULD MORE WILDERNESS TRAILS BE BUILT?

Why will trails in wilderness will be completed in two decades? (page B-40, DEIS) Later (B-102), it is suggested that most construction will be done by the end of Decade 1. Given the decrease in wilderness use, this does not seem either rational or supportable

Response: Because of the degradation and resource damage occurring on the wilderness trail system, we feel that reconstruction of existing trails is of high importance. To protect the wilderness resource, we have applied for funds to reconstruct those trails within the first decade. The actual money received will depend upon the allocation from Congress towards that effort.

TRAIL RECONSTRUCTION SHOULD BE A TOP PRIORITY

You identified 48 areas in alpine meadows and wetlands that suffer from overuse and resulting environmental damage. This is a serious issue that needs to be addressed in the management plan

The existing trail system should be maintained - a top priority.

Response: Appendix E of the Plan shows the miles of trails, by specific trail, that will be reconstructed Since the draft plan was issued, trail maintenance has been given even more priority. A total of 493 miles of trail will be reconstructed within the first decade, the remaining reconstruction will be completed mostly within the first three decades. We have applied for funds at a level to accomplish this work, as discussed above.

INCLUDE AN INVENTORY OF TRAIL RESOURCES, EFFECTS OF MANAGEMENT ON TRAILS

Include an inventory of trail resources and clearly indicate how each trail will be affected by the proposed management for that area. Also, discuss in detail how conflicts between motorized and non-motorized users will be resolved.

Response: Appendix E, Trail Management Plan of the Forest Plan, includes an inventory of existing and proposed trail resources. The environmental consequences of the plan alternatives on trails are discussed in general in Chapter IV of the FEIS The effects of site-specific, proposed projects on trails will be examined in the analysis done at project-level planning The EA process is open to public involvement, and it is encouraged.

Appendix E, Forest Plan, Table E-1, indicates how each trail will be managed, regardless of the management area. Conflicts between motorized and non-motorized uses are dealt with through designation of a "primary objective." Refer to Table E-1, Plan Appendix E. There are ten primary objectives; each trail is allocated to one of these, ie. hiker, snowmobile, cross-country. Any conflict is resolved in favor of the primary objective.

BUILD LOOP TRAILS THROUGHOUT THE TRAIL SYSTEM

Build more loop trails; they disperse use, enhance hiking, and provide better utilization of an area.

Response: In developing a preferred alternative, more emphasis was given to loop and connecting trails. Where loop/connecting trails were not detrimental to other resource values, more were included in the Plan. Refer to Appendix E, Plan.

ADD "INTERCONNECTING LINKS" TO LOOP TRAILS FOR MORE DAY HIKES

Draft Plan : Add "interconnecting links" after "loop trails" in Item 8, page E-4 - may be necessary to provide more day hikes and weekend backpack possibilities.

Response: This wording has been added; it is now on page E-4, Item 5.

CONCERN OVER THE LOSS OF TRAIL MILES FROM LOGGING, ROAD BUILDING

We are concerned over the loss of trail miles due to logging and road building activities. Also, if and when logging/road construction occurs, the contractor should rehabilitate the trail.

Response: It is Forest Service policy to restore or substitute trail miles interrupted by logging. Forest Service Manual 2405.12, R-6 Supp. 319, 1/84 refers to this. The Forest-wide Standards and Guidelines for Trails (Plan, Chapter 4) state that trail mileage will not be lost as a result of logging and/or road activities. Also, refer to the Resource Summary for Trails, Chapter 4, Forest Plan and Appendix E. The Forest Service receives substantial comment concerning the protection and expansion of the trail system after publication of the DEIS. In response, the Forest has reworded these sections in order to clarify the policy.

PROVIDE A LIST OF TRAILS THAT WILL NOT BE LOGGED OVER

Where is your list of trails? Which trails are to be logged? Which will never be logged? Please provide this information. Also, list trails leading into wilderness and provide a "clear statement" to assure that those trails will never be logged over.

Response: Appendix E of the Plan, Table E-1, shows each trail (wilderness and nonwilderness). Any trail that is located in an area assigned to timber management (either full yield or partial yield) may at some point be logged over. However, Item 3 (c), page E-6 in Appendix E and the Trails Resource Summary in Chapter 4 of the Plan have been reworded to further

clarify how trails located in timber harvest areas are to be handled and impacts mitigated.

SHOW EXISTING AND PROPOSED TRAILS ON MAPS

Trails throughout the forest should be shown on all maps.

There is no map showing the location of existing or proposed trails. Clearly mark by user type.

Response: Once Plan implementation begins, a map called the Control Map will be prepared at a scale of 2.64 inches to one mile, or larger. Included will be existing and proposed trails and their user type (or "primary objective").

WHEN WILL MAPS SHOWING TRAIL RESTRICTIONS BE AVAILABLE?

In the Plan, page B-4, you state that "Maps showing restrictions on the use of trails will be developed and made available to the public." When will these maps be issued?

Response: The Control map will list all trails; however, restrictions or closures may change, as often as yearly. This information will always be available at each Ranger District and the Supervisors office.

TRAIL LOCATION SHOULD BE ABLE TO CONFLICT WITH LONG-TERM MANAGEMENT

Page 4-189, Draft Plan standards and guidelines for MA 17, Item A.5.b: New trail location should be able to conflict with long-term management, but not short-term. For example, if scheduled timber harvest wouldn't be for another 40 to 60 years, this could be longer than the life expectancy of a trail anyway - at which point it could be relocated if necessary.

Response: New trails, or reconstructed trails, can be located in timber management areas. While the trail will remain, timber management activities will be seen and will dominate the forest area.

CLARIFY TRAIL CONSTRUCTION RESTRICTIONS IN SOHA'S

Referring to the standards and guidelines for MA 11: if trail construction and reconstruction work can only occur until August 15th, workers will have only two snow-free months.

Response: We have modified the wording in this management prescription to say: "Management activities will be scheduled to minimize disturbances between February 15 and August 15 throughout the SOHA **unless it can be determined that owls are not actively using the area for nesting when trail construction/reconstruction is scheduled.**"

TRAIL CONSTRUCTION GUIDELINES ARE TOO RESTRICTIVE IN MA 12

Restricting trail construction activities until September 31st is extremely restrictive, as winter can start in October. Unless it is proven that these activities disrupt the pine marten and pileated woodpecker, the guideline should be less restrictive.

Response: This standard and guideline (Plan, Chapter IV) has been modified to read "Trail construction and reconstruction activity should be restricted during the breeding period from April 1 - **June 15.**

TRAILS ARE NO LONGER "TRANSPORTATION FACILITIES"

Revamp your entire philosophy of trails management. Trails are no longer "transportation facilities." Each trail should be designed with the intended user in mind.

Response: Agree, and we are doing so. FSM 2405.12; R-6 Supplement #319, 1/84 states that "trails should be recognized as a recreational improvement rather than, or in addition to, being part of the transportation system." Trails are designed for the intended user (or "primary objective"); for guidelines, see the Trails Management Handbook, FSH 2309.18 In the FEIS, all trail discussions have been moved from "Facilities" to "Recreation" in various chapters.

CLARIFY OBJECTIVES IN THE TRAILS APPENDIX

In Appendix E of the Plan, page E-6, 3.g. - Does this mean that trails would be constructed primarily for administration and fire prevention and that these trails are not "system trails" and that therefore not on the map?

Item 6 a , page E-7 - "Areas where Public Use is Prohibited or Not Encouraged." What does "expansion of such use" mean? Does it mean that only the current level of use will be allowed? And if it increases, will permits be required?

Response: Item 3.g. has been deleted in response to this comment. Trails are considered recreational facilities. Item 6.a. means that additional use will not be encouraged. It is intended to keep the use at current levels. The area can be closed to public use if it is determined that use is detrimental to the resource and the management objectives for the area.

MAKING REMOTE AREAS ACCESSIBLE TO HIKERS IS A GOAL, NOT AN ENVIRONMENTAL IMPACT

In the discussion under Trail Construction, DEIS, IV-4, "to make remote areas accessible to hikers" is not an environmental impact (though it may lead to environmental impacts), it is a justification or goal.

Response: The definition of effect or impact includes..."ecological, aesthetic, historic, cultural, economic, social, or health, either direct, indirect, or cumulative . " (40 CFR 1508.8, the regulations for implementing the National Environmental Policy Act) Building trails in an attempt to spread concentrated use into areas of little or no use (make

remote areas accessible) may be a goal. However, any additional use that may result will be an environmental impact - both physical and social.

DO WE DESIGN THE TRAIL FOR THE MAJORITY OF THE USERS

The definition of primary objective is given as "the primary group that this trail is intended to serve." If 98% of a trail's use is foot and 2% is horse, do we design the trail for the primary user, foot, or upgrade the trail to accommodate the minority, horse, user?

Response: We clarified this definition in the Plan document; see Plan Appendix E. We design our trails to the "primary objective", ie. if the primary objective is hiker, then we design it to hiker standards. Note that the primary objective of a trail does necessarily not equal the primary user of trail; they may differ. A trail could have a primary objective of horse use though 80% of the current use is hikers. If a conflict between users ever arose, it would be resolved in favor of the primary objective, not user

STANDARDS FOR TRAIL MAINTENANCE ARE TOO HIGH

On a whole, the Forest Service trails are maintained to much higher standards than trails with similar use in the European Alps. Only beginner's trails and those used by horses need the high standards that the Forest Service has set.

Response: We agree that, in some cases, our policies include standards for trail maintenance that are too high. Trail maintenance will be accomplished according to the type of area served, the primary objective of the trail, and the difficulty level Refer to Table E-1 in the Plan.

WILL AREAS BE MANAGED BY THE SIZE OF THE PARKING LOT?

In the Forest-wide standards and guidelines, Trailheads, Item D: does this mean that an area is actually managed by the size of its parking lot?

Response: One tool we have to manage any area is by providing or not providing facilities. By managing the size of a trailhead parking lot, we can help in managing the "capacity" of the area or trail.

EMPHASIZE DRAINAGE MAINTENANCE FOR LESS TRAIL DAMAGE

Would like to see a greater emphasis on drainage and fixing trails each summer so that winter rains and spring melt would run-off with less trail damage.

Response: The MBS trail maintenance program does emphasize drainage; on the west side of the Cascades, it is the most important aspect of trail maintenance. Maintenance is done according to the type of user the trail is primarily designed to serve Refer to the Plan appendices, Trail Management Plan and Implementation Schedule for some additional information.

TRAILS SHOULD BE ALLOWED TO GROW IN WIDTH IN AREAS WHERE PEOPLE GATHER

Trails should be allowed to grow to a width of 48" at points where people stop and/or congregate, such as scenic viewpoints, trailside water sources, etc.

> **Response:** We agree that this is important. However, this type of use is taken into account during the construction and/or reconstruction of the trail. We like to "plan" for these places, rather than just letting them "grow." The Forest Service does not generally allow "wide spots" to occur if resource damage is a result.

HOW CAN THE FOREST SERVICE DISCOURAGE THE DEVELOPMENT OF INFORMAL TRAILS?

How will you discourage visitors from establishing additional "informal" trails?

> **Response:** We cannot prevent visitors from establishing informal trails but hopes to discourage this through education. Within wilderness, the land will be managed to meet the standards set under Limits of Acceptable Change (LAC). Refer to the discussion in Chapter 4 of the Plan, Resource Summaries. If resource damage is occurring, or when use approaches or exceeds the established LAC, consideration will be given to restricting use or reconstructing the trail. See next comment.

DON'T ELIMINATE USER-MADE WAY TRAILS

Destruction of way trails is a misguided concept. Trying to keep the public on the "officially designated" trails will never work because the objectives of climbers do not meet the objectives of the trail system. Climbers will use trails to the maximum extent possible but not at the expense of losing a mountaineering objective.

Climbers and scramblers routes and fishermen's way trails are an important form of recreation. Cross country travelers need to be responsible in treading lightly, but to eliminate way trails means the loss of such a marvelous form of recreation.

User-made trails exist because enough people want to use that particular route, we oppose abandonment or destruction of them.

> **Response:** The concept and management of user-made trails has been clarified in several sections of the Plan and FEIS. User-made trails will now be part of the trail system and managed as such. Management, however, may mean "do nothing" unless resource damage is occurring Standards for all trails are located in FSH 2309.18.
>
> In Management Area 10, Wilderness, Intensity 10C reads "If obvious user-made trails become well established, or are causing resource damage, consideration will be given to restricting use or, reconstructing these trails to protect the wilderness resource from further damage."

THERE SHOULD BE A STANDARD FOR "WAY TRAILS"

We want to be sure that "construction" does not necessarily mean engineered. There should be standards for "way trails" which have been established by boots.

Somewhere I must protect the reconstruction of fine vigorous trails merely to change the grade.

> **Response:** Reconstruction is generally based on the need to protect the resource and not necessarily for the ease of travel. The Most Difficult level in each primary objective category (hiker trail, ORV trail, pack and saddle trail, etc.) is, in our opinion, a "way trail" standard. It is nearly a user-made trail, but designed for resource protection.

WE DISAGREE THAT, WHERE TRAIL USER CONFLICTS EXIST, USE IS GIVEN TO HIKERS ONLY

We agree that protection of the environment is first and foremost, but we take exception to the idea that, where conflicts between user groups exist, use is given to hikers only. (Draft Plan, page E-4)

> **Response:** Items 2, 3, and 4 on this page, Plan, Appendix E have been modified for clarification, in response to this comment.

IF A HIKER TRAIL DEAD-ENDS ON A STOCK TRAIL, DON'T ELIMINATE THE STOCK USE

We agree that it would be nice to have trails dedicated for each user groups (Plan, page E-4), but it is not practical. We strongly disagree with the idea that if a hiker-only trail dead ends onto a stock trail, stock use is eliminated and the whole trail reverts to hiker-only We are willing to ride our trail out-and-back rather than lose the use of it.

> **Response:** It is not the intent for hiker-only trails (or any other user type) to become the primary objective when they "dead end" with another trail. This has been clarified some in the Trail Management Plan and Implementation Schedule, Forest Plan, Appendix E (Item 4, page E-4). Trail closures are a last resort, management measure. We will only close trails to different user types when one causes undue conflicts and these conflicts cannot be resolved through education

THERE ARE NOT ENOUGH TRAILS OPEN TO HORSE USE

The MBS appears to be acting against the intent of Congress by severely limiting the number of trails open to horses. Because horsepeople are being increasingly shut-out of wilderness, more trails outside (and inside) of wilderness must be maintained for them.

Page E-9, Items 3 a. and b. state that the percent of trails open to horse use is "considered to be an adequate share of the Forest trail system " I take exception to this and suggest more trails be opened to pack and saddle stock use.

> **Response:** Several new miles of trails for horses have been included in the Forest Plan over the 527 miles listed as open to horse use in the draft.

When the total trail system is completed (by the end of Decade 2, or sooner), there will be 783 miles of Primary Objective, hiker-only trails and 612 miles of Primary Objective, pack and saddle stock trails. However, opportunities for horse use may not exist equally forest-wide.

INCLUDE TRAILS CLOSED TO HORSE USE IN TABLE E-1

Add a final column to Table E-1, Appendix E of the Plan, showing trails with year-around pack and saddle stock closures.

Response: Agree; this has been added to Table H-1, and this section now covers all closures, not just ORV's.

APPENDIX E SHOWS ITEMS BEING ADVOCATED BY HORSEMEN FOR YEARS

Appendix E, Trails Management Plan, Item 7 on page E-4: this makes me wonder if the planners have ever been out in the field. We have been making requests for some of the items listed for 15 years!

Response: Appendix E, Trails Management Plan is an update of the 1979 Interim Trails Plan, which was developed with full public involvement. Appendix E updates include changes to meet present trail management philosophy and the MA allocations for the Preferred Alternative. We have revised Item 7 to better meet the needs of horsemen as well as protect the resources.

OBJECT TO DISTANCE RESTRICTIONS FOR PACK AND SADDLE STOCK AROUND LAKES

Item 7, page E-4. the concept of trails for pack and saddle stock bypassing lakes etc. is well taken but too restrictive. This statement should include "where topographically possible" and the distance restrictions should be reduced to the standard used on the Okanogan National Forest. With the current distances, we are unable to observe and control our animals if necessary.

Response: We agree that the distances make it hard for horsemen to control their stock Item 7 has been reworded to state: "Trails for pack and saddle use should, where topographically possible, bypass focal areas, such as alpine lakes, by at least 200 feet elevation or 500 yards horizontally."

USE ABANDONED ROADS FOR STOCK TRAILS

Strongly request that all possible sections of abandoned roads be open for stock use.

Response: The Forest is in the process of evaluating all of our abandoned roads for trail opportunities. The evaluation, however, may not make roads available for just horse use All user types will be considered when making this evaluation.

WE NEED MORE TRAILS THAT ARE ACCESSIBLE TO WHEELCHAIRS

The Sauk River trail would be ideal for wheelchair use. Ramps to access the river could be built, along with a shelter and restrooms. Myrtle Lake is also ideal as is Kalcema Lake - leave the roads open for ORV access.

Response: In developing a Preferred Alternative, the Forest Management Team found that the Forest is lacking in "barrier free" trails. Based on this analysis and in response to this comment and others, several miles of barrier-free trails have been added; a total of 20.5 miles will be built, primarily in Decade 1. Refer to Appendix E, Plan. The Team will continue to look for more barrier-free opportunities.

For the lakes mentioned above· Kalcema Lake is located within the Boulder River Wilderness and no motorized use (ORV access) is permitted; however, if a wheelchair is an individual's "only mode of travel" it could be allowed. Kalcema Lake would be a good, easy place for such an activity if it were not for existing overuse and resource damage. We will strongly consider a barrier-free option during the the reconstruction of this trail. In the Preferred Alternative, the area immediately surrounding Myrtle Lake is allocated to MA 1B - Semi-primitive Nonmotorized Recreation; no motorized access is permitted.

THERE IS NO MENTION OF DESIGNATED CROSS-COUNTRY SKI AREAS

I did not see any mention of designated cross-country ski areas. With the large number of participants each weekend, there are far too few areas. We don't need groomed trails - just mark existing trails and roads for skiing or multiple use.

Response: The Forest has approximately 150 miles of marked cross-country ski trails with additional mileage provided in the developed alpine ski areas (particularly Stevens and Snoqualmie Pass) While cross-country skiers may travel anywhere on National Forest lands, terrain on the Mt. Baker-Snoqualmie is limited because of the steep slopes and the potential for avalanche. While any slope may avalanche under the right conditions, it is our policy not to mark trails and invite skiers and/or snowmobilers into known avalanche potential areas

NO ORV TRAILS IN RIPARIAN ZONES EXCEPT TO CROSS ZONE OR ACCESS FACILITIES

ORV trails should be located in riparian zones only to access facilities or to cross the zone. (Reference to Plan, Chapter 4, Item A 5.a. page 4-170.)

Response: This section was unclear on the construction of new ORV trails within riparian zones. It has been clarified in the Plan: existing trails and roads may remain and cross, however, new construction will be permitted "only when stated riparian area objectives can be accomplished." Refer to Item 5 a and b.

CAN MOTORIZED TRAIL USE CROSS THE PACIFIC CREST TRAIL?

The statement on page E-7 (Draft Plan) states that no motorized use is allowed on any trail that terminates at the Pacific Crest Trail. Since the Naches

Trail crosses the PCT, but does not terminate at it, we assume that motorized use is acceptable.

The trail standard and guideline (Item 2.d.3. page E-7) should be changed to read that motorizes use shall not be allowed on any trail segment that terminates at, or crosses, the PCT, per Executive Order 11644. Also, add a new standard and guideline to say that motorized use trails should not terminate at or cross wilderness boundaries.

Mountain bikes should be added to motorized uses that will not be allowed on any trails that terminated at the PCT; it should be clear that they are not allowed on the PCT.

Response: If trails which are appropriate for motorized use cross the PCT, this motorized "crossing" is allowed. This policy, however, may be changed if management problems occur and public education is not successful. Item 2.d.4. has been clarified to read: "Motorized and mountain bike use shall not be allowed on any trail or segment of trail that terminates or intersects the Pacific Crest National Scenic Trail, unless there is a logical "destination" point or attraction before the PCNST."

This statement is applicable to both roaded management areas and unroaded management areas outside of wilderness, and to designated wilderness. It has been added as Item 1.b.13. and 2.a.8. in the Forest-wide Objectives for Trails. Also, refer to the new wording of Appendix E, Item 4.D.

PACIFIC CREST NATIONAL SCENIC TRAIL SHOULD BE CLOSED TO MOUNTAIN BIKES

Urge you to close all parts of the Pacific Crest Trail to mountain bikes.

Response: A closure notice was signed by the Regional Foresters of Regions 5 and 6 on August 31, 1988: the Pacific Crest Trail is closed to mountain bike use except by special-use authorization. Additional wording has been added to clarify this; see page E-7, Appendix E, Forest Plan.

NEED MANAGEMENT DIRECTION FOR MOUNTAIN BIKES

A list of acceptable non-wilderness trails and roads for mountain bikes should be developed, along with a snazzy brochure on mountain bike etiquette.

Mountain bicyclists should formally be given the same rights, responsibilities, and access to trails as other foot-powered traffic.

There is little current management direction and policy on mountain bike use. We recommend the following guidelines if mountain bikes must share multiple-use trails: trails must have gentle grade, adequate sight distance (500 feet), and adequate braking surface to minimize erosion. Bicycle-only trails can be steeper and rougher, as there is not the threat of biker-hiker collision.

Response: The Draft Plan did not adequately address mountain bikes. In the Trails Appendix E, Forest Plan, standards and guidelines for management have been added. Briefly, mountain bikes are a legitimate recreational activity on National Forest lands, except in designated wilderness and on the Pacific Crest National Scenic Trail. Mountain bikes will generally be

allowed on all other trails unless they are found to be incompatible with the primary objective of that trail. Refer to Chapter 4, Forest Plan, Forest-wide Standards and Guidelines for Trails, Item 2.a.(8) Refer to Table H-2, Forest Plan, Appendix H for specific trail closures. In addition, management standards for mountain bikes can be found in FSH 2309.18

GOOD AREAS FOR MOUNTAIN BIKES

The Mountain Loop Highway has the appearance of becoming a popular place to ride mountain bikes; the Monte Cristo area also has good access for mountain bikes.

Response: The Forest Service and the Federal Highways are presently planning some reconstruction and paving of the Mountain Loop Highway within the next five years. Included are plans to accommodate mountain bike travel. The road to Monte Cristo is presently a county road and the county has sole jurisdiction over its use and maintenance.

EXPLORE LOW-ELEVATION RECREATION POTENTIAL NEAR ISSAQUAH

The Forest Service has failed to exploit the low-elevation recreation potential of the area near Issaquah area. Many State, County, other groups are engaged in a coordinated program for trail recreation on the I-90 Corridor. The Forest Service should join this program and develop its trail system to tie into the forest. Above all, the Pratt River offers opportunity for low-elevation, all-year quiet recreation.

Response: The Forest is now working with the State on a trail through Snoqualie Pass, that will pass within the recently-designated Iron Horse State Park. Both the park and the new trail will cross the entire state, passing through the I-90 corridor. This trail will provide a link to several trails on National Forest land. There are no other NF lands within 25 *miles of Issaquah. In the Middle Fork Snoqualmie River area,* trail construction is in progress. A bridge will cross Dingford Creek and the trail will run up the full length of the river, from the Pratt east. No trails are planned along the river, west of the mouth of the Pratt The Pratt River trail will be retained, links are planned with trails going south into the Alpine Lakes Wilderness.

THE COST OF $200,000 TO CONSTRUCT 7.6 MILES OF "IRON GOAT" TRAIL SEEMS EXCESSIVE

Table E-2 lists $200,000 to construct 7.6 miles of Iron Goat trail for hikers; this seems excessive, especially because the trail can be built on the old road bed used as a transcontinental railway from 1892-1929.

Response: The trail cost estimate is based on the application of standard formulas used to estimate the capital investment costs of all trails shown in Table E-2. Costs are preliminary and are revised at the time of trail design. Some costs are expected to be less than the estimate, as some portions of the trail will be "brushed out" with volunteer labor if available. Some costs will be greater than the estimate; for example, portions of the trail may be constructed using "access for all" design;

interpretive signs may be installed along this historic route; and extra funds may be required to stabilize or close snow sheds and abandoned tunnels. It is likely that the final estimate may exceed $200,000.

NEED TRAIL ACCESS TO JORDAN, GRANITE, AND FALLS LAKES

In the Draft Forest Plan, you did not show trail access to Jordan, Granite and Falls Lake; it is needed.

Response: The Preferred Alternative now includes a trail (#627) from the end of road #16 to Jordan and Upper Jordan Lakes. Refer to Table E-1. Also, trail #635 has been added from Slide Lake to Enjas Lake. With these two main access trails, the remainder of the north lakes area will remain in a more primitive WROS setting to provide a challenge for those wishing to go there.

SPECIAL TRAIL CONSTRUCTION NEEDED AT EAGLE LAKE AND PARADISE MEADOWS

Eagle Lake and Paradise Meadows are very fragile areas, characterized as a Sphagnum-Ledum wet meadow. This is a very rare vegetation type and very vulnerable to heavy traffic. Trails in the area should be designed to avoid the wet meadows or special construction techniques, such as boardwalking or turnpiking, should be used. The area around Eagle Lake and the shortcut from Eagle Lake to road #6517 through Paradise Meadows is already showing signs of damage.

Response: Trail construction or reconstruction will normally avoid all wet and fragile areas (FSH); if they cannot be avoided, turnpike, puncheon, and/or boardwalks are installed. Access to Eagle Lake will be via the extension of the Barclay Lake Trail, #1055. Reconstruction is planned for the user-made trail to Eagle Lake from road #6517 to minimize resource damage to the meadows and wet areas.

PUBLIC INVOLVEMENT NEEDED ON TRAIL PROJECTS

To insure that the trail system meets the needs of the user, there needs to be a process for users to comment on abandonment, construction and reconstruction, etc. before the project has gone beyond the planning stage.

Appendix E, Plan, page E-6, Item 3.e: Will users be provided an opportunity to comment upon the abandoned or closed portion of a road system considered for management as trails? Hiking an abandoned road through a clearcut would only be desirable when the destination is superb.

Response: In accordance with the National Environmental Policy Act, and FS implementing regulations (FSM 1950), an environmental analysis will be conducted for all ground-disturbing projects. All trail actions, with the exception of annual trail maintenance plan, are analyzed separately. A key step in the NEPA process is "scoping" or determining at the beginning of each proposed project, what issues and concerns exist and who, among the public, should be contacted for input For some projects, notification might be quite informal; for others, notice published in the Federal Register is appropriate. (The yearly maintenance plan is available for public review at each Ranger Station.)

On roads that will be closed: generally, roads that will be permanently abandoned will be allowed to grow in with brush until they are trail-width, thus giving the feeling of being on a trail instead of a road.

CLOSE THE ROAD AT RUTH CREEK (#34) AND ROAD #3065

To enhance the trail system, the North Fork Nooksack road (#34) at Ruth Creek and the Twin Lakes Road (#3065) should be closed. This is an excellent day ride (horse) opportunity.

Response: Presently, Road #3065 to the Twin Lakes area is a "mine-to market" road and cannot be closed without concurrence of the mine interest and the county. Most of the trail system in and out of Twin Lakes is open to horse use; there are no plans to close these trails to horses.

KEEP THESE TRAILS OPEN TO HORSE USE

We strongly oppose your proposed closure of Trails #630, 670, and 698, Excelsior Pass-High Divide-Welcome Pass to horse use. These trails provide an excellent day riding opportunity, with about 12 miles of sound trails with access from two points.

These trails need only minor work; much could be done by volunteers (under the direction of the FS).

Response: Trail #630, from Highway 540 to Road 3060, is not closed to horse use; its primary objective is pack and saddle. Trail #670 and 698 are now part of trail #630 and the old numbers are deleted. This system was not closed in the DEIS, nor is it closed in the Preferred Alternative.

INCLUDE A TRAIL INVENTORY; INDICATE HOW TRAILS WILL BE AFFECTED BY PROPOSED MANAGEMENT

The Forest Plan should include a thorough inventory of trail resources and a clear indication of how each trail will be affected by the proposed management of that particular area. The documents should also discuss in detail how conflicts between motorized and non-motorized users will be resolved.

Response: Refer to Appendix E, Forest Plan and Table E-1. It shows a complete inventory of the trails system and indicates, for this Forest Plan, how each trail will be managed. Trail planning and management is also addressed in each management area prescription, Chapter 4, Plan.

MOTORIZED RECREATIONAL OPPORTUNITIES WERE NEVER ADDRESSED

We found, while reading the planning documents, that capability for motorized recreational opportunities was never assessed. The result is an unfair and arbitrary exclusion of a legitimate form of recreation

Response: Motorized recreational opportunities, supply, and demand are discussed in Chapter III of the EIS, under the Recreation section. The issue and concern is described in Chapter I, and miles of road open to passenger vehicles are a key output of Table II-9f. Motorized recreation opportunities were also addressed in the Forest Plan, Appendix H. This section states that all forest roads, trails and areas will remain open, except as noted in Table H-1. Table H-1 shows roads, trails and areas closed to motorized use and the reason for such closure. The National Forest operates on the principle that "everything" is open to motorized use unless a closure is needed to protect some resource.

THERE IS A LACK OF 3- AND 4-WHEEL ATV TRAILS

We are concerned about the lack of riding trails built specifically for three and four-wheeled ATV's. These vehicles cannot be ridden on motorcycle trails and jeep trails generally are not challenging enough.

Response: In the Forest Plan, Appendix H, Table H-1, we have indicated which roads, trails and areas are closed to 3- and 4-wheeled ATV's. As discussed above, the Forest is open to such use, unless specifically closed by a closure order. Much of the MBS is steep and wet and does not led itself to this type of recreational opportunity

THE 1987 STATE ORV PLAN INDICATES A NEED FOR MORE MILES OF TRAIL

The 1987 Washington State Off-Road Vehicle Plan indicates there are facility needs for motorized recreation activities in both Planning Districts 3 and 4.

The planners should understand that 4x4 use of a road does not mean the user is gaining satisfaction. The ORV trail and 4-wheel drive travelway are, in their own right, the attraction. They must be interesting to drive, reasonable to maintain, and there must be an adequate supply to meet the demand. We encourage the MBS to recognize our use and make a positive accommodation for it in the Forest Plan.

Response: As discussed in Chapter III, DEIS and FEIS, while we recognize the need for more ORV trail miles, the Forest is limited in it's suitability to provide more miles to meet that demand. A total of 43% of the land base is designated wilderness and much of the remainder of the Forest trails are not suitable for ORV use, due to steep terrain, with fragile soils and vegetation. In addition, most of the unroaded portion of the Forest is not well suited to cross-country vehicle use, for the same reasons. Refer to the Recreation section, Chapter III of this FEIS for more information. The validity of this type of recreation use is recognized and all areas and/or trails are open to such use, unless specifically closed. Refer to the Forest Plan, Appendix H, Table H-1

THE PERCEPTION OF ROADS/TRAILS OPEN TO ORV'S UNLESS CLOSED IS WRONG

The most flagrant instance of mis-statement in the MBS documents is: "Unless specifically prohibited by a formal closure or Congressional designation...all roads and trails are available for motorized recreation." These statements seem to be saying that all roads and trails are open to ORV's unless designated closed. Executive Order 11644 says that areas and trails shall be designated open or closed to ORV's based on certain criteria; thus, a presumption of open unless designated closed is wrong. These points are made abundantly clear in a case brought to federal district court, National Wildlife Federation v Morton (393 F. Supp. 1286). In this case, the BLM had issued regulations designating as officially open to ORV's all its land not otherwise restricted or closed. The court held the E.O. required all designations be based upon criteria set forth therein and the criteria are to be applied to a designation of both use and non-use.

The final plan should state the mandatory designation criteria in full per E.O. 11644, not in the highly abridged or paraphrase form, as in the Standard and Guideline 1. Also, print E.O. 11644 and 11989 in their entirities Since ORV closures far exceed openings on the MBS, redo Table H-1 as a list of specific openings rather than closures.

Response: The introduction of Appendix H, Forest Plan now includes specific references to E.O. 11644 and 11989. These orders have not been reprinted, to comply with regulations for implementing NEPA (40 CFR 1500.4) for reducing paperwork and incorporting be reference (1500.4(j)).

FSM 2303 Item 7 states; "Enhance recreation experiences through a minimum of regulations and law enforcement." In theory, ORV use is allowed anywhere on the MBS (except in designated areas such as wilderness, research natural areas, etc.) unless closed for specific reasons. In reality, much of the Forest is very steep and rocky, limiting the ORV opportunities except for trails and roads. Should ORV use be found incompatible with land allocations and use, through monitoring, the closure list will be modified (through a Plan amendment, with public notification, and in a NEPA document).

RE-EVALUATE CLOSURE CRITERIA

We call for a re-evaluation of closure criteria of public lands to 4-wheel drive and ORV use. Many of the current closure policies are inconsistent, arbitrary, and capricious. The cumulative impact of these policies is the

destruction of a previously well-used and well-distributed recreational asset which further dwindles from over-management.

Response: We feel the MBS has sufficiently evaluated ORV use on this forest. In 1977, the MBS published, with a NEPA document and public participation, a Forest-wide ORV plan. This plan was developed in response to E O. 11644. The Forest Plan revises this Plan, based on the land allocations in the Preferred Alternative and additions to the wilderness system from the 1984 Washington State Wilderness Act. Through monitoring, plus meeting standards and guidelines (Forest-wide and management area), any resource damage and/or user conflicts will be identified and resolved.

WHEN CONFLICT ARISES, IT SEEMS TRAILS ARE ALWAYS CLOSED TO ORV'S

It seems that whenever user conflict is even suggested, the road or trail in question is always closed to 4-wheel drive or ORV use. It is ludicrous when a previously open and existing jeep road must be closed because of "user conflict" when someone decides to route a hiking trail onto this route.

Response: Refer to Table H-1, Forest Plan, for the specific list of trail, areas, etc. closures to various uses. Also see the Forest Trail inventory, Appendix E; the "primary objective" for each trail is noted: hiker, motorbike, etc. Trails will be managed for the primary user type; should other users conflict with the **primary objective** user and the conflict cannot be resolved through education or other means, all uses except the primary user will be restricted

CONSIDER LOGGING ROADS FOR ORV USE

Your plan does not recognize the large network of existing and previously open network of old forest roads, logging roads, etc. (shown on maps as "jeep trails") as the substantial opportunity they are. These primitive roads are a good candidate for multi-use travelways for several types of ORV's and 4-wheel drive use. Neither the trails or transportation sections address this available and low cost resource.

I agree that soil and terrain limit the opportunities for trail use of motor vehicles, but what about old logging roads that have been closed? Are there no opportunities for use of these roads by trail vehicles and mountain bikes? What about development of old roads as a desired output of the forest plan.

Your plan does not provide for four-wheel drive recreation on the vast network of primitive travelways. We request that you manage 4-wheel drive roads (primitive travelways over 40" wide) open unless posted/gated closed, as most were in the past.

Response: We agree that old logging roads and spurs are good candidates for ORV and 4-wheel drive use. The Forest-wide Standards and Guidelines for Off-Road Vehicle Use state that ORV closures are to be used "...only when needed to minimize disturbance of wildlife, minimize recreation use conflicts, or to protect soil and water resources." Otherwise, these roads are open; refer to Table H-1 for specific closures (Forest Plan). Where old roads or travelways cross acres allocated to nonmotorized management, OVR use is not compatible and would not be permitted.

WEYERHAEUSER IS CONCERNED THAT LOGGING ROADS ARE ONLY ROADS OPEN TO ORV'S

The Proposed Plan acknowledges the need for a continuing Cooperative Road Agreement program between the Forest and intermingled landowners. Weyerhaeuser supports this. Our concern: the direction of the FS in making these logging roads the only roads open to ORV's The Plan intends to close all other roads to ORV's. This should be reversed in the Greenwater drainage, one of the most heavily-used drainages in the National Forest system. One remote area should be reserved and dedicated to the exclusive use of ORV enthusiasts.

Response: It is not our intent to close all trails to ORV use; only those listed in the closure table H-1, Forest Plan are closed. Note that all national forest roads in Washington State are closed to "non-street legal" ORV's Evans Creek area remains open to ORV's, as does the rest of the Forest, unless specifically closed.

ORV'S NOT COMPATIBLE WITH RIPARIAN AREAS

We do not consider ORV's a compatible use within riparian management areas, unless on designated trails to cross a stream.

Response: The standards and guidelines for MA 13 speak directly to ORV's in riparian areas; they have been strengthened since the proposed plan was issued. Refer to new Item A.5.b.. In addition, ORV use is not to cause ground or water channel disturbance. Existing use is permitted on roads or trails designated for ORV use. Any conflicts will be resolved "in favor of the dependent riparian resources and values (soil, water, fish, and wildlife). (MA 13D Item A 1.a.)

MOTORIZED USE OF TRAILS ENCOURAGES ADVERSE EFFECTS ON NATIVE PLANTS, ANIMALS

Motorized use of trails encourages adverse effects on native plant and wildlife communities by providing basically unregulated access to sensitive areas such as wet meadows, rare plant habitats, and erosive or fragile soil areas, that are easily degraded by ORV's. This impact seems to have been ignored in the DEIS. The final plan should specifically prohibit ORV's in sensitive areas.

Response: Appendix H, Table H-1 (Forest Plan) shows trails, roads, and areas closed to ORV (and other) use. In most cases, these closures were established to protect the land and sensitive resources, and are adequate at this time. The closure list will be reviewed at least annually, with changes handled through a plan amendment, including public notification If, through monitoring, we find that protection is not adequate, on any part of the Forest, action (such as additional closures) will be taken to protect resources, minimize conflicts, and provide for public safety

CHANGE MANAGEMENT DEFINITION OF ORV TO REFLECT ACTUAL USE OF FOREST

We respectfully request that you modify the national ORV/4-wheel drive policy to reflect the following: manage primitive forest roads open unless signed closed; use cooperative programs, such as Adopt-a-Trail/Road.

Response: It is FS policy that lands are open to multiple uses (such as ORV's) unless specifically closed (FSM 2300, Item 7 under policy: "enhance

recreation experiences through a minimum of regulation and law enforcement.") Based on this, we view that the Forest is open for all types of recreational uses unless the uses are in conflict with other use or land resources. The MBS has an "Adopt-a-Trail" program and it will be continued.

KEEP "EVANS CREEK ORV AREA" OPEN FOR MOTORIZED USE

The established intensive ORV use at Evans Creek ORV Area should continue to operate without undue restriction because of water production. The water system for the Fairfax area was in existence when the ORV area was established. Planning to accommodate both uses was a paramount consideration; that direction is still valid.

Response: The MBS intends to continue the use of Evans Creek as an ORV area; however, timber management activities are not precluded, and temporary closures may be instituted during harvest activities for safety. A monitoring plan for the Evans Creek ORV Area has been completed. If during monitoring, water or other resource damage is found, management action will be taken. This may include closure of portions of the Area to ORV use.

IS MOTORIZED USE ON THE NACHES TRAIL ACCEPTABLE?

The statement in Appendix E, page E-7 states: "No motorized use on any trail that terminates at the PCNST." Since the Naches Trail crosses the Pacific Crest Trail, and does not terminate at it, we assume that motorized use over Naches Pass is acceptable.

Response: If a trail, like the Naches Trail, is designated for motorized use and crosses the PCNST, that use will be acceptable, provided that motorized use can be eliminated from the PCNST. Motorized use is not allowed on trails that terminate at the PCNST "...unless then is a logical destination point or an attraction before the PCNST." Refer to Chapter 4, Forest-wide Standards and Guidelines, in the Forest Plan.

FORMALLY RECOGNIZE NACHES PASS AS A 4-WHEEL DRIVE TRAIL

We encourage the MBS to formally recognize the Naches Trail as a 4-wheel drive travelway and to provide for its protection in all management activities.

The Naches Trail is one of the best-known 4WD routes in the nation; we encourage you to acquire permanent right-of-way. Also, provide interpretation of the cliff and its historic uses.

Response: This is part of the MBS trail inventory and has a primary objective of jeep trail (10 - see Appendix E, Forest Plan). It will be protected and maintained as a trail. Refer to the discussion on "significant trail opportunities in the Forest Plan, Appendix E. Naches Trail is presently being inventoried for the Washington State Historic Preservation Office for potential historical designation; refer to the cultural resources implementation schedule, Appendix D.

IS NACHES PASS A ROAD OR A TRAIL?

Is Naches Pass west a road or a trail? Its primary objective is listed as 10, Jeep Use and 1 Hiker, a mix not suitable for an historic trail.

> **Response:** The Naches Pass West route, #1175, is a jeep "trail"; however, other users are not restricted from the route. The first 0 7 mile, between raods #7033 and 706521, is closed to jeep travel. This section is an actual cliff and too dangerous for jeeps.

OPPOSE SNOWMOBILE USE IN SEMI-PRIMITIVE NONMOTORZIED AREAS

We vigorously reject and ask you to delete the guideline allowing snowmobile use in SPNM MA # 1B. This is inappropriate and is a completely unjustified abuse of the goal of SPNM management

> **Response:** Appendix H, Forest Plan, discusses the standards, guidelines, and evaluation process for closure of areas to snowmobiles if necessary. A winter ROS inventory has not been completed. Our position is that areas will be evaluated and closed if the need arises.

NO WHEELED MOTORIZED USE ON GROOMED SNOWMOBILE TRAILS

In the Forest Plan, page 4-73, add that four-wheel drive vehicles and motorcycles use will not be permitted on groomed snowmobile trails.

> **Response:** We agree. This statement has been added to the Plan Appendix E, Specific Policies Applicable to the Entire Forest, Item 15.

OPEN AREAS TO SNOWMOBILE USE

Artist Ridge and Church Mountain trails #669 and 671 pass through current roadless snowmobile use areas beyond the end of F.S. road #3170. There is no conflict with hikers in the winter thus closure should not apply to snowmobiles

> **Response:** Snowmobiles are currently restricted from the Artist Ridge area because they would have to pass through the Mt. Baker Ski Area, a conflict with the intent of the ski area and cross-country skiers This closure will remain in effect. Church Mountain, from the north, accessible side, is open and receiving snowmobile use. The area beyond road #3170, Bearpaw Mountain area, will be accessible except inside wilderness. A snowmobile loop system will be provided outside of the wilderness to accommodate snowmobiles

KEEP TRAIL OPEN TO SNOWMOBILES

Mazama Park, trail 603.2 should remain open to smowmobile use, as prescribed in the Washington State Wilderness Act of 1984, where the trail passes through the Mt Baker NRA.

> **Response:** As stated in Table H-1, under specific closures for areas on the Mt. Baker Ranger District: this area is open to snowmobiles when the snow

reaches a depth of at least two (2) feet, when measured at Schriber's Meadow. The fragile alpine vegetation will be damaged if snowmobiles use the area when snow depths are less than two feet.

THE ISSUE OF A NEW HIGH ELEVATION SKI AREA IN WASHINGTON SHOULD BE ADDRESSED

The Greenhouse effect is driving temperatures up and the population boom in Puget Sound is crowding our recreation areas. We must realize that a new high elevation ski area is needed soon. Several of the only feasible sites in the state are located on the MBS Forest. Most of these sites are located within Wilderness and would have to be removed. I urge you to consider this when planning near these sites. The sites are. Coleman Basin, Sloan Peak, Hidden Lake Peak, and Heliotrope Ridge. Let me know if any studies have been done on these sites.

Response· The Forest believes that the immediate (in the near future) need for additional skiing opportunities can be met by the expansion of existing areas such as Stevens Pass and Crystal Mountain. A new ski area is also being developed at Early Winters on the Okanogan National Forest. Three of the sites mentioned are within Wilderness; the fourth, Hidden Lakes Peak, is within North Cascades National Park. It is not within the Forest Service or Park Service power to declassify wilderness to allow development of any kind This can only be done by Congress. The North Cascades Winter Sports Study of 1970 identified 13 sites for potential ski area development. These were. Glacier Basin, Twin Sisters, Schriebers Meadows, Dock Butte Basin, Snowking Mtn , Gabrielhorn, Cutthroat Pass, Liberty Bell, Harts Pass, Sandy Butte (Early Winters), Tiffany Mtn., Marten Lake Basin, and Stormy Mtn. Of these only Glacier Basin, Tiffany Mtn. and Sandy Butte were found to be good locations, all others were marginal or unacceptable.

CORRECT CAPACITY FIGURES FOR CRYSTAL MOUNTAIN AND PACIFIC WEST

The column labeled "Additional Potential Downhill Capacity" is in error. Current calculations indicate that Crystal Mtns. additional downhill capacity is more in the range of 5,000 skiers per day.

There is a considerable amount of additional downhill capacity on NF land at the Pacific West Ski area. The NF figures shown in the last two columns of this table are erroneous and need to be corrected.

Response: These figures have been corrected. See Chapter III, table III-52 in the FEIS.

DEVELOPMENT OF SNO-PARK SOUTH OF HYAK CREEK

There has been some discussion and public support for excluding from Pacific West's permit area that area south of Hyak Creek and allowing a public sno-park to be constructed. This would be a mistake. There is very little nordic terrain in this portion of Section 16, and the area is almost completely surrounded by existing alpine ski development and private land. A sno-park in this vicinity would result in numerous conflicts with the alpine operations and trespass onto private lands.

Response: The concerns are noted and will be a consideration if the area described is ever proposed for development by the ski area, or by sno-park supporters. A project environmental analysis would be done which would examine these issues.

MODIFY POLICY TO ALLOW HOUSING AT SKI AREAS

The Forest Service must modify its housing policy to attract private capital to help the development of ski-area housing.

Much of our tourism opportunity in the winter recreation field is stifled by the Forest Service policy concerning private residences on its property. The single factor that will most significantly enhance winter recreation in Washington is the ability to build private residences at the ski area baselands.

Response: National policy allows public lodging accommodations on National Forest lands at ski areas, but only where there is a public need for the facilities and where there is not suitable private land for such facilities within a reasonable commuting distance. In addition, the general public must have full access and use privileges to such facilities. Ski area permit holders, their employees, families, friends, partners, stockholders, lenders, or others with a monetary interest in the facility do not have preferential use rights over the general public. The existing policy was recently examined by a national task force and was upheld. The Forest Plan must comply with national agency policies.

30-YEAR PERMIT SYSTEM IS TOO RESTRICTIVE FOR LONG-TERM FINANCING

The special use permit system is an impediment to the successful development of the winter recreation tourism industry in Washington. The thirty-year permit does not offer a long enough period or secure enough commitment to attract the long-term financing needed to build and operate successful destination ski resorts. We would prefer an opportunity to obtain a long-term commercial lease.

Response: A new ski area permit, which increases the term to 40 years, became available in 1989. Almost all ski areas are eligible for conversion to this permit. The 40-year permit is mandatory at the expiration of any existing permit, and for any new ski areas

WHAT ARE THE MANAGEMENT STANDARDS FOR SKI AREAS?

Under Winter Sports Resorts, the management standards for water, soil and air state simply "Meet Forest-Wide Standards and Guidelines. Give extra attention to erosion prevention and control on areas cleared for ski runs." This does not indicate what air and water quality standards must be met. Nothing identifies what visual quality and riparian zone guidelines must be followed

Response: The standards and guidelines for the management of air, water and riparian resources within ski areas can be found in the Forest Plan, Chapter 4, Forest Wide Standards and Guidelines. Direction for visual quality management in ski areas has been revised. Generally, the goal will be foreground retention and middleground partial retention. It is recognized that existing base area facilities are a developed environment.

RETAIN UNDEVELOPED NORDIC SKI OPPORTUNITIES

The best ski terrain should not always be developed into downhill skiing, thus shutting out the mountain skiers and snowshoers. The same pattern is evident with the growth of "developed" nordic ski areas. Private interests are given a land use permit for a popular ski touring area and they groom and patrol it, and then charge a fee for the use of our public lands. They must not be allowed to develop all skiable terrain at these sites.

Response: The decision to incorporate nordic skiing into the operation of alpine ski areas will be made on a case-by-case basis with full public input. We anticipate that both groomed fee and nonfee backcountry nordic opportunities will be available.

THERE IS NO MENTION OF DESIGNATED CROSS-COUNTRY SKI AREAS

I did not see any mention of designated cross-country ski areas. With the large number of participants each weekend, there are far too few areas. We don't need groomed trails - just mark existing trails and roads for skiing or multiple use.

Response: The Forest has approximately 150 miles of marked cross-country ski trails with additional mileage provided in the developed alpine ski areas (particularly Stevens and Snoqualmie Pass). While cross-country skiers may travel anywhere on National Forest lands, terrain on the Mt Baker-Snoqualmie is limited because of the steep slopes and the potential for avalanche. While any slope may avalanche under the right conditions, it is our policy not to mark trails and invite skiers and/or snowmobilers into known avalanche potential areas.

THE GOAL OF WILDERNESS MANAGEMENT SEEMS HEAVILY WEIGHTED TOWARDS HUMAN USE

The goals for wilderness seem heavily weighted toward human use. Consideration of other values should have equal emphasis, such as wolf or grizzly bear habitat Given that perspective, it puts a new twist on the "spontaneity of use".

Response: Editorial changes have been made to Chapter 4, Desired Future Condition statement for wilderness (MA 10) to reflect that recreational use is only one of many resources for which wilderness is managed. Recreational use is allowed to continue within the wilderness as long as it does not compromise or degrade other resource values, such as wildlife habitat, water quality, or solitude.

EXPLAIN THE INCREASE IN WILDERNESS VISITS BETWEEN 1976-77

Was the increase in visitor use between 1976-77 due to a change in definition of area to be included in the tally for use or actual use? Please explain to your readers your guess as to why the sudden dramatic increase. Advertisement? Other changes?

Response: As stated on page III-134 of the DEIS, this increase was due to the designation of the Alpine Lakes Wilderness and resulting transfer of RVD's that would have been tallied as general dispersed recreation to wilderness recreation.

CONCEPT OF PROJECTED RECREATION USE NOT EXCEEDING CAPACITY IS STRANGE

It seems strange that "Projected recreation use will not exceed the estimated capacity for any particular activity." (II-96) If this quoted assumption were valid, no area could experience overcrowding. PLUS supports the concept, but finds it difficulty to believe that the Forest Service does Otherwise, why are formulas developed which state that people can only tolerate a given number of people/acre/year? We think that most forest users are much more tolerant than these formulas give them credit for.

Response: This statement refers to the MBS decision not to value expressed recreation demand beyond the estimated capacity (which includes a assumed experience quality level as defined by an ROS zone) for that particular zone or activity. For example: if the capacity for wilderness recreation was X and the demand for wilderness was 9X, then we restrain the FORPLAN model from accruing value for future estimated wilderness use (demand) beyond X, as it was likely that use would be restricted near this level. This was done to more accurately portray the economic effects of recreational use as limited by capacity, instead of valuing all potential use, even that beyond capacity

In reality, overcrowding can occur in any area outside of wilderness, with a resulting lowered quality of recreation experience and a change in the ROS level toward a more developed setting. FORPLAN modeling limited the total value; if overcrowding actually occurred, you could get a lower per unit value, but a higher number of users. Thus, the total value (output x unit value) remains about the same.

DISCUSS VOLUME OF TIMBER IN WILDERNESS

It would be of interest to many readers if you discussed the volume of timber in wilderness. This may dispel some of the myths being perpetrated by the preservationist groups about wilderness being all rock and ice.

Please provide a realistic picture of commercial forest land foregone in wilderness. Don't add to the hysteria and emotionalism of the forest industry.

Response: There are 721,718 acres of wilderness on the Forest; 440,196 acres are forested with trees (61%). There are 284,922 acres with a productivity of 20 cubic feet per acre per year (40% of the total wilderness acres, and 16% of the forested wilderness acres). These 284,922 acres have a standing volume of 2,309.38 MMCF or 11,564.95 MMBF (1995 standing volume). Chapter III has been amended to reflect this.

OVERLAPPING RNA AND WILDERNESS MAY CAUSE PROBLEMS

Wilderness Use Conflicts· Chapter III, DEIS, page III-135 needs to recognize the special conflicts that may arise in RNA's within wildernesses. One established RNA and three proposed RNA's occur in wildernesses.

Response: In the Preferred Alternative, where wilderness and RNA classification coincide, the most "restrictive" management prescription (wilderness intensity or RNA) regarding development and use shall be applied in those portions of the RNA which fall within wilderness.

WHERE DID THE TERM "UNIMPAIRED" ORIGINATE?

Where does the phrase "manage wilderness for the use and enjoyment of people in such a manner as will leave it unimpaired for future use and enjoyment...so as to provide for the protection of these areas, the preservation of their wilderness character...." come from? Are these words in the Wilderness Act?

Response: This first phrase is taken from Section 2 of the Wilderness Act of 1964. This section made it clear that Congress fully intended wilderness to be for the people's use and enjoyment; it is also apparent that such use and enjoyment was to be contingent upon maintenance of these areas "as wilderness," a condition the Act later defines in the final subsection of Section 2. Here, wilderness is defined as an "area where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain." The word "untrammeled" was specifically chosen by the Act's authors and means "not subject to human controls and manipulations that hamper the free play of natural forces."

THE NONDEGREDATION POLICY VIOLATES THE 1984 WILDERNESS ACT

The R-6 Supplement 81 and nondegradation policy is in direct violation of the 1984 Wilderness Act. It is appalling to see how wilderness is being managed; it is too restrictive and does not allow full use of the wilderness. We can have twice as many users and still meet reasonable wilderness requirements.

Response: It is from Section 2 of the Wilderness Act, discussed above,

that the nondegradation policy has its origins. The concept seeks to recognize the variation in the level of naturalness and solitude available in individual wildernesses. It calls for maintenance of present environmental conditions if they equal or exceed minimum standards, and the restoration of below-minimum levels, rather than letting all areas in the Wilderness System deteriorate to a minimum standard. To a reasonable degree, the conditions prevailing in each wilderness when it was classified establish the benchmark of naturalness and solitude to be sought by management. The Regional Forester's "Forest Planning Wilderness Management Direction Clarification" letter of August 4, 1986 stated: "Wilderness must be managed to prevent degradation. The nondegradation principle directs that each Wilderness must essentially be as wild as it was at the time of classification... Nondegradation applies to all values of wilderness: social, physical, and biological."

PLAN IGNORES THE NEED TO INCREASE WILDERNESS ACRES

I think that it's an accurate reflection of the Forest Service that the plan doesn't recommend any areas for wilderness designation. While not necessitating such recommendations, the Washington State Wilderness Act of 1984 certainly doesn't preclude it

One puzzling aspect of the plan is that none of the alternatives, including those such as Alternative C emphasizing dispersed recreation, include recommendations for new wilderness acreage. The demand for wilderness use is increasing to the point of discussion of restricting use; it's arbitrary and imprudent for the Forest Service not the recommend additional wilderness areas from the existing roadless areas to help meet these needs.

I support the increase in dedicated trailless areas and increased regulation of certain wilderness areas, but I think some provisions should be made for the future designation of wilderness. By excluding wilderness designation in the first phase of the plan, you are sending a clear signal that there will be little future designation of wilderness.

Response: In this first round of planning, an alternative that considered additions to the wilderness system was considered, but not developed in detail Refer to the discussion, Chapter II, FEIS (and DEIS) on Alternatives Considered But Eliminated From Detailed Study.

During the deliberations on the Washington State Wilderness Act of 1984, Congress considered all the roadless areas on the Forest. They received many recommendations from diverse segments of the public and the Act represents their judgement on which areas should be designated wilderness. The Act contains specific language to the effect that the Forest Service is not required to consider wilderness recommendations for those "released" roadless parcels in the first generation of Forest Plans. The statute does not prohibit the Forest Service from doing so, but for the MBS, it was not considered reasonable so soon after the 1984 Act. All lands remaining unroaded and undeveloped may be considered for future wilderness designation, when the Forest Plan is revised.

ACTIVITIES AFFECTING WILDERNESS AIR QUALITY SHOULD NOT BE RESTRICTED

"Designation of Class I airsheds in the new wildernesses should not have any effect on outside activities occurring outside of wilderness". As quoted above in the Washington Wilderness Act no buffers were to be established and activities outside of wilderness were not to be altered due to wilderness creation. Therefore, activities affecting wilderness air quality within the 1984 additions should not be limited.

Response: The Clean Air Act of 1977 designated the Alpine Lakes and Glacier Peak Wildernesses as Class I airsheds. The wilderness acres added by the Washington State Wilderness Act of 1984 were automatically designated as Class II airsheds as provided by the Clean Air Act. The Act allows the State of Washington to redesignate Class II areas to Class I to protect wilderness-related values. The purpose of the Class I and Class II areas is to protect the air quality related values of sensitive areas such as wilderness and national parks. Some of the key values being protected are visibility, vegetation, water quality, and clarity. Some of the threats to these areas are acid rain and other air-bourne depositions, ozone, and the smoke columns from fires. There is no relation between the provisions of the Washington Wilderness Act and the requirements of the Clean Air Act of 1977. See Chapter III, FEIS, Air and Fires section.

THE COST OF WILDERNESS REHABILITATION IS INCORRECT, NEEDS FURTHER DEFINITION

The funding levels for wilderness rehabilitation in Appendix F need to be explained. Are they proposed, minimum, or allocated levels? If the money is not available, it should be explained.

