Optimal Cover - a forest stand with: 1) four layers (overstory canopy, sub canopy, shrub layer, and herbaceous layer); and 2) an overstory canopy which can intercept and hold substantial amount of snow yet has dispersed (<1/8 acre) openings. These criteria are generally achieved when the dominant trees average 21 inches dbh or greater, have 70 percent or greater crown closure, and are in the large saw timber or old-growth condition.

Optimum Density - For wildlife, the maximum rate of animal stocking possible without inducing damage to vegetation or related resources, may vary from year to year because of environmental and/or population factors.

Organization Camp - A privately-operated facility providing lodging, meals, social, and educational recreation opportunities in a forest environment. An organization camp is operated on National Forest land under "Special Use Permit."

Output - The goods, end products, or services that are purchased, consumed, or used directly by people. Goods, services, products, and concerns produced by activities that are measurable and capable of being used to determine the effectiveness of programs and activities in meeting objectives. A broad term for describing any result, product, or service that a process or activity actually produces.

Overmature - The stage at which a tree declines in vigor and soundness, for example past the period of rapid height growth.

Overstory - That portion of the trees, in a forest of more than one story, forming the upper or uppermost crown canopy.

Ozone - An allotropic triatomic form of oxygen that is normally a faintly blue irritating gas with a characteristic pungent odor. A predominant compound in a layer of the Earth's atmosphere (the ozone layer) which plays a key role in filtering the Sun's radiation.

Partial Retention - See "Visual Quality Objectives."

Particulate (Concerning air quality) - Minute separate particle of matter suspended in air. Particulate as a measure of air quality condition or standard is expressed in microns per cubic meter.

Penstock - A sluice or gate for regulating a flow (as of water); or a conduit or pipe for conducting water.

Perennial Stream - A stream that flows year round.

Persons-At-One-Time (PAOT) - The number of people in an area or using a facility at the same time. May be used as "maximum PAOT" to indicate the capacity of an area or facility to support peak usage within established user density standards and without degradation to biophysical resources.

Planning Criteria - Criteria prepared to guide the planning process. Criteria applied to collection and use of inventory data and information, analysis of the management situation, and the design, formulation, and evaluation of alternatives.

Planning Horizon - The overall time period considered in the planning process. Spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions which would influence the planning decision.

Planning Period - One decade. The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits.

Planning Records - The body of information documenting the decisions and activities which result from the process of developing a Forest Plan, revision, or significant amendment.

Pore Space - Total space not occupied by soil particles in a bulk volume of soil, commonly expressed as a percentage.

Porosity - The degree to which the total volume of a soil, sediment, or rock is permeated with pores or cavities, generally expressed as a percentage of the whole volume unoccupied by solid particles.

Potential Yield - Sustainable output of wood fiber available after the yield foregone for the management opportunities of other resources has been deducted from the biological potential.

Precommercial Thinning (PCT) - The practice of removing some of the trees less than merchantable size from a stand so that the remaining trees will grow faster.

Prescribed Fire - A wildfire burning under specified conditions that will accomplish certain planned objectives. The fire may result from either planned or unplanned ignitions. Use of unplanned ignitions must have prior approval by the Regional Forester.

Present Net Value (PNV) - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area. (36 CFR 219.3)

Preservation - See "Visual Quality Objectives."

Presuppression - Activities organized in advance of fire occurrence to ensure effective suppression action

Primary Cavity Excavators - Wildlife species that excavate cavities in wood, for food and shelter Example woodpeckers

Primitive - See "Recreation Opportunity Spectrum (ROS) "

Program Element - Forest Service areas of responsibility, such as "Wildlife", "Recreation", "Timber" based upon the National Forest budgeting process. Used in this Forest Plan to organize the management area standards and guidelines and tie to budgeting

Programmed Harvest - The amount of timber on the Forest that is scheduled for harvesting The programmed harvest is based on current demand, funding, and multiple-use considerations

Project - An organized effort to achieve an objective identified by location, timing, activities, outputs, effects, accountability, and control of a project

Public Issue - A subject or question of widespread public interest relating to management of National Forest System. (36 CFR 219.3)

Puddling - Soil puddling is a physical change in soil properties due to shearing forces that destroy soil structure and reduce porosity. Detrimental puddling can be observed as vehicle tracks when soil is molded and when depth of rutting has reached 6 inches or more.

Purchaser Credit - Credit earned by the purchaser of a National Forest timber sale by construction of contract-specified roads. Earned purchaser credit may be used by the purchaser as payment for National Forest timber removed.

Range - Land producing native forage for animal consumption, and lands that are revegetated naturally or artificially to provide forage that is managed like native vegetation.

Raptors - Predatory birds, such as falcon, hawks, eagles, or owls

Real Dollar Value - A monetary value which compensates for the effects of inflation.

Reasonable Assurance - for the purposes of regeneration suitability decisions in the Forest planning process, "reasonable assurance" is provided when:

1) One or more reforestation projects are known to exist on NFS or non-NFS lands within the subject ecosystem or land stratum, which have succeeded in meeting Regional standards for adequate restocking (as defined in a subsequent portion of the direction), and either

2) The practices used in achieving the regeneration success are known and are accepted by experts in the field of reforestation as being generally applicable to the ecosystem or land stratum being examined.

3) Research results exist which are applicable to the subject ecosystem or land stratum and which provide the means to prescribe treatment(s) that will lead to successful reforestation.

Where a successful regeneration project cannot be found, or applicable research does not exist to demonstrate that a prescription can be written to accomplish reforestation; reasonable assurance of regeneration has not been provided. The stratum or ecotype, therefore, will be classed as not suited for timber production due to regeneration difficulty.

Management prescriptions rely on existing technology. Existing technology includes all techniques that have been proven in research or demonstrated successfully on the ground. Cost of practices will not be a criterion for excluding lands from the suitable land base at this stage in the planning process. For this round of planning, irrigation, exotic-species, and soil importation practices will not be considered as existing technology.

In determining whether or not natural regeneration may be reasonably assured, a certified silviculturist must be able to write a prescription that will provide for successful reforestation within a 5-year period following clearcutting, or a 10-year period following the seed cut when using the shelterwood method of regeneration cutting. The regeneration period is considered to start when the trees in a harvest unit are felled, and ends when the unit is adequately restocked.

Explanatory Notes: the phrase "reasonable assurance" is a subjective expression and is, therefore, not completely definable by precise objective and quantitative terms. By its very nature, the phrase recognizes the necessity of arriving at a decision through judgemental (subjective) processes rather than through precise quantitative analysis (objective) procedures based on measurable data with known statistical reliablility.

Receipts - Those priced benefits for which money will actually be paid to the Forest Service. recreation fees, timber harvest, mineral leases and special use fees.

Record of Decision - A document separate from but associated with an Environmental Impact Statement which states the decision, identifies all alternatives, specifying which were environmentally preferable, and states whether all practicable means to avoid environmental harm from the alternative have been adopted, and if not, why not.

Recreation Capacity - The number of people that can take advantage of the supply of a recreation opportunity during an established use period without substantially diminishing the quality of the recreation experience or the biophysical resources.

Recreation Development Scale (Level) - This is a scale of the level of recreation site modification and development coordinated with the ROS classes. The five development scales are described below. See "Recreation Opportunity Spectrum," and "Recreation Development."

Recreation Information Management (RIM) - A computer-oriented system for the organization and management of information concerning recreation use, occupancy, and management of National Forest lands.

Recreation Opportunity - The availability of choices for users to participate in the recreational activities they prefer within the settings they prefer

Recreation Opportunity Spectrum Class	Development Scale	Level of Site Modification
Primitive	1	Minimum site modification. Rustic or rudimentary improvements designed for protection of the site rather than comfort of the users. Use of synthetic materials excluded. Minimum controls are subtle. No obvious regimentation Spacing informal and extended to minimize contacts between users. Motorized access not provided or permitted.
Semi-primitive	2	Little site modification. Rustic or rudimentary improvements designed primarily for the protection of the site rather than the comfort of the users. Motorized access provided or permitted.
Nonmotorized		Use of synthetic materials avoided Minimum controls are subtle. Little obvious regimentation. Spacing informal and extended to minimize contacts between users. Primary access over primitive roads. Interpretive services informal, almost subliminal.

Roaded Natural	3	Site modification moderate. Facilities about equal for protection of site and comfort of users Contemporary/rustic design of improvements is usually based on use of native materials. Inconspicuous vehicular traffic controls usually provided. Roads may be hard surfaced and trails formalized. Development density about 3 family units per acre. Primary access may be over high standard roads. Interpretive services informal, but generally direct.
Rural	4	Site heavily modified. Some facilities designed strictly for comfort and convenience of users Luxury facilities not provided. Facility design may incorporate synthetic materials. Extensive use of artificial surfacing of roads and trails. Vehicular traffic control usually obvious. Primary access usually over paved roads Development density 3-5 family units per acre. Plant materials usually native. Interpretive services often formal or structured.
Urban	5	High degree of site modification. Facilities mostly designed for comfort and convenience of users and usually include flush toilets; may include showers, bathhouses, laundry facilities, and electrical hookups. Synthetic materials commonly used. Formal walks or surfaced trails. Regimentation of users is obvious Access usually by high-speed highways. Development density 5 or more family units per acre. Plant materials may be foreign to the environment. Formal interpretive services usually available. Designs formalized and architecture may be contemporary. Mowed lawns and clipped shrubs not unusual.

Recreation Opportunity Spectrum (ROS) - A conceptual framework for defining types of recreation opportunities, physical settings, and experiences a visitor can expect. It is an inventory system and a management tool. There are six ROS classes. Each class is defined in terms of the degree to which it satisfies certain recreation experience needs, based on the extent to which the natural environment has been modified, the type of facilities provided, the degree of outdoor skills needed to enjoy the area, and the relative density of recreation use. The six classes are:

1. Primitive--Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and controls. Motorized use within the area is not permitted.

2. Semi-primitive nonmotorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but would be subtle. Motorized recreation use is not permitted.

3. Semi-primitive Motorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but would be subtle. Motorized recreation use of local primitive or collector roads with predominantly natural surface and trails suitable for motor bikes is permitted.

4. Roaded Natural--Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment Interaction between users may be moderate to high, with evidence of other users prevalent. Resource modification and utilization practices are evident, but harmonize with the natural environment Conventional motorized use is allowed and incorporated into construction standards and design of facilities

5. Rural--Area is characterized by a natural environment that has been substantially modified by development of structures, vegetative manipulation, or pastoral agricultural development. Resource modification and utilization practices may be used to enhance specific recreation activities and to maintain vegetative cover and soil Sights and sounds of humans are readily evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people Facilities are often provided for special activities Moderate user densities are present away from developed sites Facilities for intensified motorized use and parking are available.

6. Urban--Area is characterized by a substantially urbanized environment, although the background may have natural-appearing elements. Renewable resource modification and utilization practices are often used to enhance specific recreation activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans are predominant on site Large numbers of users can be expected both on site and in nearby areas. Facilities for highly intensified motor use and parking are available with forms of mass transit often available to carry people throughout the site.

Recreation Residence - A privately owned structure, authorized on National Forest land under a "Special Use Permit."

Recreation Visitor Day (RVD) - A measure of recreation use Twelve visitor hours, which may be aggregated continuously, intermittently, or simultaneously by one or more persons.

Reforestation - The natural or artificial restocking of an area with forest trees; most commonly used in reference to artificial restocking.

Regeneration - The actual seedling and saplings existing in a stand; or the act of establishing young trees naturally or artificially.

Regeneration Cutting (Harvest) - Any removal of trees intended to assist regeneration already present or to make regeneration possible.

Region - An area covered by a Regional Guide. See FSM 1221.3 for organizational definitions.

Regional Forester - The Forest Service official responsible for administering a single Region.

Regional Guide - The guide developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended. It guides all natural resource management activities, and establishes management standards and guidelines for the National Forest System lands within a given Region. It also disaggregates the assigned Regional RPA objectives to the Forests within that Region.

Regulations - Generally refers to the Code of Federal Regulations, Title 36, Chapter II, which covers management of the Forest Service.

Rehabilitation - Action taken to restore, protect, or enhance site productivity, water quality, or other resource values over a period of time.

Release - Freeing trees from competition for light, water, and nutrients by removing or reducing the vegetation growth that is overtopping or closely surrounding them.

Released Roadless - See "1) Unroaded," and "Roadless Areas."

Renewable Resources - Resources that are possible to use indefinitely, when the use rate does not exceed the ability to renew the supply.

Research Natural Area (RNA) - In USDA Forest Service usage, RNAs are areas designated to ensure representative samples of as many of the major naturally-occurring plant communities as possible. An area established specifically to preserve a representative sample of an ecological community, primarily for scientific and educational purposes.

Residual Stand - The trees remaining standing after some event such as selection cutting.

Residue Utilization - Removal and use of forest residue (such as slash, litter, brush, dead trees, and snags) for energy production, home heating, or wood products.

Resource - Anything which is beneficial or useful - be it animal, vegetable, mineral, a location, a labor force, a view, an experience, etc. Resources, in the context of land use planning, thus vary from such commodities as timber and minerals to such amenities as scenery, scenic view points, or recreation opportunities.

Resource Use and Development Opportunities - A possible action, measure, or treatment and corresponding goods and services identified and introduced during the scoping process, which subsequently may be incorporated into and addressed by the Forest Land and Resource Management Plan in terms of a management prescription.

Retention - See "Visual Quality Objectives."

Riparian - Pertaining to areas of land directly influenced by water Riparian areas usually have visible vegetative or physical characteristics reflecting this water influence. Stream sides, lake borders, or marshes are typical riparian areas.

Riparian Area - A geographically delineated area with distinctive resource values and characteristics that is comprised of aquatic and riparian ecosystems. This includes floodplains, wetlands, and all areas within a horizontal distance of approximately 100 feet from the normal line of high water of a perennial stream channel or from the shoreline of other bodies of water

Riparian Ecosystem - A transition between the aquatic ecosystem, and the adjacent upland terrestrial ecosystem. Identified by soil characteristics and distinctive vegetation communities that require free or unbound water.

Road:

1. **Arterial** - A road that serves a large land area and usually connects with a public highway or other arterial road to form an integrated network of primary travel routes. The location and standard are often determined by a demand for maximum mobility and travel efficiency rather than specific resource-management service They are usually developed and operated for long-term land and resource management purposes and constant service.

2. **Collector** - A road that serves a smaller land area than an arterial road and is usually connected to an arterial road or public highway They collect traffic from local roads or terminal facilities. The location and standard are influenced by both long-term multi-resource service needs, as well as travel efficiency. Collector roads may be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility (FSM 7700).

3. **Local** - A road that connects terminal facilities with a collector road, arterial road, or public highway. The location and standard are usually determined by that required to serve a specific resource activity, rather than travel efficiency. Local roads may be developed and operated for either long- or short-term service.

Roaded Natural (RN) - See "Recreation Opportunity Spectrum."

Roaded Modified (RM) - A classification of the Recreation Opportunity Spectrum that characterizes a predominately altered environment, allowing for noticeable to strongly-evident management activity.

Roadless Area Review and Evaluation (RARE II) - A comprehensive process directed by the Secretary of Agriculture to identify roadless and undeveloped land areas in the National Forest system and to determine their uses for either wilderness or other resource management and development and to determine areas that would require further planning to make such a decision.

Roadless Areas - These lands, inventoried in the Roadless Areas Review and Evaluation (RARE II), were not designated wilderness by the Washington State Wilderness Act of 1984. See "Released Roadless," and Unroaded."

Rotation - The number of years required to establish, including the regeneration period, and grow timber crops to a specified condition or maturity for regeneration harvest. Rotation age is based on the selected management prescriptions in a Forest Plan Alternative.

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974. Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of the act. The most recent recommended program was completed in 1985.

S-8 - A map code used to designate unsuitable forest land that is not managed for timber production because technology is not available to prevent irreversible damage to soils productivity, or watershed conditions. See "Timber Resource Land Suitability Classification, (3)C."

Sale Schedule - The quantity of timber planned for sale and harvest, by time period, from the area of suitable land covered by the Forest Plan. The first period, usually a decade, of the selected harvest schedule provides the allowable sale quantity. Future periods are shown to establish that sustained yield will be achieved and maintained.

Salvage Cutting (Harvest) - The exploitation of trees that are dead, dying, or deteriorating before their timber becomes worthless. Cutting done essentially to prevent the spread of pests or pathogens is termed "Sanitation Cutting."

Sanitation Cutting - See "Salvage Cutting."

Saprophyte - A plant living on dead or decaying organic matter.

Saturation Density - (Same as tolerance density.) Intraspecific tolerance permits no future increase. Is most marked in territorial species. Space is the limiting factor to the further increase of this population density.

Sawtimber - Trees containing at least one 12-foot sawlog or two noncontiguous 8-foot logs, and meeting regional specifications for freedom from defect. Softwood trees must be at least 9 inches in diameter and hardwood trees 11 inches in diameter at breast height.

Scarified - Land in which the topsoil has been broken up or loosened in preparation for regenerating by direct seeding or natural seedfall. Also refers to ripping or loosening road surfaces to a specified depth for obliteration or "putting a road to bed".

Scenic Areas - Places of outstanding or matchless beauty which require special management to preserve these qualities. They may be established under 36 CFR 294.1 whenever lands possessing outstanding or unique natural beauty warrant this classification.

Scenic River Areas - See Wild and Scenic River.

Scheduled Timber Harvests - Volumes and acres programmed for harvest which are within the allowable sale quantity. This does not include salvage and sanitation harvesting.

Scion - A detached shoot or twig containing buds from a woody plant and used in grafting.

Scoping Process - A part of the National Environmental Policy Act (NEPA) process; early and open activities used to determine the scope and significance of the issues, and the range of actions, alternatives, and impacts to be considered in an Environmental Impact Statement.

Second Growth - Forest growth that has come up naturally after some drastic interference (for example, wholesale cutting, serious fire, or insect attack) with the previous forest growth.

Sediment - Solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface.

Sedimentary - Rock formed of sediment, such as conglomerate, sandstone, or shales, formed of fragments of other rock transported from their sources and deposited in water. Also, rocks formed by precipitation from solution, as, rock salt and gypsum, or from secretions of organisms, as most limestone.

Seedlings and Saplings - Live trees less than five inches in diameter at breast height. (See also Size Class.)

Selection Cutting - The annual or periodic removal of trees (particularly mature), individually or in small groups ("Group Selection"), from an uneven-aged forest to achieve the balance among diameter classes needed for sustaining yield and to establish a new crop of irregular distribution representative of age and/or size classes.

Semi-primitive Motorized ROS Class - See "Recreation Opportunity Spectrum."

Semi-primitive nonmotorized ROS Class - See "Recreation Opportunity Spectrum."

Sensitive Species - Plant or animal species which are susceptible or vulnerable to activity impacts or habitat alterations. Those species that have appeared in the Federal Register as proposed for classification and are under consideration for official listing as endangered or threatened species, that are on an official State list, or that are recognized by the Regional Forester as needing special management to prevent their being placed on Federal or State lists.

Sensitivity Analysis - A determination of the effects of varying the level of one or more factors, while holding the other factors constant.

Sensitivity Levels - These levels represent an evaluation of public use and concern for the scenic quality of the National Forests. In Region 6 sensitivity levels will be reviewed every 5 years, and revised as necessary. There are three sensitivity levels, each identifying a different level of user concern for the visual environment:

1. Level 1 - Highest Sensitivity Level - An example would be seen areas from Interstate and U.S. Highways.

2. Level 2 - Average Sensitivity - (Also termed "Moderate Sensitivity") Examples are seen areas from county and Forest system roads not meeting the criteria for Level 1 sensitivity.

3. Level 3 - Lowest Sensitivity - An example would be seen areas from a local road in a Management Area where timber production is emphasized.

Seral - A biotic community that is a developmental, transitory stage in an ecological succession.

Series - A level of vegetation classification that is identified by the most common species found in the tree, shrub, and/or herbaceous layer of a plant community. Series is a subdivision of a subformation.

Shall - See "must."

Shelterwood - The cutting method that describes the silvicultural system in which, in order to provide a source of seed and/or protection for regeneration, the old crop (the shelterwood) is removed in two or more successive shelterwood cuttings. The first cutting is ordinarily the seed cutting, though it may be preceded by a preparatory cutting, and the last is the final cutting. Any intervening cutting is termed removal cutting. An even-aged stand results.

Should (or ought) - Verb used in the Management Prescriptions, Proposed Forest Plan. Action is required unless justifiable reason exists for not taking action.

Silviculture - The theory and practice of controlling the establishment, composition, constitution (the distribution and representation of age and/or size classes), and growth of forests.

Silvicultural System - A process that applies silvicultural practices, including the tending (thinning, pruning, etc.), harvesting, and replacing, to a stand in order to produce a crop of timber and other forest products. The system is named by the cutting method with which the regeneration is established, e.g. clearcutting, shelterwood, selection and group selection. See "Harvest Cutting Methods."

Site Index - A numerical evaluation of the quality of land for plant productivity, ... based on the height of dominant trees in a stand at an arbitrarily chosen age.

Site Preparation - 1) An activity (such as prescribed burning, disking, and tilling) performed on a reforestation area, before introduction of reforestation, to ensure adequate survival and growth of the future crop; 2) manipulation follows harvest, wildfire, or construction in order to encourage the growth of favored species. Site preparation may include the application of herbicides; burning, or cutting of living vegetation that competes with the favored species; tilling the soil; or burning of organic debris (usually logging slash) that makes planting or seeding difficult.

Site Productivity - Production capability of specific areas of land.

Size Class - For purposes of Forest planning, size class refers to the intervals of tree stem diameter used for classification of timber in the Forest Plan data base.

seedling/sapling = less than five-inch diameter
pole/sapling = five-inch to nine-inch diameter
sawtimber = greater than nine-inch diameter

Skidding - A general term for hauling loads by sliding, not on wheels as developed originally, from stump to roadside, deck, skidway, or other landing.

Skyline Deflection - The distance a skyline cable drops below line of sight during the yarding operation

Skyline Logging - See "Logging Systems."

Skyline Tailhold - Anchors consisting of stumps, trees, deadmen, or rock bolts to hold the end of the skyline yarding cable that is opposite the yarding machine.

Slash - The residue left on the ground after timber cutting or other vegetation disturbing activity and/or accumulating there as a result of storm, fire, or other damage. It includes unused logs, uprooted stumps, broken or uprooted tree stems, branches, twigs, leaves, bark, and chips.

Slope Class - See "Topographic Class."

Small Game - Birds and small mammals typically hunted or trapped.

Snag - A standing dead tree.

SOHA (Spotted Owl Habitat Area) - A habitat area designated to support one pair of owls. See the Final SEIS for the Pacific Northwest Regional Guide.

Special Component - The portion of the regulated commercial forest land that needs specially designed treatment of the timber resource to achieve landscape or other key resource objectives.

Special Use Permit - The most common permit authorizing use of Forest lands by individuals and public agencies. Examples of use authorized are: recreation residence, pasture, power or telephone line, water transmission pipeline, powerplant, and electronic site.

Soil Stability Classes - A grouping of soil types on the Forest with respect to their tendency to erode or move from natural conditions or land use activities. The three soil stability classes used in the Forest are: 1) Stable soils; 2) Moderately unstable; and 3) Highly unstable soils. See "Topographic Classes."

Spirit Sites - Locations where an individual may seek a personal spirit power. The areas are isolated, include fresh running streams or lakes, or are near some stands of cedar. They may also be areas that are considered inbued with a power of their own.

Stand (Tree Stand) - An aggregation of trees occupying a specific area and sufficiently uniform in species, composition, age arrangement, and condition as to be distinguishable from the forest in adjoining areas.

Standard - A statement which describes a condition when a job is done properly. Standards show how well something should be done, rather than what should be done.

Standards and Guidelines - Principles specifying conditions or levels of environmental quality to be achieved.

Standard Component - The portion of the regulated commercial forest land on which crops of industrial wood can be grown and harvested with adequate protection of the forest resources under the usual provisions of the timber sale contract.

Stream Class - See Class I,II,II, and IV Streams.

Streamflow - The flow of water, generally with its suspended load, down a well-defined water course.

Streamside Management Unit (SMU) - The stream and an adjacent area where practices that might affect water quality, fish, and other aquatic resources are modified, as necessary, to meet water quality goals for each class of stream. The width of the area will vary with the management goals for each class of stream, characteristics of the stream and surrounding terrain, and type and extent of the planned activity. In the Mt. Baker-Snoqualmie National Forest, the area adjacent to wetlands and other bodies of water is termed a Wetland Management Unit (WMU). See "Class I, II, III, and IV streams."

Stream Structure - The arrangement of logs, boulders, and meanders which modify the flow of water, thereby causing the formation of pools and gravel bars in streams. Generally, there is a direct relationship between complexity of structure and fish habitat Complex structure is also an indication of watershed stability.

Stocking - The degree of occupancy of land by trees as measured by basal area or number of trees and as compared to a stocking standard, that is, the basal area or number of trees required to fully use the growth potential of the land.

Stumpage (stumpage value) - The value of timber as it stands uncut, in terms of an amount per unit of volume.

Substantive Comment - A comment that provides factual information, professional opinion, or informed judgement germane to the action being proposed.

Successional Stage - A stage or recognizable condition of a plant community that occurs during its development from bare ground to climax.

Suitable - See "Timber Resource Land Suitability Classification."

Suitable Forest Land - Land to be managed for timber production on a regulated basis. See Timber Resource Land Suitability Classification.

Suitability - The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices

Suppression - The process of extinguishing or confining a fire.

Surface Erosion - The detachment and transport of individual soil particles by wind, water, or gravity. Surface erosion can occur as the loss of soil in a fairly uniform layer across the land surface or in many small rills.

Sustained Yield of the Products and Services - The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System without impairment to the productivity of the land

Talus Slope - A collection of fallen disintegrated material which has formed a slope at the foot of a steeper descending slope.

Tentatively Suitable - See "Timber Resource Land Suitability Classification."

Thermal Cover - Cover used by animals to lessen the effects of weather; for elk, a stand of coniferous trees 40 feet or more tall with an average crown closure of 70 percent or more

Thinning - See "Intermediate Cutting" and "Precommercial Thinning."

Threatened Species - Those plant or animal species likely to become endangered species throughout all or a significant portion of their range within the foreseeable future.

Till - Nonsorted, nonstratified sediment carried or deposited by a glacier.

Timber Resource Land Suitability Classification - National Forest System lands are classified according to the following definitions:

1. **Non-forest** - Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2. **Forest** - Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for non-forest use.

3. **Unsuitable Forest Land (Not Suited)** - Forest land that is not managed for timber production because (a) the land has been withdrawn by Congress, the Secretary, or the Chief; (b) the land is not producing or capable of producing crops of industrial wood; (c) technology is not available to prevent irreversible damage to soils, productivity, or watershed conditions; (d) there is no reasonable assurance that lands can be adequately restocked within 5 years after final harvest, based on existing technology and knowledge, as reflected in current research and experience, (e) there is at present, a lack of adequate information to responses to timber management activities; or (f) timber management is inconsistent with or not cost efficient (not appropriate) in meeting the management requirements and multiple-use objectives specified in a Forest Plan land management alternative.

4. ***Tentatively Suitable Forest Land*** - *Forest land that is producing or is* capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production *without irreversible damage to soils, productivity, or watershed* conditions; (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvest; and (d) adequate information is available to project responses to timber management activities.

5. **Suitable** - Tentatively suitable forest land identified as appropriate for timber production in a Forest Plan land management alternative.

6. **Commercial Forest (CFL)** - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service, (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; and (c) where existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

Timber Production - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use other than for fuelwood.

Timber Sale Program Quantity (TSPQ) - The volume of timber planned for sale during the first decade of the planning horizon. It includes the allowable sale quantity (chargeable volume) and any additional material (nonchargeable *volume) planned for sale. The timber sale program quantity is usually* expressed as an annual average for the first decade.

Timber Stand Improvement (TSI) - Measures such as precommercial thinning, pruning, release cutting, prescribed fire, girdling, weeding, or poisoning of unwanted trees aimed at improving growing conditions for the remaining trees.

Topographic Class (Slope Class) - Divisions of the Forest important primarily for determining soil sediment outputs, tendency for soil erosion and slope failure, and difficulty in road construction and timber harvesting activities. The three classes defined in the Forest to reflect these concerns are:

A - Gentle topography, less than 35% slope.
B - Somewhat uneven topography with rock outcrops in less than 35% of the area. Steep slopes (35% to 80%).
C - Rugged highly dissected topography with rock outcrops in 35% - 100% of the area Steep slopes (50% to 90%) Stream density greater than 5 miles per section.

See "Soil Stability Class." The latter (three classes) were used in combination with each topographic class to develop coefficients such as soil sediment output caused by management activities.

Tree Line - A loose term for the limit beyond which trees cannot or do not appear. The limiting factor is most commonly altitude or geographical latitude. A distinction may be drawn between tree line and timber line, the latter being roughly the limit of timber rather than isolated trees.

Turbidity - The cloudy condition caused by suspended solids in a liquid See "Sediment."

Understory - The trees and other woody species growing under a more-or-less continuous cover of branches and foliage formed collectively by the upper portion of adjacent trees and other woody growth

Undeveloped Area - Portion of the National Forest that is essentially unroaded.

Uneven-Aged Management - The application of a combination of actions needed to simultaneously maintain continuous high-forest cover, recurring regeneration of desirable species, and the orderly growth and development of trees through a range of diameter or age classes to provide a sustained yield of forest products Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection. (36 CFR 219.3)

Unroaded - 1) RARE II roadless areas released by the Washington State Wilderness Act of 1984 from being considered for designation as wilderness during development of the initial Forest Plan, 2) In the Forest's FORPLAN Model, an analysis area identifier which includes roadless areas defined in "1" above in addition to other unroaded areas in the Forest containing tentatively suitable forest land, 3) A term used to equal the sum of recreation use or carrying capacity from the primitive, semi-primitive nonmotorized, and semi-primitive motorized recreation opportunity spectrum areas outside wilderness.

Unsuitable Lands - See CFR 36 219.14. See "Timber Resource Land Suitability Classification, Unsuitable "

Utility and Transportation Corridors - A strip of land designated for the transportation of energy, commodities, and communications. Examples are power transmission lines, pipelines, penstocks, water lines, etc. Transportation of minor amounts of power for short distances are not treated in the Forest Plan.

Utilization Standards - Standards guiding the use and removal of timber, which is measured in terms of diameter at breast height, top diameter inside the bark, and percent "soundness" of the wood.

Variety Class - A measure of visual diversity or inherent capability of the land to produce attractive scenery. There are three variety classes. See "Character Type."

Class A - Distinctive - Refers to areas where features of the landscape are of unusual or outstanding visual quality. They are usually not common in the character type.

Class B - Common - Refers to areas where features contain variety in form, line, color, texture, or combinations thereof, but which tend to be common throughout the character type. These landscapes are the benchmark from which distinctive and minimal can be judged.

Class C - Minimal - Refers to areas where features have little change in form, line, color, or texture. Includes all areas not found under Classes A and B.

Vegetation Leave Area - Area of land in which vegetation is left undisturbed in order to provide shade and organic debris to streams, or to prevent the acceleration of natural erosion processes. No regulated timber harvest is planned in these areas.

Vegetative Management - Activities designed primarily to promote the health of the crop forest cover for multiple-use purposes.

Vertical Diversity - The diversity in a stand that results from the complexity of the aboveground structures of the vegetation; the more tiers of vegetation and/or the more diverse the species makeup, the higher the degree of vertical diversity. This concept is similar but not identical to "uneven-aged management;" each may influence the other. Application of even-aged management, for example, can be designed to accomplish vertical diversity objectives. See also "Horizontal Diversity."

Viable Population - The number of individuals of a species required to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their region.

Viewshed - (Sometimes termed "Viewshed Corridor" or "Visual Corridor") Viewsheds are the "seen" landscape visible to most Forest visitors from roads, trails, rivers, and recreation areas. Most are corridors, one-quarter to two miles wide. Viewsheds viewed from primary travel routes and use areas are "Sensitivity Level 1." Viewsheds viewed from secondary travel routes and use areas are "Sensitivity Level 2."

Visual Absorption Capacity (VAC) - An estimate of the relative ability of a landscape to accept management manipulations without significantly affecting its visual character, or the relative capacity of the land to absorb visual change. Rated as low, moderate, and high.

Visual Condition - The visual appearance of a landscape described in terms of the degree of alteration of the natural appearing landscape. Descriptive degrees of alteration are:

1. Natural Appearing - Area appears untouched by man; changes are not visually evident.

2. Slightly Altered - Changes may be noticed by the average visitor but do not attract attention. Natural appearance dominates minor disturbances.

3. Moderately Altered - Changes are easily noticed by the average visitor and may attract attention. Disturbances are apparent.

4. Heavily Altered - Changes are strong and obvious to the average visitor. Changes dominate the landscape but may resemble natural patterns when viewed from a distance of 3 to 5 miles. Disturbances are major.

Visual Corridor - See "Viewshed."

Visual Quality Levels (VQL) - An inventoried measure of acceptable levels of modification of the visual resource. VQL's are used in Forest planning as an indicator of social (visual) acceptability and as an input for management decisions. VQL's become Visual Quality Objectives in the approved Forest Land Management Plan.

1. Preservation--Allows ecological changes only.

2. Retention--Human activities are not evident to the casual Forest visitor.

3. Partial Retention--Human activity may be evident, but must remain subordinate to the characteristic landscape.

4. Modification--Human activity may dominate the characteristic landscape, but must, at the same time, follow naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.

5. Maximum Modification--Human activity may dominate the characteristic landscape, but should appear as a natural occurrence when viewed as background.

6. Enhancement--A short-term management alternative which is done with the express purpose of increasing positive visual variety where little variety now exists.

Visual Quality Objectives (VQO) - See "Visual Quality Levels."

Visual Resource - The composite of basic terrain, geologic features, water features, vegetative patterns, and land-use effects that typify a land unit and influence the visual appeal the unit may have for visitors.

Wetlands - Areas that are inundated by surface water or groundwater with a frequency sufficient to support, and under normal circumstances does or would support, a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction (Executive Order 11990).

Wetland Management Unit (WMU) - See "Streamside Management Unit."

Wilderness - Areas designated by congressional action under the 1964 Wilderness Act. Wilderness is defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation. Wilderness areas are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature, with the imprint of human activity substantially unnoticeable; have outstanding opportunities for solitude or for a primitive and confined type of recreation; include at least 5,000 acres or are of sufficient size to make practical their preservation, enjoyment, and use in an unimpaired condition, and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest.

Wild and Scenic Rivers - Those rivers or sections of rivers designated as such by congressional action under the 1968 Wild and Scenic Rivers Act, as supplemented and amended, or those sections of rivers designated as wild, scenic, or recreational by an act of the Legislature of the State or States through which they flow. Wild and Scenic Rivers may be classified and administered under one or more of the following categories:

1. Wild River Areas--Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.

2. Scenic River Areas--Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

3. Recreational River Areas--Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Wilderness Recreation Opportunity Spectrum - See "Recreation Opportunity Spectrum." Wilderness ROS and their standards apply to all designated wilderness on the Forest. For specific direction regarding Alpine Lakes, consult the Alpine Lakes Area Land Management Plan.

Within each WROS Class there are Limits of Acceptable Change (LAC). LAC is a maximum limit of change allowed. Managers try to achieve the best conditions possible rather than allowing conditions to deteriorate until the threshold is reached. See "Limits of Acceptable Change."

1. Transition - This trailed class includes system trails that have a travelway worn to mineral soil over long distances, and is characterized by having a large proportion of day-users, often mixed in with overnight and long distance travelers. This area is usually adjacent to trailheads and extends into the wilderness a distance that is typically traveled in one day by a hiker. This class includes areas accessed by trail, around lakes, or other attractions used by people or pack stock, within the day-use influence area. The class extends at least 500 feet on either side of a trail; it may be wider around lakes or heavily used areas. The length of this trail class will be established for each trail depending on ease of travel, distance from trailhead outside wilderness, and destination attractions inside wilderness. Length will generally be 3 to 5 miles inside the wilderness boundary. If the day-use activity occurs entirely outside wilderness, the trail will have no Transition Class.

2. Trailed - This class includes all managed system trails. It extends beyond the Transition Class. This class extends at least 500 feet on either side of the trail but may be wider around lakes or heavily used areas.

3. General Trailless - This class includes areas not falling into the other classes. It attracts very low use because of a relative lack of trails or destination spots. The area is unmodified; user-made trails are not encouraged, but they may exist. If obvious user-made trails become well established, or are causing resource damage, consideration will be given to their reconstruction in order to protect the wilderness resource from further damage. Reclassification from general trailess to railed requires a supplement of the Forest Plan, which shall include full public involvement. This class is available for new trail construction or relocation of existing trails to protect resources or meet objectives by dispersing use. If this should occur, the trail will only be constructed to no higher than "more difficult or "most difficult" standards.