I'm not sure I understand your "wilderness rehabilitation" proposals. Do all sites cost $5,000 to repair? This seems quite exorbitant and is obviously not based on any real analysis, but is just an arbitrary formula.

The wilderness rehabilitation section is in need of revision. It states a $5,000 cost/site for restoration/rehabilitation. This cost is naively low when you examine what has gone on in the past at Image Lake, Lake Dorothy, or Snow Lake. The dollar amount needed depends on the length of the project, and it also varies greatly based on techniques used, how much source material is (or isn't) on site, how eroded the site is, and how far it is from water.

Response: Appendix F of the Forest Plan has been revised to indicate that, on many of these sites, rehabilitation will be an on-going process over several use-seasons A large portion of the cost of rehabilitation includes on-site monitoring and maintenance A range of from $2,000 to $5,000 per site has been used for general budget projection, recognizing that each site will be unique in the amount of restoration needed and the cost of the rehabilitation

NEED TO CLARIFY THE "CAMPSITES VISIBLE" LAC

"Campsites visible" needs to be clarified to indicate whether this means campsites visible if occupied, or if it means that human-caused impacts are visible from site to site.

Response: The Limits of Acceptable Change indicator for campsites visible refers to the number of occupied campsites visible to another person from their campsite. The Forest Plan, Chapter 4, has been reworded to clarify this point.

ANNUAL PERMIT SYSTEM IS NEEDED/NOT NEEDED TO PROTECT WILDERNESS VALUES

I recommend an annual region-wide wilderness permit system for hikers traveling 3 miles (each way) and all overnight use. The permit fee would make the program self-supporting. Each permit holder would receive a booklet, listing wilderness ethics etc The 3 miles is arbitrary; its purpose is to differentiate between the serious overnight user and the more casual, day hiker.

The plan does not address the need to limit the numbers of people impacting the wilderness through the implementation of a permit system

It is time that the MBS instituted a system of restrictions on visitor numbers in the wilderness. In too many areas, resource degradation due to excessive use has become a serious problem.

Response: At the present time, none of the wildernesses on the Forest require a permit for entry or use. Several areas are currently being studied and considered for possible application of a permit system to protect wilderness values from overuse. In any situation where overuse is a concern, permits will be considered as a management option along with other techniques like road closures, restricted parking at trailheads, or education to disperse use into different areas or different times. Permits will usually be considered as a "last option."

DON'T LIMIT CAMPFIRES ABOVE 4,000 FEET ELEVATION

Wilderness should foster an independent, natural encounter with nature. To limit campfires above 4,000 feet means that only those people with the money and desire to carry a stove will be allowed. This is discriminatory and does not allow for a primitive experience

It is unrealistic to prohibit campfires above 4,000 feet in elevation in wilderness areas. Most travelers in wilderness really don't know what elevation they are at. A campfire is part of the experience of camping-out in wilderness. It would be more realistic to restrict campfires in specific areas, where scavenging for fuel has become harmful to the environment.

An elevation restriction will be hard to administer when users plead ignorance, but in general I feel that 4,000 feet in the correct cut-off for most areas. Additional prohibitions should still be allowed at lower elevations if necessary, such as at Talapus and Olallie Lakes.

Prohibiting campfires above 4,000 feet elevation is an excellent and much needed move. Olympic National Park has done this for many years and most visitors rely on stoves.

Response: This provision has been changed to limit campfires in all Dedicated Trailless areas, and in other areas - regardless of elevation - where natural dead fuel is limiting or where dead trees are a part of the natural beauty. This often occurs at higher elevations. Refer to the

Forest Plan, Chapter 4. The intent of this rule is to protect the wilderness resource for others to enjoy.

WHY IS IT ASSUMED THAT ALL WILDERNESS TRAIL CONSTRUCTION WILL BE COMPLETED WITHIN TWO DECADES; CAN'T THIS CONTINUE FOREVER?

Why can it be assumed that trails in wilderness will be completed in two decades (Appendix B-40)? Later (Appendix B-102), it is suggested that most will actually be done by the end of the first decade. Given the population assumptions, this does not seem either rational or supportable. We encourage the Forest Service to build and maintain trails forever if needed.

Response: We state that most of the wilderness trail development will be completed within two decades, based on the assumption that most of the wilderness trail system is in place already, and that there are few opportunities for further construction. Wilderness trail construction and reconstruction is undertaken to protect the character of the wilderness and not to promote additional recreational use. The Wilderness Act intends that wilderness areas not be managed primarily as recreational areas, even though recreation usually comprises the highest amount of use within wilderness. There are many other uses and values within the wilderness. Recreation use is promoted and allowed until it begins to impact these other values, such as solitude, wildlife habitat, and unrestricted ecological succession.

The issuance of FSM 2320, R6 supplement 56 in 1981 (updated by supplement 81) established a Wilderness Recreation Opportunity Spectrum (WROS) for the region which established a nondegradation policy for wilderness planning and management. It is the intent of this policy to assure that appropriate diversity and wilderness character are maintained, and that primitive trailless areas do not become trailed or reduced to a trailed condition.

MORE SIGNS ON WILDERNESS TRAILS

The limit of two signs per trail junction assumes the junction of two trails. What about a limit of one per trail so if there is a junction of three trails, there can be sign for each trail.

Response: Agree. This standard and guideline for wilderness has been revised Refer to Forest Plan, Chapter 4, Forest-wide Standards and Guidelines.

DON'T USE TRAIL SIGNS IN "GENERAL TRAILLESS"

Forest-wide Standard and Guideline for signs in wilderness, #8: directional signs should not be used in the General Trailless zone.

Response: Agree. This has been revised in the Forest Plan, Chapter 4.

LIMITING TREE BLAZES LIMITS WINTER TRAIL USE

By limiting tree blazes, you are discouraging winter use of your trails With snowfall, trails are obliterated and only by tree blazes can a path be found

Response: As Guideline #7, Trails in the Wilderness Forest-wide Standards and Guidelines states, tree blazes "...may not be used for pre-construction trail location." This guideline also states that tree blazes should to avoided in marking existing trail locations except where absolutely necessary. This provision reinforces a code of Federal Regulation which states that it is against the law to cut or other wise damage any timber, tree, or other forest product, except as authorized by a special use authorization. Special trail signs, instead of tree blazes, may be used to mark winter trails; they are placed above snow lines for visibility.

SKI TOURING TRAIL MARKERS SHOULD BE USED IN WILDERNESS

The standards and guidelines for wilderness management should allow for the use of ski touring trail markers. These signs can be life saving in a whiteout and reassuring at other times. The nationally recognized ski trail marker should be used.

Response: Normally this type of sign is not appropriate within the wilderness. As discussed in the response to the comment on tree blazes, special trail signs may be used to mark winter trails. However, there are currently no existing or proposed designated cross-country ski trails within the wilderness.

DON'T DESTROY SUMMIT CAIRNS

Summit cairns and registers should not be destroyed under the guise of carrying out the policy of nondegredation. The information contained in the registers could be useful, and some old registers are historical landmarks.

Response: It was not the intent to include historical summit cairns under this direction. The wording in the Forest Plan, Chapter 4, has been revised to clarify this.

CONCERNED THAT HORSES WILL BE LIMITED FROM WILDERNESS

We are concerned with the implications scattered throughout your wilderness guidelines that horse use will be limited first. Horses were specifically guaranteed access to the wilderness during negotiations for the 1984 Wilderness additions.

Response: Horses are permitted in wilderness; however, they may be prohibited from certain trails or areas to avoid unacceptable damage to the wilderness resource. The guideline is in line with the Wilderness Act, which states, "... the imprint of man's work (shall remain) substantially unnoticable." Horse use can be damaging in high-elevation, shallow soils; coupled with the short growing season, natural recovery of vegetation can be slow. In these situations, horse use will be limited first. Where damage is extreme, the trail may be relocated or all use curtailed.

THERE SHOULD / SHOULD NOT BE RESTRICTIONS ON THE NUMBER OF PEOPLE AND STOCK ALLOWED IN THE WILDERNESS.

The MBS should institute restrictions on the number of people and stock traveling as a group in the wilderness. A limit of 12 persons and stock is the upper margin of what is environmentally responsible. This should apply to all groups, including mountaineers, and should be implemented in all wildernesses.

I feel the "12 heartbeats rule" is unrealistic for most wilderness groups...we don't want to take in more animals than necessary, for most groups two riders and three horses make a good workable unit, with combinations of this unit as the party size increases to six riders and nine horse = 15 heartbeats.

> **Response:** Party or group size limits for all of the wilderness areas in the Cascade Mountains of Washington State are currently regulated by a CFR which states: "Entering or being in all Wilderness, except the Lake Chelan Sawtooth and Pasayten Wildernesses, with a group consisting of a *combination of persons and pack or sadle stock exceeding 12 in total number* except as approved by permit specifically authorizing a higher number, 36 CFR 261.58(f)."

WILL PELETIZED FOOD BE MANDATED?

Draft Plan, page 4-85, Livestock: will peletized food be mandated?

> **Response:** The use of processed hay or grain or livestock feed that is certified weed-free will be required. Refer to Forest-wide Standards and Guidelines, Chapter 4, Forest Plan. It is currently against the law to possess or transport unprocessed hay or grain in wilderness. The intent is to protect the wilderness resource from noxious weeds, non-native plants, or other undesirable plants.

HOW CAN CAMPERS MEET THE GUIDELINE OF AVOIDING THERMAL COVER?

How can campers avoid thermal cover? By FS definition, all low-elevation old growth provides thermal comer for deer and elk Travel corridors are usually found along bodies of water, so hikers are also expected to stay away from water. These guidelines certainly will make for interesting hiking.

> **Response:** This direction is not meant to cover all thermal cover, but rather thermal cover and other important wildlife habitat where human activity has been identified as disrupting the use of the habitat or harassing animals. Even where this occurs, it may mean avoiding areas only during certain critical portions of the year. This Guideline has been clarified in the Forest Plan.

HOW CAN T & E SPECIES RECEIVE SPECIAL TREATMENT WITHIN WILDERNESS?

How can "special emphasis" be given to threatened or endangered species when the environment within wilderness cannot be manipulated? How can you tell if human influence has caused their demise?

> **Response:** As discussed in the wilderness Forest-wide Standards and Guideline, Forest Plan, Chapter 4, a number of techniques are available to

help preserve threatened and endangered species. Certain species can be re-introduced to areas where they once existed, or human or pack and saddle stock can be curtailed In certain instances, fish/wildlife habitat improvements are permitted. The latter is allowed where the improvement existed before the area was designated wilderness; any habitat manipulation must be done with minimal impact on the resource. The work requires approval from the Chief of the Forest Service.

PROTECT WILDERNESS FROM THE INTRODUCTION OF NON-NATIVE SPECIES

The Forest's concern for the introduction of non-native species of plants is laudable and we support it. The Forest should use the same attitude toward the introduction of non-native fish species and grazers (sheep and cattle) in the wilderness.

Response: The introduction of non-native fish species is not allowed under the Forest Wide Standards and Guidelines for wilderness management (Plan, Chapter 4). These guidelines call for management of native species only, and only species indigenous to an area may be reintroduced into that area. Since only one grazing allotment for sheep exists within the wilderness of the MBS (within Glacier Peak), and is only sporadically used, grazing is not a problem for wilderness managers.

THE FORMULA FOR DETERMINING THE NUMBER OF WILDERNESS RANGERS IS INAPPROPRIATE

The parameters for determining the number of wilderness rangers seem excessively broad and will probably not provide for adequate ranger/visitor contact. The figures should be reworked to provide at least one wilderness ranger per 62,500 acres and 15,000 Recreation Visitor Days (RVD's).

The National Park Service determines the number of wilderness rangers based on factors such as number of entry portals, hot spots where damage is occurring, or the need for search and rescue contact, rather than acreage or visitation figures. In other words, real reasons rather than an automatic formula.

Response: We agree that there are other ways to determine the number of wilderness rangers needed. In reality, the number of rangers is driven by the annual budget, while the number of positions requested is determined by on-the-ground factors such as "hot spots" and desired visitor contacts. These figures were included to serve as a guide to the minimum number of persons needed for wilderness management. The MBS currently does not meet this minimum number due to lack of funds.

DON'T SET LIMITS ON NUMBER OF CLIMBERS PERMITTED ON WILDERNESS ROUTES UNLESS ECOLOGICAL CONCERNS EXIST

It has been the position of the climbing community that wilderness plans should not set limits on the number of climbers permitted onto mountaineering routes, unless legitimate ecological concerns exist. Thus, the number of social encounters, or the number of camps which are visible from other sites should not be a limiting factor on access to major mountains.

Attempting to provide a range of recreational opportunities, including solitude may be an appropriate goal when dealing with trail or trailless areas within

wilderness. However, on a mountain, there are usually only a few choices of routes or bivouac sites A peak such as Mt Baker is a significant endeavor, and climbing is a unique experience. The climbing experience far outweighs the desire for solitude.

At Mount St. Helens, in the FEIS, the Regional Forester designated the upper portion of the mountain as "Primitive", in part, to limit the number of climbers. The AAC and other climbing organizations appealed and, in a decision issued on July 16, 1986, the Chief upheld the appeal, concluding that "because of the uniqueness of this particular mountain, we feel that the number of social encounters should not be a limiting criteria in determining the use of the mountain."

Response: The FS agrees that climbing a major peak is a unique experience. Fortunately for the citizens of the Pacific Northwest, Mt. Baker is not the only location for this recreation opportunity Glacier Peak, Mt. Rainier, Mt. Adams, Mt Hood, and Mt. St. Helens all provide the opportunity for a major climb. All of these climbs also have some restrictions on the number of climbers, or on the camping locations along the routes. Generally, only overnight use is restricted, with no restrictions placed on day use.

The recent resolution of the appeal on climbing numbers on Mt. St. Helens is not relevant to the situation on Mt Baker. Mt. St. Helens is not located within a wilderness area and therefore, solitude or maintenance of a primitive character is not a primary goal of management. It should be noted that there still is a limit of 100 permits per day issued on Mt. St. Helens, based primarily on controlling physical impacts to the environment.

The primary concerns with the recreation use of the Mt Baker routes focus on defining at what point the human use begins to impact the other resource values that the wilderness provides. Recreation is only one component of wilderness management. The disposal of human waste above timberline is a primary physical impact of the heavy recreational use of the climbing route. Protection of the "primitive" social character of a mountain within wilderness is also a concern which must be balanced against the recreational use. It is important to note that "outstanding opportunities for solitude" are required by the Wilderness Act. Due to the history of heavy use prior to wilderness designation, and the uniqueness of the climbing opportunity, levels of use higher than would typically be found in *the core of a wilderness will be accepted.*

The Draft Plan proposed 16 parties encountered while traveling and 15 campsites visible for this area. Generally, the highest intensity use areas of a wilderness would allow 10-12 encounters on the trail and a maximum of two campsites visible. The Forest Plan did not change these standards. The Forest hopes to work with the climbing and recreating communites to find a satisfactory middleground for these limits Mt. Baker Ranger District is currently forming an ID team to review this issue. Members of the climbing community will be included on this team

CHANGE THE ALLOCATION OF THE COLEMAN GLACIER CLIMBING ROUTE

Change the land management designation of Mt. Baker's north side on the Roosevelt and Coleman glaciers to 10A Transition or 10B Trailed I think you can do it and still remain within the definition of "wilderness."

The FS should interpret the Wilderness Act in such a way as to maintain the historical levels of climbing and hiking in the area on the northwest side of Mt. Baker (Coleman and Roosevelt Glaciers, slopes below western lobe of Coleman Glacier, and the drainage from east side of Heliotrope Ridge to south side of Bastille Ridge). The Alternative A map has a serious error in its portrayal of current use of the Coleman climbing routes. The entire Coleman should have been classified 10A Transition to reflect current use.

Amend the preferred alternative to place all climbing routes, all of the Roosevelt Glacier and all the Coleman Glacier in MA 10A rather than 10C, which better describes the area's current use.

Response: At the small scale of the DEIS maps, the allocation of the Coleman Glacier area was confusing. The Alternative J (Preferred) map now clearly shows that, below timberline, the climbing route at Coleman Glacier is allocated to Management Area 10A Transition. Above timberline, the 10E Special Area allocation is applied. Regulations and Limits of Acceptable Change for this portion of the route will be developed during Forest Plan implementation by the Forest Service and a broad spectrum of user groups, including representatives of the climbing community. This is necessitated by the growing number of climbers on this route and the ever-worsening sanitation problems above timberline.

BOULDER BASIN AND GLACIER PEAK CLIMBING ROUTE

The Boulder Basin climbing route has been the "most popular climbing route on Glacier Peak" only since the extending of the Whitechuck Road, to Owl Creek, made it accessible. This hardly sets an historical precedent for climbers. The area is often inundated with campers (presumably climbers) with every possible campsite occupied - not a wilderness experience in any sense of the term. As the basin is mostly talus fields, every campsite is visible from almost every other campsite in the basin. The visual impact is incredible.

To quote the plan: "Areas do not qualify for this (special area) class for administrative convenience in dealing with overuse." I suggest that this is exactly the reason Boulder basin has been designated a special area. The area is overused. The FS is taking the easy route when it designates Boulder Basin as a Special Area, rather than limiting use. Manage it as General Trailless rather than sacrificing it to sport mountaineering.

Response: We agree. In the Preferred Alternative, the special area allocation (MA 10E) has been dropped for the Boulder Basin area. This area will now be managed as 10 B (Trailled).

EXCESSIVE EMPHASIS PLACED ON ENCOUNTERS AND SOLITUDE IN THE WILDERNESS

The Forest is placing excessive emphasis on encounter avoidance and the opportunity for solitude. Studies of wilderness visitor behavior indicated that most activities involve preferred social interactions.

Response: Wilderness is defined in section 2 (c)(2) of the 1964 Wilderness Act as an area "having outstanding opportunities for solitude or a primitive and unconfined type of recreation". The protection of solitude is therefore one of the core elements in wilderness management.

While it is true that social interaction is a positive part of many wilderness activities, many of our visitors desire low levels of interparty contact (Stankey 1973, 1980). Interaction between parties is a frequently cited source of visitor dissatisfaction (Stankey and Schreyer 1987). A basic assumption of wilderness management is that as interaction between wilderness visitors increases, opportunities for solitude and therefore the quality of the experience decreases. The number of encounters judged to be "too many" differs between visitors and with a number of situational factors. Mode of travel is one important variable Interactions between hiker and stock parties are more dissatisfying, particularly to the hikers, than interactions between similar groups (Stankey 1973).

Party size is another factor, Stankey also reports that visitors prefer seeing many small groups to a single large group. Location of the encounters is another important variable. Interaction between parties camped close to each other is generally more of a problem than contacts along the trails or elsewhere (Stankey and Schreyer 1987). Encounters that occur in more remote sections of the wilderness also tend to be more troubling than encounters close to the edge of the wilderness.

Existing encounter levels and suggested encounter levels in the LAC's will continue to be monitored and adjustments made if necessary.

DEFINITION OF ENCOUNTERS

We used the classification system and found problems with the definitions of encounters per day. We do not know how this is arrived at Encounters per weekend day? Average per person? Average for all the year?

Response: *Encounters are measured in two settings - on the trail and at* occupied campsites In both situations encounters are an average per day over the season of use. The Forest Plan does not specify how this will be implemented. Additional investigation is required before encounters can be used to monitor use

GRAZING IN THE WILDERNESS

It should be the MBS policy to not renew livestock grazing leases in wilderness areas when they expire, as livestock directly conflict with the primary wilderness resources. We are particularly concerned that strict monitoring and regulation of the effects of livestock grazing on wilderness plant communities be instituted.

Response: The demand for grazing has historically been very low on the MBS. Portions of two sheep grazing allotments administered by the Wenatchee NF are located on the forest. These portions contain 10,000 *acres, of which 4,000 are suitable for grazing. Neither permit has been* used for some time. It is possible that someone could apply to reopen these allotments since they are still valid, as they were in place prior to the establishment of the Glacier Peak Wilderness. An application would go through the NEPA process with public review, and it is unlikely that a *permit would be issued if it conflicted with wilderness resources.*

TEMPORARY ELECTRIC FENCES SHOULD NOT BE ALLOWED IN THE WILDERNESS

Temporary electric fences shouldn't be allowed in the wilderness. Such fences would severely conflict with the wilderness setting, and might require generators. If animals are being grazed at an intensity to require these fences, then you are probably exceeding the capacity for the area.

Response: This reference has been removed from the Forest Plan wilderness standards and guidelines.

LIVESTOCK SETBACK STANDARDS ARE NEEDED FOR ALL WATER BODIES

Stringent livestock set-back standards should be established in the Forest Plan for all wilderness areas. These standards should apply to all creeks, springs, and other wetlands, not just lakes.

Response: These standards currently exist in the form of a closure order on Cascade forests This order reads: ..."The following acts...are prohibited within all Wilderness .. (6) Grazing, hitching, tethering, or hobbling any pack or saddle livestock within 200 feet slope distance of the shoreline of any lake, stream, or pond.."

FOREST SERVICE SHOULDN'T CONTINUE TO GIVE HIKERS PREFERENCE OVER OTHER USERS

"Less than half of the recreation in the wilderness is hiking"-- and the majority of that is day hiking. That is an interesting find. It means that the Forest Service should not continue in its current direction toward giving hikers preference over all other users, if they aren't even the majority of users in an area which caters primarily to them

Response: The chart which this comment is based on shows the primary reasons for entering two wildernesses on the forest. It does not show the absolute numbers engaged in any activity. It shows that 41% of users go to the wilderness to hike, 25% to camp, two percent to ride horses, etc.

WHY WAS CODE-A-SITE SPECIFIED AS A MANAGEMENT TOOL IN WILDERNESS?

In the wilderness monitoring section why are code-a-site and photo points *mentioned. These techniques won't adequately document LAC standards.*

Response: We agree, this reference has been dropped from the monitoring plan and replaced with the direction to measure changes in the LAC's in the wilderness. Specific tools to be used are not specified. David Cole's "Wilderness Campsite Monitoring Methods" should be used as a source.

DEDICATED TRAILLESS ZONE SHOULD ALLOW WAY TRAILS AND ROUTES

The description for Dedicated Trailless says that "existing trails will be returned to a natural state" and "user made trails are not permitted." The Forest Service has already destroyed countless trail miles by logging, and here you propose to destroy way-trails and routes in a area I thought was protected.

Climber trails cross glaciers and talus slope to merge with game trails on the way to summits. We see no trend that these will develop into more than that. The Mountaineers approve of the designation of this classification as "forever trailless with the proviso that climbers trails are a reality, and they will continue to exist. People who climb and fish will continue to use them and to remove them would create a far greater impact than the way-trail.

Dedicated Trailless zones within wilderness need to be more clearly defined. If this means users will be prohibited from the area so they can't leave a boot trail then the NCCC is opposed to the concept. It it means that it is an area of user-defined routes only, which are unmarked and not obvious, then the NCCC would approve. Cross country travel through trailless zones is a supreme experience.

Response: The intent for management of this zone is to preserve an area where the presence of humans is not evident. The description of this area has been rewritten to say that "obvious travelways are not permitted". The class may include way-trails and routes not discernible as human caused, the condition to be avoided is vegetation and soil loss along a continuos tread.

PLAN SHOULD SHOW RVD'S PER SQUARE MILE INSTEAD OF PER ACRE

I concur with the climbers that recreation visitor days per square mile provides a more meaningful and understandable measure of the number of people in the area than persons per acre.

Response: A RVD per square mile, per year figure has been added to the appropriate sections of the plan.

THE COEFFICIENTS FOR DEDICATED TRAILLESS AND GENERAL TRAILLESS MUST BE WRONG

The Dedicated Trailless areas are very important to the climbing community. The proposed coefficient of 0.64 RVD's per square mile for this area is too low to permit flexibility in current use for these areas. In view of current climbing use in North Cascades National Park of 32 RVD's per year, we propose a level of 50 RVD's per year per square mile would be more appropriate.

I thought the .001 RVD's of use per acre per year in General Trailless was a typographic error. The standards and guidelines for human impact are less stringent than on Dedicated Trailless, yet the RVD's for Dedicated Trailless are much higher. Obviously, the RVD's for this class should be higher than for Dedicated Trailless.

The dedicated trailless zone is to be managed forever trailless, and user made trails are not permitted. Human impact is minimal, isolation and solitude are outstanding, and user restrictions may be necessary to insure that trailless experience remain. With these guidelines, we cannot understand how this zone is projected for 85,688 RVD's.

Response: The coefficients for General Trailless and Dedicated Trailless WROS zones have been revised in the Forest Plan. The Dedicated Trailless zone now has a coefficient of .078 RVD's/acre/year or 50 RVD's/square mile /year. The General Trailless zone coefficient was raised to .25 RVD's /acre/year or 160 RVD's/square mile/year. Forest Wide Standards and

Guidelines, Chapter 4, Forest Plan have been revised to better explain carrying capacity. With the implementation of the Limits of Acceptable Change process, carrying capacity estimates based on coefficients will no longer be necessary; although they still may be useful for comparison purposes.

The presence or degree of wilderness resource deterioration will be determined through the analysis of the condition and trend of the measured changes in LAC indicators. Carrying capacities determined through the LAC process will be expressed in PAOT's at individual sites or locations within the wilderness.

CONSIDER EFFECTS OF MANAGEMENT ACTIVITIES ON ALL ASPECTS OF WILDERNESS

The documents should consider how management activities in all areas of the Forest impact wildlife, air, water quality, and other aspects of wilderness.

Response: Chapter IV, FEIS, Environmental Effects includes a discussion on the effects of management activities on wilderness.

PLAN IGNORES THE LAW WHEN IT SAYS THE STATUTE DOES NOT PROHIBIT MANAGING ROADLESS AREAS TO PROTECT WILDERNESS SUITABILITY

Only Congress can create wilderness but the MBS is attempting to set aside substantial areas of administrative quasi-wilderness in this plan. When you state (as on page III-137 of the DEIS) that "areas remaining roadless will be studied in the next round of planning... all resources, including wilderness, will be evaluated..." the Forest needs to be reminded that these remaining roadless areas have been "evaluated" over the last 30 years. The statement in the DEIS is an intent to ignore the admonitions of the letter and legislative history of P.L. 98-339.

Response: Section 5 of the Washington Wilderness Act speaks to "released" roadless areas and says, "...that such areas need not be managed for the purposes of protecting their suitability for wilderness. ." [emphasis added]. The Forest Service is given discretion to either protect suitability or not. Using this discretion, the MBS chose not to manage any roadless areas for the sole purpose of protecting wilderness suitability. This is explained in the FEIS, Chapter II, Alternatives Eliminated From Detailed Study In the preferred alternative, some roadless areas or portions of roadless areas are allocated to management prescriptions that will keep them in an undeveloped condition. Allocations were made based on the suitability of land for various uses and resource outputs, and also on the objective of the alternative and public comment. Allocations were not made to protect wilderness suitability, though they may have that effect.

Part (b)(2) of Section 5 states: "...the Department of Agriculture shall not be required to review the wilderness option prior to the revisions of the plans, but shall review the wilderness option when the plans are revised...ordinarily...on a ten-year cycle, or at least every fifteen years. ."

"RELEASED" LANDS ARE RELEASED FOR TIMBER PRODUCTION

The MBS "Analysis of the Management Situation" document (AMS, May 1985) explained how the roadless acres had been unavailable for timber management but now are released for timber production. Since additional wilderness was rejected in the AMS for this planning period, to place virtually all of the roadless acres into a wilderness type classification violates: the direction set in the AMS, the release of these acres from RARE II in 1983, and the release of the roadless areas by the Washington State Wilderness Act of 1984.

We are concerned that areas now classified as roadless, not considered by Congress for wilderness, will not be managed for a range of resources other than for their scenic quality.

Response: The AMS is an informational document, rather than direction. It states: "...these acres are now available for a full-range of resource uses; wilderness designation will not be considered in this Forest Plan. Wilderness classification may be considered during future revisions" (AMS, 1985). The Washington State Wilderness Act says these lands:

> "...shall be managed for multiple use in accordance with land management plans pursuant to section 6 of the Forest and Rangeland Renewable Resources Act of 1974, as amended by the National Forest Planning Act of 1976. Provided, That such areas need not be managed

> for the purpose of protecting their suitability for wilderness designation prior to or during revision of the initial land management plans."

Accordingly, these roadless lands are available for multiple uses, including outdoor recreation, range, timber, watershed, wildlife, and fish. Only wilderness (one of the multiple uses) has been excluded or "released" from consideration. The Act does not state the roadless lands are released solely for timber production; in fact, 60% of the released roadless areas are not tentatively suitable for timber production.

Appendix C shows, by each roadless parcel, the acres of roadless area allocated to each management area (see the table at the end of each section). Depending on the alternative, roadless acres are assigned to a variety of management, not solely scenic allocations

APPROPRIATE ALLOCATION OF ROADLESS AREAS MUST BE BASED ON A DEMONSTRATION OF HIGHEST AND BEST USE. DOCUMENT OPPORTUNITY COSTS.

The 1984 Senate Committee Report recognized the Forest Service has the authority to manage [the roadless] lands in an undeveloped condition, if and when appropriate. "Appropriate" use specifically applies to well-defined areas of undeveloped lands where the Forest Service can clearly demonstrate that such limited use management is the highest and best use, with attendant opportunity costs well-documented. In the proposed MBS Plan, the necessary justification and documentation is not done.

> **Response:** The Washington State Wilderness Act of 1984 did not include direction to allocate the "released" roadless lands based on economic "highest and best use." The preferred alternative, in the Forest Plan, is that which - in the considered opinion of the Forest Service - provides for a level of multiple uses, goods, and services that best maximize long-term, net public benefits while responding effectively to all the public issues.
>
> Opportunity costs for all alternatives displayed in the FEIS may be found in Chapter II. Resource outputs and environmental effects, and economic tradeoffs are also discussed in Chapter II. Appendix C presents outputs and effects for individual roadless areas. This appendix has been modified in the FEIS, with more discussion of the environmental consequences of implementing each alternative on the roadless areas

ALL TENTATIVELY SUITABLE ROADLESS ACRES SHOULD BE MANAGED FOR TIMBER PRODUCTION

The 40% of the roadless acres (164,500 acres) that are currently tentatively suitable for timber production should be managed for timber under the release language of the Washington State Wilderness Act.

> **Response:** As discussed above, the "release" language only states that the roadless areas are available for multiple uses, and that the Department of Agriculture shall not be required to review the wilderness option prior to Forest Plan revisions. Table C-1 in Appendix C, FEIS shows the updated acres of tentatively suitable land; also refer to the general discussion in Chapter III, FEIS. When the acres of inaccessible land and those lands allocated for wildlife and riparian management requirements are removed, fewer acres are remaining as tentatively suitable for timber production;

again, see Table C-1, Appendix C. Refer to the narrative for each roadless area parcel for the disposition, by alternative, of that parcel.

FOREST SERVICE FAILS TO COMPLY WITH RPA BY FAILING TO OPEN ROADLESS AREAS TO TIMBER HARVEST

By failing to open the roadless areas to timber harvest beyond a mere token level over the next 15 years, the MBS Plan has failed to comply with Section 10 of the Resources Planning Act.

Response: The Forest Plan presents a full range of utilization of the roadless areas for lands that are suitable for timber production. Section 10 of the RPA Act directs that ".. installation of a proper system of transportation to service the National Forest System...shall be carried forward in time to meet anticipated needs on an economically and environmentally sound basis..." It also states that any roads constructed be designed to standards appropriate for the intended uses. If any piece of land is assigned to a management use and prescription that precludes road construction, Section 10 of the RPA would be met, as the anticipated needs of an area would be unroaded use.

ROADLESS AREAS NOT DESIGNATED WILDERNESS IN 1984 SHOULD BE OPEN TO MULTIPLE USE

The 1984 Washington State Wilderness Act was tailored and heradled as the bill to close the wilderness questions for at least 10 years. It also stated that all other roadless areas should be opened up to multiple use, with no buffers around wilderness. The MBS has ignored the Act in the management of the released roadless areas, and has set up quasi wilderness. If these areas are not developed, they will probably be put into the wilderness system in the next planning phase.

Response: In this round of planning, an alternative that considered additions to the wilderness system was considered, but not developed in detail. The roadless areas (see Appendix C) were evaluated for a number of values, including wildlife, timber, recreation, cultural/historical, minerals, water, and wilderness. Sixty percent of the roadless acres are unsuitable for timber production, 17% of the area that is **tentatively** suitable is inaccessible or contains wildlife management requirements. In summary, 77% of the roadless area acres are not suitable for timber harvest. On the remaining acres, timber production was considered along with other values, resulting in a differing mix of allocations - except wilderness - in the various alternatives.

CONTRARY TO LAW AND POLICY, THE FOREST SERVICE IS CREATING BUFFER ZONES AROUND WILDERNESS

The map of the proposed alternative shows a majority of wilderness boundary miles classified in MA 1A or 1B - wilderness buffers. This is in direct conflict with the spirit and intent of Section 9, P.L. 98-339 [1984 Wilderness Act].

Holding areas as potential wilderness in the next generation of plans and creating buffer zones are not acceptable direction for this plan. The Washington State Wilderness Act of 1984 bestowed Congressional approval on the

RARE II results with sufficiency and release language...and it deemed that the remaining roadless areas be managed for nonwilderness multiple uses.

Response: Lands adjacent to wilderness are evaluated along with other National Forest lands for the potential to produce goods and/or services. No attempt is made to create a "buffer" around wilderness. Through the forest planning process - including public comment - some lands adjacent to wilderness will be designated for timber harvest, while other lands are not suitable, or have other more valuable resources that will be the focus of management in one alternative or another. In the Preferred Alternative, over 50% of the lands adjacent to the wilderness boundary are allocated to management areas that allow road construction and timber harvest.

PROTECT ROADLESS AREAS SO THEY CAN BE CONSIDERED FOR WILDERNESS AT A FIRST REVISION OF THE PLAN.

The Plan completely ignores a management option· protecting additional roadless areas for the express purpose of recommending them for wilderness at the first revision of the Plan. Reconsideration of roadless areas for wilderness is required by release language in the Washington Wilderness Act.

Response: The Washington State Wilderness Act of 1984 states that "...the Department of Agriculture shall not be required to review the wilderness option prior to the revisions of the plans,but shall review the wilderness option when the plans are revised...' (Sec. 5(b)(2). In Sec. 5(b)(3) areas not designated wilderness'...shall be managed for multiple use ... provided, that such areas need not be managed for the purpose of protecting trees suitability for wilderness designation prior to or during revision of the initial land management plans."

NEED BETTER DEFINITION OF "ROADLESS"

You need a realistic definition of "roadless." We have seen areas with improved gravel roads designated wilderness by bureaucratic fiat by merely gating the road in question, then imagining it no longer exists. The classification of "roadless areas" must be made consistent with FS policy of classing any primitive travelway (over 40" wide) as a road; if there are any roads within "roadless" areas, consider them for use - will help disperse users over more of the forest. Where an area is genuinely roadless, we strongly prefer that the area remain roadless, and undeveloped.

Response: The Forest Planning process attempts to determine how each acre shall be managed. The existence of a primitive travelway indicates the existing condition which may or may not be in conflict with the selected management for the area. If the selected management allows for roads, the area will be classified as roaded. Otherwise the "road" is non-conforming and shall be allowed to return to its more natural state. The object of the definition of "roadless" or "roaded" is to define the future desired condition of use, rather than soley to define the current existing condition.

WHAT CRITERION WAS USED TO DETERMINE A ROADLESS AREA?

I cannot determine from the documents what criterion is used to determine when an area is "roadless". Exactly what standards and criteria did the FS use for calling an area "roadless?" How big do such areas have to be? How far from roads?

> **Response:** "Roadless" as used in Appendix C, Roadless Area Analysis, are remnants of the Roadless Area Review and Evaluation (RARE II) that were not legislated into wilderness by Congress in 1984. Size on the MBS ranges from 21 acres to 51,400 acres; there was no other criterion. The definition appears in Glossary of the EIS. Refer to MA 1A and 1B prescriptions, Forest Plan Chapter 4. 1A or primitive areas are generally 3 miles from roads while 1B, semi-primitive nonmotorized areas are 1/4 mile from roads. There are no minimum size criteria, but characteristics listed under "Desired Future Condition" define other factors.

FOREST SERVICE IS OVER-CONCERNED WITH CLOSENESS OF NEARBY ROADS

The plan process tends to examine each remnant parcel in isolation from other areas and political boundaries (specifically those of Mt. Rainier National Park), with over-concern with the distance to nearby roads There are several locations at the Clearwater roadless areas where existing roads are closer to the wilderness than to the roadless area. This does not negate the wilderness status; why should it negate the worth of the roadless area?

> **Response:** Closeness of a roadless area to roads does not negate the worth of the area. It is presented as inventory information to give planners and the public a mental picture of the existing situation on the ground. The format of Appendix C was standardized for all Forests in Region 6 (Washington and Oregon) to facilitate understanding and consistency. One of the items required for each roadless parcel was "opportunity for solitude " Close proximity to a road was often cited as offering low solitude.

ROADLESS AREAS HAVE NOT BEEN INVENTORIED FOR SENSITIVE PLANT SPECIES

In general, DEIS Appendix C Roadless Area evaluations are thorough and well-presented. However, one major omission in the analysis is that at most of the areas have not been adequately inventoried for sensitive plant species or unique plant communities. This should be corrected in the FEIS.

> **Response:** An inventory was not attempted for the Forest Plan. However, this important issue is addressed in the Forest-wide Standards and Guidelines, Chapter 4 of the Forest Plan. Current direction includes consultation with the Washington National Heritage program before starting any ground-disturbing activities. The wording of this standard has been clarified in the Forest Plan and made stronger.

ESTIMATE LONG-TERM SUSTAINED YIELD OF ALL ROADLESS AREAS

Develop long-term, sustained yields estimates for timber harvest from roadless areas.

Response: Table C-1 in Appendix C shows the maximum, long-term sustained yield for the roadless areas. This number was estimated without regard to accessibility, or other legal constraints on harvest. Refer to the final section of Appendix C for the management of each parcel, by alternative.

IDENTIFY FOREST LAND AND VALUABLE MINERAL DEPOSITS IN ROADLESS AREAS

There are sites in many of the remaining roadless areas that are commercially valuable for timber and minerals. We insist that they be identified, so that they can contribute to the economy.

Response: FEIS, Appendix C presents the extent of commercial forest lands and mineral deposits for each roadless area. Whether or not these lands and deposits are developed depends on other factors such as soil, water, wildlife, fisheries, cultural/historical, recreation and other values. These other factors also contribute to the economy.

HIGH PROPORTION OF ROADLESS ACRES ALLOCATED TO UNDEVELOPED ACTIVITIES IS CONTRARY TO INTENT OF LAW

The proposed plan implementation schedule would leave over 61 percent of the total 407,000 acres of released unroaded areas in an undeveloped condition with no planned road access. With 132,247 acres not to be developed for the next 15 years, it appears that only 25,000 acres of existing roadless lands (6% of the total unroaded area) would receive any additional use whatsoever. We believe this potential situation is contrary to the intent of the Washington Wilderness Act of 1984 and the direction of the Resources Planning Act (RPA) program pursuant to the Amended RPA It does not lend credibility to the plan analysis and conclusions to note that most of the projections of recreation and Wilderness use are already obsolete.

Response: The intent of the Washington Wilderness Act and Resources Planning Act was to allow for a process to consider alternative uses of roadless areas outside wilderness. This did not constitute a decision to harvest timber or open these lands for roaded or developed recreation. The allocations recommended in the preferred alternative are, in the opinion of the Forest Service and tempered by public input, the best use of the land.

NO BELOW COST TIMBER SALES IN ROADLESS AREAS

A study should be conducted to determine whether each particular sale in a roadless area would be a below cost sale. No below cost timber sales should occur.

Response: Many roadless acres will never be harvested (see above responses regarding the percent of roadless acres that are tentatively suitable for timber harvest. Costs and revenues from timber sales will be part of an extensive evaluation during the site specific planning phase of each sale These type of analysis is beyond the scope of the forest plan, but will be completed during the environmental analysis for each proposed project. Refer to the Forest Plan, Forest-wide Standards and Guidelines, General Procedures #1.

MULTI-AGENCY AND PUBLIC COMMENT NEEDED PRIOR TO ANY ROADLESS AREA DEVELOPMENT

Existing roadless areas should be developed for recreation uses and such development only after multi-agency professional critique of site specific plans and public comment period.

Response: Refer to the Forest-wide Standards and Guidelines, General Procedures #1 and 4, Chapter 4, Forest Plan. These provide for further agency and public comment on site-specific developments. The Forest Planning process has benefited from comment and evaluation of many different disciplines and other agencies. As a result of this input, plus public comment on the Draft Forest Plan, the roadless areas have been considered for all forms of forest use, including recreation.

DELETE SEATTLE CITY LIGHT GEOTHERMAL LEASE DESCRIPTIONS FROM APPENDIX C

The FS should review current data on geothermal leases in Mt. Baker MN. Seattle City Light recently allowed their leases to expire.

Response: These leases have expired. References to them have been deleted from the narratives for Mt. Baker (west block), and Mt. Baker (south block), and Mt Baker (Noisy - Diobsud block). These appear in Appendix C.

ADD TO THE ROADLESS AREAS DESCRIPTIONS

Descriptions are sometimes incomplete. For example, Silver Creek roadless area (App. p. C-213) fails to mention it includes part of the Mather Parkway.

Response: The descriptions in Appendix C have been improved between the draft and final plans; all wildlife and mineral/geothermal lease information has been updated. Regarding Silver Creek: the roadless area boundary was placed very close to any existing roads. Mather Memorial Parkway extends one-half mile on either side of State Highway 410, therefore there is a slight overlap with a portion of the Silver Creek area on the northwest side. This information has been added to the "Description" and to the "Contribution to Primitive Dispersed Recreation" sections of the Silver Creek narrative.

NINE ROADLESS AREAS [LISTED BELOW] VALUABLE FOR RECREATION PURSUITS

[. .the State of Washington's...] Attachment D contains a non-prioritized listing by the IAC of nine roadless areas which the state sees as valuable for recreation pursuits...[they also] benefit other values on the Forest such as critical habitat, water quality and fisheries. These values and those of recreation may over-lap and enhance the decision-making process.

Response: The areas listed by IAC are shown in the table below. Also shown are the acres of each allocated to nondevelopment in the DEIS preferred alternative compared to the Preferred Alternative J. These acres will be available for primitive and semi-primitive recreation plus protection of other values as well. The Pratt, which is not an inventoried roadless area, is allocated to a combination of Scenic Forest (which include timber harvest), General Forest, MA 14 Deer and Elk Winter Range Enhancement (reduced yield timber harvest), Recommended Wild and Scenic

River, SOHA (no timber harvest), and Dispersed Recreation (no harvest). Refer to the map for Alternative J, Preferred.

Roadless Area	RARE II Parcel Number	Acres	DEIS Pref. Alt. Acres of No Devel.	%	FEIS Pref. Alt. Acres of No Devel.	%
Boulder River	6050 (BJ)	27,369	22,427	82	26,728	83

INVENTORY ALL ROADLESS AREAS ON THE FOREST, INCLUDING PRIVATE LAND

Some roadless areas, such as Annette Lake, were not inventoried in the RARE II process because they were less than 5,000 acres. Since wilderness is not an issue, the Forest should inventory and include the disposition of all roadless areas greater than 1,000 acres

Several roadless areas of the Cedar River Watershed are connected to other roadless areas...(sections near Abiel Peak and Meadow Mountain). These areas should be added to the inventory and considered for protection.

The DEIS fails to consider all the roadless land on the Forest. The review was limited by the RARE II inventory of 407,389 acres. However, in Alternative H (DEIS Preferred), the Forest Service allocates several areas to semi-primitive roadless recreation that were not inventoried. We feel that all existing roadless areas by themselves or contiguous with wilderness that are 500 acres or greater should be inventoried. Precluding private lands, especially checkerboard, as was done in RARE II is not appropriate here

Response: Areas that are undeveloped (essentially unroaded) and outside of special designation (such as wilderness, research natural area, etc.) fall into two categories· areas or portions of areas identified in the Roadless Area Review and Evaluation (RARE II) process, and all those lands not meeting the roadless/undeveloped criteria for potential wilderness designation used in RARE II

The purpose of Appendix C "Roadless Area Analysis" is to provide a detailed and site-specific analysis of the RARE II roadless areas not designated wilderness in the 1984 Washington State Wilderness Act This analysis will be used to help develop, design, and reach decisions on site-specific projects that implement the direction of the Forest Plan.

Although undeveloped lands throughout the Forest were not analyzed in Appendix C, they were considered for a wide range of alternative uses, ranging from roadless recreation to varying levels of resource development.

The areas near Abiel Peak and Meadow Mountain were both considered for nondeveloped uses in Alternatives C and G-Modified. The Preferred Alternative allocates Abiel Peak to MA 20D, Cedar River Watershed (Negociate a New Cooperative Agreement) and Meadow Mountain to MA 20D and 21A (Green River Watershed, Current Direction - which allows timber harvest).

Annette Lake was not included in the RARE II process, nor presented in Appendix C for the following reason: the area is part of the Alpine Lakes Management Unit. In 1981, after receiving extensive public comment, the Forest Service issued a FEIS and, as directed by Congress, a Management Plan for Alpine Lakes. In the Annette Lake area, 2,456 acres were set aside as a Special Recreation Area. The area is to be "...managed principally for recreation in a substantially natural condition. The area will be roadless with no motorized vehicles permitted except snowmobiles, where determined suitable.. " The Alpine Lakes Management Plan is incorporated into the Forest Plan and the designation of Annette Lake will not change.

ROADLESS AREAS SHOULD NOT BE MANAGED FOR "NON-MOTORIZED DISPERSED" ACTIVITIES

The final plan should not include any area designated as "non-motorized dispersed." The Wilderness system provides adequate opportunity for this type of planning allocation. Remaining roadless areas should be open for motorized access to ease the great demand for scenic driving on the forest.

Response: The roadless areas have been allocated to a variety of uses, in each alternative. The allocations best meet both the objective of that alternative and the resource capability of the area. SCORP has identified deficits for a number of recreation opportunities in the Puget Sound region; one of these is primitive and semi-primitive recreation. Refer to Appendix C for a more detailed discussion of each roadless parcel.

ROADLESS PARCELS SHOULD BE RE-COMBINED

The maps and narratives on the roadless areas adjacent to Glacier Peak and Henry M. Jackson Wilderness Areas are hopelessly confusing and needlessly complicated In discussing roadless areas, rational decisions to lump small, fragmented pieces together seem to have been avoided. It is hoped that this confusion will be cleared up in the FEIS.

Response: We recognize the validity of the comment. However, regional direction requires that we address each parcel separately. The current numbering system was retained to maintain consistency with the system used in Rare II.

ROADLESS AREA INFORMATION IN APPENDIX C WAS NO BETTER THAN RARE II

The roadless area evaluation was no better than in RARE II. All forested areas were termed "typical" inferring they are unimportant. Potential vehicle

trespass, "unmanageable boundaries," and other problems were used to argue against wilderness values. The FS has a responsibility to manage these areas, not shirk that duty it it seems to tough.

Response: Between Draft and Final, we have updated the resource information for all of the roadless parcels in Appendix C. We have also added a section on the environmental consequences of implementing any alternative on the roadless parcels.

PARCEL ALLOCATION CONFLICTS WITH TABLE

The data on page C-114 is confusing. Alternative H map shows all of Glacier Peak Parcels AA and AC allocated to MA 1AB. However, the table shows 105 acres of the units in "moderate development." Which is correct?

Response: In the FEIS, Appendix C, this table has been replaced with a table (for each roadless parcel) showing the exact management area allocations. In the Preferred Alternative, Glacier Peak AA and AC are both allocated to MA 1B, Semi-Primitive Nonmotorized Dispersed Recreation.

NO RIVERS SHOULD BE RECOMMENDED FOR WILD AND SCENIC STATUS

No rivers should be recommended for Wild and Scenic designation. With riparian management guidelines, further protection is unnecessary. Such a designation could well impact private property owners along the river.

Response: Riparian management guidelines are not a substitute for Wild and Scenic River designation for several reasons. Riparian management only regulates activities within 75 to 100 feet of the river; wild and scenic classification applies to an average 1/4-mile corridor on each side of the river. Secondly, riparian guidelines do not insure the continuation of the "free-flowing" character of a river. Riparian management attempts to lessen the impacts of management activities on the aquatic environment, while wild and scenic classification preserves the river and it's resources in the present condition. The impact of designation on private property owners is typically minimal - farms, homes, and cabins along a river can continue to be used as they were before designation. When scenic or access easements are necessary to protect river values, the property owner is paid for these rights. In some circumstances, the government is prohibited from acquiring private property rights from an unwilling owner.

WHAT IS THE EFFECT OF WILD AND SCENIC RIVER DESIGNATION ON PROPERTY VALUES

I own land in a proposed wild and scenic river corridor and am concerned with the effects of the Forest Service zoning on my properties values.

Response: Wild and Scenic Rivers enjoy a measure of protection from future incompatible land uses and development, there fore, designation can have a positive impact on property values and marketability. Other factors such as location of the river, type and location of the property, an advertising can have a significant influence on property values.

Recent studies on two Wild and Scenic Rivers, the Upper Delaware and the Rogue, have shown property values in the designated corridors to raise at a higher rate than those for adjacent lands The ability to buy and sell land will not be affected by designation.

INADEQUATE ELIGIBILITY ANALYSIS

Studies conducted to date have been of minimal extent and there is inadequate information to exclude any of the 47 rivers from eligibility for study to determine their suitability for future designation as "Wild Rivers" or "Scenic Rivers".

Response: Between draft and final, and based on considerable public response, we formed a special team to re-evaluate Wild and Scenic River eligibility. This group was composed of Forest Service planners, State of Washington Fishery Biologists, and outside interest group representatives. The group added to the original 47 rivers under study, for a total of 51 rivers. Rivers added were South Fork of the Tolt, South and North Forks of the Snoqualmie, and Lennox Creek. Following reassessment, 47 rivers were found to be eligible. Bar Creek, South Fork of the Cascade, Suiattle River Extension, and Jim Creek were found not to possess any "outstandingly remarkable" values and were thus dropped from further evaluation. Refer to Appendix E of the FEIS for more detail.

OUTDATED ELIGIBILITY CRITERIA USED IN WILD AND SCENIC RIVER ASSESSMENT

The evaluation process is flawed because outdated eligibility criteria are used. The Forest Service used 1970 guidelines, which were superseded by 1982 guidelines.

Response: The 1970 eligibility guidelines were presented in the DEIS, but they were not used as limiting factors for eligibility. To remove the confusion, the criteria for minimum flow, minimum length, and water quality have been removed. All rivers were re-evaluated using the 1982 guidelines, which included an assessment of the potentially "outstandingly remarkable" values of a rivers ecological setting. See Appendix E, FEIS for details.

RIVERS HAVE BEEN RATED ON A LOCAL RATHER THAN A NATIONAL PERSPECTIVE

Caution is needed in determining outstanding qualities when considered on a local versus national perspective. The river corridors on the MBS are exceptional in general and outstanding in most respects when compared to other river resources within the country. This results in downgrading river features, since you are rating the most outstanding within a field of outstanding rivers.

Response: Between the DEIS and FEIS, the Forest re-evaluated eligibility criteria for wild and scenic rivers. This resulted in a recommendation of many more rivers as eligible for classification. Refer to Appendix E, FEIS

NOT CLEAR WHAT "RECOMMENDATION FOR SUITABILITY STUDY" MEANS

The DEIS is not clear on what a "recommendation for suitability study" for potential Wild and Scenic Rivers consists of.

Response: The "recommendation for suitability study" has been removed from the Forest Plan and replaced with a complete suitability analysis. See Appendix E, FEIS.

DEIS LACKS SUITABILITY ANALYSIS ON WILD AND SCENIC RIVERS

The Draft EIS lacks a suitability analysis for wild and scenic rivers. Without an explicit discussion of the suitability criteria defined in section 8.23 of the Land and Resource Management Planning Handbook, it is unclear if the required evaluation was accomplished.

Response: Between the draft and final plans, a complete suitability analysis was completed for all eligible rivers; it is included in Appendix E, FEIS. Suitability of rivers may vary by alternative to retain the option for a high level of recreational development (campgrounds, paved roads, trails, bridges) along several rivers.

LACK OF DOCUMENTATION FOR CLASSIFICATION OF RIVERS

There is a lack of documentation for the classification of rivers; no information was provided on how each river was classified. Without this, it is impossible to determine if river segments were deleted or downgraded correctly.

Response: The information needed for classification of rivers is now included in Appendix E, FEIS, along with the criteria used to classify rivers into wild, scenic, or recreational segments. The recommendation, after suitability study, may be at a level lower than the original classification at the eligibility stage in various alternatives. However, as stated in the Forest Plan, Forest-wide Standards and Guidelines for wild and scenic rivers, all recommended rivers must be managed at the highest classification level until Congress makes a decision.

MORE PUBLIC AND AGENCY REVIEW IS NEEDED IF RIVERS ARE RE-ANALYZED

If revisions in the wild and scenic river recommendations are made, it is important that the public and other agencies be given an opportunity to review the revised analysis before it is finalized. Consider one of the following options· revise the assessment and republish is as an amendment to the draft plan and DEIS; or defer the entire Wild and Scenic River analysis until after the final plan is released. In the interim, manage the 47 rivers in accordance with section 8.12 of the Planning Handbook.

Response: A primary purpose of a draft EIS is to allow public review and comment on analysis, evaluation, and proposed actions and to give an agency an opportunity to be responsive to those comments in their decision. As a result of public comments on the DEIS and proposed Forest Plan, we made a number of changes in the Forest Plan, including changes in the Wild and Scenic Rivers analysis and recommendations for classification. Refer to the description of alternatives considered (Chapter II, FEIS); Chapter IV, FEIS, Environmental Consequences; Appendix E, FEIS; and the Record of Decision.

We did not prepare a supplemental DEIS. In evaluating changes made between draft and final, we determined that all 47 rivers had been analyzed in detail in at least one alternative in the DEIS; thus, the changes were not significant as defined in the CEQ regulations, and a supplement was not required.

MIDDLE FORK OF SNOQUALMIE INCORRECTLY CLASSIFIED

The MBS was correct to find the Middle Fork Snoqualmie River to be eligible (the proper classification should be Scenic, not Recreational) and now should reevaluate its major tributaries, the Taylor and the Pratt Rivers.

Response: Between draft and final, the potential classification of all rivers was re-evaluated. The Middle Fork Snoqualmie, Taylor, Pratt and portions of the North Fork Snoqualmie were found to be eligible and suitable for designation under the management direction of the Preferred Alternative. A scenic classification is recommended for the Middle Fork Snoqualmie River, from the wilderness boundary to the confluence of the Taylor River. Refer to the alternatives section, Chapter II, FEIS and Appendix E

SOUTH FORK STILLAQUAMISH SHOULD BE ELIGIBLE

The South Fork Stillaguamish River should be added to the list of candidates for wild and scenic river status. It possesses outstanding fisheries, wildlife, and water quality resources, and contrary to the description, receives very high recreational fishing pressure, and is a critical salmonid production area. It also contains outstanding scenic qualities, and is an important cultural use area.

Response: In re-analyzing potential Wild and Scenic Rivers, the South Fork Stillaguamish was determined to possess outstandingly remarkable values for fisheries, scenery, recreational, wildlife, historical, and ecological resources. It was thus determined to be an "eligible" river. It was further determined to be suitable for inclusion in the Preferred Alternative; rivers included here will be recommended to Congress for designation as Wild and Scenic Rivers. Refer to Chapter II, FEIS and Appendix E.

DEIS UNDERCLASSIFIES SEVERAL RIVERS

The DEIS underclassifies the North Fork Nooksack below Nooksack Falls, the North Fork Skykomish between Goblin Creek and Troublesome Creek, and the Middle Fork Snoqualmie. The draft classifies these segments as recreational when they qualify as scenic. All of these rivers were included on the first round of the Nationwide Rivers Inventory done by the Heritage, Conservation and Recreation Service (HCRS) in 1980. It was the intent of this phase of the inventory to include only rivers eligible to be wild or scenic Thus, in 1980, HCRS found these rivers eligible to be scenic. If the Forest Service intends to downgrade them to recreational, it should document the reasons for doing so in its EIS

Response: The potential classification of these river segments have been re-evaluated The North Fork Nooksack below Nooksack Falls was changed to a Scenic Classification down to the Salmon Hatchery near river mile 46. The North Fork Skykomish River between Goblin and Troublesome Creeks, and the Middle Fork Snoqualmie were also changed to a Scenic Classification. For a further discussion of river eligibility, refer to Appendix E

VALUES ALONG PRATT RIVER MUST BE PROTECTED

Since the Pratt River has been identified as a study river in Alternative G, its values must be protected, and its eligibility potential cannot be affected.

There is an outstandingly abundant flora of lower vascular plants within 200 to 300 yards of the Pratt River which is richer than that along the much wetter Elwha on the Olympic Peninsula. It is for the protection of this riparian habitat that I particularly feel that the Pratt River should be designated as a Wild and Scenic River.

Response: The Forest Service has re-evaluated the Pratt River for eligibility. It is now eligible and we are recommending for designation as a Wild and Scenic River. See Appendix E of the FEIS.

CHANGE VISUAL QUALITY OBJECTIVE IN RECREATION RIVERS

The prescription for management area 5A Recreation River should be rewritten to call for a visual quality objective ranging from retention to modification, instead of retention to partial retention. This would make it less cumbersome for the Forest Service to allow for timber harvest that may be the result of some catastrophic event.

Response: This prescription is written for the normal day-to-day management, a catastrophic event is a rarity. Forest Service Manual 2354.42 establishes the visual quality objectives for Wild, Scenic, and Recreation rivers. Within the classified river corridor (1/4 mile foreground), Partial Retention is the norm. For the viewsheds beyond classified foreground, Partial Retention is the norm for both middle and background of sensitivity level 1 corridors. In sensitivity level 2 corridors, modification is the norm.

ILLABOT CREEK HAS IMPORTANT SALMON SPAWNING, EAGLE USE

The Illabot Creek area has important salmon-spawning reaches, eagle roosting areas, winter range for mountain goats and deer, and low-elevation old growth forest. It should be added to the Wild and Scenic Rivers system.

As a major tributary to the Skagit, Illabot Creek supports significant native runs of pink, chinook, coho, chum salmon, steelhead, and Dolly Varden char. These anadromous fish ascend to about river mile 9, just below the confluence of Arrow Creek. The watershed also supports an important wintering night roost for bald eagles; there is a large contingent of Roosevelt Elk, spotted owl, and deer. These values argue for more protection.

Timber management in Illabot drainage should be scaled down to protect the eagle roosting sites. Include in the Wild and Scenic rivers system.

Response: In the FEIS Preferred Alternative, 15.3 miles of Illabot Creek are recommended for inclusion in the Wild and Scenic Rivers system. From the headwaters to the Glacier Peak Wilderness boundary is recommended as a Wild River; from the boundary to the confluence with the Skagit River is recommended as a Recreation River. Refer to Table 4-14, Forest Plan Chapter 4.

ESTABLISH SPECIAL INTEREST AREAS, ESPECIALLY AT TWIN SISTERS

These four areas - Baker Lake, Twin Sisters, Monte Cristo, and Naches Pass - should be allocated to Special Interest Areas. The one at Twin Sisters is especially significant, since the olivine substrate and its associated plant community is highly unusual.

Response: These four areas were considered for special interest areas in Alternative G. The Preferred Alternative assigns most of the Baker Lake, Twin Sisters and Monte Cristo areas to Management Areas 1A, Primitive Recreation, and 1B, Semi-Primitive Nonmotorized Recreation. The balance of the Twin Sisters area is assigned to MA 23A, Other Municipal Watersheds. The rest of the Monte Cristo area is assigned to MA 1D, Roaded Natural, and 2A, Scenic Viewshed. Allocation of these areas to MA's with an emphasis other than timber harvest will protect their unique scenic, biological, and geological features.

The Preferred Alternative assigns the Naches Pass Special Interest Area to MA 17, Timber Management Emphasis. The historic values of the area will be protected through preparation of a Historic Preservation Plan (see Appendix D, Forest Plan) and application of the Forest-wide Standards and Guidelines, Chapter 4, Forest Plan.

NEED A SUPPLEMENT TO ADDRESS ALPINE LAKES UNIT

A supplement must be issued to address the Alpine Lakes Management Unit, unfairly excluded from consideration under the Forest Plan.

Response: As discussed in "Alternatives Considered But Eliminated From Detailed Study (Chap. II, FEIS), the management direction in the Alpine Lakes plan provided for collection of certain data (not available when its Record of Decision was issued in 1981) and its incorporation into the Forest Plan. This was completed for the Proposed Plan and DEIS. In all alternatives considered in detail, provisions are made to maintain viable populations of spotted owls; protect mountain goat; wild and scenic rivers; protection of riparian areas; and incorporating timber producing lands from the Alpine Lakes Management Area into the ASQ for the final Plan. The existing Alpine Lakes Plan has not been a major issue or concern, therefore the decision was made to incorporate it into the Forest Plan without modification, except as noted above.

THE ALPINE LAKES PLAN IS OUTDATED

Since the Alpine Lakes Plan took five years to write and has been partially implemented for at least seven years, it probably should be updated and included in the LMP during this present planning exercise.

Response: As the Alpine Lakes Plan is fairly new, is consistent with the intent of NFMA, and provisions were made to incorporate some additional data (see above), the decision was made not to update it at this time Refer to Chapter II, FEIS, Alternatives Considered But Eliminated From Detailed Study Once the Final Plan and ROD are issued, all elements of the Forest Plan may be amended through a supplement. In addition, the Alpine Lakes Management Area Plan will be updated along with the Forest Plan in the next round of Forest Planning, 10 to 15 years from the ROD.

THE PUBLIC SHOULD BE ABLE TO COMMENT ON ALPINE LAKES

A major complaint I have with the Plan is its complete exclusion of the Alpine Lakes Management Area from the documents. No opportunity is open for people to voice their opinions on vital old growth areas.

We feel we have a right to comment on the proposed use of non-wilderness designated land which falls under the Alpine Lakes Management Plan. The use of this land was not specifically defined and the Forest Service is assuming that it should be used for timber harvest; the public should not be excluded from decisions on its use

Response: During the development of the 1981 Management Plan for the Alpine Lakes area, public comment was solicited and extensive effort was made to involve people in the planning effort. We have added the allocations within the Management Unit, as defined in the Alpine Lakes Preferred Alternative map, to all the FEIS alternative maps for this Forest PLan. In the draft plan, the Alpine Lakes Management Unit was defined only as MA 27. Also, refer to the MA descriptions in Chapter II, FEIS.

ADDRESS OLD-GROWTH DEPENDENT WILDLIFE; WAS IGNORED IN ALPINE LAKES

Wildlife that is dependent on old growth was given inadequate attention under the Alpine Lakes Plan and it should therefore be addressed in the current forest-wide plan.

The Forest should explain in detail the methodology and efforts of implementing MMR's within the context of the Alpine Lakes Plan.

Response: The Forest Plan provides for additions to be made to the Alpine Lakes Management Plan for wildlife habitat. Management Areas for old growth habitat (MA 11) and mature and old growth habitat (MA 12) have been added. Refer to MA 27 description, Chapter 4, Forest Plan.

CONCERNED ABOUT ROADED NATURAL ALLOCATION IN THE PRATT

The ROS map of Alternative E of the Alpine Lakes Plan shows the Pratt Valley as "Roaded Natural"...defined in part as..."areas less than 1/4 mile from roads open to public travel..." There is no road there now, and the proposed road is required to be gated to exclude public travel; indeed, the successful enforcement of this closure is one of the concerns of the current plans for the area.

Response: Page 86 of the Alpine Lakes FEIS states: "The Pratt River road system (which would be necessary for timber management) would be closed to recreation passenger car traffic." The important distinction is that there is an implied difference between the public's commercial traffic and recreational traffic. The Forest Plan carries through the intent to bar recreational traffic from this potential road system.

LITTLE OLD GROWTH PROTECTION IN ALPINE LAKES MANAGEMENT AREA

The Alpine Lakes Management Area plan did not address old growth either as a resource or wildlife habitat The draft Forest Plan indicates little additional old growth protection over the Alpine Lakes plan. A significant old growth resource exists in the Pratt drainage, particularly the "bridge" of old growth across the river between the valley side slopes. This is some of the lowest elevation stands remaining on the Forest (below 1500 feet).

Response: The issue of old growth is addressed in several sections of the the Alpine Lakes Land Management Plan FEIS; see short versus long term effects (page 88) and the response to public comments, page 118.

As stated on page 118 of that FEIS: "Low elevation old growth forest were considered when the Alpine Lakes Wilderness boundary was drawn in 1976. There are over 950 acres below 2000 feet elevation and over 21,211 acres between 2000 and 3000 feet elevation in the Wilderness...In addition to the wilderness, the management unit contains over 3,300 acres below 2000 feet elevation and 5,252 acres between 2000 and 3000 feet elevation in the Dispersed Recreation Allocation. Asahel Curtis Area at 2,400 feet elevation is dedicated to remain old growth forest. This topic will be addressed further in the Wenatchee and Mt. Baker-Snoqualmie Forest Plans..."

The "bridge" of old growth (mentioned in the comment) was actually logged (by railroad) in the 1940's. Most of the old growth was removed, but scattered old growth trees were left. Since that time, the area has regenerated to a dense stand of understory hemlock with scattered old growth above it. This stand is partially located within the General Forest allocation of the Alpine Lakes FEIS, and can be considered for timber harvest. However, any value of the stand as a "bridge" for old-growth dependent wildlife would have to be considered in the project environmental analysis, with full opportunity for public input.

At the lower end of the Pratt, the stand often referred to as "old growth" is actually less than 160 years old. The old growth overstory was removed from this area in the 1940's when it was railroad logged. There are about two dozen very large, old trees scattered over several hundred acres, left after the original logging. There are no plans to remove these large trees.

THE PLAN SHOULD ALLOW AND ENCOURAGE ACCESS TO CLAIMS.

In Alternative H, the land available to prospecting is reduced to 71% on the MBS. This is not reasonable at all, especially when part of the Forest Service charter is to promote mineral exploration and development.

The final plan should allow and encourage access to claims (as provided by existing mining laws) and should remove unnecessary restriction and regulation which discourage prospecting and rockhounding. Access to both riparian and upland areas is critical.

Response: Under the U.S. Mining Law of 1897 the public has the right to enter onto open public lands to explore for mineral resources. The Wilderness Act legislated 721,216 acres or 42 percent of the lands administered by the MBS be withdrawn from mineral entry. In the Preferred Alternative, only an additional 11,000 acres or 0.6 percent is recommended for withdrawal from mineral entry for management objectives such as Developed Recreation Sites or Research Natural Areas.

In designated Wilderness, only valid rights filed prior to December 31, 1983 retain rights to access and development. These withdrawn lands are a Congressional designation and are outside the decision space of the Forest Plan.

Excluding wilderness, 99% of the Forest is available for mineral entry. The MBS Forest Plan Forest-wide Standards and Guidelines (Plan, Chapter 4) provide for exploration, development, and production of mineral and energy resources while minimizing effects on the surface resources. The Preferred Alternative identifies 22% of the area available for mineral entry as environmentally sensitive. Mineral entry is not precluded in these areas, but activities will be relatively restrictive in nature or somewhat expensive to implement in order to minimize adverse effects on the environment.

National Environmental Policy Act (NEPA) legislated that all effects on the environment be evaluated prior to undertaking management activities. Therefore, the FS must complete an environmental analysis (with documentation either in a Decision Memo, environmental assessment, or environmental impact statement) prior to the undertaking any site disturbing mineral activity. In wilderness and other sensitive areas, this analysis can be expensive and time consuming because of complexity of issues and risk of effects

EXISTING CLAIMS WITHIN WILDERNESS NEED ACCESS

Miners, both recreational and commercial, with claims existing before the Wilderness designation must continue to be allowed rights of entry and access to these claims.

Response: According to 36 CFR 228.15(b), holders of unpatented mining claims **validly** established in wilderness prior to inclusion shall be accorded the rights provided by the US mining laws. Part (c) states that persons with valid mining claims within wilderness shall be permitted access by means consistent with the preservation of wilderness. A validity investigation by a qualified Forest Service mineral examiner is necessary

to establish validity as defined by mining laws and in compliance with 36 CFR 228.

NEW ALTERNATIVE RECOMMENDED TO MEET MINERALS NEEDS

As the Plan relates to minerals, the principles of Alternatives D, B, and H are the most desirable, in this order; G is completely unacceptable. The newly-created PLUS alternative (as outlined in this document) is the one which most fully meets our needs.

Response: A new alternative, Alternative I, has been developed in detail and displayed in the FEIS, based on the objectives and goals of PLUS

WHAT PROCESS IS USED TO EVALUATE DANGEROUS MINING WASTE, ENVIRONMENTAL IMPACTS, COMPATIBILITY, ETC.

For the mineral resource the "appropriate environmental analysis" to be conducted needs to be explored. If this refers to NEPA, such should be clearly stated. The procedures, criteria, and relationships of future site-specific activities to the overall plan need discussion/explanation. Without these, it is difficult to assess future and cumulative impacts. Further, the monitoring protocol for periodic inspections to ensure compliance with approved operation plans should be included.

What are the "minimal to moderate" restriction on the mineral resource activities that the Plan allows? Again, there should be discussion of NEPA.

Response: As described in the FEIS and the DEIS, Chapter I, the Plan guides all natural resource management activities and describes resource management practices, levels of resource production and management, and the availability and suitability of lands for resource management. This Plan embodies the provisions of NFMA and other laws pertinent to natural resource management. Chapter 1, Forest Plan includes a discussion of the relationship of the Plan to Project Planning. The plan is not intended to encompass or replace the environmental analysis at the project level. The type of NEPA document prepared (EIS, EA, or Categorical Exclusion) is determined at the project level based on the issues, concerns, and sensitivity of the proposal. Refer to Forest-wide Standards and Guidelines, *General Procedures, Item 1., Forest Plan Chapter 4*

This selection of the type of NEPA documentation is most appropriately done on a case-by-case basis. Mining-related activities are usually initiated by industry which is dependent upon supply/demand. Prediction of mining interest, location, kind, etc. under such a dynamic, market-based industry is difficult and presents a question to whether this effort is an effective use of time/budget. It is most appropriate at the time when proposals are known that cumulative effects be addressed (Operating Plans required per 36 CFR 228 as stated in Chapter 4) At this time, we know the scope and location of the activities proposed and are better able to evaluate the environmental consequences. Forest-wide and management area standards and guidelines as documented in the Plan will guide the evaluation, analysis, mitigation, and implementation plans.

Monitoring of operations is an integral part of implementation of the Plan. Direction for monitoring of mineral activities is include in Chapter 5 of the Plan.

STATE THE PROCESS THE FS WILL USE WHEN MINING IS INCOMPATIBLE

The process the FS will follow when mineral activities will be incompatible with the management objectives should be identified in the plan. As presented, it is unclear who carries what responsibilities and whether or not there is a threshold above which the project scope needs to be reassessed. It is also important to explain the requirements placed on the proponents of the mineral activities.

Response: It is not the purpose of the Forest Plan to restate policy and procedure that is currently referenced in Forest Service Manual and Handbook direction. If mineral activities are incompatible with law they will not be approved. If mineral activities are incompatible with management objectives and cannot be made compatible, the proponent can request a review of the objectives to see if they can be amended to allow the activity. Any such amendment to Plan objectives would first be subject to analysis, review, and documentation following NEPA regulations.

DISCUSS THE IMPACTS OF MINERAL INTERESTS

With respect to mineral interest's activities varying from that which has been predicted, the Plan needs to discuss the impacts of this to the plan, the process, and cumulative effects analysis, etc. As the ensuing impacts may be significant, they need to be discussed, despite the uncertainty.

We support efforts to "be directed toward minimizing adverse environmental impacts on the surface resources and toward reclaiming the site." But what will be done to specifically carry this out? This needs to be discussed.

Response: The FEIS addressed the impacts of mineral interests to the degree of certainty that we have in our projections. Project-level planning on proposals is the most appropriate level for environmental analysis of effects and rehabilitation plans. FS policy, as referenced in FSM 2800, provides for securing performance bonds, which are used to reclaim areas disturbed by unauthorized activity when reclamation was not *appropriately completed by the operator per the approved operating plan.* For further discussion, see above response.

DISCUSS CONTRACT CONDITIONS

The contract conditions for mineral/energy exploration and development need to be discussed.

Response: A discussion of contract conditions for exploration and development is outside the scope of the Forest Plan. These conditions are most appropriately treated on a case-by-case basis per discussion above.

HOW IS "BEST USE" DETERMINED IN REGARD TO WITHDRAWALS

What standards specifically will be used to help determine whether mineral development is the highest and best use and whether a withdrawn area should be revoked? What is meant by "withdrawal" in this instance?

Response: Withdrawal in this instance means that the area is not open to entry under one or all of the mining, mineral leasing or land laws of the United States.

As directed in FSM 2760, requests for new withdrawal from mineral leasing should be made rarely. New withdrawals will be evaluated by assessing mineral potential, displaying a range of alternatives, conducting an analysis showing that the use or special features of the area cannot be adequately preserved or protected through other means, include in the withdrawal the minimum area needed for the intended use and revoke withdrawals where protection is no longer needed or appropriate.

Existing withdrawals, except for wilderness, will be periodically reviewed Withdrawals will be revoke where no longer needed and revocation will be given priority in highly mineralized areas where National Forest surface resources would not be seriously damaged or could be reclaimed.

CLEARLY STATE THE OBJECTIVES OF THE PROGRAM

Clearly state the objectives of the program, which I assume is to encourage development. Specify the types of stipulations on leases and permits that are mentioned as goals of the minerals program. I think that the statement regarding confidence in the industry's ability to conduct activities in sensitive areas should be eliminated. The FS should not suggest that mere confidence in the industry will direct mining activities in sensitive areas.

Response: The goal for the mineral program is stated in the Forest-wide Standards and Guidelines in Chapter 4 of the Plan. The statement regarding "confidence in the industry's...." has been modified.

ELEMENTS TO CONSIDER IN THE PLANNING PROCESS

The MBS should consider the following elements in the planning process. 1. Mineral Potential Map. .2.A comparison of mineral potential with availability ..3. A discussion of how minerals are affected by each alternative ..4. A point-counterpoint discussion of how minerals affects the other resources...5. A narrative section on minerals containing a history of development and mineral production, value of past production, projected mineral demand, and current operations...6. A list of current mineral withdrawals, acres involved, and mineral potential for locatable and leasable minerals...7. A narrative section on definitions of mining exploration ..

Response: A mineral resource overview and mineral potential map for locatable and leasable mineral resources were prepared using the R-2 mapping system. These maps were prepared using the most recent information available through US Geologic Service, US Bureau of Mines, and State literature and reports. This base information was used in analysis of the alternatives and used in developing the Preferred Alternative. These maps are available upon request.

Chapter IV, FEIS provides a discussion of direct effects on minerals by alternative. Rating the restrictive nature that management objectives will have on mining activities (e g. low through highly restrictive) illustrates a relative degree of expense and effort needed to carry out a proposed activity.

Effects of mineral activity on other resources is described in each resource section of Chapter IV, FEIS. A narrative of the existing situation and potential production is presented in Chapter III, FEIS.

Withdrawals are displayed as a direct effect to mining activities in Chapter IV, FEIS. Withdrawals are displayed by acreage and type by alternative. Refer to the glossary for a definition of mining terms.

INDICATE HOW MANY LEASE APPLICATIONS FOR MINERALS

How many lease applications for minerals? Acres don't mean as much.

In the Summary, it is stated that "a number" of mineral lease applications are currently in the system. For a report with many variables quantified, it seems strange that this number would not be easily obtained and inserted in this summary. Obviously, the quantity of these applications and the size of the operations that they propose is of great concern to the public interest.

Response: The number of lease applications was provided in Chapter III, DEIS, pages 156 to 157. These figures have been updated; see Chapter III, FEIS At this writing, the Forest has received 76 geothermal leases applications, with 25 applications pending A total of 18 oil and gas leases have been received by the Forest. The Summary has also been updated, with exact numbers as of the time these documents went to press.

INDIVIDUAL MINING SHOULD BE CALLED "RECREATIONAL MINING"

Since there is controversy between commercial mining and the individual who mines for recreation a different term should be used for the individual who mines for recreation in order that the layman does not confuse big business with recreation. I suggest the term "recreational prospecting" be adopted to fill this need

Response: The FS is in the process of developing a regional policy on this particular recreational activity. The term recommended for use currently is recreational collection of minerals. This policy will more clearly define what degree and level of collection or prospecting activities are considered recreational.

ALLOW ROCK COLLECTING IN RECREATIONAL AND SCENIC RIVERS

In "recreational" and "scenic" designated river sections, you should allow primitive gold panning, ore float, and rock collecting, as it is presently for mineral tracing and specimen collecting purposes.

Response: Only "wild" designated river sections will be withdrawn from mineral entry; refer to MA 5C standards and guidelines, Chapter 4, Forest Plan. "Recreational" and "scenic" designated sections will not be

withdrawn. However, mining activities may be highly restricted in these designations to meet compatibility requirements of Wild and Scenic River designation.

Gold panning, ore float, and rock collecting fall under recreational collection of minerals, provided that these activities are conducted for a non-commercial, recreational purpose. Recreational collection of minerals may not be not restricted by a withdrawal from mineral entry if such activities are compatible with the purposes of the withdrawal. Usually, only filing of mining claims, exploration, and development are precluded by withdrawal.

ADDRESS RECREATIONAL PROSPECTING IN THE FINAL PLAN

Recreational prospecting has not been addressed in the forest plan. The final plan must consider this important form of recreation.

Response: The direction in the Plan for recreational collection of minerals is in Chapter 4, Forest-wide Standards and Guides for Recreation. The recreational collecting of locatable minerals is a legitimate use of a mining claim. The Mining Law of 1872 provides for this activity on Federal Lands and also provides protection to existing claims from recreational collection.

ADOPT STRINGENT REGULATIONS FOR RECREATIONAL MINING

We are very concerned about the recent increase in "recreational" mining on the national forests. We urge you to adopt stringent regulations for such activities, particularly for such destructive techniques as suction dredging. We question whether such activities are appropriate at all on public lands. What are the specific guidelines that will be used to regulate "recreational" mining?

The DEIS and Forest Plan are deficient in discussing management options and strategies for controlling the impact of recreation mining. This has become a real problem in such areas as around Green Ridge lake in the Alpine Lakes Wilderness and Hansen Creek in the I-90 corridor. Does recreation mining come under the mining laws? If the staking of new claims is banned in wilderness, why is there no prohibition on recreation mining? The parties responsible for damage may be different, but the results are the same.

Response: The U.S. Mining Law provides for all valuable mineral deposits on Federal lands to be free and open to exploration. Only when prospectors wish to file for a reserved right or claim can other legislation regulate mineral entry. The Wilderness Act withdrew designated wilderness areas from mineral entry after December 31, 1983. All claims located within wilderness areas prior to this date must be found valid by a certified Forest Service mineral examiner before development-type operations will be approved. Prospecting and certain types of assessment work are permitted activities in Wilderness as stated in Section 4d(2) of the Wilderness Act.

Management direction for mineral entry and development is clearly defined by these two laws. Prospecting and recreational collection of minerals is also permitted as long as the activity is being conducted in a manner that is compatible with wilderness or with the purpose for other types of

withdrawals. However, there is less of a clear distinction, as we are experiencing on a localized level, when recreational collection of minerals is practiced so intensely on a area that significant resource damage begins to occur. This degree of activity is not compatible with Forest-wide Recreational Goals or Standards and Guides and will be dealt with administratively. At this time, we are developing a regional policy to more clearly define how we will deal with this form of recreation in the future to reduce resource impacts and still provide for this recreational opportunity.

PLAN MAKES LITTLE MENTION ON EVALUATION CRITERIA OR PROCESS OF SMALL HYDROPOWER APPLICATIONS

The MBS Plan makes little mention of how it intends to address applications for small hydroelectric power development within the forest boundaries. In fact, the Plan only mentions the number of applications pending and their current disposition.

Hydroelectric power development severely impacts fish and fish habitat. Many of the problems associated with proposed hydroelectric development go well beyond an instream flow issue. The FS should identify its policies and standards related to hydroelectric development and take an active role in the quantification of these impacts and use its permitting authority to protect fish, soils, wildlife, and water quality.

The process for issuing FERC licenses and permits needs to be more thoroughly discussed, including the minimum standards that are required.

> **Response:** The Plan does address minimum standards for management of all activities, including small hydropower development. See Chapter 4, Forest Plan, Forest-wide Standards and Guidelines and specific MA standards and guidelines. As stated in the Minerals and Energy Section of Chapter 4, an appropriate environmental analysis will be the basis for making recommendations and determining necessary stipulations for protection of other resources. In this analysis, all hydropower proposals will be evaluated by the standards set by the Forest Plan.
>
> Some MA prescriptions purposely exclude small hydropower development due to incompatibility with management goals for the area e.g. Management Area 1A, Primitive. Other allocations provide for small hydropower development in compliment with maintaining other resource values as specified in that MA.
>
> The Forest Plan is only the first and very broad level of analysis for small hydropower development. Except where management allocation precludes small hydropower development, proposals are evaluated on a site-by-site basis. Extensive studies are performed to address issues surrounding effects on fish, soils, watershed, wildlife, recreation, etc. The FS makes their recommendation to the Federal Energy Regulatory Commission (FERC) on approval to license based on the involvement in and the findings of these studies. Our recommendation is based on compatibility of the proposed project with the Forest-wide Standards and Guidelines and all site-specific requirements. The authorities, roles, and process for issuing FERC licenses and the Forest Service's participation in the overall process is outlined in Forest Service policy direction FSH 2709.15. This document is the most appropriate instrument to address this subject.

TABLE IV-5 IS UNCLEAR AS TO THE INFORMATION IT REPRESENTS

Table IV-5 of the Draft EIS states that hydro projects may be precluded by land allocation. The Preferred Alternative H only allocates five small hydro projects on the entire Forest. Projects should be precluded based on project design and not on allowable projects. Small hydro projects should be evaluated on a site-specific basis. Benefits of each project should be weighed along with impacts resulting from construction and operation. The assumptions used

in selecting the allowed number of projects as portrayed in the Table IV-5 are unexplained.

Alternative C allows only three hydropower projects. From the standpoint of fish/wildlife benefits (lack of impacts), this is preferred. The State of Washington supports a low level of hydropower development on the MBS.

Response: We have added text to the narrative for Table IV-5 in FEIS, to better explain it. The table displays the number of potential hydropower projects that would be precluded by allocation versus not precluded within each alternative. Both "allowed by allocation" and "questionable" are numbers of projects that would not necessarily be precluded. "Questionable" category refers to projects that would undergo more expensive mitigation for resource protection or to meet compatibility with management objectives. The MA prescriptions with which hydropower development is not compatible include: 1A - primitive dispersed recreation, 1B SPNM, 1C SPM, 5, and 10 Wilderness. The number of allowed projects vary by the MA in which they are located, by alternative. Refer to the text for Table IV-5, Chapter IV, FEIS. It has been updated, and an error in Alternative C corrected.

All projects will be evaluated on a site by site basis upon specific project design, through a detailed environmental analysis tiered to the Forest Plan. No projects will be recommended for license that have known significant impacts to fish/wildlife that are incompatible with law, the Forest-wide Standards and Guidelines or management area standards and guidelines.

LOCATION OF EXISTING UTILITY CORRIDORS

What is the existing utility corridor coming from Mt. Rainier National Park and going north along Highway 410?

Response: Figure III-31 in the DEIS displayed a corridor in the most southern portion of the forest, crossing Highway 410 and connecting into a east/west corridor. This corridor was intended to display the transmission line that services Crystal Mountain ski area As this is a service line not a utility corridor, it has been deleted from the map.

ARE UTILITY CORRIDORS DESIGNATED IN THE PLAN?

The Plan should identify specifically the utility corridors that have been designated, and if none have been designated, explain why. Reference could be made to Figure III-31, Utility Corridors, found in the DEIS.

Response: The scale of the page-sized map, Figure III-31 in the DEIS made showing accurate corridor locations difficult. In the FEIS, utility corridors are displayed on the Preferred Alternative map. Locations should be more readily identifiable at the larger scale. Management of all proposed and existing corridors displayed on this map will be guided by the Utility Corridors (MA 25A) standards and guidelines. The corridors are shown as a line; the actual width of the corridor is not mapped.

THE FOREST PLAN SHOULD ADDRESS ENERGY IN FOREST MANAGEMENT GOALS

Page 4-1, Forest Management Goals: these goals should address energy, including corridors and renewable energy resources. The Standards/Guidelines on page IV-103 should reference the Project Plan and Right-of-Way Maintenance plan as important documents which guide the construction and maintenance of BPA transmission rights-of-way within Management Area 25. These are documents required by the BPA/Forest Service Memorandum of Understanding.

Response: The Plan does address energy in the Forest-wide Goals in the minerals and energy section of the Forest-wide Standard and Guidelines section of Chapter 4.

A discussion of the current management agreements between BPA and Forest Service is noted in the Affected Environment section, Chapter III, FEIS. A reference has been added to the "The Built Environment - Utility Corridors" section, FEIS, to reflect that the existing BPA corridors are under memorandum of understanding agreements and the existing Utility Corridor Project Plan and Rights-of-Way Maintenance Plan guide construction and maintenance activities. Also see new Item 1. under Forest-wide Standards and Guidelines, Utility and Transportation Corridors, Chapter 4.

ADDITIONAL ANALYSIS ON EFFECTS OF ALTERNATIVES ON UTILITY CORRIDORS IS NEEDED

The DEIS has also done a good job of addressing corridors. We particularly like the use of a corridor and the descriptions of the built environment. For decisionmaking purposes, we suggest that the FEIS identify, in table form, the effect of the alternatives on the acreage available for corridors (exclusion area and avoidance area). This should also be done for renewable energy resources such as small hydro, and geothermal. Chapter IV, "Environmental Consequence," should analyze the affect of the alternate plans on both existing and planned corridors.

Response: The Northern Cascades Corridor Availability Study, prepared by Bonneville Power Administration and , in draft at this writing, provides an analysis of corridor availability by avoidance and exclusion areas. The Forest Service believes this is the appropriate vehicle to address this subject.

Table IV-42, Chapter IV FEIS displays the effect to energy balance by each alternative. Because existing utility corridors and one potential corridor are allocated in all alternatives (see Forest Plan Chapter 4, Utility and Transportation Corridors), the effects by alternative to utility corridors allocated is negligible.

Table IV-5, Chapter IV is again included in the FEIS; it contains an analysis of effects of each alternative to small hydropower development. FEIS Chapter IV, Minerals - Direct Effects Section contains a discussion on effects by alternative on the acres available for geothermal development.

CORRECTION IN SURPLUS ENERGY AND DEMAND PROJECTION

The statement of the duration of the energy surplus attributed to BPA, page III-17, DEIS is incorrect. BPA currently projects the regional energy surplus to last until 1994, assuming medium load growth.

On Page III-168 the load growth information should be revised to show an annual growth rate of 0.3 to 2.7 (BPA Forecast of Electric Consumption in the Pacific Northwest, October 1986). It should be noted that BPA's/NW annual load growth is from the 1986 forecast. On page III-168, last paragraph, it should be noted that BPA is currently evaluating transmission requirements (loads and reliability) for serving the Puget Sound Area. Expansion of transmission capacity on the Stevens Pass Corridor is being considered and could be needed prior to the year 2000 rather than after the year 2000 as mentioned.

Response: Corrections have been made in Chapter III of FEIS.

ADD REFERENCE ON CORRIDOR STUDY

The Plan and FEIS should also reference the 1986 Western Regional Corridor Study for information on corridors. The corridor study was prepared by the Western Utility Group, an ad hoc group of western utilities. It was intended to describe consolidated utility corridors for the Western United States and was originally published in 1980. The 1986 edition was recently transmitted to all Forests.

Response: This reference has been added to the general list of references in the FEIS.

WHAT ARE THE IMPACTS FROM THE INCREASE IN BTU'S?

There is a big jump in the production of energy materials over five decades: from 0 to 477 billion BTUs per year. What kinds of environmental impacts and environmental analyses are to be expected from this?

Response: Chapter IV, FEIS contains, by resource section, a discussion on environmental effects relating to energy production. This discussion format provides for a more detailed treatment of the subject instead of summarizing in the energy section of Chapter IV.

FOREST SHOULD CONSIDER LAND EXCHANGE IN GREENWATER DRAINAGE

The MBS should consider land exchange in the Greenwater drainage, to acquire private lands from Weyerhaeuser Company that can effectively improve the opportunity for off-road vehicle (two, three, and four wheel) facilities. This drainage contains one of the most significant areas on the Forest (outside watersheds) suitable for this type of recreation. Because of this, and proximity to population, the area is currently heavily used by ORV's, but much of the use is without sanction, on private lands.

Response: Negotiations are underway to acquire Weyerhaeuser Company lands in the Greenwater drainage. In September, 1984 the U.S acquired 1300 acres from Weyerhaeuser Co. in the Greenwater Lakes area. This has been noted in Chapter III, Affected Environment, FEIS.

SUPPORT FOR ACQUISITION OF NON-FEDERAL LANDS IN THE ALPINE LAKES AREA

Alpine Lakes Management Area (DEIS, III-161): there are "three land exchange cases in progress for acquisition of 8,000 acres of non-federal land... all districts except White River." PLUS supports federal acquisition of intended wilderness pursuant to the direction of the Alpine Lakes legislation.

Response: The acquisition of intended wilderness lands on the MBS has been completed.

SULTAN RIVER LAND EXCHANGE OPPOSED

PLUS opposes the proposed Sultan River land exchange. The selected land is covered with active mineral claims. We are confident that mineral sources do exist. Prospectors have spent much time and money developing these claims. Currently, there is very limited access to this area and little non-prospecting activity.

Response: The mineral resources of the area will be examined and the mineral situation considered in the NEPA process for specific exchange proposals.

EXCHANGES SHOULD BE BASED ON EQUALITY OF SITES

The final plan should recommend land exchanges only if they do not significantly reduce either the lands available for developed recreation, motorized recreation, mineral development, or timber harvest. Instead of using the equal value policy, the MBS should exchange based only on equality of sites.

Response: The Federal Land Policy and Management Act of 1976 requires that the value of the lands exchanged by the Secretary of Agriculture shall be equal or equalized by cash payment Land exchange proposals are developed for a number of reasons. Specific land exchanges will be developed in accordance with the standards and guidelines of the Forest Plan. The final decision as to whether to proceed with an exchange is done through the NEPA process and a site-specific analysis. All resource uses are analyzed as well as public comment in development of alternatives. Exchanges will not be made unless they are in the public interest.

PRIVATE LANDS IN THE SNOQUALMIE PASS AND GREENWATER AREAS SHOULD BE PURCHASED

There is next to nothing in the Plan concerning the checkerboard ownership in the Snoqualmie Pass and Greenwater areas. These land should be purchased as soon as possible.

Response: The Forest Plan provides general land ownership direction for these areas in Chapter 4. The appropriation of funds for the purchase of these lands has not been given priority. More specific project analysis will be done as land exchanges are proposed. A land exchange to acquire land in the Snoqualmie Pass and Greenwater areas is currently being developed.

MINING CLAIM ON THE SULTAN SHOULD BE RETAINED

The mining claim on the Sultan held by the Boeing Rockhounders and New West Prospectors Club provides recreation for club members and associates. If this area is traded to the Watershed, existing mineral rights and access to the claim should be retained. The Everett Water District does not need this area to maintain their water supply.

Response: The mineral resources of the area will be examined and the mineral situation considered in the NEPA process for specific exchange proposals.

CERTAIN WETLANDS ALONG NORTH FORK NOOKSACK RIVER SHOULD BE ACQUIRED

A beaver pond and associated wetlands near the Nooksack River are very important to wildlife in the Glacier area. It is within the Forest boundary, SW1/4SW1/4 Section 6, T.39 N., R.7 E. The wetlands cover a broader area and flow mostly north and west. Would Federal acquisition of this land would be possible?

Response: Acquisition of this parcel is legally possible. Proceeding with acquisition depends on availability of funds and of course the desire of the landowner to sell. We have not requested funds for acquisition of this parcel but are currently making an examination of it's potential value for Threatened and Endangered Species habitat.

DON'T EXCHANGE LANDS ADJACENT TO NATIONAL PARK UNLESS RESOURCES PROTECTED

Regarding the land adjustment map (Plan, Appendix G): lands adjacent to National Park Service areas should not be available for exchange to private interests unless specific safeguards of National Park Service resources are included in the exchange.

Response: National Forest lands adjacent to the National Park boundaries will be managed in accordance with the standards and guidelines, goals and objectives for the respective management area. Direction will vary; some adjacent lands are allocation to MA 1B, Semi-primitive Nonmotorized Dispersed Recreation, some to Wilderness (MA 10), while others may be allocated to MA 17, Timber Emphasis. Any proposed project in lands adjacent to Park Service lands will, in the environmental analysis,

consider the adjacent National Park as an issue and concern, with appropriate agency involvement.

MAINTAIN FORESTED LAND BASE

Because of the limited land base on the MBS, the goal statement in the Forest Plan for Land Adjustments should include a statement requiring maintenance of the existing suitable land base for timber harvest. Over the years, whether mandated by Congress or not, the MBS forest land base has been decreasing because of land exchanges. Generally, what the FS receives is cut-over lands with younger trees in exchange for mature timber.

Response: The General Exchange Act of March 20, 1922 requires the Secretary of Agriculture to base exchanges on equal values. Land exchange proposals are developed for a number of reasons. Specific land exchanges will be developed in accordance with the standards and guidelines of the Forest Plan. Refer to the Land Classification groups under each MA, Chapter 4, Forest Plan The final decision as to whether to proceed with an exchange is done through the NEPA process and a site-specific analysis. Scoping will include contacts with all interested public groups, individuals, etc All resource uses are analyzed as well as public comment in development of alternatives.

OPPOSE PURCHASER CREDIT FOR TIMBER SALE ROADS, ESPECIALLY WITH CURRENT DETRIMENTAL EFFECTS

In these times of federal budgetary crises, it seems indefensible to promote land management practices such as providing free road construction to logging companies, especially considering the negative aspects of the excessive timber harvest levels: increased soil erosion and siltation with its effects on fisheries, increased highway maintenance costs from flooding and washouts, etc.

Response: Between draft and final plans, and in response to public comments, a method for meeting water quality and riparian management requirements was developed. Meeting these management requirements results in a set maximum number of acres available for timber harvest, per decade, by watershed, based on their current condition (acceptable or unacceptable). Refer to new Appendix H; management requirements are also discussed in Chapter II, FEIS, and Appendix B. Additionally, refer to the Forest-wide and MA specific standards and guidelines for water, soils, and riparian areas.

As far as free road construction for the logging companies is concerned, on the MBS, timber sale roads are primarily financed with Purchaser Credit, i.e. the timber stumpage values are offset by the costs of road constructed by the timber purchaser. Few roads are constructed with appropriated funds for timber access exclusively.

MAINTAIN TRANSPORTATION SYSTEM AT LOWEST DENSITY REQUIRED

Add to the Goals (Chapter 4, Forest Plan) under Facilities: "Maintain the transportation system at the lowest density required to meet administrative needs and to access facilities."

Response: The transportation system maintained is that which supports the overall goals and objectives of the Preferred Alternative. One recreational use of the MBS, which continues to be in demand, is driving for pleasure. The system planned will meet the needs of all resources, under the Preferred Alternative, while protecting soil, water, and other resources.

CONFLICTING STATEMENT RE: ROADS IN MOUNTAIN GOAT WINTER HABITAT

In the introduction of MA 15, "Desired Future Condition," it says no new roads will be constructed to access winter range. Under Facilities, later in the management prescription, it states: "construction and reconstruction activities shall be timed to avoid conflict with mountain goat winter habitat use." These statement appear to be in conflict; can we or can't we construct roads in mountain goat winter range?

Response: This statement has been clarified in the Forest Plan. The MA 15 Mountain Goat Habitat MR prescription states: "No new roads permitted which access mountain goat winter habitat." The standards and guidelines also speak to timing reconstruction activities so as not to conflict with goat winter use. See Chapter 4, Forest Plan.

ACKNOWLEDGE NEED TO ACQUIRE RIGHT-OF-WAYS; ALLOW SUFFICIENT RIGHT-OF-WAY WIDTH

The DEIS needs to acknowledge the need to acquire right-of-way for all Federal and Forest highway routes.

Designated recreation areas should have sufficient right-of-way width to allow for reconstruction of bridges and other needed improvements.

> **Response:** Rights-of-way are discussed in the Forest-wide Standards and Guidelines for Land Uses, Forest Plan, Chapter 4. The appropriate regulations (36 CFR 212.8, 9, 10, and 11) are also mentioned.

LET ROADS CLOSE NATURALLY

Let roads close and revegetate naturally instead of by machine. Sign them "drive at your own risk" etc.

> **Response:** CRF 223.37 states that "All temporary roads will be revegetated within 10 years by artificial or natural means." In each site-specific NEPA document, this standard is addressed. The type of closure method varies, depending upon potential safety problems and the need to provide drainage and control sedimentation. Refer to the Forest Plan, Chapter 4, Forest-wide Standards and Guidelines for facilities. Road closures for certain management areas are discussed under the specific MA standards and guidelines (such as MA 1A and 1B, which specify how temporary roads to access catastrophic timber loss must be returned to near natural condition). We do not sign roads "drive at your own risk" as this does not reduce our liability for accidents that may occur

DESCRIBE PLANNED ROAD MAINTENANCE

Describe planned road maintenance, i.e. priorities, types, erosion control measures, structures, culvert cleanout, etc.

> **Response:** Refer to the Forest Plan, Chapter 4, Forest-wide Standards and Guidelines for facilities In addition, planned maintenance is discussed in project-level environmental analysis documents.

WHY DOES ROAD MILEAGE VARY LITTLE BY ALTERNATIVE?

I don't understand why the road mileage, except for Alternative C, varies little by alternative, even though the timber harvest level varies.

> **Response:** Referring to Table II-9a, Chapter II, FEIS: the actual miles of *roads constructed - especially local, timber purchaser roads - varies* considerably, from 18 miles of arterial/collector roads in Decade 1, Alternative I to 6 miles, Decade 1 in Alternative G-Modified. Local roads vary from 174 miles of construction, Decade 1 in Alternative A to 75 miles of new local roads, Decade 1 in G-Modified. The road miles for each alternative are a function of the allowable timber harvest and the other objectives of the alternative.

ROAD CLOSURES

Which roads will be closed beyond those listed? What is the criteria?

Response: The closing and opening of roads is dynamic process that is constantly changing. It is impossible at this time to list those roads that may be closed or reopened in the future. The criteria for closing roads are based on the need(s) for access balanced against the need to protect the various resources. Some typical reasons for closure are:

1. Protection of threatened and/or endangered species.
2. Protection of winter range habitat for deer, elk, and goats.
3. Short term timber sale roads that are no longer needed.
4. To reduce use pressure on sensitive areas.
5. To reduce maintenance costs on low use roads.

Refer to Chapter 4, Forest Plan, individual MA standards and guidelines for guidelines on road closures to meet the objectives of various MA's.

WHAT MILES OF ROADS WILL REALLY BE BUILT?

There appear to be inconsistencies between the miles of road construction and reconstruction developed by FORPLAN (Chapter II, DEIS) and the road mileage listed in the 10-year implementation schedule in the Plan.

The numbers for road construction appear inconsistent. Does "ultimately" mean after five decades?

When is the Plan considered implemented? I.e. How does the decade rate of construction of 185 miles of roads contribute to the 823 miles expected to be completed as a result of implementation of the Plan?

Response: The numbers in Chapter II (based on FORPLAN runs) and in Appendix A, the Timber Sale Ten-Year Schedule are different. FORPLAN miles are based on a theoretical rate and density of road construction that is appropriate over the long term. The 10-year implementation schedule is based on a proposed timber sale plan that is subject to adjustment as time passes. The actual miles for each sale will be adjusted at least annually, in Forest Plan amendments, as the environmental analysis and NEPA documents for site-specific projects are completed.

Ultimately" for the arterial and collector roads means at the end of Decade 2. Local roads will continue to be built as projects are scheduled, over the planning period.

NEW ROAD MANAGEMENT

What strategy will be used to manage new roads?

Response: This will vary on a road by road basis. The management strategy for each road depends on the purpose the road is built as well as the impacts of the road on the adjacent resources. Refer the Resource Summary for Roads, Chapter 4, Forest Plan and also to each MA prescription, Chapter 4, Forest Plan. In addition, the NEPA document for proposed, site-specific projects will include more information.

EXPLAIN 10-YEAR ROAD SCHEDULE

Discuss the 10-year road construction schedule in Appendix B, Plan. How and why were projects selected? What is the order of project activity?

Response: Projects were identified in the following categories:

1. Recreation access needs.
2. Timber access needs.
3. Correction of safety problems.

Projects were then prioritized, based on a combination of factors that included each District Ranger's priority rating, amount of recreation traffic, amount of timber traffic, benefits of correction of road related fish habitat and other resource problems, and significance of any safety problems to be corrected. Also, refer to Resource Summaries, Chapter 4, Forest Plan.

ANALYZE AND ADOPT A PLAN TO CLOSE NON-ARTERIAL ROADS NOT IN USE

Adopt a policy that will close all non-arterial roads that are not being actively used for resource management; this will protect wildlife values and prevent resource abuse, such as wildlife poaching, and theft of timber and snags. Why was such a plan not analyzed in the draft? It makes economic and environmental sense and would help mitigate impacts of road construction.

Response: Local roads not actively in use (for any type of activity) are generally closed. Road closures are also used in various management areas to meet the objectives of wildlife use, etc. The Resource Summary for Roads (Chapter 4, Forest Plan) discusses the general use of road closures; also, refer to Forest-wide Standards and Guidelines for facilities, and Element L. Facilities for each Management Area, Chapter 4, Forest Plan.

DISCUSS EFFECTS OF ROADS

Are roads on the MBS contributing to adverse environmental impacts, especially water quality?

Road construction probably results in the greatest amount of ground disturbance. This section of the DEIS (Chapter IV) only identifies the number of miles and types, but no mention of condition.

Response: Chapter IV, FEIS, Soil, Water, and Road sections have been rewritten, and the sediment tables updated.

DISCUSS EFFORTS TO PREVENT ADVERSE EFFECTS

Need to discuss current conditions and efforts to prevent adverse effects of roads and road construction.

Response: Refer to Chapter II, FEIS, Mitigation measures common to all alternatives. Also, see the specific mitigation discussion at the end of each resource section in Chapter IV, FEIS. Current conditions of Forest roads are discussed in Chapter III, Affected Environment, FEIS. The condition of the Forest's watersheds is discussed in Chapter IV and the

procedure to meet water quality and riparian MR's is discussed in Chapter IV and new Appendix H.

ADD TO FOREST MANAGEMENT GOALS

Under the Forest Management Goals for Facilities, the State recommends adding Item 6, which could read. "Maintain the transportation system at lowest density required to meet administrative needs and to access facilities." Referring to page 4-4, Plan.

Response: No wording changes were made in the Forest Plan, as the above suggestions are already incorporated within Items 1, 2, and 4, Forest Management Goals for facilities.

NO DISCUSSION OF FERTILIZERS, PESTICIDES

There is no discussion in the plan of whether fertilizers and/or herbicides will be used as part of logging practices.

We are highly concerned that the issues of pesticides, herbicides, and fertilizer use in the forest did not appear to be addressed in the DEIS.

It is not clear what methods for vegetation management are currently being carried out on the Forest since 1984, as the injunction on pesticide use continues. This should be discussed.

How will the MBS proceed in the event the injunction on herbicides is lifted? The programmatic EIS is not sufficiently specific to cover the MBS, and does not sufficiently document the potential use of various pest management techniques once the injunction is lifted. Will further environmental analyses be conducted when the injunction is lifted?

Response: The use of fertilizer as one option in managing for timber was (in the DEIS) and is (in the FEIS) is discussed in the following sections: Appendix B, Chapter III, Development of Timber Options for FORPLAN; Forest Plan, Chapter 4, Resource Summaries for vegetative management; Forest-wide Standards and Guidelines, Chapter 4, Plan; and MA 17, Item E. The latter gives general direction on where fertilizers may be prescribed. The exact practices will vary by site, and will be determined at the project-level environmental analysis.

As discussed in Chapter III of the FEIS, the Record of Decision for the Final Environmental Impact Statement (FEIS) for Managing Competing or Unwanted Vegetation was signed on 12/8/88. The court injunction against herbicides was lifted May 24, 1989; however, the Forest Service is under an administrative stay, imposed by the Chief, not to use herbicides. When the stay is lifted, the MBS will incorporate the direction from ROD and Mediated Agreement. Regional Interim Instructions are provided in my [Regional Forester's] 2150 memo, dated July 21, 1989, or as updated. Further, site-specific environmental analysis with full and on-going public involvement are key parts of the Regional direction.

As for methods currently in use, Chapter III of the DEIS discussed the various hand and mechanical methods currently in use - refer to the Commercial Timber and Built Environment sections. Prior to 1984, the chemical program on the MBS was very small. These sections have been updated.

THE REFERENCE TO THE REGION 6 VEGETATION MANAGEMENT EIS IS NOT SUFFICIENT TIERING - MORE SITE-SPECIFIC ANALYSIS MUST BE DONE

Reference is made (page IV-2 DEIS) to the vegetation management DEIS. You go on to state that in Chapter IV " ..the environmental effect of herbicides will not be discussed; their effects are examined, in detail, in October 1987 DEIS." If the intent is to incorporate information by reference, this must be made more clear. Further, this is not sufficient tiering - the vegetation management EIS is for all the Forests in Region 6 and describes the pesticides to be used, health effects, and typical environmental risks and effects. However, it does not lay out the specific nor the unique characteristics of the MBS.

Chemicals, Herbicides

Response: This section of Chapter IV has been updated in the FEIS to reflect the current situation of the Region 6, Final Vegetation Management FEIS. Refer to the Plan, MA 17, Item E. for general direction on where fertilizers may be prescribed. The exact practices will vary by site, and will be determined at the project-level environmental analysis. Each analysis will tier to the Regional Programmatic EIS and will have full and on-going public involvement. A separate analysis may be appropriate, rather than including the methods of vegetation management in a timber sale or road project environmental analysis.

FEIS SHOULD INCLUDE MORE DISCUSSION OF PESTICIDE USE IN THE N.W.

We suggest that the EIS include a comprehensive discussion of the status of pesticide use on Federal lands in the Pacific Northwest. This could tie in the references to pesticides made throughout the documents.

Response: The references to the Region 6 Programmatic FEIS for Managing Competing and Unwanted Vegetation have been updated in the Final EIS and added to the Plan. A more in-depth discussion of a regional situation is is outside the scope of this Forest Plan.

QUESTION ABOUT THE PRESCRIPTION FOR MA 17, ITEM E. 16.

Under E. 16. for MA 17: what is the connection to the vegetation management EIS?

Response: The methods of vegetation management listed in E. (now item) 15 represent various tools which may be used to achieve this activity. Their application or use will be guided or constrained by direction from the FEIS, Managing Competing and Unwanted Vegetation, R-6, November 1988. A site-specific environmental analysis will also be done.

MBS SHOULD GOVERN ITS VEGETATION MANAGEMENT PROGRAM ACCORDING TO THE R-6 FEIS

In Forest-wide Standards and Guidelines for Pest Management: we suggest the MBS will govern its vegetation management program according to the final programmatic EIS.

There needs to be reference to the vegetation management EIS, which is in the final stages of development.

Response: Wording to this effect has been added to the Forest-wide Standards and Guidelines for Vegetation Management; see Chapter 4, Plan.

WHAT ARE "PROPER CONTROLS" FOR CHEMICALS?

In Chapter IV, page IV-28 of the DEIS: what are "proper controls" for chemicals? Are buffer zones required around spray application? What procedures are used to minimize entry of fertilizers into streams? Is there a monitoring procedure to evaluate impacts of chemical application?

Response: This discussion has been modified in the FEIS. References have been added to the discussion on Forest-wide Mitigation Measures for Water

and Riparian Resources (Chapter II, FEIS), the discussion on Best Management Practices in Appendix I, FEIS, and the Region 6 FEIS on Managing Competing and Unwanted Vegetation.

CLARIFY STATEMENT THAT "CHEMICALS ARE RELATIVELY IMMOBILE IN THE SOIL"

It is stated that "Chemicals used in forestry are relatively immobile in the soil." (DEIS, page IV-17. This statement needs clarification and should be expanded upon. For example, the herbicide "tordon" was identified as being used in forestry practices in a recent FS document entitled "Draft EIS for Managing Competing and Unwanted Vegetation." The EPA claims this chemical is mobile in soil and could therefore move to the groundwater and surface water.

Response: The referenced comment has been amended, with more specific discussion of chemical mobility in soil plus reference to the Final EIS for Region 6 vegetation management, which discusses the topic in greater detail.

WHEN USE IS LEGAL, ASSURE THAT NON-TARGET NATIVE PLANTS ARE NOT AFFECTED

Should the use of chemical herbicides again become legal on the MBS, a careful set of application guidelines and monitoring safeguards should be implemented to assure that a minimum of non-target, native plant species are affected incidentally. Broadcast application of all biocides should only be employed in the last resort. Application areas should be field-censused prior to application to determine the presence or absence of any sensitive species.

Response: If and when the administrative stay is lifted and herbicides are again one of the vegetative management tools available, the above listed concerns will be addressed at the project-level environmental analysis, including tiering to the regional programmatic FEIS, where appropriate.

OPPORTUNITY COST ANALYSIS FOR RIPARIAN MR'S IS INCOMPLETE

The discussion beginning under "Opportunity Costs Analysis" (DEIS, Chapter 2, Page 14) should be deleted. The planning process did not establish any quantified link between environmental change and fish production; therefore, the riparian MR opportunity cost analysis only considered the cost to timber with and without the riparian MR, but not any offsetting benefit for fish production.

Response: The commenter makes a valid point. While we stated that the riparian MR was being applied to protect against loss of fish production, no change in fish production between the "with" and "without" riparian MR runs was included (because of a lack of any predictive model of fish response to environmental change). The text in the FEIS, Chapter II, and in Appendix B (Chapter VI, Section E) has been changed to indicate that the quantified opportunity cost analysis is for the timber program only, and does not include a quantified value change for fish.

ALT. C HAS THE HIGHEST RATIO OF DISCOUNTED BENEFITS TO DISCOUNTED COSTS

If one works through DEIS Table S-3 and calculates the return on dollars invested, Alternative C comes out a hands-down winner at $3.92 returned per dollar spent, compared to Alternative H with $2.95 returned per dollar spent, and A and E-Departure tied for last at $2.60 returned per dollar spent.

Response: When considering alternatives that are mutually exclusive (if one is implemented, none of the others can be implemented) the economic criterion of choice is maximum present net value (PNV), not maximum benefit/cost ratio (i.e., maximum dollars returned per dollar invested). The point of maximum PNV is the point at which the change in discounted benefits just equals the change in discounted costs. Up to that point, each additional dollar spent yields more than one dollar in return. After that point, each dollar spent yields less than that dollar in return. As long as investments continue to be made up to the point of maximum PNV, the returns to society are greater than the costs, and the net value to society continues to increase. Two implicit assumptions are that the budget needed is available to spend up to that point, and that the discount rate used represents the marginal rate of return that would be achieved in the next best use of the funds. (Therefore, as long as PNV is greater than or equal to zero, money could not be spent elsewhere on the next marginal project and receive a greater return.)

Maximizing the benefit/cost ratio, or returns per dollar spent, is the appropriate economic criterion when there are several alternative projects available to pursue that are independent of each other, and the question is which one should be done first, second, etc., until available budget is exhausted. In this case, one would want to carry out first the project that returns the greatest amount per dollar spent; then do the project that provides the next greatest return per dollar spent; and so on down the list, until ones budget is used up.

The Forest Plan alternatives are mutually exclusive. They are formulated so that they fall within a reasonably expected budget range. Therefore, from a strictly economic standpoint, to provide the most value to society that we can from managing the Forest we should choose the alternative that maximizes present net value to society. Of course, as discussed in the

DEIS Chapter 2, Section A, and more thoroughly in Appendix B Chapter IV, Section A, the choice of alternatives is not made based strictly on the economics in the analysis. There are other nonpriced and nonquantified factors that come into play that are outside the scope of the economic analysis, but which are taken into consideration for the final decision. The combination of the economic and other factors is termed the "net public benefit." But the same principle applies. As the Plan alternatives are mutually exclusive, we want to choose that alternative that contributes the most to society, or maximizes "net public benefit."

DISCOUNT RATE USED IS TOO HIGH; DISCOUNT RATE USED IS TOO LOW

The interest rate used by the Forest Service is 4%. That rate is far too high. The range of real rates used by economists in my business (litigation) extends between 1 25% and 2%, or 3% at the very most. The Forest Service rate is apparently derived from corporate security rates in the early 1980's, which was an anomalous period in the nation's economy.

The discount rate used in determining the economical land base is 4%; a truer representation of a market-established discount rate is 7-1/2%.

Response: Forest Service planning regulations require the use of a 4% discount rate for long-term investments (FSM 1971.71). The 4% rate was derived in 1979 by Forest Service economists from Federal Reserve data for after-tax returns on long-term Aaa-rated corporate bonds over the period 1960-1978. The average real return over this time period, reflecting long-term expectations in the capital markets of returns to new productive (marginal) investments, was about 2.25% to 2.33%. This figure was adjusted by the average tax rate on corporations of (at that time) about 40% to obtain a pre-tax marginal return rate of about 3.9%. This was rounded off to 4% in the proposal made, and later codified in the Forest planning regulations, for use as the appropriate discount rate for long-term resource investments.

STATE STATISTICAL ERROR; COSTS OF UNCERTAINTY NOT CONSIDERED

Your failure to state some reasonable error with all your data is an egregious omission which must be corrected before the validity of any of your predictions can be evaluated.

The costs of uncertainty are not well considered in the Plan; e g., inclusion of the allowable cut effect, expected gains from thinning and genetic improvement, etc.