4. Dedicated Trailless - This class is managed forever trailless; user-made trails are not permitted. It may include popular attractions accessed only by cross-country travel. Human impact and influence is, by design, minimal; therefore user restrictions may be necessary to insure that trailless experiences remain. Dedicated Trailless areas should be of a size that will allow for a meaningful experience and can be reasonably protected for the experiences and remoteness identified. Generally the class is at least 1,000 acres in size and contain whole drainages or basins out of sight and sound of trails or areas outside the wilderness.

5. Special Areas - The intent of this class is to provide for significant changes in standards or other management guidelines for unique areas. Areas that qualify for Special Area designation include congressionally acknowledged areas, areas of significant cultural or historic value, areas with special considerations, and areas with limited management options to deal with unique situations. Areas do not qualify for this class for administrative convenience in dealing with overuse. The class is rare and will not exist in many wildernesses.

Wildfire - Any wildland fire that is not a prescribed fire.

Wildland - Uncultivated land, other than fallow, virtually uninfluenced by human activity. It may be neglected altogether or maintained for such purposes as wood or forage production, wildlife habitat, recreation, or protective plant cover.

Wildlife Fish User Day (WFUD) - One WFUD consists of 12 hours of recreation that is the result of fish or wildlife, such as hunting, fishing, birdwatching, etc.

Will - Verb used in the Management Prescriptions, Proposed Forest Plan. Is not restrictive; applies only to a statement of future condition or an expression of time. Not used in the place of "shall."

Windfall - A tree thrown or the stem or other parts (such as branches, foliage, or fruit) broken off or blown down by the wind.

Wood Residue - The residual wood remaining as a result of timber cutting, other vegetation disturbing activity, storms, fire, or other natural event. It includes any unutilized woody material. See "Slash" and "Residue Utilization."

Yarding - The moving of logs from the stump where cut to a central concentration area or landing. See "Logging Systems."

Yield Tables - Tables that estimate the level of outputs that would result from implementing a particular activity. Usually referred to in conjunction with FORPLAN input or output. Yield tables can be developed for timber volumes, range production, soil and water outputs, and other resources.

Appendices A-

Final Environmental Impact Statement

Land and Resource Management Plan

Mt. Baker-Snoqualmie National Forest

APPENDIX A
ISSUE, CONCERN, AND OPPORTUNITY IDENTIFICATION PROCESS

INTRODUCTION

This appendix displays the process used to identify public issues, management concerns, and resource opportunities (ICO's), including the public involvement activities and contacts and consultation with others throughout the planning process. The tie between the ICO's and the alternatives is also discussed.

Changes Between DEIS and FEIS - ICO's

Several changes have been made to the list of issues, concerns, and opportunities since the Draft Environmental Impact Statement (DEIS) was released in December, 1987. All are based on public response to the draft. Once the analysis of public comment was completed, the Forest Supervisor and planning team members met with the Regional Forester to review the major issues identified by the public and set a course of action, moving toward preparation of a Final Environmental Impact Statement (FEIS) and Forest Plan.

Some key issues identified by the public in response to the DEIS included:

- a number of technical issues related to the timber supply ICO;
- need for a hydrologic cumulative effects analysis;
- several facets of fisheries habitat management;
- wild and scenic rivers, specifically concern about the eligibility analysis done and the lack of a suitability analysis;
- management direction in the Cedar River watershed;
- and need for new or modified alternatives.

The resolution of these issues are discussed throughout the final documents, especially Chapter II, Appendix B, new Appendix H (documentation of developing a management requirement for hydrologic cumulative effects), and in Appendix J, Forest Service responses to substantive comments. Modifications made to the ten major issues, concerns, and opportunities listed in the DEIS, as a result of public response are discussed in this appendix.

In brief, the list of ICO's was reorganized, to reflect more recent public concern. Several draft document ICO's were retitled, also to reflect changing conditions and to respond to public comments, especially in the key areas mentioned above. The transportation issue and wood residue management opportunity were incorporated as facets of other major ICO's and dropped as separate issues. Wild and Scenic Rivers is now addressed as a major issue; it had been a facet of the recreation ICO. **The major issues and concerns addressed in this FEIS are:**

- **Development versus Nondevelopment of the Forest**
- **Timber Supply**
- **Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity**
- **American Indian Religious and Cultural Use**
- **Recreation Opportunities**
- **Wild and Scenic Rivers**
- **Management of Municipal Watersheds**
- **Effects of Timber Management and Related Activities**
- **Adjacent and Intermingled Lands**

The last section of this appendix discusses these changes in detail The major ICO's, the conflict involved, major groups interested, and indicators of response and their measurements are described in in Chapter I of this FEIS.

PROCESS FOR IDENTIFYING ISSUES, CONCERNS, AND OPPORTUNITIES

In June 1979, the Forest Supervisor notified the public that the Mt. Baker-Snoqualmie National Forest was beginning the preparation of a comprehensive land and resource management plan. Notification was accomplished through the news media and a Forest mailing to 3,300 persons and organizations. The notice included an announcement that workshops were scheduled for the purpose of identifying Issues, Concerns, and Opportunities (ICO's) that should be addressed in the Forest Plan.

To facilitate interest in the workshops and provide the public with examples of ICO's that might be addressed, the notice also included a preliminary list of 70 ICO's. These were developed from input to earlier planning efforts, letters to the Forest, newspaper articles, and the Management Team's knowledge gained through day to day contacts with forest users and the interested public.

This first phase of pubic involvement took place at workshops in Bellingham, Mt. Vernon, Seattle, and Tacoma. The Tacoma and Seattle workshops were held in conjunction with the Wenatchee National Forest. Some 160 people attended the meetings. In addition, 19 people provided written comments in later correspondence. Comments tended to focus on issues and/or concerns regarding management of the National Forest as perceived by those members of the public participating in the workshops and responding by letter

Consultation with Others, Prior to Issuing the DEIS

Agencies

In October 1980, the Forest conducted a briefing for various agencies and levels of government that were believed to have an interest in the Forest Planning process. Two objectives were accomplished at this meeting:

1. Participants were informed that the Forest would be preparing a land management plan, the major steps in the planning process were described and the estimated schedule was presented.

2. Most of the agencies designated a contact person that would serve as a liaison with the planning team. Agencies also indicated the "level" of participation in the planning process they estimated would be appropriate for their agency.

Contacts were established with the following agencies and government entities:

U.S. Government: Bonneville Power Administration; Bureau of Indian Affairs; Department of Energy; Environmental Protection Agency, Fish and Wildlife Service, National Marine Fisheries Service; and National Park Service.

State of Washington: Departments of Commerce and Economic Development, Ecology, Fisheries, Game, Natural Resources, Social and Health Service, and

Transportation; Energy Office, Interagency Committee for Outdoor Recreation; and Parks and Recreation Commission.

Counties: King County Planning; Skagit County Planning

Municipalities: Tacoma City Water.

Within the first year of the planning process, contacts were also made with additional county and local government bodies. These are identified in Appendix G, with their plans and policies.

Washington State Department of Game: From the outset of the planning process, wildlife has been recognized as one of the key forest resources Long standing agreements between the Forest Service and the State have further recognized that the Forest Service had primary responsibility for the habitat used by wildlife, whereas the State retained responsibility for the wildlife itself. Therefore they are mutually dependent upon each other.

The MBS and the Washington State Department of Game (WDG) mutually felt that it would be beneficial to both agencies if a WDG wildlife biologist were assigned to the Forest Planning Team as a full-time Interdisciplinary Team member. This was formally accomplished with the execution of an Intergovernmental Personnel Agreement (IPA) between the two agencies. The purpose of the Agreement was to involve a wildlife biologist associated with the WDG in the development of the Forest Land and Resource Management Plan The benefits to the Forest Service included: gaining the commitment of the Department of Game to the Forest Plan, improving the relationship between the organizations; and, strengthening the credibility of the Plan with external environmental groups. The benefits to the Department included: direct access and impact on the development of the Forest Plan; experience with a complex, long-range planning process; protection of sensitive animal needs; and, increasing credibility with external environmental groups.

Indian Tribes

As the planning process proceeded, it became increasingly evident that the Forest needed to address issues and concerns expressed by several of the Indian Tribes that use the Forest. In order to assess the type and amount of use on the Forest by Indians, the Forest entered into a contract with an archeologist consultant, Astrida Onat, to contact the various tribes and obtain the necessary data needed to address Indian concerns. A condition of the contract stipulated that site specific information was to be kept confidential; therefore, that information is not available for public review. (Non site-specific information has been made available to the public.) This effort resulted in the issuance of an inventory 1/ which documents the sites and uses of the Indian Tribes on the Forest This report has been one of the primary sources of information and data used in the Forest Planning process.

Meetings have occurred at various levels with the Indians and the Forest Service. In many cases, site-specific concerns are discussed at the Ranger District level, with consultation between the Forest Service and the tribe(s) using the area. In most cases, consultation to date has surfaced Indian concerns about harvesting old growth timber and road construction.

1/ Blukis Onat, Astrida and Hollenbeck, Jan L. (ed), Inventory of Native American Religious Use, Practices, Localities and Resources; Study Area on the Mt. Baker-Snoqualmie National Forest; April 1981.

Most of the briefings and resulting involvement in Forest Planning have usually been with representatives of several tribes (Lummi, Nisqually, Nooksack, Samish, Sauk-Suiattle, Swinomish and Tulalip Tribes). A concern at these meetings has been that any protection provided to inventoried religious, ceremonial, and cultural use sites through the Forest Planning process would not provide for any permanency since they (Indians) would have to fight the same battles every time the Plan was revised.

Additional American Indian involvement during the planning process included involvement during the Washington State wilderness bill proceedings. Some of the Tribes were very active in providing input that resulted in some areas being designated as wilderness in 1984.

Other Consultations

Three public liaison groups have participated in the Forest Planning process since 1980. A wide breadth of special interests are represented in the three groups. The three groups selected their own names: The Timber Industry Liaison Group, the Conservation Liaison Group, and the Recreation Liaison Group. Those participating on a regular basis are:

Timber Industry Liaison Group: Northwest Forestry Association (formally Industrial Forestry Association and Northwest Pine Association), Northwest Independent Forest Manufacturers, Western Forest Industries Association, plus several companies that purchase national forest timber.

Conservation Liaison Group: Alpine Lakes Protection Society (ALPS), Audubon Society, Mountaineers, North Cascades Conservation Council (NCCC), and Sierra Club.

Recreation Liaison Group: Backcountry Horsemen of Washington, Inc., National Campers and Hikers Association, Pacific Northwest 4-Wheel Drive Association, Tacoma Water Department, Travel Trailer Clubs of Washington, and Washington State Snowmobile Association.

The liaison groups act as sounding boards to keep the Forest Service informed about the general interests, concerns, and reactions of people in their special interest areas to the various aspects of the planning process. The liaison groups have also been willing to relay information gained in working with the planning team to those forest users with similar interests.

The liaison groups are small, for workability, and have no advisory or decision making authority. Liaison group members are people who have a strong interest in the management of the Mt. Baker-Snoqualmie and want to be involved in the technical details of the process.

Since continuity is a must for the success of these liaison groups, members committed to work with the Forest Planning team through the planning process, including committing a minimum of one day (or equivalent) every three months on the Forest Planning effort. Meeting agendas, dates, and activities were set by the groups, with the planning team providing, to the extent possible, any information requested. The groups meet at two-three month intervals during the planning process; less frequently after the draft was released. The groups choose not to meet together.

The planning team received specific input and suggestions on planning processes and methodology. The Conservation Group prepared a 100+ page alternative for

the draft EIS; the timber industry group provided information on assumptions and setting constraints for benchmark runs. The recreation group has provided information on horse and motorized use on the Forest, and provided trail information post-DEIS.

During preparation of the draft plan, a number of common concerns were identified by both the conservation and timber industry groups: determination of productive forest lands; development of yield tables; constraints; model formulation; economic efficiency; development of management requirements; and commodity and amenity values.

There was no intent that liaison groups replace public participation in the planning process. Hopefully the groups provide more insight and awareness of concerns that various users have regarding management of the MBS.

SELECTED ISSUES, CONCERNS, AND OPPORTUNITIES (ICO's)

Criteria and Screening Process Used

In order to determine which of the many issues and concerns could be realistically addressed in the Forest Planning process, criteria were developed to help narrow the scope of the ICO's.

The number of times an issue or concern was mentioned by either the public or the Forest Management Team provided the initial screen to narrow the number. It was assumed that the number of times an issue was mentioned reflected the degree of concern for that issue.

Scoping also included redefining the issues into broad terms and identifying the sub-issues or facets which would be considered as part of a major issue. Many of the preliminary 70 issues and additional ones mentioned frequently by the public and Forest Management Team became facets of major issues. Some issues were dropped because they did not meet the criteria listed below.

A major issue or facet of a major issue:

- ranks as a top 20 issue for either the public or the Forest Management Team or, is required by NFMA planning regulations;
- is not project (District or specialized) level planning;
- is not beyond control of Forest Service;
- and, is not an inherent part of actual planning process. (Example: public involvement is not an issue since it is part of the process.)

The following table illustrates the disposition of the 70 preliminary issues and the additional concerns identified by the Forest Management Team:

Appendix A

Table A-1 Disposition of Preliminary Issues, Management Concerns and Additional Public Issues

Preliminary Issue No.	Issue Subject	Disposition of Issue	Deferred, Resolve Outside Forest Plan Process
1	General Visual Resource Management	Facet of Major Issues 1, 2, 3, 4, 5, and 8	
2	Visual Resource Mgt. In Special or Scenic Areas	Facet of Major Issues 1, 2, 3, 4, 5, and 8	
3	Visual Resource Rehabilitation	Facet of Major Issues 4 and 5	
4	Visual Resource Mgt. Effect on Other Resources	Facet of Major Issues 1, 2, 3, 4, 5, and 8	
5	Wildlife and Fish "Essential" Habitats	Facet of Major Issues 5, 8, and 9	
6	Wildlife, Plant Diversity	Major Issue 7	
7	Threatened and Endangered Species	Facet of Major Issues 2 and 7	
8	Backcountry & Wilderness Fisheries	Not a Major Issue	X
9	Old Growth Timber	Facet of Major Issues 1, 2, 3, 5, 6, 7, and 9	
10	Anadromous Fish Habitat	Facet of Major Issues 5, 6, 7, 8, and 9	
11	Landownership Adjustment	Facet of Major Issue 1	
12	Utility Corridors	Facet of Major Issues 2 and 8	
13	Electronic Sites	Facet of Major Issues 2 and 8	
14	Public Access to Forest Service Trails	Not a Major Issue	X
15	Effects of Intermingled Ownership on Natl. Forest	Major Issue 1	
16	Recreation/Resource Conflicts	Major Issue 4	
17	Dispersed Recreation Opportunities	Facet of Major Issues 2, 3, 4, 5, and 8	
18	Developed Recreation Opportunities	Facet of Major Issues 2, 4, 5, and 8	

Preliminary Issue No.	Issue Subject	Disposition of Issue	Deferred, Resolve Outside P.Process
19	Future Recreation Demand	Facet of Major Issues 2 and 4	
20	Range Opportunities	Facet of Major Issue 7	
21	Role of Fire	Facet of Major Issues 5 and 7	
22	*Timber Harvest Residues*	*Opportunity 10*	
23	Fire Prevention & Insect & Disease Control Cost/ Benefit	Facet of Major Issues 5 and 7	
24	Public Control to Reduce Fire Risks	Not a Major Issue	X
25	Cultural Resources	Facet of Major Issues 1, 4, 5, and 9	
26	Clean Air Act	Facet of Major Issue 5	
27	Use of Chemicals	Facet of Major Issues 3, 5, 6, 7, and 8	
28	National, Regional, and Local Needs	Required by NFMA & Part of Planning Process	
29	Effect of Forest Service on Community Lifestyles	Facet of Major Issues 2 and 4	
30	Ethnic Groups Opportunities	Facet of Major Issues 3, 4, and 9	
31	Public Transportation for Low Income Use of Forest	Not a Major Issue	X
32	Public Involvement	Required by NFMA & Part of Planning Process	
33	Adjacent Land Development	Facet of Major Issue 1	
34	Community Dependence on National Forest Timber	Facet of Major Issue 3	
35	Timber Mgt. on Lands Previously Termed "Marginal"	Facet of Major Issue 3, 5, 7, 8, and 10	
36	Wood Residue Utilization	Facet of Opportunity 10	
37	Non-Tmbr Resource Impact on Timber Harvest Level	Facet of Major Issues 2, 3, 4, 6, 7, and 9	
38	Adjacent Land Management	Facet of Major Issue 1	

Appendix A

Preliminary Issue No.	Issue Subject	Disposition of Issue	Deferred, Resolve Outside P.Process
39	Hardwood Conversion	Facet of Major Issues 7, 9, and 10	
40	Timber Harvest Level	Major Issue 3	
41	Intensive Timber Management	Facet of Major Issues 3, 5, 6, and 7	
42	Tentatively Suitable Forest Land Allocation to Other Uses	Facet of Major Issues 2, 3, 6, and 7	
42a	Clear Cut Size	Major Issue 5	
42b	Logging Practices	Major Issue 5	
43	Wilderness User Conflicts	Facet of Major Issues 4 and 8	
44	Administrative Use of Motorized Equipment in Wilderness	Facet of Major Issues 4 and 8	
45	Wilderness Over-Use	Facet of Major Issues 2 and 4	
46	Mineral Development in Wilderness	Not a Major Issue	X
47	Dispersed Recreation Facilities	Not a Major Issue	X
48	Road Openings & Closings	Facet of Major Issues 4 and 8	
49	Pacific Crest Trail Management	Facet of Major Issues 2 and 4	
50	Pollution Abatement	Facet of Major Issue 6	
51	Naches Pass Road	Facet of Major Issues 4 and 8	
52	Transportation System	Major Issue 8	
53	Natl. Forest Water Needs	Facet of Major Issue 6	
54	Water Quality	Major Issue 6	
55	Floodplains & Wetlands	Facet of Major Issue 6	
56	Sensitive Soils Identification	Facet of Major Issue 6	

Preliminary Issue No.	Issue Subject	Disposition of Issue	*Deferred, Resolve* Outside P.Process
57	Definition of "Unacceptable" Soil Damage	Facet of Major Issue 6	
58	Location of Productive Soils	Facet of Major Issue 6	
59	Soil Resource Protection	Facet of Major Issues 5, 6, and 8	
60	Soil Restoration	Not a Major Issue	X
61	*Soil Problems in Watersheds*	*Facet of Major Issue 6*	
62	Geothermal Development	Not a Major Issue	X
63	Rock, Sand & Gravel Mgt.	Not a Major Issue	X
64	Mineral Resource Potential	Facet of Major Issue 2	
65	Mineral Resource Availability	Not a Major Issue	X
66	Management of Non-Wilderness Roadless Areas	Major Issue 2	
67	Further Planning of Designated Roadless Areas	Major Issue 2	
68	Entry of Roadless Areas for Timber Management	Facet of Major Issues 2, 3, and 9	
69	Research Natural Areas	Facet of Major Issues 2 and 7	
70	Management Problems Research	Required by NFMA & Part of Planning Process	
70a	Planning Concerns	Most Concerns Covered by NFMA Requirements	
70b	Social, Economic, and Environmental Interrelationships	Facet of Major Issues 3, 5, and 8	
70c	Multiple Use/Single Use	Facet of Major Issues 2, 3, and 7	
	Forest Management Team Concerns		
M1	Roadside Revegetation	Not a Major Issue	X

Preliminary Issue No.	Issue Subject	Disposition of Issue	Deferred, Resolve Outside P.Process
M2	Soil & Water Monitoring	Facet of Major Issue 6	
M3	Cost Effective Paved Roads	Project Level Planning	X
M4	Coordinated Planning	Required by NFMA & Part of Planning Process	
M5	Second Entry Logging	Project Level Planning	X
M6	Summer Staffing Needs	Project Level Planning	X
M7	Use of Past Planning	Part of Plan Process	
M8	Calculation of Amenity Values	Part of Plan Process	
M9	Water Monitoring	See Issue M2	
M10	Ski Area Administration	Project Level Planning	X
M11	Departure from Non-Declining Flow	Facet of Major Issue 3	
M12	Present Timber Mgt. Plan	See Issue M7	
M13	Cost/Benefit of Alternatives Planning Process	Required By NFMA & Part of Planning Process	
M14	Land Allocation	See Issue 70a	
M15	Forest Boundary Establishment	Project Level Planning	X
M16	Funding & Personnel Requirements	Project Level Planning	X
M17	Energy and Capital Investment	Project Level Planning	X
M18	Heavy Canadian Visitation	Facet of Major Issue 4	
M19	Integration of All Plans	See Issue M7	
M20	Energy Needs	Not a Major Issue	X
M21 M22	Role of Fire	See Preliminary Issue 21	
M23	Range of Recreation Opportunities	Facet of Major Issues 2, 4, and 6	
M24	Coordination of Recreation Opportunities	See Issue M4	

Preliminary Issue No.	Issue Subject	Disposition of Issue	Deferred, Resolve Outside P.Process
M25	Recreation Demands and Opportunities	Facet of Major Issues 2, 4, and 6	
M26	Trail Systems	Facet of Major Issues 4 and 8	
M27	Land Allocation	See Issue 70a	
M28	Forest Plan Priority	See Issue M4	
M29	Data Use and Collection	See Issue 70a	
M30	Forest Plan Funding	See Issue 70a	
M31	Forest Plan Changes	See Issue 70a	
M32	Scenic Quality of Forest	See Preliminary Issue 1	
M33	Use of Regional Commercial Forest Land Stds.	See Issue 70a	
M34	Usefulness of Plan	See Issue 70a	
M35	Flood Proofing Road-Stream Crossing Structures	Project Level Planning	X
M36	Reforestation	See Issue 42c	

1979 Initial List of Major Issues, Concerns, and Opportunities

In the fall of 1979, the Forest Supervisor with the Regional Forester's approval, selected the following major issues and management concerns to be used as a basis for developing the Forest Plan. These are not listed in order of importance.

1. Adjacent And Intermingled Lands

Not all land owners have the same land management objectives. In areas of mixed ownership, however, objectives and subsequent land practices of all owners affect the management of adjacent lands. Non-Federal lands affect management of National Forest lands and management of the National Forest affects adjacent non-Federal land owners.

- o How should national forest lands adjacent to non-Federal land owners be managed?
- o What management activities should be conducted on national forest lands that are located near private developments?

2. Allocation of Areas Designated For Further Planning in RARE II

The RARE II process designated the Eagle Rock (06054) and Glacier Peak (L6031 Monte Cristo) areas to further planning. The Eagle Rock area contains 34,100

acres and the Glacier Peak parcel contains 57,320 acres. The National Forest Management Act regulations direct that the Forest Plan address such areas.

- How will the land be allocated and the resources managed in areas designated for further planning in RARE II?

3. Effects Of Timber Management And Related Activities

The Forest is managed for a mix of land uses including timber, recreation, water, wildlife, scenery, etc.. The mix of these uses and how each activity is carried on has an impact on other resources. Timber harvesting and road construction are important activities on the MBS which impact other resources.

- What management direction is needed for timber harvest and road construction activities to benefit or maintain the quality of other resources?

4. Management of Non-Wilderness Areas Allocated in RARE II

The RARE II process allocated 20 areas or parcels totaling over 631,000 acres to non-Wilderness use on the MBS. Many of these areas possess outstanding scenic attractions. They also contain other high amenity and high commodity values. The commercial forest land within these area is calculated in the Forest annual allowable harvest totals; however, this timber was not available for harvest during RARE I or II. Consequently, timber harvesting in the roaded portions has proceeded at a faster rate, making it more difficult to meet environmental quality objectives.

- Within non-Wilderness areas, to what mix of uses will lands be allocated and how will the resources be managed?
- At what rate should the Forest Service enter non-Wilderness areas for management of the various resources?

5. Recreation Impacts and Conflicts

The outstanding scenic quality of the MBS coupled with its proximity to a large metropolitan area results in a strong demand for developed and dispersed recreation opportunities. Some recreation uses are incompatible with each other and some recreation activities cause resource damage because of the level of use or type of use

- To what extent can the Forest provide recreation opportunities and how should they be managed?

6. Timber Harvest Level

Concerns continue about the amount of timber available for harvest and how this affects inflation, jobs, energy, and the environment. The availability of timber from the National Forest is one of many complex social, economic, and environmental factors in western Washington. An understanding of the interrelationship of these factors and the weight or value attached to each varies among the public.

- What is the capability and suitability of the MBS to produce timber?

- What should the timber harvest level be considering all resources on the Forest and their relationship to social, economic, and environmental factors including local, regional, and national demands?

7. Water Quality

The Forest has 18 watersheds covering 128,178 national forest acres that are used by the public for domestic and industrial purposes. Many Puget Sound Area cities, towns, and communities are consumers of water originating on the Mt. Baker-Snoqualmie.

- What activities should be permitted within municipal watersheds?
- What measures should be taken that will maintain or enhance water quality?

8. Wildlife, Fish, and Plant Diversity

There is increasing recognition that diversity is important in the ecosystem and that management activities may or may not contribute to the enhancement or maintenance of this diversity.

- What management direction is needed and where should action be taken that will maintain and/or enhance plant, wildlife, and fish diversity to meet multiple use objectives?

9. Transportation System Development And Management

Transportation systems (roads, trails, helispots, etc.) are necessary for forest management, protection, and use. At present there are 2,789 miles of road and 1,428 miles of trail on the Forest. New roads and trails will be needed; however, there is increasing concern over the ultimate extent, standards, and management of roads and trails. Management of the transportation system is largely determined by land allocation and management of the various resources.

- What management direction is needed to minimize the effects of road and trail construction on other resources?

Evolution of Major ICO's During Preparation of the Draft EIS

The initial list of ICO's identified 9 issues and concerns to be addressed in the Forest Plan. But, by nature and design, public issues and concerns are not static. Between 1979 and the issuance of a draft EIS and proposed plan, there were changes in policy and procedure as well as shifts in the concerns of the public. The original list was revised and updated during the preparation of the draft documents.

Original Issues # 2 and 4 were revised following the 1984 Washington State Wilderness Act. A single issue was drafted to better reflect the release of the RARE II roadless areas, and the focus of public concern.

Two other ICO's were identified: American Indian Religious and Cultural Use and Wood Residue Management opportunity. These revisions and additions are described in more detail below.

Revisions and Additions, DEIS List of ICO's

"Released" Roadless Areas: At the beginning of the planning process, the RARE II roadless areas on the Forest had been designated by the RARE II process as "Further Planning" areas or "Non-Wilderness" areas. The allocation and management of these areas was to be addressed in the Forest Plan. In 1984, Congress addressed the RARE II roadless area issue in the State by passing the Washington State Wilderness Act of 1984. Roadless areas, or portions thereof, were either designated wilderness or "released" for other uses. This legislation addressed the two RARE II issues (#2 and 4) on the initial list of ICO's. For the draft EIS, the allocation and management of these "released" roadless areas remained a major issue. The following ICO was addressed in the DEIS

Unroaded Areas

- How should the released, unroaded areas be allocated and how will the resources be managed?
- At what rate should the Forest Service enter those unroaded areas that are allocated for development?

There are approximately 427,000 acres of undeveloped, unroaded lands that have been released from wilderness consideration by the 1984 Washington State Wilderness Bill These acres represent approximately 55 percent of the roadless areas inventoried during the RARE II process Until the Forest Plan is revised, either at the 10-year up-date or during any earlier revisions, these acres are now available for a full range of resource uses; wilderness designation will not be considered in this Forest Plan. Wilderness classification may be considered during future revisions.

Many of these acres possess scenic attractions; they also contain other high amenity and high commodity values. The commercial Forest land within the roadless areas has been calculated in the Forest annual allowable harvest totals; however, this timber has not been available for harvest since the beginning of the RARE I process in 1972. Consequently, timber harvesting in the roaded portions of the Forest has proceeded at a faster rate making it more difficult to meet environmental quality objectives

The allocation and management of these released, roadless areas - 25 percent of the net Forest acres - is a major issue.

Facets to Consider

-Identify opportunities to retain or enhance scenic values.
-Projected utility corridor needs
-Commodity values for timber and minerals.
-Land allocation impacts on community lifestyles.
-Dispersed roaded and unroaded recreation opportunities.
-Dispersed and developed recreation opportunities.
-Old growth: rate of harvest.
-Old growth: retention for selected wildlife species; for aesthetic values; for religious and cultural use for American Indians.
-Threatened and endangered wildlife, fish, and plant species.
-Wildlife, fish, and plant diversity.
-Establishment of additional research natural areas.
-Recreation and firewood opportunities close to urban centers to encourage fuel conservation.

American Indians: As discussed previously in this Appendix , the Forest recognized the need to address issues and concerns of the Indian Tribes that use the Forest. This issue was added to the list of ICO's addressed in the DEIS.

American Indian Religious and Cultural Use

- What policy and management direction is needed to comply with the American Indian Religious Freedom Act and various treaties?
- What are the effects of meeting this direction in terms of outputs and costs?

At least 23 American Indian tribal groups have occupied or used territory within the National Forest boundary. Currently, about 15 tribal groups use the Forest for religious, ceremonial, and/or cultural purposes.

In 1981, an inventory of religious use, practices, and localities on the Mt. Baker-Snoqualmie National Forest was completed. Over 300 cultural use areas and sites were identified, totaling nearly 450,000 acres or 26 percent of the net Forest acres. Some sites cover less than one acre; other larger areas average between 3,000 and 15,000 acres. Use-areas and sites are located throughout the Forest but are concentrated in the northern half.

The inventoried use areas can be placed in five broad categories: cedar sites, ceremonial flora, spirit sites, legendary sites, and cemeteries and archaeological sites. These categories are useful in identifying the attributes of isolation, privacy, and purity that are important in maintaining the usefulness and utility of the sites to American Indian users. There is a wide variation in compatibility between types of management activities and categories of religious, ceremonial, and cultural use.

Since the completion of the 1981 inventory, the Forest has initiated a consultation process with the Tribes. When proposed ground-disturbing projects fall within any of the inventoried use-areas, the proposed activity is reviewed in detail with representatives of the Tribe(s) which may be affected. To date, the consultation process has been generally successful. However, as more management activities are proposed, the potential for conflict will increase.

Facets to Consider

-Old growth retention.
-Access and development.
-Streamside management.
-Fisheries.
-Timber harvest levels.
-Privacy (solitude).
-Plant diversity and abundance
-Cedar retention and regeneration.
-Water quality.
-Impacts on Indian culture
-Impacts on other uses and outputs
-Wildlife.
-Cumulative effect.

Wood Residue Management: More recently the Forest recognized the opportunity *existed to increase the utilization of waste wood residues This opportunity* was been added to the DEIS list of major ICO's, as described below:

Wood Residue

- What are the impacts of wood residue removal on wildlife, soil productivity, erosion, nutrient cycling, and air quality?
- Will the Forest create political problems by promoting residue utilization on natioal forest land which may undercut the small woodland owner and compete with private enterprise?

The Forest has made steady progress in increasing the utilization of residues by promoting the availability of logging material to the public woodcutter. The MBS has responded to the challenge of increased public demand by selling or free-use removal of a large volume of wood to markets. In some areas, innovative timber sale purchasers are taking advantage of low cost, per acre material to process firewood or chips. In spite of these successes, the Forest is not close to meeting the potential residue market demand. A number of internal and external barriers have acted as disincentives for most operators. There is not enough value or profit margin in most cases to warrant removal.

At the same time, the timber industry in the Puget Sound area is evolving from a market with a predominance of plywood and lumber to a larger emphasis on wood fiber production. The Forest has large quantities of waste wood residues that are not being utilized. The opportunity exists for this supply of wood residue to be marketed both within the United States and abroad, primarily to Pacific Rim countries.

Facets to Consider

-Management of habitats for wildlife indicator species.
-Utilization of levels and standards for present and future timber harvest activities
-Compliance with Clear Air Act.
-Soil productivity and impacts that can be anticipated for various management activities.
-Costs and benefits of insect and disease control.
-Social, economic, and environmental relationships.
-Existing agreements.
-Open versus closed roads.
-Effects on fish habitat, recreation use, water quality, and other resource values.

Evolution of Major ICO's Between DEIS and FEIS

As discussed earlier in this appendix, the list of major issues, concerns, and opportunities has been revisited during the preparation of this FEIS. All revisions made are in response to public comments received on the draft EIS and proposed plan. Also, refer to Chapter I, FEIS for descriptions of the final ICO's, the planning questions, and indicators of response to ICO's.

Revisions to Unroaded Areas ICO: Based on public comment - which focused on development versus nondevelopment of unroaded lands on the MBS - this major issue is titled **Development versus Nondevelopment** Some public comments referred to the release of the roadless areas, but many others focused less on RARE II remnants and more on the general issue of whether the Mt Baker-Snoqualmie should be developed (more commodity emphasis) or managed to emphasize amenity resources. While this issue encompasses aspects of timber supply, old growth, and recreation opportunities, the RARE II parcels not designated wilderness in the 1984 Act are still to be allocated; it was felt this issue is still a major one, and needed to be identified separately. The

planning questions were not modified, but the indicators of response have been adjusted. The two, quantifiable indicators selected are those that best show how the alternatives respond to the issue. The indicators are: existing roadless areas allocated to nondevelopment, and roadless areas assigned to a roaded management prescription, but not developed in the next 15 years.

Revisions to the Timber Harvest Level ICO: This major issue has also been retitled, to better reflect the high concern from both timber industry and the general public. **Timber Supply** is the issue addressed in this FEIS, and it includes the issue of wood residue. The retention or harvest of old growth was frequently mentioned by the public in commenting on timber supply; however, the old growth issue is addressed as a separate ICO. The questions to be answered were not changed and only slight adjustments were made in the indicators of response. See Table I-1, Chapter I of the FEIS, page I-11.

Revisions to Old Growth and Diversity ICO: The title of this ICO has also been revised, again to better reflect what our public is telling the Forest: old growth is a major national issue and as a resource, it is important for biological diversity, wildlife and fisheries habitat, water quality, recreation, aesthetics, as well as industrial raw material. Wildlife habitat and fisheries also received considerable public comment, reinforcing that they are major public issues. The issue addressed in the FEIS is entitled **Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity.** The planning questions were not changed; the indicators for responsiveness to old-growth wildlife indicator species and to big game indicator species were modified for clarity.

American Indian Religious and Cultural Use ICO: This issue remains a major ICO, addressed in the FEIS. The second planning question was rewritten to better reflect multiple use.

Revisions to Recreation ICO: This issue is now titled **Recreation Opportunities.** Public comment received on the draft only reinforces that recreation use - of all types - is a major public issue on the MBS. Trails will be considered as a recreation opportunity, rather than as a transportation facility, to reflect a new program, the National Recreation Strategy. Also in response to public comment, the list of planning questions to be answered has been expanded and the indicators of response updated to include miles of trails, and miles of roads open to public use.

New ICO: Wild and Scenic Rivers is identified separately as a major issue for the final planning effort. There was considerable public comment on the elgibility study done in the DEIS; wild and scenic river legislation is still under discussion and there is continued public concern (support and opposition). **Wild and Scenic Rivers** is addressed as a major ICO separate from the recreation issue (where it was handled in the draft EIS). Planning questions and indicators of response are displayed in Chapter I, FEIS.

Revisions to Water Quality and Municipal Watersheds ICO: While public and agency concern over water quality (including the cumulative effects of management activities on watersheds) continues, the Forest team felt this issue needed to be retitled to focus on the management issue of municipal watersheds, especially the Cedar River watershed. This reorganization of ICO's better reflects the kind of public comments received. The issue in the FEIS is **Management of Municipal Watersheds.** The planning questions were not changed; however, miles of roads constructed within watersheds was dropped as an indicator of response. It was felt this is a function of the timber harvest

level, which is also an indicator. Cumulative effects are also addressed in the Effects of Timber Management and Related Activities issue.

Dropped Transportation System as a Major ICO: There was considerable public comment on the issue of roads - building more or less, opening and closing to public use, etc. However, the transportation system is a facet of the development versus nondevelopment issue, the recreation opportunity issue, and the effects of timber management issue. In addition, the transportation system is a function of the land allocation, rather than an allocation itself. Therefore, this has been dropped as a separate ICO, and will be addressed as a facet of several others. The trail system is discussed under the recreation opportunities ICO.

Revisions to the Effects of Timber Management and Related Activities ICO: This topic remains a concern of major interest to elected officials, agencies, organizations, and individuals. In response to public comment, and to reflect the focus on hydrologic cumulative effects, water quality, and protection of fish/fish habitat, the description of this issue has been revised. The planning question did not change, but adjustments were made in the indicators of response: "acres meeting VQO of retention/partial retention" and "fishery production potential" were dropped and "sediment produced from all sources" was added as an indicator.