Response: Unfortunately, the data available to work with for this planning effort vary widely in detail and completeness. Many of the numbers used are from small data samples or based on professional experience working in the field on this Forest. Some inventory data are old. Many of the cause and effect relationships (production functions) are newly developed and will not really be tested until monitoring occurs after Plan implementation. Therefore, to attempt to attach statistical error estimates to all the numbers used in the FEIS and Plan would be relatively meaningless. The important point to note is that all the numbers, particularly those projected several decades into the future, are indicators of relative magnitude and direction. They are not to be taken

as absolutes. But in that all alternatives are evaluated with a consistent set of numbers and relationships, the relative merit of the various alternatives can still be assessed. This is the reason that the decision-making process is based on a consideration of all relevant factors - quantitative and qualitative - not just strictly on numbers.

The costs of uncertainty were dealt with explicitly in some instances and implicitly in many others. Specific sensitivity analyses were done for timber costs, stumpage price trends, and the discount rate (Appendix B, Chapter VI, Section F) using the Benchmark runs. Implicit considerations of uncertainty occurred all through the development of the data and functions to use in the analytical process because of the data problems noted above. Resource specialists and IDT members worked to stay on the conservative side and to check results for reasonableness when dealing with sketchy data and untested relationships.

USE AND DISPLAY SOIL EXPECTATION VALUES (SEV) FOR TIMBER ANALYSIS

Timber analysis based on soil expectation values should be presented.

Response: Soil expectation value (SEV) is the present net value of an infinite series of rotations for a timber stand, beginning with bare ground. Similar to calculating the economic potential of an acre of farmland for growing corn every year into the indefinite future, the SEV calculation indicates the economic potential of an acre of timberland for growing trees. The SEV calculation assumes that the same management practices, timing, and relative costs and benefits will apply to all rotations.

A financial analysis of various timber management regimes that are the basis for the Forest's timber management prescriptions are discussed in Appendix B, Chapter III.E of the FEIS. This analysis was part of the process of developing the intensities and yield tables for the managed stand prescriptions. The analysis does not show SEV; rather, it shows the PNV for just the first rotation from bare ground This actually encompasses the bulk of the SEV (sum of the PNV over the infinite series of rotations), especially for longer rotations. For instance, at 70 year rotations, the PNV of the first rotation is about 93% of the SEV. At 100 year rotations, the PNV of the first rotation is over 98% of the SEV for the infinite series. Therefore, the PNV values shown in the section reference above are adequate proxies for SEV because of the length of the rotations on this Forest.

PRICE/DIAMETER ADJUSTMENTS TO TIMBER VALUES PROBABLY BIASED

The Forest adjusted the stumpage values by diameter class, based on PNW Experiment Station research which is questionable for accuracy we have since learned. It is unlikely that the MBS tailored the actual price variations using timber sold from the Forest.

Response: We used the price/diameter adjustments for the Forest specified in the 4/27/84 Regional Office memo with revised direction for economic analysis for Forest planning, applied to selling values for timber (mill pond value plus manufacturing cost). The 100% value ratios were indexed to 24" logs, which was the best estimate we had of the average of all timber

harvested on the Forest over the period we used for timber value data. After creating the price/diameter value series at the sell value level, manufacturing costs were subtracted to get mill pond prices for use in the model.

Because the predominant harvest historically on the Forest had been larger diameter trees, we had no other transactions data from which to derive the price/diameter relationships. We did make one adjustment in the application of the RO direction after talking with the PNW researchers who developed the price/diameter estimates: we developed sell values and applied the price/diameter ratios at that level rather than to the mill pond values, as that was the original data source for the PNW work. Refer to the planning records for more detail.

USE OF HORIZONTAL DEMAND CURVES FOR TIMBER IS INAPPROPRIATE

The FS makes the assumption that the demand curve for timber is flat, that is, that the price of timber from individual forests will remain unaffected by the amount of timber sold annually. This assumption may be erroneous with the proposed reductions in timber harvests for the National Forests in Washington and Oregon.

The reliance of the MBS Forest Plan on the Washington Office directive (2/3/81) to use only horizontal demand curves in the plan inevitably leads to irrational conclusions.

Response: The debate over whether or not to use horizontal timber demand curves (functions) in Forest planning has been a long and vigorous one. We used horizontal demand functions for timber in response to Washington Office and Regional Office direction. However, to more completely respond to this comment:

If a horizontal demand function for stumpage is used at the Forest level, the implication is that no matter how much the Forest's timber harvest level increases or decreases, there will be no change in the unit price of stumpage in the market into which the Forest sells its timber. I.e., the Forest is essentially operating in a perfectly competitive market for stumpage.

On the other hand, use of a downward-sloping demand function implies that as the Forest sells more stumpage into the market, stumpage prices will go down, as buyers are willing to pay less for each additional unit of stumpage on the market Conversely, if the Forest reduces its sale of timber into the market, stumpage prices will rise as buyers are willing to pay more for smaller quantities of stumpage.

The concerned or interested reader is referred to the Pacific Northwest Regional Office's series of LMP Task Force Reports - specifically, Report #8-97 "Use of Horizontal Demand Curves for Timber Pricing" (K.Greer and K.Connaughton) - for the FS rationale to use horizontal demand functions at the local Forest level for planning purposes. Basically, the issue revolves around whether the local Forest can actually affect prices of stumpage in the market into which it sells. Further, there is the problem of the accurate specification of the demand function. Demand functions for any good are notoriously difficult to specify. There are a number of factors ("demand shifters") other than quantity of timber on the market

that will affect the price at any given time. These must be defined and appropriately accounted for in the demand function specification. These other variables may or may not vary in concert with the variations in quantity of stumpage supplied into the market. The degree to which substitutes are available also affects prices.

The MBS sells stumpage into a market that is regional in nature, much larger than the five-county area defined as the Forest's primary zone of influence, stretching from Canada into Oregon. Stumpage demand in the Pacific Northwest is derived from the demand for finished wood products (including paper), with the largest demand coming from lumber needed for housing and other construction. Wood product prices are established across a much broader region than that encompassed by an individual Forest's area of influence. Demand for stumpage reflects those regional or national price levels. Changes in output by an individual Forest will likely have little effect on stumpage prices because of the relatively undifferentiated nature of stumpage, available substitutes, and the ability for mills to shift their buying areas in order to acquire needed raw material input. Also affecting the regional picture are imports - primarily from Canada; and exports - primarily to Pacific Rim countries.

The MBS currently provides between 10% and 20% of the timber supply in it's five-county area of influence. That percentage falls off rapidly in the broader regional timber market. Because of fluid market boundaries and substitutability, there is little indication that changes in the timber output from the Forest, all other things being constant, will affect prices over the long term in the regional stumpage market and in the broader finished wood products market. It is true that short term localized price changes could take place in initial response to changes in the Forest's timber sell level. But over time these localized changes would disappear as the regional market adjusted: if prices dropped, buyers from further away would be attracted and bid the prices back up; if prices rose, local purchasers would seek supplies further out until the decrease in local demand helped bring prices back down

In summary, the Forest used horizontal demand functions for timber in its planning process in accord with Washington Office and Regional Office direction. However, given the nature of the local and regional timber markets, and the difficulty in adequately specifying a demand function, we would have used horizontal demand functions for timber anyway at the Forest level.

Aggregation of timber outputs from the National Forests at the Regional level presents a somewhat different picture. At that scale, it is more likely that changes, in total, of stumpage supplied from the Forests could affect the regional timber markets. I.e., it is more likely that there exists a downward-sloping demand function for stumpage at the regional level, and it is somewhat less problematic to specify a demand function at that scale. This was not an issue that the individual Forests could deal with in the process of preparing their Forest Plans. It was necessary to wait until there was an indication of the magnitude and direction of timber supply from the Forests in aggregate, as reported through the draft Forest Plans, before an assessment of the Regional change and potential price effects could be estimated. The Regional Office conducted that assessment in June 1989, using the anticipated timber outputs as reported in the draft Plans ("Timber Supply in the Pacific Northwest: Aggregate Implications of Forest Plans," USDA Forest Service, PNW Region, June 1989). (For a more

detailed discussion of that report and its findings, see the comments and responses under "Timber Supply and Demand" in this Appendix.)

REAL PRICE TRENDS SHOULD BE USED; SHOULD NOT BE USED; SHOULD BE USED ON VALUES OTHER THAN JUST TIMBER; REAL PRICE TREND SENSITIVITY SHOULD BE TESTED

The FS discussion about the selection of 1% as the [real] price growth for timber is disturbing. The "compromise" contradicts long-standing historical evidence of 2%-3% annual price rises for timber. Selection of a 1% timber price growth trend skews the analysis away from commodity forest outputs to amenity outputs.

While we disagree that an arbitrary 1% trend is a true reflection of the future price appreciation rate, we agree to the use of a 1% rate if its implications are fully evaluated for significance in the "benchmarks" and alternatives. The trends significantly affect land allocations and timber values, and it is imperative that these effects are shown in relation to, at least, the Preferred Alternative.

If the overoptimistic assumption of a 1% real annual increase in timber values has been retained in this plan, it should be dropped forthwith.

Timber stumpage is given a real price trend of 1% while other resources are given no such trend. The result is to increase timber prices 65.4% over beginning prices after 50 years. There is no justifiable basis for such a trend being given solely to timber stumpage except to mislead the reviewer by altering the outcome of the economic analysis.

Given the potential effect of the different stumpage price trends on the Mt. Baker-Snoqualmie's outputs and timber economics, there should be a sensitivity analysis of how price trends affect the maximum present net value benchmark and the Preferred Alternative.

The limited results of the price trend benchmark analysis are significant. The trends have a major bearing on the management intensities, PNV, thinning and probably total harvest. Therefore each alternative and especially the Preferred Alternative, must fully analyze the implications of the assumed price trend.

Response: Just like the debate over horizontal demand functions, so too was the debate over use of real price trends long and vigorous. The responses quoted above indicate the range of opinion on the subject. Again, the Forest followed Washington Office and Regional Office direction by using the 1% price trend for stumpage over the first fifty years of the planning horizon, and no price trends on other resource costs and values. Again, a somewhat more in depth response is warranted.

The argument for using real price trends on timber was based on historical data that showed a long-term average trend for stumpage (primarily Douglas fir) of around 2%-3% annually, with some short-term fluctuations. Those in favor of this approach wanted that trend extrapolated into the future. A 2% trend would result in prices after 50 years 169% higher than the beginning point. A 3% trend applied over 50 years would result in prices 338% higher than the beginning point. These are compared to the 64% real increase after 50 years from a 1% trend. The end figures go up exponentially because the rates are compounded annually.

The argument against using real price trends on timber was based on a belief that extrapolation of past trends that far into the future carried enormous amounts of uncertainty with it, particularly in the face of new product technology, increasing substitutability of other materials for wood in construction, and a leveling off of demand for demographic reasons. A small error in a trend that is compounded annually can have enormous consequences if carried many years out into the future. Persons supporting the use of no real price trend (0% trend) argued that the conservative approach was to evaluate all alternatives on the same basis of constant real prices and costs. Estimated future real price increases could be tested through sensitivity analysis, and information derived from that analysis, if significant, incorporated into the final decisions on land allocations and degree of intensive management.

In addition, another group argued that it was not appropriate to apply a real price trend to timber values without also using real price trends for other resource values expected to rise in real terms in the future -- particularly primitive-type dispersed recreation and anadromous fishing. And they argued that real increases in costs, particularly labor costs, had caused and would continue to cause real price increases in costs that should be applied on the cost side of the equation.

These arguments were presented to the Regional and Washington Offices by various proponents of the different views. After much deliberation, a relatively conservative compromise approach was adopted. A real price trend for timber of 1% would be applied as the base case. Sensitivity analyses using 0%, 2%, and 3% trends would be done with the benchmarks during the analysis of the management situation (AMS) process. If sensitivity analysis over a reasonable range of rates showed major effects on allocations, outputs and economics, similar sensitivity analyses would be shown for the alternatives to provide more complete information for the decision-maker in choosing a preferred alternative for the Forest Plan.

The compromise rate of 1% was chosen to acknowledge the high probability of some real increase in timber prices over the first part of the planning horizon. But it is less than the historical rate, reflecting expectations about changing technology, demographics and demand in the future. And the lower rate minimizes compounding error if the rate is overstated.

It was also decided that trends would not be applied to costs or other resources in Region 6. Earlier attempts to derive such trends had resulted in a large degree of variability and some unacceptable results when applied in FORPLAN runs. It was felt that there simply were not good enough data to develop either cost trends, or trends for goods and services that have traditionally been nonmarketed.

The sensitivity analyses run during the AMS process on the maximum PNV with management requirements benchmark (BM Run #7) showed changes of less than 5% in harvest acres and volumes over the first five decades, and in long-term sustained yield for the planning horizon for both 0% and 2% trends; PNV changed by less than 10%. The 3% trend caused significantly higher increases in acres and volumes harvested, long-term sustained yield, and PNV. But tentatively suitable acres brought into solution increased by on 0.2%. See FEIS Appendix B, Chapter VI.F for a more thorough discussion of these sensitivity runs.

Although the 3% trend caused some significant changes in benchmark results, it was felt that application of this rate over 50 years was simply unrealistic under just about any scenario. As noted earlier, timber prices after 50 years increase by 169% with a 2% trend; with the 3% trend, that increase after 50 years jumps to 338%. On the other hand, the 0% and 2% trends caused changes that were relatively minor, particularly in drawing any more tentatively suitable lands into solution. Therefore, we did not carry the sensitivity analysis of price trends over into the evaluation of the alternatives in the DEIS and FEIS.

In reality, use of real price trends would have even less effect in the alternative runs than in the benchmarks. In the benchmarks FORPLAN was allowed to allocate lands to timber or nontimber management. For the actual alternatives, most of the land allocations were made to best respond to the planning issues and concerns, and to provide contiguous and spatially feasible management areas to the extent possible

The major effects that real price trends would have in the evaluation of the management alternatives would be in timber harvest scheduling and in intensities assigned for timber management. In the sensitivity analyses, application of trends was directly correlated with increases or decreases in acres subject to increased management intensity, such as applying precommercial thinning or commercial thinning prescriptions. However, in all cases, the higher the trend, the lower the first decade harvest. FORPLAN will tend to hold back harvest as much as possible if the combination of growth rate and price trend is greater than the discount rate. So while the application of timber price trends may lead to higher overall harvest levels for the 150-year planning horizon, harvests in the first decade or two will not increase.

Adams and Haynes (1989) have projected that real prices increases for stumpage in the Douglas fir region (primarily western Washington and Oregon) will be in the range of 2.5%-4% over the next 20 years, then will drop to near zero. The range depends on the timber supply situation during that time; after 2010, the supply is expected to increase substantially while demand levels off (see the discussion under "Timber Supply and Demand" in this Appendix). A 2.5% real increase over 20 years results in prices at that time about 64% higher than today - just about the same increase as a 1% real trend applied over 50 years. They predict that these higher real prices will be achieved more rapidly, but will intersect with the price trend used in the Forest's modeling at about 50 years

The higher price trends would result from a more significant reduction in public timber harvests than was apparent from the levels reported in the draft Forest Plans at the time Adams and Haynes did their analysis This situation will be monitored during Forest Plan implementation. The most immediate effect would be to assess on a site-by-site basis the feasibility of increasing the management intensity being applied for timber prescriptions. In particular, more rapidly rising real timber prices could make commercial thinning economically viable in more areas. The standards and guidelines in the Plan are written so as to be able to take advantage of those opportunities as they occur.

APPROPRIATION OF FULL REQUIRED BUDGET TO IMPLEMENT PLAN UNLIKELY

Projected outputs for timber volume and revenue achieved under each alternative reflect an ideal maximum which assumes that the full required budget is appropriated each year. Experience is that the federal government is not likely to continuously and reliably budget for programs and measures for many years into the future The Plan must commit to an automatic triggering of an amendment process, or otherwise commit to an automatic correction of the ASQ and other operations in the face of the absence of sufficient funding to carry out the Plan and operations.

Response: As stated in Chapter 1 of the Forest Plan, and reiterated in Chapter 5, the activity and output levels displayed in the planning documents are estimates; achieving those levels will depend on the annual budgeting process.

We believe the concern expressed by this comment is that the Forest will not carry out a balanced resource management program if budgets are less than required to carry out fully the direction of the Forest Plan. In particular, the concern is that the timber management portion of the Plan will be budgeted at higher levels than other resource areas and will be implemented the same way, resulting in a timber-dominant program.

There is no "automatic trigger" built into the Plan to respond to differing budgetary levels. However, a paragraph in the section "Implementation Direction" in Chapter 5 of the Plan (Chapter 5.B) speaks to the concern over unbalanced programs and possible undesirable effects from that imbalance: "Projects are scheduled in response to the management direction in the Plan, planned outputs of goods and services, near-term management needs and opportunities, and the annual budgeting process. **If there is a conflict between standards and guidelines and program outputs, projects will be in full compliance with standards and guidelines set forth in this Forest Plan."** (Emphasis added.)

The intent of this Forest Plan is to provide a balanced program of land and resource management that responds to the issues, concerns and opportunities identified during the planning process, that is sensitive to public needs and resource demands; that achieves the management goals set out in Chapter 4 of the Plan, and that will proceed toward the desired future condition defined for the Forest. The degree to which that intent is met will be assessed as implementation proceeds and monitoring is accomplished Major deviations, whether for budgetary or for other reasons, may require an amendment or revision of the Forest Plan.

PRESENT NET VALUE ANALYSIS DOESN'T INCLUDE ALL COSTS AND BENEFITS

On the topic of PNV, it looks to me as though timber receipts are the only monetary benefits considered, and timber jobs the only sector of the economy considered. I think PNV is a bogus indicator of value unless ALL costs and benefits are considered, and not a few selected ones.

Benefits such as maintenance of quality and quantity of recreation, preservation of visual amenities, ecological communities and habitat for species of concern were not considered in the Net Present Value analysis. Similarly, environmental cost of noise, soil erosion, and visual impacts due to activities such as logging were not considered in the NPV analysis. If it is

not possible to attach a dollar figure to these types of costs and benefits, the EIS should say as much in the discussion of NPV.

Response: Costs, benefits, present net value and net public benefits were discussed in the DEIS, Chapter II.F.4, in some detail. Detailed discussion and displays of the economic concepts and variables used in the planning process can be found in Appendix B of the DEIS and FEIS, Chapter IV. See also the FS responses to the comments "RECREATION VISITOR DAYS DON'T MEASURE TOTAL RECREATION VALUE" and "ADDRESS NONCASH BENEFITS" under the "Values" section of this Appendix.

OUTDATED INFORMATION USED

The proposed Plan utilizes outdated information to assess what economic values are foregone should the Plan be implemented. It does not recognize the recovery of the forest products industry from the 1981-1982 depression to the present.

Response: We have made every attempt to use the best available information for the planning process, given time and budgetary constraints. Information that was gathered and used in the early part of the planning process, and which has changed significantly over the past ten years, has been updated to the extent possible for the FEIS. We are just now into the beginning of a new Integrated Resource Inventory, which will replace the old timber-only inventory. Because this was dictated by budget and Regional Office priorities, we were not able to accomplish it sooner. For a discussion of why we have continued to use timber values and costs developed earlier in the process, see the "Values" section, "MARKET AND NONMARKET VALUES ARE INCORRECTLY DEVELOPED AND USED" and the "Costs" section, "COSTS ARE OUTDATED...."

INCLUDE ROAD MAINTENANCE COSTS

An additional cost accounting apparently not used is the maintenance cost of logging roads. Only the asset value of the roads seems to be presented (e.g., DEIS Table III-20) Unless a road is completely abandoned, it is not an asset; it is a liability. You must include the maintenance costs of each road when you analyze its economic "benefits."

Response: There are two different cases involved here. The first is the net cash flow related to timber sales in a given year -- what is now reported in the TSPIRS "Statement of Timber Sale Revenues and Expenses" (Report 1) This case is the related to Table III-20 cited above. The second case is the contribution of road maintenance costs to the net economic value calculations of timber and other management activities for the Forest.

In the first case, the Forest Service considers the capital costs of road construction and the costs of timber purchasers' road maintenance activities in a given year as timber sale-related costs. In the section discussing this issue (Sale Cost Accounting) and Tables III-18 through III-20, road asset values from capital investment (Table III-20) are shown separately, while the timber sale receipts and costs are net of road construction costs. Purchasers' road maintenance costs related to timber sale activity are included in the timber sale costs. Timber purchasers pay for all sale area road maintenance costs during the operation of the sale. The Forest Service considers ongoing road maintenance costs from appropriated funds as basic land stewardship costs. Once a sale is completed but the permanent roads are left open, the annual maintenance costs are not considered to be necessarily timber related; rather, they are part of the costs of the overall management of the Forest.

In the second case of overall economic net benefit calculations, the ongoing road maintenance costs were included for all types of roads that remain open. These costs for the government average $300/mile/year (1982$). DEIS Table III-68 displays road construction and maintenance costs. (The Maintenance Costs - Appropriated Funds line should have been tagged "cost/mile, arterial-collector-local/year." The "local" was inadvertently omitted.)

EVALUATE HIDDEN COSTS TO OTHER RECREATION SITES OF LOGGING ROADLESS AREAS

Also evaluate in the EIS the hidden costs of logging roadless areas where forcing more people into fewer trails elsewhere will cause more money to be spent to repair trail, campground, lake shore, and meadow damage.

Response: One of the purposes of developing the Forest Plan and its associated monitoring requirements is to have a better basis for managing resource use and damage. In some cases, additional trails will be provided to offset, at least to some degree, those lost in roadless areas that are logged The intent of the Plan would be not to allow resource damage to occur in alternative recreation areas, through whatever management means required. If the Forest is successful in this regard during Plan implementation, there should not be additional budget costs that were not anticipated in the development of the Plan.

There may be economic costs to recreation users of primitive areas who are no longer able to use certain roadless areas for that type of recreation because of logging and roading. This will be the case if there are few or no alternative sites that can be substituted for the lost site. In general, if more users are crowded onto fewer trails, the congestion and reduction in quality of experience will mean a loss of value to those users. This loss in proxied in the Forest Plan economic modeling by not valuing recreation use past the estimated capacity of the land to support a given level of recreation experience. In actuality, if congestion occurs because that capacity is exceeded, the value to the users will decline. The modeling assumes that the total value of users over capacity times reduced value for all user would be about equal to the total value of users up to capacity times full value for all users.

COSTS USED ARE OUTDATED, OF UNCLEAR DERIVATION, AND INCONSISTENT W/BENEFITS

The fixed and variable costs used in the economic efficiency analysis, listed in Appendix Table B-15, are old (based on 1975-1980 data), and their source is not documented.

All the costs and values are outdated and based on inconsistent years and data; for example, stumpage values are based on "cut" sales from FY1977-FY1983, while logging costs are based on "sold" sales from calendar years 1973-1982.

Response: The five pages following Table B-15 discuss the source and derivation of each cost category, what activities are included in each cost category, and some of the problems and limitations encountered. Specific numbers, worksheets and equations may be found in the planning records.

As much as possible, costs were developed using a multi-year data series, weighted where appropriate and indexed to a base year, in order to get a reasonable average figure for planning purposes. Data years actually ranged from 1977 through 1985, depending on the cost category and available data. We believe that these average costs are a good representation, in real dollar terms, of the costs of Forest management activities. Some adjustments were made to costs prior to the publication of the Draft EIS that were known to have shifted significantly since their initial development in the earlier part of the decade. We do not believe that there have been significant shifts in the multi-year averages, when adjusted for inflation, that would deem it necessary to revise those costs for the FEIS.

The fact that the data series for logging costs and stumpage values were somewhat different does not create any serious bias or distortion in the economic analysis. Both were taken from multi-year series of seven to ten years in length, were weighted for appropriate factors such as volumes, diameter, species, etc., and were indexed to a common base year. These series are long enough to catch business cycles as well as technological trends. They picked up the economic highs of the late 1970's as well as the lows of the early 1980's They picked up the major changes in fuel prices of the 1970's and the increases and then decreases in real labor costs across the late '70's and early '80's. We are not aware of any significant trends in the past four to five years that would cause major shifts in these values in real dollar terms.

CLARIFY WHO INCURS THE COSTS FOR THE TIMBER SALE-RELATED ROADS

On page III-51, it's very unclear as to whether or not the road costs in Table III-20 are road costs that contractors bear in harvesting timber or are costs that the Forest Service incurs. If incurred by the Forest Service, it appears from looking at the Table III-18 (Timber Sale Costs, Receipts, and Cash Flow -Harvest Basis) that selling trees is a losing proposition.

Another major consideration is the cost of these roads - who pays for them? Not the timber companies - the taxpayer does.

Response: The roads shown in Table III-20 are timber sale-related roads built by the timber purchasers. The roads are built at the purchaser's cost, but the purchaser receives a credit, up to a maximum stated at the time the sale was bid, against the price that has to be paid to the Forest Service for the timber harvested -- hence, the term "purchaser credit roads." These costs are not included in the "Timber Sale Costs" columns of Tables III-18 and 19, but are also netted out of the "Receipts" column in the same tables. Therefore the "Cash Flow" figures would not be reduced again by the road asset values in Table III-20; to do so would be double-counting costs. The positive cash flows shown in Tables III-18 and 19 are correct.

JUSTIFY APPARENT DISPARITY BETWEEN COSTS OF LOGGING AND RECREATION ROADS

Lumber roads are estimated to cost $20,000/mile, while secondary recreation roads cost $150,000/mile. Both types of roads must carry heavy vehicles, so the great difference in cost strikes me as inappropriate.

Response: Table III-68 on page III-65 of the DEIS shows construction costs for roads of different standards. This table lists "Temporary" roads with a construction cost of $21,000/mile, "Local" roads costing $145,000/mile, and "Arterial and Collector" roads at $280,000/mile (all in 1982$). The reader has apparently correlated "lumber roads" to temporaries and "secondary recreation roads" to locals This is a misperception.

Temporary roads are those roads that are built to a very low standard, generally within a sale area, that gives logging equipment and trucks access to various working areas for the sale. They typically consists of spurs and short lengths of road connecting landings. As soon as the sale is complete the roads are "put to bed"; that is, they are closed off, recontoured, waterbarred if necessary, and revegetated. They rarely become part of the permanent road system.

Local roads are fairly low-standard, one-lane roads that connect destination points such as timber sale areas, trailheads, or campgrounds to larger, higher-standard roads (collectors or arterials). These are the roads by which trucks haul logs away from timber sale areas, and which later recreationists may drive. Local roads built to a timber sale area or to a trailhead will average about the same cost and be built to about the same standard. Temporary roads, on the other hand, are built only for short-term use by heavy, high-clearance vehicles and equipment within a sale area. Because they are built to a much lower standard, are generally quite short segments, and are designed for very short-term use, temporary roads cost significantly less than locals.

Costs of temporary roads in the economic analysis are included in the logging costs. The $21,000/mile converts to an average cost of about $8.00/MCF. These costs are borne by the timber purchaser. Local roads associated with timber harvest ($145,000/mile) are modeled partly as miles built and partly on a per acre harvested basis. Local roads required for recreation use are modeled as miles built and are also priced at $145,000/mile. See Appendix B, Chapter III, Sections B.2 and F.4 for additional details.

COSTS FOR ROAD CLOSURES

Were costs for [road] closures, permanent or temporary, included in order to keep road densities low enough for other resource protection?

Response: Yes; the Plan calls for many roads to be built to a lower standard than used to be the case, then either closing them outright until needed again for timber management activities, or maintaining them at a low maintenance level during that interim period In the model, annual costs of low standard maintenance were used to represent either case. The assumption was that the costs of closing and later re-opening a road and bringing it up to useable standard would be approximately the same as the costs of annual low standard maintenance (essentially keeping culverts cleaned out and arresting any erosion problems that develop)

LOGGING COSTS BY DIAMETER AND VOLUME

It seems more reasonable to use historical costs with empirical yield tables and the new method with DF-SIM; otherwise values would be inflated.

Response: The logging costs differentiated by diameter and per acre volume, as developed from the paper by Fight, LaDoux and Ortman (1984), were indexed to the Forest's historical values This tied the logging cost for the average diameter and volume to existing stand conditions, allowed for diameter and volume differentiated costs for use in managed stands (both of which will typically be smaller than for existing stands), and reflected the conditions on the MBS that differ from the Coast Range where the Fight, et al. cost model was developed.

INCLUDE LOSSES OF FISH AND WILDLIFE AS COSTS

The losses of fish and wildlife need to be modeled accurately, and those due to activities need to be charged as costs, and evaluated in calculation of PNV.

Response: Changes in fish and wildlife populations in response to other management activities, as well as to habitat enhancement programs, have been modeled to the extent our current knowledge allows. Losses of fish and wildlife populations are not calculated directly as costs; rather, they show up as decreased benefits. When two alternatives are compared that have differing levels of fish and wildlife populations, the alternative with lower populations (assuming values greater than zero and relatively marginal changes) will show a lower overall PNV than the alternative with larger populations. The difference in PNV between the two alternatives is the cost (more precisely, the opportunity cost) of the reduction in

population levels. Adding that reduction of benefits into the alternative with lower populations as an additional cost would be double-counting.

CONCERNED ABOUT BELOW COST SALES

Another major consideration: isn't it true that in 76 out of 123 national forests in the U.S., the government has consistently lost money selling timber? This may not be entirely true here in the Northwest, but why should the American taxpayer subsidize the timber industry to cut the trees from the public lands which are supposed to belong to everyone for multiple use?

From the high amount of acreage declared suitable for harvest, it appears that below cost timber sales are likely.

Response: The Timber Sale Program Information Reporting System, TSPIRS, was developed to provide information on the "below cost timber sales" issue. The 1987 and 1988 Draft TSPIRS Reports show the following information, (stated in $1000):

	1987	1988
Total Timber Sale Revenues	$29,378	$36,245
Total Operating Expenses	$16,989	$13,422
Remaining Value Before Payments To State	$12,389	$22,823
Payment To States	$ 7,021	$ 8,014
Net Gain	$ 5,368	$14,809

Costs for Timber Access Roads are included as one of the items under "Operating Expenses "

MBS SHOULD END DEFICIT TIMBER SALES BEFORE IMPOSING USER FEES

We hear much about user fees, the recreation initiative, and other ways to pay for recreation on the national forests. But it is not extreme to ask the Forest Service to put an end to deficit timber sales before imposing user fees on the recreating public.

Response: The MBS has not had any deficit timber sales. In fact, timber sales experienced a net gain (before payments to counties), as shown in the table of the previous response. (Annual TSPIRS Reports)

The only user fees charged to the recreating public on this Forest are those for fee campgrounds, recreation residences, special forest products (Christmas trees, firewood, transplants, etc.) and those fees paid to the Forest's Special Use permittee's (ski areas, outfitter guides, etc.)

MOTORIZED VS. NONMOTORIZED RECREATION VALUES NOT RIGHT

Our skepticism over your valuation of recreation outputs of the MBS is confirmed in the statement on DEIS p. II-119 that "on a per acre basis, motorized use is more valuable than nonmotorized use." This is a ridiculous conclusion to draw and is merely the result of the "linear thinking" of FORPLAN, which recognizes merely quantity, not quality.

Response: The capability of lands on the Forest to support various types and qualities of recreation were assessed using the criteria from the ROS Handbook. These criteria take into account the factors necessary to achieve and maintain the quality of recreation experiences at various levels. Estimates of the maximum number of RVD's per acre that can be supported by various lands on the Forest for various types of recreation (recreation capacity) resulted from that assessment process. As an example of the differences in needs to achieve recreation experiences of different types that are satisfactory to the users, Roaded Modified recreation can tolerate a higher level of use on an area basis (e.g., 3.1 RVD's per acre), while Semi-primitive Nonmotorized recreation experience requires a lower maximum density use (e.g , 0.6 RVD's per acre) to provide a satisfactory experience of that type. Thus, there was a quality variable built into the recreation capacity coefficients.

The Forest is required to use RPA values specified for Region 6 unless other more region-specific values are available and have been evaluated and approved by the Washington Office. The latter was not the case, so we used the RPA values as required. The RPA values represent the value that people would be willing to pay, over and above their current expenditures, to access and use the recreation resource itself. In other words, these values represent what a person would pay to the owner of the recreation resource for access and use, after arriving at the site - if such a market actually existed.

The statement that motorized use is worth more economically than nonmotorized use on a per acre basis is the result of multiplying the capacity coefficient in RVD's per acre times the economic value per RVD. So, for Roaded Modified recreation, this would be:

3.08 RVD's/ac x $9.38/ac = $28.89/ac.

For Semi-primitive Nonmotorized recreation, the figures would be:

0.58 RVD's/ac x $13.25/ac = $7.68/ac.

These results have to be kept in proper perspective. First, to say that the former is more valuable than the latter in Forest planning requires that all capacity on the Forest is in demand. If demand is less than capacity (total available acres for the recreation type times capacity per acre), then the RVD's of supply in excess of demand would have zero value. The Forest incorporated this factor through the use of demand curves applied to recreation in the FORPLAN modeling. Recreation was only valued up to the point of expected demand (use). Any capacity in excess of that expected use was not valued in the model. Primitive and semi-primitive recreation use received full value, as demand is at least as great as capacity. Roaded recreation was not valued at full capacity in the first decade or two, as expected demand is not currently as large as capacity on the Forest

Second, these results are all dependent on changes in use and land allocations being marginal. If major changes occur -- for instance, most or all of the lands available for one type of recreation are eliminated - then the relative values would change, unless there were available substitutes within a reasonable travel distance.

The uncertainty surrounding all these numbers is one of the reasons that economics is used as a tool in the planning process, rather than seen as giving the answer. Economics helps guide the analysis and decision-making process. But other factors are also taken into account, such as the

inability in the modeling process to account for demand potentially exceeding capacity in reality, leading either to deterioration of the quality of experience, or to rationing schemes that would drive up the willingness to pay for the experience.

RECREATION VALUES SHOULD VARY WITH DEMAND AND SUPPLY

Roaded recreation evaluation doesn't appear to take into account that "value" changes with scarcity, and that there is a point of diminishing returns. The value of unroaded recreation should increase as demand is not met [demand exceeds supply], and the value of roaded recreation should decrease as demand is exceeded.

Response: While the comment is conceptually correct, the ability to define a continuum of quality and associated values within each step of the Recreation Opportunity Spectrum (ROS) system is beyond both the available data and the modeling capabilities we currently have.

We attempted to proxy this situation in a "lumpy" manner in two ways. First, the ROS classes reflect gross differences between experiences of roaded and unroaded dispersed recreation, and, within those two broad categories, several steps of experience levels going from more to less influence by development and other human activities. These ROS levels have different economic values associated with them in the planning process. The lower end of the value range is associated with those experiences that are more common, have many available substitutes, and for which there is abundant supply. The higher end of the value range is associated with those experiences that are less common, have few available substitutes, and for which there is limited supply in relation to demand.

The second part of our approach to dealing with this problem was to limit the recreation valued in the planning process to the levels of expected demand. If that projected use is below capacity - for instance, roaded recreation opportunity in the first and second decades exceeds expected demand - a dollar value was assigned only to the level of use, not to total capacity. Conversely, if projected use exceeds available supply, only the projected use is valued.

This process gives some recognition both to variations in recreation quality/type and to the interaction of recreation demand and supply. But if projected use exceeds supply, it does not allow for an increase in the dollar value assigned to that type of recreation. And if supply far exceeds projected demand, the dollar value assigned to that type of recreation does not decrease for planning purposes.

These types of limitations on data and modeling capability occur throughout the planning process. Nothing is perfect, and assumptions have to be made. The value of using a formal analytical and economic process is that approaches are structured and standardized, assumptions are stated "up front" and treated consistently, and quantification is used to the extend possible to help guide the evaluation and decision-making processes. Beyond the limitations of data and the capabilities of analytical tools, it is the decision-maker's responsibility to make the best judgement possible, accounting for all relevant information as best possible.

RECREATION VISITOR DAYS DON'T MEASURE TOTAL RECREATION VALUE

I object to the economic analysis in the Plan of simply measuring recreation use days. We believe this understates the present and future economic recreational impact of conservation and protection of the forests.

> **Response:** See "ADDRESS NONCASH BENEFITS" which follows later in this section for a discussion of noncash benefits that are priced (RVD values) and those that are nonpriced Some of the nonpriced benefits related to recreation are discussed there In addition, option and existence values *for present and future recreation opportunities, wildlife-related* activities, etc. are part of the total value of recreation. Finally, there are distributional benefits (and costs) that accrue in terms of employment and income effects.
>
> The economic efficiency analysis part of the planning process quantifies to the extent possible the cash and priced noncash benefits (and costs). The employment and income effects are part of the economic impact (distributional or equity) analysis that looks at who benefits and who pays the costs of management programs and activities. These two analyses are *separate processes and are not additive.*
>
> Nonpriced noncash benefits are discussed throughout the planning documents in qualitative terms. The final decision process brings together the information from the economic efficiency analysis, the economic impact analysis, nonpriced noncash benefits, and any other pertinent factors relating to the decision to be made in an assessment of the "net public benefit" that will result from choosing one alternative or another. The economic efficiency analysis results (present net value), of which the RVD priced values are a part, are only a subset of the total set of values and conditions that make up the "net public benefit."

DISPERSED RECREATION VALUES TIED TO CAPACITY, NOT USE

It should also be noted that you tie dispersed recreation values to capacity, not estimated use. It seems that the most appropriate and quantifiable [approach] would be use rather than capacity.

> **Response:** It is true that, in the FORPLAN model, recreation values ($/RVD) are attached to RVD's of capacity This was for modeling convenience as much as anything, as RVD's of capacity by ROS class are the primary recreation variable in the model that vary by alternative. However, *recreation capacity was given a positive economic value* ***only*** *up to the* point of expected demand (use) for that ROS class in a given decade. Any capacity in excess of that expected use was not valued in the model.

RECREATION WILLINGNESS-TO-PAY VALUES ARE NOT COMPARABLE WITH TIMBER VALUES

The MBS timber values are not comparable to the other resources since they fail to reflect finished lumber prices to the consumer.

The MBS *incorrectly tries to justify the incorrect mixing of valuation by* saying that the point of valuation is the Forest The timber values used in the analysis are stumpage values which reflect the value added as the trees are harvested, processed, and eventually distributed in finished form to the

ultimate consumer. On the other hand, the RPA non-market values are comparable to a "finished product" price valued at delivery to the consumer. Recreation and wildlife user days are consumed in the woods and were developed by adding what people pay (in travel and expenditures) to reflect the value of the resource. So, the stumpage value excludes all the costs and values that accrue to the resource, but recreation is valued at its consumptive point with all of the costs and revenues included.

Response: The values used for timber and for recreation/wildlife are conceptually comparable. Each measures the willingness to pay for the land/resource taken as an input on the Forest. The value of recreation is not the **total** value of the recreation "finished product " Rather, it measures what people would be willing to pay to use the land (or wildlife) as an input into the total recreation experience if they had to pay some sort of access or use fee. The total value of the recreation experience encompasses the costs in time, travel and equipment that people expend, along with the nonpriced value represented by access/use of the land or resource on the Forest. Only the last part - the net willingness to pay over and above actual expenditures - is represented in the Forest Service values for recreation and fish/wildlife user days in the planning process. These values are comparable to timber stumpage values - the value at first point of access on the Forest prior to processing into a finished product.

RPA FISH VALUES ARE NOT APPROPRIATE FOR THE PACIFIC NORTHWEST

It is our understanding that RPA values are not based on local ex-vessel price of fish or regional studies determining the value of anadromous fish to commercial and noncommercial fisheries. The RPA values are based on national averages; therefore, the Forest Service has neglected to apply the best available data and most reasonable information based on local economic conditions.

Response: RPA values are developed at the national level, but they are adjusted by Region, given the best available data. Also affecting prices among Regions are differences in the quality and comparability of similar activities and outputs, and the extent to which the outputs and opportunities from the National Forests are a large enough part of total regional supplies to affect regional prices.

CALCULATION AND VALUATION OF WILDLIFE/FISH USER DAYS UNCLEAR

How did the Forest calculate WFUD's and value them?

Response: The derivation, projection and valuation of WFUD's followed the same general process as that for other recreation, as discussed in some detail in Appendix B, Chapter III.F.5&6. On the demand side, historic data were used as the basis for projecting recreation use of fish and wildlife (WFUD's). On the supply side, recreation capacity was developed in terms of the ROS system. This system defines recreation in terms of type and quality of experience (primitive, roaded natural, etc.) rather than as types of activity (hunting, fishing, camping, hiking, etc.).

[NOTE: All recreation activity in the planning and modeling process is expressed in terms of standardized 12-hour days. RVD's are used for all recreation not related to fish and wildlife. Recreation associated with

the latter are expressed as Wildlife/Fish User Days (WFUD's) which are also standardized 12-hour days. If the average duration of a wildlife observation activity day is 4 hours, it takes three such activity days to make up one nonconsumptive WFUD. On the other hand, if a big game hunting day on the average occupies 8 hours, it takes only 1.5 such days to make up one hunting WFUD. One ramification of this standardization is that the economic value of a nonconsumptive wildlife activity day will be multiplied by three to get the WFUD value, while the economic value of a big game hunting activity day will only be multiplied by 1.5 to get its associated WFUD value.]

It was necessary to develop a "crosswalk," using historical data, between the activity types and the ROS class. Up until 1981, the Recreation Information Management (RIM) system did not track recreation use by ROS, but only by activity type. Since the original use projections were based primarily on historical data from the 1970's, the "crosswalk" was necessary to convert the projected recreation use by activity type into projected use by ROS class.

In the planning and modeling process, recreation in terms of ROS class was the primary focus for mapping, tracking and reporting. However, economic values of recreation use are defined in terms of activity type -- hunting, fishing, camping, hiking, etc. For purposes of economics, it was necessary to keep a parallel accounting of recreation supply and projected use by broad activity types, varying primarily by major differences in economic value. For instance, general dispersed recreation activity may have similar economic values per visitor day, but hunting, fishing, wilderness use, and nonconsumptive wildlife use all have significantly higher values. In order to reflect those higher-valued recreation activities, RVD's and WFUD's by those activity types were tracked along with ROS class.

It should be noted that the recreation (RVD and WFUD) projections used in planning and modeling are specifically for on-Forest activities. Historical use patterns and best estimates of future activity were used to derive the projected supply and future use There are places in the planning documents where broader contexts of demand and supply are discussed that go beyond Forest, or even Puget Sound area, boundaries. For instance, demand for nonconsumptive wildlife use is said to be running significantly higher than for consumptive wildlife use That projection, though, was made in terms of all types of nonconsumptive wildlife use *occurring a mile or more from peoples' residences (USFWS, 1980 National* Survey of Fishing, Hunting and Wildlife-Associated Recreation). Yet, historical data for the Forest, sketchy though it was, indicated that nonconsumptive wildlife use was a much smaller relative portion of total wildlife use on the Forest. This is not surprising, in that people can find many nonconsumptive wildlife-related activities much closer to home than the Forest, while the number of substitute opportunities for hunting off-Forest are much smaller.

Economic values used for WFUD's were the RPA values for Region 6, as required by Regional and Washington Office direction. At the time that the modeling and analysis were done, there were no Washington Office-approved alternative values more specific to the Forest that were developed in a manner methodologically consistent with the RPA values.

For additional details on the development and modeling of WFUD's, consult the Forest's LMP planning records. Derivations of the 1985 RPA values are discussed in Appendix F of the 1985-2030 RPA Program FEIS (USDA, 1986).

WILDLIFE AND FISH USER DAYS (WFUD'S) ARE DOUBLE-COUNTED

There is a double-count in the wildlife and fish user days. Consumptive or nonconsumptive use can be found in all four types of recreation use [developed, roaded dispersed, unroaded dispersed, and wilderness].

Response: Table II-9f of the FEIS (Table II-7f in the DEIS) shows estimated recreation outputs by alternative for developed, nonwilderness roaded dispersed, nonwilderness unroaded dispersed, and wilderness recreation. Each of these categories except developed recreation includes wildlife and fish-related recreation use. Also shown separately in the table is a summary of wildlife and fish use. This is for informational purposes and are not double-added into the total recreation use.

In the actual modeling of recreation capacity and use, WFUD's - both consumptive and nonconsumptive - were tracked as a subset of the major recreation breakdowns (developed, roaded, unroaded, and wilderness). WFUD's have higher economic values than general dispersed recreation. They were tracked and modeled separately in order to reflect those relative value differences. See Appendix B, Chapter IV.D for further discussion on development and use of RVD and WFUD values in the planning process.

DISAGREE WITH VALUES USED FOR FISH AND WILDLIFE

By State standards, all wildlife-oriented recreation carries with it a value to the State. This true value needs to be recognized in the Forest's Plan. ..[commercial] fishing costs are a multiplier which drives the State's economy and need to be included in the price (value) of our resources. Each commodity should be valued at its market place.

Response: The FS examines economic efficiency from the standpoint of the national economy. The value of goods and services produced from the Forest is the value they have at the time they are harvested, caught, experienced or whatever on the Forest (or in the ocean or rivers in the case of anadromous fish). This is the economic **addition** to the national economy. While processing adds to the value at intermediate or final markets, that value added is also a cost to the economy in terms of using land, labor and capital that could have been directed elsewhere, potentially to a higher use.

The values used in the Forest planning process for economic efficiency analysis reflect the value of the resource as an initial input to a production process that will produce a final good In the case of recreation, that final good is created primarily at the point of experience - the access to and use of the land is incorporated by the person, along with whatever expenditures it took to get there, to create the recreational experience. The value of the resource is the net willingness to pay to use the resource, over and above the expenditures made to get to the site and back. This is the value used in the economic efficiency analysis for recreation. The expenditures are incorporated into the impact or

distributional analysis, which uses the input-output model (IMPLAN) to display how those expenditures on recreation multiply to drive the economy.

In a similar vein, the commercial ocean fishery for salmon brings salmon from the water into the boat and to the dock at a cost, just as there is a logging cost to get the tree cut down, onto the truck, and to the mill. In the latter case, mill price minus haul costs and logging costs (stumpage) is the recognized value of the tree in the woods. Likewise, the net value of the fish in the water is its dockside price minus the costs of hauling the fish to the dock and catching it in the first place. Here, too, the expenditures that add value through processing to the final market are not reflected in the economic efficiency analysis, but rather their effects on the local and regional economy are reflected through the impact analysis that shows how catching the fish leads to a whole series of expenditures that multiply through the economy, provide income and support employment.

WILDLIFE AND SPORT FISHERIES VALUES AS NONCASH BENEFITS

Are wildlife and sport fisheries increases included as noncash benefits?

Response: Yes; it is assumed that all of the supply of fishing and hunting opportunities, as well as opportunities for appreciative (nonconsumptive) wildlife use, will be taken up by visitors to the Forest, whether above or below the current situation. It is also assumed that all increases or decreases will be relatively marginal, so that assigned values are not affected Increases in fishing RVD's are derived directly from expected fish production A series of calculations relate production to harvestable fish; harvestable fish available, through angler effort per fish caught, to WFUD's; and thence to the economic (noncash) value of the recreational use of the increased fish production. We do not have similar direct relationships established for hunting or nonconsumptive use. For these activities, values are applied directly to the projected increase in hunter and nonconsumptive user days, with the assumption that the habitat maintenance and enhancement will provide the necessary resource base to fulfill those anticipated use levels. Value (demand) cutoff points are used to avoid assigning values to projected hunter and nonconsumptive user days that exceed the capacity for those uses reported by the model. (See previous response to comment for additional discussion of use of value or demand cutoff points.

MARKET AND NONMARKET VALUES ARE INCORRECTLY DEVELOPED AND USED

We believe the values used for market goods have been incorrectly derived and the costs used are overstated. Also, the nonmarket values are incorrectly developed and used. The methodology used to combine market and nonmarket values is fundamentally incorrect.

These [nonmarket] values appear to be based on a highly theoretical economic study. A simple, common-sense review of the values assigned to various recreational activities suggests that they are skewed. For example, $8.47 per RVD for alpine skiing is belied by the substantial sums of money that people pay in transportation, equipment, lift tickets, accommodations, food and other costs associated with downhill skiing. Under such circumstances, recreational resources should simply be excluded, like other amenities, from the calculation

of PNV, which should be limited to commodities with readily ascertainable market values.

Response: We believe that the development of timber values (see Appendix B, Chapter VI.D.a) is appropriate and reflects reasonable average stumpage values that would occur over a typical timber industry business cycle (e.g., the highs of the late 1970's, through the lows of the early 1980's, and back on the upswing by the mid 1980's).

Derivation of costs, and responses to questions about whether or not they were biased or overstated, are discussed under in responses to comments above.

It is true that values of nonmarketed goods and services cannot be specified as precisely as those for goods and services that are exchanged in a marketplace. However, the methodology for estimating nonmarket values has been developing and evolving for at least 30 years. In the last 10 years, much more consensus has been reached on both the appropriate methodologies and on the meaning of the values derived. While there is still some disagreement over specific values obtained (the same is often true with derivations of the "right" stumpage value - a market good - as well), the methodology used by the FS to develop values for nonmarketed goods and services is in accord with the latest techniques in the economics profession. See Appendix F in the 1985 RPA Program Update (USDA, 1986) and the same appendix in the draft 1990 RPA Program (USDA, 1990) for thorough discussions of these methods. The 1990 draft also has a good references section. The reader who pursues these references will find that the example quoted in the comment above concerning value of alpine skiing is confusing expenditure values with net economic value. See also the discussion earlier in this section concerning the comparability of recreation and timber values.

The purpose of combining market and nonmarket values is not to end up with a number that is accurate in the same way as a financial statement or short-term financial analysis would be. This would be impossible, even using only market values, given the lengthy planning horizon and the uncertainties surrounding any projections over that time period. Rather, it serves to provide an **index** of the relative values of various alternatives. The economics do not provide the entire picture of all the values associated with the management of the Forest. There are many that still are beyond quantification. But the economic values, both market and nonmarket, do provide a picture of the relative magnitude of the measurable values involved, and of the relative tradeoffs in value as management goals, objectives and activities change among alternatives.

The Preferred Alternative is based only in part on the economic analysis. The issues, concerns and opportunities defined during the planning process, as well as legal management requirements, are major drivers of the Forest Plan goals and objectives, the subsequent standards and guidelines, and the land allocations. The decision is based on the Regional Forester's estimate of that mix of land allocations, activities and outputs that gives the greatest "net public benefit" of all the management alternatives considered. The economic present net value is a major subset of the net public benefit, but is not by any means the entire picture.

ADDRESS NONCASH BENEFITS

Noncash benefits, particularly of the spiritual values of the forest, need to be more specifically addressed in your plan and in the accompanying EIS. Even if these are difficult to measure, they should be at least given thought and words.

Response: *Noncash benefits include both those that are quantified, such as* the net economic value of an RVD, and those that are not quantified, such as the value of preserving wildlife species or the aesthetic values associated with maintenance of high quality scenic views. Part of the value of spiritual renewal experienced by recreationists is reflected in the net willingness to pay by people for the recreation experience, and is part of the economic value quantified through the planning process. Part of the value of spiritual renewal experienced is not priced; there is no known way at present to derive and put a number on aspects such as higher productivity resulting from rest and relaxation, or from reduced propensity to commit crimes because of the availability of more open space and natural landscapes.

Many of these nonpriced, noncash benefits are recognized in the planning, evaluation and decision-making process. They are referenced throughout the documents in sections on wildlife, wilderness, scenery, etc. These values are part of the "net public benefit" referred to in an earlier response in this section. The decision-maker takes into account the <u>full</u> set of values, not only those on which we have actually been able to put some price. Again, the economic present net value is a subset of the overall "net public benefit," which encompasses all the factors, quantified and nonquantified, that relate to the decision to be made.

DON'T LIKE RPA VALUES

Use of the 1985 RPA program assessment values has been consistently criticized by resource management agencies in the Pacific Northwest. These arbitrary valuations are really only the opinion of one group of economists (and on a national perspective).

Response: Appendix F of the 1985-2030 RPA Program FEIS, and the same appendix of the 1990 Draft RPA Program, give thorough discussions of the development of the RPA values, as well as provide additional references. Review, discussion and critique have provided continual stimulation to improve and refine the values, both conceptually and empirically. A large number of economists have been involved in one way or another in the development of the values. Not surprisingly, various resource advocates generally argue that the values for "their" resource are generally too low, while values of other (often competing) resources are generally too high.

RESIDENT AND ANADROMOUS FISHERIES NOT ADEQUATELY CONSIDERED IN BENCHMARKS

The Forest Service assumed that its benchmark analysis provided appropriate "decision space" for evaluating alternative management scenarios and evaluating associated resource impacts, based on the belief that anadromous fishery value and yields would not alter benchmark outputs, the planners elected to omit this information from the FORPLAN model. Resident fishery values and potential values are not included in the benchmark analysis.

Response: Fish modeling was one of the weaker points in our benchmark analysis during the "Analysis of the Management Situation" process, primarily because of the difficulty on this Forest of defining with any confidence any direct connections between marginal changes in other management activity levels and fish production. This difficulty of defining production relationships, particularly with regard to stream sediment loading, is primarily a result of the topography of the Forest as it affects streams. In the Puget Sound basin, anadromous fish spawning occurs more in steeper stream segments with swifter-moving water than it does on slower-moving stretches. Therefore, the damaging factor for spawning gravel tends to be streambed scouring with larger material rather than siltation with fine sediments. Differentiating between natural and management-related sources of large scouring materials has been more difficult that defining those sources for fine sediments, as has been done on other Forests. See additional discussion that has been added to Chapter III, Fish in this FEIS.

It is true that a benchmark run was not included that maximized resident and/or anadromous fish production capability on the Forest. However, the maximum primitive and semiprimitive nonmotorized recreation benchmark should have served as a proxy for the maximum opportunity for protecting and restoring fish habitat. What was not included at that point in the process was a dollar estimate for maximizing fish production, nor an estimate of the fish production coming from the benchmark.

The inclusion of three investment and production levels in the DEIS and FEIS for the Forest Plan was built on the assumption, discussed above, that there is not a direct connection between levels of management activity and fish habitat, **assuming all BMP's and Standards & Guidelines are applied.** That last caveat is critical, for if any BMP's or S&G's are not applied, then current levels of fish habitat and production will not be maintained, and the assumption of production levels relying solely on investment levels in habitat restoration and enhancement breaks down.

Given all the above, the lack of a fish maximization benchmark was not critical for adequate consideration of anadromous and resident fish production in the decision-making process. Monitoring and additional research over the next five to ten years should improve the available information in this area greatly, allowing much better modeling of fisheries during future Plan revisions. See Chapter 5, Forest Plan.

FORPLAN WAS NOT PROPERLY VALIDATED

The Forest Service never made its decision to employ the FORPLAN system on a national basis subject to any public notice and comment. Furthermore, the FORPLAN system was not properly validated before implementing this mandatory tool. The few documents surrounding this decision suggest that the selection of the FORPLAN system was made quietly and quickly.

Response: FORPLAN is the analysis tool adopted by the Forest Service to help develop plans for the National Forest system. FORPLAN was adopted for use nationally in 1979 to ensure a degree of consistency among Forests in their planning and modeling efforts. It was adopted after considering the only other viable candidate optimization and scheduling model available at the time -- the Integrated Resource Planning Model (IRPM). FORPLAN is simply a tool to assist in the analysis for forest planning - it does not make decisions, nor select the alternative that best meets net public benefits.

Appendix B of the DEIS included a discussion of the model and its use; a summarized discussion of FORPLAN was and is included in Chapter II. Additional documentation of the decision is available in the planning records. (Refer to the Public Involvement section of this appendix for additional comments/responses.)

MODEL SHOULD BE EXPLAINED IN DETAIL

The model itself should be explained in some detail, including how it will be used as a management tool (not to dictate the outputs of the Forest, but to direct management decisions and evaluate alternative activities). I hope this is true; it's bad management to let computer models dictate decisions.

Response: As explained in Chapter II, DEIS and FEIS, the FORPLAN model was used as an analytic tool. It is used to optimiza the design of each alternative (after the goals and objectives of the alternative are determined by the Forest Service, to respond to various public issues and concerns). The results of FORPLAN outputs help guide the decision-making process; the model itself, however, does not make decisions. Refer to Section B, Chapter II, FEIS and Chapter III of Appendix B for more information.

"ECONOMIC EFFICIENCY" NOT MEANINGFUL FOR DEVELOPING FISH PRESCRIPTIONS

The DEIS states (Appendix B, Chapter III.D.2) that "Though these [Category II - Management Requirements] prescriptions were designed to meet minimum constraints, they were still developed considering economic efficiency." The subsequent discussion indicates that this was really done only for wildlife, not fish. Since no benchmarks or quantitative linkages to environmental change were developed for fish, it is impossible to have any meaningful analysis for "economic efficiency "

Response: The "Riparian and Fish Habitat Management Requirements" prescription (13A) was developed in response to the planning regulations (36 CFR 219.27) that require protection of riparian areas and fish habitat from unacceptable degradation. Because the regulations specify a minimum level of resource protection that has to be met under any circumstance, the

economic efficiency question become one of "cost-effectiveness" - i e., *what is the least-cost way of achieving that resource protection. In this* case, the opportunity cost of meeting the riparian and fish management requirements is timber harvest foregone. So the economic question considered was how to meet the management requirements for protection of riparian and fish resources while minimizing the amount of timber harvest foregone.

INAPPROPRIATE USE OF DFSIM MODEL FOR OTHER THAN DOUGLAS FIR SPECIES

Also [object to] the MBS's inappropriate use of the DFSIM model when the current state of the art is the SPS model. The Forest Service use of DFSIM has forced the use of incorrect information into FORPLAN. Please review the technical report which is a part of this total response.

Was DFSIM adjusted for the slower growth rate of silver fir and others?

Response: DFSIM was used to project all yields for the DEIS. After consideration of public input -- specifically the group of timber technical issues -- and further review of available and suggested yield simulators, the Stand Projection System (SPS) was used to develop projected yields for western hemlock and true fir portions of the working groups for the FEIS. See Appendix B Chapter III.E.2 for details on how new SPS model was incorporated into the development of FEIS yield tables.

NO DISCUSSION OF WILDLIFE MODELING

Appendix B, page B-92 states wildlife as being one of the yield coefficient developments discussed in the section. Nowhere in the documents can we find *any explanation of models used to predict wildlife responses to activities.*

Response: Additional information has been incorporated into the FEIS, Appendix B concerning the wildlife habitat and population response models. See FEIS Appendix B, Chapter III.B.

QUESTION WILDLIFE MODELING

[The way wildlife habitat changes were modeled] (page B-46) doesn't allow for fragmentation, size or spacing of patches. This results in an inflated inventory. There should be a coefficient of reduction calculated and ground-truthed as has been done to allow calculation of dispersion factor

Response: The separate programs used to estimate wildlife habitat changes did take into account the effects and rate of harvest by management areas. The standards and guidelines for wildlife management areas were modeled to take into account fragmentation, size and spacing characteristics.

NEED MORE INFORMATION ON CONSTRAINING COEFFICIENTS

The development of various constraining coefficients for input into FORPLAN is *not presented, and a complete discussion of how these coefficients were*

developed is requested. Also, a discussion of any sensitivity analysis conducted with these coefficients is requested.

Response: Development of modeling coefficients and constraints is discussed in Appendix B, Chapter III.F. For a discussion of sensitivity analyses carried out on a limited number of variables, see FEIS Appendix B, Chapter VI, Sections F and H.

HOW WERE AZ'S USED?

Were allocation zones used to predict changes in wildlife and fish or just analysis areas? We would like to see population estimates for alternatives by drainage

Response: AZ's were not used to predict changes in wildlife and fish; these changes (except for WFUD's) were handled outside the FORPLAN model and consequently estimations for populations by drainage are not available at this time.

QUESTION USE OF SINGLE MODEL, DFSIM

I am concerned that your calculations are based on use of single computer model developed for Douglas Fir forest between 3,000' and 4,000' elevations ("Douglas Fir Simulated Intensive Management" Model), which is then extrapolated to other forest types and elevations. I am also concerned about the fact your models are based on assumptions about regrowth, including 10-15% enhancements based upon genetics and 10% enhancements based upon increased use of fertilizers and pesticides. It is disturbing that there is little actual field data to support such assumed enhancements

The structure of the forest model is inaccurate because it fails to stratify the forest by species, even though the forest will be managed for about 40 percent Douglas fir and 60 percent hemlock/true fir in the future, with management prescriptions as well as yields of these species differing significantly.

Response: Many of these assumptions have changed in the FEIS; refer to Appendix B, Chapter III, section 2.

ALLOCATION ZONES PREVENTED FORPLAN FROM DEVELOPING AN OPTIMAL PLAN

FORPLAN makes use of a concept called allocation zones to ensure that all the lands in an area defined as a zone are managed in a compatible manner. Normally, several alterative packages of management prescriptions are input for each zone, and FORPLAN allowed to select the optimal package, i.e., the one that best contributes to the objective of maximizing net present value of the overall plan. However on this forest, the planning team input only a single predetermined package of prescriptions for each zone, thereby preventing FORPLAN from developing an optimal plan.

Response: The allocation zone feature of the FORPLAN model was used to carry forth the objectives and spatial concerns of the alternatives. The model was then called upon to chose from a wide range of silvicultural and scheduling choices to optimize the objective function. By modeling both

spatial integrity and optimization, FORPLAN was able to more realistically estimate outputs and meet the objectives and goals of the alternatives. Each of the nearly one dozen alternatives analyzed in detail for the DEIS and FEIS had a separate package of prescriptions specified by zone. The results of evaluating multiple alternatives, within the decision space defined by the benchmarks, helped us develop the best possible plan for the Forest. This use of FORPLAN also was in accord with our approach of using FORPLAN as a tool to assist in the evaluation and decision-making processes, rather than for making the actual decisions.

CONSTRAINT FOR HARWOOD MANAGEMENT?

Page B-90: was such a constraint ever applied in the development of any alternative? If not, why not?

Response: *No. Ruffed grouse was dropped from the planning process as a* wildlife indicator species, and hardwood management on the Forest was not identified as an ICO.

SELECTION OF LEVEL IDENTIFIERS

Page B-27: had the Forest opted to use other, non-timber oriented identifiers, wildlife and other resources could also have been modeled. With the appropriate link between activities, sediment and fish production, fish *populations could have been modeled.*

Response: To a certain degree, this is true; however most other outputs and activities are unrealistic to handle on a per acre basis and can be better dealt with on an AZ basis Careful choice is required in selecting identifiers. They need to be relevant across a number of resources and issues. Too many combinations can lead to unmanageable model size. Some identifiers may also prove not to be effective or beneficial in the modeling process, primarily because of data limitations. For instance, in our initial FORPLAN formulations, deer winter range was used as an identifier in Level 2. However, we found that it simply did not add anything to the information coming out of FORPLAN; rather, we could get better results using models external to FORPLAN for wildlife habitat and population responses. See FEIS, Appendix B, Chapter III C. (Fish projection modeling and problems are discussed in Appendix B, Chapter III.B)

EXPLAIN COEFFICIENT DEVELOPMENT

Explain coefficient development, especially road-related.

Response: Development of coefficients is discussed in FEIS Appendix B, Chapter III.F. *Additional detail not included in the Appendix B discussion* can be found in the Forest's planning records.

THERE IS NO INTERAGENCY COOPERATION BETWEEN FOREST SERVICE, NATIONAL PARKS

A serious deficiency exists in the Forest Plan in its treatment of management directions for lands adjacent to the North Cascades National Park. There is no systematic documentation of existing cooperation between the USFS and the NPS and there is only vague reference to the types of cooperation envisioned in the future under the Plan This is indeed unfortunate since adjacent federal lands under different jurisdictions offer many opportunities for complimentary management.

There should be mention of cooperative efforts in terms of recreation, visual resource management, wilderness, and vegetation.

> **Response:** As documented in Appendix A, DEIS and FEIS, the Forest coordinated with the National Park Service in developing issues and concerns, and throughout the planning effort (as per NFMA regulations, 36 CFR 219.7). Additional data on supply has been added to the Recreation section of Chapter III, FEIS in response to this and other public comments. The first goal statement, under Forest-wide Standards and Guidelines for recreation is "encourage public and agency participation in recreation planning." Cooperative efforts in other resource areas (such as protection, wild and scenic rivers, wilderness, etc.) are included throughout Chapter 4, Forest Plan. Also built into the monitoring plan (Chapter 5, Forest Plan) is a planned, annual monitoring/management review with adjacent agencies, including the National Park Service. Additionally, National Park Service participation and input regarding management issues and concerns is invited by the Ranger District interdisciplinary teams during the scoping phase of all proposed projects adjacent to National Park lands.

UPDATE APPENDIX G REGARDING NORTH CASCADES NATIONAL PARK

Appendix G should be updated with respect to the management plan issued in 1987 for the North Cascades National Park Complex In addition, attention should be drawn to conflicts between that Plan and the MBSNF Plan. In our view these relate to the management directions set by the NPS Plan for developing an approach to ecosystem management with adjacent land managers and the lack of recognition of this need in the MBS Plan.

> **Response:** Appendix G has been updated, including the conflicts with plans and policies of others section, in this FEIS.

PLAN DOES NOT DISCUSS ECOSYSTEM MANAGEMENT

The MBS Forest Plan is to be commended on representing a good example of current management according to the prevailing management paradigm, i.e., the RPA. In the next decade, the emerging management paradigm will be ecosystem management. The Plan is deficient in its failure to recognize the changes that will come under the new management concept. There is not an obvious and explicit connection of Plans by the multiple managers of the North Cascades Ecosystem (including those in Canada). This must be the next planning effort; it would be a step forward to recognize, in this plan, the evolution toward ecosystem management that must take place.

Interagency Cooperation

I would recommend joint management of the North Cascades ecosystem between the MBS, North Cascades National Park, Okanogan and Wenatchee Forests, and Manning Provincial Park, in Canada, to ensure the survival and biological requirements of wildlife.

The final plan should consider the role of the MBS in the Greater North Cascades Ecosystem. Instead you approach management with a dark-ages state of knowledge of ecosystem functioning and planning. You even state (Appendix D-35) that you will only use the minimum of cooperation with other state and federal agencies necessary to achieve wildlife around the National Forest!

Response: The addition of discussions focusing on diversity and long-term productivity in Chapter III, FEIS and in a new section in the Forest-wide Standards and Guidelines (Chapter 4, Forest Plan) responds to this comment The elements of diversity considered include, but are not limited to: viability, distribution, and abundance of wildlife and plant communities; the structure and composition of forest; the role of agents *such as fire and insects; long-term productivity; and fragmentation of* scarce community types. In addition, the new Integrated Resource Inventory, which is currently underway, is designed to measure physical and biological attributes of vegetation, not simply tree size and class The old growth component of the inventory should be completed in 1991.

The referenced page in Appendix D is from Management Area 24, Minimum Management, a prescription developed to meet NFMA and regional planning direction. No lands in any alternative displayed in the FEIS are allocated to MA 24; it is not selected in the Preferred Alternative.

FAVOR MORE PROTECTION OF LANDS AROUND MT. RAINIER NATIONAL PARK

Another concern I have is for the protection of Mt Rainier National Park. Mt. Rainier National Park is a small park and is severely impacted by the ecological conditions prevailing on the lands surrounding its boundaries. In addition, Mt. Rainier National park is subject to very high visitor loads, but a large part of what every visitor sees during any visit to Mt. Rainier National Park is the land surrounding the National Park. For these reasons, the FS cannot ignore Mt Rainier National Park nor its visitors when managing the lands surrounding the park.

Response: Cooperative efforts in other resource areas (such as protection, wild and scenic rivers, wilderness, etc) are included throughout Chapter 4, Forest Plan. Also built into the monitoring plan (Chapter 5, Forest Plan) is a planned, annual monitoring/management review with adjacent agencies, including the National Park Service. Additionally, National Park Service participation and input regarding management issues and concerns is invited by the Ranger District interdisciplinary teams during the scoping phase of all proposed projects adjacent to National Park lands.

NO TIMBER HARVEST NEAR MT. RAINIER NATIONAL PARK

The excessive timber cutting right up to the National Park boundaries is making Mt. Rainier National Park an island in a sea of clearcuts.

Areas adjacent to Mt. Rainier National Park that are slated for logging under alternative H should be spared in some locations, so that there will not be obviously incompatible uses immediately adjacent to the park.

National forest policy should be coordinated with national park policy to prevent their working at cross-purposes. So far, this has not been done with any positive effect. Clearcuts exist right up to the boundary of Mt. Rainier National Park. No effort has been made to protect whole ecosystems, as they actually exist on the ground.

Response: In the Preferred Alternative, based on public comment and to meet the objectives of the alternative, lands near Chenuis Creek and adjacent to Mt Rainier National Park have been allocated to MA 1B, semi-primitive nonmotorized dispersed recreation. Mather Memorial Parkway, one major travel-route into the Park, is allocated to MA 8, Special Area with emphasis on scenery (and no scheduled timber harvest). While other acres adjacent to the park are allocated to MA's that permit timber harvesting, National Park Service participation and input regarding management issues and concerns is invited by the Ranger District interdisciplinary teams during the scoping phase of all proposed projects adjacent to National Park lands. The Forest-wide Standards and Guidelines for visual resource management (see Chapter 4, Forest Plan) also apply.

PLAN VIOLATES MULTIPLE-USE SUSTAINED YIELD ACT

Plan is in violation of multiple use-sustained yield act because it does not provide for sustained yield, it isolates the timber resource from the remainder of the Forest, it does not provide for multiple use of all lands, and it violates the established function of the Forest by harvesting at 17% below potential yield.

Since the Organic Act clearly establishes at the outset that a "continuous supply of timber for the use and necessities of citizens of the United States" was preeminent, U.S. v. New Mexico, 98 s. Ct. 3012, 3017 (1978), and later Congressional policy embodied in MUSY Act directed the Secretary of Agriculture "to develop and administer" renewable resources, including the renewable timber resource, in order to obtain "the products and services" produced by such resources, at a minimum it can be said that the clear intent of both these laws is to emphasize timber outputs from the forest while still balancing other uses. In short, the additional resource uses of the forest created by the MUSY Act did not detract from the primary forest uses, timber and water. Sierra Club v. Block, 622 F. Supp. 843, 859, 860 (D.C. Colo 1985). The timber resource must not be subordinated to other forest use.

The allowable timber sale quantity (ASQ) in the MBS Plan for the next decade will be 17% lower each year than the current potential yield, that is, 170 MMBF down from 203.8 MMBF. The cumulative effect over ten years of a 17% reduction in the annual timber sale program is the total loss of 338 MMBF. This violates the established function of the MBS as clearly stated in the Organic Act and transgresses the fundamental policy of the MUSY Act of developing and administering the renewable timber resources for its products and services.

Response: *Sustained yield of timber for all alternatives can be found in* the FEIS The Multiple Use-Sustained Yield Act declares that National Forests be "administered for outdoor recreation, range, timber, watershed, and wildlife and fish purposes." and defines multiple use as "the management of all the various renewable surface resources of the National Forests so that they are utilized in the combination that will best meet the needs of the American people." It also allows "that some lands will be used for less than all of the resources" and that those uses are "not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output."

While the goals and objectives of the alternatives presented in the FEIS differ, they are all consistent with the Organic Administration Act of 1897, the Multiple-Use Sustained-Yield Act, and - except for Alternative NC (No Change) - NFMA. The range of alternatives addresses public concerns about multiple use management, as well as many other concerns The Preferred Alternative maximizes the net public benefits.

NEITHER ALTERNATIVE NC OR A ARE TRUE "NO ACTION" ALTERNATIVES

Alternative NC was included to comply with an order to include a "true no-action alternative" and Alternative A is referred to as a no-action alternative. Neither of these is a no-action alternative, both are "continued action" alternatives. As such, we do not believe they comply with NEPA.

A No-Action Alternative should be modeled using minimal level management regimes. Presenting as analysis of minimum level effects would give a much truer "baseline" against which to compare your other alternatives.

Response: As defined in the Council of Environmental Quality's "Forty Most Asked Questions" (Federal Register, 3/23/81), the "no action" alternative when "an action, such as updating a land management plan where ongoing programs initiated under existing regulations will continue, even as new plans are developed. In these cases "no action" is "no change from current management direction or level of management intensity" and the "no action" alternative may be thought of in terms of continuing with the present course of action until the action is changed " In addition, NFMA implementing regulations (36 CFR 219.12 (f)(7)) state that "At least one alternative shall reflect the current level of goods and services provided by the unit and the most likely amount of goods and services expected to be provided in the future if current management direction continues. Pursuant to NEPA procedures this Alternative shall be called the "No Action" alternative." For all forest plans, this alternative is labeled "Alternative A" and is the No-Action Alternative required by NEPA

Alternative NC (No Change) was developed in response to decisions made regarding a 1986 appeal; the substance of the appeal was that a true no-action alternative representing current management plans (and without MR's) was not included in Forest Plan EIS's Refer to discussion in Chapter II, DEIS. Alternative NC emulates the existing Timber Management Plan, with its Potential Yield as the timber output; coordination with other resources is guided by the Ranger District Multiple Use Plans. Alternative NC does not incorporate the management requirements noted in the NFMA regulations. Implementation of this alternative would require modification of the regulations.

A minimum-level management benchmark was formulated and is displayed in Appendix B.

INCLUSION OF MR'S IN EVERY ALTERNATIVE LIMITS THE DECISION SPACE

Decision space is limited by including MR's in every alternative, thus violating the direction of the National Environmental Policy Act which requires "examination of a wide range of alternatives."

Response: As stated in Chapter II, the imposition of management requirements in all alternatives considered in detail is a NFMA requirement. One alternative, the No Change Alternative, has been developed which does not include Management Requirements. Management Requirements can be viewed as assuring that we are meeting Multiple-Use Sustained-Yield of all of the resources as noted in the MUSY Act of 1960.

ALTERNATIVE G SHOULD NOT HAVE BEEN INCLUDED IN THE DEIS

Portraying an alternative developed by a special interest group does not conform with the NEPA requirement that the responsible federal official prepare and include the alternatives to the proposed action. Alternative G was not authored by the government.

Including Alternative G, the selected choice of a vested interest group, does not meet the standard of "full and fair discussion of significant environmental impacts" as required by 40 CFR 1502.1.

Forest Service has "committed it's resources" by including Alternative G in the various alternatives to the proposed action, and to this extent has violated 40 CFR 1502.2(f) which states. "Agency shall not commit resources prejudicing selection of an alternative before making a final decision (1506.1)""

Response: NEPA requires that public participation in the process begin "as early as possible" in the preparation of an EIS; the scoping process, a first step after publishing the Notice of Intent in the Federal Register, is a first point for public involvement. Refer to the discussion on Appendix A, FEIS, for public involvement efforts, including formation of the MBS public Liaison Groups.

NFMA at 16 U.S.C. 1601.(b) requires the Secretary to "provide for public participation in the development, review and revision of land management plans". In light of this requirement, and as provided for in FSH 1909.15, each Liaison Group was invited to provide information and suggestions in the development of alternatives More discussion is available in the MBS planning records. Two of the three groups declined, the Conservation Liaison Group suggested goals and objectives and, using the same standards and guidelines and available allocations as used in all DEIS alternatives, worked with MBS staff in developing Alternative G.

In the public response to the DEIS, several additional alternatives were submitted by the public. These were all considered (Chapter II, FEIS) and one was developed as an alternative considered in detail. Alternative I. Members of the Public Land User's Society worked with MBS planning staff in the mapping of Alternative I.

Note that 40 CFR 1506.1 defines a "commitment of resources" as a) an action that will have an adverse environmental impact on the human environment, or b) an action that will limit the choice of a reasonable alternative.

NO ALTERNATIVE ALLOCATES OVER 75% OF TENTATIVELY SUITABLE LANDS TO TIMBER PRODUCTION

The range of alternatives in DEIS is inadequate because no alternative manages over 75% of the tentatively suitable lands for timber production

The DEIS range of alternatives is inadequate because all alternatives maintain too much roadless area.

Response: Several alternatives not considered in detail, and benchmarks not developed into alternatives, did develop more of the roadless areas and manage more of the tentatively suitable lands for timber production. See Chapter II and Appendix B, FEIS for further discussion of these

alternatives/benchmarks and why they were not developed into alternatives considered in detail.

THE RANGE OF ALTERNATIVES IS UNDULY RESTRICTED

The range of alternatives is unduly restricted. First, no alternative in the DEIS contains an ASQ above 208.3 MMBF. Each alternative requires a significant reduction in the annual allowable sale quantity, as compared to the Potential Yield in the current plan. It is obvious the range of alternatives has been restricted and there is no "reasoned choice " (California v. Block)

A comprehensive range of alternatives was not provided. For example, an alternative that maximizes fish and wildlife resources was not included; this would be very useful for comparative purposes.

The DEIS should consider a broader range of alternatives in terms of impacts on native American religious uses of the national forest. For example, not one alternative protects more than 46% of the cedar areas.

The alternatives presented do not represent a reasonable range of alternatives, as is required by NEPA The most appropriate alternative available is the PLUS alternative, with an annual nt timber sale level of at least 220 MMBF.

There isn't a single alternative I can support; they are not balanced to provide the needs of all Forest users. The plan drafted by the Public Land Users Society is a fair as possible to all user groups.

Response: NFMA (36 CFR 219.12) states that alternatives shall be distributed between the minimum and maximum resource potential to reflect, to the extent practicable, the full range of major commodity and environmental resources uses and values that could be produced. The alternatives in the FEIS provide, in comparative form, a range of options. They allow the issues to be sharply defined and provide the Regional Forester and the public a clear basis for choice among them. Refer to Chapter II, FEIS for discussion of the alternatives that were not examined in detail, as well as the alternatives considered in detail in this FEIS.

An ASQ of 203.8 is based on the existing Timber Management Plan, which does not incorporate the provisions of the National Forest Management Act, including identifying lands which are not suited for timber production (36 CFR 219.14) and development of management requirements (36 CFR 219.27. The range of alternatives considered in the FEIS includes alternatives that assign a high percentage of the tentatively suitable acres to a timber harvest prescription (Alternatives NC, A, B, and I). Refer to Alternatives Described in Detail, Chapter II.

Alternatives C and G-Modified, with lower annual timber harvests/road construction and high levels of fish production and dedicated and effective acres for wildlife respond to the "maximum fish and wildlife" end of the range of alternatives. Protection of inventoried American Indian religious and cultural use areas is also highest in Alternatives C and G-Modified. Because expected frequency of human encounters was the criterion used to develop the percentages (Table II-9o, Chapter II, FEIS), even lands allocated to MA 1B Semi-primitive Nonmotorized dispersed recreation do not offer the highest level of protection. Within the minimum and maximum resource potential, the range of alternatives considered is broad.

Alternative I was developed in response to public comment on the DEIS, with a goal of producing 220 MMBF annually, producing big game animals, more trails and more roaded recreation opportunities (goals of the PLUS plan). Refer to Chapter II, Alternatives, FEIS.

NO ALTERNATIVE HARVESTS THE OLD GROWTH FAST ENOUGH

None of the alternatives harvest the remaining old growth quickly enough, in the first decade. These stands need to be converted to young, fast growing stands.

Response: The MBS a deficit-inventory forest, meaning that old-growth stands available for harvest must be metered out for 70-80 years before the second growth on the Forest is ready for harvest. If the harvest of old growth is accelerated in the early decades, future harvest levels must decline until the younger stands are ready for harvest. This option of departing from the non-declining flow policy was evaluated in the departure alternatives (E-Departure, H-Departure) in the DEIS.

NO ALTERNATIVE INCREASES THE AMOUNT OF OLD GROWTH ON THE FOREST

The range of alternatives is inadequate in that no alternative proposes an increase in the amount of old-growth forest. Why not allow some previously harvested areas to revert to old growth ?

Response: The intent of Alternative C is to allow some of the acreage that is presently in an ROS class of Roaded Natural to revert to an ROS class of Primitive. This would be accomplished by road closures and halting timber harvest activities. Over time, through the natural process of vegetative succession, these areas could eventually revert to "old growth".

NO ALTERNATIVE RETAINS ALL ROADLESS ACRES IN UNROADED CONDITION

No alternative allocated all the roadless lands to retain their unroaded character.

Response: As explained (page II-27) in Chapter II of the DEIS, "an alternative where 100 percent of the roadless areas would remain undeveloped was not considered practical because of the size and location of a number of the individual roadless parcels." In the FEIS, 93% of the roadless areas would remain undeveloped in Alternative C, and 92% would remain undeveloped in Alternative G-Modified.

FINAL SHOULD INCLUDE AN "INTRINSIC RIGHTS OF NATURE" ALTERNATIVE

While a range of alternatives is presented in the DEIS, that range is nowhere near complete. Every one of the alternatives, including C and G, are *utilitarian in nature. People need to know that they do have the choice of* leaving the world alone! The final should include an "intrinsic rights of nature alternative."

Response: An alternative that comes close to this respondents wishes was considered, but not developed in detail: the Earth First! Alternative. Elements of this alternative, including rehabilitation of habitat for anadromous fish, more recommended wild and scenic rivers, and larger, unfragmented acres of old growth remaining, were incorporated into the alternative recommended as the preferred - Alternative J. See Chapter II, FEIS, Alternatives Considered But Eliminated From Detailed Study.

NO CLEAR PICTURE OF THE ROLE OR OVERALL GOAL OF THE FOREST

The chapter (Forest Management Direction, Chapter 4, Plan) seems to address the management goals of user groups without ever stating the role or overall goal of the Forest in managing the forest landscape as a whole.

Response: The goal or objective of the Forest Plan (the Preferred Alternative) as a whole is summarized in Chapter II, FEIS, Alternatives Considered in Detail. While Chapter 4 of the Plan does not repeat this goal or theme statement, the various goals, standards, and guidelines in the Plan reflect the more specific management that will lead to this desired future condition for the entire Forest. Since the proposed plan was released, Section B, Chapter 4, Plan, the Desired Future Condition, has been revised; this should provide a better idea of the overall "look" of the Forest as a whole (in ten years and in 50 years).

INCLUDE A FEED-BACK LOOP TO DETERMINE WHEN GOALS ARE/ARE NOT BEING MET

For the Management Goals to be meaningful, the EIS needs to includes something to help determine when goals are met, and note when they are slipping behind some schedule. This is essential for accountability, documentation, and evaluating results.

Response: See the discussion under Plan Implementation, Chapter 5, Forest Plan. This section explains the connection between Goals, the monitoring plan, and amendments to the Plan. In addition, Table 5-1, the Monitoring Plan includes a "threshold of variability" for each item monitored, along with the method of monitoring, measure, frequency, etc.

REWRITE THE GOAL FOR OLD GROWTH

The Department recommends the Forest Goal for old growth be rewritten as follows: Goal: "To provide naturally-evolved old growth ecosystems for the preservation of natural genetic pools; for habitat for plants and wildlife species associated with old-growth ecosystems; and for contributions to the diversity spectrum."

Response: While we have not incorporated this exact recommendation, new Forest Management Goals and Forest-wide Standards and Guidelines have been included for Diversity and Long-Term Productivity. Refer to Chapter 4, Forest Plan.

WILDLIFE AND FISH FOREST MANAGEMENT GOALS ARE TOO NARROW, DON'T INCLUDE PLANTS

Under Wildlife and Fish: the Forest Management Goal is limited vertebrate species and is therefore too narrow. The FS mandate is to manage "habitats for all existing native and non-native and desired non-native plants, fish, and wildlife species in order to maintain at least viable populations of such species." (FSM 2670.12) The goal statement should reflect this.

Response: Forest Management Goals for Diversity and Long-Term Productivity have been added to Chapter 4, Forest Plan, responding to this comment.

NO ALTERNATIVE MEETS THE FIRST WILDLIFE GOAL

The first Forest Management Goal for wildlife comes directly out of the language of the Planning regulations - maintain viable populations of existing native and desired non-native vertebrate species - yet the MBS does not display any alternative that meets this goal.

Response: The Preferred Alternative, and others, will maintain viable populations of all vertebrate species on the Forest, through application of wildlife management requirements (MR's), and by maintaining and improving habitat for Management Indicator Species See Chapter 4, Forest Plan: Forest Management Goals and Forest-wide Standards and Guidelines

ADD TO THE RECREATION FOREST-WIDE GOALS

Add a goal to recreation: coordinate with and consider the views of public and private sector agencies and organizations to develop partnerships between these groups and the Forest Service toward better satisfying public needs

Response: We agree; a similar statement has been added to the Forest Management Goals, Section A of Chapter 4, Forest Plan.

ADD TO RANGE MANAGEMENT GOAL

On page 4-2, Forest Plan: add to the Range goal "where they don't conflict with other resource goals, including those for wildlife, riparian management "

Response: This suggested modification has been made

ADD TO FOREST-WIDE GOAL STATEMENT

Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive Species: add to the goal statement that the Forest will consult with DNR - Washington Natural Heritage Program in determining protection for State listed threatened, endangered, and sensitive plant species

Response: The Forest has no authority for State listed species. We will, *however, continue our frequent coordination, sharing of information, etc.* Refer to Item 5, under Threatened, Endangered, Sensitive Species

ADD DEVELOPMENT OF SPECIES MANAGEMENT GUIDES AS A GOAL

The development of species management guides for sensitive species is required and important; it should be stated as a separate goal

Response: The development of management guides for sensitive species is included in the Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive Species, Item #5, Chapter 4, Forest Plan.

STANDARDS AND GUIDELINES SHOULD BE MORE/LESS RESTRICTIVE

The language in the Forest-Wide Standards and Guidelines, and the management area prescriptions is too broad, allowing for too much discretion on the part of the land managers.

For the most part, the prescriptions for each MA do not contain the level of specificity necessary to be of real guidance to the federal land manager They are very general, leaving room for a wide span of interpretation. Without question, the land manager must be given room to allow for special circumstances; however, a minimum level of specific guidance must be provided.

The language in the Forest Wide Standards and Guidelines, and management area prescriptions is too restrictive, much more so than required by law. In certain areas, the terms "must" and "shall" are used; more permissive language should be inserted to maintain flexibility to manage the forest.

The DEIS and Plan violate the Resources Planning Act, NFMA, and NEPA by establishing Forest-wide Standards and Guidelines and individual management prescriptions that are inflexible, and do not result in multiple use or sustained yield of the timber resource.

Most of the guidelines can be interpreted in different ways, depending on who is reading them I would like the guidelines to be more "black and white "

These Standards and Guidelines are written more like a wish list than standards Words such as "should and could" are not sufficient guidance to insure that on-the-ground results meet management goals.

> **Response:** The standards and guidelines for each management area include language (such as "shall") determined necessary to meet the objectives of the MA, and that will achieve the Desired Future Condition. The level of detail provided is very specific in some cases, such as "no scheduled timber harvest." In other MA's, the exact practice to be used will be determined at the project level, site-specific environmental analysis. In all cases, additional direction is determined and prescribed in the project-level NEPA document.

STANDARDS AND GUIDELINES AND PRESCRIPTIONS CONTRAVENE RPA, NFMA, NEPA

The Forest-wide Standards and Guidelines and the management area prescriptions contravene RPA, NFMA, and NEPA since they pre-determine forest practices without public participation and preclude achievement of timber harvest levels.

> **Response:** The standards, guidelines, and prescriptions are designed and written to allow multiple-use management while meeting the objectives of each management area, laws, policy, and regulation. During the process of developing final management prescriptions, the planning team presented the proposed prescriptions to the three Liaison Groups, whose membership represented a wide-range, diverse number of interest groups, organizations, and timber industries. (Refer to Appendix A, FEIS for more information about the Liaison Groups) During 1984 and 1985, a number of meetings were held with each Group; the comments and suggestions received were used to finalize prescriptions for the DEIS. These are documented in the Planning Records.

We also received considerable public input on the Forest-wide and management area standards and guidelines during the comment period for the DEIS. A number of changes have been made in the Forest Plan in response to these comments. In addition, the planning team involved members of the Public Land Users Society to work with us in developing and mapping an alternative to reflect the goals, objectives, and land allocations of PLUS. The results of these working meetings are displayed as Alternative I in the FEIS.

STANDARDS AND GUIDELINES PURPOSE OBSCURES WHAT SHOULD BE THEIR INTENT

The FS DEIS Preparation Guide (1985) states that standards and guidelines "provide the description of how things will be done on the ground." This is inconsistent with the stated purpose of standards and guidelinas found in the Plan. The two purposes listed obscure the basic intent to provide specifics.

Response: The introduction to the Forest-wide Standards and Guidelines section has been revised, based on this and other comments We believe the wording now in the Forest Plan is more specific.

ADD CONSULTATION WITH STATE FOR STATE-LISTED T, E, & S PLANTS

For Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive Plants: add to the goal statement, consultation with DNR-Washington Natural Heritage Program in determining protection for state listed plant species.

Response: The Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive Species includes consultation with the Washington *Natural Heritage Program for technical information. For state-listed* plants, the Forest Service has no authority. We will continue the relationship of frequent coordination and sharing of information.

CONSIDER STANDARD FOR NATURALLY FISH-FREE SYSTEMS WITHIN WILDERNESS

In standards and guidelines: some consideration should be given to maintenance of naturally Fish-Free systems in wilderness.

Response: This section has been changed; see Forest-Wide Standards and Guidelines for Wilderness, Fish and Wildlife subsection, Plan Chapter 4

CLARIFY FOREST-WIDE STANDARD AND GUIDELINE UNDER RECREATION

The standard and guideline (page 4-71) under Recreation states: "Appropriate recreational facilities will be considered for all water impoundment projects." Neither the type of projects nor type of recreational facilities viewed as "appropriate" were defined. Please clarify the intent and the likely impact on Crystal Mountain.

Response: In the Forest Plan, this Forest-wide Standard and Guideline has been reworded to state. "Appropriate recreation facilities will be *evaluated for recreation mitigation for all proposed hydroelectric* projects." This should clarify the type of water impoundment projects intended. The type of facility will vary by site.

PLAN DOES NOT REPRESENT ALL INTENSITIES OF MANAGEMENT AREAS

Intensity 13C is full represented, but where are 13A, 13B, and 13D.

Response: The intensity selected for the Preferred Alternative's Desired Future Condition is displayed in the Forest Plan. This was 13C in the proposed plan; 13D is applied in the Preferred Alternative, Forest Plan. The other intensities in this management area were applied to other alternatives and are described in Appendix D, FEIS. The Plan document contains only those prescriptions selected for the Preferred Alternative.

CHANGE WORDING FOR DESIRED FUTURE IN MA 1A AND 1B

The management prescription for 1A and 1B should prohibit timber management, not just describe it as "not appropriate."

Response: The standard and guideline under element E. Timber does state that there is no scheduled timber harvest. The wording in the Desired Future Condition for MA 1A and 1B (where "not appropriate" appeared) has been changed in the Forest Plan, in response to this comment.

WILL ROADS BE PROVIDED IN MA 1A AND 1B FOR CATASTROPHIC SALVAGE

Under the dispersed recreation prescription, timber harvest may take place in the event of catastrophic events. The roads are generally 1/4 to three miles away; the need for quick access to utilize the salvage is essential and should be added to the prescription.

Response: Under Facilities, Program Element L. for both management areas 1A and 1B, provisions have been made for temporary road development to salvage catastrophic timber loss. These roads are to be returned to a near natural condition the the harvest project is complete.

SCENIC LANDSCAPE AREAS NOT ADEQUATELY DEFINED

Scenic landscapes areas (yellow) with timber managed at less-than-full yield are not adequately defined.

Response: Some rewording has been added to the standards and guidelines for both MA 2A and 2B since the DEIS was released Refer to the Forest Plan, Chapter 4. In addition, foreground (2A) and middleground (2B) are mapped in different colors on the FEIS alternative maps.

STANDARDS FOR LOCATION OF ROCK PITS IN MA 2B IS TOO RESTRICTIVE

We are not convinced that rock pits and stockpile sites must be relocated away from all seen areas, as stated in MA 2B. This seems excessive, and possibly very costly for road building and mining activities.

Response: The prescription for MA 2B (Scenic Middleground) regarding the location of rock pits is not absolute. It reads "should be located" not "must be located."

STANDARDS FOR WINTER SPORTS (3C) NEED STRONGER MINERAL WITHDRAWAL LANGUAGE

The mineral withdrawal language in MA 3C (Winter Sports Areas) should be stronger, similar to specific language in MA 3D (Private Sector sites) section G, a through f. We believe this language to be more appropriate.

Response: We feel the language in MA 3C, Minerals and Geology is appropriate for the goals and objectives of this management area. The standards and guidelines provide for analysis of areas not previously withdrawn, with withdrawal action initiated if appropriate. Any proposed mineral entry must be considered on a case-by-case basis, with appropriate environmental analysis and NEPA documentation. All Forest-wide Standards and Guidelines plus those for MA 3C must be met, prior to any mineral entry.

CLARIFY HOW INTENSITY LEVELS A THROUGH F ARE DETERMINED FOR MA 17

It is not clear how intensity levels 17A through 17F are determined for a specific area mapped 17. We realize this is set at project level planning, but the wording under the management area prescription could be clarified by adding "the intensity level selected for any acres allocated to MA 17 will vary with site productivity, timber type, accessibility by road, and other objectives."

Response: This statement is already included in the Forest-wide Standards and Guidelines, but has now been added to MA 17, Forest Plan.

CLARIFY WILDLIFE MAINTENANCE/ENHANCEMENT IN MA 17

Under Item C. for MA 17: you should refer to how MA 17 relates to maintaining wildlife habitat, not just enhancement of habitat. The Forest-wide Standard and Guideline, page 4-88 seems to apply to all lands The way MA 17 is written it seems to preclude maintenance of wildlife habitat, but it isn't clear.

Response: In response to this and several similar comments, we have added Item C 1.b. which repeats the Forest-wide standard and guideline for maintaining, protecting, and improving habitat of management indicator wildlife species.

UNDER MA 17, WHAT CRITERIA WILL BE USED TO DETERMINE DEGRADATION?

Under Timber Element E.10 c. for MA 17: what criteria will determine or be used to determine the prevention of degradation? What are the selected methods available for site-specific analysis?

Response: All activities must meet at least the Forest-wide Standards and Guidelines, in this case for the soil resource. Specific and quantifiable standards are listed there; see Chapter 4, Forest Plan. Also, refer to the Monitoring Plan, which includes the method of monitoring, frequency etc. for the soil resource Refer to new Appendix I, Best Management Practices, which will be selected and applied for each project; these are site-specific. Chapter II, FEIS includes the mitigation measures that apply Forest-wide, in each alternative.

INCLUDE INFORMATION ON TRANSMISSIONS FACILITIES IN MA PRESCRIPTIONS

Management Area prescriptions should describe whether those areas are classified as avoidance or exclusion areas for transmission facilities.

Response: Avoidance and exclusion classifications have been inserted in the Forest-Wide Standards and Guidelines for Utility and Transportation Corridors, Chapter 4, PLan.

MBS INTERPRETATION OF MMR'S FAR EXCEEDS INTENT OF NFMA

Mt. Baker-Snoqualmie's interpretation of MMR's has resulted in restrictive land-use prescriptions that far exceed what was intended by NFMA.

Response: The National Forest Management Act (NFMA) set legal guidelines for management of the National Forests. The guidelines were interpreted by the Secretary of Agriculture, in cooperation with the Committee of Scientists and with public and professional involvement, to develop regulations. Direction from the Chief of the Forest Service and Region 6 resulted in management requirements (MR's) which reflect the requirements of the laws and regulations in NFMA. The MR direction ensures that minimum legal requirements are applied to all alternatives in Forest plans consistently across all National Forests. MR's exist for dispersal of created openings, water quality, riparian, and wildlife habitat, as required by NFMA. (Refer to 36 CFR 219.27.) The Forest management team strove to select the most efficient prescriptions to meet the management requirements. The explanation of MR's and their development has been expanded; see new Appendix H, FEIS.

MMR'S WERE DEVELOPED WITHOUT PUBLIC INVOLVEMENT

Minimum Management Requirements (MMR's) were developed and implemented without public comment, as required by NEPA and NFMA. The true opportunity costs of the MMR's were bypassed

Thorough public involvement and participation in all phases of planning is required by NFMA. The MBS's lack of involvement, particularly in the development and use of the MMR's is a clear violation of this intent.

Response: The National Forest Management Act (NFMA) set legal guidelines for management of the National Forests. The guidelines were interpreted by the Secretary of Agriculture, in cooperation with a Committee of Scientists and with public and professional involvement, to develop regulations. Direction from the Chief of the Forest Service and Region 6 resulted in MR's which reflect the requirements of the laws and regulations in NFMA. The MR direction ensures that minimum legal requirements are applied to all alternatives in Forest Plans consistently across all National Forests. MR's exist for dispersal of created openings, water quality, riparian and wildlife habitat as required by NFMA.

The general concept of management requirements was presented and questions entertained during a series of Liaison Group meetings held in 1984. Refer to the planning records.

In the DEIS, documentation in Appendix B, Appendix J, and Chapter II of the DEIS explained how the MR's were developed. These documents provided reviewers with the information needed to comment on the development of Management Requirements. Comments received on the draft documents were considered in preparation of the FEIS.

Appendix J - now called Appendix H - has been revised in the FEIS and now includes some of the information from Appendix B related to the selection of the most efficient methods of meeting the necessary requirements. The hydrologic cumulative effects analysis was completed, in response to agency, tribal, and public comments. The resulting method to meet water

quality and riparian management requirements is documented in new Appendix H. Also, see Chapter II, FEIS, Appendix B, and the Forest Plan, Forest-wide Standards and Guidelines for Water Resources and Riparian Areas, Chapter 4.

INCLUDING MANAGEMENT REQUIREMENTS IN EVERY ALTERNATIVE LIMITS DECISION SPACE

The decision space is limited by including MR's in every alternative, thus violating the directive of the National Environmental Policy Act, which requires "examination of a wide range of alternatives".

Response: As stated in Chapter II, the imposition of management requirements in all alternatives considered in detail is a NFMA requirement. One alternative, Alternative NC (No Change), displayed in detail in both the draft and final plans, does not include management requirements. The No Change Alternative emulates the existing Timber Management Plan, with its Potential Yield as the timber output.

OLD GROWTH AND RIPARIAN INVENTORIES NEEDED

Despite having acknowledged a need for old growth and riparian habitat inventories, you plan timber harvesting in both areas. To adequately assess the impacts of this activity, the inventories should be done first.

Response: The information needs section of the Plan has been revised. In response to public comment and in conjunction with the new Integrated Resource Inventory old growth/potential old growth characteristics will be inventoried and mapped. Mapping will be completed in 1990, with the entire inventory completed sometime after that. As new data is available, it will be used in project planning and in the next round of Forest Planning (or sooner, if the Plan is amended or supplemented.)

INFORMATION NEEDS SECTION NEEDS CLARIFICATION

The Information Needs section of the Plan is not clear How important is this information? Where will it eventually be gathered? What will the FS do in the meantime? How will the information be used?

While identifying needs for additional information is very important, the role of this information and the commitment to obtaining it needs to be discussed. Are the projects on-going or planned? Who is responsible and what is the time frame? Some sort of prioritization would also be helpful,

Response: The text of Chapter 2, Information Needs, Forest Plan has been clarified. Many individual "needs" are tied to activities that must be monitored (see the Monitoring Plan, Chapter 5, Plan). The information needs are part of the Forest Plan. As the Plan is implemented and program budgets sought, the information needs will be assessed, prioritized, and added to the various implementation schedules. Until such time, existing data will be used.

INFORMATION NEEDS SHOULD INCLUDE AN INVENTORY FOR RNA

Information Needs should include a current inventory for additional areas needed to fill unfilled Research Natural Area needs

Response: The Preferred Alternative provides for five new or additions to the national network of RNA's. Chapter III, FEIS includes a discussion on the potential for the MBS to supply additional RNA sites.

NEED AN INVENTORY OF THREATENED, ENDANGERED, SENSITIVE PLANTS

The Plan needs to include, in the Information Needs section, an inventory for threatened, endangered, and sensitive plants.

Response: During the life of this plan, the Forest will begin to gather a data base for rare plants. The Information Needs sections, Chapter 2, Plan now reflects this.

MORE RESEARCH ON THE IMPACTS OF LOGGING ON FISH AND WILDLIFE NEEDED

I believe that the FS needs to conduct additional research into the impact of logging on wildlife and fisheries. There are significant gaps in our knowledge; only after serious efforts are made to understand all components of the forest system can I be fully confident that the FS is acting in the national interests.

Response: In response to this comment, the MBS has conducted an extensive cumulative effects analysis (tied to impacts of activities on watersheds and fisheries - see Appendix H), added to the Information Needs section of Chapter 2, Forest Plan, and updated the monitoring plan (Chapter 5, Plan). Additional field monitoring and inventory on the northern spotted owl is documented in Chapter III, FEIS. It is our intent that this Forest Plan, with its planned inventories, research needs, and monitoring, will add considerably to the body of information on the effects of timber harvest activities on fish and wildlife. As we gain new insights, plan amendments will be considered, if necessary; and the Forest Plan will be revised in 10 to 15 years.

FISH DATA IS LACKING

Throughout both the Plan and DEIS, the FS announces its dedication to preserving fish habitat. They cannot achieve this goal without the information they acknowledge they lack. Frequently, supporting data constitutes general literature searches which are not geographically relevant to the MBS.

Response: In response to this (and other similar) comments, the Forest has completed additional research and rewritten the Fisheries sections of *Chapters III and IV, FEIS* *Additionally, the method developed to meet the* water quality and riparian management requirement (hydrologic cumulative effects analysis) is site-specific to the Forest, and serves to address effects to fisheries and fish habitat. Refer to new Appendix H. In addition, there are numerous items listed in the Information Needs section, Chapter 2, Forest Plan that will - when completed over the life of the plan - greatly increase our knowledge. Also, refer to the monitoring plan, Chapter 5, Plan.

SUGGEST CHANGES IN FISH-WATER-RIPARIAN INFORMATION NEEDS

Information Need #10 (Fish-Water-Riparian) should be rewritten to get rid of the impression that +/- 30% is something more than an arbitrary number picked out of the air.

Number 4 needs to be rewritten to omit the double negative, what does a -20% reduction in the percent of vegetation types?

What is the basis for the 15% loss described in Information Need #5?

Information Need #3 appears to be an inventory item but it reads like a research need.

Response: These changes/rewrites have been made in the Forest Plan.

ADD TO INFORMATION NEEDS LIST

I suggest adding the following to Chapter 2, Information Needs: 1) determine the extent of the transient snow zone and its probability of occurrence of rate of water delivery to soil during rain-on-snow conditions; 2) effects on different types of forest cover on rate of water delivery to soil during rain-on-snow conditions, 3) determine under what site conditions foret roads collect and redirect subsurface water; and 4) determine the relative importance of sediment from valley glaciolacustrine deposits reworked by major streams and Type 4, 5 streams in adversely affecting spawning gravels of anadromous fish.

Response: These have been added.

ALTERNATIVE H NOT APPLIED THE SAME ACROSS THE FOREST

Alternative H (DEIS preferred) was not applied to the Forest in the same way across the different Ranger Districts.

Response: The specific allocations do vary from District to District, depending on the land characteristics, soils, capability to provide outputs, goods, and services This does not mean that the goals of an alternative were not evenly applied. The Land and Resource Management Plan is a Forest-wide plan, and the Forest Management Goals and Forest-wide Standards and Guidelines (Chapter 4, Plan) are applied over the entire Forest. Each Ranger District is a unique combination of resources and opportunities, and the acres of each MA and intensity reflect those differences

CALLING LOSS OF LIMITING HABITAT TYPES REVERSIBLE IS AN ERROR

Because of the long regeneration time involved with timber production, loss of thermal cover, travel corridors, calving/fawning areas, and other limiting habitat types cannot be considered reversible.

Response: As defined in FSH 1909 15(05)(15), irreversible is "[A] term that describes the loss of future options. Applies primarily to the effects of use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity that are renewable only over long periods of time." Based on this definition, we feel the regeneration time you refer to (to recreate thermal cover) is not irreversible.

DIVIDING THE FOREST INTO MA'S ARTIFICIALLY SEPARATES THE ECOSYSTEM

The uses for which MA's are designated very often conflict, which presents the major problem in forest planning for multiple use. The division of the natural landscape into management areas artificially compartmentalizes and separates ecosystem components, which actually exist as interwoven parts of a whole. The Pratt River is an example; it's been divided up into mutually exclusive units, that only really exist on paper.

Address the guidelines for coordination of wildlife management with timber management; do the same for sensitive areas for fish.

Response: The Multiple Use Sustained Yield Act defines multiple use as "the management of all the various renewable resources of the National Forests so that they are utilized in the combination that will best meet the needs of the American people." In the alternatives displayed and analyzed in this FEIS, we have developed a number of ways to best meet the "needs" of the people, as expressed in the public issues and concerns Each alternative presents a different combination to meet various ICO's in different ways. Refer to Chapter II, FEIS. Not all uses will occur in every management area, but many activities and uses (deer and elk winter range, for example) will occur across a number of management areas. In MA 14, deer and elk winter range is expressly managed for, but not to the exclusion of many other uses and activities. Enhancement of deer and elk winter range may also occur in - for example - MA 17 timber Emphasis or MA 2 Scenic Viewshed. It is not the **primary** objective of those MA's, but is

still a compatible use. Some activities are not compatible; refer to the specific standards and guidelines for management areas, Chapter 4, Forest Plan. These are also summarized in Chapter II, MA Descriptions, in the FEIS.

The coordination of fish and wildlife management within timber management areas is addressed in the Forest-wide Standards and Guidelines, which apply across the entire forest, and in the specific standards and guidelines for MA 17. Each project will include a site-specific environmental analysis, documented in a NEPA decision document. In this and the analysis file, the specific coordination of, for example, a timber sale plus stream rehabilitation project for fisheries, is documented. Public participation is a key element in project-level planning. Refer to Chapter 5, Implementation, Forest Plan.

NO WORST CASE ANALYSIS PRESENTED

This EIS does not present worse case scenarios.

The MBS admits a clear lack of information on a variety of resource issues that would be affected by the preferred alternative, yet no worst case analyses are *presented. These include native plant communities, listed species of plants* and animals, old growth communities, effects on water quality and fish, etc/

Response: NEPA regulations (40 CFR 1502 22) state that when an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an EIS and there is incomplete or unavailable information, the agency should make it clear that the information is lacking. Refer to these regulations (CEQ, 40 CFR Parts 1500-1508, April 1986) for additional information.

In many cases, lack of information does not necessarily mean that an evaluation of reasonable foreseeable significant adverse effects can not be made, or that the information is essential to a reasoned choice among alternatives in the FEIS. Disclosures of this nature have been done throughout the FEIS, Appendices, and Forest Plan. Refer to Part G. of Chapter IV, FEIS for a discussion of the adverse environmental effects that cannot be avoided (though many can and will be reduced through mitigation).

FS WILL NOT RESPOND TO PUBLIC COMMENTS IN GOOD FAITH

The Forest Service has no intention of responding to public comments in good faith; you have already decided what to do.

Will the final plan be the most popular alternative? How the final is decided is crucial; the draft plan seems to be more of a smokescreen to absorb public comment than an actual proposal which can be commented on.

FS chief Dale Robertson stated recently that half of the old growth remaining in the Pacific Northwest will have to be harvested in the next 50 years. He is quoted as stating; "alternatives just don't exist if you want to maintain the Forest industry in the Northwest." We wonder why the Forest service provides a public comment period when they, at the national level, seem to have determined the outcome anyway.

Robertson's statement reflects an attitude that the Timber industry has the *overwhelming preference, no matter what any opposing arguments may indicate...* I believe that it is entirely probable that the acceptance of public comment is designed to serve as a public pressure "relief valve."

Response: The National Environmental Policy Act Implementing Regulations require an agency preparing a Final EIS "shall assess and consider comments both individually and collectively, and shall respond by one or more of the means listed below: (1) modify alternatives including the proposed action; (2) develop and evaluate alternatives not previously given consideration by the agency, (3) supplement, improve, or modify it's analyses, (4) make factual corrections; or (5) Explain why the comments do not warrant further agency response, citing the sources authorities and reasons which support the agency's position and, if appropriate, indicate those circumstances which would trigger agency reappraisal or further response."

The introduction of this Appendix explains, briefly, the in-depth analysis of public response to the DEIS and displays some of the results. Nearly 12,000 forms, letters, and reports were received, read and re-read, and analyzed. It also explains that the analysis was not a vote count. The overall and site-specific comments were used, extensively, by the Forest Management Team to set a course for the final plan.

The MBS plan has been modified substantially since the draft was issued, primarily in response to public comment. Some of the areas in which we have modified the alternatives/the planning process include:

- corrected or adjusted a number of the "timber technical issues" including: new site index values, new managed and empirical yield tables, new genetic gain values, and more;
- the management requirement for riparian areas and water quality will be met through the method developed in the hydrologic cumulative effects analysis; need for this was noted in comments from agencies and Tribes (see Appendix H);
- developed and displayed in detail in the FEIS an alternative that reflects the goals and objectives of the PLUS organization (Alternative I);

- developed a new Preferred Alternative that responds better to public comments received on the draft plan, including more miles of trails, adjustments in site-specific land allocations (such as Damfino Creek), more wild and scenic rivers recommended, etc.;

- re-evaluated eligibility criteria for wild and scenic rivers, in response to public and organization comments; this resulted in 30 rivers recommended as suitable for designation in the National System in the Preferred Alternative; and more.

Refer to Chapter II, FEIS plus the first page of each chapter in that document - "Changes Made Between Draft and Final" - for more detail. In addition, we are committed to continued, meaningful public involvement as we begin plan implementation, and project-level environmental analysis.

TIMING OF PUBLIC REVIEW PERIOD IS POOR

The timing of the public review of this plan is not conducive to field study by members of the public. Snowpack over most of the MBS this time of year precludes visiting areas, thus we are severly limited in the quality of our response. Site-specific comments should be accepted through the fall for the purposes of identifying more specific "boundaries" between management areas.

The time line for public comment is too short and has been in the winter when access to independent study was not possible.

Response: Based on public requests, the Regional Forester extended the review period from 90 to 115 days, a time frame that was felt to be adequate Refer to the Forest Plan, Chapter 5, for a discussion on the boundaries of management areas. The boundaries for management areas that are legally established and described, such as wilderness, NRA, Skagit Wild and Scenic River, and Alpine Lakes Management Unit are fixed. The exact boundaries of other management areas will be field verified, during plan implementation. During site-specific project planning, there will continue to be opportunities for public involvement, from scoping of issues, to providing information for alternatives. Again, refer to the Forest Plan, Chapter 5, Implementation Direction.

THE PUBLIC WAS NOT VERY WELL INFORMED OF MEETINGS

The method of securing input on these proposed alternatives was very limited. Little publicity was given, meetings were held but not well advertised. The public should be kept better informed in simple, direct language

Response: Refer to the Summary of Public Participation, Appendix J for a discussion of the media activities, newspaper press releases, etc held to advertise the 11 open houses and other activities In addition, a Public Summary of the DEIS was printed as well as a small, fold-out brochure "Forest Planning...A Blueprint for the Future" in an attempt to present the draft plan and EIS in simpler language While we did not hold hearings or accept oral input, cards, reports, letters, and response forms were received from nearly 12,000 respondents. The public comment period was extended, in response to public requests.

WE WANT TO WORK WITH THE FS TO DEVELOP AN ALTERNATIVE

We request, by this letter, an opportunity to work with the Forest planning team, before publication of a final plan, to fully develop a viable, implementable alternative based on the broad concepts outlined in the PLUS Alternative.

Response: This was accomplished, during the spring of 1989. Detailed documentation of these working/mapping meetings is available in the planning records. To be fully implementable, the alternative was to meet all laws and regulation (including management requirements (as per 36 CFR 219.27)) was to utilize the same management areas and prescriptions as the other alternatives. The results of this effort are displayed in the FEIS as Alternative I.

NO PUBLIC REVIEW AND COMMENT ON THE VEGETATION MANAGEMENT AND SPOTTED OWL EIS

The Plan and DEIS do not consider the environmental impacts of the vegetation management DEIS or the proposed Pacific Northwest regional guide spotted owl supplement. To the extent that either of these outside environmental impact statements impact the MBS Plan and DEIS at a later date, the public has been denied the opportunity for meaningful public review and comment.

Response: Appendix H of the DEIS did discuss the potential effects of the Spotted Owl SEIS on several alternatives. The potential effects of the Managing Competing and Unwanted Vegetation EIS were discussed in Chapter III of the DEIS, pages III-34, -164, and -167. Both Regional EIS's had extensive public review periods and opportunities for questions/answers at public meetings held throughout Oregon and Washington The Record of Decision, Managing Competing and Unwanted Vegetation FEIS has been published, and this plan will meet the conditions of that document, plus the mediated agreements, as discussed in Chapters I and III, FEIS. In the Preferred Alternative, spotted owl habitat is inventoried, identified, and protected following the direction in the Supplemental Final EIS amending the Regional Guide.

WILL THE PUBLIC BE INVOLVED IN PROJECT PLANNING?

Will the public be involved in the early stages of project Planning ?

Response: Yes. All proposed projects are subject to an environmental analysis, as per the National Environmental Policy Act. The first step in this process is "scoping", which requires the responsible official to inform interested and affected individuals, agencies, Tribes, adjacent landowners, etc. about the proposed project and invite participation in the planning process. If a person is concerned about specific areas or types of projects, they may write to the District Ranger or Forest Supervisor and request notification of any projects that might fall within their area of concern.

STATE NEEDS TIME TO REVIEW STATE-WIDE IMPACT OF ALL WASHINGTON FOREST PLANS

Do not adopt the Forest Plan until the State has had the time to comment on the state-wide aggregate impact of all Draft National Forest Plans for Forests in Washington, and to make recommendations.

Response: The 90-day review period on the MBS plan was extended to 115 days, in response to public requests. The Forest management team has made a number of presentations to various State agencies since the DEIS was released (Refer to Appendix J, Public Participation since the DEIS.) Included in these was a briefing for Brian Boyle and officials at the Department of Natural Resources regarding the analysis completed between draft and final plans for a better method to meet water quality and riparian management requirements We feel that since the DEIS and Proposed Plan were released, in December 1987, there has been adequate time to receive all comments and meet and work with all interested State agencies. As of March, 1990, no state-wide aggregate response has been received.