Adjacent and Intermingled Lands ICO: This issue remains a major ICO in the FEIS. The indicators of response were adjusted; where an indicator was included in another ICO, and did not serve as a specific measure for this issue, it was dropped. The remaining indicator of response is timber harvest level.

Dropped Wood Residue ICO: This management opportunity was dropped as a major ICO for the FEIS. There was very little public comment on this ICO. Agency comment focused on the growing concern from air pollution from burning residue and domestic wood burning for heat. Other comments were concerned about utilization of residue not leaving enough for soils and wildlife. Aspects of the wood residue are addressed in the Old Growth and Fish, Wildlife, and Plant Diversity and Timber Supply ICO's.

The table below shows the evolution of the ICO's during the planning process.

Table A-2
Evolution of Major ICO's During the Forest Planning Process

1979 Initial List	DEIS ICO's	FEIS ICO's	Rationale for Evolution - DEIS to FEIS
Allocation of Areas Designated for Further Planning in RARE II	Unroaded Areas	Development Versus Non-development of the Forest	Retitled to reflect public comment
Timber Harvest Level	Timber Harvest Level	Timber Supply	Retitled to reflect public and management concerns. Includes DEIS Wood Residue ICO as a facet.
Wildlife, Fish, and Plant Diversity	Old Growth and Diversity	Old Growth Ecosystems and Fish, Wildlife, and Plant Diverstiy	Retitled in response to public comment and growing concern over old growth ecosystems and diverstiy.
(new)	American Indian Religious and Cultural Use	American Indian Religious and Cultural Use	No change.
Recreation Impacts and Conflicts	Recreation	Recreation Opportunities	Slight adjustment in title to better reflect public comment. Includes trails as a facet (from the DEIS Transportation ICO).
-	-	Wild and Scenic Rivers	New major ICO, based on public comment on the DEIS
Water Quality	Water Quality and Municipal Watersheds	Management of Municipal Watersheds	Retitled to focus the issue. Water quality remains a facet of this ICO as well as the Effects of Timber Management ICO.
Transportation System Development and Management	Transportation System	(dropped)	Dropped as major ICO, facets included in Recreation and Effects of Timber Management ICO's. Little public comment.
Effects of Timber Management and Related Activities	Effects of Timber Management and Related Activities	Effects of Timber Management and Related Activities	Facets include more emphasis on the cumulative effects of activities on watersheds, fisheries.
Adjacent and Intermingled Lands	Adjacent and Intermingled Lands	Adjacent and Intermingled Lands	No change.
Management of Non-Wilderness Areas Allocated in RARE II	(replaced by Unroaded Areas ICO)	-	
(new)	Wood Residue	(dropped)	Dropped as major ICO, but still included as a facet of the Timber Supply ICO. Little public comment.

THE TIE TO THE ALTERNATIVES - TRADE-OFF EVALUATION

ICO's are used to build alternatives within the range defined by the benchmarks; this process is described in Chapter II and Appendix B.

Many ICO's are "competitive" and will require trade-off evaluation. In many instances, several interests compete for the same geographic area. The following examples illustrate some of the competing interests that have been addressed and evaluated. Again, these are only a few examples.

- Old growth located in suitable timber land has value as habitat for wildlife species dependent on old growth, value for diversity, for aesthetics, as well as having value as commercial timber. This is addressed in the issues of Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity, Timber Supply, and Development versus Nondevelopment.

- Lower elevations typically have deeper soils, more vegetative cover (including commercial timber), contain many of the Forest's riparian zones, recreation values that can accommodate several types of opportunities, and habitat for a variety of wildlife species. The issues of Recreation Opportunities, Timber Supply, and Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity address these competing resources.

- Higher elevations with scenic attractions are sought by a variety of recreationists. Many of these users seek to recreate on the same area, but their mode of travel varies, including foot, cross-country skis, horses, trail bikes, mountain bikes, 3 and 4-wheel drive vehicles, and snowmobiles. These competing users are addressed primarily in the Recreation Opportunities ICO.

The Mt. Baker-Snoqualmie's potential capability to respond effectively to each ICO is discussed in the FEIS: refer to the Responses to Major ICO's in Chapter II; also see Table II-10 (qualitative) and II-14 (quantitative) - response, by alternative, to the major issues and concerns.

Each ICO is treated differently in at least one of the alternatives. This facilitates the trade-off analysis, enabling the reviewer to evaluate the effects of different treatments

DESCRIPTION OF THE ANALYSIS PROCESS

CHAPTER I - INTRODUCTION

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER I

There are no significant changes in this chapter between the DEIS and FEIS.

* * * * * * * * * * * *

A. The General Planning Problem

1. Nature and Complexity of the Problem

Long range planning on the National Forests around the country was changed dramatically with the passage of the National Forest Management Act of 1976 and the subsequent approval of its implementing regulations in 1979 (P.L. 94-588, 10/22/76; 36 CFR Part 219, 9/19/79, as revised 9/30/82). For the first time in the history of the National Forest System, comprehensive, coordinated land and resource management plans were to be done for each Forest. Prior to that time, planning efforts had concentrated on either single resources (e.g., timber, wilderness, or a particular wildlife species), or on relatively small geographic subunits of the Forest (area planning, unit planning, etc.). The complexities of going from single resource or subunit area plans to Forest-wide integrated resource plans promised to increase geometrically as the size and scope of the planning process increased.

The Mt. Baker and Snoqualmie National Forests were administratively combined in 1974. During the late 1970's, the Mt. Baker-Snoqualmie National Forest was in a difficult management position because the Ranger District Multiple Use Plans approved in 1967-8 were outdated. In 1973, the Multiple Use Plans were amended to provide for the protection of the wilderness character of those lands inventoried in RARE I and to serve as interim guides during the preparation of comprehensive land-use plans.

Land-use planning projects were underway when the Forests were combined. The Alpine Lakes Management Act of 1976 designated the Alpine Lakes Wilderness and Management Unit and required preparation of an Alpine Lakes Management Plan, implemented in 1981. Continued objections to timber harvest and road building in roadless areas and jurisdictional reversals of the RARE I decision initiated a second roadless area review and evaluation process (RARE II) in June 1977. The legislative process subsequent to RARE II culminated with the Washington State Wilderness Act of 1984. In 1979, a DEIS was issued proposing a revision of the 1963 Timber Management Plan. This proposal was terminated to concentrate efforts on developing a Forest Plan.

The Mt. Baker-Snoqualmie National Forest is a land and resource complex which covers about 1.7 million acres of land along the west side of the Washington Cascades. The Forest extends from the Canadian border in the north to Mt. Rainier National Park in the south.

The Forest encompasses nearly 600,000 acres of timberland that meet legal and environmental tests of potential suitability for full-scale timber management.

It contains about 721,700 acres of designated wilderness in eight wildernesses as part of the National Wilderness Preservation System. Over 1,000 miles of rivers and streams and nearly 12,300 acres of lakes support populations of resident fish and runs of anadromous fish--salmon, steelhead, and sea-run cutthroat trout. About 24,000 acres of streamside lowlands provide wintering habitat essential to the maintenance of viable deer and elk populations. Large wintering populations of bald eagles roost and feed on dying salmon along the Skagit River.

The Forest is also important for the economic livelihood of a portion of the region's timber industry, and it is the source of recreation and relaxation for a large number of visitors every year. Potential and active conflicts over competing uses of the Forest's resources abound. For example, mountain goats, the northern spotted owl, pileated woodpeckers, and the marten all represent a wider range of species that are dependent on old-growth forest stands. While this shrinking component of the Forest is vital to the survival of these species, it is also economically important to those loggers and timber mills who historically have bought, cut and processed timber purchased from the National Forest lands.

The rivers which support anadromous fish runs are also economically important, as they provide the spawning grounds for the great runs of salmon and steelhead which are caught by commercial fishermen, Indians, and recreational anglers, both offshore and in the rivers. Maintenance of the anadromous fish populations is important economically and culturally (for American Indians) and requires protection of the fish spawning areas. Offshore and down river management outside the Forest boundary are also critical pieces of this management puzzle, but the Forest Service has little control or jurisdiction over these areas.

The Mt. Baker-Snoqualmie is in the backyard of over 2 million Washington State residents who live in the Puget Sound area, plus an additional 2.6 million in the Vancouver, BC area. Canadians make regular use of the Forest for recreational purposes. Demands are high for recreation experiences and opportunities on the Forest, ranging from the very primitive to the highly developed Recreationists currently spend over 5 million visitor days per year on the Forest; roughly half these visitor days are spent at developed sites and half spent engaging in dispersed recreation activities of various types.

The economic uses, recreational demands, and ecosystem maintenance requirements are often in conflict The challenge for Forest managers is to use the Forest planning process to find the mix of commercial, recreational and other competing uses which will have the highest overall value from a societal standpoint, while at the same time maintaining critical and diverse ecosystems, including vegetation communities and wildlife and fish species. Planning to achieve this social "optimum" on 1.7 million acres of land ranging all the way from low elevation dense forest to high elevation rocks and ice is a complex task. It is further complicated by the presence of more than 200,000 acres of privately owned lands within the Forest boundaries over which the Forest Service has little or no jurisdiction or influence.

2. Analytical Techniques

The mandate to the Forest Service by NFMA was to develop a Forest Plan that would result in the management of all the Forest's resources in an integrated fashion; resolve to the degree possible the primary issues, concerns, and management opportunities (ICO's) facing the Forest; and accomplish all this in a manner which would have the highest "net public value" for society. This was no small task, particularly when nothing of this scale or complexity had ever before been attempted, and the directions and policies for carrying out the planning process were generally untested.

It was a foregone conclusion that computers would be necessary to manage the massive amounts of data existing or soon to be generated. Computers were already being used to manage data bases of various kinds, and several different optimization programs had begun to be used on a limited scale for timber resource planning and for some area planning.

The size of the task had to be decreased without losing the most important information and relationships. Even with complete data and knowledge of all the resource interactions that take place on the Forest, the magnitude of using all that information would make it difficult to develop a meaningful plan that would relate to the important management issues, and could be utilized to make a decision about a preferred path of management. Since such complete information does not exist, problems of imperfect and missing data, and lack of quantifiable knowledge of resource interactions compounded the size of the problem.

The best way to cope with this type of situation is to use a "model" which, as an abstraction from reality, can focus on most of those areas which are important planning issues, can incorporate the resources for which data exist, and can help pinpoint areas where lack of data or knowledge of resource interactions is critical to the planning and decision process and must be developed. After considering a number of options, in 1979 the Forest Service Washington Office chose the FORPLAN (FORest PLANning) model for this role (1920 memo from Associate Chief Leisz to Regional Foresters, 12/3/79). FORPLAN can be used to simulate management practices, while at the same time optimizing for any given objective. As a manageable abstraction from reality, it can be used to manipulate information and look at alternative approaches to management, calculating tradeoffs and opportunity costs.

Although FORPLAN is a very flexible model, each Forest has different data and resource situations, and each has staff with varying analytical skills. Thus, it was necessary for each Forest to develop supplemental programs and processes for data manipulation and analysis prior to running FORPLAN, as well as for post-FORPLAN analysis. Also, the economic values for timber prices have to be developed outside FORPLAN from original sources and adjusted (e.g., by a statistical package such as SPSS) into reasonable proxies of prices to apply across a range of timber classes and sizes as specified for FORPLAN.

Forest Plans are created in an environment that includes qualitative, political, and social considerations as well as "hard" scientific and economic data and relationships. The analytical processes and tools provide the basis for shrinking the large amount of more quantitative data down to a manageable size and for providing a base of information that can be used in conjunction with those factors that are more qualitative in nature. The complex of data bases, computerized and noncomputerized models and processes (with FORPLAN as the centerpiece) became the analytical tools with which to carry out the heart of the planning process mandated by NFMA. They provided an enormous amount of useful information. But the final decisions were made in that broader context of qualitative, political and social considerations. The modeling tools and processes guided and aided, but did not control, the decision-making process.

B. NFMA Planning Steps

NFMA outlines 10 steps required in the Forest planning process. These steps are further refined in the implementing regulations (36 CFR 219.12). All ten of the steps are discussed below. Note that this Appendix deals primarily with the technical, analytical steps of the process (Steps 3, 4, 5 and 6). Steps 1, 2, 7 and 8 deal with more judgemental or subjective parts of the planning process and are primarily dealt with in Chapters I and II and Appendix A of the FEIS. The execution steps (9 and 10) are referenced in the Forest Plan.

1. Identification of Purpose and Need

Requires identification of public issues, management concerns, and resource use and development opportunities (ICO's) to be addressed in the planning process. Requires public input and involvement and coordination with other government agencies and Indian tribes in the identification of the ICO's. ICO's and their development are discussed in detail in Chapter I of the FEIS.

2. Development of Planning Criteria

Requires development of criteria to guide the planning process, including criteria for data inventory and collection, analysis of the management situation, and the design, formulation, and evaluation of the alternatives. Laws, policies, ICO's, technical and economic considerations, and resource integration and management requirements as delineated in 219.13-27 of the planning regulations shall be used in developing the criteria.

3. Inventory Data and Information Collection

The Interdisciplinary (ID) Team determined what data was necessary based on the ICO's The analysis of the management situation (AMS), formulation and evaluation of alternatives, and monitoring require data on resource capabilities, resource interactions, existing supply and demand, expected outputs, benefits, and costs. Existing data were used whenever possible but were supplemented with new data, if feasible, to help resolve sensitive issues or management concerns. For instance, data on the location of essential deer and elk winter range were not developed until well into the AMS step. And assessment of the acceptable disturbance levels by watershed (hydrologic cumulative effects analysis) was not completed until after the DEIS was released. Inventory data are on file in the Forest Supervisor's Office. Much of the data can also be reviewed in the AMS document (May 1985).

4. Analysis of the Management Situation

The analysis of the Forest's management situation examines past land and resource availability and use; current patterns; expected future demands made on the Forest for resources and land use, and the capability of the Forest to meet (or not meet) those demands. The AMS process is also used analytically to define theoretical production limits of goods and services from the Forest, hypothetically assuming for each "benchmark" run that provision of one resource would be maximized, disregarding all others.

These benchmark runs help to determine the "decision space" for the Forest Plan: what are the outer limits past which it is not physically, biologically, or economically possible to produce a feasible combination of Forest goods, services, and land use assignments. For example, assume that an unlimited timber production (benchmark) run is made that yields an annual allowable sale quantity (ASQ) of 340 MMBF. An actual EIS alternative, which will include a number of other resource objectives and constraints, cannot produce any more than 340 MMBF. Most likely, the actual ASQ will be significantly less for the alternative than for a benchmark.

The AMS process also involves a number of economic runs. Maximum present net value (PNV) runs are made first to set the outer limits for economic "value" (assuming no other constraints apply). Then major constraint sets are added individually, and the change in PNV analyzed to get an indication of the "opportunity cost" of the constraint set. Finally, policy changes, such as allowing flexible harvest scheduling (departure from non-declining yields), are examined to look at the relative costs of those policies. In general, economic runs are done with all economic values: market (e g., timber) and nonmarket or assigned (e.g., dispersed recreation). However, an additional set of runs is done with market prices only, and the PNV, activities, outputs, and land allocations compared with the full economic runs.

Two other runs are required by the regulations. One is an estimate of the "minimum management" necessary to meet basic land ownership and resource protection requirements for the Forest, without any active management or production programs. The second is a projection of the goods and services produced if current management direction is maintained.

The AMS step is the first step that requires major use of FORPLAN in the planning process. It sets the stage for the development of the alternatives and provides estimates of the costs and benefits of basic resource constraints *and tradeoffs, which are useful in further development of management strategies* and alternatives. The Regional planning direction requires 11 primary benchmark runs, some variations on those runs, constraint set opportunity cost analysis, and some runs to test the sensitivity of the benchmark results to different levels of timber management costs.

Region 6 has a formal review process for the AMS step involving the Regional Forester and his staff. The Mt. Baker-Snoqualmie finished the AMS review process in April, 1985. Results of the AMS and associated analysis are detailed in the Forest's AMS document (May, 1985). Additional discussion can be found in Section VI of this Appendix.

5. Formulation of Alternatives

This step is the key to a usable and defensible Environmental Impact Statement and Forest Plan The Forest ID Team is required to develop a broad range of management alternatives which are responsive to the ICO's, meet legal and policy constraints, emphasize different mixes of resource uses, are cost efficient, and are implementable.

Using the information developed in the first four planning steps, the ID Team and Forest Management Team developed a range of alternatives which they felt best met the required criteria. Management strategies, standards, and guidelines were developed to represent the most cost efficient mix of management practices that would achieve the management objectives for the various alternatives. The alternatives were mapped, input to R2MAP, converted to FORPLAN data sets, and run through FORPLAN to optimize PNV, given the desired land use assignments, minimum management requirements, and other constraints necessary to meet the objectives of each alternative.

For the DEIS, eight alternatives were formulated and run completely through the analysis process. Departure schedules were run on two of these. (Additional potential alternatives were considered, but not analyzed in detail; refer to Chapter II of the DEIS). Two of the eight alternatives are required by the regulations: continuation of current management direction, and attempting to meet RPA targets. A ninth alternative, NC or No Change, has been developed to represent the existing timber management plans.

For the FEIS, two alternatives developed in detail are added: Alternative I, in response to strong public support and comments; and Alternative J, the new Forest Service Preferred Alternative. In addition, significant modifications were made to Alternative G in response to public comment and to better meet its objectives.

On the other hand, three alternatives (D, E, & F) and departure schedules on E and H, all presented in detail in the DEIS, were dropped from further consideration in the FEIS. They received very little support in comments on the DEIS and were not needed to provide a full range for analysis with the additional alternatives that were added.

A full discussion of the alternative development process can be found in Section VII

6. Estimated Effects of Alternatives

This planning step is crucial for appropriate decision making. It requires the estimation of the physical, biological, economic and social effects of each alternative. As much information as possible is necessary from this step for the Forest managers to make appropriate assessments as to the ability of each alternative to respond to ICO's, the relative tradeoffs among alternative land and resource management paths, and the relative on-Forest and off-Forest costs and benefits of pursuing different management alternatives

The Forest ID Team first defined in general terms the interrelationships among resources (e.g. what will happen to sediment production or to certain wildlife groups when a new road is built; conversely, if wildlife habitat is protected at a certain level, what are the implications for timber growth and harvest, opportunity to build roads, etc). The numbers of interrelationships are vast, and good data defining those relationships are scarce. The resource managers and specialists used available research literature and field experience to define as many of these interrelationships as possible.

The second step was using the estimated activities, outputs, and economics (provided primarily through FORPLAN runs) to assess the magnitude of the effects, based on the interrelationships they had defined. The results of this analysis are documented in Chapter IV of the FEIS. Some additional details of that process can be found in Section VIII of this Appendix.

7. Evaluation of Alternatives

In this step, the information developed from the estimated effects of alternatives was used to evaluate the alternatives against established criteria, compare their overall effects and ability to respond to ICO's, and ultimately to choose a preferred management alternative for the Forest Plan. It is the bridge between the more quantitative analytical portion of the planning process, and the more qualitative and subjective decision portion. This step was carried out by the ID Team and Forest Management Team.

8. *Preferred Alternative Recommendation*

The Forest Supervisor reviewed the evaluation of the ID Team and Management Team and chose an alternative to recommend to the Regional Forester as the preferred alternative to become the Forest Plan.

9. Plan Approval

This step occurs when the Regional Forester signs the Record of Decision (ROD). The ROD is the decision document for the FEIS. The ROD clearly states the decision as well as rationale for the decision and the right to appeal.

10. Monitoring and Evaluation

A monitoring plan is included as part of the Forest Plan. Monitoring and evaluation of the implementation of the Forest Plan and subsequent effects will be critical to its success. Monitoring and evaluation should identify areas where change or modification is needed. This may occur because of sample data that were used which do not reflect an actual on-the-ground situation, inaccurate estimates of resource interactions and effects, or changing environmental (physical, biological, economic, or social) conditions. Modifications needed may be able to be postponed until the next round of planning (10-15 years), or they may be sufficiently large or critical to require immediate change in the Plan.

CHAPTER II - DATA INVENTORY AND INFORMATION COLLECTION

CHANGES BETWEEN DRAFT AND FINAL -- APPENDIX B, CHAPTER II

- o References to data updates that took place between the DEIS and FEIS are made.
- o Reference is made to the use of the Stand Projection System (SPS) yield simulator for development of the managed stand yield tables for true fir and western hemlock types in the FEIS.
- o Changes in the definition of the FORPLAN Level 1 identifier are described These changes relate to the recalculation of site productivity indices for the North and South portions of the Forest, and to the adoption of the SPS yield simulator for true fir and western hemlock stands.

* * * * * * * * * * * *

A. Data and Resource Inventories

The requirements of NFMA and its implementing regulations placed unprecedented demands for data of many kinds on the national forests Step 3 of the NFMA planning process (36 CFR 219.12(d)) specifically provides for data collection and resource inventories as part of the forest planning process. Part B of this chapter shows the broad range of data inventories and sources used during the development of the Forest's AMS, EIS, and Forest Plan. Data inventories for the 1963 Timber Management Plan, upon which Alternative NC (No Change) is based, were collected prior to 1963 and prior to subsequent plan amendments that changed the land base and potential yield.

Historically, the most comprehensive data collection had been done for timber; the most recent timber inventory was completed in 1976 However, there were still many problems, errors and omissions in the timber inventory. Data for other resources such as recreation, minerals, wildlife habitat, and fisheries were weak or non-existent when the planning process began.

The Mt. Baker-Snoqualmie National Forest has begun a new integrated resource inventory, which will replace the old timber-only inventory Potential old growth will be re-inventoried by Fall, 1990. Physical and biological attributes of stands -- not just size and age class -- will be measured. The rest of the integrated resource inventory will be completed by 1995

Ideally, complete data collection would have been done before the planning process proceeded. Constraints of time, budgets, and logistics resulted in completing the process with less-than-complete or perfect data.

Under the planning timeline established in the late 1970's, it was anticipated that all plans would be done within about four years. Data collection could only take a small portion of that total time. Wherever possible, existing data inventories were used. Where additional data were necessary, those inventories relating to the most critical resources and issues were done first. Lower priorities were accomplished if time and budget allowed.

In spite of difficulties, a number of positive factors from this process resulted. Among these: data were gathered for resources for which none had existed before; existing data were improved; serious data gaps were identified and the need to rectify them noted, either for immediate action, or for future attention if not absolutely critical to the planning process; finally, it became apparent that a comprehensive and coordinated computer-based data base system, using up-to-date technology, should be a high priority for the National Forest System. Institution of that system has begun; a system-wide Geographic Information System (GIS) is being established. The Mt. Baker-Snoqualmie began local installation of the GIS system in 1989.

This chapter provides a brief introduction to the major uses of data and resource inventories in the land management planning process It concludes with a list of the data sources and resource inventories used in developing the FEIS and Forest Plan.

A note about terminology: as discussed in Chapter III, B, 2, the primary computerized data base for the Forest planning process is a grid-based mapping system called R2MAP. When the term "resource layer" is used in this chapter, it refers to a set of resource information that has been mapped and entered into R2MAP as a specific data layer. An example would be "Existing Visual Condition." Several different data layers can be overlaid in the computer to produce a composite map, the same way one could physically overlay mylar data maps on a light table to see the overlaps and interactions produced from combining several maps.

1. Capability Areas

A capability area is a geographically specific area of land with a defined set of resource characteristics that will respond to a given set of management practices with a corresponding set of physical, biological, economic, and possibly social outcomes and effects. For instance, a specific area of land (say, 118 acres), locatable on the ground, that has the following characteristics is a capability area: is on the North end of the Forest (old Mt. Baker National Forest); is already roaded; is in the Principal working group (i.e., predominantly Douglas-fir and Western hemlock vegetation); has low to moderate slope; and vegetation is predominantly mature sawtimber.

The definition of capability areas on the Forest went through several refinements before the final specifications of resource characteristics and resulting delineations were decided. FORPLAN allowed only six categories of resource characteristics, so it was important to find and use those characteristics that potentially have the greatest effect on an area's responses to management activities, and to discard those that have little effect. For instance, in an earlier version of the capability delineations, deer winter range (as mapped at that time) was a resource characteristic used to delineate a capability area; it was later dropped and carried as a separate resource layer in R2MAP instead.

a. Levels and Level Identifiers. A large number of individual resource characteristics were used in the definition of the capability areas. There were five categories, or levels, of characteristics, and several variables, or identifiers, within each level. (As explained in Chapter III,C,2, there are six levels of characteristics allowed in FORPLAN; only five levels are used.)

Table B-1 lists the resource characteristic categories - levels - and the identifiers within each of those categories - level identifiers - that were used to delineate capability areas. A complete discussion of the level identifiers is found in Chapter III,C,2.

Table B-1
Resource Characteristics Used to Delineate Capability Areas

Level 1 - General Location, Water, Newly Acquired Lands, Developed Recreation

North	Mt. Baker NF
South	Snoqualmie NF
Water	Water (lakes, streams, ponds, etc).
New FS Lands	Newly acquired NFS lands with no resource data
Camp/Picnic	Existing developed site camp and picnic grounds
Camp/Ski	Existing campground within a developed ski area
Ski Areas	Existing developed ski areas
Rec. Residences	Private rec. residence areas and organization camps

Level 2 - Not Used

Level 3 - Roading and Accessibility Condition

Roaded	Currently roaded and economically accessible
Unroaded	Currently unroaded but economically accessible 2/ (i.e., can be roaded to access harvest areas)
Inaccessible	Currently unroaded and economically inaccessible (i.e., available for harvest only w/aerial systems)
Wilderness	Congressional-designated wilderness

Table B-1 Page 2 of 2

Level 4 - Working Group

Upper	True fir/Mtn. hemlock timber stand (higher elevations)
Principal	Western hemlock/Douglas-fir stands (mid-elevations)
Mixed Conifer	Douglas-fir/Western redcedar/hardwood stands (mostly lower elevations - approx. 70% conifer & 30% hardwood)
Inacc. Types	Aggregation of working groups in inaccessible lands (Level 3 identifier), grouped because of small acreages of individual working groups
Unsuitable	Forest lands unsuitable for timber production, as determined under the NFMA regulations
Nonforest	Lands with less than 10% tree crown cover; brush and grass lands; rocks; ice

Level 5 - Slope and Stability Classes

Slope Class A	Less than 35% slope; all stability classes
Slope Class B	35%-80% slopes; rock outcrops <35% of area; stream density <5 miles/section; all stability classes
Slope Class C	50%-90% slope; rock outcrops 35%-100% of area; rugged high dissected topography; stream density >5 miles/section; all stability classes

Level 6 - Condition (Age and Size) Class

Mature Large	Mature large sawtimber (generally 240+ years old)
Mature Small	Mature small sawtimber (generally 140+ years old)
Poles	Immature small sawtimber and poles (80+ years old)
Seeds and Saps	Seedlings and saplings (avg. 20 years old)
Reforestation	New regeneration growth (avg. 10 years old)
Mx. Conif. 1	Mixed conifer poles through large sawtimber
Mx. Conif. 2	Mixed conifer reforestation and seeds & saps
Inacc. 1	Mature large and small sawtimber on inaccessible lands
Inacc. 2	Immature small sawtimber and poles on inaccessible lands
Inacc. 3	Reforestation and seeds & saps on inaccessible lands ("Inaccessible" used as defined for Level 3)

2/ "Unroaded" designation is not identical with RARE II roadless area lands.

b. Data Sources for Level Identifiers. Following is a brief discussion of the data sources used as the basis for the level identifiers. A much more complete discussion of the reasons for and complexities of some of the identifiers can be found in Chapter III,C,2.

Level 1. Level 1 identifiers actually represent three different resource characteristics: general location on the Forest, lands without other data or resource characteristics, and developed recreation sites. One level can be used for three different resource characteristics because they are completely independent; there is no overlap between one characteristic and another, as tracked in the model. North and South are used in combination with one or more of the resource characteristics represented by Levels 3-6. Lands without any other resource characteristics (no characteristics represented in Levels 3-6) -- e.g , newly acquired lands without inventoried physical and biological information, and water -- are represented only by Level 1. And acres in developed recreation sites are carried separately from other acres, tracked Forest-wide rather than by North and South, and represented solely by a Level 1 identifier. (Putting the developed recreation identifiers in Level 1 was for convenience; they could have gone in any of the levels).

The North and South delineations are based on the boundaries of the Mt. Baker and Snoqualmie National Forests. Originally, up through the DEIS, productivity measures developed using 1976 timber inventory data were coincidental with the North and South delineations. After public comments on the DEIS, the Stand Projection System (SPS) timber yield simulator was added and productivity estimates were redone. There are now two productivity classes to use with the Douglas-fir Simulator (DFSIM) and two for use with SPS. These productivity classes are associated, respectively, with the Douglas-fir types north and south, and with the western hemlock and Pacific silver fir types north and south. These delineations do not match completely with any of the other level identifiers; therefore, the productivity classes were dropped as one of the level identifiers. Productivity is now incorporated through the application of DFSIM to Douglas-fir stands, north and south, and the application of SPS to western hemlock and Pacific silver fir stands, north and south. See Chapter III, Section F of this Appendix, and "Documentation of the Development of Managed and Empirical Yield Tables" (revised 9/89) in the Planning records for details of the development of the productivity classes and timber yield coefficients.

Newly acquired NFS lands without resource data inventories, bodies of water, and the developed recreation sites were inventoried, mapped, and input to R2MAP as separate data layers.

Level 2. This level was originally used to denote deer winter range. It was later dropped because of a lack of usefulness as a resource characteristic for the delineation of capability areas. Winter range was ultimately remapped and carried as a separate resource layer in R2MAP.

Level 3. These identifiers reflect the roaded status of Forest lands. Also included are the wildernesses. This level was based on: the RARE II roadless area maps, plus any additional unroaded acreages between 1000 and 5000 acres; by the map on which areas accessible by roads and those not suitable for roading because of topographic, soils, or economic factors had been specified; and by the wilderness base map. The wilderness identifier could have gone anywhere; Level 3 was chosen because of its indication of lands as developed or non-developed.

Level 4. The working groups in Level 4 were developed from the ecoclass typing done as part of the 1976 Forest timber inventory. Ecoclass typing was done based on an assessment from aerial photos and sample plots on the ground of the potential climax vegetation for every acre. Included in the ecoclass typing were unproductive forest lands (those with average growth of less than 20 cubic feet/acre/year) and non-forested lands (those lands with crown or canopy cover of less than 10%). The ecoclass layer exists in R2MAP.

Most timber stands on the Mt. Baker-Snoqualmie National Forest are mixtures of species; there are very few areas of pure, single-species stands. The first three working group identifiers are groupings of the potential climax species types representing the mixes generally found here. These groupings correspond fairly closely to elevational ranges as well, from Upper at the higher elevations, to Mixed Conifer at the Forest's lower reaches.

Level 5. Slope classes include all three stability classes, from low hazard to extreme soil stability problems. The slope classes (also referred to as topographic classes) were derived from the Soil Resource Inventory, which is mapped into R2MAP.

Level 6. The condition class level identifiers represent a combination of size and age of timber stands on the Forest. Identification and classification of stands according to their size and estimated age was done as a part of the 1976 timber inventory (Chapter II, part A), based on photo interpretation and plot sampling. The basic age class/size class data were input to R2MAP as a separate data layer. The two Mixed Conifer and the three inaccessible condition class identifiers were developed later from the original data, in order to aggregate small acreages and save on model size.

Every unique combination of these layers on the Forest is a capability area. Capability areas can vary widely in size, depending on over how many acres the unique combination of resource characteristics stays constant. Note that the same combination of characteristics occurring on two non-contiguous land areas make two different capability areas. Though never counted, there are probably between 10,000 and 50,000 individual capability areas on the Forest, as delineated by these particular resource characteristics.

2. Analysis Areas and Allocation Zones

a. Analysis Areas. The number of capability areas was far too large to work with in FORPLAN. For planning purposes, the capability areas were aggregated into "analysis areas" by dropping the locational specificity of each capability area Thus, all capability areas with the same level identifiers (e.g., North/Roaded/Principal/Slope A/Mature Sawtimber) were grouped as one analysis area without any locational identifier (other than the North or South identifier). These are know as "resource homogeneous - spatially noncontiguous" analysis areas.

The individual acres of an analysis area could be found scattered around in different size parcels over various parts of the Forest. Though lacking a specific location on the Forest, each analysis area's resource characteristics were the same for all acres within the AA. Thus, for planning purposes, all acres within an AA responded in the same manner to application of various management practices. (We could map the AA's outside FORPLAN and see where they were physically located, but FORPLAN did not know where they were).

In the final version of the analysis areas used for the model, collapsing the capability areas into analysis areas resulted in 121 land-based analysis areas. An additional analysis area was created for Water (Level 1 identifier only). The newly acquired NFS lands and developed recreation sites, as discussed above in the Level 1 identifier description, added another five analysis areas. (Four additional "dummy" one-acre analysis areas used for modeling purposes will be discussed in Chapter III,C.)

b. Allocation Zones. Allocation zones (AZ's) are geographically contiguous areas comprised of all or portions of analysis areas. AZ's provide for a degree of geographic definition and control within the model not allowed by the analysis areas alone.

Allocation zones were developed from two data bases, the hydrographic mapping of the 66 major watersheds on the Forest, and the roadless area/wilderness map layer. Zone boundaries were delineated primarily on the watershed boundaries, with the roadless areas providing secondary boundaries An exception to the watersheds as primary delineators was for the wildernesses, which were each specified as separate allocation zones. In those eight cases, the watershed separations within the wilderness were ignored. There were 86 allocation zones delineated for the model.

3. Production (Yield) Coefficients

The term "yield coefficient" refers to a figure representing the amount of a management activity input or a physical or biological output per some unit, usually of time, area, or other intermediate activity or output. For instance, a value of 4.5 acres of silvicultural exam for every acre of timber harvest is a yield coefficient. Similarly, a figure of 2.58 miles of new road construction per square mile is a yield coefficient. Timber volume of 8000 cubic feet per acre comes closest to the original derivation of the term "yield coefficient" used in earlier timber scheduling optimization models such as Timber RAM.

Yield coefficients, as a whole, represent one of the most critical links in the FORPLAN model. They are the quantification of the input and output sides of the production functions embodied in the model. It is through the yield coefficients that the activity and output figures are generated, along with their associated costs and benefits. These figures - either physical/ biological units, or dollars - are the basis for the solution of the linear program optimization algorithm. The basis of the yield coefficients is data.

Data (and data estimates in some places) were used to estimate yield coefficients of the types listed below:

- Sawtimber yields
- Firewood
- New road construction
- Developed recreation capacity
- Dispersed recreation capacity
- Wilderness recreation capacity
- Expected recreation use ("demand")
- Sediment outputs
- Old growth
- Timber management-related activities
- Anadromous fish production
- Wildlife populations

Chapter III,F describes in detail the development of these yield coefficients.

4 Determination of Suitability for Timber Production 1/

NFMA regulations (36 CFR 219.14) define the timber resource land suitability process and state that National Forest System lands shall be identified as not suited for timber production if:

a. The land is not forest land as defined in section 219.3;
b. Technology is not available to ensure timber production from the land without irreversible resource damage to soils productivity, or watershed conditions;
c There is not reasonable assurance that such lands can be adequately restocked as provided in section 219.27(c)(3);
d. The land has been withdrawn from timber production by an Act of Congress, the Secretary of Agriculture or the Chief of the Forest Service.

Not suited categories b. and c. will be referred to, respectively, by mapping symbols S-8 and J-8, which were used throughout the suitability process. In addition to S-8 and J-8 there were forest acres identified as not suited due to reforestation difficulty (category c. above) in the Mountain Hemlock Zone.

Determination of tentatively suitable forest land in the Mt. Baker-Snoqualmie National Forest took place over the period October 1980 through January 1986. "Change" best describes this period. Changes resulted from 36 CFR 219 revision, Forest Service planning procedure direction changes, Regional and Forest concern and review, the Washington State Wilderness Act of 1984, and Forest Planning data base changes resulting from boundary corrections, updating for land exchanges, and better defining developed recreation sites.

Following is a brief description of the process used to identify lands not suited for timber production. Table B-2 shows the results.

1/ More detailed documentation is in the Mt. Baker-Snoqualmie Forest Planning Records, 1920 file number 84.

a. Skills Utilized. Principal participants from the Supervisor's Office were the Forest Soils Scientist, Forest Silviculturist, Area Ecologist, and Forest Planning Team Resource Planning Specialist.

Others from the Supervisor's Office involved were. the Forest Supervisor, the Planning Staff Officer, Forest Fire, Biological Sciences, and Range Staff Officer and Timber Staff Officer; the Forest Planning Team Leader, Economist, and Recreation and Wilderness Specialist; Fisheries Biologist, Hydrologist, and the Logging System Specialist.

District level expertise included the District Ranger, Foresters, and Reforestation Specialists, Biologists, Hydrologists, and Soil Scientists attached to the district or technical zone.

Table B-2
Land Suitability for Timber Production 1/ - In Acres

	Totals	Not Suited for Timber Production	Tentatively Suitable for Timber Production
I. Mt. Baker-Snoqualmie N.F.	1,983,800		
A. Other Ownership		259,800	
II. Net National Forest	1,723,500 2/		
A. Water		17,400	
B. Non-forest		382,200	
C. Forest lands developed for other than timber production purposes (36 CFR 219.3)		22,800	
III. Forested Lands (II. - IIA, B, and C)	1,303,100		
A. Withdrawn from scheduled timber production (36 CFR 219.14)(a)(4))			
1. Wilderness		440,200	
2. Research Natural Areas 3/		1,000	
3. Jim Creek Naval Station		1,000	
B. Growing less than 20 cubic feet *per acre per year and not* included in III.A., C., or D.			
1. Classified as unsuitable		6,700 4/	
2. Classified as suitable			0
3. Classified as separate suitability component			0
C. Irreversible resource damage (36 CFR 219.14(a)(3))		95,500	
D. Regeneration difficulty (36 CFR 219.14(a)(3))		159,700	
E. Regeneration difficulty lands classified as a separate suitability component			0
IV. Forested lands not suitable for timber production (III A + B1, + C + D)		704,100	
V. Land tentatively suitable for timber production (III. - IV).			597,000

VI. Land status under current timber management plan	Non-commercial Forest Land	Commercial Forest Land
	1,142,500	579,800

1/ Reference 36 CFR 219.14 and Regional Planning Direction 1920, November 10, 1983
2/ R2MAP Land Management Planning Data Base acres used in II. through V.
3/ Long Creek Research Natural Area is included in Wilderness.
4/ Inadequate response information; there is not adequate information available, based on current research and experience, to project responses to growth or yield from timber management practices (FSH 2409.13-21).

b. Forest Land. The 1976 timber inventory included in-place ecoclass 2/ mapping of the entire Forest. This data was entered into the Total Resource Inventory (TRI) data base system. The in-place mapping resulted in land classification and acres of productive (capable of producing 20 or more cubic feet of wood per acre per year) and unproductive forest land (not capable of producing 20 cubic feet of wood per acre per year); nonforest vegetation (forbland, meadowland, and shrubland); non-vegetation (water); ecoclass formations, excluding forest and nonforest vegetation with less than 20% vegetative cover; and administrative or agricultural use areas, e.g. buildings, heliports, pastures, developed recreation sites, power lines, and rock pits.

This timber inventory data were transferred from TRI to the R2MAP Forest Planning data base and have been updated through fiscal year 1988 for timber sales and other necessary changes. The 22,800 acres meeting the definition of forest land developed for non-forest uses (36 CFR 219.3) includes existing roads (16,726 acres); ski areas (5,934 acres); and electronic sites (127 acres).

Forest inventory data for forest land capable of producing 20 or more cubic feet of wood per acre per year was completed, including: acres in-place, ecoclass, tree size class, tree class (mature, immature or reforestation), stocking, species, volume, average age, average site index, etc. Inventory data for forest land not capable of producing 20 cubic feet of wood per acre per year was incomplete; it included only ecoclass and acres in-place. More information was needed to complete the suitability process.

1. Forest Land Not Capable of Producing 20 Cubic Feet of Wood Per Acre Per Year. - These lands total 240,124 acres in the Forest and were considered to meet the definition of forest land except for 2,343 acres in ski areas. Location and disposition of the remaining 237,781 acres in the suitablity process is summarized in Table B-2a.

   Most of these forest lands not capable of producing 20 cubic feet of wood per acre per year occur in rugged terrain and under the severe climatic conditions of the sub-alpine environment; their potential for timber production was believed to be very low to not feasible. There is no historical data on timber management of these forest lands. It was felt that the minimum additional information needed was to verify and develop an estimate of their timber volume. For these forest lands not withdrawn from scheduled timber production (82,400 acres) shown above, the additional information needed was determined as follows:

2/ 7/16/75, 1630, 2410, Stand Mapping, letter to Directors and Forest Supervisors from Director of Timber Management, Region 6. Distributed "Stand Mapping and Classification," current instructions for mapping timber stands. This is tied into the Region 6 ecoclass designation system; "Pacific Northwest Ecoclass Identification", Regional Guide 1-2, Feb. '75.

Sampling 1976 timber inventory aerial photos, the number of trees per acre and the percentage of unproductive forest in each of the following land classes was estimated; sawtimber, pole timber, seedlings and saplings, and nonforest (less than 10% tree cover). Using 1976 timber inventory plot and other available data, an average tree volume coefficient was developed to estimate net timber volume per acre. The latter ranged from a low of 2,314 to a high of 5,121 board feet per acre. These volume estimates involved professional judgement, so could vary between estimators. These lands have insignificant timber volume using either the high or low estimate. These lands passing the suitability screen were classified unsuitable for timber production as described in footnote four, Table B-2.

c. Forested Land Withdrawn from Timber Production. These are shown in Table B-2. There are eight wildernesses and three research natural areas in the Forest. Long Creek Research Natural Area is withdrawn with wilderness. Jim Creek Naval Station includes forest land used by the United States Navy.

d. Identifying Forested Land not Suited for Timber Production. Completion of not suited categories a. and d., Section II. 4. of the suitability process have been completed and the results are shown in Table B-2 (III. and III.A.1.-3.). The identification of not suited forested land in categories b. and c. was carried out over a prolonged period (over five years). The not suited forested land acres shown in Table B-2 are summarized below by forest productivity class.

Table B-2a

Summary of Forested Land Acres Not Suited 1/

			Productivity Class	
			20 Cu.Ft./Ac/Yr. or More	Less Than 20 Cu.Ft./Ac/Yr.
III.	A.	Withdrawn		
		1. Wilderness	284,928	155,282
		2. Research Natural Areas	906	74
		3. Jim Creek Naval Station	1,014	0
	B.	*Less than 20 Cu.Ft./Ac./Yr.*		
		1. Insignificant Volume		6,715
	C.	Irreversible Resource Damage (S-8)	39,850	55,626
	D.	Regeneration Difficulty		
		1. J-8	63,752	15,987
		2. Mountain hemlock	75,899	4,097
		Total	466,349	237,781

1/ For documentation see 1920, March 24, 1986, Forest Planning Records.

The process of identifying not suited forested land in categories (2) and (3) is described in detail in the Forest Planning Records, file 84. The four phases of the process are listed below:

1. Identifying J-8 and S-8 on forested land producing 20 Cubic Feet or more Wood per Acre per Year. See above, or Glossary, definition of J-8 and S-8.

2. Revision of Phase One Results in S-8 Acres. The Forest Supervisor expressed concern that total S-8 acres were less than the districts had submitted and directed that the identification be reviewed. The review resulted in an increase in S-8 acres and a decrease in J-8 acres.

3. Identifying Forested Lands with Regeneration Difficulty in the Mountain Hemlock Zone. See the description of Management Area 19, Chapter II of this environmental impact statement, and standards and guidelines in the Proposed Forest Plan.

4. Identifying J-8 and S-8 in Forested Lands not Capable of Producing 20 Cubic Feet of Wood per Acre per Year.

Irreversible resource damage criteria for S-8 lands were developed at both the Regional Office and Forest levels. The general criterion used to identify these sites was that conditions be so sensitive to human disturbance that soil and water resources could not be adequately protected through the use of any acceptable silvicultural treatment. Forest personnel took this general criterion and developed indicators -- e.g., active slumps, topographic features, subsurface drainage capabilities, soil characteristics such as clay content and depth -- to identify these lands. Ranger District personnel then used their knowledge combined with these indicators to identify areas susceptible to irreversible resource damage (S-8 lands).

The identification of forested lands where regeneration difficulties would occur followed the same general path. Criteria used fall into two major categories: physical limitations of the soil for planting (size, volume, thickness and a real extent of coarse fragment content, and bedrock exposure), and environmental limitations to seedling survival (drought susceptibility, frost pockets, etc.). The Forest developed general criteria for lands where these factors could be a problem; e.g., south and west exposures with shallow soils. Ranger District personnel used these general guidelines in combination with their knowledge of past plantation failures and identified areas where regeneration problems could be expected to occur again (J-8 lands).

5. Allocation and Scheduling Alternatives

The Forest Plan EIS alternatives were developed by the ID Team and the Forest Management Team. An initial set of alternatives was developed and analyzed for inclusion in the DEIS after the AMS had been completed. The AMS process used data from numerous sources to analyze the Forest's past management activities and resource output levels; to assess current situation; and to estimate future conditions and demands. The analysis areas, allocation zones, and yield coefficients, along with economic data on costs and benefits were all used in FORPLAN to make "benchmark" runs, discussed in Chapter I. This information, along with other resource information carried outside the model, was all used to develop and analyze a broad range of alternative management regimes for the Forest.

After the DEIS was completed and public comment was taken, the ID Team and Forest Management Team developed two additional alternatives to include in the FEIS -- one in response to strong public comment, and the other as the new Forest Service Preferred Alternative. One other alternative was redone with significant modifications in response to public comment and to better meet its objectives. In addition, three alternatives and two departure schedules that had been included in the DEIS were dropped from further consideration in the FEIS. There was little public comment or support for them, and the remaining alternatives, along with the new additions, provided the necessary full range of alternatives for analysis.

6. Monitoring

A monitoring plan is included in Chapter VI of the Forest Plan. At intervals established in that document, management practices will be evaluated to determine how well objectives have been met, how accurate effects and cost projections are, and how closely management standards and guidelines have been applied. *The results of monitoring and evaluation will be used to analyze* implementation of the Forest Plan and determine if an amendment or revision is necessary

7. Subsequent Programs for Plan Implementation

The Forest Planning data base provides biological, physical, geographical and economic data that can be used to develop programs for plan implementation. As new or improved data becomes available, the data base can be updated. Much of this data is currently stored in the TRI System and in resource layers in R2MAP. Concurrently with plan implementation, a new Geographic Information System (GIS) will be implemented which will integrate the Forest's data bases and over time replace the TRI and R2MAP resource layers. During plan implementation, with the shift from a Forest level emphasis to the project level, use of GIS technology will allow automated access to many resource data layers that will be mapped at project level scales. GIS will be used to track, display, and analyze past, present, and future conditions.

B. Data Sources Used in the Analysis

A complete listing of references can be found in Chapter V of the Forest FEIS. The following data sources were key in the analysis process:

- Timber data regarding existing volumes, growth, size class and ecoclass were based on a Timber Resource Inventory of the Forest completed in 1976. Data for the 1963 Timber Management Plan (as amended) upon which Alternative NC (No Change) is based were collected in the timber inventory prior to 1963 and prior to subsequent amendments that changed the land base and potential yield.

- *Data on suitability for timber production were developed locally from a* combination of local experience of professionals, aerial photo interpretation, and field verification.

- Managed yield tables for timber production were developed using the DFSIM yield simulation model (along with its management strategy optimization companion model, DP-DFSIM) for the Douglas-fir types, and SPS for the western hemlock and Pacific silver fir types.

- Empirical yield tables were developed jointly by Forest and Regional Office personnel, utilizing the 1976 Timber Resource Inventory.

- Basic soil information was available from the Soils Resource Inventory (SRI) for the Mt. Baker and Snoqualmie National Forests.

- Slope and soil stability information was developed from the SRI's.

- Class I and II streams were inventoried and mapped, then updated through the Planning process.

- Class III and IV stream lengths were estimated on a density basis based on field information derived from a sampling.

- Basic recreation data were derived from information collected in the field and stored in the Recreation Information Management System (RIM).

- RIM data were converted to recreation potential utilizing the Recreation Opportunity Spectrum System (ROS).

- The visual resources of the Forest were inventoried prior to the start of the planning process These data were updated during planning.

- The relative ability of the landscape to absorb management activities was determined utilizing the Visual Absorption Capability (VAC) system.

- Major viewsheds on the Forest were mapped during the planning process and were used to give more specificity to changes in the visual resource.

- Information on potential wild and scenic rivers was based on the National Rivers Inventory (NRI) conducted by the National Park Service. These data were supplemented by field data and input from local citizens and groups.

- Information on deer, elk and goat range was collected and mapped during the planning process in cooperation with the Washington Department of Wildlife.

- Information on anadromous and resident fish habitat and production potentials was derived from field surveys and supplemented by data from the Washington Department of Wildlife, Washington Department of Fisheries and Indian Tribal Biologists.

- Information on cultural resources was obtained from the Forest Cultural Resource Overview, completed in 1987.

- Information on religious, cultural and ceremonial uses by Indian Tribes was available from an inventory completed by a contractor in 1981.

- Land status information was available from the Land Status Atlas which is maintained on the Forest and was updated during the planning process.

- Information on the possible occurrence on the Forest of threatened, endangered, or sensitive wildlife, fish and plant species was verified by the Fish and Wildlife Service.

- Information on existing and potential transportation systems was available from plans developed prior to the planning process and was updated during the planning process.

- Information on the social and economic environment of the Forest's zone of influence was available from a social and economic overview developed by contractor in 1981. These data were updated during the planning process.

- Information on the minerals potential of the Forest was developed from data from the U.S. Geological Survey and the Bureau of Mines.

- Economic benefits and trends were derived based on Region 6 Planning Direction. Economic costs were derived from historical cost collections on the Forest, updated to the base year.

CHAPTER III - THE FOREST PLANNING MODEL (FORPLAN)

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER III

- o Minor changes in analysis area delineations and revisions in the FORPLAN Level 1 identifier are described.
- o Minor modifications to prescriptions, standards and guidelines made between the Draft and Final are described.
- o The use of the Stand Projection System (SPS) yield simulator for developing managed yield tables for true fir and western hemlock stands is introduced Changes made to incorporate SPS into the development of the yield tables and the selection of timber management intensities are described. The development of revised empirical and managed yield tables for use in FORPLAN is detailed
- o Revisions in the criteria for carrying out commercial thins are described, and revised calculations for estimated genetic gain from planting improved stock are displayed.
- o The hydrologic cumulative effects analysis and the resulting harvest acreage limits for the water quality management requirement are introduced.
- o An enhanced description of the Forest's approach to modeling anadromous fisheries is incorporated
- o Discussion of wildlife population response models used outside of FORPLAN is given in greater detail.
- o Timber Sale Program Quantities for alternatives are updated to reflect the final alternatives incorporated in the FEIS.

* * * * * * * * * * * *

A. Overview

Forest planning is a very complex process The resources which must be considered are numerous; there are a large number of planning issues (ICO's) involved; the data needs are enormous; and the analytical techniques need to bring together the resource data and the issues in such a way as to facilitate effective decision-making. To assist national forests in accomplishing this process, a number of interrelated computer programs and models have been developed Several of these have been used on the Mt. Baker-Snoqualmie in the development of the Forest Plan and Draft Environmental Impact Statement (DEIS), and the Final Environmental Impact Statement (FEIS).

The central analytical model used is FORPLAN (Forest Planning Model). There are three major parts to FORPLAN (Johnson, 1981). The heart of FORPLAN is a linear program (LP) algorithm (Unisys' FMPS). A linear program consists of a series of linear equations which define the problem to be solved. The system of equations consists of an "objective function" and a series of "constraints." The objective function specifies what values are to be either maximized or minimized during the solution of the LP. The constraint equations define the resources available and the physical or policy limitations within which the solution must be found. FORPLAN was used in analysis of all alternatives except Alternative NC (No Change).

The other two parts of the model are a matrix generator and a report writer. The matrix generator automatically sets up the matrix structure required for the LP algorithm to use in solving the problem. The matrix consists of rows and columns with coefficients, which represent the linear equations in the problem. The purpose of the matrix generator is to allow the user to input data in a structured format and have those data automatically and consistently written into the appropriate matrix format for the LP. This makes the matrix-building process much less tedious, and allows for more flexibility in making data changes or adjusting the model constraints.

The report writer converts the solution found by the LP algorithm into usable information for the user. It reports such things as acres assigned to management emphasis and intensities, outputs and activities by period, and costs and benefits associated with a particular run. There are optional reporting capabilities to design reports with specific combinations of information needed to answer specific questions.

The first version of FORPLAN (now known as Version 1) was the first linear programming model available for forest planning which incorporated both land allocation and harvest scheduling optimization capabilities. Prior to FORPLAN, Timber RAM (Resource Allocation Model) had been used quite widely in timber management planning as a harvest scheduling optimization model. In the late 1970's, another linear programming model called MUSYC (Multiple Use Sustained Yield Calculator) was developed to incorporate resource considerations other than timber in the optimization process. Out of these earlier efforts, FORPLAN was born.

FORPLAN, Version 1, allowed the user to "simultaneously" solve for the optimal patterns of both land allocations assigned to management strategies and timber harvest schedules over multiple periods. Resource output, or "yield," tables and economic cost and benefit tables were hooked together to form "management emphasis" or prescriptions, which described how the lands would be managed and what could be expected for outputs, effects, benefits, and costs. The greatest flexibility was allowed for the timber output. A range of stand ages could be specified during which commercial thinnings and/or final harvest could be accomplished. Existing and regenerated timber stand ages and inventory acres and volumes were tracked. The FORPLAN model "shell" had to be followed by the user, but within that structure, users on different Forests had great latitude to design the substance of the model to meet the particular planning issues and resource situations found on their Forest.

FORPLAN, Version 1, represented a major step forward in modeling capabilities for forest planning. However, it was evident that greater flexibility was needed in design of a particular Forest's model. There was need for greater capabilities to deal with data and issues that related to spatially contiguous, but nonhomogenous, areas in combination with data, such as for timber stands, that were generally modeled in homogeneous, but spatially noncontiguous, areas. There was need for the ability to model a much wider range of resource outputs and effects. And there was need for the ability to model forest management activities separately from the outputs.

The second version of FORPLAN, known initially as DE-FORPLAN (Direct Entry FORPLAN) was originally designed specifically for modeling problems encountered by planners in Region 3 (Southwest Region). They needed the capability to directly enter management prescriptions and associated yields, costs, and benefits for contiguous, nonhomogeneous areas as a single bundle. However, this new version of FORPLAN was quickly expanded into what is today known as FORPLAN, Version 2. This is the version of FORPLAN used by the Mt. Baker-Snoqualmie National Forest during the development of the Analysis of the Management Situation (AMS), the DEIS, the FEIS, and the Forest Plan. This Forest was one of three national forests across the country to serve as test forests for the development and debugging of Version 2. A number of the enhancements and capabilities that now exist in Version 2 are a direct result of needs and ideas developed during the testing process on this Forest.

FORPLAN, Version 2, has a number of important differences from Version 1. Among these are:

- capability to model up to 200 separate activities and outputs,
- use of "theming" by eight "level identifiers" to hook up the various parts of the model, rather than using table numbers;
- specification of both homogeneous, noncontiguous areas and nonhomogeneous, spatially contiguous areas for analysis, either separate or coincident;
- specification of coordinated land allocation and resource scheduling strategies, which allow specific combinations of management strategies to be assigned to all or portions of spatially contiguous areas;
- ability to set up linear functions to define outputs or activities as functions of other activities, outputs, or acres (significantly reducing the number of yields tables that would otherwise have been required to deal with up to 200 activities and outputs).

1. Basic FORPLAN Components

The major components with which FORPLAN, Version 2, on this Forest operates are analysis areas (AA's), prescriptions, yields, economics, allocation zones (AZ's), coordinated allocation choices (CAC's), constraints, and the LP objective function.

Analysis Areas. These are areas on the Forest which are homogeneous in resource characteristics, but spatially noncontiguous. Any one AA represents all acres of land on the Forest which, according to the best available inventory data, are of the same timber or vegetation type and age class, have the same topographic slope, are on the northern or southern part of the Forest, and are roaded, unroaded, or "inaccessible". See Section C for a more detailed description and delineation of these characteristics.

Because the AA's represent all acres on the Forest which are homogeneous in resource characteristics, they contain acres that are not necessarily contiguous with each other. Acres of an AA may be scattered in small groups all over parts of the Forest. Although at first this may seem inconvenient from an analytical standpoint, it does allow the model to treat all acres of any particular AA the same in solving the linear program problem. All acres of an AA respond in the same manner to resource management activities· a given activity will result in the same outputs and environmental effects, will cost the same, and will have the same economic benefits when applied to any or all acres in an analysis area.

Prescriptions. These are used in FORPLAN in a somewhat different sense than the term is defined by the NFMA regulations (see Section D). A FORPLAN prescription is made up of a particular management emphasis, management intensity, and the associated activities, outputs, costs, and benefits that result when that emphasis and intensity are applied to a particular analysis area. The management emphasis and intensities are tied directly to the management strategies, standards, and guidelines which are described in the *FEIS* and *Forest Plan*. *The FORPLAN* prescriptions are abstractions of the narrative management strategies, and reflect the intent of the strategies to the best degree possible within the model, tying the estimated outputs, activities, costs, and benefits of those strategies to a particular piece of land (analysis area).

Yields. Yields represent the level of activities required to carry out a management emphasis and intensity, and the level of outputs and environmental effects expected (at least for those which can be dealt with through the model). The term "yields" is a holdover from the days of Timber RAM, when the only outputs in the model were the timber yield tables. As the model was expanded through MUSYC and into FORPLAN, the term "yields" came to be applied to all outputs and activities. timber yields, new roads constructed, sediment outputs, pairs of spotted owls, etc.

Economics. The economics in the model represent the costs of carrying out the activities associated with a management emphasis or emphasis/intensity combination (for instance full timber management with precommercial thinning), and the economic benefits derived therefrom. Economic benefits may be either cash (timber stumpage) or noncash (dispersed recreation visitor day benefits).

Cash, or market, benefits exist where there is a market for the sale of the good or service being produced, such as timber or commercial harvest of *anadromous fish. Noncash, or nonmarket, benefits are used where people are* deriving value from the good or service being provided, but where there is no market in which to exchange that good or service for cash This latter situation occurs primarily for dispersed and wilderness recreation outputs in the Mt. Baker-Snoqualmie FORPLAN model.

Allocation Zones. One of the advantages of Version 2 over Version 1 is that both contiguous and noncontiguous land areas can be modeled at the same time. Analysis areas define the resource homogeneous, but spatially noncontiguous, land areas in the model. Allocation zones (AZ's) represent areas of the Forest which are spatially contiguous, but include nonhomogeneous resource areas. As will be discussed in more detail in Section C, AZ's were defined to coincide with areas of particular interest from a spatial standpoint, to provide a method to deal with issues relating to specific spatially contiguous areas, and to handle more effectively problems of modeling spatially-related outputs such as Recreation Opportunity Spectrum (ROS) areas and new road construction.

Coordinated Allocation Choices. These allow the user to specify analysis area/management emphasis combinations on allocation zones in order to model a specific pattern of management on a given geographical area. Because analysis areas are not spatially contiguous, prescriptions assigned just to analysis areas will not necessarily provide a spatially coherent management pattern. By use of coordinated allocation choices applied to AZ's, a pattern of management - which can include several different management emphases within one spatial area - can be specified which reflects one of several possible ways to manage an area. This capability, which does not exist in Version 1, allows the user to maintain the versatility of resource homogeneous analysis areas while at the same time being able to lay out one or several potential management strategy mixes on a geographically defined area. More about the advantages, and some of the tradeoffs, involved with the use of allocation zones and coordinated allocation choices will be discussed in Section C.

Constraints. These are the "guts" of FORPLAN, or any linear program. Constraints are necessary to define the resources available and the limitations within which the model can work during the optimization process. The data which are input to FORPLAN describing the analysis areas, resource yields, and economics provide the basic resource availability information. Constraints in FORPLAN are used primarily to set limits on the model that proxy legal, policy, and desired management requirements Some of the more standard constraints used are those which require non-declining yields from the timber solution over the life of the model, absolute constraints that require certain activities or outputs to be less than or greater than some limit, and constraints which control the rate at which lands can be accessed on a decade-by-decade basis for timber harvest. Because constraints are used to make FORPLAN represent necessary and/or desired management, their careful and thoughtful formulation and application is a must.

Objective Function. This is the "driver" of any linear program solution, within the limits set by the available resources and constraints that are applied. An objective function is an equation which defines some value that the analyst wants either maximized or minimized. Most of the FORPLAN benchmarks and alternatives are run with an objective function that defines and maximizes economic present net value (PNV) over the time period covered by the model. Economics then becomes the driving factor in the solution of the model, unless there is an absolute constraint that has to be met. Constraints override the objective function, they specify that certain conditions have to be met, no matter what.

As an example: the model is operating under an objective function to maximize present net value, but also has an absolute constraint requiring at least a certain amount of timber volume even if it results in a lower PNV than would otherwise occur without the constraint. In this case, the model may have to bring into solution some timber lands that would otherwise be left out because they have a negative PNV, or their use in another type of management would result in a higher PNV on a per acre basis. In order to get the volume required by the constraint, the model will take any additional volume it needs regardless of cost to PNV, up to the point that the constraint is met. (If the timber constraint asks for more volume than is available in total for a given time period, the run will be "infeasible"; that is, it is not possible to achieve the constraint with the resources available in the model).

It is also possible to maximize some other activity or output such as timber volume, recreation visitor days, etc. And it is possible to minimize, rather than maximize, an objective function. For example, budget costs or sediment production could be minimized. Again, whatever the value or resource specified by the objective function, and whether it is maximized or minimized, the objective function acts the same. It drives the solution of the LP, subject to the resources available and the constraints that have been established.

NFMA and its implementing regulations place major emphasis on the use of a cost-efficiency criterion in the forest planning process. FORPLAN accommodates this emphasis very well in the modeling process. The validity and reasonableness of the model solutions depend heavily on assumptions regarding the interconnections between analysis areas, prescriptions, yields, economics, and constraints. To the extent that the specifications made (whether based on "hard" data or more on best professional estimates and assumptions) are appropriate and reasonable, the use of the linear program and maximization of present net value will result in a cost-efficient solution for achieving the objectives of a given alternative.

Chapter III, F in this appendix discusses how the coefficients for each of these components were developed and incorporated into the FORPLAN model.

Recognition of Model Limitations. A number of objections are raised periodically to the use of linear programming in land and resource management planning. The issues most commonly raised are assumptions of linearity, non-negativity of decision variable values, and continuous (infinitely divisible) decision variables (Bell, 1977; Kent, 1980). The linearity assumption is most often criticized as being unrealistic to apply to the natural world, which is often nonlinear. But this is often not a major limitation, particularly if the range over which changes are considered are not very large, or if the nonlinear problem can be broken up into linear sections that approximate the nonlinearity over the range of consideration.

In any case, one must keep in mind that the linear program is a **tool** to aid decision-makers; it does not provide the answer by itself. Particularly in land and resource management planning processes, the application of judgment and consideration of factors not incorporated into the model are requisite for effective decision-making. As an abstraction from reality, the LP-based model allows the decision-maker to consider very complex problems, and alternative solutions to those problems, in a fraction of the time that would be required to find the best combination of decision variables by hand (Field, 1977; Iverson and Alston, 1986).

B. Analysis Process and Analytical Tools Used

1. Overview

Early Stages of the Planning Process. The analytical process required for the Forest Plan and its associated Environmental Impact Statement is outlined in sequential form by the National Forest Management Act of 1976 and its implementing regulations (36 CFR Part 219, 9/17/79; revised 9/30/82). Chapter I of this Appendix reviews that process

Although it is laid out in the law and regulations in a sequential or linear manner, the planning process began in several areas simultaneously. Of immediate concern was the "scoping" process to determine the nature of the issues, concerns, and management opportunities (ICO's) facing the Forest. Public involvement, along with Forest staff input, was utilized to define the major ICO's for the Forest. At the same time, an assessment was begun of the status of data on the Forest that would be relevant for the planning process. Initial efforts were made to define the specifics of the analytical process, so that data needs to carry out that process could be determined. It was not necessary to wait for the completion of the ICO delineation, as public input during the two Roadless Area Review and Evaluations (RARE I and II), the development of the draft revised Timber Management Plan, and the Alpine Lakes planning process had provided major indications of the issues and concerns surrounding national forest management in the Washington Cascades.

The choice of a major analytical model to use in forest planning was made by the Washington Office in 1979 (USDA Forest Service, 1979). All national forests were required to make use of FORPLAN as a multiple resource allocation and scheduling optimization model. Therefore, efforts were begun to collect and organize data in a manner that would respond to the ICO's, and that would work within the framework of FORPLAN.

Initial efforts were directed primarily toward defining the analysis areas to be used in the model, developing yield tables for existing and managed timber stands, collecting cost data for timber management and associated activities, and determining the appropriate timber stumpage prices to use in the model. Although by no means the only issues facing the Forest, timber management activities and associated road building were recognized as major issues with which the Forest would have to deal in the planning process. For this reason, and because a significant amount of work had been done just prior to the start of the Forest-wide planning process toward the development of the draft for a revised Timber Management plan, the early analytical efforts were directed in large part toward the timber resource. (Approval of the draft Timber Management Plan was held up at the last moment in favor of dealing with that resource within the comprehensive land and resource management plan).

In 1981, the Mt. Baker-Snoqualmie, along with the Shoshone and Allegheny National Forests, was chosen to test a developmental version of DE-FORPLAN. DE-FORPLAN, which later was called Version 2, became the major analytical model for the Forest, both for the Analysis of the Management Situation (AMS) benchmark runs, and for the DEIS and FEIS alternatives.

The adoption of Version 2 as the Forest's planning model added some additional analytical requirements. Spatially contiguous allocation zones had to be defined. With the significantly expanded capacity for modeling outputs and activities separately, thought had to be given to which activities and outputs needed to be modeled to best respond to the ICO's. Then decisions had to be made about which activities and outputs actually could be modeled, given the availability of data and the knowledge of resource interactions, or the ability to estimate resource interactions with some level of confidence. A determination had to be made about which activities and outputs could best be dealt with on a "per acre" (analysis area) basis, and which would best be suited for modeling on a "per area" (allocation zone) basis. Finally, coordinated allocation choices (CAC's) had to be developed and a strategy worked out for using them to model the benchmarks and alternatives in the most cost efficient manner.

The primary activities and outputs which are most responsive to the ICO's and which can be reasonably modeled within FORPLAN are timber management (harvest and silvicultural activities), road construction and maintenance (arterials, collectors, and locals), recreation capacity and use (wilderness, nonwilderness dispersed, and developed), sediment outputs from harvest and road construction activities, and anadromous fish outputs in response to varying investment levels in habitat management. Acres by various categories can also be tracked in FORPLAN; e.g., management areas, old growth, ROS, and visual quality.

Some resources are dealt with outside FORPLAN in separate models and assessments and incorporated into the final results. These include fire management, areas open or closed to mineral development, and quantity and quality of wildlife habitat and associated population changes by time period over the planning horizon.

Recreation capacity and demand (expected use) estimates were developed after most of the timber information was assembled. Road construction estimates were developed in several different ways and tested to find the method which most realistically represents the actual scheduling and construction of roads on the Forest. As will be discussed in more detail later (Section F), the roads problem represented one of the most intractable dealt with in the development of the model. Estimates of anadromous fish response to varying levels of investment in habitat maintenance and improvement were developed fairly early, but were not incorporated into the model until after the benchmarks were run.

Analysis of the Management Situation and the "Planning Pause". As part of the review and quality control process for forest planning, Region 6 did a formal review of the Forest's Analysis of the Management Situation (AMS) documents by the Regional Forester and his staff. The Mt. Baker-Snoqualmie went through this process twice: in March, 1983 and April, 1985.

The Regional Office review of the first AMS was in the final stages when a "pause" in forest planning, particularly for Region 6, was called by the Washington Office and the Assistant Secretary of Agriculture. There were several forest planning issues which the Assistant Secretary felt had not been adequately dealt with in the Forest Plans sent to the Washington Office for review. These issues included: the quality and quantity of tradeoff analysis being done and displayed; the lack of analysis of the opportunity costs of constraints used in the modeling process; the development and rationale for management requirements (known then as "minimum" management requirements, or MMR's) developed as required by NFMA and the regulations; and the lack of consistency among Forests in such things as economic values used, management requirements (MR's), and inconsistent management area determinations along contiguous boundaries of adjacent Forests.

The other major factor contributing to the pause in planning was the 9th Circuit Court's ruling in the case of California v. Block (Ninth Circuit Court Opinion) in which the State of California's contention that the EIS for RARE II was insufficient was upheld by the Court. The judge's ruling stipulated a number of conditions about information that would be required in an EIS dealing with the disposition of roadless areas before that document would meet the requirements of the National Environmental Policy Act of 1969 (NEPA). It was decided at the Washington level that direction would have to be reformulated so that Forest Plan EIS's would meet the requirements stipulated by the Court.

Region 6 received special scrutiny because of the size and controversial nature of its timber and road building programs, and the highly controversial issue of roadless area development in the Pacific Northwest. As a result, the planning process came to a virtual halt in the Region while task forces were formed to totally revamp the Region's planning direction for the Forests. The "planning pause" was a mixed blessing Although it sent a lot of Forests back several steps in the planning process, it also provided time to take a second look at work that was completed and a chance to make some changes.

On this Forest, a "second look" was given to some items that had not worked particularly well in FORPLAN during the benchmark runs for the first AMS. A number of changes were made in the structure of the model to eliminate factors that were not providing useful information, to slim down the model in order to bring down its size and run time/costs, and to bring in additional parts needed for improved modeling or to meet the new planning requirements.

A separate problem came to light during the "planning pause" which required a major change in the Forest's tentatively suitable timberland base. It was discovered that major regeneration difficulties were occurring in higher elevation timber stands (generally above 4200 feet) which were dominated by mountain hemlock. Although these stands supported large standing volumes, they were very old - some up to 800 years - reflecting a slow stand re-establishment and growth rate. After a good deal of study and debate, it was decided to remove slightly over 80,000 acres of these predominantly mountain hemlock stands from the tentatively suitable category because of a lack of assurance that they could be regenerated successfully within five years, as required by the regulations. The 80,000 acres were all located on the three northern districts. The decision included setting up a research and evaluation project for the first decade of the Plan, which will test a variety of harvest and regeneration methods to determine if there are feasible ways to solve the regeneration problems. If so, those acres will be added back into the tentatively suitable base for the next round of planning. If not, they will continue to remain out of the tentatively suitable base and available for nontimber allocations.

Another major factor affecting the planning process during and immediately after the "pause" was the formulation and passage of the 1984 Washington Wilderness Bill. The bill resolved the wilderness issue for a large number of roadless areas on the Forest, adding about 350,000 acres of designated wilderness to the National Wilderness Preservation System, and nearly doubling the acres of wilderness on the Forest. While the Act resolved a major portion of the roadless area question, it also entailed a change in the Forest land base in the model, and required additional analysis of the remaining parcels of roadless area lands not designated as wilderness.

All of the above changes combined to create major changes for the structure and content of the FORPLAN model. When running the benchmarks for the first AMS, Version 2 was still in an experimental stage. This Forest had one of the most complete and complex models in the nation, costs and run time were high (between $1200 to $2000 per run). By restructuring the model in light of the above changes, the IDT aimed to cut the size of the model while losing as little useful information as possible. Major results of restructuring were a decrease in AA's (from about 240 to 134) and a decrease in AZ's, from about 110 to 85.

A second AMS document was completed under the new Regional planning direction, including all the major land base changes discussed above. The revised AMS was reviewed and approved in April, 1985.

Prescriptions, Standards and Guidelines. Prior to initial development of the FORPLAN model, the ID Team did some development of management strategies, standards and guidelines. Although not fully developed and documented in narrative form at the time, the work provided a sufficient basis for creation of the FORPLAN prescriptions for the initial AMS benchmarks. The strategies needed were primarily timber management (with varying silvicultural intensities), recreation management, and wilderness.

Part of the revised planning direction (from "the pause") required a more rigorous development of the timber management prescriptions for FORPLAN. Those prescriptions were developed and approved by the Regional Office for use in FORPLAN. The benchmark runs for the second AMS again used a fairly limited set of prescriptions -- the revised timber management prescriptions with various silvicultural intensities, wilderness, wildlife management requirements, and minimum level management (min level). These were also based on the original management strategy work done prior to the initial AMS review.

After the second AMS review, the Planning Team, ID Team, and the Forest Management Team finalized the narrative versions of the desired management strategies, standards and guidelines, resulting in a total of 27 management strategies for the DEIS and Plan. Only minimal modifications, additions, and deletions had to be made to the FORPLAN prescriptions to bring them into line with the finalized management strategies. No changes were required in the benchmark runs; the basic prescription set used remained essentially the same. Most of the final management strategies were represented through the model; some, such as utility corridors, were not because of data and/or modeling limitations.