THE FORPLAN RUNS FOR ALTERNATIVES SHOULD HAVE BEEN AVAILABLE TO THE PUBLIC

Prior to publication of the draft EIS, only the FORPLAN computer runs for benchmarks were available The same was not true for alternatives The MBS, in following regional policy, prohibited the public from examining the FORPLAN computer runs for alternatives, which are the heart of Forest Service assertions about the level of sustained yield and the economics of timber production To provide informed comment on these important issues requires a computer programming expert to interpret reams of printouts. We do not think NFMA was designed to put the public and local communities at the mercy of a computer programmer.

The short, 90-day period in which to respond to the MBS draft documents does not provide the public with any opportunity to determine to what extent the FORPLAN system and forest FORPLAN model have actually resulted in formulation of reasonable alternatives and maximizing long-term net public benefits in an environmentally sound manner (required 36 CFR 219 1)

Response: The benchmark runs were available because they were part of a previously released document, the Analysis of the Management Situation. Refer to "Steps in the Planning Process" DEIS, Chapter I (also FEIS, Chapter I) The FORPLAN runs for the DEIS are necessarily part of that document. Prior to publication and release of the DEIS, all FORPLAN runs were considered "pre-decisional, working papers "

The planning team held a number of meetings with the Liaison Groups (see Appendix A, FEIS for description of these groups) in 1981, and the agendas included discussion of FORPLAN and our forest plan model. Documentation is available in the planning records

After the release of the DEIS, the FORPLAN runs for alternatives were made available to the public. The public review period was extended to 115 days, in response to public requests. There does exist, outside of the Forest Service, a considerable knowledge of FORPLAN, and we received a number of comments that focused on the FORPLAN model We did attempt to answer all FORPLAN/modeling questions at the series of open houses (informational meetings) held throughout the Puget Sound area in February, 1988, after the DEIS was released

PLAN INCORRECTLY MAPPED MOUNTAIN HEMLOCK; INCLUDE IT IN TENTATIVELY SUITABLE

The following modifications should be made to the tentatively suitable timber base: the area to the ridge top in parcel MK is suitable, as is the remainder in Section 12,T.38N., R.7E Also Sections 3 and 10 of T.37N.,R.6E, and all of the Loomis Mountain area are suitable, but are not shown as such.

Response: Current information indicates that these sections are unsuitable as mapped. Continued field verification of timber suitability is an integral part of forest plan implementation.

THERE ARE INCONSISTENCIES BETWEEN TABLES AND MAPPED AREAS FOR GLACIER PEAK

The table on page C-122 shows parcel LI with 190 acres of moderate development, but the map shows all of LI allocated to MA 1AB. The same discrepancy may also apply to parcel LJ

The table on C-114 shows 105 acres of parcel AC allocated to "moderate development while the Alternative H map shows them as MA 1AB.

Response: The table entry for parcel "LI" was in error; the area is allocated to MA 1AB in Preferred Alternative. Both the table and map for Parcel LJ was correct. The map for parcel AC is correct; the table was in error. These tables have been reformatted (to show acres allocated by alternative by management area) and the errors corrected in Appendix C of the FEIS.

MAP SHOWING OLD GROWTH, TIMBER SUITABILITY IS INCORRECT

The old growth map (your definition) shows an old growth stand from the edge of the Mt Baker Highway to nearly the ridge-top of Church Mountain, and that this slope is also tentatively suitable. Slope and soil conditions (as evidenced by the regular flooding and earth slides in Fossil Creek) show the sensitive character of this area. There is similar flawed information for the slopes of Dock Butte, and the west and east shores of Baker Lake.

Response: At the scale of the old growth and tentatively suitable maps, it is difficult to discern the actual boundaries. In the areas you mention, there is old growth in a number of sections. The area immediately around Church Mountain is not tentatively suitable. A large-scale Control Map will be prepared as one of the first steps of Plan implementation. In addition, the new old growth inventory - part of the Integrated Resource Inventory - will be completed in fall, 1990.

UNSUITABLE LAND IS ALLOCATED TO MA 17

I am concerned that the preferred alternative includes areas as MA 17 Timber Emphasis that are shown as unsuitable on the timber suitability map.

In Jackman, Thunder, and Watson Creek area alone there is about 2.5 square miles of MA 17 in mapped unsuitable land. Have you truly removed the unsuitable areas in MA 17?

Response: There may, in fact, be some acres of unsuitable land within the boundaries of MA 17. Not every acre allocated to MA 17 will necessarily be harvested; parcels of highly unstable soil or rock cliffs - which will be identified at the project-level planning stage - will not be harvested. Where small parcels of unsuitable land were surrounded by suitable land that, to meet the goals and objectives of the alternative, were allocated to MA 17, the unsuitable parcels were included. However, these lands will not be harvested. Generally, allocations of 20 or 50 acres of dispersed recreation were avoided, for practicality of management. In the Preferred Alternative, most of the Jackman, Thunder, and Watson Creek area is now allocated to management area 1A Primitive Dispersed Recreation. Refer to Chapter III, FEIS, Commercial Timber section for a discussion of the timber land suitability classification

DISCREPANCY IN MAPPING TIMBER RESOURCES FOR THOMPSON CREEK AREA

The maps with the Alpine Lakes Management Plan show Thompson Creek and all of the Lower Pratt River (area adjacent to the river) as General Forest and within the commercial forest base. The North Bend Ranger district is proceeding with timber sales based on this plan. However, the Draft Forest Plan maps show much of these areas as unsuitable. Which map is correct?

Response: To some extent both maps are correct. The Alpine Lakes Plan mapped areas where timber harvest was generally appropriate. The Timber Component map broke the commercial forest land into standard, special, and marginal components. The Forest Plan has taken this planning one step further by mapping timber suitability. The marginal timber component lands along Thompson Creek are not suitable for timber harvest under the Forest Plan. For the Lower Pratt, planning is still at a very cursory stage, with only broad, general areas identified for possible timber harvest. Due to the map scales for both Alpine Lakes and the Forest Plan, it is hard to get very site specific, and neither of these maps are field verified. Field verification for timber suitability is an essential step in the process.

WINTER RANGE MAP INACCURATE

In T.37 N., R.9 E., on the east side of Baker Lake, the deer and elk winter range map appears to be incomplete.

Response: District wildlife biologists updated and remapped deer and elk winter range between draft and final. As the Plan is implemented, and the Integrated Resource Inventory completed (1995), additional corrections may be necessary.

THE MR MAP FOR WILDLIFE SHOWS LESS OLD GROWTH THAN IS ON-THE-GROUND

The MR map for wildlife shows less mature/old growth habitat than we think is actually on the ground This should be adjusted, based on ground-verified information, as available.

Response: Changes made for the FEIS included updated the old growth information for old growth harvested through 1988. As these harvest units would not show at the scale of the resources maps, the updates have not been made on the old growth resource map. The accelerated old growth

inventory will be completed by fall of 1990, and amendments/corrections to the plan will begin at that time.

CLARIFY THE MOUNTAIN GOAT HABITAT ON THE MAP

You should clarify the mountain goat habitat shown on the Deer and Elk Winter Range and Mountain Goat Habitat map. Is this only winter range? Also, change the name of the map to clarify this.

There are inaccuracies in the mountain goat habitat map; specific sites where goats have been observed include the back side of Three fingers, Big Bear and Liberty Peaks. Observations were made here in July, 1985 by a study team representing the Washington State Department of Wildlife.

Response: As noted in the Forest-wide Standards and Guidelines, and in the MA 15 prescription, standards and guidelines, current and historically used mountain goat winter range is in the process of being identified and verified As actual winter range is identified, the Plan may be amended and the standards and guidelines for MA 15 Mountain Goat Habitat applied.

The FEIS wildlife map includes that mountain goat habitat which is optimal thermal cover, plus cliffs. These areas may be used year-around.

MA 1A-B SHOULD BE DIFFERENT COLORS; MAP AREAS FOR DEER AND/OR GOATS CONFUSING

Probably the single most confusing portion of the Public Summary was the maps, which attempted to depict management use by color code. Prescription 1A and 1B (which allows snowmobiling) are shown in the same color This glitch renders the packet virtually useless to the snowmobiler.

I couldn't tell which of the orange areas (for deer and/or goats) would allow timber harvest and which would not; the symbols were identical.

Response: In response to a number of comments from the public, we have improved the color scheme for the FEIS alternative and resource maps. MA 1A and 1B are shown in different colors on the alternative maps. Also, MA 14 (Deer and Elk Enhancement - which was 14B in the DEIS) plus 15A and 15B (Mountain Goat MR and Mountain Goat Habitat Improvement) are now shown in different colors.

DEVELOPED RECREATION SITES SHOULD BE MAPPED

The maps indicate that existing developed recreation sites...are not mapped due to small acreage. Given the importance of these sites to large segments of the public, they should be large and easy to identify on all maps.

Response: Unfortunately, the scale of the alternative maps makes mapping sites the size of most developed campgrounds, picnic areas, trailheads, etc. difficult to impossible. As we begin to implement the Forest Plan, the team will prepare a "Control Map" of the Preferred Alternative; this map will be produced at a larger scale than the current 3/8 inch = 1 mile. At the larger scale, developed sites will be mapped. In addition, all existing campgrounds, etc. are shown on the Forest Recreation map, available at all Forest Service offices in the Puget Sound region.

ALL TRAILS SHOULD BE MAPPED

Under the requirements of full disclosure, we request that you publish a map of all system trails, all known abandoned trails, and all new or rehabilitated trails proposed in the Forest Plan.

Response: The proposed new trails inside Wilderness is shown on the alternative maps accompanying the Forest Plan. A map of all system trails, plus proposed trails is part of the Planning Records, available at the Forest Supervisor's office. As we complete the control map for the Forest Plan, this trail map will be incorporated. Additionally, all trail construction and reconstruction projects will include appropriate public involvement and follow the NEPA process.

MAPS SHOULD SHOW ROAD CLOSURES

Showing proposed road closures on the alternative maps will be very useful. Also, note whether the road will be simply gated or obliterated/revegetated, so that it more easily returns to the natural landscape.

Response: Which miles of particular roads, by alternative, has been added to the text of Chapter IV, FEIS. On the maps, these closures can be determined by comparing unroaded management areas (such as 1A or 1B) and the location of the named road. Any more graphic description is impossible at the scale of the alternative maps. The 25 miles of system roads that will be closed in the Preferred Alternative because of land allocations will be returned to the planned resource use (such as semi-primitive, nonmotorized recreation) Refer to the Forest Plan, Forest-wide Standards and Guidelines for Roads, Chapter 4 Seasonal road closures (to protect wildlife habitat, for example) will usually be accomplished by a gate or sign.

CLARIFY ALTERNATIVE C MAP

The Alternative C map appears to have several roaded areas allocated to MA 1A and 1B; was this the intent?

Response: Yes; see the response to the previous comment.

PROTECT GREENWATER TRAIL AND LAKES AREA

The Greenwater Trail and Greenwater Lakes area are not protected as an entrance to the Norse Peak Wilderness. Congress directed the Forest Service to acquire these lands (1984 Wilderness Act) to protect the trail.

There is no indication in the DEIS of the roadless land along Greenwater Lakes. This qualifies and is all federal ownership, due to provisions of the Washington State Wilderness Act. This was enacted specifically to provide for a protected trail corridor outside the wilderness.

Response: In the Preferred Alternative, this area has been allocated to MA 1B, Semi-Primitive Nonmotorized Recreation, a change from the draft plan. Refer to the standards and guidelines in Chapter 4, Plan for MA 1B; there is no scheduled timber harvest or road construction in MA 1B.

INTEGRATE THE ALPINE LAKES PLAN BETTER

You should integrate the Alpine Lakes Management Area Plan better, showing similar colors as the other allocations on the maps.

> **Response:** Because the allocations in the Alpine Lakes Management Area do not "fit" those in the Forest Plan, we choose to show the Area (MA 27) all in one color. However, on the FEIS maps, the allocation codes (such as GF for General Forest) from the Alpine Lakes Plan are shown.

GIVE MORE VISUAL PROTECTION TO CARBON RIVER AND MOWICH RIVER ROAD

In the final plan, the Carbon River and Mowich River roads should be given more visual protection.

> **Response:** The Carbon River road corridor has been reallocated to MA 1D, Roaded Natural, which will provide higher visual protection than provided in the draft plan.

DON'T HARVEST TIMBER IN THE MT. BAKER NRA

The Forest Service cannot be trusted to manage areas without detailed and specific instructions. Here we have an area that clearly was deleted from any wilderness consideration for the purpose of retaining a snowmobile route to the summit of Mt. Baker. We do not support the interpretation that Congress gave the Forest Service the flexibility to harvest timber in the National Recreation Area.

> **Response:** The Washington Wilderness Act of 1984 states that "The Secretary shall administer the recreation area in accordance with the laws, rules and regulations applicable to the national forests in suck a manner as will best provide for (1) public outdoor recreation (including but not limited to recreation use); (2) conservation of scenic, natural, historic, and other values contributing to public enjoyment; and (3) such management, utilization, and disposal of natural resources on federally owned lands within the recreation area which are compatible with and which do not significantly impair the purposes for which the recreation is established." Congress clearly intended, when it established the NRA, that outdoor recreation was to be the preeminent use in the NRA, and other uses (including timber harvest) could be allowed if they did not significantly impair use of the recreation resource or other natural values of the NRA.
>
> There are (in R2MAP acres) 8,740 acres within the NRA; approximately 443 acres are tentatively suitable (the most acreage within which timber harvest activities **could** be proposed). The Standards and Guidelines in the management prescription for the MA 4, Mt. Baker NRA, coupled with the site-specific analysis that will accompany any project-level activity in the NRA, will ensure that those resources for which the NRA was established will not be significantly impaired.

CONSIDER MAINTAINING AREAS NEAR MT. RAINIER NATIONAL PARK AS ROADLESS

Consider maintaining roadless areas in the following locations near Mt. Rainier National Park: 1) the area south of the Carbon River Road (1 3/4 miles in length); 2) the area contiguous to the park boundary from the Carbon River to the wilderness; 3) Section 31, small part of Section 36 east of the wilderness boundary; 4) area due north of Northern Lakes; 5) area contiguous with the park boundary along Huckleberry Creek, Lost Creek, and up to Fawn Creek; and 6) area along the east boundary in Sections 3 and 11.

Response: In the Preferred Alternative, the sites listed above have been allocated to the following management areas: 1) this area is in MA 1D, Roaded Natural; 2) the area south of Chenuis Creek is in MA 1B, Semi-Primitive Nonmotorized [no timber harvest or road construction]; 3) Sections 31 and 36 are allocated to MA 17, Timber Management Emphasis; 4) in this area, land is allocated to MA 17, 1B, and 2B Scenic Viewshed - refer to the Alternative J map; 5) Huckleberry Creek to Lost Creek is in MA 2B Scenic Viewshed with the rest of the area allocated to MA 17, 1B, 2B, 15 Deer and Elk Winter Range Enhancement, and MA 8 Special Area (Mather Memorial Parkway); and 6) the west half of Section 3 is in MA 8 Special Area (Mather) with the rest of this area either allocation to MA 1B Semi-primitive Nonmotorized or 2A Scenic Viewshed.

Doug MacWilliams
Forest Supervisor
Mt. Baker-Snoqualmie National Forest
1022 First Avenue
Seattle, Washington 98104

Dear Mr. MacWilliams:

I would like to congratulate you on your excellent work writing the Mt. Baker-Snoqualmie National Forest Plan. I know from personal experience the difficulties of satisfying competing demands. I am confident you and your staff will produce a document that strikes the proper balance for sustained yield and true multiple use of the nation's resources.

I would like to address an issue that has been brought to my attention and pass along my comments to you. The recently proposed Backcountry Areas and Trails 2000 concepts are, I believe, excellent programs that should be given careful consideration in the Forest Plan. These programs promise to provide the casual forest visitor with a valuable recreational experience As the population of Washington state increases and as the tourist industry grows, greater demands will be placed on the National Forests. Rebuilding old trails and adding new ones will alleviate overcrowding and will help disperse visitors over a larger area

Please keep the Trails 2000 and the Backcountry Areas in mind as you work to develop a final draft of the Forest Plan. I look forward to working with you on this important concept

Sincerely,

Brock Adams

Mr Doug MacWilliams, Supervisor
Mt Baker-Snoqualmie National Forest
1022 1st Avenue South
Seattle, Washington 98104

Dear Mr. MacWilliams:

I am writing to express some of my priorities and concerns for the Mt. Baker-Snoqualmie National Forest As you are well aware, thousands of Washington residents enjoy the trails in our National Forests as a means of outdoor recreation. Trails are essential for hiking, backpacking, fishing, hunting, horseback riding, and many other pursuits.

Washington is one of the fastest growing states in the nation, and many are drawn here by the unique quality of life that the Pacific Northwest offers. There is no better way to enjoy this outdoor setting than by trail. Unfortunately, the supply of trails so critical to outdoor recreation has been dwindling for years In the past several years, money for repairing and maintaining our trails system has been pretty tight

The result has been a significant deterioration both in the quantity and quality of trails in our parks and forests. Some trails are now beyond maintenance and thorough reconstruction is needed Of course, the result of this decay has been fewer trails for outdoor enthusiasts to enjoy. This loss of trails is detrimental not only to outdoor enthusiasts, but to the thousands of others who gain their livelihood in the recreation industry.

Recently, the Washington Trails Association has proposed the creation of Backcountry Areas, public land set aside for non-motorized trail recreation. New and rebuilt trails in Backcountry Areas would provide our citizens with the opportunity to walk and hike in a variety of settings, from low elevation streams to high ridge tops, where a variety of natural features can be enjoyed These features include majestic trees, inspiring mountain peaks, and beautiful meadows I am pleased to endorse both the concept of Backcountry Areas and I encourage you to give this plan full consideration as you prepare your final Forest plan.

I am also concerned about efforts to reverse Mt. Baker-Snoqualmie's progressive and fair policy on conflict between motorized and non-motorized users. I believe that most ORV users are law abiding, courteous and sensitive to the concerns of hikers and horsemen However, in cases where conflict exists, appropriate steps have not always been taken to adequately address the legal rights of non-motorized users. Your forest is a notable exception to this condition.

J-518

ORV enthusiasts and non-motorized trail users should be able to enjoy Washington's beautiful and serene environment without the unnecessary conflicts that currently exist in many of our national Forests One cause of this conflict is the failure of the multiple-use trails designation Hikers simply do not use trails where ORVs are allowed. Thus, multiple-use trails become single-use trails at the expense of hikers

The ORV policy of Mt. Baker-Snoqualmie National Forest reduces conflict better than any other Forest in Washington State. Its guidelines come closest to the letter and spirit of the Executive Orders and C.F.R. statute Section D of its 1986 Management Plan states that the Forest's policy should be to "insure that Off-Road-Vehicle (ORV) use, including snow type, is managed to mitigate their impacts on other resources, promote safety, and minimize conflict with other uses " As you continue work on your forest plan, I encourage you to follow the 1986 guidelines on conflict as closely as possible.

When we get together later this month, I would also like to discuss the proposed Cascade exchange involving U.S. Forest Service and Plum Creek Timber Company lands. I understand that you have some serious reservations about the legislative nature of this proposal and I am interested in hearing your views.

It would also be useful to discuss other issues in the proposed alternative forest management plans for the forest, including your thoughts on timber production from the Pratt River area, relative to its value as a recreational area.

Sincerely,

ROD CHANDLER
Member of Congress

To Whom it May Concern

As a member of the Washington State House of Representatives' Natural Resources Committee, I have become increasingly concerned about the retention of old-growth timber When taking the entire ecosystem into consideration, it is evident that old-growth timber should be left standing for the proliferation of birds and wildlife

I am also appauled at the decresing amount of dollars which the Federal Government is accepting for the sale of timber from the sale of Forest Service lands It seems that the amount accepted is much less than the current open market pricing I understand that, by the time the Forest Service develops logging roads, the Government actually loses money on the sale of Forest Service timber

I recently came accross some shocking statistics regarding the Forest Service's 1986 budget allocations for recreation and wildlife, and fish protection It seems that only 10% was directed for recreation and a smaller percentage for protection purposes Perhaps the Forest Service should re-evaluate some priorities

Specifically, I would like to urge action on the following issues

1 Expansion of the size of the Spotted Owl habitat areas to 45,000 acres in order to fully protect them from logging
2 Support of the concept of protected corridors of old growth timber which link areas of habitat.
3 Enforcement of a moritorium on logging in the Cedar River Watershed until full protection of the Spotted Owl can be guaranteed
4 Reduction of the annual allowable sale quantity of timber to at least 125 mullion board feet.
5 Finally, I would like to urge support for the conservationists' Alternative G I oppose the Forest Service's preferred Alternative H for overemphasizing timber production to the detriment of old-growth habitat, roadless recreation, and fisheries

Recreation and Fisheries are both extrememly important to the citizens of the State of Washington for economic and astetic reasons Forest planning can either protect or destroy our valuable natural assets I urge you to again, take great care and consider the conservationist's alternatives

Sincerely,

GRACE COLE

Mr. J.D. MacWilliams
Forest Supervisor
Mt. Baker-Snoqualmie N.F.
1022 First Avenue
Seattle, WA 98104

J-520

Dear Mr. MacWilliams.

I am writing to provide an official comment regarding the Mt Baker-Snoqualmie National Forest Land and Resource Management Plan. I would like to thank you for extending the comment and review period until May 2nd, which provides a greater opportunity for citizen involvement

I would like to start by reiterating that, as a public official, my policy is to develop the public lands in such a manner as is consistent with protection and maintenance of the resource. No one questions the importance of the timber industry to Washington State, both as a source of timber products and jobs The real questions are how much of the public lands to allocate to the timber industry, what timber harvest levels are consistent with sustainable yields, and to what extent the timber industry should be subsidized by the American people

I support multiple use of the national forests, by which I would include motorized and non-motorized recreation, fisheries, wildlife, and watershed protection, as well as mining and forestry activities. Although the U S Forest Service acknowledges all these other activities, it treats everything as subsidiary to logging. Over the past decade, the Forest Service has spent an average of about $200 million on logging roads, with an additional average $100 million spent on logging roads through the Purchaser Credit Program. Funding for recreational facilities, trail construction and maintenance, and fish and wildlife enhancement have been paltry in comparison.

I believe that Mt. Baker-Snoqualmie N F , located adjacent to a fast-growing urban area, has special, non-timber, obligations The population of the Puget Sound area has more than doubled since 1950, and is projected to double again by the year 2020 At the same time, people's interest and involvement in outdoor activities have increased dramatically A 1986 State of Washington study found over 700,000 households in our state that hike or backpack on a regular basis Businesses that produce camping equipment and other outdoors equipment now account over $300 million in sales in the Puget Sound area alone, and directly employ several thousand people. I have seen estimates that 26,000 jobs are directly dependent on Mt Baker-Snoqualmie N F -- but only about 4,000 of these jobs are timber-related, while recreation, fish and wildlife related uses account for the rest. It is important that the Forest Service acknowledge these facts and adjust its policies accordingly

An excellent way for the Forest Service to recognize the importance of recreational interests would be to endorse the Trails 2000 proposal. In Mt. Baker-Snoqualmie N.F , the amount of recreational trails have declined from about 2,000 miles in the 1940's to less than 1,400 miles today. The Preferred Alternative Management Plan would involve further destruction of 200 miles of trails. According to your own estimates, during a summer weekend, over 20,000 hikers use Mt. Baker-Snoqualmie trails. Your agency has identified 48 areas in alpine meadows and wetlands that suffer from overuse and resulting environmental damage. This is a serious issue that needs to be addressed in the Management Plan. I hope that you will work to restore and maintain existing trails, increase trail mileage by new construction, and protect areas remaining roadless areas that are suitable for additional trails. The Washington Trails Association has identified five such areas: Helen Butte/Jackman Creek, Mt. Dickman, Eagle Rock, Ragged Ridge, and the Pratt River valley. I think that the Forest Service should carefully consider these proposals

I am concerned about the level of the timber harvest from the National Forest System As you are probably aware, I have asked the General Accounting Office to examine the assumptions used by your agency in determining the Allowable Sale Quantity (ASQ) off the public lands I am concerned about the fact your calculations are based on use of a single computer model developed for Douglas Fir forest between 3,000' and 4,000' elevations ("Douglas Fir Simulated Intensive Management" model), which is then extrapolated to other forest types and elevations I am also concerned about the fact your models are based on assumptions about regrowth, including 10-15% enhancements based upon genetics and 10% enhancements based upon increased use of fertilizers and pesticides It is disturbing that there is little actual field data to support such assumed enhancements Under the circumstances, I believe it would be prudent to reduce the harvest level to 128 million board feet (Alternative G)

I believe that the Forest Service needs to conduct additional research into the impact of logging on wildlife and fisheries There are significant gaps in our understanding of how logging affects wildlife, including the change to the single canopy-level of second growth forests, the loss of cavity nesters, the loss of herbaceous ground cover and shrubs, the changes in lichen and fungi, the effect of slash and debris on regrowth, the relationship of landslides to stream siltation, and how the loss of canopy shade trees changes stream water temperature and affects stream fauna Only after serious efforts are made to understand all components of the forest system, can I be fully confident that the Forest Service is acting in the national interest.

Spotted owls are only one example of how little the Forest Service values non-timber concerns. Recently the Fish and Wildlife Service decided not to list the spotted owl as an endangered species. There is, however, certain evidence that this was a political decision, not a scientific one. The bulk of scientific evidence strongly suggests the spotted owl is in great trouble. The State of Washington considers the spotted owl to be an endangered species, and recommends allocating 4,500 acres to protect each nesting site I am deeply concerned about how your agency proposes to protect the spotted owl.

First, you only allocate 1,000 acres per SOHA. Second, you have clearly chosen to place SOHAs in higher elevation sites which do not interfere with logging operations. The result is that only 24% of the 84 SOHAs actually contain spotted owls! Finally, there are no protected corridors between areas of suitable owl habitat You plan would clearly doom the owl to extinction

I think it is extremely important to protect the few remaining lowland (below 2,500') tracts of old-growth forest. Recent studies by forest ecologists at the University of Washington indicate that over 90% of the Pacific Northwest's original old-growth forest has been logged, and that several of the important lowland communities are virtually extinct. One forest ecologist at U.W has contacted me with the following information· looking for stands of Douglas Fir that are greater than 450 years and greater in size than 100 acres, he found exactly 12 such stands in the State of Washington 4 in Mt. Baker-Snoqualmie N.F., 2 in Olympic N.F., 1 in Gifford Pinchot N.F., and the rest in National Parks. These areas should clearly be protected I call upon the Forest Service to put their resources into an immediate search for the few remaining tracts of ancient trees, and protecting these, rather than quibbling about the definition of "old-growth forest" so that these areas can be cut. I believe you should use the more restrictive definition of old-growth that was formulated by your own Pacific Northwest Research Station.

J-521

I also call upon you to recognize the value of protecting roadless areas in the Helen Butte-Jackman Creek area, the Mt. Dickman area, the Eagle Rock area, the Ragged Ridge area, and the Pratt River Valley area There are Special Interest Areas that deserve protection, including the Twin Sisters Botanical Area, the Naches Pass Historical Area, and the Baker Lake and Monte Cristo Scenic Areas. In addition, the Scenic Corridor of the North Cascades Highway deserves enhanced protection.

The public is extremely interested in protecting Washington's riparian areas and wetlands. Several of the best candidates for Wild & Scenic River status are found within Mt. Baker-Snoqualmie N.F. You should give increased attention to this list, which includes· the Nooksack River (North, South, and Middle Forks); the tributaries of the Skagit and Sauk Rivers (Noisy, Diobsud, Illabot Creeks and Baker, White Chuck and Suittle Rivers); the Stillaquamish River (North and South Forks, Canyon Creek, and Boulder River), the Skykomish River (North Fork, Rapid, Tye, Miller, Foss, and Beckler Rivers), the Snoqualmie (Middle Fork, Pratt, and Taylor Rivers), Carbon River; White River; Clearwater River, and Greenwater River.

Thank you for your consideration.

Sincerely,

Mike Lowry
Member of Congress

Mt. Baker-Snoqualmie National Forest
Attention Public Affairs
1022 First Avenue
Seattle, WA 98104

Dear Mt. Baker-Snoqualmie National Forest Staff:

My family has been hiking in the Mt. Baker-Snoqualmie National Forest since the 1960's. Last summer we took a family hiking trip through the area to Glacier Peak. This forest deserves protection from destructive logging practices and excessive road building. It is too important both as priceless wildlife habitat and for recreation to be opened up to more logging and roads.

I support the Alternative G of the draft forest plan because it addresses the growing need for more recreational opportunities in the Forest and also balances the needs of wildlife with timber production. The Forest Service's Preferred Alternative H, on the other hand, does not adequately balance timber production with recreation and wildlife. In this alternative there will be over 180 miles of new road construction and logging in areas that are now roadless and protected for wildlife and recreation.

It is important that special areas within the Forest be protected. These areas include Monte Cristo and Baker Lake Scenic Areas, Naches Pass Historic Area and Twin Sisters Botanical Area In addition, the old growth areas of the Forest should be protected for spotted owl and other wildlife habitat. Spotted owl habitat areas should be expanded to 4500 acres with protected corridors linking them. Roadless areas should also be preserved, especially for recreation

Because of the importance of recreation, both to the economy of the area and to the many hikers within the state, trail construction and reconstruction should be increased. Hiking trails should be off limits to all motorized, off-road vehicles and should not be re-routed to facilitate increased logging.

I fully support the Forest Service's plan to request wild and scenic river status for five rivers in the Forest. There should be, though, other river and river segments also included in the recommendation, including the middle fork of the Snoqualmie, all of the forks of the Nooksack, the Stillaguamish the Skykomish, the Skagit and the Sauk, as well as rivers originating on Mt Rainier, the Carbon and the White and their tributaries.

In order to give the much needed increased emphasis on wildlife and recreation, the Forest Service should decrease its logging in the Forest to 128 million board feet The public is ready and eager for this change in priorities within the Mt. Baker-Snoqualmie National Forest.

Sincerely,

Jolene Unsoeld
State Representative
22nd Legislative District

May 2, 1988

Doug MacWilliams
Forest Supervisor
Mt. Baker-Snoqualmie National Forest
1022 First Avenue
Seattle, Washington 98104

Dear Mr MacWilliams

We thank you for the opportunity to comment on the Draft Environmental Impact Statement regarding the Proposed Land and Resource Management Plan for the Mt. Baker-Snoqualmie National Forest The management of the Forest will affect the citizens of Seattle in many ways. Our concerns with the proposed plan fall into two areas elements of the forest plan that might affect the plans and operations of the City's water and electric utilities, and aspects of the plan that are of considerable interest to the citizens of Seattle, who use the National Forest for recreation, education, and many other purposes.

VALUES OF THE NATIONAL FOREST

The Mount Baker-Snoqualmie National Forest contains some of the closest undisturbed environments to Seattle, and is very important to our citizens as a natural area with substantial scenic beauty and ecological value. Many of Seattle's citizens enjoy the solitude, lush forests, and diverse animal life of the Mt. Baker-Snoqualmie National Forest. Many fish in its numerous streams and lakes, hike in its forests and meadows, or raft on its marvelous rivers. The Forest has many special wildlife habitats that are worthy of protection. The Mt Baker-Snoqualmie's wonderful old-growth forests are of special interest to many citizens because of their unique contribution to the biological diversity of the Puget Sound region.

The Forest provides many opportunities for conducting environmental education and research programs, and contributes to our understanding of nature We are particularly concerned that our schoolchildren have the opportunity to learn about and appreciate our natural areas, and the Mt. Baker-Snoqualmie National Forest is very important among these.

J-523

Recreational opportunities in the National Forest not only enhance the quality of life in the Puget Sound region significantly, but also provide substantial economic benefits through tourism and the support of outdoor recreation. Many jobs are provided in these industries, and it is important that we maintain the kind of natural environment that will continue to encourage and support these activities Because of its great natural values, the National Forest also provides an attraction for businesses to locate in our area, stimulating economic development. To preserve the quality of life and the economic well being of our region's inhabitants, it is essential that the natural and scenic values of the Mt Baker-Snoqualmie National Forest be preserved.

The management of the Mt. Baker-Snoqualmie National Forest is also important to Seattle citizens because the City owns considerable land adjacent to National Forest land, and because our utilities operate important facilities within the Forest's boundaries. Our water and electric utilities have expressed concerns with some elements of the proposed plan

ISSUES OF CONCERN TO CITY UTILITIES

Parts of both of the City's municipal watersheds fall within the Mt Baker-Snoqualmie National Forest, as do several of our hydroelectric power generating and transmission facilities. Our watersheds on the Cedar River and the South Fork of the Tolt River are the primary sources of municipal and industrial water for the approximately 1 1 million customers of the Seattle Water Department. In addition, Seattle City Light's facilities on the Skagit River provide electric power to customers in Seattle.

Cedar River Watershed

We are pleased to note that the Seattle Water Department has had a long-standing working relationship with the Mt. Baker-Snoqualmie National Forest, a relationship that has provided benefits for both the City and the Forest Service. Our association has resulted in cooperation on several issues important to the City of Seattle. A prime example of this cooperation is the 1962 Cedar River Watershed Cooperative Agreement, which is based upon the objectives of both protecting water quality and managing timber resources in the Watershed We expect this type of cooperation to continue in the future, particularly with regard to the management of National Forest lands in the Cedar River Watershed.

The City of Seattle is completing a reevaluation of its management goals for the Watershed and developing a long-term management plan. Because the Forest Service is the second largest land owner in the Watershed, it is essential that the planning processes of City and the Forest Service be coordinated. One major element of the emerging Watershed management plan will likely be an increased emphasis on the protection of valuable wildlife habitats, particularly old-growth forest. The effectiveness of the City's watershed management program would benefit substantially from the cooperation of all land owners in the management of their lands in the Watershed. This cooperation can serve the long-term goals of both the City and the Forest Service. We share important goals and concerns for the Watershed, and can build upon the 1962 agreement to better pursue those goals.

The three management intensities for the Cedar River Watershed (20A, B, and C) include different provisions for dealing with the following issues of importance to the City: (1) policies for exchange of remaining National Forest lands in the Watershed for City lands elsewhere; (2) protection of old-growth forest and unroaded areas in the Watershed; and (3) public recreation on National Forest land in the Watershed.

Land Exchange. It has long been a goal of the City to obtain ownership of all lands in the Cedar River Watershed, and we now own more than 80 percent of these lands. Ownership of Watershed lands provides the City with the greatest level of control over activities in the Watershed that can affect water quality, a major management concern for the Water Department. Expediting the ongoing land exchange with the Forest Service is of major interest to the City.

Intensity 20A, included in the preferred alternative, has provisions to continue the current program of land exchange, but provides no protection for any of the remaining old-growth forest on National Forest lands. Although intensity 20A would allow the City to gain eventual ownership of all federal lands in the Watershed, it is not compatible with the City's objective of reserving a portion of the remaining old-growth habitat in the Watershed.

Intensity 20C, on the other hand, provides for the protection of some old-growth habitat in the Watershed, but also includes a provision for the Forest Service to retain ownership of all National Forest lands in the Watershed. This provision would be incompatible with the City's goal of obtaining eventual ownership of all lands in the Watershed.

Of the three management intensities for the Cedar River Watershed, a plan similar to that described in intensity 20B would best accomplish the ownership and habitat protection goals of the City. The stipulation in intensity 20B that the City would agree to protect the old growth to be exchanged is in keeping with the City's goal of protecting this valuable and diminishing habitat, and intensity 20B provides for eventual City ownership of federal lands in the Watershed in a shorter time period than would be the case under 20A.

As noted below, however, we do not feel that the resolution of issues of concern to both parties should be limited to adoption of one of the three proposed management intensities. We feel that it is possible to develop a new management intensity that may better serve the interests of both parties. A critical element of this new management intensity should be the coordination of our respective programs for the protection of old-growth habitats.

Protection of Old-Growth Forest. It is fairly certain that a major element of the City's long-range plans for the Cedar River Watershed will be the exclusion from timber harvesting of substantial areas of City-owned lands in the Watershed, including not only most of the City's remaining old growth but also large areas of second-growth forest that could eventually develop into old growth. Much of the City's existing old growth is adjacent to old growth on National Forest land containing old growth. The second-growth forests reserved by the City could also add a large, contiguous area of forested habitat that would provide a continuous, complimentary network of forested habitats throughout the Watershed. Clearly, by working together on the important goal of protecting certain old-growth forests in the Watershed, the City and the Forest Service can accomplish much more than would be possible otherwise.

Protection of old-growth habitats in the Cedar River Watershed could provide a valuable linkage between old-growth habitats to the north and south. The need for this linkage has been pointed out by many individuals who are concerned that the habitat of spotted owls in Washington may become too fragmented for the species to survive. The value of protecting old-growth habitat in the Watershed would be substantially enhanced by the City's long range plans for protection of its forest habitats in the Watershed, as well as through current negotiations by which the City will obtain several thousand additional acres of old growth from the remaining private land owners in the Watershed. Almost all of this land is adjacent to National Forest land. The City

is prepared to reserve these lands to enhance a Forest Service program to protect species using old-growth habitats in the Watershed.

Protection of old-growth habitats in the Watershed may make a substantial contribution to the protection of species that depend on old growth, such as the spotted owl. Research conducted by the Water Department, although not yet completed, has indicated that as many as five spotted owls may be using old-growth habitats in the Watershed, including at least one mated pair In keeping with the City's goals for protecting this valuable habitat and the species that depend upon it, we strongly urge the Forest Service to consider designating areas of old growth in the Watershed for the protection of spotted owls and other old-growth dependent species.

We urge you to consider protecting old-growth forests in three areas of the Watershed west of Meadow Mountain (Gronski timber sale area), Abiel Peak, and Findley Lake Our research indicates that a pair of spotted owls has a home range in the area west of Meadow Mountain This is excellent habitat for spotted owls and should be designated as a SOHA Protection of the old-growth in the Abiel Peak area of the Cedar River Watershed would enhance the value of protecting old-growth in the Annette Lake area to the north, as proposed in the preferred alternative. The old-growth near the Findley Lake area may also support spotted owls, and would be of value for protecting other old-growth dependent species

To enhance a habitat protection program on National Forest lands in the Watershed, the City is prepared to commit to the protection of large areas of old-growth habitat near Meadow Mountain, Abiel Peak, and Findley Lake that we are now in the process of acquiring from private owners The City is ready to consider other creative alternatives to contribute to structuring a total package for old-growth reservation, including acquisition and exchange. In addition, considerable old-growth in the Findley Lake basin has already been designated for protection by the City.

Protection of Unroaded Areas. Several roadless areas of the Cedar River Watershed are connected to other roadless areas outside of the Watershed. We believe that these areas should be added to the inventory of roadless areas on National Forest land and that they should be considered for protection in the proposed forest plan. The areas include sections near Abiel Peak and Meadow Mountain

J-525

Control of Public Access. In all three of the management intensities for the Cedar River Watershed, dispersed recreation would be allowed on National Forest lands. It has long been the City's policy not to allow unsupervised dispersed recreation in the Cedar River Watershed We have adopted this policy to assure adequate protection for our unfiltered water supply. A Watershed management program providing for strict control over human activities in the Cedar River Watershed is a requirement of public health agencies In addition, as a result of recently adopted amendments to the Safe Drinking Water Act, the regulations regarding allowable activities in watersheds supplying unfiltered water are being more strictly interpreted

If we do not achieve the objectives of the new drinking water regulations, we face the prospect of constructing and operating very expensive filtration facilities In its long-term program of land acquisition and control, the City has made a substantial investment in providing a high quality water supply without additional, expensive treatment We are very concerned that this investment be protected The provisions in intensity 20C, which would result in an increase in dispersed recreation in the Watershed, would present significant problems for the City in complying with the new regulations and other expected changes to these regulations The City, therefore, opposes intensity 20C

We believe that an agreement on closure of National Forest lands in the Watershed to dispersed recreation can be achieved, and that provisions for such an agreement should be reflected in the forest plan. Day use of the Cascade Crest and the McClellan Butte trails, which is currently allowed, would continue to be allowed under any such agreement.

Recommendation The City is highly interested in exploring a variety of options for protecting portions of the remaining old-growth habitats in the Watershed, for expediting the land exchange, and for controlling public access to federal lands in the Watershed. However, rather than recommending that one of the three management intensities be adopted in its present form, we recommend that an appropriate alternative be developed cooperatively by the City and the Forest Service

Skagit River Hydroelectric Facilities

The City is concerned with the potential impacts of logging activities on anadromous fish and bald eagles in the Skagit River system These impacts could jeopardize Seattle City Light's considerable efforts and expenditures to protect and enhance habitats for fish and eagles in the Skagit drainage.

Logging and road construction near streams can result in increased sedimentation and turbidity, with consequent degradation of habitats for fish. It can also reduce the availability of roosting and perching sites for bald eagles or cause disturbances that may lower the quality of such sites. We strongly urge the Forest Service to protect remaining roadless areas and old-growth forests adjacent to streams in the Skagit River drainage to protect wildlife habitat, water quality, and fisheries. Of particular importance are the areas adjacent to Diobsud, Illabot, Rocky, Patent, and Olson creeks, and the Cascade River

Seattle City Light has experienced no significant problems with the operation of its facilities on the Skagit and Sauk rivers related to their inclusion in the federal Wild and Scenic River system Although City Light transmission lines parallel or cross several candidate rivers, we anticipate no problems with the designation of these rivers as Scenic or Recreational.

ISSUES OF CONCERN TO CITIZENS OF SEATTLE

The proposed forest plan indicates that the availability of opportunities for primitive and semi-primitive recreation will decrease in the future, while the demand for such activities will increase. We are concerned that the proposed recreational trail system may not be adequate for the growing population served by the National Forest Several recent proposals contain valuable suggestions for addressing this problem The Trails 2000 proposal, developed by the Sierra Club, advocates the rebuilding of 250 miles of abandoned trails and the construction of 350 miles of new trails by the year 2000.

Implementing the Trails 2000 program would result in a vastly improved trail system that would provide public access to many excellent roadless areas. Low-elevation, forested trails that are open nearly year-round, such as the Greenwater Lakes and Pratt River trails, are particularly important These areas are much more accessible than forests and meadows at high elevations, which are in more rugged terrain and available to hikers only part of the year

We are also concerned about the loss of many existing trails through timber harvesting and road construction in areas that are now roadless Harvesting in many areas will fragment the trail system and seriously reduce the quality of recreational experiences While protection of roadless lands within the Skykomish Ranger district is adequate under the preferred alternative, it is not sufficient within the remainder of the

National Forest. Important areas such as Jordan, Damfino, and Chenuis creeks should be added to the preferred alternative as Semi-primitive, Nonmotorized Management Areas

The Backcountry Areas proposal of the Washington Trails Association is one that we support. If implemented, this proposal would protect several roadless areas near Seattle that have substantial potential for backcountry recreation, including Jackman Creek, Mt. Dickerman, Eagle Rock, and Ragged Ridge As noted in the proposed plan, the Forest's Wilderness Areas are already reaching their maximum capacity for recreation, yet the demand is expected to grow in the future. Reserving many roadless areas for primitive and semi-primitive dispersed recreation would take some of the pressure off of the designated Wilderness Areas. Protecting free-flowing rivers in the National Forest is essential to the protection of the fish that inhabit them and the quality of recreational experiences in the riverine environment. Many rivers in the Forest offer excellent scenery, rafting, kayaking, fishing, wildlife habitat, and opportunities for enjoying nature. We were disappointed that only five rivers were recommended in the proposed forest plan for inclusion in the federal Wild and Scenic River system. There are other rivers that we feel have outstanding values, such as substantial anadromous fish runs, fine old-growth forests, and excellent recreational opportunities These include the Stillaguamish, White Chuck, Pratt, and White rivers, and Diobsud and Illabot creeks. We urge you to add these rivers to your recommendations

Wildlife and fish in the National Forest provide many benefits to our citizens, and it is very important that native wildlife and fish species, and their habitats, be well protected. We commend you for including programs to enhance fish and wildlife habitats in the proposed plan. Our fisheries specialists are concerned, however, about the heavy reliance on artificial spawning and rearing structures. The success of these techniques is not assured We feel that a greater emphasis on preventing loss by protecting streams and watersheds is a more prudent approach

We encourage efforts to study the endangered grizzly bear and gray wolf, which once were widely distributed in our region. The Forest Service should avoid any actions that might preclude their reintroduction

Our old-growth forests are especially important habitats Not only does this unique and diminishing environment possess great aesthetic value, but it also contributes substantially to regional biological diversity and to the preservation of

the many kinds of plants and animals that are partly or totally restricted to it. Most of the region's low-elevation old growth has already been logged, making the remaining forests particularly valuable not only to hikers and nature enthusiasts but also to the wildlife species that once inhabited vast areas of the Puget Sound lowlands. Important areas that should be given greater protection include the excellent old-growth forests along Irene, Higgins, and Canyon creeks, and along the Cascade and White Chuck rivers.

The welfare of the spotted owl is of special concern to many residents of Seattle. This species, which is dependent on old-growth habitats, was recently listed as endangered in the state by the Washington Department of Wildlife The survival of the spotted owl depends on the protection of the very large stands of old-growth habitat in which it lives. Biologists inform us that the 1,000 acres of old growth included in Spotted Owl Habitat Areas (SOHAs) under the proposed plan is not enough. The City has conducted research on this species that supports this conclusion The results of our research and the research of others indicate that a pair of owls require at least 2,200 acres of old growth, and may need as much as 4,000 acres. We would be pleased to share the results of the City's research with the Forest Service.

We are also concerned that some of the old-growth habitat that is proposed for protection in the National Forest may not be adequate in quality for the spotted owl or other old-growth dependent species, and that many of the designated SOHAs are not presently inhabited by spotted owls. We urge the Forest Service to evaluate more closely the needs of these species and to initiate an inventory of wildlife habitats that is ecologically oriented. Until these issues are resolved, the conservative approach would be to avoid harvesting in areas that may later prove to be critical to the survival of old-growth dependent species.

We also recognize the importance of the timber resources of the National Forest to the citizens of Washington It is important that the Forest Service assist the communities that have traditionally relied on National Forest timber These communities are vulnerable to the dramatic market fluctuations that occur in the timber industry Avoiding serious dislocations for this important industry in Washington will require a balanced program for managing our forests Addressing the larger and more complex issues of the long-term stability and economic well being of these communities will require creative solutions and a broader perspective than has been taken in the past.

There are many ways that the Forest Service can assist these communities in meeting their economic needs without sacrificing a large part of the remaining old-growth forest in our region. In the 1985 Forest Service assessment under the Renewable Resources Planning Act, it is stated that small, nonindustrial woodlots have the greatest potential for increasing the nation's wood supply. Many individuals have observed that the timber resources on nonfederal lands in Washington are not being used nearly as efficiently as they could be. Forest Service programs to stimulate and support increased wood production on these lands, such as the State and Private Forestry Program, can increase jobs in the timber industry to offset the reduction in harvest of old growth on federal lands. We strongly urge the Forest Service to increase the emphasis on such programs. Substituting lumber exports for log exports would also increase timber-related jobs in the state

In the long run, however, diversification of local economies now mostly dependent on volatile timber markets may provide the stability these communities need. We encourage the Forest Service to work with these communities to find innovative solutions to the problems that they may face during the transition from an economy based on resource extraction to a more diversified one.

CONCLUSIONS

The proposed forest plan (Alternative H) is an improvement over past management plans. However, Alternative G contains many provisions that would contribute more to the protection of the values of the National Forest described in this letter We urge you to carefully consider incorporating many of these provisions into the forest plan

Again, we thank you for the opportunity to comment on this important planning document Your staff has been most helpful in providing information to us, and we commend your sincere efforts to solicit and consider comments from all those who are interested in the management of the Mt. Baker-Snoqualmie National Forest.

Sincerely,

Charles Royer

CITY OF BELLINGHAM
OFFICE OF THE MAYOR
TIM DOUGLAS

May 2, 1988

Douglas McWilliams, Forest Supervisor
Mt. Baker-Snoqualmie National Forest
1022 First Avenue
Seattle, WA 98104

Dear Mr McWilliams

I am most concerned about a provision in the proposed plan for the Mount Baker Snoqualmie National Forest. Apparently, Coleman Glacier is designated as a special area within the wilderness classification. Proposed standards limit the average number of parties encountered to 16, the number in the party to 12, and campsite *visibility to 15 seen from other campsites.* Each of these standards emphasizes the sense of wilderness but would deny to significant numbers of people access to a glacier experience.

For years, Coleman Glacier has provided one of the outstanding educational opertunities for American citizens. Thousands of visitors each year take advantage of the quick accessibility of the glacier, and many of these same people use this route for ascent of Mount Baker. Should the *proposed plan be* adopted as is, thousands of visits each year would be prohibited

Since the historic use has not threatened the ecology of this special resource, I urge you not to impose the restrictions reflected in your plan We need to assure that future generations understand and appreciate the geologic forces at work in the Pacific Northwest Our regional economy depends on the use--thoughtful of course--of our outstanding outdoor attractions. Please feel free to contact me should you wish further comments on this matter

Sincerely,

Tim Douglas, Mayor
City of Bellingham

REPLY TO ATTN OF: ROVP (Farrel/556-0882)

SUBJECT: Draft Environmental Impact Statement (DEIS) - Proposed Land and Resource Management Plan, Mt. Baker-Snoqualmie National Forest, Washington

TO: Mt. Baker-Snoqualmie National Forest
ATTN Forest Plan
1022 First Ave.
Seattle, WA 98104

1 We appreciate the opportunity to review the subject DEIS and offer the following comments

a As shown on the attached map, the Mt Baker-Snoqualmie National Forest is subject to military overflights in the form of low-level training missions. Inasmuch as low-level overflights do have the potential to disrupt the solitude and naturalness of areas directly under their flight paths, we recommend you include consideration of low-level training missions in your discussion and decisionmaking process wherever solitude and naturalness are desirable attributes within the forest system. Within that context, we further recommend you consider location, altitude, and frequency of flights.

b Geographic areas which are appropriate for military overflights and low altitude training routes are becoming increasingly rare. In selecting overflight training routes, the military must consider mission requirements and fuel costs as well as environmental constraints Ideally, training routes are located within areas which are relatively isolated, have diverse topography and minimal commercial activity, maintain sparse human populations, and contain lands under federal jurisdiction. It is apparent these characteristics are also very compatible with National Forest Systems. Therefore, the Air Force generally supports Management Plans which do not restrict use of the airspace for military overflights

2 If we can be of further assistance in any manner, please contact Mr. David Farrel, at (415) 556-0882.

Attn Forest Plan

Dear Sir

We have reviewed the Proposed Land and Resource Management Plan and Draft Environmental Impact Statement (DEIS) for the Mt. Baker-Snoqualmie National Forest. We would like to commend the Mt. Baker-Snoqualmie National Forest for establishing a management area and standards and guidelines for utility sites and corridors

Our specific comments on the management plan and EIS are listed below. We have included a map which illustrates Bonneville Power Administrations (BPA's) existing and proposed corridors recommended for designation The proposed corridors were taken from the Pacific Northwest East-West Corridor Study completed in 1977 by BPA and the Forest Service Due to the importance of corridor planning on the Mt Baker-Snoqualmie National Forest and the possible need for additional transmission within the next 10 years, BPA will contact the Forest to discuss corridor availability and suitability in the next several months. If there are any questions on our comments before that time, please contact John Hooson, Facilities Planning Branch, Office of Engineering, (503) 230-3299, or FTS 429-3299

J-530

Specific Comments on Proposed Plan

1. The Proposed Land and Resource Management Plan should identify specifically the corridors that have been designated, and if none have been designated, explain why. Reference could be made to Figure III-31, Utility Corridors, found in the DEIS.

2 Page 4-1, Forest Management Goals - We recommend that the Forest Management Goals address energy, including corridors and renewable energy resources. The Standards/Guidelines on page IV-103 should reference the Project Plan and Right-of-Way Maintenance Plan as important documents which guide the construction and maintenance of BPA transmission rights-of-way within Management Area 25 These are documents required by the BPA/Forest Service Memorandum of Understanding.

3 Page 4-120 to 4-218, Management Area Standards and Guidelines - It would be helpful if management area descriptions describe whether they are considered an avoidance or exclusion area for transmission facilities. This will help ensure consistency with other Forest Service (FS) and Bureau of Land Management (BLM) plans and the requirements of BLM and FS directives

4. Page 4-214 to 215, Management Area 25 - The Standards/Guidelines do not make clear how large an area is encompassed by Management Area 25. For example, does it include only the land permitted (right-of-way), or is area allowed for expansion?

Specific Comments on Draft EIS

1. The DEIS has also done a good job of addressing corridors We particularly like the use of a corridor map and the descriptions of the built environment For decisionmaking purposes, we suggest that the Final EIS identify, in table form, the affect of the alternatives on the acreage available for corridors (Exclusion Area & Avoidance Area) This should also be done for renewable energy resources such as small hydro, and geothermal.

2 The statement of the duration of the energy surplus attributed to BPA on Page III-17 of the Draft EIS is incorrect BPA currently projects the regional energy surplus to last until 1994, assuming medium load growth.

3 Page III-167 to 168, The built Environment - Utility Corridors - On page III-168 the load growth information should be revised to show an annual growth rate of - 3 to 2 7 (BPA Forecast of Electric Consumption in the Pacific Northwest, October 1986) It should be noted that BPA's/NW Energy Planning Council's draft 1988 forecast will show an increase in annual load growth from the 1986 forecast On page III-168, last paragraph, it should be noted that BPA is currently evaluating transmission requirements (loads and reliability) for serving the Puget Sound Area Expansion of transmission capacity on the Stevens Pass Corridor is being considered and could be needed prior to the year 2000 rather than after the year 2000 as mentioned

4. Chapter IV, "Environmental Consequences," should analyze the effect of the alternate plans on both existing and planned corridors as mentioned above

5 The Forest Plan and Draft EIS should also reference the 1986 Western Regional Corridor Study for information on corridors. The corridor study was prepared by the Western Utility Group, an ad hoc group of western utilities It was intended to describe consolidated utility corridors for the Western United States and was originally published in 1980 The 1986 edition was recently transmitted to all Forests

6. We recommend that the alternative plan maps illustrate in color, Management Area 25 It is mentioned on the map legend, but cannot be found on the maps.

We appreciate this opportunity to review and comment upon your plan and EIS

REGION 10
1200 SIXTH AVENUE
SEATTLE WASHINGTON 98101

MAY 2 1988

RECEIVED
MAY - 3

REPLY TO ATTN OF WD-136

Environmental Protection Agency
1200 6th Ave., WD-136
Seattle, WA 98101

Doug MacWilliams
Forest Supervisor
Mt. Baker-Snoqualmie National Forest
1022 First Avenue
Seattle, Washington 98104

Dear Mr. MacWilliams

In accordance with our responsibilities under the National Environmental Policy Act (NEPA) and Section 309 of the Clean Air Act, the Environmental Protection Agency (EPA) has reviewed the Proposed Land and Resource Management Plan and accompanying Draft Environmental Impact Statement (DEIS) for the Mt. Baker-Snoqualmie National Forest (BSNF) We would like to thank the BSNF staff for their efforts in assisting us in our review of the DEIS and Plan by providing an overview meeting (January 8, 1988), invitations for further discussion, and opportunities for field visits. These have helped highlight and clarify issues we believe are important to a successful and environmentally sound management plan.

The preferred alternative includes reduced timber harvest from current levels and with a significant emphasis on anadromous fish habitat improvement projects. The DEIS emphasized identifying the potential and significant adverse impacts to the environment from activities associated with timber harvesting, mineral extraction, and other activities.

We determine the environmental effects of the proposed alternatives by reviewing the process by which the forest management activities are carried out. This may include the procedures, decisions and time-frames necessary to comply with environmental standards, prevent adverse effects, and improve existing conditions. Some components we believe are important in the forest management process are

A data base of existing conditions from which technical experts and the public can judge the expected effects and level of prediction uncertainty,

Best Management Practices (BMPs) and prescription development,

Identification and selection of BMPs for a particular activity and how uncertainty of BMPs are factored into selection,

Through on-site inspection and administration during an activity, verifying that a particular activity is occurring as prescribed in contracts, leases or permits,

Environmental monitoring before, during, and after completion of an activity to determine whether impacts were accurately predicted,

J-532

Feedback mechanism that is built into the process such that forest activities causing a problem will be corrected before they are allowed to continue,

Upgrading BMPs or prescriptions to correct inaccurate predictions,

The use of NEPA for project preparation and implementation.

Based on our review of this process, EPA has rated the documents EC-2 (Environmental Concerns - Insufficient Information), a summary of EPA's rating system is also enclosed. The documents did not include as much detail on existing environmental conditions, especially water quality, which we believe can reasonably be included in a document of this type This information is important because it provides the baseline for understanding the environmental consequences and priorities for plan implementation. The feedback mechanism was not clearly described such that actions needed to correct problems discovered through administrative and field monitoring will be corrected. Our main concern is that the level of detail and commitment for water quality and fishery habitat monitoring is not commensurate with the sensitivity of the resource. Further elaboration of EPA's concerns, as well as specific comments on the DEIS and Plan are enclosed.

Though our concerns cover a broad range of issues we believe that they can successfully be addressed in the Final EIS and Plan, and that they will contribute to the successful administration of the BSNF. Toward this end, the EPA is willing to provide all possible and appropriate assistance. If we can be of help, or answer any questions you may have, please call Wayne Elson (206-442-1463, FTS 339-1463) of my staff or Paul Kaldjian (202-475-8797, FTS 475-8797) of EPA's Office of Federal Activities We have appreciated the opportunity to participate in this review and look forward to continuing participation in the NEPA process as the EIS and Plan are finalized.