Some minor modifications were made in the prescriptions, standards and guidelines between the DEIS and the FEIS, partly in response to public comment and partly as a result of further fine tuning done by Forest staff. Some additional intensities were added in the timber management prescription, with corresponding changes made in FORPLAN to include those new intensities. Several management intensities with their own standards and guidelines were developed for specific Special Areas, while the deer and elk winter range management requirement intensity was dropped. The special area intensities were not tracked separately in FORPLAN, so there was no change required in that management prescription. An additional intensity was added in the Cedar River Watershed prescription, but that change did not require any changes in FORPLAN because of the way the Cedar River Watershed is modeled. Other than these changes, the final management strategies again were mostly represented through the model, in much the same form as they existed in the model for the DEIS.

Alternative Development, Analysis and Assessment. Development of the alternatives to be considered in the DEIS and FEIS was a combined ID Team and Forest Management Team effort, based on initial suggestions and guidelines from the Planning Team. Alternatives were mapped, input to R2MAP, and converted into FORPLAN data as sets of coordinated allocation choices and constraints representing the desired land-use assignments and objectives of the alternative.

The "No Change" alternative has been developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to "require inclusion of minimum management requirements (MMR's) in the Current Direction Alternative for each Forest Plan." The substance of the appeal was that a "true no-action alternative representing current management plans' was not included in Forest Plan EIS's. In response to this, a No Change Alternative has been developed to represent the existing timber management plans, and consequently does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA.

Alternatives were run under a "maximize present net value" (PNV) objective function, to assure the most cost efficient solution of the road building and harvest scheduling options, given the land-use assignments, constraints, and other resource considerations. To assure that noneconomic lands would not be assigned to timber harvest unless needed to meet a constraint - even if assigned to a timber management strategy - a combination timber harvest-min level intensity was used. That allowed any acre assigned to timber management to go to a nonharvest intensity if it detracted from the objective function (generally with a negative per acre PNV) by being subject to harvest.

The NFMA regulations require a great emphasis be placed on cost efficiency of individual and aggregate management strategies in the alternatives (36 CFR 219.12(f)(8)). The timber prescriptions are the most sensitive to cost efficiency and the most malleable in this regard. The combination of methods for developing the individual timber prescriptions (using DP-DFSIM, see Section D) and solving for the optimal mix of management intensities in FORPLAN with a maximum PNV objective function resulted in a high degree of correlation between the model results and the intent of the regulations.

Each alternative was run as a separate coordinated allocation choice. There was no attempt to mix the CAC's together and allow the model to choose pieces of each for an optimal solution. Although this had the effect of limiting the range of choice for the model's solution, it was necessary to maintain the intent of the Management Team for each alternative and the spatial integrity of the management areas. Allowing the model to choose among competing CAC's is possible, but raises problems of inconsistent and illogical management area assignments and boundaries which must then be fixed by constraint, and rerun

The assessment of alternative designs needed to achieve a wide range of alternatives with differing objectives was made by the ID Team and Forest Management Team prior to their mapping and subsequent entry into FORPLAN. They used the results of the benchmark runs and the tradeoff and constraints analysis done during the development of both the first and second AMS documents, along with professional judgment in this alternative development process. Allowing the model to choose the land allocations (although it did choose the timber management intensities) would have been a very inefficient way to design alternatives that approached in a number of different ways the Forest's ICO's. For each alternative run, the IDT provided an assessment of that alternative's physical, biological, economic, and social effects on the basis of criteria established beforehand. These criteria allowed assessment of both the kind of resource interactions and the magnitude of resource interactions for any given alternative.

2. Analytical Process and Tools - Details

The following subsections give more detail of the analytical process prior to FORPLAN, the use of FORPLAN, and any analysis done outside of FORPLAN.

Analysis Prior to FORPLAN. A good deal of analysis, using a variety of tools and techniques, took place prior to the development and running of FORPLAN. The earliest analytical efforts centered around delineation of AA's; development of timber yield tables, management costs, and stumpage benefits; and road construction needs and costs. Later efforts were made to estimate recreation capacity and future use, recreation costs and benefits, modeling requirements to proxy wildlife and riparian MR's, and anadromous fisheries response to varying habitat maintenance and enhancement investment levels. AZ's were delineated. Alternatives and associated coordinated allocation choices were developed, mapped, and input.

Analysis Areas and Basic Resource Data. The Mt. Baker-Snoqualmie used a grid mapping system, R2MAP, as its basic mapping, manipulation, and data query system for Forest-wide planning data. (The actual R2MAP version used is COLMAP, which includes capability for handling a larger number of code combinations and enhanced output manipulation and reporting capabilities). R2MAP resource layers provided the base information for most of the initial resource data information and manipulation done in the planning process for nonlinear (area) data. Like most grid mapping systems, R2MAP is very efficient in storing and manipulating area data represented by squares, or "cells," on a map; but it deals poorly with linear data, such as roads and streams, particularly if the scale of the cells is over 5 acres or so. The R2MAP cells each represent 21.1163 acres. Linear data, including narrow corridors such as streamside management units, were dealt with outside of R2MAP.

Although a cell represents 21.1163 acres, when calculating total acres in a given area, R2MAP truncates the figure back to the nearest integer. Thus, for every calculation made, there is the potential of one acre being lost, if *normal rounding would round the total up to the next highest integer instead of* down. In order to correct for that, a routine was included in all the FORTRAN programs which read R2MAP output, or "track", files to build FORPLAN data sets. This routine takes the truncated acres, converts them back to number of cells, which has to be an integer, remultiplies by 21.1163, adds a factor of 0.5, and then truncates again. But the adding of 0.5 allows the truncation to give the same results as rounding. So FORPLAN deals in "true" acres, while R2MAP deals with truncated acres.

Early in the planning process, it was decided that AA's would be resource homogeneous, but spatially noncontiguous. FORPLAN allows AA's to be identified by up to six characteristics. Given the nature of the issues facing the Forest, it was felt that characteristics representing the site productivity of the Forest, vegetative cover types, vegetation ages (particularly relating to ages of timber stands), and slope steepness and slope stability would be important factors in identifying land areas which would have similar outputs and responses to management activities that were applied to them. Another physical/biological characteristic, identified deer and elk essential winter range, was added. Finally, a set of characteristics identifying administrative and economic conditions was added. See Chapter III, C for details.

During the AA delineation process, it was apparent that certain areas on the Forest which were currently unroaded could never be roaded economically, even though they contained lands that otherwise would be suitable for timber management. The Forest's logging systems engineer and transportation planner identified those areas on the Forest that were too steep, too unstable, and/or had too little timber in the area to justify building roads into the area. This determination was made either on the grounds that the land across which roads would have to be built could not support those roads without unacceptable environmental damage, or that the amount of timber being accessed was insufficient economically to justify building the roads, given any forseeable timber stumpage prices. (Any lands within a mile of an existing road system were not included in this category, as long-span skyline systems could access those lands for harvest from the existing roads). These lands so identified are called "inaccessible" lands. They are "inaccessible" only in the sense that roads can not be built into them. For modeling and planning purposes, they are still available for timber harvest, but only by aerial systems.

Most of the information needed was stored in one form or another on R2MAP layers. Some of the inventory data were better than others; but, with no time to redo major inventories, such as timber size class, it was recognized that certain inconsistencies would remain in the data through this round of planning. Field checking during plan implementation will discover numerous areas where, on an acre by acre basis, the ground conditions are different than what is shown in the resource mapping. This is inevitable with any data base system unless perfect inventories with 100% sampling are available. Major errors were corrected. There are still some areas of inconsistencies between resource data and field-checked information; however, R2MAP system with grid cell size of 21 acres does not lend itself to accuracy to the nearest acre.

A number of Forests in Region 6 have used the Total Resource Inventory (TRI) data base, which is managed by a hierarchical data base management system (System 2000, or S2K) to supplement their grid mapping systems In this latter process the TRI polygon cell data and the R2Map grid cell data were "synchronized" at the time of R2Map data input, so that TRI extracts could provide meaningful information to supplement R2Map extracts for the same Forest area. This was not done on the Mt. Baker-Snoqualmie.

The Forest TRI data base was in reasonably good condition because it had been installed and corrected for use in the timber management planning effort. In the spring of 1980, Ranger Districts were involved in bringing the TRI Cell data file up to date and tracing each TRI Compartment and Cells. A freeze was put on changing TRI cell boundaries Activities that had not been entered as TRI cells were reported on a 1" per mile scale map. Computer extracts of TRI cell data were coded into R2MAP at 1 inch = 1 mile. R2MAP input consisted of the basic planning data base; unproductive forest (<20 CF/AC/YR), productive forest by ecoclass and condition classes (size, maturity, and age related coding), non forest vegetation and nonvegetation ecoclasses. Following this transfer of data to R2MAP, TRI was used on a limited basis for forest-wide planning, primarily to spot check R2MAP data or extract information not entered into R2MAP

The analysis areas were developed by "overlaying" the relevant resource data layers in R2MAP within the computer. Each of the characteristics mentioned above had several different possible values associated with it. When the data layers were overlaid, each cell was tagged with a combination of "identifiers". Each cell, or group of cells if they had identical identifiers, became a "capability area". A capability area is a specific area of land, or geographic location, that has the same resource characteristics (in terms of the physical, biological, economic, and administrative characteristics described above). Any capability area will respond in terms of physical, biological, and economic effects in an identical manner to any other capability area with the same characteristics, even if they are spatially separate.

A Forest the size of the Mt. Baker-Snoqualmie can have 10,000-50,000 capability areas, too many to deal with in a model. Capability areas that are identical (or very similar) in nature, other than their geographic location, can be combined into "analysis areas", because for most modeling purposes they will give the same response and therefore be treated the same within the model. When the initial AA's were combined from the capability areas, there were over 240 AA's that went into the model. FORTRAN programs written on the Forest were used to convert the R2MAP results into FORPLAN data files. These analysis areas were used for the first benchmark runs for the initial AMS development.

During the restructuring of the model after the AMS, the initial delineations made for AA's were reexamined. After assessing the usefulness of variables, the three steep slope stability breakdowns were collapsed into one, and the deer/elk winter range identifier was dropped. It was felt that the winter range base data could be tracked as easily through R2MAP, and management area assignments for deer/elk winter range would be tracked as management emphasis identifiers in FORPLAN. With these changes, the resource data layers were overlaid again in R2MAP, and 129 AA's (including water) were created. These were used in the FORPLAN runs for the DEIS.

After the DEIS was released, some additional model refinements were made, and the vegetation database was updated for timber sales between 1983 and 1988. During this process, 7 AA's with very small acreages (all Seeds/Saps and Reforestation) were aggregated with close neighbors and dropped from the model. Therefore, for the FEIS model runs, 122 AA's (including water) remained.

An additional 5 AA's were created to separate out developed recreation areas, and to track newly acquired lands for which there was no resource data. The developed recreation sites had initially been included in the nonproductive/nonforest lands category where they could not be dealt with adequately. The new Forest acres were picked up during refinement of the 1984 wilderness boundaries; they had to be assigned to some category for accounting purposes. These changes were made between the approved AMS and the DEIS alternative runs.

Finally, 4 more "dummy" one-acre AA's were created to carry Forest-wide costs such as for the genetics program, fixed costs, etc. The use of dummy AA's is a technique developed in the FORPLAN modeling process as a "trick" to get around FORPLAN limitations in dealing with certain costs, benefits, or outputs occurring Forest-wide, rather than on a per-acre or per-area basis. One acre is added for each dummy AA, but 4 or 5 "dummy" acres are an infinitesimally small percentage of 1.7 million acres.

Allocation Zones. Allocation zones are spatially contiguous areas defined along geographic bounds that represent important issue areas (e.g., watersheds), have special geographical significance (a designated wilderness, for example), or are areas that represent potential management problems or opportunities. The AZ's were first delineated on the Mt. Baker-Snoqualmie by using major watershed boundaries, roadless area and wilderness boundaries, and the boundaries of major scenic corridors and travel routes. These were outlined on maps, input to R2MAP, and overlaid to produce the AZ boundaries. The AZ's were then overlaid with the AA layer in R2MAP to create a combined layer in which each AZ was defined by its boundary and the acres of various AA's it contained. In the formulation used, the entire Forest was covered by AZ's, so all AA's (except the dummy AA's) were encompassed by one or more AZ's.

An important note: although FORPLAN uses both analysis areas and allocation zones as mapped areas, and ties yields, costs, and benefits (i.e., prescriptions) to them, only coincidentally will the final output ever show either of these areas. (For instance, wildernesses are each defined as an AZ, so the management area and the AZ are coincident). AA's and AZ's are artifacts created for the purpose of modeling, but they are transparent to the final product. The final product for the Forest Plan alternatives is the management area, which will generally cut across both analysis area and allocation zone boundaries But the existence of AA's and AZ's allows the modeling of activities, outputs, effects, and economics related to those management areas.

While restructuring the model after the first AMS, it was felt that delineation of AZ's by major scenic and travel corridors was not providing useful modeling flexibility and information. Also, the 1984 Wilderness Bill changed the wilderness and roadless area boundaries. Therefore, the AZ'a were redesigned, with the new wilderness and remaining roadless areas and the 66 major watersheds on the Forest serving as boundary delineators. The result was 86 AZ's covering the Forest. These zones were used in FORPLAN for AMS benchmark runs and the DEIS and FEIS alternatives. See Chapter III,C for more discussion of AZ's.

Timber Yield Tables. The latest timber inventory was completed for the Forest in 1976; it was used during the development of the 1979 draft Timber Management Plan, which was not released in final form. This work provided the base for developing the timber yield tables for FORPLAN. Statistical analyses were run using SPSS 1/ to group the species into a manageable number of "working groups".

Working groups and age classes were developed from the TRI data base that was entered into R2MAP. The initial resulting working groups and age classes for analysis purposes were:

Working Group

Upper - True fir and mountain hemlock stands
Principal - western hemlock and Douglas-fir
Mixed - Mixed conifer (Douglas-fir/western redcedar) and hardwoods.

1/ Nie, Norman H., C. Hadlai Hull, Jean G. Jenkins, Karin Steinbrenner, and Dale H. Brent, Statistical Package for the Social Sciences, Second Edition, McGraw-Hill Book Company, 1975

Age or Condition Class

Mature large sawtimber (230+ years old)
Mature small sawtimber (130+ years old)
Immature small sawtimber and poles (70+ years old)
Seedlings and saplings (15+ years old)
Reforestation (newly regenerated stands, 0-15 years old)

Eventually, one more timber-related working group and five more condition classes were created to take care of areas with acreages too small to break out into the initial separate classes. The working groups in the "inaccessible" areas were lumped into one, because of small acreages when the working groups were broken out separately, and the age classes therein were grouped into three· mature large and small sawtimber; immature small sawtimber and poles, seeds and saps and reforestation. The age classes in the mixed conifer working groups were grouped into two categories: large sawtimber down through poles; seeds and saps and reforestation.

Yield tables for existing pole and larger stands, including stand age, volume per acre, average stand diameter, and average stand basal area per acre, were developed from the 1976 stand inventory plot data using SPSS. Adjustments were made for mortality and other factors so that the final yields represented net green volume.

Yield tables for managed stands, including existing stands 20 years old and younger, were developed through the use of the DFSIM 2/ (Douglas-fir Simulator) yield generator, DP-DFSIM 3/, and the Stand Projection System (SPS) 4/. At the time the DEIS was published, DFSIM was the only yield simulator in existence and accepted by the Forest Service for managed westside Cascade stands. In response to input from the timber industry, SPS -- a yield simulator of more recent vintage -- was evaluated for use in the western hemlock and Pacific silver fir stands. It was agreed among Forest staff, Regional Office silviculturalists and external timber interests that SPS was more suitable for use in the western hemlock and Pacific silver fir stands than DFSIM, and new managed yield tables were generated. DFSIM would continue to be used to generate yield tables for Douglas-fir stands.

The DP-DFSIM program incorporates the biological relationships in DFSIM, and includes objective functions to maximize timber or present net worth which aid in selecting the best commercial thinning regimes. SPS is built on a data set derived from western hemlock stands, with equations that allow conversion of other stand types to the western hemlock data. Because none of the three working groups for the Forest -- Upper, Principal and Mixed Conifer -- are pure species groupings, it was necessary to apply the different yield models to portions of each working group. For instance, 82% of the Upper working group in the North is western hemlock and true fir, while 18% is Douglas-fir. The yield tables are applied accordingly.

4/ Arney, James D., Stand Projection System (SPS) (Version 86.1), Applied Biometrics, Spokane, WA, 1986.

For the mixed conifer working group, a hardwood yield table based primarily on red alder data was developed separately to model the yields from the hardwood portion of the stand (about 30%). Yields from DFSIM are applied to the conifer portion of the stand. If the mixed stand is converted to pure conifer, the DFSIM yields are applied to the entire regenerated stand.

Adjustments were made to the results from both DFSIM and SPS when developing the yield tables to bring down the estimated growth reported by the models after the first 100 years. It is known that they overstate growth projections after that point. Hand adjustments were made to the projected yields to bring them more into line with existing data.

A sample old growth (empirical) yield table is shown in Table B-3. The yield table extends from the existing stand age out another 20 decades (200 years). Shown for each age are the standing net green volume per acre, the average stand diameter per acre, and the average stand basal area per acre. Table B-4 shows the same information for a regenerated pure Douglas-fir stand. The full set of yield tables used in the model can be found in Forest process documents and in the model data set.

Timber Management Costs. Timber management costs were gathered from project records, contract records, budget estimates, and estimates by District and Supervisor's Office personnel. Costs were collected for direct silvicultural activities, plus timber harvest support costs, such as visual and cultural resources planning, soil and water planning and monitoring, and fuels inventory. It was decided to track logging system (stump-to-mill) costs as well as silvicultural costs. Logging system costs were collected primarily using the timber sale appraisal system handbook, 2400-17 records, and estimates by the logging system engineer. Timber management costs were identified as to whether they occurred on a per-acre or a per-thousand cubic feet (MCF) harvested basis, and whether they varied by land characteristic, such as topographic slope. Logging system costs for all ground systems (tractor, hi-lead, short- and long-span skyline) were combined into a weighted average. Logging costs for aerial systems were kept separate because of the large cost increase over ground systems. Costs were defined on a per acre or per MCF basis.

Between the two AMS reviews, a paper released by Fight, LeDoux and Ortman (1984) described in detail logging cost equations for logging in second growth coastal Douglas-fir stands. These equations defined costs as varying both by tree diameter and by volume harvested per acre. The original logging costs on the Mt. Baker-Snoqualmie did not have both these variances. New cost figures were developed from the equations given in the paper; they were significantly lower than the historical costs used in the first AMS. That was not surprising, as the equations were based on managed coastal range second growth stands, while the historical costs were based on harvesting wild old-growth stands in the much steeper and more difficult ground of the Cascades. However, the relative spread of costs according to diameter and per acre volume appeared to be reasonable from the limited data available on the Forest. Therefore, for the revised model, the equation values were indexed upward to the Forest's historical cost level. This resulted in logging system costs reflecting the Forest's situation and experience, but providing cost differentiation by diameter and per acre volumes as well.

After much discussion, it was decided not to use higher logging and sale preparation costs for prescriptions with small harvest units (5-10 acres). No data existed for either of these situations because of a lack of history of dealing with small units. In terms of the total logging and sale prep costs, the increase would have been relatively small, in the judgment of the logging systems engineer Although this may slightly understate the total costs, there is no indication that the potential magnitude of difference would influence the model on whether and when to harvest timber.

Lowering logging costs for regenerated stands was also discussed, but not done, again primarily for lack of experience with harvesting managed stands. In any case, those costs would not come into play until at least 60-70 years out in the planning horizon, by which time, the discounting would lower the present value of the costs to between 6-10 cents on the dollar, making any adjustment insignificant.

Timber Values. Timber values shown in the model are mill pond values (value at the mill deck) for stumpage. The values were developed from the Timber Sale Statement of Accounts "Cut and Sold" reports for the period 1977-1983. The values used were the reported "cut" values; i.e., the value paid by the purchaser at the time the timber was actually cut, scaled, and billed. Using cut values tends to remove the "futures" and speculation problems that come with using "bid" values. Cut values also better reflect the existing market conditions in any given year. Even though the contracts have been bid in earlier years, purchasers will tend to cut those stands under contract with prices reflecting the current state of the market. For instance, if the market has taken a downturn and stumpage prices have fallen along with final product prices, purchasers will, if possible, leave stumpage standing which they have contracted at higher prices and cut lower priced timber bid on more recently.

Timber working groups are composed of mixes of species, so the timber values used are based on weighted averages of the individual species prices, according to the composition of the working group and the amount of timber of each species cut in each of the years for which data were gathered. Average manufacturing prices for the working groups were added to the stumpage values to get pond values. Prices by diameter were then developed utilizing standard Region 6 methodology as contained in the Regional planning direction.

The use of pond values allowed tracking logging system (stump-to-mill) costs, as noted above, as well as reflecting differences in net stumpage values depending on changes in logging system costs (primarily whether aerial or ground system). This reflects the actual situation, in which wholesale lumber and wood products values set the prices which mills are willing to pay to have material on their decks to process. In turn, these mill pond values are what the timber purchasers use to estimate how much they are willing to pay for stumpage after taking into account the specific costs of getting the wood to the mill from a specific sale area.

After a great deal of discussion Region-wide and nation-wide, timber values in the model were appreciated at a 1% per year rate for the first five decades. This value represents an anticipated real price increase in stumpage values over the general price level.

Road Construction. Modeling new road construction in a realistic manner is difficult in FORPLAN, particularly for Forests like the Mt. Baker-Snoqualmie that do not have the majority of their permanent road system built yet. It was almost impossible in Version 1; in Version 2, with the addition of spatial area (allocation zone) capability, greater flexibility was available for road modeling.

Dealing with the construction of roads independent of timber harvest scheduling, such as arterials and collectors, is not a particular problem with Version 2. In Version 2, the miles of road desired can be specified for each AZ, with the fine tuning problem one of making sure that the appropriate segments are scheduled to be built in an implementable order between AZ's.

The major problem is trying to model a road system that is correlated to the scheduling of timber harvest done by the model, but which will be built proportionately more rapidly than the area into which it is built will be harvested. In areas that are currently unroaded, a certain amount of roading in advance of the rate of timber harvest must take place in order to achieve dispersion of harvest units, to meet adjacency requirements and silvicultural guidelines. For an unroaded area, it is not correct to assume that, beginning with the first harvest in an area, for each acre (or thousand cubic feet) harvested, a certain fraction of a mile of road will be built. This is what results if road construction is modeled on strictly a per acre or per MCF harvested basis. On the other hand, if the roads are laid out on a per acre (AZ) basis, the model may choose to implement a coordinated allocation choice, thereby triggering the building of the roads, but then harvest none or only a portion of the timber actually available to be harvested in any given decade in the area. Thus, if the projection of roads to be built had been based on an expected harvest of 20% of an area in the first decade, but the model actually chose for some reason to schedule only 5% for harvest, the amount of road building modeled would be significantly overstated, and the PNV for the alternative would be lower than it actually should be.

After much trial and error, a modeling scheme was developed that reflected to some degree the desired forward roading needed in areas that are primarily unroaded, but was also responsive to the actual rate of harvest scheduled by FORPLAN. Early in the analysis process, the transportation planning engineer and Forest Soil Scientist did an analysis of nine sample areas and derived a road density in terms of miles per section (640 acres) needed to fully support timber management in an area. These densities by logging system were adjusted on a weighted average basis to reflect the logging system mix used by FORPLAN.

The scheme involved examining existing roads by AZ, the planned arterials and collectors for that AZ for the alternative being analyzed, and the acres specified by the CAC for that alternative that would be subject to any level of timber management (from full yield to partial yield, and extended rotations)

To calculate the remaining local roads to be built, the acres of roaded vs. unroaded lands in the AZ, and the acres of each type subject or not subject to harvest were assessed. The total miles of local roads needed to bring the area subject to timber harvest up to the full density for timber management were calculated, whether the area was currently partly roaded or unroaded. If the AZ was less than 25% roaded, 50% of the new local roads were built over four decades at a declining rate (25/15/5/5) on a per area basis, regardless of the harvest scheduling. If the AZ was more than 25% but less than 50% roaded, 35% of the roads were built over four decades (15/10/5/5) on a per area basis. The balance of the new local roads to be constructed were divided by the acres in the AZ subject to timber management. This coefficient was used (after some grouping to keep model size down) in conjunction with the actual acres scheduled by the model to be harvested in any given decade. Thus, the model reflects some advance roading in unroaded areas, but not in areas that are primarily roaded. The balance of the roads are constructed directly as a result of each acre of timber harvested. Refer to the planning records for more information.

The entire process is embodied in a series of computer programs which rely on the data for the existing road system by AZ, the planned arterials and collectors estimated by AZ for each alternative (mapped and measured), and the acres subject to timber management for each AZ, as specified by the coordinated allocation choice for the alternative. The output of the computer programs is a set of allocation zone yield tables for new arterial and collector and new local road construction, if any, (the latter representing the advanced per area roading), and a coefficient for each AZ giving the miles of road to be built per acre harvested.

Road construction and maintenance costs were developed by the transportation planning engineer from historical cost data, taking into account the trend toward building roads used predominantly for timber harvesting to lower standards and then closing them or maintaining them at lower maintenance levels. Road construction costs included preconstruction and construction engineering as well as the actual construction.

Recreation Capacity. Capacity of the Mt. Baker-Snoqualmie lands to support various types and qualities of recreational use varies by land type and by the management applied to that land. Since about 1980, the emphasis has shifted from managing for specific recreation activity types to managing for recreation experience levels. The Recreation Opportunity Spectrum (ROS) system was developed for use nationwide to guide land assessment and land management in this shift in emphasis toward experience levels.

Although recreation use, or "demand", is of major interest to the Forest, it is influenced primarily by factors outside the Forest, such as the Puget Sound and Vancouver, BC area populations, income, tastes and preferences, weather, etc.

The Forest has more ability to affect, through management, the "capacity" to support various types and experience levels of recreation. This can be done by changing management direction and/or expenditure levels for an area. The ID Team decided early in the analysis process that modeling recreation capacity should be the major focus in FORPLAN, with projected use figures employed to keep from overvaluing recreation use on the Forest in any given decade of the planning horizon.

The Forest Service definitions of the ROS classes were used to define ROS capacity for dispersed recreation outside wilderness. Capacities were defined primarily in terms of miles of road or trail, lakes, streams, and major landforms or attractions; the spatial relationship to roads and other developments; and the expected frequency of interaction with other recreationists (see Forest process documents). Results of this analysis were per acre coefficients showing the maximum annual Recreation Visitor Days (RVD's) by ROS class an acre of land can support.

Forest recreation specialists developed a "Wilderness ROS" designed specifically for the unique properties of wilderness. Less research and information were available to guide the determination of per acre capacity coefficients for the wilderness ROS classes. The resulting coefficients were primarily the best judgment of recreation specialists from several Region 6 Forests, the Regional Office, and the Recreation Research Office of the Pacific Northwest Forest and Range Experiment Station in Seattle.

The second stage in modeling recreation capacity was to take the land-use assignments for each alternative and map the resulting ROS classes, using the ROS criteria in conjunction with the management area standards and guidelines. The resulting ROS areas were input to R2MAP, adjusted to consistent boundaries (to correct minor mapping errors), and converted from the R2MAP track file output into per area (AZ) yield tables by computer program.

The ROS capacity yields were modeled as being achieved over a period of four decades for nonwilderness and two decades for wilderness. The existing ROS as mapped for the Forest was used as a starting point in Decade 1 of the planning horizon. A linear progression from the existing to the alternative capacity was assumed to occur over the two or four decade time span. Best estimates were that these time spans reflected the length of time it would take to reach the full effects of the alternative's management area assignments and management activities on the Forest's ROS. The ROS classes are most affected by levels of development, particularly road or trail construction. It was assumed that most of the trail construction in the wilderness would be completed within two decades, and that most of the road systems would be in place outside the wilderness within four decades.

Recreation "Demand". Estimated projections of recreation use on the Forest (often termed "demand") were necessary to keep from overvaluing recreation on the Forest for any given decade, as well as to see when and where demand was greater than capacity. When recreation capacity was being modeled, more RVD's could come out of the model than there would be demand for in that decade. Since the recreation values are applied to the capacity RVD's, this would overstate (perhaps in a very large way) the value of recreation for the alternative. So estimated demand was used to set up a "cutoff" point for recreation values.

Recreation use projections were made using multivariate ordinary least squares regression analysis. Historical RVD's by activity type were regressed on the Puget Sound population and on year as a trend variable for 1971-1982. From the regression equations derived, initial projections of use were made based on the Washington State Office of Financial Management population projections through the year 2030. The resulting activity type RVD's were converted to ROS classes through a crosswalk developed by the recreation staff. (Prior to 1984, the Recreation Information Management System did not track recreation use by ROS class. Thus, a shift had to be made from the historical data classifications to the desired use of ROS).

The recreation use projections were used in the Demand Curves section of FORPLAN to set up a two-step demand curve for each ROS class by period. This formulation allowed RVD's to be valued up to the point that they filled the first demand step; i.e., where supply and demand are equal. For any capacity produced past that point, the value given in the model to those RVD's was zero. If the capacity did not equal or exceed projected use, all the capacity was valued. (This is a slight simplification of a relatively complex technical part of the model. Please consult the Forest economist and the FORPLAN Users Guide for more information on formulation of demand curves used in the model).

Winter Dispersed Recreation. Because the nature of land use and accessibility changes during the winter when snow is on the ground and many roads are not plowed, the ROS classification actually changes from that experienced during the summer. It was not possible to model that change from summer to winter directly in FORPLAN, therefore, a Forest-wide estimate of capacity and existing use was made by District and SO recreation staff. These figures were carried on a one-acre analysis area for the Forest, along with associated cost and benefit estimates. This is an area where additional data is needed.

Recreation Costs and Benefits. Recreation benefits are for the most part considered "nonmarket" in that they are values which are not traded directly in the economic marketplace, yet they still exist for consumers. The recreation values used in FORPLAN were taken from the 1985 draft RPA program, as prescribed by Region 6 planning direction. These nonmarket, or "assigned," values were developed by the Washington Office staff, in conjunction with a research contract let to John Loomis and Cindy Sorg of Colorado State University. Some felt the original values derived were too high for marginal valuation; rather, the values were believed to be closer to average values for all recreation. A subsequent reduction was made to accommodate this prevailing belief. The adjusted values were the ones used by Region 6 Forests. Recreation benefits were tied directly to RVD's and were not trended.

Recreation costs on the Mt. Baker-Snoqualmie were felt by the recreation staff and the ID Team to be more directly connected to the land available for management by ROS class, rather than to the actual RVD load experienced. A great deal of recreation management is required from season to season (e.g. maintenance of facilities), which is more a function of size of the area and the facilities in existence, rather than of the number of people that might use them. (This is not a perfect correlation. For the next round of planning, when budgets and recreation use data by ROS class are available, regression analysis would provide a more suitable basis for modeling recreation costs).

A second decision made was to model recreation costs based on the dollars estimated to manage the recreation facilities to standard, rather than at current budget levels, in order to avoid building in consistent underfunding.

On the basis of these two assumptions/ decisions, recreation management costs were developed on a per acre basis for the acres in each ROS class. The same process was carried out for Wilderness ROS as well.

Wildlife Management Requirements. The development of the wildlife management requirements (MR's) began shortly after the first implementing regulations for NFMA were enacted in 1979, and has continued to the present time. ("Management requirements" were known as "minimum management requirements" in the DEIS. The terminology was changed in line with Washington Office direction.) A significant amount of analysis was done prior to running FORPLAN in terms of gathering data on available habitat, delineation of essential habitat, and specification of areas required to meet MR's (which changed several times during the planning process). The development and analysis of the management requirements are discussed in more detail in Chapter VI, B. A thorough discussion can be found in Appendix H to the FEIS.

Riparian Management Requirements. NFMA regulations require that "... special attention shall be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes, and other bodies of water. This area shall correspond to at least the recognizable area dominated by the riparian vegetation..." (36 CFR 219.27(e)). Riparian vegetation is recognized as critical vegetation for a large number of vertebrate and nonvertebrate wildlife species, critical for protection of stream and lake water quality, and thus critical for aquatic species as well.

Early in the planning process the ID Team recognized that the critical issue regarding riparian areas would be the degree to which timber harvest could take place in or adjacent to riparian areas, and how that harvest would be guided and controlled to prevent unacceptable damage to the riparian area. There was less concern over riparian areas in non-timber management areas, as only incidental disturbance of the riparian vegetation would take place.

After a period of conceptualizing and discussion, the ID Team arrived at a schematic representation of how timber harvest could be accomplished in riparian areas within an acceptable level of disturbance, while still protecting streambanks, maintaining stream shading, and providing a buffer against sediment moving into the stream. Basically, harvest would occur in small patches (schematically represented as diamonds and triangles) within the managed riparian area (streamside management unit) at different rotation lengths. Roughly 25% of the area would be left unharvested; 50% would be managed at about a 160-year rotation; and the other 25% would be subject to normal rotation management. The scattering of small units of varying rotation lengths, interspersed with unharvested areas, would allow some timber yield from these areas while still protecting stream banks, maintaining stream shading, provide a buffer against sediment movement to the stream, and maintain essential riparian habitat for dependent wildlife species.

To decide on an appropriate riparian zone width by stream class for modeling purposes, the Forest hydrologist and soil scientist did sampling studies in the field and map examination. This work indicated that riparian zones of 200 feet on either side of Class I and II streams, 100 feet on either side of deeply incised Class III streams, and 10 feet on either side of Class III lightly incised streams would be adequate for minimum riparian zone protection. These figures are for modeling only, to be considered a proxy for the actual project design , where riparian zones will vary from site to site according to slope, soil stability, channel incision, etc. The Regional Office approved this modeling scheme in 1984. Class IV, intermittent and ephemeral, streams are recognizing by the Forest-wide Standards and Guidelines as requiring consideration for protection during site-specific project planning. They were not allocated specific riparian zone widths for modeling.

Riparian zones were too narrow to map in the grid system of R2MAP. Class I and II streams were measured by electronic planimeter from Forest maps. Class III streams are not mapped consistently or completely, so their mileage was estimated using density factors by topographic class developed during the sampling process done by the hydrologist and soil scientist.

For most benchmark analysis, a constant acreage of streamside management unit (SMU) was developed from the miles of Class I, II, and III streams in areas subject to timber management, multiplied by the respective acres of SMU per mile of stream. (These acres were subtracted from wildlife MR acres so that the protected acres were not double counted).

For the alternative analyses, a slightly different approach was used to develop data sets for use in FORPLAN. The miles of Class I and II streams going through management areas subject to timber harvest at a higher intensity than that allowed by the SMU were measured by AZ from the alternative maps. A FORTRAN program then used the appropriate riparian zone widths to calculate total Class I and II acres needing protection. These acres were calculated as a percent of the total acres in those management areas, and a proportionate percent of acres in each AA within the management areas were assigned SMU designation. A separate program did roughly the same thing for Class III streams, except that the miles of stream were estimated by a density factor according to the acres by topographic class within those management areas subject to more intensive timber harvest. These acres, too, were designated for SMU status.

Finally, the program assigned 25% of the designated acres to a minlevel SMU prescription for no harvest, assigned 50% to an extended rotation SMU prescription that has a limited range of silvicultural intensities available, and left the other 25% in the original management strategies where they would be subject to normal timber management. These SMU prescription assignments were set up as part of the coordinated allocation choice for each AZ, for each alternative. (Acres in management areas subject to timber harvest at an intensity equivalent to or less than the SMU prescription were not designated as SMU. They were considered to be adequately protected within the original management area).

Water Quality Management Requirement. In providing feedback to the DEIS, a number of public agencies, tribes and private citizens described what they believed to be an insufficient treatment in the DEIS of the cumulative effects of timber harvest and other ground-disturbing activities on watersheds.

Between the DEIS and the FEIS, the Forest worked with the Regional Office to develop a methodology for identification of those areas on the Forest where the risk of adverse hydrologic cumulative effects was greatest, a procedure for determining the "threshold" limits for activities in those areas, and a means of incorporating those limits in the FORPLAN model as a management requirement.

An additional concern expressed by many respondents during the public review of the DEIS was the lack of a predictive model tying sediment production to fish production (see the discussions of anadromous fisheries later in this section). This led to the inclusion of fisheries as a major component of concern in the hydrologic cumulative effects analysis.

The process used by the Forest included a preliminary sensitivity analysis of all watersheds using factors that included management history, climatic conditions, presence of landslides, inherent soil stability, stream channel stability, and off-site impacts. This preliminary analysis resulted in all watersheds being assigned to one of three categories: those in acceptable condition that are generally stable, and where normal management activities can continue to take place (I); those with some recent management activity that, along with some natural events and features, has resulted in some adverse impacts to water quality and/or quantity (II); and those with a high frequency of management activities in recent decades that, combined with natural events and geomorphic features, produce highly unstable and dynamic watershed conditions that have resulted in significant adverse impacts to water quality and/or quantity (III).

Additional detailed analyses of Category II and III watersheds were conducted by ID Teams composed of experienced Supervisor's Office and District personnel. The process used was developed with assistance from the Regional Hydrologist. Major components included were: present and past in-channel stability, streambank stability, status of large woody debris, channel pattern, past harvest rates, road density and condition, presence of landslides, amount of unstable soils, and ability to revegetate and recover. At the end of the analysis process, a consensus was reached for the Category II and III watersheds on the maximum harvest rate per decade (based on tentatively suitable lands in the watershed) that would maintain acceptable watershed conditions, or which would allow improvement of those watersheds that are currently in an unacceptable condition.

Harvest limits to insure attainment of water quality and riparian management requirements were incorporated into FORPLAN as a result of the hydrologic cumulative effects analysis These harvest limits are established by use of a first decade accessibility constraint for each applicable watershed, as represented by one or more allocation zones in the model. The next four decades have a general flow constraint on final harvest acres applied Forest-wide, by North and South. This latter constraint maintains the water quality management requirement in a general way for the Forest, but does not artificially over-constrain the model's harvest and scheduling choices. The harvest constraint for the water quality MR is described in somewhat more detail in Chapter VI.B of this appendix. More comprehensive is the discussion in Appendix H of the FEIS. The most detailed explanation and the results of the analyses of individual watersheds are on file with the Biological and Earth Sciences staff, Supervisor's Office.

Sediment. Sediment yields for the model were based on calculations done by the Forest soil scientist of the amount of background sediment (natural sedimentation) coming from different areas, and the additional sediment in tons per acre that could be expected from road construction and timber harvest activities. The major resource variables for sediment outputs were slope steepness and soil stability class. For the first AMS benchmark runs, the stability classes for the less steep slopes (A and B) were grouped together for modeling purposes. It later became apparent that the three stability classes for the steep slope class (C) were not contributing much information, so they were grouped into just the slope class. Thus, for the second AMS and the DEIS/FEIS alternative runs, the three slope classes were the major variables affecting the amount of sediment coming from natural sources and/or from development activities. Sediment coefficients were developed for background sediment and on a per acre basis for harvest.

Anadromous Fisheries. Relationships between anadromous fish production and Forest management activities, particularly those resulting in additional sediment in the streams, were difficult to quantify. The difficulty for this Forest in defining these cause-effect relationships, or production functions, is to a large degree a result of the topography of the Forest as it affects streams. In the Puget Sound basin, anadromous fish spawning occurs more in steeper stream segments with swifter-moving water than it does on slower-moving stretches. Therefore, the damaging factor for spawning gravel tends to be streambed scouring with larger material rather than siltation with fine sediments. Differentiating between natural and management-related sources of large scouring materials has been more difficult than defining those sources for fine sediments, as has been done on other Forests.

The approach taken to provide for anadromous fish was to develop Standards and Guidelines (both Forest-wide and prescription specific), require implementation of Best Management Practices (BMP's), and incur investment costs that, at the minimum, will maintain existing levels of anadromous fish runs, which are considered minimal for population viability. In addition, two higher levels of investments were identified: 1) maintain existing populations, plus restore original spawning grounds to production; and 2) restore spawning grounds plus bring other potential spawning and rearing areas into production by techniques such as removing stream barriers.

Using a spreadsheet program, investment costs, fish output in numbers and pounds, and commercial and sport fishing benefits were estimated by fish species. They were then summarized for the investment level. A particular investment level was specified for each alternative, and the costs, outputs, and benefits reported. These investment levels correspond to management strategies 13A, 13B, and 13C respectively. Strategy 13D has the investment level of 13C for anadromous fisheries, but includes additional investment for resident fisheries habitat.

During the review of the Draft EIS, a number of comments were made questioning the way in which the Forest dealt with the anadromous fisheries. In particular, questions were raised concerning no apparent connection between levels of harvest activities and road building in an alternative, and levels of fisheries investment and production.

As discussed above, the lack of quantified relationships between timber management activities (including road building) and production of large streambed-scouring gravels and stones led to a separation in the modeling process of management practices from fish production. Instead, the assumptions of the application of Standards and Guidelines, BMP's, and investment levels in fish habitat restoration and enhancement were developed. This allowed the specification of levels of fish production to vary by alternative without regard to the overall level of timber management in that alternative. The concern over maintenance and protection of fish habitat in conjunction with timber management and road building activities resulted in the fisheries resource being a major component in the hydrologic cumulative effects analysis.

If S&G's and BMP's are applied in full, and if the water quality MR harvest acreage limits are applied by watershed, there should be no negative effects on the fisheries resources from management activities. This is an area that will receive close monitoring during Plan implementation, and in which more research will be conducted (given available funding) between the release of this Plan and the development of the next one.

Use of FORPLAN in the Analysis Process. FORPLAN played a central role in the analysis process during the AMS and the alternative formulation and effects analysis steps. During the AMS, FORPLAN was used to model required benchmark runs and assist in calculating maximum production capabilities and the opportunity costs of legal and policy constraints During the alternative analysis process, FORPLAN was used to model the alternatives for the DEIS and then for the FEIS FORPLAN was used in the alternatives analysis to 1) find the most cost efficient combination of prescription intensities within the desired land-use assignments for the alternative by maximizing PNV; 2) estimate activity levels, outputs, and environmental effects of implementing an alternative; and 3) ensure that the objectives of the alternative were achievable within the desired land-use assignment pattern and the various constraints required.

AMS Benchmark Analysis. The benchmark runs were formulated according to Region 6 revised planning direction. Eleven basic benchmark runs were done, varying such factors as non-declining yield vs. fluctuating harvest from decade to decade; timber yields taken at utilization standard (financial rotation) vs. 95% culmination of mean annual increment (CMAI); with and without MR's (known then as MMR's); and with all economic values (market plus assigned) vs. market values only.

Two resource specific benchmarks were done; one maximizing timber outputs, and the other maximizing primitive and semi-primitive nonmotorized recreation.

Finally, current management direction was modeled as a benchmark. This was done with three runs: 1) current management direction with no NFMA requirements incorporated (therefore legally not implementable), 2) current direction with NFMA requirements incorporated (primarily MR's); and 3) current direction with NFMA , but no first decade timber harvest requirement.

In addition to the benchmark runs, several sensitivity and constraints analysis runs were done. Three constraints analysis runs allowed examination of opportunity costs of incorporating wildlife and riparian MR's and the accessibility and dispersion constraints. Three sensitivity runs were done to test the effects of 0%, 2%, and 3% real price trends on the activities, outputs, and land assignments chosen by the model, in comparison to the standard 1% price trend incorporated by Regional direction. Two sensitivity runs were made to test the effects on the model outcomes of increasing or decreasing the timber-related costs by 20%.

An important difference between the benchmark formulations and the alternative runs was that in the benchmarks, the model was allowed to choose land-use assignments (management emphases) among a limited set of prescriptions, as well as choose intensities. In the alternatives, the land-use assignments were fairly well fixed using a much larger number of prescriptions; the model was still allowed to choose among intensities.

Differences between the benchmark formulation used for the first AMS versus that used for the second have been discussed in some detail above. Additional details regarding specific modeling formulation and coefficient derivation, and the benchmark analysis and results will be discussed in Chapter IV, C and D.

Alternative Analysis. FORPLAN was used in the alternatives analysis as an optimizing program, given the land-use assignment for an alternative decided on by the Forest Management Team; as a timber harvest scheduler, within the range of timber management assignments given and the range of intensities used in the model; and as a generator of activities, outputs, and effects from various production functions and yield tables built into the model, relating specifically to the optimal solution arrived at through the solution of the LP algorithm.

Once a FORPLAN data set was built reflecting the alternative land-use assignments and constraints, the model was run with a maximize PNV objective function. The activities, outputs, and effects reported from the model were used directly, if possible, in the assessment of the outcomes and effects of the alternatives. In some cases, more post-FORPLAN analysis was required.

Except for Alternative NC, all alternatives used in the DEIS and in the FEIS, as well as the departure options for Alternatives E and H, were run through FORPLAN. For E-departure option, timber output was maximized, rather than PNV When that solution was reached, it was "rolled over" to a maximize PNV objective function; i.e., the value of the timber objective function achieved in the first run was reset as a constraint to be achieved in the first five decades, and the model was rerun to maximize PNV. This assured the most economical solution for the run, while still attaining the initial timber outputs. (When FORPLAN is run under an objective function other than maximize PNV, it pays no attention for solution purposes to the costs and benefits in the model. Prescriptions that make equal contributions to the objective function will be chosen randomly, regardless of whether they are very cheap or expensive to implement. The "rollover" technique allows the user to have the model re-solve, given the initial objective function value, but choosing the most economical prescriptions to reach that result).

Alternative A (No Action) was also run with a maximize timber objective function, with the solution rolled over to a maximize PNV run. Alternative H-departure was run with a maximize PNV objective function, but the NDY constraint was relaxed. A maximum change in timber outputs of 20% (plus or minus) per decade was permitted. Additional detail on the use of FORPLAN in the alternatives analysis for the FEIS, the constraints set, and the results can be found in Chapter VII, B and Chapter VIII, C 2-5. Details on FORPLAN analysis of those alternatives considered in the DEIS but dropped from the FEIS can be found in the DEIS in the same sections just noted.

Analysis Done in Addition to and/or After FORPLAN. Because of the flexibility and capabilities of Version 2 of FORPLAN, it was possible to handle a number of resource activities that other Forests modeled outside of FORPLAN within the model on the Mt. Baker-Snoqualmie. However, there were still a number of areas that did not lend themselves to analysis through FORPLAN, either because of model or data limitations.

Nearly all monetary costs (including lump sum costs that would not affect model solution) were included in FORPLAN to assure that they were calculated into PNV. The cost efficiency of individual projects, i.e. a fish habitat improvement project, will be further assessed at the time of project selection.

Fire Management. The fire management program, including expected fire activity and fire management staffing levels, was handled outside FORPLAN. For each alternative, the fire management staff used the National Fire Management Analysis System (NFMAS) model 5/ to develop probable fire activity levels and optimal staffing requirements for the levels and types of activities represented in the alternative.

Anadromous Fish. A spreadsheet-based model was used to assess the economic benefits for each anadromous fish habitat investment level. After the pounds of fish by species were estimated by the fisheries biologist, those figures were put in the model, which used estimates of average pounds per fish, catch-to-escapement ratios, commercial fish values, sport fish values, and average angler days per fish caught to estimate the economic benefits associated with each level of investment by species. The model calculated commercial, Indian, ocean sport and river sport fishery values separately, then summarized them for the species. Total benefits for each investment level were derived by summing across all species. These values by investment level were carried in FORPLAN by a "dummy" one-acre analysis area (see earlier discussion in Section B.2 of this chapter), along with pounds of fish, angler days, and investment costs. Detailed calculations are in the Forest's planning records.

Wildlife Habitat Changes. Model size and lack of area-specific data in the model made it necessary for the age class (seral stage) changes in SOHA's, deer and elk winter range, and mountain goat winter range to be tracked after the model had run. Separate programs and spreadsheets were developed, using FORPLAN's Flatfile information for input. Harvest by AA by decade was prorated to the AA's within the habitat under study. Using R2MAP acres of initial inventory by age class within the habitat area, the programs showed how age class acres changed over time as harvest took place. Indices were developed by the wildlife biologists to indicate the number of animals that could be supported per acre for each seral stage group. The indices, multiplied by the seral stage acres, gave an estimate of the number of animals that the habitat could support. For a more detailed discussion on wildlife habitat changes see Appendix H).

5/ USDA, FSH 5109.19, Sept. 1985.

Minerals. Areas of mineral potential, defined in terms of low, medium, and high were provided by the Forest's minerals specialist and input to R2MAP. The management strategies were then grouped according to their relative restrictiveness for mineral exploration and development. These two layers were combined with each alternative layer to derive, by alternative, acres of levels of mineral potential subject to differing degrees of restriction for exploration and development.

Trails. Potential trails to be built, in and outside wilderness, for each alternative were determined through discussion among District, Supervisor Office, and Planning team recreation specialists. Construction schedules were estimated, construction costs were added to the total alternative costs, and the alternative PNV was adjusted accordingly.

Cultural Resources, American Indian Religious Use. Alternative effects on cultural resources, particularly inventoried American Indian religious and cultural sites, were estimated outside the model. The alternative layer and the cultural resources layer were used to identify which sites would be compatible with the overlying management areas, which would be disturbed, and what would be the estimated extent or severity of the disturbance.

C. Analysis Area Definition and Delineation

1. Analysis Areas

This section details the delineation of the analysis areas used in the model as run for the second AMS and the EIS alternatives. Major changes between the first and second AMS formulations are noted. There were no major changes between the DEIS and FEIS.

Within the constraints of data availability/reliability and model capabilities/size, the analysis areas were delineated to recognize significant physical, biological, economic, and social/political/ administrative differences among lands on the Forest. Although the resolution of the data in FORPLAN is ostensibly down to one acre, the R2MAP cell size of 21.1163 acres effectively limits the input data resolution to the nearest 21 acres. The model, however, treats each cell as 21 separate acres, even if they have all the same characteristics, thus giving the impression within the model that data resolution occurs down to an acre.

As described in Part B, 2 of this Chapter, AA's were created by overlaying R2MAP resource data layers. The first step was to create the geographically specific "capability areas". Because there are thousands of individual capability areas on the Forest, they were aggregated so as to retain common resource characteristics, but not their geographic definition. Thus, capability areas with the same resource characteristics scattered around the north half of the Forest in various locations were lumped together under one title or code as an "analysis area". In this manner, the capability areas on the Forest were initially aggregated into more than 240 AA's. After the winter range identifier was dropped and the steep slope stability classes aggregated for the second AMS (discussed above), there were 129 AA's remaining.

Five more AA's were defined after the second AMS review to identify separately acres in developed recreation sites and to carry for accounting purposes newly acquired lands which lacked resource data. And four "dummy" AA's were added to the model as carriers for various costs, benefits, activities and outputs which are most appropriately modeled on a Forest-wide basis. Although assigned one acre each, they do not really represent land area, but are simply a modeling technique to represent some Forest-wide information in one figure, rather than breaking it out across all AA's.

After the DEIS was released, some additional model refinements were made, and the vegetation database was updated for timber sales between 1983 and 1988. During this process, 7 AA's with very small acreages (all Seeds/Saps and Reforestation) were aggregated with close neighbors and dropped from the model. Therefore, for the FEIS model runs, 122 AA's (including water) remained, as defined by the level identifiers, along with the 5 AA's for new lands and developed recreation sites, and the 4 "dummy" AA's.

2. Analysis Area "Level Identifiers"

FORPLAN allows any area to be represented by up to eight identifiers, also known as the eight "level" identifiers. In the Mt. Baker-Snoqualmie FORPLAN model, Levels 7 and 8 were reserved for the management emphasis (prescription or management area strategy) and management intensity (level of investment or management activity), respectively. Levels 1 through 6 were used for the analysis area identifiers. After the first AMS benchmark formulation, the Level 2 identifier was dropped (even though it still shows in the model documentation maintained in the identifiers section at the front of the model data set). Following are listings and discussion of each of the five remaining level identifiers.

a. Level 1 - General Location/Developed Recreation/Miscellaneous

North	Mt. Baker NF
South	Snoqualmie NF
Water	Water (lakes, streams, ponds, etc).
New FS Lands	Newly acquired NFS lands with no resource data
Camp/Picnic	Existing developed site camp and picnic grounds
Camp Ski	Existing campground within a developed ski area
Ski Areas	Existing developed ski areas
Rec. Residence	Private rec. residence areas and organization camps
FW-1	Forest-wide AA carrying fixed costs and anad. fish
FR-1	Forest-wide AA carrying developed rec. information
WF-1	Forest-wide AA carrying winter dispersed rec. info.
GN-1	Forest-wide AA carrying genetic program costs

The North and South identifiers are based on the boundaries of the Mt. Baker and Snoqualmie National Forests, respectively. Originally, up through the DEIS, productivity measures developed using 1976 timber inventory data were coincidental with the North and South delineations. After public comments on the DEIS, the Stand Projection System (SPS) timber yield simulator was added and productivity estimates were redone. There are now two productivity classes to use with the Douglas-fir Simulator (DFSIM) and two for use with SPS. These productivity classes are associated, respectively, with the Douglas-fir types north and south, and with the western hemlock and Pacific silver fir types north and south. These delineations do not match completely with any of the other level identifiers; therefore, the productivity classes were dropped as one of the level identifiers. Productivity is now incorporated through the application of DFSIM to Douglas-fir stands, north and south, and the application of SPS to western hemlock and Pacific silver fir stands, north and south.

Additional categories were added to this level to represent water, the developed recreation analysis areas, newly acquired NFS lands, and the one-acre "dummy" AA's. These were simply put in Level 1 for convenience.

Location. The North/South breakdown reflects the old Mt. Baker and Snoqualmie working circles, which were the bases for development of potential harvest figures (roughly equivalent to allowable sale quantity - ASQ) in the 1979 draft Timber Management Plan. There was some question early in the process about whether ASQ on administratively combined Forests would have to be calculated separately, rather than for the combined Forests as a whole. The North/South definition would allow this type of calculation. North/South also allows some general location specification of the analysis areas. And timber stands and yield tables still utilize the North/South delineation, even though productivity is no longer directly correlated.

Developed Site Recreation. The developed site AA's were delineated during the time between the approved AMS and the DEIS alternative runs. Initially, developed sites were not identified separately in R2MAP, but were lumped in as part of the unsuitable/nonproductive lands. At this time, developed recreation appeared not to be a separate issues; also, small areas like campgrounds were difficult to represent in a grid mapping system where one cell covers 21 acres.

The issue decision was an error Existing developed recreation sites were areas that had to be dealt with specifically, in terms of level of management, closures, expansion, etc. Furthermore, it was not easy to answer the questions raised about how many sites were on the Forest and how much acreage they incorporated. After discussions with recreation staff, it was decided to represent each campground, picnic ground, group recreation area, organization camp site, and recreation residence (summer home group) area by at least one cell in R2MAP. Although the actual sites might not be 21 acres, the consensus was that the area actually managed for a site, including a buffer zone around the actual units, could easily average 21 acres per site across the Forest. An inventory of sites was done, and each site was mapped with at least one cell in R2MAP. Developed ski areas were an exception; they are much larger and were mapped to the extent of their current area under permit.

The new developed recreation analysis areas were created on a Forest-wide basis through R2MAP. Rather than tracking each individual camp and picnic site, they were aggregated Forest-wide for analysis purposes. AA acres from the first AMS formulation were reduced according to the acres of developed recreation site AA's taken out of them, and the total Forest acres re-balanced.

Newly Acquired National Forest System Lands. The "newly acquired FS lands" AA's were created following the approved AMS, while some wilderness and roadless area boundary adjustments were made. During the time since the AA base had been revised for the second AMS, some additional land acquisitions and trades had taken place, and for these acres no resource data were available. To keep the total Forest acres accounted for, the "new FS" AA was created as a place holder. Its only available prescription is "New FS - Minlevel."

Forest-wide ("Dummy") Analysis Areas. Four "dummy" AA's were specified to handle some Forest-wide outputs and fixed costs. Use of the "dummy" one-acre AA's is a technique to deal with modeling problems in FORPLAN that don't lend themselves to being tied to analysis areas, allocation zones, or other activities or outputs. The few additional acres do not count toward the Forest total nor do they affect the model solution, other than through the values they carry. When the one-acre AA is specified to be in solution, it is as if whatever is carried with that AA is being applied or implemented Forest-wide.

The one-acre AA's were designed to carry the following:

FW-1 - Forest-wide fixed costs and the three anadromous fish investment levels. The latter include the investment costs; fish output in pounds; angler days in RVD's; and benefits, both commercial and sport fishing.

FR-1 - Developed recreation capacity, use, costs, and benefits Forest-wide for existing developed recreation sites.

WF-1 - Winter dispersed recreation capacity use, costs, and benefits Forest-wide.

GN-1 - Forest-wide costs of the genetics program which are not assignable directly to the timber management program.

b. Level 2 - Not Used

Level 2 was originally used in the formulation for the first AMS to designate deer and elk winter range. In the process of trimming down the model for the second AMS, it was determined that deer and elk winter range as a land identifier was not providing any useful information or capability for modeling, and could as easily be dealt with as an external resource layer through R2MAP. Thus, it was dropped from the model.

c. Level 3 - Roading and Accessibility Condition

Roaded	Currently roaded and economically accessible.
Unroaded	Currently unroaded but economically accessible 6/ (i.e., can be roaded to access harvest areas)
Inaccessible	Currently unroaded and economically inaccessible (i.e., available for harvest only w/aerial systems)
Wilderness	Congressionally-designated wilderness

6/ "Unroaded" designation is not identical with RARE II roadless area lands.

Current status and future use of unroaded lands on the Forest are major issues. Whether an area is roaded or not also has important physical, biological, economic, and social implications. For the first AMS, the unroaded category was defined as "roadless," in line with the definition of roadless lands as used in the RARE II process. In fact, the RARE II roadless lands and the Level 3 "roadless" in FORPLAN were identical at that time.

The 1984 Wilderness Bill was passed between the first and second AMS reviews, converting upon passage about 350,000 acres of RARE II (and Level 3) "roadless" lands to designated wilderness A large number of small parcels of the original "roadless" lands were left outside the new wilderness boundaries; a number of these leftover parcels were under 100 acres in size.

After a great deal of consideration, it was decided during the model restructuring process to change the definition of lands that were not roaded to incorporate those lands (approximately 100,000 acres) that were not included in the RARE II inventory because they were less than 5000 acres. The rationale was that all the major areas of unroaded land were at issue, not just the RARE II roadless lands, particularly when portions of the RARE II roadless lands now existed as small, isolated parcels. Also, from an economic standpoint, any blocks of currently unroaded lands greater than 1000 acres in size would require additional roading for timber harvest, with the attendant implications for harvest economic feasibility, budgets, and alternative present net value. Thus, the revised "unroaded" base was delineated as the balance of the RARE II roadless lands <u>plus</u> the additional 100,000+ acres of unroaded lands mentioned above. (The RARE II parcels had to be kept in the unroaded base and tracked in order to comply with the 9th Circuit Court ruling on the RARE II FEIS and subsequent interpretations of that ruling).

Delineation of, and the rationale for, defining "inaccessible" lands were discussed earlier (part B of this chapter). These lands remained tentatively suitable for timber management, but no roads would be built. Timber harvest could only be accomplished by aerial systems.

"Wilderness" was kept separate as an administrative designation. Wilderness is legislatively withdrawn from timber harvest availability and other resource development activities, and has limited management options available. Separate wildernesses were tracked as individual allocation zones (see below).

d. <u>Level 4 - Working Group</u>

Upper	True fir/mtn hemlock timber stands (higher elevations)
Principal	Western hemlock/Douglas-fir stands (mid-elevations)
Mixed Conifer	Douglas-fir/western redcedar/hardwood stands (mostly lower elevations - approx. 70% conifer & 30% hardwood)
Inacc. Types	Aggregation of working groups in inaccessible lands (Level 3 identifier), grouped because of small acreages of individual working groups
Unsuitable	Forest lands unsuitable for timber production, as determined under the NFMA regulations
Nonforest	Lands with less that 10% tree crown cover; shrub, forb and grass lands; rocks; ice

The type of vegetative cover (or lack thereof) found across the Forest is one of the most important resource characteristics to consider. Vegetation information in terms of types, sizes, ages, and densities of trees is important to timber interests, and other major resources, including wildlife, recreation etc.

As mentioned in Part B above, the 1976 timber inventory and the subsequent analysis done for the 1979 draft TM Plan provided much of the basis on which the timber data for FORPLAN were developed. The stratification of the timber types into the three major working groups provide classes that respond in a similar manner to applied management practices, whether timber or non-timber. They represent general elevational zones, which is important for wildlife habitat considerations. They represent similar economic "zones" in terms of the benefits derived from stumpage. However, because of the diverse nature of the Mt. Baker-Snoqualmie's forest, it must be recognized that these working groups are statistical averages, abstracted from a statistical sample. They are useful for long-range planning on a Forest-wide basis, but would need to be supplemented for any short-range or site-specific planning. The number of working groups is small relative to the actual number of species represented on the Forest, primarily because of the inventory sample stratification and resultant difficulties in getting statistically reliable estimates for groups smaller than the three used.

Sample size played an important role in the aggregation of all types into one in the inaccessible areas. While still available for timber management, the sample sizes on this relatively small amount of land were too small to break out by the three major working groups.

Combining the four forested land working groups with the productivity indices embodied in Level 1 and the age and size classes represented in Level 6 gave a fairly complete picture of the forest status for any given acre in the model. Because timber management is a major activity and issue on the Forest, the delineation of the status of the forested lands was important. This formulation of the information on a per acre basis lent itself very well for use in a linear program for solving land use and scheduling problems.

The first four working groups listed above include all acres that are tentatively suitable for timber production on the Forest, and only those acres. Their basic makeup by major types is shown. There were originally about 80,000 acres more of the Upper working group, but when the decision was made to take a good portion of the mountain hemlock type out of the tentatively suitable base, much of the Upper working group, where the mountain hemlock was predominantly found, went into the Unsuitable group.

The "Unsuitable" working group contains the acres of land (but not water) outside of wilderness determined unsuitable for timber management because of legislative withdrawals, stand regeneration difficulties, for protection of fragile soils, and for other reasons required by law or policy.

The "Nonforest" working group tracks the balance of the land acres on the Forest that are not in the previous working groups: brush, grasslands, rocks, and ice. Since the range (livestock) program on the Forest is almost non-existent, grass and brushlands were not kept as a separate working group. This category also includes lands with scattered tree cover (less than 10% crown cover).

e. Level 5 - Slope and Stability Classes

Slope Class A	Less than 35% slope; all stability classes
Slope Class B	35%-80% slopes; rocky outcrops 35% of area; stream density 5 miles/section; all stability classes
Slope Class C	50%-90% slope; rock outcrops 35%-100% of area; rugged highly dissected topography; stream density 5 miles/section; all stability classes

Topographic classes are important primarily for determining sediment outputs, tendency for soil erosion and slope failure, and difficulty in road construction and timber harvesting activities. The slope classes above were defined to reflect those concerns. Originally, each slope class had two or three soil stability ratings associated with it. Because of the less steep slopes in Classes A and B, the soil stability factors were not carried for those classes in the original model formulation. However, Slope C carried three soil stability breakdowns. Soil stability problems show up most in relation to road construction. Steepness of slope affects other management activities to a greater degree than does soil stability. After the first AMS, it was discovered the three breakdowns in C did not provide much useful information, compared to the number of additional AA's created. The three breakdowns were collapsed into one and averaged (with weights) any associated coefficients, such as sediment production.

f. Level 6 - Condition (Age and Size) Class

Mature Large	Mature large sawtimber (generally 240+ yrs. old)
Mature Small	Mature small sawtimber (generally 140+ yrs. old)
Poles	Immature small sawtimber and poles (80+ yrs. old)
Seeds & Saps	Seedlings and saplings (avg. 20 years old)
Reforestation	New regeneration growth (avg. 10 years old)
Mx. Conif. 1	Mixed conifer poles through large sawtimber
Mx. Conif. 2	Mixed conifer reforestation and seeds and saps
Inacc. 1	Mature large and small sawtimber on inaccessible lands
Inacc. 2	Immature small sawtimber and poles on inaccessible lands
Inacc. 3	Reforestation and seeds and saps on inaccessible lands ("inaccessible" used as defined for Level 3)

Level 6 identifiers are an integral part of the vegetation definition, particularly for timber types. However, the age and size class approximations are also important for determining the status of old growth and wildlife habitat.

The condition class categories were taken from information gathered during the 1976 timber inventory These data were updated through fiscal year 1988 for additional harvest units, leading to an increase in reforestation acres. The aggregation of ages in the mixed conifer and inaccessible working groups represents problems of statistical sample size. Each of these condition classes, when combined with a working group and a productivity class (North or South), has a beginning average stand age, stand average diameter, basal area per acre, and standing net green volume per acre associated with it in the timber yield tables. Harvest costs and stumpage benefits are tied to these combinations.

It is important to note that the classes here represent existing vegetation states. The model tracks the changing age of a stand as it grows and then is cut some time in the future. But in this version of FORPLAN, the six level identifiers always stay the same, even if something were to actually change after an area was harvested. For example, if a stand of mixed conifer mature sawtimber were harvested in Decade 2, the AA identifiers in Decade 3 would still indicate mixed conifer mature sawtimber, even though the stand would then be reforestation, and even if it had been converted to pure conifer. As the planning horizon progresses through the model, one has to watch the internal reports tracking stand ages by decade and type of management actions taken, and not rely on the level identifiers to describe the current status of the stand.

Representation of the Timber Inventory in FORPLAN

The Mt. Baker-Snoqualmie National Forest Forest inventory was conducted in 1976 and is based on a plot expansion system with an inventory plot every 1.7 miles. Each plot represents 1,804 acres of forested lands. The emphasis of the inventory statistics was tree species, volume, and number of acres in each (Table B-4a). Shortly after this stratification was completed, an in-place mapping project to determine acres by vegetative condition was completed; i.e., acres of vegetative condition with tree species, size classes, and stocking levels. This information was combined with plot data to develop a forest timber model with volumes by different stratification (Table B-4a, section labeled "1976 (1977) Inventory Biological Forest Model"). The results were used in the development of the draft Timber Resource Plan in 1978.

In preparation for the Forest Planning effort, the timber model was updated to 1982, with subsequent changes in 1986 for the 1984 Washington Wilderness Act, and in 1989 for other activities through 1988. These changes are also displayed in Table B-4a, on the following page.

With the exception of the last two columns in Table B-4a, all acres and volumes are based on what used to be called "Commercial Forest Lands" and on the 1975 empirical volume information for those acres brought forward through time. The last two columns represent the change from Commercial Forest Lands and the 1975 empirical yield table to the tentatively suitable land base and the 1989 empirical yield tables.

These tentatively suitable acres and their corresponding growth and yield tables were then transferred to the FORPLAN computer model for use as the starting point for all alternatives. Further information on the transition from 1976 Forest Inventory acres to FORPLAN acres can be found in the Forest Planning records.

Table B-4a
Acreage and Volume of the Timber Inventory 1976-1988

1976 Inventory Plot Expansion (CFL) 1/			1976 (1977) Inventory Biological Forest Model (CFL)			1982 Update (CFL)			1986 Update (CFL)		1988 Update (CFL)		1988 Update (Tentatively Suitable)

1/ CFL=Commercial Forest Lands
2/ Abbreviation M = Mature, I = Immature LS = Large Sawtimber, MS = Small Sawtimber, PL = Pole Timber, SS = Seedlings & Saplings, REF = Reforest
3/ Condition classes (Level 6) as defined in FORPLAN by North and South (Level 1) Acres carried in FORPLAN are further disaggregated into Working Groups Upper Principal and Mixed Conifer (Level 4)
4/ Does not Include Reserved or Deferred Lands
5/ Based on An In-place Mapping System acres in R2MAP
6/ Volumes based on 1975 empiricals are brought forward
7/ Acres based on 1982 update (1920 letter June 2, 1982) Does not include reserved or deferral lands
8/ Based on R2MAP data adjusted for roads land exchanges and legal
9/ Based on R2MAP data adjusted for roads, land exchanges and unsuitable lands
10/ Based on 1989 Empirical Yield Tables

Tentatively Suitable Lands. Lands determined to be tentatively suitable for timber management are defined through the following level identifiers:

Level 3
- Roaded
- Unroaded
- Inaccessible

Level 4
- Upper
- Principal
- Mixed
- Inaccessible Types

Level 5
- Slope A
- Slope B
- Slope C

Level 6
- All condition classes

Any acre with one of these identifiers will be tentatively suitable for purposes of the model. Any AA with one of these level identifiers cannot, by definition, have another level identifier that falls outside this list. Thus, all Roaded, Unroaded and Inaccessible lands are, by definition, tentatively suitable. The same is true with all lands given the Slope Class identifiers. To reduce confusion for lands not tentatively suitable, only one identifier - Level 4 "Unsuitable" or "Nonforest"' or, Level 3 "Wilderness", along with a Level 1 identifier of "North" or "South" - was used to identify those lands.

Table B-5 and B-6, respectively, summarize acres in each FORPLAN level identifier and list the level identifier and total acres for each analysis area carried in FORPLAN.

Table B-5
Summary of Acres in Each FORPLAN Level Identifier 1/

Level Identifier		Acres
Level 1	North	1,088,924.
	South	604,553.
	Water	17,349 2/
	New FS	4,260
	Camp/Picnic Developed Sites	1,787.
	Campground in Developed Ski Areas	63.
	Developed Ski Areas	6,333.
	Recreation Residences and Organization Camps	548.
Level 2	- Not Used	
Level 3	Roaded	391,235.
	Unroaded	155,665
	Inaccessible	64,057.
	Wilderness	714,025. 3/
Level 4	Upper	178,016.
	Principal	327,237.
	Mixed Conifer/Hardwood	41,647.
	Inaccessible (Aggregate of Types)	64,057.
	Unsuitable	263,979. 4/
	Non-forested	104,516.
Level 5	Topographic/Slope Class A	115,457.
	Topographic/Slope Class B	349,313
	Topographic/Slope Class C	82,130.
Level 6	Mature Large Sawtimber (Conifer)	226,247.
	Mature Small Sawtimber (Conifer	34,733.
	Poles (Conifer)	69,157.
	Seeds and Saps (Conifer)	72,142
	Reforestation/Plantations (Conifers)	102,974.
	Large Saw/Small Saw/Poles (Mixed Conifers)	35,398
	Seeds/Saps/Reforestation (Mixed Conifers)	6,249
	Large and Small Saw (Inaccessible)	50,759.
	Poles (Inaccessible)	9,191.
	Seeds/Saps/Reforestation (Inaccessible)	4,107.

1/ Total acres carried for the Forest in FORPLAN were 1,723,821. The acres above total more, as most acres have more than one of the attributes listed.

2/ All measurable bodies of water (lakes, reservoirs, ponds) on the Forest, in areas such as wilderness, unsuitable, and non-forest lands

3/ Acreage does not include water (an additional 7,581 acres).

4/ Does not include acres in water, wilderness, or developed recreation sites.

Table B-6 Page 1 of 3

Summary of Analysis Area Acres Carried in FORPLAN 1/

3. Allocation Zones

Allocation zones have been discussed previously, but a short review here is relevant. AZ's allowed the Forest to deal with spatial problems that could not be dealt with using the noncontiguous analysis areas. In particular, they were used to deal with the road system construction problem on an area basis, and to predict ROS from an alternative with a known land-use assignment pattern.

AZ's can also be used for reporting, which is useful to get either direct or prorated information about a specific geographic area. The AZ's for the second AMS and the EIS alternative runs were delineated based on wilderness boundaries (each wilderness was a separate AZ); major unroaded areas; and the 66 major watersheds. Watersheds in particular provided useful spatial delineators, as management often changes on hydrographic boundaries (ridgetops). Watershed boundaries incorporated into the AZ's were used in the application of the water quality MR developed for the FEIS as a result of the hydrologic cumulative effects analysis.

(NOTE: Some AZ numbers, as shown below in Table B-7, are missing because of aggregations among zones made after the initial delineation and numbering process.)

Table B-7 Page 1 of 2

Allocation Zones and Acreages Carried in FORPLAN

AZ Code	AZ Name	Acres
Z02	Illabot	15,507.
Z03	Chilliwack, Mostly Unroaded	11,673.
Z04	Canyon Creek	17,447.

D. Identification of Prescriptions

The NFMA implementing regulations define a "management prescription" as "Management practices and intensity selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives" (36 CFR 219.3). To define the concept further, a management practice is "A specific activity, measure, course of action, or treatment" and a management intensity is a management practice, or group of practices, applied at a specific level of investment or cost in order to achieve a correlated level of output of goods and services (36 CFR 219.3).

A management prescription consists of a general goal statement for the prescription; a description of lands where the prescription is applicable; a statement of the desired future condition for the lands and associated resources to which the prescription is applied; and a list of detailed standards, guidelines, and constraints which control how the prescription is implemented. The Forest's management prescriptions were created within the following framework: (1) satisfy the "management requirements" in Part 219 27 of the regulations; (2) develop an adequate range of alternatives to ensure the available options are properly examined (Part 219.14(b)-(c)); and (3) formulate each prescription as the most cost efficient combination of management practices to meet the resource management objectives of that prescription (Part 219.12(f)(8)).