Sincerely,

Robert S. Burd
Director, Water Division

U S ENVIRONMENTAL PROTECTION AGENCY COMMENTS

DRAFT ENVIRONMENTAL IMPACT STATEMENT AND PLAN

MT BAKER-SNOQUALMIE NATIONAL FOREST

DEIS

Affected Environment

Additional detail on the current status of water quality is needed There is no organized summary is presented which covers the whole Forest A watershed inventory would be a logical place to present information documenting water quality conditions It is difficult to evaluate effects on water quality which would result from implementing the various options without documentation on the current status

III-13 The DEIS states that all waters on the BSNF are classified by the state as Class AA Excellent Further, that Forest-wide mitigation measures, water quality standards for the state are met through application of Best Management Practices (BMPs), water for domestic use and fish are key resources protected by BMPs The process for how this will be carried out should be explained further

Most headwater streams on the forest are naturally almost sediment free It would be useful to identify the ones that are not, identify the causes for this, and what is being done to prevent sedimentation, and differentiate between natural and man-induced causes

"Among the water quality attributes that affect water use by fish, temperature can be a concern Removal of streamside vegetation usually increases summer water temperatures in direct proportion to the amount of increased sunlight on the water surface Changes in water temperature begin to have a detrimental effect on fish/fish habitat when a threshold amount or percent of streamside vegetation that provides shade is removed within a watershed or basin Mitigation in the form of limiting removal of vegetation along streams, etc , has generally been successful in the past " While the DEIS elaborates on the process, it should be concentrating on current conditions within the Forest Again, where are conditions unacceptable, what are their causes, and what things are being done to rectify the problem

III-15 For the comprehensive list of municipal watersheds listed in Table III-2, have there been instances of waterborne disease? Any significant source related water quality problems should be summarized

III-19 For purposes of Forest planning, width of riparian areas on BSNF is at least 100 ft back from water's edge on both sides of all perennial streams Does this include intermittent streams that do not directly supply domestic water, are not used by fish, or contain enough water to be a major contributor to streams that contain these characteristics? How and when is the boundary determined for protecting all other riparian areas, including wetlands?

J-533

III-27 The text uses the definition of old growth "mature, large sawtimber, at least 21 in diameter at DBL " Does this cause any confusion with roadless areas that may have virgin growth not meeting this definition? Also, the glossary definition (page V-46) seems to be different

III-72 Discussions on riparian zones and wetlands need to be expanded to include current conditions and issues unique to the BSNF The discussion in the DEIS is too vague to clearly understand existing conditions

III-74 "Major effects to fisheries resource and habitat come from stream sedimentation resulting from road building, timber harvest activities, and recreation over-use on erodible soils, and from vegetation disturbances along streams, primarily that which removes shading vegetation or leaves excess debris in the streams " This is more a discussion of environmental consequences than affected environment The DEIS needs to describe what these have done to the BSNF environment and what is being done to curtail or reverse impacts

III-74 Are all stream miles fishable? What is the current condition and ability of the forest to produce fish--are all stream segments hosting what they should?

III-147 The term "hydrocarbons" should be changed to "volatile organic compounds" to reflect current terminology

The text explains that activities on BSNF land that can contribute to suspended particulates are burning vegetation, logging activities, road construction, campfires, and vehicular traffic on gravel roads But what are the conditions on the Forest?

Washington State Department of Ecology has set a required 35 percent reduction in emissions of total suspended particulates from prescribed burning by 1990 What is the base from which this percentage reduction reduction is derived? The 1976-1979 levels?

III-148 Is the 35% reduction by 1990 (p III-147) based on better wood utilization? How much is currently being contributed based on the tons of particulates for each acre yarded, each acre cleared for roads, each acre broadcast burned, and each acre of mountain goat habitat created?

III-155 Current mining of olivine is 30,000 tons/year from one mine The DEIS says that "since the resource is virtually inexhaustible, these deposits will meet any foreseeable demand " Are there no environmental impacts or concerns resulting from the operation of this mine, now or in the future? What NEPA procedures are followed for this and the 4,000 mining claims properly recorded on the Forest

III-156 The EIS should explain the environmental process that is followed if coal, oil, gas, geothermal or leachable minerals will be mined or pumped This also goes for the extraction of sand, gravel, and stone

III-162 Road construction probably results in the greatest amount of ground disturbance of any forest activity Still, this section of the DEIS only identifies the number/miles of roads and what types, but no mention of the condition Are the roads on the BSNF contributing to the adverse impacts to the environment, especially water quality? Current conditions and efforts to prevent adverse effects need to be discussed.

III-164 It is not clear what methods for vegetation management are currently being carried out on the Forest, since 1984, as the injunction on pesticide use continues This should be discussed.

Environmental Consequences

IV-2 An important part of implementing the final Forest Plan will be monitoring the accuracy of these predictions to provide more and better information for future planning

IV-2 Reference is made to the vegetation management DEIS, "for planning purposes, it is assumed that herbicides will be available The use of chemicals for site preparation and release has been a small program in the past In this chapter, the environmental effect of herbicides will not be discussed, their effects are examined in detail, in October 1987 EIS [sic] " If the intent here is to incorporate information by reference, this must be made more clear Further, this is not a sufficient tiering -- the vegetation management EIS is for all the forests in Region 6, and describes the pesticide to be used, the health effects, and typical environmental risks and effects, however, it does not lay out the specific nor the unique characteristics of the BSNF

IV-2 Under "Cutting Vegetation" as a general effect of management activities on the environment, we suggest adding that cutting vegetation also changes the timing and flow peaks See page IV-14 bottom

IV-3 Under "Burning Vegetation and Other Debris," the fact that burning is less costly is not an effect, rather, a justification, of the method The tendency to confuse impacts with justifications should be avoided

IV-3 It is not clear how planting vegetation increases noise from motors, logging whistles, and people Further, the significance of these environmental impacts and how they can be avoided should be discussed

IV-4 In the discussion under Trail Construction, to "make remote areas accessible to hikers" is not an environmental impact of the activity (though it may lead to environmental impacts) but a justification or goal of the activity Mixing impacts with justifications confuses the issues

IV-6 For Table IV-1, does this mean that the preferred alternatives will contribute 67,000 new tons of erosion/year? Is this in addition to the existing 72,000 tons per year above natural rates? Are all these caused by human activity?

IV-9 The discussion of the cumulative effects of each alternative is only in generalities There needs to be a comprehensive discussion of all cumulative impacts somewhere, showing the cross-media and temporal relationships The current presentation of the cumulative impacts is compartmentalized, which discourages evaluation of areawide relationships among and between forest management and natural activities

IV-10 Having a section on the impacts of soil on water may be misleading because soil itself does not have the impact on water, but rather the soil disturbances that cause erosion, sedimentation, and mass wasting The crucial elements are how the soil gets to the water, how much, and whether this affects beneficial uses

IV-11 The DEIS states that "Changes in soil which increase surface erosion and/or mass wasting can have a major effect on fish spawning and rearing, when the material reaches stream channels and is deposited as sediment The extent to which fisheries will be affected depends upon the type and size of the disturbance and the susceptibility of a particular soil to be involved in a mass wasting event " The various causes of sedimentation affecting fisheries and how they can be avoided should be discussed

IV-14 The Built Environment Section, on page IV-146, includes a discussion on the two types of mitigation for road construction An evaluation of the effectiveness of various mitigation techniques for road construction, when each should be used, and the trade-offs between the two should be provided

IV-15 It would be helpful if the time-units for Figure IV-1 were provided

IV-16 While all alternatives will have a relatively low risk of creating disturbance in wetlands, the alternatives that prescribe the most ground-disturbing activities (NC,A,D) create the most risk Any areas that are disturbed will be rehabilitated How this is to be ensured, what the process for doing so will be, and who the responsible parties are need to be explained

IV-16 For Table IV-4, the text says "percents will have a very rough estimate of the effects of harvest activities on water " There should be a narrative describing the relationship between the two A table of anticipated impacts to water for each watershed should be included This could be part of a comprehensive cumulative impacts analysis

IV-17 Chemicals used for vegetative control can create water toxicity Chemical entry into streams is mainly through direct application to stream surfaces and drift or run-off from nearby treatment units Standards and guidelines (Appendix D and Plan) provide specific direction for any application of chemicals near water At present, the Forest is still enjoined from any use of herbicide The full implications of this should be discussed The plan must also describe those elements of pesticide use that are site-specific to the BSNF, but only generally described in the programmatic vegetation management EIS

IV-19 It is not sufficient to "insure" that impacts to water resources from mining will not be significant because of the regulatory controls available for water resources The mechanisms and processes for carrying out the regulations need to be presented

IV-20 If the accumulations of sediment in streambeds become significant when the roaded portion of a sub-basin area exceeds 2-3 percent, and the average road density on the BSNF is between 3 percent and "somewhat less than 3%," it appears that the accumulations are or are about to become significant Therefore, the assumption that road construction will not contribute a critical level of sediment is tentative This needs to be evaluated much more thoroughly In addition, how the percentages are calculated, and how the percentages will change over the next decades should also be discussed

IV-21 It is stated that mitigation measures, proper construction, and timely maintenance can help negate these effects from runoff and major sedimentation from road systems The extent to which the adverse environmental impacts will be prevented, the mechanisms for doing so, and the commitments toward protection need to be described

IV-21 It is the nature of cumulative impact analysis to analyze the combined effects of many minor effects Therefore, it is not sufficient to address only the major causes

The EIS needs to discuss further the situation when insufficient data is available to predict cumulative water quality effects A statement of intent to collect data over the life of the plan, how important the missing data is to the Plan and EIS, how decisions will be made despite the absence of important information, and what assumptions were made in making those decisions are needed

IV-23 Discussion of the class of watersheds and existing conditions seems more appropriate under Chapter III, the "Affected Environment "

IV-25 Forest Service thoroughly identifies the relationships in cumulative impact assessment, however, with the approach that was taken certain environmental effects can be masked

IV-26 It is not clear why the Deer Creek study is referenced, the information gained from the study and how it can be applied should be discussed

IV-27 The discussion on mitigation measures for water is too general For example, the procedures to be followed, the source of options for mitigation, the decision-making processes in choosing mitigation measures, etc , are an important part of this section This is necessary for determining the ability to minimize the impacts to water quality

IV-61 There is no real discussion of the effects of changes in soils on fish The only discussion is that the streams in western Washington and Oregon are highly vulnerable and that there may be major effects on fish There needs to be discussion of specific areas for this to be useful

IV-61 In the discussion of the effects of recreation on fish, there is no discussion of the measures that will be used to mitigate the impacts to fish populations, nor the criteria for when they need to be applied They should be included

IV-63 The discussion here is too generic, centering around the types of impacts that may occur Nothing specific to the BSNF, nor precautions that will be taken are discussed This leads to confusion between what could possibly happen, and what could be expected if mitigation or proactive decisions were not made

In trying to identify the environmental consequences of the alternative on the various resources of the BSNF, there is no real indication of what to expect and what will be done Other than adding the maps, and some constraints contained in the Standards and Guidelines and the Mitigation Measures, there seems to be few BSNF specific planning requirements While some of these are in other FS documents, the purpose of the plan and EIS is to translate these into specifics for the BSNF

IV-64 To assume that mineral related effects on fisheries resources on the forest will not be major, based on compliance with state and federal laws and following an environmental assessment with reclamation goals and mitigation measures, is not appropriate We suggest specific reference to the requirements of NEPA Secondly, because there are different ways of complying with the law, and different interpretations of the law, how the FS will proceed must be explained What, for example, is the process that will be followed to establish a mining operation on the BSNF?

IV-64 The effects of land uses on fish is a generic statement of the impacts of hydroelectric power plant development on fish and fish habitat It is important that the criteria for what is acceptable and what is not should be discussed (The FERC Cluster Impact DEIS on the Snohomish River may be useful here) Also, the process FS will follow if an applicant wishes to put in a dam needs to be included in the EIS The FS role in ensuring no unnecessary adverse environmental impacts needs to be explained

IV-64 The presentation of the impacts of roads to fish is again a presentation of broad categories of what can occur, and of general events that are known to occur, rather than specific discussions of what is taking place on the BSNF

IV-65 The statement that road construction, timber harvesting and small hydro construction/operation is beneficial to fish/fish habitat needs to be elaborated upon Under what circumstances is this the case and how is this determined?

IV-65 What are the threshold levels for fish and fish habitat and what will be one if management activities cause a drop below this level? It is not sufficient to say the impacts are adverse and unacceptable, rather, the ways and processes for avoiding, protecting, and mitigating need to be discussed

IV-65 It is stated that "Timber management activities generally have less cumulative effect on spawning habitat quality than do forest roads " The meaning of this comparative statement is unclear Is it based on habitat monitoring on the BSNF? Both have the potential to cause adverse environmental impacts and need to be addressed as such

IV-65 A cumulative impact assessment is more than saying that something can cause cumulative effects It is identifying the various elements needed to prevent future problems This needs to be reflected in the FEIS

IV-65 The criteria for determining how much large woody debris from timber harvesting activity is too much should be explained How successful have projects that are intended to restore large woody debris been on the BSNF?

IV-66 What is being done to accommodate for data gaps needs to be explained, the NEPA implementing regulations address the issue of missing or incomplete information can be used to address the lack of studies on cumulative effects to salmon from small hydroelectric power development

IV-67 We were not able to find the minimum shading requirements for timber harvesting and fish under "Direct Effects "

The DEIS does not disclose the potential impacts on air quality both inside and outside of the BSNF by prescribed burning activities on Forest lands The DEIS does a good job of quantifying the emissions from prescribed burning for each alternative and correctly indicates that such burning would be done in accordance with the State of Washington smoke management plan (SMP) However, the DEIS needs to provide some discussion regarding the location and frequency of burning activities and the downwind air quality impacts such burning would have, even when conducted in accordance with the SMP This would include

(1) expected concentrations at communities downwind of burning activities (using the SMP to identify impact areas and dispersion modeling to estimate concentrations),

(2) expected concentrations at residences, recreational areas, etc , immediately downwind of individual burns (based on recent data collected in Oregon), and

(3) impacts on visibility, both in nearby Class I areas, within the new wildernesses which are not Class I areas, and both inside and outside the BSNF

The technical tools for performing these analyses are now available and the quality of the results are adequate for comparing the potential air quality impacts of the alternatives

IV-127 Volatile organic compounds are also emitted by prescribed burning activities and should be included here

The conclusion regarding carbon monoxide is incorrect even though the data for I-5 at Northgate and the state and federal standards are correct The measured 8-hour average of 11 ppm at Northgate exceeds the state and federal standards of 9 ppm Although traffic volumes in the I-90 corridor are less than that of I-5 at Northgate, this data, in and of itself, does not justify a conclusion that the carbon monoxide standards are not exceeded through the I-90 corridor

IV-128 The use of the terms "total suspended particulates" and "suspended particulates" on these pages needs to be revised to be consistent with the current terminology per EPA's July 1, 1987, revisions to the national ambient air quality standards (NAAQS) for particulate matter (52 FR 24634-24669 and 24572-24715) In these rulemakings, EPA revoked the NAAQS for total suspended particulates (TSP), promulgated new NAAQS for particulate matter with aerodynamic diameters less than or equal to a nominal 10 micrometers (PM_{10}), and retained the prevention of significant deterioration (PSD) increments for TSP In order to implement these revisions, EPA defined the terms "particulate matter" (40 CFR 51 100(oo)), "particulate matter emissions" (40 CFR 51 100(pp)), "PM_{10}" (40 CFR 51 100(qq)), "PM_{10} emissions" (40 CFR 51 100(rr)) and "total suspended particulate" (40 CFR 51 100(ss))

When discussing the emissions from prescribed burning activities (page IV-128, paragraphs 3, 4, 5, 6, 7, page IV-129, Table IV-38, paragraphs 4, 5) the term "particulate matter emissions" should be used When discussing historical ambient concentrations of particulates (page IV-128, paragraph 6) in relation to state and local standards, the term "total suspended particulate" should be used

IV-128 Paragraphs 6 and 7 need to be expanded to include the discussion of downwind impacts as indicated above

IV-129 Although it is technically correct to indicate that changes in visibility are affected by "particulate matter emissions", it would be better to discuss the fine particle (i e less than 2 micrometers in aerodynamic diameter) emissions which have a much greater effect on visibility It is still true that prescribed burning is the primary contributor to such fine particle emissions in Western Washington

IV-146 In the discussion of mitigation and adverse impacts, it is important to identify the resource being affected

IV-147 It is stated that "Other mitigation measures are discussed in the last section of this chapter " We suggest that there be one place where all mitigation related to roads should be included or summarized The same suggestion is also to be applied to all other categories This would be of great assistance to document to reviewers, as well as to those that will be applying the EIS and Plan

IV-151 It is not clear whether a resource area is the same as a management area. The nature of this unit should be explained with a definition

IV-152 Explain the meaning of "the identification of an 'adverse effect' is somewhat subjective " It is very important that the criteria for making this determination be discussed

IV-152 The adverse environmental effects that cannot be avoided should be further discussed If a certain level of impacts are acceptable, the FS must identify to what extent these impacts are acceptable, again providing criteria for making this determination

IV-157 Under "The Fish Resource" there is no discussion of mitigation measures but, rather, a general presentation of potential problems and the application of BMPs These relate not to the practical options to be used or developed, but to generally known experiences

IV-159 The standard referred to under Regeneration Assurance needs to be discussed, including what it is, who applies it, and where it can be found

IV-159 Under Suitable Lands, the standards are more specific, but there should be an evaluation of the environmental results of past activities for use in future decision making The protocol for using the information should also be made available

IV-159 How the lands are evaluated for classification needs to be discussed This would include discussions of the accuracy of methods and identification of the responsible officials

IV-161 The standards that have been developed need to be identified more specifically By stating that special attention will be given to activities in riparian areas, there are no assurances that the riparian areas will be adequately protected and that potential impacts will be properly mitigated For example, what will and will not be allowed in riparian areas should be discussed

IV-161 The context of the statement on BMPs and the EPA is not clear The purposes for which the reports are prepared and are carried out needs to be discussed, as well as how they affect Forest Service management activities

IV-161 How protection of water quality standards is ensured through BMP implementation, needs to be explained further

IV-162 For the Mineral Resource the "appropriate environmental analysis" to be conducted needs to be explored If this refers to NEPA, such should be clearly stated The procedures, criteria, and relationships of future site-specific activities to the overall plan need discussion/explanation Without these, it is difficult to assess future and cumulative impacts.

Further, the monitoring protocol for periodic inspections to ensure compliance with approved operation plans should be included

IV-162 The introduction to the specific Management Areas is confusing A clear distinction between mitigation measures and standards and guidelines must be made Without this, it is difficult to differentiate between what is required by law or policy and what is specifically designed to minimize or eliminate the environmental impacts of a given decision or activity

IV-162 Though it is "expected" that the mitigation measures will be effective, assurances must be made, and feedback mechanisms must be implemented, to ensure this

IV-166 We suggest that the DEIS include a comprehensive discussion of the status of pesticide use on Federal lands in the Pacific Northwest This could tie in the references to pesticides made on pages IV-171,-172,-175,-169, and elsewhere throughout the document

IV-167 How will it be determined where and whether water temperature is an issue? *And doesn't it usually become an issue until after the shading requirement* goes below 80%, and it is too late?

IV-167 The process for issuing FERC licenses and permits needs to be more thoroughly discussed, including the minimum standards that are required

IV-168 Under 13B, silvicultural treatments will be permitted only when riparian objectives can be met How are the riparian objectives determined, and who makes the decision whether or not the treatments are consistent with the objectives A reference to another section of the DEIS may be in order

FOREST PLAN

Management Situation

2-19 In this Information Needs Section, it is not clear how important the current absence of this information is to the plan and DEIS where the information will actually be gathered, what the FS will do in its absence, and how the information will eventually be used While identifying the needs for additional information is very important, the role of the future information and the commitments to obtaining it need to be discussed For example, whether the projects are ongoing or planned, and who the responsible parties are need to be identified, including reasonably expected time frames for gathering the information Some sort of prioritization would also be helpful

Responsiveness to Issues, Concerns, and Opportunities

3-7 In stating that an environmental analysis will be done, we suggest referencing *the NEPA regulations to clarify the nature of the environmental analyses* For clarification, "other resources" should be explained

3-7 For the estimated soil sediment output estimates to be meaningful, the current sediment outputs need to be stated, including a breakdown of what fraction is activity generated and what is natural background

Forest Management Direction

4-1 For the management goals to be meaningful, the EIS needs to include something to help determine when goals are met or when they are slipping behind some schedule This is essential for accountability, documentation, and evaluating results

4-4 Under "Protection" for forest management goals, it is not clear what is being *protected and what this needs protection from*

4-7 It is stated that "Resident fish habitat will remain essentially as it existed prior to the Plan implementation" and that "Anadromous fish habitat will have improved significantly " It is not clear that this is a result of improved water quality on the BSNF We suggest making the correlation between fish habitat improvement and what specifically is being improved that results in an improvement to the habitat

4-12 To avoid confusion and to provide a clear indication of the actual extent of wildlife habitat improvement, we suggest providing actual acreages as well as acre equivalents Further, the Glossary needs to provide a more useful and concise definition of acreage equivalent

4-13 In our review edition of the Forest Plan, the page numbers go from 4-12 to *4-16* It does not appear that any pages are missing

4-16 There is a big jump in the production of energy materials over five decades--from 0 to 477 billion BTUs per year What kinds of environmental impacts and environmental analyses are to be expected from this?

4-17 We support the concept whereby the level of involvement will vary commensurate with project complexity However, this needs additional discussion The criteria for determining what levels of involvement are appropriate, the monitoring to confirm predictions, the contingency plans, the responsible parties, the level of environmental analysis, etc , all need to be tied into this procedure for it to be meaningful

4-17 It is stated that "Emphasis will be placed on the protection of riparian areas so that *their integrity is maintained* " Riparian integrity needs to be clearly defined Under such an approach what level of impact still preserves the integrity of the area?

4-18 What does it mean monitoring will be done at "several levels of intensity, the most common will be end-product reviews, which are highly cost and time effective" and that "more intensive monitoring will be done as needs arise"? In many cases, intensive monitoring is needed to gather baseline information against which to compare impacts Is this need provided for in the above statements? Is long-term monitoring encouraged under this approach? Finally these statements also need to be tied into the threefold procedure of implementation, effectiveness, and validation monitoring

4-41 Acknowledging and identifying the activities that have the greatest impact on fish and fish habitat is good as the first step However, protection, mitigation and restoration of fish habitat should not only be a primary emphasis of the fishery program, but of all activities that may have adverse impacts on fish/fish habitat There is no apparent coordination of the fisheries program with other resource management programs

4-42 We support the high investment level in habitat improvement Fish habitat capability should also be monitored

4-42 How is catchable fish related to total fish, and how are the figures 100 catchable fish/lake acre and 55 catchable fish/stream mile determined, developed, and monitored?

4-57 The Minerals section begins by stating that "This section contains a (1) 'brief' description of the minerals management program and (2) summary of how the mineral resources and activities will be managed " A full discussion of the program and management under the Plan needs to be included It is not found on page 4-99 under Forest-wide Standards and Guidelines We suggest completing the minerals discussion under this section

4-57 The process the FS will follow when mineral activities will be incompatible with the management objectives should be identified in the plan As presented, it is unclear who carries what responsibilities and whether or not there is a threshold above which the project scope needs to be reassessed It is also important to explain the requirements placed on the proponents of the mineral activities

4-57 What standards specifically will be used to help determine whether mineral development is the highest and best use and whether a withdrawn area should be revoked? What is meant by "withdrawal" in this instance?

4-57 The statement that "Through monitoring, the processing of mineral management activities can be made more efficient, reclamation techniques can be made more successful, and objectives can be made more achievable" is misleading Monitoring is a process of identifying needs and trends, accurately identifying and appropriately using the information gathered by monitoring helps lead to project success Monitoring alone does not ensure success

4-57 There must be a discussion of future site-specific NEPA analyses For example, what kind of environmental impact evaluation process will be followed for anticipated mining activities?

4-57 The confidence in industry's ability to conduct activities in sensitive areas needs to be demonstrated by a willingness for environmentally protective activities If "restrictive" management objects will be changed based on industry's ability, such will have to be documented and ensured

4-58 What are the "minimal to moderate" restriction on the mineral resource activities that the Plan allows? Again, there should be discussion of NEPA

4-58 With respect to mineral interests on the BSNF, it is stated that the actual amount of activity may vary significantly from that which has been predicted The Plan needs to discuss the impacts of this to the Plan, the planning process, and cumulative effects analysis, etc As the ensuing impacts may be significant, they need to be discussed, despite the uncertainty

4-62 This is the kind of commitment we believe is appropriate with protection of the environment from FS activities "As funding levels vary primary priority will be given to resource management and protection, with secondary priority given to user convenience " However, the Plan should continue further to be clear that protection of water quality and beneficial uses will be given priority

4-63 The numbers for road construction appear inconsistent First of all does "ultimately" mean after five decades? Secondly, at what point in time is the plan considered implemented? In other words, how do the average road construction rates of 185 miles for locals (18 5 miles?) and 5 2 miles for arterials and collectors through the first decade contribute to the 823 miles (714 + 109) expected to result from Plan implementation?

4-63 Which roads will be permanently closed, beyond those listed? If they are not yet known, what will be the criteria for closing roads?

4-63 Appendix B should be discussed For example, how and why these particular road projects were chosen and what the order of project activity will be need to be discussed

4-69 Forest Service documents (DEIS Preparations Guide and Outline Appendix D, 1985) state that standards and guidelines "provide the description of how things will be done on the ground " This is inconsistent with the stated purpose of standards and guidelines found in the Plan Their purpose is to identify anticipated direction for activities on the BSNF, and to use in the formulation of the Forest's planning model and development of alternatives These two purposes obscure the basic intent to provide specifics We suggest that FS make the standards and guidelines more applicable to all who follow plan implementation

4-89 It is important that the Plan explain and discuss cooperative efforts for fish habitat restoration projects and fish stocking programs, for example with states, tribes, or any others

4-91 Under Management Practices for Timber Management, it is stated that "Management intensities will vary with site productivity, timber species, other resource management objectives, and timing of implementation " In the same way, the Forest Service should ensure that monitoring intensities correspond directly with management intensities and site sensitivities

4-93 The reference for guidance on created openings should be presented For example, how was it decided that a clearing is considered closed when the tree is 4 5 feet high? Is this from other Forest Service documents? Further, what does "when other resources management considerations prevail" mean? And where in the Plan are the "particular management objectives" to be found?

4-95 To meet the Forest-wide standards and guidelines for soil, air, water, and riparian areas what are the FS's responsibilities over and against those of the state and private contractors? What kinds of arrangements are made with the contracted harvester, mineral lessees, special use permit holders, etc ? What does the contract include?

4-96 The statement that says that the FS will "Plan and accomplish rehabilitation projects as necessary to meet soil and water objectives and standards" needs to contain specific information to be meaningful Again, criteria, commitments, etc , need to be included

4-97 With reference to BMPs and water quality standards, the Plan and EIS must be consistent and accurate on the relationship between the two throughout the document

4-97 This section lacks the specific commitments to water quality and riparian areas needed to ensure adequate protection

4-97 It is stated that "Geographical boundaries of riparian areas are determined by on-site characteristics " What are these characteristics? How much of the area around the riparian area is included within the area to protected? Further, large bodies of water in addition to those listed, will be included, how large is large?

J-538

10664

4-98 It is apparent that the vegetation cover referred to in the top paragraph are what are commonly referred of as buffer strips This should be made clear In addition, it is important to identify specifics for how they will be implemented

4-98 We support the decision to inventory and map riparian areas for the Forest-wide data base but discussion of this needs to be much broader Discussion should include the data that the Forest will be collecting This is very useful for cumulative effects Specific guidance is needed so that data collection will be consistent across the forest How will the information gathered here be used to address the information needs identified on page 2-19? How will decisions affecting riparian area be handled without this inventory?

4-98 The reference to cumulative impacts needs to be supported by further discussion

4-99 We support efforts to "be directed toward minimizing adverse environmental impacts on the surface resources and toward reclaiming the site " But what will be done to specifically carry that out? This needs to be discussed

4-99 The contract conditions for mineral/energy exploration and development need to be discussed

4-108 There needs to be reference to the vegetation management EIS in the final stages of development in the Pacific Northwest How will the USFS proceed in the event the injunction is lifted? The programmatic EIS is not sufficiently specific to cover the BSNF And the EIS does not sufficiently document the potential use of various pest management techniques once the injunction is lifted Will further environmental analysis be conducted after the injunction is lifted?

4-117 Under the Fire Prevention Plan there is reference to specific direction relative to those elements and issues crucial to the successful and environmentally sound completion of a project/activity Every management activity on the Forest needs such specific direction However, there is still the need for additional discussion to make the document useful There should also be specific time frames and identification of responsibilities

4-120 The accompanying maps do not show the management areas for riparian and fish habitat emphasis Page 4-98, #10, implies that these areas are not known If the resolution of the maps is such that the riparian and fish habitat areas cannot be shown on the maps, they still need to be identified somehow

4-120 For the most part, the prescriptions for each management area do not contain the level of specificity necessary to be of real guidance to the federal land manager They are general and set in very general terms, leaving room for a wide span of interpretation Without question, the land manager must be given enough room to allow for special circumstances However, a minimum level of specific guidance must be provided

4-143 Under WINTER SPORTS RESORTS, the standards and guidelines for Water, soil, and air state, simply "Meet Forest-wide S&G Give extra attention to erosion prevention and control on areas cleared for ski runs " This does not indicate what air and water quality standards must be met Nothing identifies what visual quality and riparian zone guidelines must be followed Further, what kinds of contractual arrangements are made with the ski areas? What kinds of monitoring and cumulative effects analysis is carried out?

J-539

4-169 Under RIPARIAN AND FISH HABITAT EMPHASIS, to maintain consistency and thorough environmental protection, there needs to be specific guidance on how riparian zones are to be delineated There is also reference made to "this strategy"--what strategy? There is no strategy discussed or presented

4-170 Under "Planning" for "Fish & Wildlife", how is it known when the standards are met?

4-170 Intensity 13C is fully represented, but where are 13A B & D?

4-170 Under (C)(1)(b), which trees are not planned to be harvested--how will it be determined which trees are needed for slope stability or future wood debris?

4-170 Under (C)(1)(c), for monitoring streamside vegetation, it is not clear whether 80% shade is 80% of the existing total watershed

4-170 Under (C)(1)(d), current levels of habitat capability and riparian vegetation diversity need to be identified Discussion needs to be given to what criteria will be used for determining which places are selected for improvement

4-170 Under (C)(1)(e), for managing wetlands, is it meant that wetlands will only be protected if T&E species are involved or if they are at least several acres in size It appears that this may unnecessarily neglect some important wetlands How is the "several acres in size" to be interpreted

4-171 Under Habitat Improvement (C)(2), fish & wildlife habitat to be emphasized How is this emphasis to be realized, i e , what does emphasize mean and what specific activities will be encouraged and actually carried out?

4-171 Under timber (E) What does "A range of silvicultural treatments will be permitted only when riparian objectives can be accomplished" mean? This needs to be elaborated upon There should also be inclusion of BMPs for mitigation, as well as contract conditions

4-171 Under (E)(2)(a), the purpose of the reference to Fl is unclear

Under (E)(2)(b), what happens if more than 10% of the area is damaged, and what defines the area? How is this enforced and monitored?

Under (F)(1)(a), what does it mean to permit watershed improvements and maintenance? Should they not be required? We suggest that a more active, rather than passive, approach be taken

Under (F)(2)(a), how is no more than 10% soil exposure ensured?

Under (F)(2)(b), how are disturbance, widely distributed, and project area to be interpreted?

4-172 For mineral extraction, a statement of protection of riparian values is not sufficient How will this be determined or ensured?

4-172 Why is NEPA mentioned under (J)(1) and not (J)(3) or (J)(4)?

4-172 What is (J)(4), Land Ownership Planning, and how is this area special And what does it mean that "federal and non-federal lands shall contain equal amounts of riparian habitat"? If this refers to land exchanges then such must be made clear

4-172 Under (L)(1), it is stated that "Locating roads in riparian areas can only be done if riparian values are protected " How it is determined and ensured needs to be explained

Under (L)(2)(a), *it is not* clear what is meant by the "stated riparian area objective? Should the word "to" instead be "by"?

4-172 Under (L)(2)(e), there should be a high priority for protection above and beyond correction Further, how does "high priority" translate into management reality?

4-190 How are the Timber elements under (E) ensured and who implements it?

4-191 Under (E)(10)(c), what criteria will determine or be used to determine the prevention of degradation? What are the selected methods available for site-specific analysis?

4-191 Under (E)(16), what is the connection to the vegetation management EIS?

4-192 There must be, included under (E)(21), a reference to NEPA Is this a part of the NEPA scoping process, and does this contribute to the decision-making for determining adding a sale project?

4-193 Under (E)(25), the Timber Harvest Administration should include development, implementation and verification of BMPs that are doing what they are intended to do. This means monitoring Under (29) or (30), FS should ensure that the environmental components of the sale have been satisfactorily done

4-194 Under (F), FS should consider requiring BMPs, site monitoring, and tracking cumulative effects before, during, and after project activity

Implementation of the Forest Plan

A main concern on the proposed Plan is that the level of detail and the commitment to monitoring and feedback mechanisms was not commensurate with protection needed by the environment The feedback mechanisms need to be made clear so that standards and guidelines, best management practices, standard operating procedures, intensity of monitoring, and timber sale administration are adjusted when monitoring indicates a need Inclusion of these components will significantly strengthen the accuracy and effectiveness of the FEIS and Plan Further, the regulatory requirements in NEPA and the National Forest Management Act (NFMA) support the development of a detailed monitoring plan and feedback mechanism

NEPA requires that EISs include mitigation Without a detailed monitoring plan, it will be difficult for the Forest to comply with the Council on Environmental Quality's NEPA regulations which require that an EIS shall contain "means to mitigate adverse environmental impacts (40 CFR 1502 16(h)) " *When adverse effects on water quality and* fisheries are potentially significant, they must be mitigated A detailed monitoring plan needs to accompany any proposed mitigation activity in order to measure its effectiveness and ensure that necessary corrections are implemented

NFMA also provides the basis for a monitoring plan The National Forest System Land and Resource Management Planning Regulations (36 CFR 219 11(d)) state that a Forest Plan shall contain a "Monitoring and Evaluation Requirement that will provide a basis for *a periodic determination* and evaluation of the effects of management practices " Since the effects of management practices for timber outputs can significantly affect water quality and fisheries, a detailed monitoring plan is warranted

The development of a detailed water quality monitoring plan should be based on a list of current beneficial uses, present condition, and desired future condition for each stream or a watershed unit which is small enough to adequately protect the beneficial uses (similar to the concept in goals for roads in Table 4-18). The present condition and desired future condition can be expressed in terms which best describe the beneficial use (e g percent fish habitat capability) The monitoring plan should include types of surveys, location of sampling, parameters to be monitored, indicator species, budget, procedures for using data or results in plan implementation, and availability of results to interested and affected groups Enclosed is a copy of our monitoring guidance Appendices A and O of the Final Nez Perce National Forest Plan, October 1987 includes the level of detail and approach to water quality and fishery monitoring which we believe can accomplish the stated objectives

5-1 The cumulative impacts of *the projects listed in Appendices A-H should* be discussed How these projects will affect the plan and in turn the environmental impacts of the plan also need discussion

5-2 If "outputs and activities in individual years may be significantly different from those in Chapter 4 and 5, depending on fiscal budget," how accurate is the plan? Is this why there are so few specifics? Does this imply that though individual years may vary, the net result after 10 years will be as projected? *How will FS proceed in the face of uncertain budgets?* If this is a real concern, it will affect the plan and DEIS, as well as the activities and environmental impacts, and must be discussed

5-2 The complete NEPA process needs to be described here, not just the case for a categorical exclusion Include scoping, EISs and discussion of cumulative effects See NEPA regulations 1508 4, 1508 7, and 1500 4(p)

5-2 It is stated that "The monitoring Plan ensures that activities reasonably conform to the Management Area direction, and that outputs *satisfy the Plan* objectives " At what point is "reasonably" no longer satisfactory? In other words, what is the threshold for unreasonable? Criteria are needed

5-2 In the case of monitoring for environmental protection, we believe that compiling results in an annual report for evaluation by an interdisciplinary team could be ineffective if monitoring shows that action is needed immediately Long-term monitoring is not sufficient by itself The *monitoring plan contains no timely feedback mechanism* for results from ongoing monitoring, especially of specific activities, like when a timber contract may be violated or an operation needs to be altered to protect water quality

5-3 While annual evaluations may be a good way of tracking cumulative effects, they preclude the ability for immediate action We recommend a plan for monitoring to provide immediate feedback on a site- and action-specific basis

5-3 What does it mean that "Procedures prescribed by NEPA will be followed as the Forest Supervisor determines the appropriate action " It is not clear what NEPA procedures have to do with monitoring results that indicate a reduction in water quality on Forest Service lands NEPA is not the mechanism whereby environmental impacts are mitigated, rather, it is a process by which to identify mitigation measures

5-3 Of the several variables across the top of Table 5-1 that merit special discussion, "Precision" and "Reliability" are mentioned They need further elaboration to be useful How they were determined, who measured them, with what, and to what end they can be used would be very helpful information

5-4 Under the heading "Method of Monitoring" in Table 5-1, the table confuses the way something is to be monitored (the method) with the indicator that is to be monitored, which, in some instances in the Table, is implied under "Unit of Measure " If is important that the Table be very clear about keeping the variable to be monitored (e g , turbidity) distinct from the method (e g Secchi disk or cobble embeddedness) These in turn, must be kept distinct from the attribute represented by the variable, i e , the attribute to be protected (e g , water quality)

For example, under Time-Impacts to Growing Stock Levels on page 5-5 "aerial surveys" and "stand exams" are a method of monitoring, but under Fish/Water- Evaluate Fish Habitat Capability Trends, on page 5-7, Quality and Quantity of Spawning Areas " "stream stability," etc , are not monitoring methods, they are attributes the land managers are concerned about protecting The table needs to be tightened up (It should be noted that "stand exams" and "aerial surveys" still lack specific criteria)

The Monitoring Plan as tabulated does not monitor the impacts of activities to resources, there needs to be an approach that links monitoring water quality to specific activities taking place on the Forest An inventory of watersheds and there current condition would be the first step

5-4 The Monitoring Plan needs to include an additional column to discuss what happens (or reference where in the plan it can be found) if the "threshold of variability" is exceeded There needs to be discussion of a specific course of action if the threshold is exceeded

5-6 It doesn't follow, under Fish/Water -- Effectiveness of Fish Habitat Restoration and Enhancement Projects, where the objective is to determine whether the habitat treatment results in an increase in habitat quality, that the unit of measure is the number of structures This is only quantitative and is not a true measure of improved habitat quality

5-6 The Table needs to include a column that provides a baseline to identify the level of a variable before an activity is initiated How else will the threshold of variable be determined?

In some cases units are needed for the threshold of variability above and beyond a straight percentage increase or decrease

The "Method of Monitoring" column for Fish/Water needs to be revisited and clarified. As presented, it is very confusing

Riparian are monitoring needs to occur before projects as well as after Long reporting periods such as 2 and 5 years may not be frequent enough to prevent damage from occurring in other areas

5-7 The Watershed Condition Class Assessment under Fish/Water needs a whole table and section for itself Table 5-1 should contain "Watershed Condition" as an "action/effort to be monitored "

5-4 Table 5-1 should be broken into two tables, on for monitoring actions and efforts, the other to monitor natural resources It is too confusing to combine output monitoring with (environment) effects monitoring They should be separated

B-1 What is the prioritization method for project implementation?

B-2 The projects left out of the listing, considered not major, appear significant How will they be identified and implemented?

C-2 For the wildlife habitat improvement schedule of Table C-1 the activity for wetland forage and habitat improvement is not specific but should be, to be consistent with the rest of the table

C-3 The structure available for each type of habitat improvement should be discussed, including what the opportunities, options, and requirements are

F-1 The funding levels on the right side of the page need to be explained Are they proposed, minimum, or allocated levels? If the money is not available, such should be explained

SUMMARY OF THE EPA RATING SYSTEM
FOR DRAFT ENVIRONMENTAL IMPACT STATEMENTS
DEFINITIONS AND FOLLOW-UP ACTION *

Environmental Impact of the Action

LO--Lack of Objections

The EPA review has not identified any potential environmental impacts requiring substantive changes to the proposal The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal

EC--Environmental Concerns

The EPA review has identified environmental impacts that should be avoided in order to fully protect the environment Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact EPA intends to work with the lead agency to reduce these impacts

EO--Environmental Objections

The EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative) EPA intends to work with the lead agency to reduce these impacts

EU--Environmentally Unsatisfactory

The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality EPA intends to work with the lead agency to reduce these impacts If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the CEQ

Adequacy of the Impact Statement

Category 1--Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action No further analysis of data collection is necessary but the reviewer may suggest the addition of clarifying language or information

Category 2--Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action The identified additional information, data, analyses, or discussion should be included in the final EIS

Category 3--Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts EPA believes that the identified additional information, data analyses, or discussions are of such a magnitude that they should have full public review at a draft stage EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS On the basis of the potential significant impacts involved this proposal could be a candidate for referral to the CEQ

J-542

NATIONAL FOREST
WATER QUALITY MONITORING
RECOMMENDATIONS

GENERAL MONITORING GUIDELINES

Priorities. Greatest priority should be given to assessing fishery impacts in the following order: 1) endangered anadromous runs; 2) other anadromous runs; 3) resident salmonids; 4) and others, including warm water species.

Site Selections. Site selection for monitoring impacts on the above fish population should reflect the need for a representative range of environmental conditions, e.g., soil type, channel morphology, *and erosion potential*. *Special attention should be given to* watersheds with the greatest sediment production potential. Consideration must also be given to monitoring in heavily developed watersheds and in watersheds developed or disturbed in increments over time to evaluate cumulative effects upon fishery resources.

Paired Watersheds. Paired watersheds should be selected wherever possible, consisting of a representative stream reach in the watersheds to be developed and a comparable reach in an undeveloped *watershed. Control (or reference) reaches should be selected based* upon similarity in stream slope, elevation, streamside vegetation, bank stability, fishery, soil type, stream classification, etc.

Timing. Timing of monitoring should emphasize detecting impacts from first entry into a watershed. This may require prior monitoring to establish adequate baseline data in both the developed and undeveloped watersheds.

Frequency. Frequency and location of monitoring should be periodically adjusted to reflect needs or problems identified in the ongoing monitoring. Typically, monitoring at a specific site will be initially intensive, with a later shift to periodic trend verification.

Long-Term Monitoring. Certain aspects of the monitoring should be designed to evaluate impacts not detectable on a short-term basis. Examples are long-term stabilizaton of logging roads, recovery rates of degraded streams, persence of large woody debris, etc.

IMPLEMENTATION MONITORING

This on-site monitoring should evaluate the correctness of Best Management Practices (BMP) implementation. This information will be critical in determining whether adverse instream habitat impacts were caused by inadequate BMPs or improper implementation of BMPs. In general, however, we feel that the specific method used to evaluate the correctness of BMP implementation are best identified by the U.S. Forest Service (USFS).

EFFECTIVENESS MONITORING

Stream Monitoring Parameters. Both fish density (by species and age class) and fish habitat quality should be evaluated. Habitat quality should not be confined solely to substrate composition (e.g., cobble embeddedness and percent fine sediment by depth), but should also include such factors as pool/riffle ratio, amount and size of large organic debris, vegetative cover, channel morphology, etc. Data should be gathered by the most cost effective method while insuring data quality, and utilization of standard methods of measurement and analysis.

J-543

CALIBRATION MONITORING

The total monitoring effort should be carefully designed so that one outcome is to improve our ability to predict via models: 1) the actual sediment loading to a stream; 2) the actual impact of those sediments on fish habitat; and 3) the actual impacts of those sediments or other fish habitat changes on fish population.

INTERAGENCY SUPPORT/COORDINATION

Technical Fisheries Advisory Committee. To improve interagency coordination (and to provide technical assistance and support), we suggest that the USFS establish a technical fishery advisory committee in each state. This group could consist of representatives of government agencies who manage the resource or whose activities impact the fisheries resource. By meeting quarterly, or as significant issues arise, this group could identify, and hopefully resolve problems as they develop. They could also play a key role in assisting the USFS in preparing and presenting the annual monitoring report discussed below.

Annual Monitoring Report. We suggest that an annual public meeting be held to brief all parties on the monitoring results. To minimize travel costs, the USFS could review results from individual forests within a state at a single meeting. This would also facilitate comparison of results from different forests. The technical fisheries advisory committee could help the USFS develop, and present a consensus on impacts and needed actions.

Written material should focus on an analysis of planned vs actual actions and impacts. For example, where water quality problems occurred, the USFS should clearly define the nature and cause of the problems, the corrective actions taken, and the procedures to be used to prevent future occurrences. This material, together with supporting data, should be made available to all parties prior to the public meeting. A more formal written report summarizing long-term trends and impacts should be prepared periodically, possibly at 5-year intervals.

STATE OF WASHINGTON
OFFICE OF THE GOVERNOR

OLYMPIA
98504-0413

BOOTH GARDNER
GOVERNOR

May 2, 1988

Mr. Doug MacWilliams
Forest Supervisor
Mt. Baker-Snoqualmie National Forest
1022 First Avenue
Seattle, Washington 98104

Dear Mr. MacWilliams

I appreciate having this opportunity to comment on behalf of the state of Washington on the proposed management plan for the Mt Baker-Snoqualmie National Forest. The state of Washington wants a forest management plan which is both environmentally sound and provides an acceptable and stable supply of amenities and commodities, and I trust you will find the state's comments constructive.

The Forest Service is developing management plans for the seven national forests in Washington State These will have significant socio-economic and natural resource impacts on the state and those local communities and industries which rely upon forest resources In view of this, I have asked the appropriate state agencies to review each forest plan to determine whether it is consistent with state goals and policies I have also asked them to suggest positive steps which could be taken by the Forest Service to accommodate state concerns This review has included coordination with the Commissioner of Public Lands as the attached letter documents

The state's response is divided into several components Attachment A lists the key state policies, analyzes the preferred alternative with regard to them and indicates certain steps that the state believes should be taken Detailed state wildlife and fisheries concerns and prescriptions are in Attachment B Timber supply data and concerns are in Attachment C Attachment D provides data on state recreation needs And, Attachment E is a compilation of page-specific technical comments from state agencies

The Mt Baker-Snoqualmie National Forest is an irreplaceable resource for residents of Washington State Many in the forest products industry are dependent on the Forest for timber supply, the Forest's rivers and streams

J-544

provide crucial habitat for fish, the Forest is the home for much of the state's wildlife and it provides a wide variety of recreational opportunities for many Washington's residents, over one half of whom live within one-half day drive of the Forest.

Obviously, the Forest's capacity to meet the extensive demands on it is not infinite and therein lies the source of the problem. finding a way to balance the many competing objectives. This is a difficult task and I want to commend you for your excellent effort to date to formulate a long-term management plan to meet these differing objectives

As the enclosed state response indicates, Washington wants a stable and reliable supply of timber for its forest products industry, stability for timber-dependent communities, opportunities for its residents to enjoy the various recreational pursuits the Forest has to offer, and protections for habitat aimed at meeting state wildlife and fisheries goals While the state comments indicate its policies for these areas I recognize in the end there will have to be a balance among these diverse, and sometimes competing, state policies.

In this regard some basic questions have been raised about the Forest's current calculation of its timber supply base and amounts of old growth As the discussion in Attachment A indicates, the forest products industry has raised what we regard to be some legitimate questions regarding timber supply If through further examination it is determined that the Forest has significantly underestimated the Forest's timber supply base and that an upward adjustment can be made, the task of balancing differing objectives will be far easier. Concern has also been expressed by environmental representatives regarding the amount of old growth remaining in the forest We would like to discuss with the Forest Service its definition of old growth and the effects this definition has on estimates of old growth inventory

We have also noticed what appears to be a case of double counting in the Mt Baker-Snoqualmie National Forest Plan, with the Forest claiming a portion of the supply from other regions as part of its total supply picture for its own region The state's concern is that this is a misleading supply figure and, in fact, the industry in this region may have less timber available than projected This has significant ramifications for both industry and timber-dependent communities and highlights the need for an accurate assessment of timber supply from each forest and for an aggregate look at the supply from each of the seven forests in Washington along with the supply from non-Federal owners.

We would like to work closely with you, industry and environmental representatives to resolve these issues. Until such time that the state is comfortable with the Forest's analysis of the timber base and old growth supply the state is not in a position to make allocational choices for the other valuable amenities and resources. Decisions made on an uncertain data

base may lead to false choices regarding utilization of very important resources. We have, therefore, opted to provide the Forest only with state goals for these resources so that you are informed about the broad resource requirements that the state sees for the Forest. Information in Attachment A is not intended to be interpreted as the final state position.

In closing, I have asked the appropriate state agencies to conduct an aggregate impact analysis of all seven Washington Forest Service plans. We will not select or propose a preferred alternative plan for any national forest until this evaluation is done. Consequently, I urge the Forest not adopt individual forest plans until the state has had the opportunity to comment on the statewide aggregate impact. This will allow additional time for the state to work with you to develop and refine an acceptable final statewide position on all forest plans in Washington State

If you have questions or wish to follow up on any of the suggestions contained in this letter, please contact Bob Nichols of my office at (206) 586-0820

Sincerely,

Booth Gardner
Governor

Brian Boyle
Commissioner of Public Lands

May 2, 1988

The Honorable Booth Gardner
Governor of Washington State
Legislative Building
Olympia, Washington 98504

Dear Governor Gardner

I have been pleased to participate in the coordinated state agency review of the Mt Baker-Snoqualmie National Forest Plan I strongly support inclusion and balancing of all state agency policy goals for national forest management within one state response I believe the policy review process for the Mt Baker-Snoqualmie plan has been a useful one and that the resulting policy comments broadly incorporate the policy goals of the Department of Natural Resources

I look forward to continuing to work with you and your staff so that our overall statewide recommendations on national forest plans will reflect a reasonable balance among diverse state natural resource and economic development objectives

Sincerely,

Brian Boyle
Commissioner of Public Lands

BB cpj

ATTACHMENT A

POLICY COMMENTS

POLICY 1 -- THE NATIONAL FORESTS SHOULD PROVIDE A RELIABLE FLOW OF RAW MATERIAL TO HELP SUPPORT THE VIABILITY OF THE STATEWIDE FOREST PRODUCTS INDUSTRY

The state of Washington expects the national forests to continue as a major supplier of wood for the state's vital forest products industry. Timber sales should provide a level of stumpage, species mix, and availability to meet industry needs without dramatic variations which distort stumpage prices and make long range industry planning difficult Providing a fairly stable flow of timber from national forest lands which avoids dramatic fluctuations is a preferred approach for the Mt Baker-Snoqualmie National Forest

Our review of the planning documents has raised a number of questions relating to a stable flow of timber that need to be clarified in the final EIS so that the state and the public can fully assess the consequences of the planned action.

The preferred alternative for the Mt Baker-Snoqualmie plan has an annual allowable sale quantity (ASQ) of 170 million board feet. This compares with a harvest of 210 million board feet per year for the 1976-1985 period This is nearly a one-fifth decline, and a substantial reduction from the mid-1960s level where, for example, the 1965 harvest was 484 million board feet Such declines have resulted from competing interests and amenity values (e g., land reserved for wilderness and projected needs for wildlife and recreation) and have had, and will continue to have, economic implications for the many mills which rely on the Forest for their timber supply

Understandably, the forest products industry has expressed concern regarding this decline in the Forest's timber supply In their attempt to address this issue, the industry has reevaluated the Forest's technical calculations to establish the available timber supply base Their specific concerns are listed in Attachment C The state has met with the industry representatives and has been advised of their numerous questions regarding the accuracy and validity of the Forest's timber supply figures We believe there is merit to at least some of the issues raised by industry and are troubled that, in discussions between the Forest Service and industry on this issue, there has not been any resolution. The substantial discrepancy between the industry and the Forest Service over the timber supply base is a major concern since, in the state's attempt to meet and balance state policy goals, we need to have a data base on which key participants can agree in order to provide a solid foundation from which we might evaluate various state options. Further, to the extent industry concerns are correct, they may represent a significant opportunity to adjust upward the supply of harvestable timber. Relative agreement on the timber supply base is a most critical element in evaluating these management plans and we urge continued discussions to resolve these very important issues We do not believe a final EIS should be released until the discrepancies have been resolved.

POLICY 2 -- PROMOTE LONG-TERM COMMUNITY STABILITY

It is the state's policy to encourage the balanced growth of the economy consistent with the preservation of Washington's quality of life and environment. Inherent in this policy is the provision of adequate opportunities and revenues for stabilizing and broadening the state's economic base while maintaining high natural resource and environmental values. In addition, it is the state's policy to provide communities with access to opportunities for productive and coordinated development to encourage community stability and economic vitality.

In Policy number 1, the state discussed the need to resolve issues relating to the Forest's timber base This is not only important from the perspective of the timber industry's need for stable supplies of raw material, but also from the point of view of stability within timber dependent communities With the exception of the pulp and paper mills, the vast majority of the industry's workforce in the five county Mt Baker-Snoqualmie region is employed in small establishments. These tend to be significant basic employers for those smaller communities in the eastern portions of these five counties. The amount of timber harvesting that occurs on the Forest has obvious impacts on forest receipts and revenue for local governments (as well as for the state) in those counties that are more dependent upon timber harvests from the Forest Counties such as Skagit will particularly experience more difficulty in funding important local government services.

If discussions with the industry task force do not result in an upward revision in the timber supply base, we see some significant destabilizing forces at work for these timber dependent communities We say this for several reasons

Already local communities have been affected adversely by recent efficiencies in the forest products industry For example, in Skagit County, 320 (22 6 percent) lumber and wood products jobs were lost in the period 1977-1986 Despite a vigorous wood products industry, these efficiencies have resulted in a statewide decline in jobs The statewide industry has undergone fundamental change, down 15,900 jobs from 1978 highs, and this massive job loss has created high unemployment and stagnant local economies in counties dependent upon forest employment.

More importantly, the state's review and analysis of the Forest's planning documents determined that approximately 40 percent of this region's timber supply comes from areas outside of the the five county area In particular, this supply comes from the Olympic peninsula and southwestern Washington The state foresees short and long-term major declines in the two areas' timber availability. This suggests that a good portion of the present timber supply for the five county Mt. Baker-Snoqualmie forest products industry may be unavailable in the future. The Olympic National Forest's DEIS projects a decline in total (federal and nonfederal) supply during next three decades A similar situation exists in southwestern Washington where industry timberlands are projected to undergo significant declines in future timber availability.

As a result of recent changes in Forest Service management regulations, land previously included in the timber base will be set aside for purposes other than timber harvest, i e., spotted owls and various minimum management requirements (although specific amounts are in question) We also recognize that some of the recent timber volume presently available to the forest products industry in the Mt. Baker-Snoqualmie region is from resale timber which will be unavailable in the future.

The state, given these reasons, sees the need for greater initiative in two areas to help the state maintain its objective of promoting community stability. With the considerations noted above and, since the Mt. Baker-Snoqualmie National Forest contributes significant economic and amenity values for the five-county area and the state as a whole, both areas involve closer coordination between the Forest and the state.

First, if the Forest chooses an alternative which creates negative socio-economic impacts, it should work with the state in exploring possible mitigation measures in order to avoid conflicts with federal and state job and community assistance programs. It makes little sense for federal and state agencies to undergo considerable effort and expense to alleviate economic hardships on local communities without close coordination with the Mt. Baker-Snoqualmie National Forest which is a major economic force in the area.

It may be noted there is a wide range of community problem areas that can be the focus of public and private partnerships which should be considered by the Forest Service. As a dominant landowner, producer of timber, and source of direct or indirect employment in the area, the Forest Service is invited to involve itself more closely in the area's economic development (e.g., joint economic planning, rural development, new and small business development, community and public school development) planning activities.

The Job Training Partnership Act (JTPA) of 1982 might serve as a model that could be utilized in such a partnership effort. JTPA encourages more integration with state and local programs, strong public and private partnerships, an emphasis on training rather than income support or public employment, and flexibility to plan and manage programs tailored to local circumstances. JTPA training funds might be used to support training directly responsive to the needs of specific industries and businesses. JTPA funds available for employment-generating activities could assist a wide variety of economic development activities when they increase job opportunities for JTPA-eligible persons.

Long-term economic diversification of forest-dependent communities should be a joint long-term cooperative commitment of federal, state and local governments. As a first step it should be noted that the state has some concern over the emphasis in the Forest Service model on the estimation of timber value, the Forest's major revenue producer. Equal emphasis on all potential economic resources, including recreation, tourism, wildlife, etc., would help local communities identify diversification goals.