1. Overview of the Process

The prescriptions for this planning process were developed in two stages. Early on, the IDT made an initial outline of management prescriptions, considering factors such as the ICO's, and compatibility or noncompatibility among different management practices and desired end results. From this list, the initial FORPLAN prescriptions were developed. It was recognized that not all prescriptions necessary for on-the-ground management could be modeled through FORPLAN, for reasons discussed in earlier sections Therefore, the prescriptions developed for FORPLAN related initially to timber, recreation, and wildlife management. With some modifications and variations, these were the basic FORPLAN prescriptions used for both AMS benchmark runs.

Prescriptions Developed for the DEIS. After the approval of the second AMS, the IDT and Forest Management Team met for several weeks to finish developing all the management prescriptions needed for alternatives analysis and development of the Forest Plan The Forest-wide Standards and Guidelines were developed first, followed by the individual prescriptions Team members initially drafted portions of the Forest-wide Standards and Guidelines and the individual prescriptions most relevant to their resource specialty, or their District. Then small groups revised the product. Final decisions on each of the Forest-wide Standards and Guidelines and individual management prescriptions were made by the IDT and Management Team as a group.

The rules under which the group operated were·

1. Meet the requirements of the NFMA regulations and Region 6 planning direction,

2. Assure that the prescriptions, standards and guidelines represented a balance among resources, keeping in view the goal of the prescription, the management requirements of the regulations, cost efficiency, and implementability on the ground;

3. Incorporate direction for all resources and activities within a prescription (where not already covered by the Forest-wide Standards and Guidelines), so that management areas (prescriptions applied to a specific piece of ground) would be unique; i e , they would not need to overlap in order to adequately deal with all resources on that piece of ground.

4. Maintain future options and management flexibility to the maximum extent possible.

Using these criteria, through a highly interactive process, a range of prescriptions was developed which allowed the Forest to adequately examine resource management opportunities over a broad range of alternatives, while meeting the management requirements for vegetation manipulation, soil and water conservation, riparian areas, resource protection, silvicultural practices, diversity, and cost efficiency. In total, 26 prescriptions were developed that would be used to define management areas. A number of these prescriptions contained several possible management intensities.

It was known prior to running AMS benchmarks that the FORPLAN model solutions run with economic objective functions and the overall economic efficiency of the various alternatives would be most sensitive to the timber management prescriptions and intensities. Prior to reformulating the model for the second AMS, the timber management intensities (in terms of rotation lengths, types of silvicultural activities during the rotation, timing of intermediate thins, and so forth) were reformulated, using DP-DFSIM, discussed earlier.

The IDT/Management Team group had this information when completing the prescriptions for the DEIS; thus, cost efficiency of the timber management prescriptions was assured. Economic considerations were taken into account for other non-timber prescriptions through the use of experience and professional judgement of the resource specialists.

Once the prescriptions, standards and guidelines were final, desired management areas for the alternatives could be delineated by assigning prescriptions to different land areas.

After the prescription package was complete, the FORPLAN prescriptions required to model the DEIS alternatives were completed. Little change was required for the base set of FORPLAN prescriptions used for the benchmark runs (timber management, wilderness, wildlife MR's, and minimum level management). Additional prescriptions were added to represent the range of management activities actually present in the alternatives.

Changes in Prescriptions for the FEIS. Partly in response to public comment and partly as a result of further fine tuning, some minor modifications were made in the prescriptions, standards and guidelines between the DEIS and the FEIS. Some additional intensities were added in the timber management prescription, with corresponding changes made in FORPLAN to include those new intensities. Management intensities with their own standards and guidelines were developed for the following Special Areas: Heather Meadows, Sulphur Creek Botanic Area, and Mather Memorial Parkway. The special area intensities were not tracked separately in FORPLAN, so there was no FORPLAN change required for that management prescription. The deer and elk winter range management requirement intensity was dropped An additional intensity was added in the Cedar River Watershed prescription, but that change did not require any changes in FORPLAN because of the way the Cedar River Watershed is modeled. Other than these changes, the final management strategies for the FEIS were again mostly represented through the model, in much the same form as they existed in the model for the DEIS.

The titles of the management prescriptions and intensities finalized for the FEIS and Plan, along with the management area numbers used in the Plan, are shown in Table B-8. There are actually only 26 prescriptions; numbers 8 and 9 were aggregated into one. Rather than renumber all the others, 9 was not used. (Refer to Chapter II, Appendix D, and the Forest Plan document for detailed descriptions, standards and guidelines of management prescriptions

considered and adopted.) The prescriptions and intensities marked with an asterisk were modeled as FORPLAN prescriptions.

	16	Threatened and Endangered Species
		16A Northern Bald Eagle
		16B Grizzly Bear
		16C Peregrine Falcon
		16D Gray Wolf
	17	Timber Production Emphasis - Investment Level
*		17A Minimum Investment: Natural regeneration
*		17B Low Investment: Natural regeneration and prelommercial thin
*		17C Low Investment: Plant
*		17D Low Investment: Plant genetically-improved stock
*		17E Low Investment: Plant genetically-improved stock and commercial thin
*		17F Moderate Investment: Plant genetic stock, PCT, possibly fertilize
*		17G High Investment with Regular Rotation: All silvicultural activities
*		17H High Investment with Extended Rotation: All silvicultural activities
*	18	Research Natural Areas (RNA's)
*	19	Mountain Hemlock Zone
	20	Municipal Watershed - Cedar River (City of Seattle)
*		20A Current Direction, 1962 Agreement
*		20B Exchange all N.F. Lands to City of Seattle with stipulation that old-growth stands will be maintained as habitat for old-growth dependent wildlife species.
*		20C Retain N.F. Lands but wildlife habitat for old-growth dependent and other species will be maintained in accordance with NFMA.
*		20D Negotiate new Cooperative Agreement with City of Seattle; in interim, retain lands and otherwise follow 1962 Agreement.
	21	Municipal Watershed - Green River (City of Tacoma)
*		21A Current Direction 1984 MOU
*		21B Public recreation prohibited except limited controlled hunts and recreation use of Pacific Crest National Scenic Trail
	22	Municipal Watershed - Sultan River (City of Everett)
*		22A Closed watershed. No activity except protection of watershed and production of hydropower
*		22B Current situation. Restricted watershed; recreation use only in developed sites. Provide for timber production, protect watershed values beyond legal requirements, maintain fish, wildlife habitat
*		22C Retain N.F. land. Open watershed, full multiple use.
	23	Watershed - Other Municipal
*		23A Timber harvest, moderate recreation opportunities
*		23B No timber harvest, limited recreation opportunities
*	24	Minimum Management
	25	Special Uses - Utilities
		25A Utility Corridors
*		25B Electronic Sites
*	26	Administrative Sites
*	27	Alpine Lakes Area

The Alpine Lakes Area prescription needs a special note of explanation. A decision was made early in the planning process to keep the Alpine Lakes Management Unit land allocations as they were originally approved in the Alpine Lakes Management Plan. That plan was recent, had incorporated public input and review, and had been approved by Congress. The only changes made were those required to incorporate MR's from NFMA. Thus, prescription 27 is just a cross-reference to the Alpine Lakes Management Plan, in which more specific land allocations and associated prescriptions are found. The FORPLAN model was constructed so that the actual Alpine Lakes allocations were modeled appropriately.

2 Prescription Categories

The prescriptions and intensities, along with the Forest-wide Standards and Guidelines, can be grouped into broader categories, as outlined in Table B-9:

Table B-9

I. Forest-wide Standards and Guidelines
General Standards and Guidelines applicable to all lands and resources on the Forest, no matter where they occur

II. Management Requirements
- 11. Old Growth Habitat Emphasis
- 12. Mature and Old Growth Wildlife Habitat
- 13. Riparian and Fish Habitat Emphasis (Intensity A)
- 15. Mountain Goat Habitat (Intensity A)
- 16. Threatened and Endangered Species
- 24. Minimum Management

III. Recreation and Scenic Areas
- 1 Dispersed Recreation
- 2. Scenic Viewshed
- 3. Developed Recreation

IV. Fish and Wildlife Habitat Enhancement
- 13. Riparian and Fish Habitat Emphasis (Intensities B, C, D)
- 14. Deer and Elk Winter Range w/Emphasis on Habitat Improvement
- 15. Mountain Goat Habitat (Intensity B)

V. Water Production
- 20 Municipal Watershed - Cedar River (City of Seattle)
- 21. Municipal Watershed - Green River (City of Tacoma)
- 22 Municipal Watershed - Sultan River (City of Everett)
- 23. Watershed - Other Municipal

VI Timber Production
- 17. Timber Production Emphasis - Investment Level

VII. Designated and Special Resource Areas
- 4 Mt Baker National Recreation Area
- 5. Wild and Scenic River - Potential
- 6. Skagit Wild and Scenic River
- 7. American Indian Religious and Cultural Use
- 8 Special Areas
- 10. Wilderness
- 18 Research Natural Areas
- 19. Mountain Hemlock Zone
- 27. Alpine Lakes Area

VIII. Developed Special Use Sites
- 25. Special Uses - Utilities
- 26. Administrative Sites

The underlying purpose for each category of prescription, major assumptions made, and economic and other criteria considered are described below.

Category I - Forest-wide Standards and Guidelines. Their purpose is two-fold. First, there are certain requirements, such as soil and water conservation, endangered species preservation, and harvesting timber only from suitable lands (with special exceptions), that are required to be considered throughout the Forest, no matter what prescription was being applied. The Forest-wide Standards and Guidelines document that direction in one place. Also, the Forest-wide Standards and Guidelines establish broad guidelines relating to goals and objectives for various types of management activities carried out on the Forest, relating them to the structure of National Budget Activity Codes for programming and budgeting. This is important to avoid redundancy, as a number of management prescriptions allow several different types of resource uses within one management area. For instance, recreation use (dispersed and/or developed) may occur in almost all management areas, not just those having "recreation" in the title.

The criteria for developing the Forest-wide Standards and Guidelines included whether broad laws and policies existed that would affect all Forest lands, and whether redundancy in the individual prescriptions could be reduced by using Forest-wide Standards and Guidelines instead.

Economic efficiency considerations are not as significant at this level as they are for specific prescriptions, as the Forest-wide Standards and Guidelines wae either too general to incorporate cost efficiency considerations, or they relate to constraints on actions required by law or policy. Constraints on activities generally tend to reduce direct cost efficiency, in the financial sense; however, the constraints are necessary to improve long run societal economic well-being. Cost efficiency considerations in applying the required constraints come into play more in the specific management prescriptions.

Category II - Management Requirements. This category includes those management prescriptions and intensities that are required to achieve basic resource protection as required by NFMA and further defined by the NFMA regulations and the Region 6 planning direction. Included are prescriptions required to maintain viable fish and wildlife populations, protect riparian zones, and conserve soil and water resources. (Management practices to assure diversity maintenance are built directly into the vegetation management prescriptions and intensities, or are governed by the Forest-wide Standards and Guidelines).

These prescriptions were developed in response to the requirements of NFMA and the Region 6 planning direction. The areas to which they are applied were determined in conjunction with Region 6 planning direction, such as the requirements for size and distribution of spotted owl habitat areas (SOHA's), and requirements for other wildlife habitat areas. Ranger District involvement and input from the Washington State Departments of Wildlife and Fisheries were also part of the process of determining the areas to which these prescriptions would be applied. (See Chapter VI, B.)

It was assumed for the wildlife management requirement prescriptions that no timber harvest could be allowed if the minimum required habitat areas only were assigned to these prescriptions. The limiting factor at the minimum is old growth for thermal cover and/or breeding habitat. Since minimum areas dedicated to preservation of the existing stands are used, no harvest is allowed.

For the riparian prescription, it was determined that adequate protection of Class I, II, and deeply incised Class III streams could be maintained while allowing some timber harvest. On the average, riparian areas will be managed at about a 160-year rotation. In reality, some areas will remain uncut, a larger portion will be managed at the extended rotation, and a small portion (generally at the outer edges of the riparian zone) may be managed at normal rotation. The exact pattern will depend on site-specific characteristics.

Though these prescriptions were designed to meet minimum constraints, they were still developed considering economic efficiency. The wildlife management requirement approaches were all analyzed to determine if it would be more cost efficient to use a minimum area dedicated to no timber harvest, or to use a larger area and manage it with a combination of extended harvest and a smaller dedicated core. For the Mt. Baker-Snoqualmie, the answer was to dedicate the areas to non-harvest (see Forest planning process records on file in the Supervisor's Office). The riparian management requirement intensity was developed so that a certain amount of timber harvest can take place, thus enhancing the economic return from the management of the area, while still meeting the required minimum protection for the riparian zone.

Category III - Recreation and Scenic Areas. These prescriptions were designed to manage areas specifically for either dispersed or developed recreation, or to provide a visually pleasing view to travellers from major road and trail corridors, particularly in the foreground areas.

The dispersed recreation management intensities provide opportunities for a variety of different recreation experience levels. No timber harvest is allowed by the dispersed primitive, semi-primitive nonmotorized, and semi-primitive motorized management intensities. An minimum rotation of 125 years is allowed by the roaded natural intensity. The first three provide for essentially undeveloped recreation opportunities, and are applied to unroaded lands, or lands with closed roads. The roaded natural intensity was designed to manage primarily for dispersed recreation that relies on roaded access; but harvest is limited and other development activities are secondary uses.

Intensities E and F were designed specifically for the No Action alternative (Alternative A). Intensity E was developed to model the remaining general dispersed recreation areas in the Alpine Resource and Upper Forest Resource Zones designated in the Ranger District Multiple Use Plans. Dispersed recreation, both non-roaded and roaded, are dominant practices in these areas. The resulting ROS can only be determined by mapping from the current direction land allocations. Intensity F was developed to reflect the original administrative designation of the 1926 Mt Baker Recreation Area. This Recreation Area had different boundaries than the one created by the Wilderness Bill of 1984. Intensity F is used only in Alternative A.

The developed recreation management intensities provide for management of various types of developed recreation sites. Campgrounds and ski areas have different management needs, and thus, different intensities.

The scenic viewshed prescription was developed in conjunction with the visual resource management handbook. The intensities allow for management meeting high visual quality standards in designated foreground and middleground areas in accordance with the visual management system. (Meeting visual quality standards for background areas is provided for in the Forest-wide standards and guidelines, and in standards and guidelines for individual prescriptions.

Background visual areas can be managed at normal rotation, with attention paid to size and shaping of harvest units where necessary to meet visual considerations.) The assumption was that this prescription would only need to be applied along travel corridors that go through areas otherwise under active timber management. The foreground is to be managed at approximately a 200-year rotation, using small harvest units. The middleground is to be managed on a minimum rotation of 100 years, if that intensity is applied. Allocation of lands to this prescription varies by alternative, depending on the alternative's objectives.

Economic efficiency considerations played a role primarily through the determination that the highest values for dispersed recreation activities would be accrued only if no timber harvest was allowed in those areas. Areas managed for road-oriented recreation, and areas managed to meet visual quality objectives, could allow some timber management at lower intensities and longer rotations, thus increasing the overall cost efficiency of the areas.

Category IV - Fish and Wildlife. The management prescriptions represent active management to enhance and improve habitat capability to support production of harvestable wildlife and fish. Timber harvest in the deer, elk, and mountain goat winter ranges is used to allow creation and maintenance of a desired seral stage mix in the habitat area, as well as to produce small amounts of timber. Cutting in small units creates a habitat mix of age classes so that, at any one time, there will be areas for forage production, hiding cover, and thermal cover. Timber harvest allows the manager to control the timing and spatial arrangement of these age classes to achieve the appropriate mix of areas.

Wildlife enhancement intensities can be applied to habitat appropriate for that use, as delineated in the resource base. In general, these prescriptions are applied to areas that incorporate, but are larger than, the minimum habitat areas managed under Category II prescriptions (see discussion above). When this is the case, the enhancement prescription is applied to the entire area, and the minimum habitat area becomes a part of the entire enhancement area, subject to management under the enhancement intensity.

Management intensities for fish specify varying levels of investment necessary to restore or enhance anadromous and resident fisheries habitat. The criteria for developing these intensities were the estimated investments required to restore original habitat, make existing potential habitat usable, and open up new habitat areas.

Economic considerations for the wildlife enhancement intensities consisted primarily of using commercial timber harvest (with associated costs and benefits) to accomplish the desired habitat improvements. For the fisheries intensities, it was assumed that the escapement allowed by downstream and ocean management would be sufficient to utilize the habitat made available under the application of the intensity chosen. The benefits of additional fish production to the Indian and non-Indian commercial and sport fisheries were calculated, along with Forest-wide costs for implementing habitat improvements.

Category V - Water Production. This set of prescriptions applies to the 18 "municipal" watersheds on the Forest. Some of the watersheds do not supply cities or towns, but supply lodges, campgrounds, summer home groups, etc. These prescriptions were developed to assure that the activities allowed within watersheds are compatible with production of potable water for domestic users.

The Cedar River prescription intensities reflect the current agreement and understanding between the Forest Service and the City of Seattle; modifying that agreement to allow the retention of old growth areas within the watershed for spotted owl habitat; examining the option of retaining ownership of the NF lands within the watershed, rather than exchanging them to the City of Seattle after they are harvested; and negotiating a new coop agreement with the City, while retaining existing land ownership and continuing to follow the existing Agreement until a new agreement is concluded.

This range of intensities reflects the range of management options identified by the ICO's for the Cedar River watershed. Logging with primarily natural regeneration is the silvicultural prescription for the watershed under the first two intensities, as the lands would be traded to the City after harvesting, requiring no more silvicultural activities. Also, in the first two intensities, no recreation would be allowed. The third intensity would manage the watershed essentially as normal National Forest System lands, with both timber harvest and recreation activities allowed, but with guidelines to protect the portability of the water. The fourth intensity would provide for management to continue as in the first intensity (with the exception of carrying out any more land exchanges) while a new agreement was being negotiated. Upon concluding a new agreement, the Forest Plan would be amended to incorporate the terms and direction of that agreement.

The Green River prescription intensities were developed to reflect the current agreement the Forest has with the City of Tacoma, and to examine the option of restricting recreation use in the watershed solely to controlled big game hunts and the Pacific Crest Trail. The goal in both instances is to provide a satisfactory and safe water supply to the City. These intensities reflect concerns arising during the watershed agreement negotiations during 1984-85.

The Sultan River prescription intensities came from the ICO's relating to the management of the Sultan River watershed. The options are: (1) close the watershed to all activity except water and hydro power production, with the end goal of trading out of the NF lands in the basin; (2) maintain the watershed in NF ownership with limited management activities, including some recreation use and some timber harvest (essentially the current management); and (3) open the watershed to a full range of management and uses. Again, production of water and water quality protection would be paramount.

The prescription for all other municipal, or domestic, watersheds has two intensities One would be a full management option; the other would prohibit timber harvest and limit recreational use.

Consideration of factors other than cost efficiency were generally more important in the development of the watershed prescriptions. The Cedar and Green River intensities represent different philosophies of how best to meet the needs of the municipal user for quality water and still make maximum use of the land. The Forest Service generally supports more use, particularly recreational, of the watersheds than do the cities. Negotiations on these points go back for many years with both cities. The Forest Service takes the view that the more use an area can tolerate while still meeting its basic objective, the higher the total value to society. The cities generally feel that increased use means increased need for costly water treatment facilities downstream. They have been traditionally more worried about recreational use than timber harvesting; they feel the human effects in watersheds can be more tightly controlled in a logging operation than in developed site or dispersed recreation use.

In the intensities allowing more use, timber harvest was considered a contributor to overall cost efficiency of watershed management, with recreation adding some. But the real criterion considered here was a look at options in levels of use.

Category VI - Timber Production. This category contains the prescription for full timber management, and the associated intensities representing differing investment levels available to achieve full timber management. The criterion for developing this prescription was normal rotation timber management. The criterion for development of the intensities was to lay out different possible silvicultural paths to achieve full-yield timber management. These paths represent different combinations of silvicultural activities (reforestation, precommercial thinning, and commercial thinning in various combinations) and their associated investment and return levels.

Cost efficiency was a major consideration in the development of this prescription, particularly in developing the intensities. The development of the timber management prescription and intensities is described fully in the next section (III E).

Category VII - Designated and Special Resource Areas. The purpose of this category is to provide management direction for the special resources and specially designated management areas on the Forest, such as wilderness and the Skagit Wild and Scenic River. The criterion for the development of each prescription within this category was the presence of an existing or proposed special area designation. Each prescription was developed on the basis of the management requirements that need to be specified for an area to protect the resource of interest, provide for compatible uses, and specify the intensity of those uses.

The mountain hemlock prescription was developed to apply to those lands in the predominantly mountain hemlock type that were deemed unsuitable for timber management because of regeneration problems, but about which little data exists. On the recommendation of the Forest Supervisor, the Regional Forester agreed that these lands would be set aside in a separate management area, if not needed to fill some other non-timber resource need. Experimental harvests and regeneration attempts will be made over the next decade, on a research basis, to determine if there are silvicultural means of overcoming the regeneration problems. If so, the lands will be returned to the tentatively suitable base in the next round of planning. If not, they will remain classified unsuitable and be available for land-use assignment on that basis.

In general, cost efficiency was not a real issue in the development of these prescriptions. A number of areas were already designated: wildernesses, research natural areas, Skagit Wild and Scenic River, and Mt. Baker National Recreation Area. The major economic consideration was to what extent timber harvest could be allowed in an area without compromising the values being protected; and, if allowed, at what intensity in order to remain compatible with the overall management intent for the area. The specific intensities allowed are defined in the standards and guidelines for each prescription.

Category VIII - Developed Special Use Sites. There are a large number of existing and proposed developed administrative sites, ranging from ranger and guard stations to powerline corridors and sites for location of electronic equipment (radio, TV, radar, etc.). This category of prescriptions was developed to provide management direction specifically for these sites. In general, these sites will be managed specifically as management areas, rather than being included within the umbrella of another management area such as municipal watershed or dispersed recreation.

The major assumptions for these prescriptions were that management activities in and around these sites would be quite limited, and that recreational use would range from limited to prohibited, depending on the nature of the site. (Some administrative sites will serve as visitor information sites.) Cost efficiency was not particularly a consideration for these prescriptions.

Summary Comments about Cost Efficiency. The role that cost efficiency played in the development of the management prescriptions has been described. In addition, cost efficiency was a criterion in developing alternatives (resulting in management areas) where management prescriptions are applied to the ground. For instance, while cost efficiency did not play any particular role in the development of Category VIII prescriptions, it would play a very major role in the application of Prescription 26 to identify a new utility corridor in a particular alternative. So while the initial development of a prescription might not have had much to do with cost efficiency, its application to the ground was another story. That part of the process will be covered more thoroughly in Chapter VII.

Another area of cost efficiency not receiving a great deal of attention in the prescription development process was that of budget or management cost. Only in developing the timber management intensities (17A-17H) were the costs of associated management practices explicitly considered (see the following section). Part of the reason is that many management prescriptions do not have a range of management practices available. Thus, the only range in costs would come when the decision was made to use, or not use, a particular management prescription. This showed up in the overall PNV of the alternative runs, which included the costs of management, as well as the benefits, resulting from application of any given management prescription.

3. Prescription Standard and Guideline Table.

Table B-10 shows the prescriptions and how they vary by selected activities. The prescriptions available in each alternative vary by the multiple-use objectives of that alternative Where a full range of timber management intensities is appropriate to meet the multiple-use objectives, the FORPLAN model had the option of choosing the combination of intensities that would meet the objective. In some cases a full range of timber management intensities was not appropriate to meet the objectives of the alternative and prescriptions were constrained. Refer to Appendix D and the Forest Plan.

Table B-10 Prescription Comparison by Selected Activities Page 1 of 3

Prescription	VQO	Timber Harvest	Roads	Land Ownership
1A	Preservation	No scheduled harvest	No new, existing closed	Group II, acquire
1B	Retention	No scheduled harvest	No new; existing closed	Group II, acquire
1C	Partial Retention	No scheduled harvest	No new;	Group II, acquire
1D	Partial Retention to modification	Scheduled; extended rotation	Existing; new may be constructed	Group III - available for exchange
2A	Retention	Scheduled; extended rotation	Existing; may be constructed	Group III - available for exchange

23B	Variable; retention to modification	No scheduled harvest	Construction limited	Group III - available for exchange
24	Variable; retention to modification	No scheduled harvest	New construction unlikely	Variable - little change likely
25A	Generally modification	No scheduled harvest	Permissible	Group III - available for exchange
25B	Variable	No scheduled harvest	Permissible	Group III - available for exchange
26	Variable; retention to modification	No scheduled harvest	Permissible	Group III
27	Varies according to Alpine Lakes Management Plan			

E. Development of Timber Options

1. Introduction

This section briefly reviews the criteria and process used to develop the analysis area yields for timber in tentatively suitable forest lands, and summarizes the development of FORPLAN timber prescriptions and their relationship to the management area prescriptions. Detailed documentation of development of both empirical and managed yield tables and intensities can be found in "Documentation of the Development of Managed and Empirical Yield Tables", September 1989 (revised), in the Forest Planning Records Yields for existing timber condition classes, as listed in part C above, that have poles and sawtimber are called "empirical yields" because they are based in part on continuous Forest inventory plots (inventoried two or more decades).

2. Overview of Process

Part D, above, described the 26 prescriptions and associated intensities which, in combination, identify management area prescriptions developed by the IDT to address the Forest's Planning ICO's. Sixteen of the 26 prescriptions (including 33 intensities) allow some degree of timber production. These were all carried in FORPLAN.

The silvicultural options that were developed for each of the management emphases are referred to as management intensities in FORPLAN. They reflect the different combinations of management practices and the different timing choices for implementing those practices. In essence, they represent alternative investments in levels of timber management to achieve the objectives of a management area.

Before continuing, a brief review of the criteria and process used in developing yields for timber in tentatively suitable lands will be presented.

How Timber Yield Tables Were Developed

1. Criteria

(a) Coordinated development and certification with the Olympic National Forest. Also coordinated with Region 6 Timber Management.

(b) Utilization Standards
  (1) 9" to 6" top existing stands.
  (2) 7" to 4" top - Existing Stands Precommercially or Commercially Thinned.
  (3) 7" to 4" top - regenerated stands.

(c) Made a deduction for "holes" (unstocked and nonstockable areas, defect and breakage).

(d) Develop Managed Yield Tables (MYT) for 3 basic evenaged management intensities plus modifications (23 intensity combinations were run in DFSIM 1/ by Mt. Baker-Snoqualmie, and the Olympic made many runs). Many trial runs were made and reviewed by IDT members before the 23 intensity combinations were selected. Two variables were PCT and CT ages.

(1) Cut-plant-cut
(2) Plus PCT
(3) Plus CT with entry cycles not less than 20 years and minimum CT entry 3,000 board feet per acre.
(4) Plus fertilization where determined feasible.
(5) Modify (2) and (3) by planting improved stock.
(6) Modify (3) to an extended rotation (200 years) for visual resource management.
(7) Use 3-year lag time between harvest and reforestation.

These criteria have not changed except a cut-natural-cut (natural-FH) and a cut-natural-PCT-cut (natural-PCT-FH) have been added; (1) was modified by planting genetically improved stock and (6) was developed with and without planting genetically improved stock.

After receiving comments on the DEIS and the production of managed yield tables, these same evenaged management intensities were used to develop yield tables using SPS.

(e) Modify yield table or scheduling to model other resource management objectives.

(f) Do not plan to CT stands unless they have been precommercially thinned (TSE may warrant CT in some stands).

(g) Do not CT stands if they are past culmination of mean annual increment (CMAI).

(h) Do not CT stands unless individual trees have crown ratios meeting or exceeding those prescribed in the Silvicultural Examination and Prescription Handbook. District Rangers have reported most stands that have not been precommercially thinned are overstocked, and crop trees do not meet the minimum 40% live crown ratio needed to respond to thinning in a reasonable period of time.

1/ Curtis, Robert O., Gary W. Clendenen, and Donald J. DeMars, A New Stand Simulation for Coast Douglas-fir: DFSIM User's Guide, USDA Forest Service General Technical Report PNW-128, May 1981.

(i) Stands receiving a CT should be expected to show a growth response to treatment. Condition class ages are one important aspect of the commercial thinning issue. Individual immature pole stands will be ages 72 and 79 in the South and North working groups, respectively, in 1995 (midpoint of the first Forest Plan decade). Immature small sawtimber stands will be age 101 in 1995. Combined pole/immature sawtimber empiricals in FORPLAN will be ages 78 and 91 in the South and North, respectively, in 1995. In addition to these ages, Chambers 8/ stated that the Washington State Department of Natural Resources, since about 1970, has recognized that commercial thinning in stands 40 years and older without prior silvicultural treatment will not produce a significant increase in usable wood.

(j) When conducting a CT in white woods, give priority to wetter plant associations. Research has shown that these plant associations are less susceptible to stem and root rots. 9/

(k) CT may be conducted in any stand that has a positive PNV over the rotation length. (Later DP-DFSIM runs indicated that commercial thinning is almost always uneconomical in and of itself on this Forest, resulting in a more negative PNV when added to the silvicultural regime for a rotation.)

The criteria enumerated in (g) through (k) above for commercial thinning were developed after the release of the DEIS and in response to public and internal comments. It is anticipated that the current stand structure on the Forest will allow for only a limited number of commercial thins in the first decade. Because of theis, the acres commercially thinned and the resulting contribution to ASQ are accounted for outside FORPLAN. There will be intensive monitoring of CT to ensure these guidelines are followed and adjustments made when conditions warrant.

(l) Use three working groups in planning unit.
(1) North Conifer
(2) South Conifer
(3) Mountain Hemlock Zone Conifer
(4) Hardwood-Conifer Mix

Number (3) above has been removed as a working group. In FORPLAN numbers (1) and (2) above are arranged in:
Level I - Timber Class/Developed Recreation/Miscellaneous
North - Mt Baker National Forest
South - Snoqualmie National Forest

Hardwood-Conifer Mix appears in FORPLAN in:
Level 4 - Working Group

8/ Chambers, Charles J., A Second Look at Thinning: The Effect of Thinning on Allowable Cut - The State Position, DNR Note No. 17, January 1977, Washington State Department of Natural Resources, Olympia, Washington.

9/ Symposium on Research and Management of Annosus Root Disease in Western North America, April, 1989.

The conifer-mix condition class occurs in both the North and South including about 10% of the total tentatively suitable acres. Volume make up in this existing condition class (Mix Conif.1; see Section III.C. above) includes approximately 70% conifer and 30% hardwood.

Upper and Principal used in Level 4 occur in both North and South and were used principally to value timber outputs from analysis areas.

(m) Develop the following empirical (existing timber) yield tables for exisitng working group timber condition classes:
  (1) Conifer Mature Large Sawtimber - north and south.
  (2) Conifer Mature Small Sawtimber - north and south.
  (3) Conifer Combined Pole and Immature Small Sawtimber - north and south.
  (4) Combined Pole and Sawtimber for north and south mixed conifer/hardwood.

In FORPLAN (1) and (2) above were combined in Inaccessible to represent mature large and small sawtimber yield. In (3) the separate pole and immature small sawtimber empiricals were combined to save model space.

(n) Use 1976 Timber Inventory Plot Data to develop empirical yield tables and to estimate mean productivity for working group managed yield tables.

(o) Empirical Yield Tables will be projected to begin in 1995 (midpoint plan decade 1).

(p) Yield of existing condition classes listed below and their future regenerated acres will be projected from the managed yield tables:
  (1) Conifer Seedlings and Saplings (Average 20 years old)
  (2) Conifer Reforestation (Average 10 years old)
  (3) Hardwood Reforestation, Seedlings, and Saplings

2 Managed Yield Tables Developed

(a) Hardwood - Used data from six inventory plots typed hardwood and developed a yield table (cut-plant-cut) using tables and equations reported by Charles J. Chambers of the Washington State Department of Natural Resources 10/.

10/ Chambers, Charles J. "Empirical Yield Tables for Predominantly Alder Stands in Western Washington," Washington Department of Natural Resources Report No. 31, September 1974.

(b) North and South Conifer - Methods and results of determining productivity are documented in Forest Planning Records. Briefly, the method involved using inventory plot site index 100 (total height at age 100) and published data to arrive at an average productivity (mean annual increment) for each the North and South working groups, and then arriving at a site index 50 (total height at age 50), which represents that average productivity within the yield simulator (DFSIM or SPS) model. The process included some adjustment for stocking. The deduction for "holes", defect, and breakages is 10%. Initially, many yield intensities were run using DFSIM as noted above.

Douglas-fir site index values were 95 and 79 North and South, respectively These were used in DFSIM For western hemlock and Pacific silver fir, Washington Department of Natural Resources Publication 22R was used to convert Barnes to Wiley, or Handley's equations to Wiley, for Pacific silver fir. This produced average site index values at age 50 for western hemlock and Pacific silver fir of 73 and 70 North and South, respectively. These values were used in SPS.

(c) Commercial Thinning Practice - The IDT developed detailed criteria for selection of timber stands that could be selected for CT. Briefly these criteria are:

(1) Plan CT only in stands accessible by road on suitable lands.
70% or greater Douglas-fir in stand is preferred
Candidate stand should not be past CMAI.
In true fir and hemlock stands, give priority to wetter plant associations.

(2) Stands meeting criteria (1) above can be commercially thinned:
In Slope Class A - about 98% is accessible by road;
In Slope Class B - about 94% is accessible by road;
In Slope Class C - about 70% is accessible by road.
Note: See description of Level 5, Slope and Stability Classes, in Section III.C. above.

(3) All stands meeting criteria (1) above can be CT'd if they are located not more than 300 feet above roads or 1200 feet below roads. The IDT analyzed the potential number of acres and stratification using only Douglas-fir stands meeting criteria for commerical thinning to determine the possible acreage. True fir and hemlock CT acres were considered to be small in number and were not evaluated in the FORPLAN model. These acres were handled outside the model and will be monitored for significance.

(4) Tentatively suitable analysis areas identified by Principal and Mixed Conifer in Level 4 - Working Group, described in Section III. C. above, were stratified where stands meeting the criteria for CT would be most likely to located.

(d) Fertilization Practice - Analysis determined that only about 2% of tentatively suitable acres may meet criteria and feasibility for this practice. Increase in LTSY would be insignificant, even if this practice were applied to all potential acres. These acres are scattered, which precludes contracts, or increases contracting costs, and they tend to be more in bottom lands, which could result in environmental conflict in or near streamside zones. The decision was made to permit fertilization practice, but not include yield intensities in FORPLAN.

(e) Genetically Improved Seedlings - Estimated genetic gain was stratified and calculated by Douglas-fir and western hemlock/Pacific silver fir on the North and South portions (Level 1 identifier) of the Forest, respectively. The average gains used are:

North Douglas-fir	+1%
North true fir/western hemlock	+1%
South Douglas-fir	+2%
South true fir/western hemlock	+2%

(f) DP-DFSIM 11/ - During the "Planning Pause" to review planning direction and standards, the Region 6 westside Forests were directed to use DP-DFSIM to develop managed yield intensities. DP-DFSIM is a computer program linking dynamic programming 12/, DFSIM, and FORPLAN. The dynamic programming makes a search among possible thinning patterns given an objective, a set of constraints, and an assumed investment level.

The biological relations expressed in the DFSIM computer model form the biological center of DP-DFSIM. The FORPLAN Version 2 approach to activities and outputs, costs, revenues, and some constraints is used.

Objective functions in the program are to maximize timber or present net worth in selecting the best thinning regime. The program calculates and reports detailed stand data, costs, present net worth, objective maximizing paths, and volume. An enhancement produces both cubic and Scribner board foot volume adjusted for "holes", defect, breakage, and genetic gain. All managed yield intensities were re-run in DP-DFSIM. Many intensity combinations were run (over 100 runs total) for those regimes which included intermediate thinning harvest(s) and the best intensity regime was selected. Commercial thinning is not cost efficient; no thinning occurred when the optional constraint "thinning must pay" was used in DP-DFSIM. However, in response to comments received after the DEIS, some commercial thinning will be scheduled in appropriate stands (see discussion in Part 1 of this section).

The SPS yield simulator was adopted for western hemlock and true fir stands after public comment on the DEIS was received and evaluated. There is no dynamic programming model similar to DP-DFSIM for SPS.

11/ Johnson, K. Norman, and Kathy E. Sleavin, DP-DFSIM--Overview and User's Guide, *USDA Forest Service, January 10, 1984 Unpublished Draft.*

12/ DOPT (Brodie et. al., 1979) The Model Brodie built for DFIT to express the dynamic programming algorithm was used and substantially modified.

However, as the growth patterns, costs and benefits are not grossly dissimilar, analysts relied on the results of the many original DP-DFSIM runs as guidance for efficient management intensity regimes to apply to the western hemlock/true fir stands with yield tables calculated from SPS.