Second, the Mt. Baker-Snoqualmie National Forest is a significant contributor of timber for the five-county area (approximately 18 percent of total supply from all owners over the 1975-84 period). While the state recognizes that

providing an even or adequate flow of wood supply from all owners in the Forest's region is not within the Forest's responsibility, the state does believe that timber dependent local communities would benefit from a greater cooperative relationship among all timber landowners in the area regarding harvest levels since fully 82 percent of the present timber supply comes from non-National Forest Service lands. With the majority of the timber harvests occuring on non-federal lands in the Mt. Baker-Snoqualmie impact area, a coordinated strategy among all classes of landowners to address current and future economic -- and possibly, environmental and natural resource -- problems would be very beneficial We would be willing to work with the Forest and other landowners in further exploration of this idea.

POLICY 3 -- WILDLIFE/FISHERY MANAGEMENT AND HABITAT PROTECTION SHOULD EMPHASIZE STATE SPECIES GOALS

The state and the Forest Service have joint responsibilities for wildlife and fish within Forest Service jurisdictions While the Forest Service is responsible for habitat, the state is responsible for wildlife and fish populations. Obviously these are two complementary responsibilities and there needs to be close coordination between the state and the Forest on wildlife and fish management activities. After review of the proposed management plan and EIS for the Mt. Baker-Snoqualmie National Forest, the state is concerned that none of the alternatives presented provide the wildlife and fish habitat protection at levels necessary to achieve state management goals

Specific state goals for the Mt. Baker-Snoqualmie National Forest are to

- o Recover populations of threatened and endangered species.
- o Increase black-tailed deer population 10 percent and protect winter range.
- o Maintain or increase elk populations and associated winter range.
- o Maintain or increase watchable wildlife populations.
- o Increase wild steelhead populations to maximum sustainable harvest levels.
- o Increase wild anadromous cutthroat and wild resident trout populations in some waters up to potential carrying capacity levels (to provide "trophy" fisheries).
- o Increase (and maintain) these same wild trout species populations to (at) desired harvest levels in other waters.
- o Maintain or increase regionwide wildlife species diversity.
- o Maintain regionwide genetic diversity within and among populations of the same species.
- o Fully mitigate for wildlife and fisheries losses due to logging practices.

Related to our concern over the Forest's habitat management activities, the state is also concerned about Forest Service mitigation policy for wildlife habitat areas. The U.S. Forest Service established policy on fish habitat

indicates the following priorities regarding fisheries management where feasible, protect existing habitat from degradation, rehabilitate areas in which existing habitat has been degraded as a result of management activities, rehabilitate, where feasible, areas in which natural forces have caused habitat degradation, and, enhance habitat through development practices. The state fully supports this published Forest Service policy and believes a similar policy should be established for wildlife.

Our specific concern is that the Forest Service proposed management plan and DEIS indicate losses for wildlife populations (except for the bald eagle) across all alternatives rather than maintaining them at current levels. In order to protect existing populations, the Forest Service needs to establish a clear policy to protect existing habitat from degradation and to provide mitigation for areas degraded as a result of management activities by replacement in kind on site, or replacement in kind off site, or other replacement negotiated with state agencies of jurisdiction.

The state recognizes that its fish and wildlife goals constitute goals and that their full attainment might not be possible given other values which also must be considered in developing the final management plan for the Forest. The state has listed specific recommendations in Attachment B to meet state wildlife and fish objectives, which may have impacts on timber supply, and we urge that the Forest give them every serious consideration. But, to reiterate what was discussed in Policy number 1, we need as a first step to resolve issues relating to timber supply on the Mt. Baker-Snoqualmie National Forest If, indeed, an upward adjustment in the timber supply base is possible as suggested by industry representatives, the opportunity may be there to better meet state fish and wildlife goals without compromising timber supply

In order to meet these state wildlife and fish goals there are five key policy concerns which the state would like the Forest to address

A. Riparian Management

Riparian zones are a key part of any forest ecosystem. While constituting only a fraction (2-3 percent) of the total forest land base, these zones are essential for all fish and for 70 percent of all wildlife species which utilize riparian habitats to meet all or a portion of their life requirements These zones are concentrated in a very small area yet provide a rich and diverse habitat for a wide variety of wildlife occupying different niches within the zones. Moreover, riparian zones provide a natural sediment filter protecting water quality and fish habitats, and are a source of large woody debris which creates additional fish habitat The stream is also protected by trees within the riparian zone moderating temperature fluctuations crucial for fish survival.

The proposed management plan's prescription for riparian zones on perennial streams allows up to 67 percent of the standing volume in the first 75 feet of the zone to be harvested over time. The outer 25 feet of the zone may be managed according the adjacent land prescription, which means it may be cut if the adjacent land is clear cut. In the smaller, lightly incised or intermittent streams, the plan allows for a ten foot buffer which is totally inadequate for fish and wildlife protection.

Studies have shown that wildlife and fish species diversity is reduced significantly as streamside zones are decreased. Since riparian habitats are so critical for wildlife and fish, they merit special protections and the state recommends a riparian zone as wide as the potential height of the tallest trees in the zone. This prescription should apply to all waters bearing fish as well as smaller Class III streams featuring key wildlife habitats. Specific and detailed prescriptions for riparian zone management may be found in Attachment B.

B Road and Travel Management

Road construction, use, and maintenance present the greatest potential impact on the environment of all forest practices. At least four acres of wildlife habitat are directly removed for each mile of new road constructed. Increased access leads to more poaching, harassment, and vehicle/animal accidents Many species of wildlife avoid roads which reduce habitat carrying capacity and wildlife numbers. In addition, roads are a major source of increased sedimentation in forest streams and excessive road densities decrease high quality viewing and hunting opportunities.

The Forest's preferred alternative proposes a road density in excess of three miles per square mile open to public use without restriction. Further, the state is concerned over the Forest's proposed approach to opening roadless areas for wildlife habitat improvement and hunter access. The state believes road and travel management should emphasize avoidance of special habitats, unstable slopes and sediment-vulnerable areas and open road densities should be compatible with prevailing wildlife use. In order to protect habitat carrying capacity, the state believes open road densities and elk, deer and goat winter ranges should be less than two miles per square mile. Detailed state recommendations on the Forest's road and travel management plans relating to the Mt. Baker-Snoqualmie plan may be found in Attachment B.

C Dead and Down Woody Debris

In the forest ecosystem, dying, dead and down trees provide a wide variety of habitat niches for many wildlife species and they are essential components of any forest ecosystem.

Region 6 Forest Service policy is to maintain dead and down woody material at a level sufficient to support 40 percent of the potential woodpecker populations. The state can accept this specific policy on extensively managed land allocations. However, the Forest Service sets the Minimum Management Requirement level for other cavity nesters at 20 percent The state believes this level is not sufficient to support viable populations for cavity nesters forest wide as researchers support 40-60 percent level to ensure viable populations. See Attachment B for additional state recommendations in this area

J-548

D. Old Growth Ecosystems

Only recently have we begun to appreciate the value of old growth. We now know that old growth is more than just big and old trees, rather, old growth constitutes a rich ecosystem supporting a wide variety of wildlife and plant species. Specialized niches and other species requirements rarely found in stands managed on economic rotations include large amounts and sizes of standing dead and down wood, large organic debris, lichen (a major winter food source for elk), and a four-layered canopy. Further, many wildlife species have evolved in close association with stable old growth ecosystems and are not readily adaptable to unstable ecosystems (i.e., managed stands). Some species adapted to the old growth system are totally or primarily dependent on it for their life support and population viability These ecosystems are unique, supporting wildlife and plant species that are found only in old growth.

Given these benefits, and the fact that we are only now beginning to understand the value and complexity of these ecosystems, the state recommends a conservative approach in this planning cycle to the way the Forest Service manages for this irreplaceable resource. The old saying, "the first rule of intelligent tinkering is to save all the pieces" is applicable Our knowledge of life cycles, population dynamics and species dependence on old growth is far from complete How large does an old growth area have to be to retain its most limited species? What would the loss of that species mean to society?

Time is needed to thoroughly evaluate these issues. In order to accommodate this end, unroaded areas with large blocks of old growth acreages need to be maintained in an unroaded status to provide the necessary habitat, solitude and gene pool to maintain viable populations Further, since many species depend on old growth for protection during migration and dispersal and become vulnerable to predators when they must travel great distances between old growth stands, corridors between such stands must be maintained. To this end, we suggest that any one drainage has a total of at least 5 percent old growth and, where larger blocks occur, they should be favored for protection over the fragmented and isolated stands which are not known to be occupied by MISs (management indicator species) This recommendation is designed to provide both sufficient habitat and travel corridors to help ensure population viability In addition, the state believes some legitimate questions have been raised by environmental representatives regarding how much "bona fide" old growth forest -- and we recognize there are definitional problems -- remains in the Mt. Baker-Snoqualmie National Forest If, in fact, such old growth is far less than Forest Service estimates, the concerns expressed by the state regarding the need for, and continued viability of, what remains of the old growth forest in Washington become accentuated A reexamination of the amount of old growth remaining in the Forest would be beneficial.

As a final note, the state is concerned that the Forest's proposed management areas for spotted owls are to some degree misaligned The proposed plan has designated some areas for SOHAs (spotted owl habitat areas) where we believe there are no known spotted owls. other areas where we believe spotted owls exist are left unprotected by the proposed plan. The state has conducted extensive surveys about where spotted owls exist and do not exist in the Mt. Baker-Snoqualmie area and we describe this information at the end of Attachment B.

J-549

E. Fishery Resources

The fish resources of the Mt. Baker-Snoqualmie Forest have significant economic and recreational value and the state places high priority on maintenance and enhancement of these fish populations and protection of their habitats Numerous user groups are also very concerned about the future of these fisheries, especially since the demand for sport fishing is projected to significantly increase in the near future and is expected to exceed the supply in a very few years.

A major state concern is that the Forest planning documents fail to recognize the potential for the alpine lake recreational fishery In fact, the Forest's documents virtually make no mention of this resource. The Mt. Baker-Snoqualmie National Forest has a major resource here worth millions of dollars The state believes that the planning document significantly underestimates the value of this resource and Attachment B provides in considerable detail the actual and potential value of this recreational fishery Attachment B also addresses what the state sees as deficiencies in the way Forest planning documents calculate the value of all fisheries in the Forest and argues that the Forest's value of $2.1 million for the combined salmon and game fish (in streams and high lakes) is highly inaccurate. The true value of these resources approaches $20 million per year, even using the Forest's overly low assigned values.

With this in mind, it is important that the final Forest Management plan take steps the state sees necessary to protect this resource. In this regard, we have already discussed suggested changes in riparian zone management practices In addition, the state believes the Forest's proposed reliance on Best Management Practices (BMPs) is inadequate since the state's experience is that these BMPs have not been sufficient to avoid adverse impacts to fish habitat in the past In the place of BMPs the state strongly recommends the need for minimum management requirements to be developed for fish in order to provide strengthened forest-wide requirements for protection of fish habitat. And, finally, the state believes that the Forest should place more emphasis on non-degradation of habitat protection activities instead of your unspecified habitat enhancement projects, the feasibility and funding for which is uncertain

POLICY 4 -- THE NATIONAL FOREST PLAN SHOULD MEET STATE OBJECTIVES FOR RECREATION, SCENIC RIVERS AND ROADLESS AREAS

The Mt Baker-Snoqualmie National Forest lies in portions of two SCORP (Statewide Comprehensive Outdoor Recreation Plan) planning districts - District 3 (Skagit & Whatcom Counties) and District 4 (King, Pierce, Snohomish Counties). Planning District 4 exhibits the most intense user pressures on recreational opportunities and facilities of any area in the state. This is both a result of high density population in the four county District and the high attraction of the Puget Sound to recreational users from Canada and the rest of the state. Part of this attraction lies in the forest environment and the associated recreational potential it offers to a diversity of activities and much of what occurs on the Forest in terms of recreational endeavors can occur nowhere else. We would like the Forest Service to consider some specific needs identified in the 1985 Washington SCORP and the 1987 Washington Off-Road Vehicle Plan in establishing Forest objectives for recreation.

1. General Recreation Needs.

The 1985 SCORP identified day-hiking, backpacking, boating, and snowmobiling as activities in District 3 which require additional opportunities to meet user needs. By 1990, specific facility needs for Planning District 3 are 276 more day-hiking trail miles, 109 more backpacking trail miles, 106 more moorage slips/launch lanes for boating, additional trail miles for snowmobiling are also needed in this district

By 1990, specific facility needs in District 4 will be 15,951 more picnic facilities, 9,448 more camping facilities, 2,860 more bridle trail miles, 992 more day-hiking trail miles, 986 more backpacking trail miles, 891 more moorage slips/launch lanes In winter recreation, downhill skiing shows the heaviest use pressure in this district Snowmobiling and cross country skiing also require additional opportunities to meet the projected demand We are also concerned that the proposed plan is inadequate with regard to meeting both motorized and primitive/semi-primitive recreation objectives

It should be noted that within the IAC's (State Interagency Committee for Outdoor Recreation) NonHighway Road Funding Program (NHR), three broad priorities have been established (1) direct provision of day use areas, campgrounds, trails and trailheads, equestrian facilities, (2) site specific planning development, renovation, land acquisition, and (3) assisting projects which help resolve user conflicts This program has a limited capability to assist federal project proposals directed at a non-ORV clientele hikers, equestrians, fishermen, etc

2 ORV Needs

The 1987 Washington State Off-Road Vehicle Plan indicates there are facility needs for motorized recreation activities in both Planning Districts 3 and 4. Currently (1987), to meet recreation demand, District 3 needs 95 more motorcycle trail miles, 54 more four-wheel drive trail miles, and 16 more ATV (all-terrain vehicles) trail miles. District 4 has higher needs for all activities 313 more trail miles are needed for motorcycling, 213 more trail miles are needed for four wheel driving, and 80 more trail miles are needed for ATVs

Statewide, the greatest off-road vehicle (ORV) needs are for opportunities for trail riding Users rank scenic backcountry trails as their highest ORV experience category. For all forests, the ORV Plan gives the following rank order for project development (a) New four-wheel drive opportunities. (b) Maintenance of existing motorcycle opportunities. (c) Development of new motorcycle opportunities.

The IAC's ORV funding program has a limited capability to assist federal agency project proposals directed toward the users of trail motorcycles, four-wheel drive vehicles, and ATVs.

3 Scenic Rivers

The Washington State Scenic Rivers Program supports the five rivers the Forest Service recommends for suitability study They are as follows (a) North Fork Nooksack River, (b) North Fork Skykomish River, (c) South Fork Skykomish River, (d) Tye River, (e) Middle Fork Snoqualmie River The Scenic Rivers Program recommends that the Beckler River be considered for study as it is a tributary to the South Fork Skykomish River, which is on the list to be studies. The Stillaguamish River is also currently under review for study by the Scenic Rivers Program.

4 Recreational Demand and Roadless Areas

We are pleased the Forest recognizes the significance the Mt Baker - Snoqualmie National Forest has for this state's urban population In fact, given its proximity to this state's population center, this Forest is one of the ten most heavily visited national forests in the country. This demand will continue in the years ahead as this state's population and the interest in outdoor recreational opportunities increases Clearly, because of the recreational opportunities it contains, this Forest occupies a very central place in Washington and, in large measure, offers much of the "quality of life" that is so highly valued by the state's residents

The state is troubled, however, over the current and projected, imbalance between the demand for recreation opportunities and the projected supply. In particular, we are concerned over the shortages of primitive and semi-primitive opportunities since, with increased use, the quality of these opportunities will be compromised Simply put, this state wants to minimize situations in which those who enjoy primitive and sem-primitive activities will be faced with either overcrowding or restrictive permit systems

The Forest Service, we recognize, understands that "it cannot meet current or future demand for unroaded, non-wilderness dispersed recreation without seriously altering the expected recreation on these lands." Given other competing demands, it is a very difficult task to preserve the remaining opportunities

In an effort to help the Forest Service in this regard, Attachment D contains a non-prioritized listing by the IAC of nine roadless areas which the state sees as valuable for recreational pursuits. Apart from recreational interests, the roadless areas benefit other values on the Forest such as critical habitat, water quality and fisheries These values and those of recreation may in fact overlap and enhance the decision-making process. Each of the areas finally chosen will have to address as many of the highest values for each of these elements as possible Roadless areas chosen, in an ecological sense, must serve both the human and biological environment. We also enclose in Attachment D a current IAC summary of recreational demand for the Mt Baker-Snoqualmie region which may be helpful as supplementary information to that used by the Forest. As the introduction indicates, a fuller-scale study is in process and results should be available by late this year or early next year.

T-550

OTHER KEY POLICY CONCERNS

A. The State's Water Resources Must Be Properly Utilized and Protected

The Forest Service has broadly addressed the issue of management activities/impacts on water quantity but provided little to no detail on the cumulative impacts of forest activities on watersheds and water resources. The state of Washington is responsible for the granting of water rights. The Forest Service needs to address the matter of federal reserved water rights as part of their planning process so that the state can more efficiently allocate, protect, and adjudicate its water resources. The state is also responsible for the protection, beneficial allocation and utilization of permits for environmentally sound water resource projects The Forest Service needs to stay in close touch with state and regional water resource planning groups (i.e., the State Hydro Power Task Force, and the Northwest Power Planning Council) to ensure close state/federal coordination. The Forest Service should also take a broader view concerning hydropower and the protection of instream values. i.e., rivers need to be protected from hydro-development that would produce unnecessary power.

One of the major goals of the state is to protect and preserve instream values through the establishment of instream flows When water withdrawal is proposed on Forest lands either the Forest Service or the applicant should consult with the Departments of Ecology, Fisheries, Wildlife and affected Indian Tribes regarding cumulative impacts on fisheries, wildlife and water resources and mitigation strategies.

B. Protect Water Quality

The state of Washington and the U.S Forest Service share the common goal of protecting state water quality. Land use practices on Forest Service lands have the potential of modifying both the quantity and quality of our state waters. Sedimentation from road building, logging and grazing activities can degrade existing water resources.

The plan states that state and federal water quality standards will be met or exceeded. We are, however, uncertain how the Forest Service intends to do this Fundamentally, we believe in the plan and interdisciplinary Team process but need extra assurance that the lack of plan specificity will facilitate goal accomplishment. Detailed information is needed rather than non-specific wording. We recommend adoption of the riparian prescription found in Attachment C We insist, as a minimum, the Forest Service address the Timber/Fish/Wildlife process and the Best Management Practices (BMP's) set forth in the rules and regulations affecting water quality. This process would provide assurance the state needs to approve the forest plans for water quality compliance.

One of the state's major concerns is how sedimentation will be controlled Most sediment control guidelines, standards and BMP's are not specific. The state believes definitive standards must be set to ensure water quality criteria can be met. This could initially be accomplished by creating a set of minimum standards controlling practices responsible for sedimentation, i e., roads should avoid riparian zones, wetlands, and

meadows and road densities should be limited. The use of minimum standards assume that the forest will strive for better and more creative controls but assures at least a set of minimum requirements. Evaluation of alternatives is based on predicated sediment loading by alternative, however, there is very little discussion of the sediment model or its documentation Since we cannot determine how effective the model is, we have no accurate way to evaluate the alternative We need to be able to validate the model and determine its effectiveness Consequently, we can only treat the data in the alternatives as indicated rather than actual yields.

C. The U.S Forest Service should participate with the state and other forest landowners in watershed management plans where needed to coordinate harvesting and protection measures.

It is state policy to encourage forest landowners in specific watersheds and others to voluntarily coordinate land use and development plans to provide the most effective pattern of development to meet the needs of landowners while protecting watershed values such as fisheries habitat, water quality, and stable water flows In this way, extra protections planned in one part of a watershed can be taken into account elsewhere in the watershed, even across ownership boundaries Likewise, plans for more intensive development activities in one part of a watershed need to be taken into account by landowners elsewhere in the watershed, considering the specific resource needs and past activities in that area. This will be especially important if the USFS plans more intensive localized harvesting in shared watersheds as part of a strategy designed to maintain forest-wide harvest levels while also providing greater wildlife habitat protection

D Protect Air Quality

The cooperative Smoke Management plan, which sets standards for smoke management in the state, was developed with the state's air quality goals in mind The Forest Service is a cooperator and complies with the comprehensive guidelines of the plan All Forest Service plans adopt these standards by reference and therefore comply with state standards.

E Protect Historical and Archaeological Sites.

It is the policy of the state of Washington to designate, preserve, protect, enhance, and perpetuate those structures and sites which reflect outstanding elements of the state's historic, archaeological, architectural, or cultural heritage.

In line with this policy the Mt Baker-Snoqualmie National Forest has developed a professional program to identify, evaluate, and protect significant archaeological sites important to Washington's heritage. The program adequately addresses preservation issues and does not conflict with state policy

J-552

ATTACHMENT B

This attachment provides in detail state concerns about the ability of the plan to meet state fish and wildlife management goals and contains specific recommendations. See Policy 3, Attachment A for further clarification.

A. PLAN ASSUMPTIONS

1. Modelling for fish and wildlife is inadequate or unexplained.

FORPLAN model level identifiers are based strictly on parameters needed to determine timber outputs The geographic specificity to allocation zones consisting of watersheds and roadless areas were not used to model wildlife and fish outputs. An elevational breakdown could be inserted in the empty level 2. Even without it, big game outputs could be modelled based on forage and cover regulationships and roading, assuming proportions of the area in winter and summer ranges. Response of fish to activities needs to become a model yield; the Forest should work with others to develop and test such a model.

Model restrictions did not allow maximum benchmarks to be run except for timber and recreation Though some modelling was accomplished out of FORPLAN, projected outputs do not show realistic trends or amounts of change which would be expected due to habitat alteration. Nowhere in the documents was wildlife coefficient development explained, except for snag habitat.

To count on investments to maintain viable fish populations is inappropriate Restoration or enhancement of rearing areas is ignored in favor of spawning, though rearing habitat is likely limiting for all but chum and pink salmon.

2. Economics

Economic analysis is an integral part of the forest planning process Cost, benefit, and present net value (PNV) are highlighted in the comparison of alternatives and are an integral part of determining net public benefits, as required by 36 CRF 219 12(f) Because the state administers resources whose economic values are quantified as part of their evaluation, we are concerned about what may be inequitable treatment given various resources

This inequality arises on more than one analysis level Use of the allowable cut effect and the four percent discount rate affects the economic benefit of intensive timber management practices including old growth harvest We believe the plan underestimates the value of non-commodity resources for PNV quantification *Animals are public* resources which, in the economic sense, are vital inputs for a variety of consumptive and non-consumptive goods Enhancements represent real benefits and impacts produce real losses, both of which affect PNV

There are several ways that PNV figures are biased away from fish and wildlife values and towards timber. First, an arbitrary reduction of 37 5 percent was made from the numbers derived by Loomis and Sorg for the 1985 RPA documents. We believe the justification for that reduction is not economically valid. With Travel Cost Method (TCM), an implicit demand curve is mathematically derived, and consumer surplus determined Net, not total, willingness to pay is measured by consumer surplus We agree that TCM studies are highly site-specific. However, the conjecture that study locations are typically high quality sites should be substantiated by quantitatively comparing "average" sites with the Loomis and Sorg sites before any value reductions take place.

In fact, there is reason to believe that the Loomis and Sorg results underestimate applicable wildlife values. TCM measures only the recreation use component. Other recognized sources of value include existence of the resource, option to make future use of it, and ability to pass on the resource to future generations. For certain ecosystems and some species of fish and wildlife, especially those that are well-publicized or whose existence is threatened, we would expect these components to add significant value. They are ignored in your evaluation process.

Another general area of concern is the Forest's apparent lack of information regarding resident fish populations and its effect on PNV. There is virtually no mention made of the alpine lakes fishery as a major recreational resource within the Forest. A recent (1987) survey of the state's recreational fishing population reveals that there are about 793,800 user days of fishing recreation expended in alpine lakes fishing by licensed anglers only To estimate total user-days, one must multiply this number by 1.2 (approximately 20 percent of high lakes anglers are juveniles who are not required to purchase licenses). The "real" use estimate is about 952,000 angler days. Although we do not have information specific to those lakes within the Forests, we believe a close estimate of angler use can be derived using the number of lakes within the Forest, their proximity to major population centers, and several other factors. We believe that angler use of alpine lakes on Forest land is about 305,700 angler days (about 114,642 WFUD's)

We believe this estimate realistically approximates what is happening on the Forest Your own study in the Alpine lakes Wilderness Area showed use comparable to our estimates, about (400-550 user-days per lake). Your estimate in the DEIS (page III-76) shows an estimated use of only 54,950 lake user-days per year which is far to low. Even if Forest lakes receive only the statewide average use of 397 angler-days, the use would still equal 86,198 WFUDS

We believe *your* estimated use of stream fishing on streams which emanate from the Forest is also underestimated. Although we do not have specific data on user-days of resident trout fishing on streams and beaver ponds only within Forest boundaries, we can produce a fairly accurate estimate of this fishery within the entire WDW administrative region (Region Four)

These fishermen generate approximately 967,600 user days of recreation, or 343,686 WFUDs (in Forest Service jargon -- using the .342 and .375 conversion rates) within the seven-county Region (licensed anglers only) After expanding these numbers to include all anglers, these numbers rise to 1,206,000 angler days and 430,600 WFUDs.

We have no simple method to extract out the proportion of stream/beaver pond fishing that takes place only on Forest lands. One method would be to apply your ratio of 40 percent to 60 percent, given in Table III-29 (depending on what this is based upon). This would result in 171,963 WFUDs expended on resident fisheries on Forest land (114,642 WFUDs for lakes x 1 5 = 171,963)

Using the Forest's figures of $56 55 for anadromous RVDs. $14 70 for resident trout, and the conversion factors given (.375 WFUD/angler-day, and .342 WFUD/angler-day), we calculate a combined value for sport fishing only, for game fish only, of more than $17,400,000 in the waters affected by the Forest's Management activities

This value does not include the value of the commercial steelhead fishery, nor does it include the value of salmon commercial and sport fisheries. If, as you suggest, 50 percent of the anadromous fishing is produced from Forest land (water), then over 9 6 million dollars of the above is produced from the Forest.

Based on the above, we would argue that the Forest's value of only $2.1 million for the combined salmon and game fish (in streams and high lakes) is highly inaccuate. The true value of these resources approaches $20 million per year, even when one accepts the Forest's very low assigned values. However, we cannot accept these values It appears unreasonable to us to state that angler-days are only worth $4.13 for resident fishing and $21.21 for anadromous fishing, as the Forest has done (we will be glad to supply detailed calculations).

Recreational use in fish resources is underestimated and the value per user day is undervalued. The benefits bias of timber versus recreation was further compounded by assuming maximum operating and maintenance costs Forest-wide over time for recreation. Although we have no good way of converting our statewide hunter use information into a close estimate of use on Forest land only, we suspect the same under-estimation of use took place for hunters as well We believe that the Forest is underestimating and, therefore, undervaluing hunting, trapping, and appreciative wildlife use in the same manner that fishing recreation has been undervalued Much of the Forest's recreation use data is now almost ten years old.

Another biasing factor is the failure to incorporate fish and wildlife losses as costs in PNV calculations. We believe such losses are large, both cumulatively and for certain site-specific management actions. Failures to count these impacts as costs in your analysis provides an implicit subsidy to the management activities which cause

the adverse effects. From a technical standpoint, it should be pointed out that the proper measure of value for this purpose is willingness to accept payment (WTA), not willingness to pay (WTP), which is determined by TCM WTA magnitudes are typically higher than those of WTP. In addition, losses should be measured relative to existing condition of the resource, not to its future condition under the current direction alternative This underscores the need to develop a quantified linkage between activities, changes in habitat and changes in fish populations.

Finally, the plan introduces a distinct bias by attributing a one percent real growth rate to timber prices, while holding other resource values constant over time. Taking into account your statement that demand for fish and wildlife oriented recreation is expected to increase each year, we believe that timber values are unjustly favored by this assumption At a minimum, studies on trends for fish and wildlife values must be found to substantiate a flat growth rate before such treatment can be considered valid. The forest should run a sensitivity test on 0, 1, 2 and 3 percent real price trends for non-cash as well as all cash resources, not just timber.

3. Monitoring

We would gain much more assurance of management success from a Plan which set out the What, Where, When, How and By Whom. We see a need for a plan which (1) sets goals. (2) describes areas; (3) assigns tasks. (4) defines methods. (5) lays out a schedule. (6) details who is responsible, and sets out clear performance standards (i.e., acres of habitat, numbers of animals/fish, etc.), and (7) details how monitored information will be fed back into the operations.

The maps supplied, some of the appendices, and the Monitoring Plan are helpful in this respect, but (with a few exceptions) the whole Plan lacks the necessary cohesiveness that would allow it to drive its own implementation Its credibility is damaged by placing too much reliance on other Forest Service manuals which have been implicitly included by reference.

One other area we find disturbing is the large amount of information that must be collected just to "rough tune" the Plan. We agree emphatically that this information is necessary, in fact, essential to the planning process. It appears that the Monitoring Plan (Chapter 5) contains a schedule to gather most of this needed information, however, not all needs are covered, the schedule is protracted over a rather long time period, and the data gathering needs are so great, we doubt the Forest can assemble the required information within a meaningful time frame unless Forest field staff is increased significantly In a few cases, some information needs are not addressed at all

One positive note regarding the Forest's Plan is the stated intent to initiate an effort to collect the information listed in Chapter 2. We believe this effort is long overdue and extremely important. The

J-553

negative of this is that the Plan and DEIS do not make a strong commitment to actually accomplish the data collection plan We note several references in these documents which link information collection capabilities directly to funding capabilities. The importance of specific information needs might necessitate a reprioritization of available funding, at least on an interim basis

4. MMRS

We appreciate inclusion of the maps delineating habitat areas with the documents sent us. These greatly help envisioning areas that will be managed by special prescriptions for specific species of wildlife. What we find disturbing about these maps is specific designations of principal management direction only. For example, in the Nooksack River area there exists a large block of land designated only as a SOHA. It is implied that this area is also to be managed as elk winter range, pileated woodpecker habitat, and marten habitat. However, it is only designated as Spotted Owl Habitat.

What would happen, for instance, if data showed a SOHA to be more appropriate elsewhere due to monitoring, and the area was abandoned as a SOHA. Would it still be protected for elk wintering grounds? We would much appreciate a system which layers each of these habitat areas which have been designated for "multiple" needs. In other words, the area identified above should also be designated (secondarily) as elk winter range, and (tertiarily) as marten/woodpecker habitat.

Along this same line, the amount of overlapping uses of specially managed areas gives us some concern This practice forces prey and predators together on small "inclusions" and increases stress on populations. It is possible such stress could elicit artificial selection processes which may alter the long-term viability of some species. We recommend that the Forest have a geneticist look into this aspect of habitat alteration. Another concern about maximum overlapping of land allocations is the fact that areas can be destroyed by catastrophic events, leaving no substitute areas available to maintain existing numbers or to act as dispersal sites.

We recommend that more habitat areas be established for old growth dependent species. These habitat areas would be in addition to those identified as the MMR level and separate from other land allocations. Estimates indicate that at least 30 percent more habitat areas would be necessary to replace stands which would eventually be lost to fire, blowdown, or other catastrophe and less than 100 percent occupancy rate. Without replacement stands, the loss of even one habitat necessary to the distribution grid has the potential to bring one or more species below MMR (legal) levels

We also believe the Plan places too much reliance on high elevations old-growth to achieve its "quota" of old growth habitat The Plan also relies on a vast amount of unknown information and the collection of which is based on an uninsured funding base In most cases, wilderness areas within the Forest complex are at too high an

elevation to be regarded as optimal fish and/or wildlife habitat. While these areas provide some summer range for deer and elk, they do not provide optimal year-round habitat for spotted owls, pileated woodpeckers, marten, and other wildlife We suggest that the Forest reappraise some of these areas from an ecological standpoint, and affirm those areas that are truly suitable habitat. Combining the stand ages and small and large saw timber influences MMR habitat suitable. A proportionate decrease in wildlife numbers needs to be made to reflect this.

The Forest's intent is to build roads into the "heart" of certain roadless areas. Once these areas are roaded, there is no option open to regain the ecosystem characteristics that they provide. We recommend instead that the Forest's logging plans for these areas in the near term include a conservative timber harvest approach that works only around the perimeters of these important areas. Then if it is found that unroaded old-growth is required to meet specific wildlife or recreation demands in the future, these areas can be readdressed with more restrictive management prescriptions.

We are pleased that the Forest's analysis determined that dedicating, rather than managing, old-growth for MMR habitats was the appropriate strategy.

B. FISH AND WILDLIFE PRESCRIPTIONS AND DATA NEEDS NECESSARY TO MEET STATE FISH AND WILDLIFE GOALS

1. State species goals

Public lands represent the major source of fish and wildlife for user groups in the state of Washington. However, all alternatives reduce big game species and all MMR species None of the alternatives presented in the DEIS "optimizes" habitat for any wildlife species of concern. Your MMR levels and management direction do not reflect the state's goals in regard to wildlife populations. We intend to maintain elk populations at, or above, present levels, increase deer populations by 10 percent, fully recover bald eagle, spotted owl, and peregrene falcon populations, and maintain pileated woodpeckers, marten, fisher, and other old growth indicators at viability levels above "minimum reproductive levels." There is some indication that grizzly bears and wolves may also be present on Forest lands. If this is the case, there may also be plans to recover populations of these species.

The Plan proposes to reduce already critical winter range by clear-cut logging and road building It also proposes to "push" roads into presently roadless areas without waiting to see if the monitoring plan calls for some of these areas to be left roadless. We are also disturbed to see entire watersheds (Sultan and Cedar Rivers) almost entirely left out of your Plan. We also take exception with the Forest's definition of winter range. Coniferous tree stands "40 feet tall with 70 percent canopy closure are not "optimal winter range" for deer and elk. True multi-aged, multi-species stands, with the oldest trees at least 125 years old,

better define the true winter-range needs of deer and elk. Table C-1 indicates the intent to "create openings" (harvest timber) in critical winter range We would like the Forest to consider doing a limited amount of selective timber harvest in these areas. This would preserve snow interception and thermal protection capabilities and still provide forage capabilities of these areas. Lichens and moss provide important winter forage for elk and goats.

The Forest should specify management goals coordinated with state management goals for each stream, lake, and beaver pond complex. The state management strategy calls for increasing sport fishing opportunities for resident fish and increasing the diversity of these opportunities It is important to know that a particular water be managed for sport trophy fishing, commercial and sport wild anadromous capability, unique species (such as golden trout, grayling, lake trout, etc) high intensity fishing, etc.

Another area of concern to us is the Forest's stated objective of maintaining only "existing resident fish habitat capability values" and to "increase" anadromous fish habitat only through "habitat improvement" projects (artificial means). In the case of anadromous fish, our short term goal is to increase runs of wild winter-run steelhead in all Region Four rivers, up to MSH To accomplish this, the habitat capability must be increased. In some instances, where the goal is to provide catch-and-release fisheries, the objective is to attain a habitat capability of 100 percent of the potential This is also true of resident fisheries in the "trophy" category (such as Middle Fork Snoqualmie). We are gradually achieving our goals of bringing wild winter-run steelhead populations back from the depressed state of the 1970's The following table shows the degree of progress made thus far, and what our ultimate goals are for the four-river systems on which we have good data.

Total wild steelhead escapement is listed below each river name by year. This includes both harvested fish and spawning escapement.

Year	Snohomish	Skagit	Green	Lake Washington
1980-81	2,954	4,308	1,083	--
1981-82	4,160	.9,609	2,121	--
1982-83	5,158	7,732	1,526	--
1983-84	6,432	8,963	2,188	1,250
1984-85	6,508	8,511	2,286	474
1985-86	7,790	11,098	2,778	1,816
Future Run-size target**	8,000	12,000	2,000	1,800
			1,800*	1,200*

* Upper river -- upstream of city water diversions and Howard Hanson dam.
**Based on weighted usuable rearing habitat of these river systems. are approximations based on continuing research.

As our data collection proceeds, we will have more specific goals for the other five river systems in Region Four. All these rivers are slated for similar management and will follow similar management direction (increased wild production).

2. Riparian Prescription

Riparian ecosystems make up only a small portion of the forest land base on the Mount Baker-Snoqualmie National Forest, but support a greater density and diversity of wildlife than any other habitat type. Several wildlife species, including certain threatened and endangered species and all species of fish, are dependent on riparian habitats to meet all or a portion of their life requirements. Management within riparian zones should emphasize the needs of wildlife and fish. To remedy particular shortcomings noted in the plans' prescription for riparian zones, we have a number of recommendations

In defining zone boundaries for planning purposes, we suggest adoption of the zone proposed by Meehan et al and Swanson et al, which includes the body of water and all vegetation directly influencing aquatic processes. At a minimum, this would extend from the ordinary high water mark a distance equal to the potential height of the tallest trees. Soils, vegetation and topography should then be used to modify zone width, where appropriate. For example, flood plains and associated wetlands should be incorporated. This riparian zone prescription should apply to all waters bearing fish as well as most small Class III streams featuring key wildlife habitats.

Management within the riparian zones should emphasize maintaining cover and vegetative diversity, stabilizing soils, and recruiting large organic debris and snags. We recommend at 100' no harvest zone along anadromous stream reaches. Low management intensity would be appropriate for the rest of the riparian zones LOD should be retained at 750 pieces per mile where possible Large snags should be retained at the level needed to provide for 100 percent of the potential population for cavity excavator species Down wood for wildlife should be available at a minimum of 4 logs per acre, 20" at large end and 20' long, or the largest size available Where cuts occur, selective harvest of intermediate-size trees 5" dbh to 18"dph would be best for wildlife where 70 percent canopy cover can be retained. Clearcuts should be avoided, unless a site-specific justification of fish and wildlife benefit can be made Clearcut units should be limited to 5 acres. Under any cutting method the rotation in big game winter range should be long to produce optimal thermal cover, with maximum harvest per decade covering no more than 5 percent of the zone in any on watershed Roads should be 250 feet or more from streams or wetlands Salvage sales are inappropriate for riparian zones

The added protection provided by our recommended changes above will also limit those areas in need of repair or improvement by limiting riparan damage from road construction or timber management. This will reduce the need for high levels of funding for mitigation and assure the most important and cost-effective areas are improved. We suggest that natural protection and non-structural improvements receive a higher priority throughout the forest.

There should also be some recognition of the Memorandum of Understanding (MOU) with the state of Washington regarding activities in fish-bearing waters In that MOU, the Forest Service has agreed to comply with the State Hydraulic Code.

We are concerned that the minimum management requirements (MMRs) for riparian areas provide standards that can be measured and monitored Best management practices are qualitative at best and it is documented that the degradation of stream habitats and water quality has occurred despite the use of BMPs. We recommend that the riparian prescription provided above be adopted for general use in all zones.

3. Dead and Down Woody Debris

Forest Service Region 6 policy has been to maintain dead and down wood at a level sufficient to support 40 percent of the potential woodpecker populations. The MMR level for cavity nesters was set at 20 percent by way of a "best guess." We do not agree that the MMR level for cavity nesters will maintain viable populations of all dependent species. Thomas et al (1979) defines the 20-40 percent level as, "snag habitats produced by these levels are marginal and will probably not support viable populations" and the 40-60 percent population level as, "snag habitats produced will probably maintain viable populations "

An inventory constraint should be employed to produce the appropriate snag levels, particularly areas with shorter rotations where the large diameter snag would not normally be produced before harvest occurs. Providing such a constraint will not only ensure the snags will be allowed to accumulate, but will provide a measure of the amount of falldown in timber ASO. Without calculation of this falldown, which should be coordinated with other forests, we expect your timber inventory, ASO, and receipts to be inflated above actual levels. We also have a concern for the larger sizes of down wood, *20" at large end by 20' long or more, and we suggest similar* treatment as noted above for snag habitat

Finally, the number of snags retained during harvest, in our experience, rarely reflects the number of remaining a few years out into the future Additional snags and green trees must be left to account for losses due to fuelwood cutters, fire, safety considerations, and natural decay. We suggest a vigorous and effective enforcement effort, following the issuance of Forest-wide direction that standing dead or live trees may not be taken as *fuelwood except in excess of wildlife needs Similarly, salvage* sales should be limited to those necessary to prevent the spread of pests or disease, except in excess of wildlife needs

Monitoring/research should be conducted to, (1) determine population trends at varying snag management levels, and (2) refine or substantiate the definitions used in Thomas, et al (1979).

4. Road and Travel Management

A forest-wide road system of more than three miles per square mile open to public vehicular traffic is inadequate in terms of its impacts on *wildlife, particularly when it is considered* that the density figures likely include roadless areas, other no-cut areas, and exclude non-system roads Actual road densities in suitable forested acres are likely to be considerably higher than expressed. The Plan should identify miles of open and closed roads (including non-system roads) on a watershed basis and describe the methods for implementing closures, timing of closures, and locations.

We disagree with the belief that roadless areas need to be roaded and managed in order to provide high quality big game habitat. That *position ignores the critical nature of security areas.* Wildlife use in unroaded (undisturbed) habitat is always higher than in similar roaded habitat Some species are virtually eliminated by actively used roads. Building roads and harvesting timber in roadless areas will not provide both roaded recreation and big game habitat. Roaded recreational opportunity can be increased by developing roadless areas, but the supply for roaded recreational opportunity already exceeds the demand Further, increased and easier access to back-country areas results in more restrictive hunting regulations, less hunting freedom and opportunity, and fewer mature bulls and bucks.

To mitigate adverse effects from forest roads, we urge the following measures be adopted as standards throughout the Forest

- New road construction should avoid areas described by Brown et al and Thomas et al as special habitats These include riparian zones, wetlands, meadows, and places with critical uses, such as deer and elk travel corridors and calving areas, and your old growth habitat MMR areas Special habitats and natural and created openings should be screened by buffers of natural vegetation.

- It is also critical to limit the density of roads open to public traffic to accommodate the prevailing wildlife use Our recommended forest-wide standards are included above and in page-specific comments

5. Fisheries Resources Need Greater Protection and Enhancement. MMR's Need to be Developed For Fish

One source of concern stems from the decision of Region 6 not to develop MMR's for fish Planning requirements should be the same for all wildlife species. We do not agree that BMP's are sufficient to avoid adverse impacts to fish habitat as stated in the MMR documents. The Forest's BMP's have not done an adequate job of protecting water quality in all streams. Deer Creek (N.F. Stillaguamish tributary), the North Fork Stillaguamish, Finney Creek, and others in the Region, now experience temperatures and turbidity

levels above state water quality standards Yet the plan assumes that following BMPs will adequately protect water quality. We question the assumption that unspecified habitat improvement projects with uncertain funding will be sufficient to increase fish losses.

We see that most of these important data and information gathering needs are outlined in Chapter Two of the Plan, however no timetable is given. We believe the following needs should be given a very high priority, and should be completed prior to implementing a "fixed" plan.

- o Inventory all stream and beaver pond habitat within the Forest.
- o Either validate the Fish Habitat Capability Index, not only for anadromous fish, but for resident fish as well, or develop multiple parameteers, multiple summer and winter habitat capacility indices
- o Determine at least wild salmon and steelhead spawning habitat requirements that meet state species escapement goals.
- o Inventory all lakes on the Forest Develop a data base on each lake's physical and biological characteristics and fishery management history (method of planting, fish species, numbers of fish, frequency of plants, natural vs. planted, etc.) WDW biologists would welcome the opportunity to share in this effort.
- o Select and intensively survey a group of index lakes and streams to obtain a more precise estimate of angler use.

6 Mitigation for Fisheries

The state of Washington's fishery policy stresses habitat protection and mitigation for fishery resource losses, and we have concern over the Mt Baker Snoqualmie Forest's basic treatment of adverse fishery resource impacts. Resource losses should be regarded as a definite, mandatory mitigation responsibility, not as an optional planning element or discretionary budget item Our prior responses to other draft National Forest plans have also highlighted this important policy. We request that the Forest treat fish production losses (attributable to their operations) as a mitigation need requiring the firm, dependable funding that is fitting for a definable resource commitment

The logic for this request is based on perpetuation of fishery resources. If a hydropower developer, for example, blocked 30 percent of the fish production potential of a watershed, there would be no question as to the mitigation responsibility involved and its level (a full 30 percent) The cumulative effects of environmental alterations such as logging and associated road building which would lower production of fish by the same 30 percent should be treated in a comparable manner. Timber harvesting and associated activities such as road building have become major exceptions to this rule of compensation.

The key to defining this mitigation responsibility is quantified linkage between levels of environmental modification and changes in fish production The current draft plan makes no attempt to do this nor does it recognize development of this quantified relationship as a long-term need. Our common requirement today is for quanitification of any project-expected impacts on trout, salmon, and spiny ray species. Mitigation requirements are then designated to address these impacts.

7. The Sikes Act provides that Forests must jointly develop with the state a Statewide Comprehensive Plan, and provide funding for fish and wildlife improvements This plan is years overdue We would like to work with you in the development of such a plan.

8 The state has attached detailed maps identifying a total of 84 known spotted owl sites (a site is an area with clusters of individual spotted owl response locations which represent a separate spotted owl individual/pair) on the Mt. Baker-Snoqualmie National Forest There is a number of areas throughout the forest which have not been surveyed (either within the last three years, or at all) And, there is a large area of checkerboard ownership in the middle portion of the forest that is a Special Area of Concern for spotted owls because it has very few known owls with the remaining habitat extremely fragmented and widely scattered. There are separate recommendations for each of these situations

1 In order to meet the state goal of maintaining viable populations, the Mt. Baker-Snoqualmie National Forest should maintain all currently known sites and historic sites (until they can be surveyed and status of owls determined) State data indicates each area should have a 3,800 acre SOHA established within 1 8 - 2 1 miles of the next center of activity (see attached guidelines, existing site status, and map).

2. All historic sites, which have owl records prior to the last three years, but have not been recently surveyed, should be surveyed to determine status and. if owls are present, should have SOHAs established

3. Some sites may need to be established between known areas to ensure corridors between and adequate distribution of sites for dispersal purposes

4 Within Special Areas of Concern, further harvesting of spotted owl habitat (old growth and mature forest stands) will aggravate current fragmentation of spotted owl habitat, making dispersal particularly difficult. These areas which have been identified on the forest are

a <u>The checkerboard ownership area from Township 19N to 22N.</u> This area is a vital link both north-south and east-west for the Cascade spotted owl population. There is only one known pair in this entire area and only 7 documented sites

(3 of which are historic). There are the three known sites in the Cedar River Watershed (one of which is historic) although there are no SOHAs designated in the Draft Forest Plan. SOHAs should be established for all known sites in the watershed.

b The NW Block of the Darrington District and the SW Block of Baker River District. There should be no further harvesting or planning of sales until the status of spotted owls in this block has been determined. There is only one nest site identified in this area (Gee Creek) and four of the nine known sites are historic Eight of the nine sites are heavily fragmented. This entire area needs to be intensively surveyed.

c The area on the Skykomish Ranger District bounded by the South Fork Skykomish/North Fork Skykomish/Cascade Crest. This area forms a large distribution gap on the forest Six of the eight known sites are historic. The entire area needs to be surveyed before proceeding with harvesting.

d. The Pratt River block on the North Bend District. This block is the last contiguous block of habitat before the large area of checkerboard ownership. It is crucial to maintain owls in this area

5. Specific management recommendations and guidelines follow

For spotted owl sites that are

	Status	Recommended Guidelines
1.	Within SOHAS	Section 2,3,4
2.	Adjacent to SOHAs (they do not include the primary use areas or known locations)	Move to appropriate area, then use Sections 2,3,4
3	Outside SOHAs	Establish a SOHA, then use Sections 2,3,4
4	Historic Sites	Survey, then establish a SOHA then use Sections 2,3,4
5.	SOHAs without Sites	
	a. Surveyed Repeatedly	Drop from network unless needed for distribution or replacement areas.
	b. Never Surveyed	Survey to determine locations of owls

6. Management Check Points

a. Specific threshold points must be defined for occupancy, reproduction and survival that can be used in research and monitoring to determine if population viability is being maintained.

b If viability is not being maintained in all, or portions of, the forest, specific procedures must be set in motion to provide higher levels of management protection (e.g., increasing sizes of areas, increasing densities of sites, not harvesting any additional spotted owl habitat).

RECOMMENDED GUIDELINES

1. Distribution and Selection of Sites

A. Special Areas of Concern

Special Areas of Concern are geographic areas within the Forest where there are distribution gaps, fragmented and limited remaining spotted owl habitat, and very low, scattered occurrences of owls These areas require retaining the best management options for owls in order to avoid isolating individual sites and subpopulations over time across the Forest.

1. Within special areas of concern there should be no further harvesting of spotted owl habitat that will aggravate distribution problems, rather distribution should be improved by managing for an increase in spotted owl habitat over time.

2. Conduct comprehensive surveys within all special areas of concern to determine current distribution of owls.

3. Over time, develop links between isolated pairs and/or subpopulations by allowing the stands to develop naturally or, by using silvicultural treatments

4. Key areas which would help bridge distribution gaps or would help complete SOHAs that occur on private or state land within the forest should be identified Encourage the participation of these other landowners to help maintain spotted owls in these areas.

B. Areas Outside Special Areas of Concern

1. In order to meet state species goals for spotted owls, all currently known sites should be maintained.

2. Sites that are not currently occupied, or that have not been surveyed may need to be selected to ensure adequate distribution within all provinces.

J-558

3. Priority for selection of sites should be

   a Areas that have been consistently occupied by breeding pairs.

   b. Areas that have been consistently occupied by pairs (or areas with the highest level of occupancy over time)

   c. Areas with a known breeding pair in at least one of the last three years

   d. Areas with a known pair within at least one of the last three years.

   e. Areas with single birds observed repeatedly in the last three years.

   f. Areas with single birds observed in at least one of the last three years

   g. Areas with historic (prior to the last 3 years) locations of birds.

   h. Areas of spotted owl habitat with no known occupancy.

   i Areas that are not currently spotted owl habitat but are capable of producing spotted owl habitat in the future in the shortest amount of time.

4. The objective for sites selected is occupancy by pairs and long-term viability. Departures from the priority of selection may be made in some cases if it is to the benefit of the long-term viability of owls at that site.

5. Historic sites and unsurveyed areas should be inventoried to determine distribution and status of owls.

2. Size and Configuration of SOHAs

A. Establish a SOHA for each site selected.

B. State data indicate that SOHAs should be designed to contain 3,800 acres of the best available spotted owl habitat. If research and monitoring show viability to be in jeopardy, it may be necessary to increase these by one to two standard deviations above the mean.

C. SOHA configuration should be determined by the spotted owl location information for the area. If the nest or center of activity is known, it must be included in the SOHA. If the site is based on one or a few response locations, they should be included in the SOHA. If telemetry data is available it should be used to design the SOHA. Total SOHA size should still be as large as stated in 2.B.

D. Habitat for the SOHA should be within a 1.8 mile radius of the nest or activity center. If spotted owl habitat is not available within the recommended distance, expand the radius 0.3 miles and select the closest available habitat. If sufficient spotted owl habitat cannot be found at these maximum radii, select the next oldest forest stands to develop the SOHA.

E Design the SOHAs to ensure that they are contiguous and compact as possible to minimize fragmentation.

F. Any land management activities (including unsold timber sales within the 1.5-1.8 mile radius which would fragment the SOHA should be dropped.

3. Replacement Areas for SOHAs

A. Ideally, one replacement area should be available for every two designated SOHAs.

B. Use sections 1, 2, and 4 to select and manage replacement areas in the event of the catastrophic loss of any SOHA

4 Management of SOHAs and Replacement Areas

A. Timber harvest, salvage logging, or firewood cutting should not occur within the designated SOHA/Replacement areas.

B. Consolidate fragmented SOHA/Replacement areas over time by managing existing young stands to become spotted owl habitat.

C. If habitat that is not currently spotted owl habitat is being used for all or a portion of SOHA/Replacement areas, use silvicultural prescriptions to create spotted owl habitat in those areas over time.

D. The nest site and main activity centers of the owls should be identified before any timber harvest or timber sales take place within the 1.8-2.1 mile radius area.

E. Size of the management areas (SOHA/Replacement) should be maintained through time. If the suitability or size of a management area is affected by a catastrophic event (fire, blowdown, volcanic eruption, etc.), then additional acres should be added.

F. Road construction through centers of activity in SOHA/Replacement areas should be avoided. Outside centers of activity, roads may be allowed after consultation with the local biologist Unneeded roads and spurs should be closed and allowed to revegetate.

G Review new mineral, oil, and gas operating and development plans. Develop recommendations to minimize impacts to spotted owls and their habitat.

J-559

H. If timber sale units are to be harvested adjacent to SOHA/Replacement area boundaries, they should be designed and managed to minimize the chance of windthrow and fire damage to the sites.

I. Use seasonal restrictions for activities within 1/4 mile of owl nest sites or centers of activity. Suggested times are February 1 - August 31. If, after monitoring a site (at least through May 1), it is determined that the owls are not nesting, biologists may recommend that activities could begin at an earlier date

J. Retain forested corridors within and between SOHAs. If such corridors do not exist, manage habitat to create them

DEFINITION OF TABLE HEADINGS

SITE NAME - A spotted owl site is defined as an area with documented spotted owl use during the breeding season and information which indicates the area is within a single pairs' defended territory. SOHA name is listed below site name if the two do not correspond

LEGAL DESCRIPTION - Township, range and section for each spotted owl site

SITE STATUS - Describes spotted owl site as either in (I), adjacent (A), or out (O) of 2200 acre SOHA

LAND STATUS - Describes management status of the spotted owl site

LAST KNOWN LOCATION - Identifies most recent spotted owl location at a site *and whether it was a pair (p) or single (s) location*

PAIR, YEAR - Identifies if the site has ever had a pair location (Y), or not (N) and if it has the most recent year

MANAGEMENT CODE - Identifies a set of prescriptions for each site based upon site status and whether or not the site is *recent or historic*

SOHA SHOULD INCLUDE SUITABLE HABITAT IN AREA OF - Identifies recommended area for establishing, adjusting or expanding a spotted owl habitat area

COMMENTS - Self-explanatory

DEFINITION OF TABLE HEADINGS

SITE NAME - A spotted owl site is defined as an area with documented spotted owl use during the breeding season and information which indicates the area is within a single pairs' defended territory SOHA name is listed below site name if the two do not correspond
LEGAL DESCRIPTION - Township, range and section for each spotted owl site
SITE STATUS - Describes spotted owl site as either in (I), adjacent (A), or out (O) of 2200 acre SOHA
LAND STATUS - Describes management status of the spotted owl site
LAST KNOWN LOCATION - Identifies most recent spotted owl location at a site and whether it was a pair (p) or single (s) location
PAIR, YEAR - Identifies if the site has ever had a pair location (Y), or not (N) and if it has the most recent year
MANAGEMENT CODE - Identifies a set of prescriptions for each site based upon site status and whether or not the site is recent or historic
SOHA SHOULD INCLUDE SUITABLE HABITAT IN AREA OF - Identifies recommended area for establishing, adjusting or expanding a spotted owl habitat area
COMMENTS - Self-explanatory

ATTACHMENT C

SUMMARY OF FINDINGS AND CONCLUSIONS

1. About 76,000 acres of Silver Fir land in the so-called Mountain Hemlock Zone were misclassified as unsuitable. The average net green volume per acre on these lands is 6 percent higher than for the overall large sawtimber class The real productivity of these lands is more than twice as high as that estimated by the Forest Service. They are capable of producing over 100 cubic feet per acre per year, which implies a potential contribution of 38 MMBF per year (76,000 x 100 CF x 5 BF/CF), before reductions for economic, wildlife or other considerations.

2 The conversion ratio used to restate FORPLAN cubic feet timber outputs in terms of board feet is too low and underestimates actual board-foot volume for the first decade of the preferred alternative by at least 4.3 percent.

3. There are numerous, serious errors in the managed yields including their on an incorrect site index, misuse of DFSIM to predict Hemlock/True Fir yields, incorrect entry into FORPLAN, exclusion of fertilizer, and incorrect adjustment for genetic improvement As a result, managed yields for 60 percent of the forest are *underestimated by over 50 percent, and* thus for the overall forest by over 30 percent

4 An examination of the distribution of acres for each decade over the next 150 years shows that there will always be enough suitable mature forest habitat to provide for a higher percentage of the maximum potential population of cavity excavators than the 40 percent sought in the preferred alternative. The preferred alternative's 3 percent reduction in all existing and regenerated yield tables is therefore totally unnecessary

5. Arbitrary harvest timing constraints are being applied to more than 50,000 acres of unroaded lands containing mature sawtimber and currently classified as economically inaccessible These constraints force the areas to be harvested within the first 5 decades or not at all, with the result that only 4,000 acres are harvested and the remaining 46,000 acres effectively become de factor wilderness.

6. Productivity (Site Index) has been grossly underestimated on the 70 percent of the forest occupied by species other than Douglas Fir, because it was erroneously reduced by the percent normal stocking of the existing forest. Site index represents the potential of land to grow trees, and is independent of current stocking. This error was compounded by using a yield simulator, *DFSIM, that is only suitable for use with 80 percent or* purer Douglas Fir to derive 50-year site index

7. Future yields for naturally regenerated stands were adjusted down to not exceed existing stand yields that reflect the current, less than normally stocked forest, even though the plan calls for planting 25 percent of the naturally regenerated acreage to ensure adequate stocking.

8. The plan is based on an obsolete (1976) inventory whose lack of stratification forces use of broad, size-oriented grouping of timber stands, rather than 10-year age classes preferred by FORPLAN. Use of such broad classes in FORPLAN has been previously demonstrated to cause ASO to be biased on the low side.