(g) Criteria for Selecting FORPLAN Intensities in DP-DFSIM - The basic driving force in selection is due to the fact that Mt. Baker-Snoqualmie is a "deficit old growth" Forest. The basic objective is to obtain the most volume in the shortest rotation, so the long-term sustained yield can be reached sooner. Trade-offs are in terms of rotation ages and total volume - it is best to get a heavy early thinning volume and a short rotation. Criteria used are:

(1) Rotation Ages - Shortest rotation 95% CMAI and CMAI preferred.

(2) Volume - Most total volume in shortest rotation.
Select thinning with the greatest volume over 3,000 board feet per acre minimum, while meeting other criteria.

(3) Rotation MAI - Consider in conjunction with volume and PNW

(4) PNW - Consider cost per acre against volume difference between intensities. Maximum PNW may be the best due to the shorter rotation.

(5) DBH - Two intensities very similar, consider selecting one with the greatest rotation DBH Compared how intensities varied from a DBH of 17 inches.

(6) Percent Basal Area Removed in Thinning - Region 6 Standard is not more than 40%. The Forest guideline is not more than 35%, preferably about 30 to 33% removed.

(7) Feasibility - considered feasible to implement on-the-ground.

(8) Special - The extended rotation was designed for the visual management objectives of growing big trees
A maximizing regime with 3-thirty year interval thinnings was required.
A residual stand of about 50 TPA after the age 107 thinning harvest.
Largest stand DBH, considering other criteria.

(9) Judgement - There is no finite way to fully weight all criteria, so final selection is a judgement considering all criteria.

In the DP-DFSIM Natural-FH intensity simulation, volume in 1N and 1S intensities (see Table B-11) exceeded volume of empirical yield tables. It was assumed that a Natural-FH intensity would not exceed empirical volume projections for existing stands, so the volume was adjusted.

(h) Summary of Conifer Managed Yield Tables Selected for FORPLAN - Table B-11 lists results of pertinent DP DFSIM runs made. For intensities which include CT the results of DP DFSIM Maximizing Timber and PNW are shown and the regime selected based on the above criteria. Selected SPS runs are also shown.

The hardwood managed yield table applies to existing condition class Mx. Conf. 2 (mixed conifer reforestation and seeds and saps), and can be applied to any regenerated stand converted to hardwood. The conifer managed yield tables apply to existing condition classes - Seeds/Saps, Reforestation, and Inacc. 3 (Reforestation and Seeds/Saps on inaccessible lands) - and can be applied to any managed stands which result from the regeneration harvesting of existing conifer or mixed conifer-hardwood stands (Mx. Conif.1) The latter is termed conversion to pure conifer. Since Inacc 3 was predominantly in conifer types, the hardwood managed yield table could not be applied. (Refer to Chapter III, C for definition of Level 6 - Condition Class).

The hardwood management yield intensity was initially developed for the purpose of managing habitat for the ruffed grouse wildlife indicator species. This intensity was included in the model. Under Maximizing Timber or PNV objective functions, the FORPLAN program never selected this intensity in runs made. A constraint would be required for this intensity to be selected. Subsequently, ruffed grouse was dropped from the planning process as a wildlife indictator species; thus, *no hardwood management requirements were incorporated in the* alternatives or model.

The silvicultural prescriptions and their associated yield tables were developed based on the silvicultural characteristics of each working group.

3. *Empirical Yield Tables Developed*

For a discussion of the empirical yield tables developed, see "Unmanaged (Wild) Stands" in the next section (F), Part 3.

4. Scheduling Options Developed

Once the vegetative management objectives were identified for each management area (MA), the appropriate IDT members worked together to develop a range of harvest scheduling options. The overriding criterion in this process was that the silvicultural prescription and the associated yield table(s) achieve the vegetative management objectives for the MA. A range of scheduling timing choices, rotation ages, and investment levels were examined for each MA and, whenever possible, made available to the FORPLAN model.

It was necessary to reduce the number of prescriptions included in the FORPLAN model to keep it within feasible size limits. The process of running different yield intensities and selecting the most efficient ones has been briefly described above.

3. Range of Timber Management Options Considered

As discussed in part C of this chapter, analysis areas were delineated by six *level identifiers. Lands determined to be tentatively suitable for timber* management are defined through the following level identifiers·

Level 3 - Roading and Accessibility Condition
Roaded
Unroaded
Inaccessible

Level 4 - Working Group
- Upper
- Principal
- Mixed Conifer/hardwoods
- Inaccessible Types

Level 5 - Slope and Stability Classes
- Slope Class A
- Slope Class B
- Slope Class C

Level 6 - Condition (Age and Size) Class
- All Condition Classes

FORPLAN timber management prescriptions were developed for every combination of management emphasis and intensity which included scheduled timber harvest in tentatively suitable forested land. For any one prescription combination of management emphasis and management intensity, the model was also offered several timing choices on when to implement the prescription. Also for each management emphasis and AA combination which involved timber management options, the model allowed for an assignment to "Minimum Level-Suit. Lands" (Not Economic in Solution). This prescription was used as the final economic suitability test (36 CFR 219.14(c)(3) and 36 CFR 219.14 (d)). The latter is abbreviated "SM" in the Level 8, FORPLAN Management Intensities shown below:

Management Intensities	Intensity Abbreviation	Yield Simulator
Cedar River - Harvest/Minimal Plant - No Silv Followup	CD	SPS
Developed Rec Use	DV	N/A
Minimum Level - Suit. Lands (Not economic in solution)	SM	N/A
Minimum Level - Unsuit/Nonfor Lands In TM Emphases	UM	N/A
Minimum Level - Water In TM Emphases	WM	N/A
Natural Regen.-Final Harvest	NR	SPS
NR-PCT-Final Harvest	NI	SPS
Plant-CT-Final Harvest	CT	DFSIM
Plant-CT-Final Harvest (Conv. To Pure Conif.)	XC	DFSIM
Plant-Final Harvest	FH	SPS
Plant-Final Harvest (Conv. To Pure Conif.)	XF	SPS
Plant-Final Harvest (Conv. To Pure Hardwood)	YF	HW
Plant-Final Harvest (Conv.) DFSIM	2F	DFSIM
Plant-Final Harvest DFSIM	F2	DFSIM
Plant-PCT-CT-Final Harvest	PC	DFSIM
Plant-PCT-CT-Final Harvest (Conv. To Pure Conif.)	XB	DFSIM
Plant-PCT-CTX3-Final Harvest	EX	DFSIM
Plant-PCT-CTX3-Final Harvest (Conv. To Pure Conif)	XE	DFSIM
Plant-PCT-Final DFSIM	P2	DFSIM
Plant-PCT-Final Harvest	PT	SPS
Plant-PCT-Final Harvest (Conv) DFSIM	2P	DFSIM
Plant-PCT-Final Harvest (Conv. To Pure Conif.)	XP	SPS

FORPLAN could select from any of approximately 80,000 prescriptions/timing choices to meet the objective for a particular Plan alternative.

Cost Efficiency of Timber Management Intensities (Stage II Analysis)

Analysis of the individual management intensities has identified the intensity of harvest with the highest PNV for each major category of land as required by 36 CFR 219.14(b). The following table was taken from the Stage II FORPLAN Analysis, which was run between the DEIS and FEIS. This analysis includes the revised yield tables developed from both the SPS and DFSIM yield simulators. Overall moderate intensities produce the highest PNV. Principal working groups had the highest contribution while inaccessible lands always generated negative returns.

Yield Simulator	Productivity Class	Working Group	Intensity	PNV 1/ (M$/AC/150 years)
DFSIM	North	Inacc.	PL-PCT-FH	-.05
		Princ.	PL-PCT-FH	5.24

		Princ.	NR-PCT-FH	5.12
		Upper	NR-PCT-FH	4.44

1/ Includes value of existing stand plus value of the regenerated managed stand.

F. Development of Yield Coefficients

The term "yield coefficient" refers to a figure representing the amount of a management activity input or a physical or biological output per some unit, usually time, area, or other intermediate activity or output. For instance, a value of 4.5 acres of silvicultural exam for every acre of timber harvest is a yield coefficient. Similarly, yield coefficients might be 2.58 miles of new road construction per section (square mile), or a value of 0.02 tons of sediment per mile of new road construction per year. Timber volume of 8000 CF/AC comes closest to the original derivation of the term "yield coefficient" used in earlier timber scheduling optimization models such as Timber RAM.

Yield coefficients, as a whole, represent one of the most critical links in the FORPLAN model. They are the quantification of the input and output sides of the production functions embodied in the model. It is through the yield coefficients that the activity and output figures are generated, along with their associated costs and benefits. (Costs and benefits will be examined in detail in Chapter IV.) These figures (either physical/biological units, or dollars) are the basis for the solution of the linear program optimization algorithm.

Quantification of the yield coefficients was one of the most difficult and potentially controversial aspects of building the FORPLAN model. In many cases, they represent a first attempt at quantifying production functions which had been dealt with only in qualitative terms. Understanding what the numbers are and their origin is important for understanding the results of the benchmark and alternative runs. An overview of some of this material was given earlier in Part B fo this chapter. Further detail is provided below.

The length of the planning horizon - 150 years - required estimation of quantified coefficients over that time period Estimates past 10 or 20 years, 50 years at the very most, have confidence bounds that become almost infinitely wide That limitation was recognized, and a basic assumption was made that yield coefficients past the first 10 or 20 years really represented indices and trends, rather than absolute values, as they may be significantly off target in absolute terms by the year 2030. Since all alternatives were run with the same values, the relative differences among alternatives could be assessed, which was important for the decision-making process.

Since Forest Plans will be redone every 10-15 years, the absolute magnitudes of the estimated outputs and activities are really most important for the time period covered by the adopted Plan; i.e., the next 10-15 years. Past that, relative values had to suffice if any yield quantification was to be used.

This subsection details the development of the yield coefficients used in FORPLAN. It also discusses how other yield coefficients were developed and used in offline analyses, such as for tracking the effects of an alternative on wildlife habitat and associated populations. The organization follows that of Part B of this chapter. Then, other yield coefficients used in the model are described, plus coefficients used outside the model. This subsection concludes with explanations and notes on various modeling conventions and techniques that were used to accomplish the intent of the production functions and the purposes of the alternatives The reader will be referred to Part B for details already covered, and to Forest planning process records for complete information.

1. Analysis Areas

Coefficients for analysis areas are simply acres. The total acres for each AA were derived as described in detail in Part C of this chapter. The model generally operates on a "per acre" basis, hooking activity and output coefficients to each acre of an AA. Because AA's might be split among different management emphases, not all acres of an AA would necessarily get the same activities and outputs associated with them. In total, the model would not count more acres of an AA than existed in the control total given (see Table B-6)

2. Allocation Zones

There are 86 allocation zones (AZ's) defined for the Forest. As discussed earlier, these are spatially contiguous, but resource heterogeneous areas. In gross form, outputs and activities applied to allocation zones are carried in number of units per area. For instance, AZ04 may have 1.6 miles of new arterial and collector roads slated for construction in Decade 1 for the entire area; and, there may be 5085 acres of semi-primitive nonmotorized ROS acres, yielding a potential of 2949 RVD's annually in Decade 1. (Although these coefficients are gross numbers per area, FORPLAN actually carries them as a per-acre equivalent: one acre is calculated as a percent of the entire zone, and that percentage of the zone yield is carried in the model).

3. Timber Yield Coefficients

More data were available from which to calculate timber yield coefficients than for any other output, though even that data base was not complete. A number of assumptions and adjustments had to be made to get a full set of yield estimates ranging over 200 years.

As described in Part B, timber yield coefficients were developed from two primary sources. The yields for existing, unmanaged (wild) stands were developed from the 1976 National Forest Inventory (NFI) data for the Forest. The yields for existing managed stands (identified in FORPLAN as Reforestation and Seeds and Saps under Level 6) and for regenerated managed stands (those stands reestablished after harvest of an existing stand) were developed from the Douglas-fir yield simulator (DFSIM) for Douglas-fir, and from the Stand Projection System (SPS) for western hemlock and Pacific silver fir. The final regenerated stand yields used in FORPLAN for Douglas-fir were derived from DFSIM after the cost-efficiency determinations using DP-DFSIM for each timber management intensity were made (see part E of this chapter). DP-DFSIM runs specified timing of thinnings, basal area removal, rotation length, etc. These factors were fed back into DFSIM to develop the final managed stand yield tables. SPS was used to develop final regenerated sand yields for western hemlock and Pacific silver fir, with the intensities and regimes chosen based on the initial analyses done with DP-DFSIM.

As mentioned earlier in this section, DFSIM was used for Douglas-fir portions of the working groups (which are only about 45% at a maximum of any of the working groups). SPS was used for the western hemlock and Pacific silver fir portions of the working groups. And hardwood yield tables were developed based on the empirical yield data for predominantly alder stands in Western Washington 13/.

13/ Chambers, Charles J. "Empirical Yield Tables for Predominantly Alder Stands in Western Washington," Washington Department of Natural Resources Report No. 31, September 1974.

Unmanaged (Wild) Stands. Empirically-based yield tables were developed from the 1976 NFI inventory data using stand average diameter, existing basal area, and growth (estimated mean annual increment) as factors to estimate future growth, diameters, and volumes per acre. Yields were originally developed for poles, immature small sawtimber, small sawtimber, large sawtimber, and mixed conifer/hardwood stands, according to statistical groupings done from the NFI data. These groupings were the basis for delineation of the Level 6 working group identifiers. Poles and immature small sawtimber were later combined into one class. Also, because of small sample size, poles, small sawtimber and large sawtimber were grouped together in the mixed conifer type; and small and large sawtimber were grouped in the inaccessible areas.

To develop the most accurate yield picture, NFI plots were used in developing yield tables only if they fell in lands determined to be tentatively suitable. Plots in wilderness (pre-1984 Washington Wilderness Act) and in the portion of the mountain hemlock zone classified as unsuitable were not used in development of empirical yield tables.

The FORPLAN yields are taken by the model at the midpoint of each decade (period) in the model. The first model period is calculated as 1990-1999, so the empirical timber yield coefficients for Decade 1 have to reflect expected diameters and volumes as of 1995. The initial empirical yield tables were developed for the next 200+ years, based on the 1976 NFI data as the starting point. From these tables, the existing stand yields for FORPLAN were calculated using the estimated diameters and volumes from the empiricals as of 1995, and every 10 years thereafter, for 210 years (the model allows a maximum of 20 periods of yield data). This adjustment allowed the model to reflect more accurately the expected diameters and volumes available for tracking harvest, inventory, and growth. One other adjustment had to be made when developing the empirical yields; the yield model tended to overstate the growth rate for large sawtimber, so the yield model was run with a cap on the basal area of these stands, allowing some increase in average stand diameter, but only minimal increases in stand volumes in that condition class.

Managed Stands. The process of developing managed stand prescriptions using DP-DFSIM model was described earlier. One major adjustment made to managed stand yields was to slow down growth rates after the first 100 years, as it is known that DFSIM has a tendency to overestimate growth and yields after 100 years. In consultation with the Regional Office, it was agreed that the forecast yields from DFSIM would be reduced by 1% per decade after age 100, e.g. 1% at age 110, 2% in year 120, etc. SPS-generated yield tables were also reduced by 1% per decade after year 100.

Another major adjustment made to the managed stand timber yield tables was deduction of volume from the DFSIM yields for "holes," defect, and breakage not accounted for in DFSIM. This deduction was 10% across the Forest in the Douglas-fir yield tables, based on work by Meyer 14/. The adjustment for SPS yield tables was only 2% for "holes," defect and breakage. (See "Documentation of the Development of Managed and Empirical Yield Tables," September 1989, in the Forest's Planning Records for additional detail.)

14/ Meyer, Walter H., "Relation Between Actual and Normal Yields of Immature Douglas-fir Forest."

A third major adjustment to the yield tables incorporated predicted planting of genetically improved stock in harvested units. Originally, the model was given the choice of planting genetic or natural stock. This choice doubled the number of management intensities, but left the model choosing almost all genetic stock. The slightly increased planting costs did not outweigh the additional value from estimated faster growth over the rotation, especially since the basic costs of the genetics program and seed orchards were carried separately as a lump sum cost per period. Therefore, the natural stock option was abandoned, and increased growth from genetic stock was incorporated into all the yield tables.

The Regional Office, Forest silviculturist, and geneticist agreed on a 20-year schedule for incorporating genetic stock into the planting program. The Forest silviculturist calculated a program-average factor for increased growth of 1% for all North species and 2% for all South species. These average genetic gain factors were acceptable to the Regional Office. Though this may seem low compared to some gains for genetic stock, it represents the fact that not all planted stock will be of genetically improved material until 20 years out, and that improved stock may not necessarily provide the high additional growth experienced on higher site lands or in the Southeast.

Table B-12 shows the volume adjustments for DFSIM and SPS model yields.

Table B-12
Summary of Adjustments for Holes, Cull, Breakage, Age Over 100 Years and Genetics for DF-North/South for Artificially Regenerated Stands

Age Class	Age Factor	Cull Breakage Holes	Genetic Gain	Weighted Adjustment

Adjustments Made to Timber Yield Coefficients for Modeling Purposes. In addition to adjustments discussed above, two other adjustments were made to all the yield tables, both unmanaged and managed. The first dealt with acres of land put into roads as new permanent system roads are constructed; those acres will be unavailable for future timber growth and harvest once roads are built. The second adjustment was made to account for large trees maintained within area subject to harvest to provide habitat for cavity nesting wildlife.

a. Adjustments for Roads

There are an estimated 13,700 acres of tentatively suitable lands currently occupied by roads, and not available for other activities. Because of their linear nature, existing roads are not tracked in the R2MAP data layers Thus, when allocation choices were mapped into R2MAP, the number of acres actually available for timber management were overstated. This overstatement was dealt with by reallocating 3.5% of the acres in "Roaded" analysis areas (all of which are tentatively suitable) to a separate management emphasis, Suitable Nonproductive in Roads, which was a minimum level management emphasis. This process assigned approximately 13,700 acres to the management emphasis for existing roads in all alternatives.

The FORPLAN model employs a "Model 1" formulation. In Model 1, compared to a Model 2 formulation, it is not possible to reassign a management emphasis or intensity to a land area once an initial assignment has been made. For instance, it is not possible to tell the model to assign a timber management prescription to an area until after the first harvest, and then change the prescription to a wildlife habitat improvement area.

The Model 1 limitations created a problem regarding lands that would be taken out of the timber base as new roads were constructed. If some reductions were not made, hundreds of miles of new roads would be "built", taking up several thousand acres of suitable lands in the process, but FORPLAN would go along attributing timber growth and harvest to acres covered by gravel and asphalt.

The solution to this problem was to make adjustments in the timber yield tables to approximate the acres of land taken out of production by the construction of new roads. It was estimated that when full roading is achieved, approximately 4.5% of the Forest's tentatively suitable acres will be in roads. Since it was not possible to shift additional acres out of the base to the "Suitable - Nonproductive" category after the initial management emphasis assignments were made, the IDT chose to proxy the decrease in available lands for timber growth and harvest after roads were constructed by reducing the timber yields for regenerated stands. This required three different splits in the yield tables, according to the existing and future roading status.

As mentioned above, all "Roaded" analysis areas had 3.5% of their acres assigned to the "Suitable - Nonproductive" management emphasis during the development of the CAC data base. Therefore, in the yield tables for regenerated stands on these analysis areas, it was only necessary to reduce the yields by 1% to proxy the full reduction in yields required to reflect the fully roaded status.

"Unroaded" analysis areas had no reductions in acres. It was assumed that these lands would yield full timber volumes from the existing stands in the initial harvest, as logs cut from roadbeds being constructed would be sold along with the logs harvested from the rest of the area. However, once the roads were built, there would be no timber grown back on them Therefore, the fully roaded status was reflected in the timber yield tables for the "Unroaded" analysis areas by making a 4.5% reduction in the regenerated stand yields.

Finally, acres or timber yields for the "Inaccessible" analysis areas were not reduced; these areas are currently unroaded. By definition, no roads will be built in them, therefore, no volumes will be lost from future harvest. (Any apparent advantage this gives the "Inaccessible" AA's over other AA's in the model in terms of timber yields and benefits is offset by the significantly higher cost in harvesting those areas, as only aerial systems are allowed).

b. Adjustments for Cavity Excavators

Primary cavity excavators are a management indicator species (actually a group of species) fror this Forest. These animals require snags, both live and dead, as their habitat. NFMA and implementing regulations require maintenance of habitat to provide for viable populations of the management indicator species. A "viable" population of cavity excavators was determined by the wildlife biologists to be 20% of the maximum potential population for the Forest. To maintain sufficient numbers of live and dead snags to support this 20% population, it was estimated that 1.5% of the net green volume per acre from timber harvest operations would have to be left unharvested. Therefore, the minimum cavity excavator requirements were modeled by reducing all yield table volumes, for both wild and managed stands, by 1.5%.

Several alternatives examined providing cavity excavator habitat for populations above the 20% level. Alternatives A, H and J provide for 40% of potential maximum population levels; Alternative C examines a 60% level. For each of these alternatives, timber yields were reduced by 1.5% for each 20% increment in the cavity excavator population levels.

c. Summary of Yield Table Adjustments

Reduction for each 20% potential population of cavity excavators managed for in an alternative (Taken from all yield tables, wild and managed)	1.5%
Reduction for suitable lands actually in roads (Taken only from regenerated stand yield tables)	
"Roaded" Analysis Areas	1.0%
"Unroaded" Analysis Areas	4.5%
"Inaccessible" Analysis Areas	0.0%

d. Timber Yield Table Examples

Table B-13 shows the final empirical yield table for mature sawtimber on the North part of the Forest, after all the adjustments described above were made. This table is for an alternative that manages for 40% of maximum potential population for cavity excavators. The beginning stand age is 240 years. The first two lines of numbers in the table are the volumes per acre in thousand cubic feet. Each number, beginning in the second column, is the MCF that would be harvested from one acre of land at the midpoint of the decade. Thus, if the FORPLAN solution calls for 5000 acres of North Mature Sawtimber to be harvested in Decade 1, the model would report that 40,750 MCF of timber would be harvested in Decade 1 from those acres; this would be a total for the period. An average annual output can be derived by dividing the period total by 10. (E.g., 8.15 MCF/ac x 5000 ac = 40,750 MCF/dec.; 40,750/10 = 4,075 MCF/yr.)

The third and fourth lines of numbers show the average stand diameter (quadratic mean diameter) for each of 20 decades. Lines 5 and 6 show the basal area per acre for each decade. The basal area cap on mature sawtimber mentioned above can be seen here: 295 square feet per acre.

The last two lines of numbers (zeroes in this example) are counters used in the yield tables to indicate whether in any given decade a stand is: younger than minimal utilization standards would allow, meets minimum utilization standards but is below 95% culmination of mean annual increment (CMAI); at or above 95% CMAI, but below 100% CMAI, or is at or above 100% CMAI. These markers are numbered 3, 2, 1, and 0, respectively. The zeroes in Table B-13 indicate that the mature sawtimber stands are above 100% CMAI in all decades.

Table B-14 shows an example of a managed yield table built from DFSIM for Douglas-fir on the North end of the Forest. The table is for an intensity that plants, precommercial thins, takes a commercial thin in Decade 5, and then can final harvest anytime from the eighth decade on, given the requirement of achieving at least 95% CMAI. If final harvest is permitted at utilization standards (e g., in a departure alternative), as indicated by the "2 " in row RZ1 of the table, then final harvest could occur anytime from Decade 3 on. The lines are read the same as for the unmanaged stand yield table. The extra rows beginning with "J" in the commercial thin tables are the volumes, diameters, and basal areas of the thinning volumes only; the final harvest values are in the "R" rows below them.

The rest of the timber yield tables used can be found in the FORPLAN data set or the Forest Planning records. More specifics on reading the other codes in the tables can be found in the FORPLAN Version 2 User's Guide and by consulting with the Forest Planning staff.

4. Road Construction Coefficients

The process used to model roads and develop road construction coefficients has been described in section B of this chapter. Road construction coefficients are used two different places in FORPLAN. The miles of arterials, collectors, and locals to be constructed for an allocation zone are shown as miles per AZ by time period, and are found in the AZ (coordinated allocation choice) yield tables; they vary by alternative. Miles of local roads to be constructed per acre of timber harvested are shown as miles of road per acre in the activity/output relationships (composite yields) section of FORPLAN

All of the arterial and collector roads to be built were modeled on a zone basis. As soon as the model schedules the zone for implementation (which would be either in Decade 1 or 2 under the modeling strategy used), the model shows the miles of arterial and collector roads constructed by decade, as laid out in the yield tables. The model "builds" these roads, whether or not it schedules any other activity in the area. This follows the intent of the Forest Management Team to finish developing the arterial and collector road system in the next two to three decades. Those roads will be used not only for timber access, but also for recreation, administration, and other resource access use.

As described earlier, the local road modeling was split so that some local roads would be built on a zone basis, and some on a per acre basis. The purpose of this was to avoid the inaccuracies of either having all of the roads built strictly in response to each acre of timber harvested, or of having them all built strictly on a zone basis. The former strategy leads to an underestimate of the actual rate of road construction in the earlier decade of the planning horizon, particularly for currently unroaded areas, because it does not reflect the additional roading required to spread out harvest units to meet dispersion constraints and silvicultural guidelines. The latter strategy can overestimate the amount of road building in the earlier decades, because, when modeled on a zone basis, the roads are built when an AZ is implemented. They will be built even if the model chooses not to schedule timber harvest from those acres until later in the planning horizon. This can result in a situation of having local roads built for two or three decades before the timber is actually scheduled for harvest from those zones. This is not realistic for the local road system, which is built primarily to service timber harvest activities and future silvicultural practices.

The modeling strategy for local road construction attempts to reflect the need for local roads to be constructed proportionately faster than harvest would take place, while still maintaining a degree of responsiveness as to when harvest actually was scheduled. The "advance" roads show as "fixed locals" in the zone yield tables, while the road construction tied to harvest acres shows up in the composite yields section (dependency functions) as a time dependent per-acre activity.

If an AZ is less than 50% roaded currently, a portion of the total local roads to be built are scheduled to be built on a zone basis. These roads reflect the additional roads required to spread out harvest units. They would be built independently, and in addition to, roads built on a per acre of timber harvest basis. If an AZ is more than 50% roaded, all the roads would be built on a per acre of timber harvest basis. It was assumed that there are sufficient roads in the area (on the average) to allow dispersing the harvest units, so roads could be built at a rate tied solely to the acres of timber being harvested.

The local roads needed to reach the estimated density of 4.44 miles per section for full management were calculated on a zone by zone basis for each allocation choice, taking into account the existing road system, planned new arterial and collector roads, acres subject to timber harvest, and roaded versus unroaded acres. After making calculations to determine how many (if any) miles of local roads would be built on a zone basis, this figure was subtracted from the total miles of locals to be built for the zone, and the net local roads figure was converted to a per acre coefficient reflecting the acres in the zone subject to timber harvest. Therefore, every zone could have a different per acre coefficient for local road construction.

Because of the design of FORPLAN, the only way to carry each of the per acre coefficients through to the timber management emphases assigned to that zone would have been to have a differently coded timber management emphasis for each zone. The 85 additional management emphases would be far too many to deal with in terms of model size; therefore, four timber management-road class emphases (Level 7 identifiers) were created to reflect the one timber management prescription that uses ground-based harvest systems. (The aerial systems timber management emphasis was retained as originally developed).

As the road data were being developed for each alternative, the resulting per acre coefficients for each zone were grouped into four categories. This was done by hand, taking into account major breaking points in the spread, as well as harvest acres involved. These grouped coefficients were then run through a program to calculate weighted averages for each group, the weight being the number of acres in each zone subject to timber harvest. A weighted average for the entire set was also calculated. The timber harvest prescription for each zone for a given allocation choice was then assigned to one of the four timber management-road class emphases; G1 being the lowest coefficient per acre, and G4 being the highest. As the allocation choice track file data were processed further into the CAC files for FORPLAN, the timber management prescription assignments, which came out of R2MAP as one code, were translated into the appropriate timber management-road class emphasis by reference to the grouping discussed above. For instance, the zones with per acre road coefficients falling between 0.0 and 0.65 miles/section (0.0 and 0.00102 miles/acre) would be assigned timber management emphasis G1; those from 0.65 to 0.89 miles/section (0.00103 to 0.00139 miles/acre) would be assigned G2; etc. This scheme allowed the model to reflect at the zone level the appropriate level of local road construction tied directly to timber harvest activity.

In summary, the process for modeling local roads reflects the need to have some roads built proportionately faster than timber harvest was scheduled, in order to achieve harvest unit dispersion and meet silvicultural guidelines. At the same time, it allows a good portion of the local road construction to occur at the time when harvest is actually scheduled to take place. In addition, the local roads to be constructed in conjunction with timber harvest reflect fairly closely the calculated requirements for a specific zone, through the use of weighted average coefficients for a group of zones.

Management emphases other than full timber management which still involve timber harvest, such as Scenic Viewshed or Enhanced Deer and Elk Winter Range, were assigned the weighted average local road construction coefficient for all zones. It was felt the increase in numbers of management emphases required to carry each harvest-related prescription as four management emphases in the model did not increase precision enough to warrant the increase in model size.

5. Recreation Capacity

The recreation capacity coefficient required a great deal of attention and modeling effort. Recreation capacity is the estimated capability of a land area to support a given recreation experience level, generally expressed in terms of Recreation Visitor Days (RVD's) per acre per year. The criteria used to assist estimating recreation capacity were from the Recreation Opportunity Spectrum handbook (1986) as modified by Regional direction and adjustments by Forest recreation specialists to meet specific land and resource conditions on the Forest.

Dispersed Recreation. Recreation capacity was modeled in two steps. First, the acres of each ROS type, both wilderness and nonwilderness, were mapped. This was done by the Planning Team's recreation specialist, using the appropriate ROS criteria and management area prescriptions, standards and guidelines in conjunction with the alternative maps. The approach used was to map the ROS classifications as they would exist after major adjustments in land management had taken place, such as roading and harvesting currently unroaded areas. This was termed the "resulting ROS".

This information was input to R2MAP and overlaid with the AZ's, giving a track file of acres of ROS by AZ for the alternative. The track file of ROS acres was run through a program which read the information, read another file with the existing (current situation) ROS acres, and wrote out zone yield files showing the movement over time from the existing situation ROS to the resulting ROS, in terms of acres by ROS classification for each period.

The change in ROS from the existing situation to the resulting ROS was predicated on an estimate of how fast the land and resource changes governing the delineation of the ROS classes would take place. These changes are affected primarily by road construction and timber harvest. It was estimated that critical changes in terms of roads constructed and areas harvested would take place for nonwilderness AZ's over the first three decades following implementation of the allocation zone, so that by Decade 4, the ultimate ROS configuration would be reached. The zone yields for nonwilderness ROS acres were assumed to move from existing to resulting ROS by 40% in Decade 1, 30% in the second, and 30% in the third. These changes were adjusted to the midpoint of the decade, so the ultimate ROS was reached by the midpoint of Decade 4.

In wildernesses, trail location was the controlling factor for most of the WROS delineations. It was estimated that the majority of the trails affecting WROS determination would be built late in Decade 1. The full change appeared by the midpoint of the second decade.

The second step in modeling ROS capacity was connecting acres of ROS for wilderness and nonwilderness areas to RVD's. This was done by the capacity coefficients (RVD's/acre/year) discussed below. These coefficients were located in the composite yields section of the model. The model read the ROS acres from the zone yield files and applied the RVD coefficients to them to get total RVD's.

a. Wilderness Capacity

The original estimates for wilderness use and capacity were made based on a process developed by Forest recreation specialists. However, by the second AMS effort, a separate definition of wilderness ROS had been made, and the ROS capacity estimates were revised accordingly. Because WROS was new, estimates of capacity by ROS class were made primarily by the best judgments of wilderness and recreation specialists on the Forest and in the Region. Both social criteria (party size, encounters per day, etc.) and resource criteria (vegetation impact, soil erosion, etc.) were used in estimating capacity. These WROS capacity estimates were used in FORPLAN:

Wilderness ROS Class	RVD's/acre/year
Transition	15.0
Trailed	4.0
General Trailless	0.25
Dedicated Trailless	0.078
Special	1.0

All of the figures are relatively untried estimates, and will be subject to revision over time with refined data and experience. However, when multiplied by acres in each area, the coefficients approximate the estimated total wilderness capacity for the Forest. The General Trailless capacity figure is very small since it reflects a large area of land, much of which is actually unusable for recreation, other than as "seen area" from travel routes. The Dedicated Trailless capacity figure is smaller yet, reflecting a high degree of solitude (relatively few users) over a large area. The same capacity coefficients were used for all eight wildernesses, even though there are undoubtedly characteristics related to each area that would change the actual figures somewhat from those shown here. However, there is neither sufficient research nor data at this point to make those refinements.

b. Nonwilderness Capacity

The original capacity coefficient estimates for nonwilderness dispersed recreation were revised somewhat for the second AMS and the alternatives. Adjustments were made for some errors and for significant shifts in methodological approach. As mentioned in section B, the recreation capacities show the estimated RVD's per acre per year of a given recreation experience level that different Forest lands can be expected to support. The criteria for developing these estimates were taken and used as guidelines from the ROS Handbook. The following coefficients were used in FORPLAN.

Nonwilderness ROS Class	RVD's/acre/year
Rural Dispersed	7.23
Roaded Natural	3.60
Roaded Modified	3.08
Semi-primitive Motorized	3.45
Semi-primitive Nonmotorized	0 58
Primitive	0 08

These coefficients vary somewhat from those used in the AMS benchmark runs because of additional refinements made after the benchmark runs were complete.

c. Winter Dispersed Recreation

Winter dispersed recreation ROS was not mapped in detail for this analysis. At present, there is too little information to do detailed modeling. Total winter dispersed recreation capacity estimates were developed for the Forest by the District and Supervisor Office recreation specialists. These estimates were not expected to change significantly from alternative to alternative. Therefore, the total capacity by decade was put in an AA yield table, and was brought into the model on a one-acre AA, as described in section C of this chapter. Total estimated annual capacity Forest-wide for winter dispersed recreation was about 250,000 RVD's annually. This included both motorized and nonmotorized dispersed winter recreation activities (snowmobiling and cross country skiing).

Developed Recreation. Developed recreation capacity was dealt with directly through the AA yield tables in the same manner as winter dispersed recreation. A one-acre AA was used to carry the developed recreation, although the developed site recreation AA's that were developed later could have been used for the same purpose.

Developed recreation capacity figures were estimated by the Forest's recreation specialists based on practical, capacity for all existing sites, including those currently closed for budgetary purposes. Three categories were designated: campground and picnic sites, developed ski areas, and other developed recreation sites (organized group camps and recreation residences). Following the conventional approach to measuring developed site recreation capacity, the estimates were made in annual Persons-At-One-Time Days (PAOT-DAYS). This measure is the practical capacity of a site in PAOT's times the average length of the annual use season in days. The estimates were also made in RVD's to facilitate comparison of capacity with use, which is modeled in RVD's.

The capacity figures for developed recreation were built directly into AA yield tables and brought into the model on a one-acre analysis area. The estimated developed site recreation capacities for existing sites were:

Campgrounds and Picnic Areas	633,300 RVD's per year
Developed Ski Areas	3,436,300 RVD's per year
Org. Camps, Rec. Residences, Other	1,051,000 RVD's per year

6. Recreation Use ("Demand")

An overview of how recreation use or "demand" figures were derived and incorporated into the model was discussed above, in part B Additional details concerning the actual equations used and intermediate steps taken to arrive at the final numbers used in FORPLAN can be found in the AMS document (May, 1985) and in the Forest planning process records.

There are three major limitations in the reliability of the projected use data. First, regional per capita income was not included along with population as an explanatory variable in the regression equations. The specification of the regression equations would have been somewhat better if income had been included. However, this variable has been used with mixed results nationwide. In the RPA documents, per capita income was found to have a significant explanatory effect on the variations in recreation use over time. However, some central Sierra National Forests in California did not find that correlation. It is possible that per capita income would be a stronger explanatory variable in densely populated areas such as the Puget Sound region, than in more sparsely populated areas, but that hypothesis has not been tested.

Second, use data were projected for recreation activity types and then had to be converted to ROS. The Recreation Information Management System was not tracking recreation data by ROS until 1981, the year after the end of the historical data period used.

Third, the 1984 Wilderness Act required changes in acres of wilderness. The data projections were based on historical data that included only Glacier Peak and Alpine Lakes Wildernesses. Adjustments based on best estimates of the recreation staff were made to increase total projected wilderness use and to reduce the nonwilderness use projections accordingly. Additional assessment and adjustments between wilderness and nonwilderness use projections were made between publication of the DEIS and the FEIS. It appeared that the original projection of wilderness use related to the new wilderness areas was about 100,00 RVD's low.

The final limitation: any projections of human use of anything over a 50-year time span are unquestionably shaky. The figures should only be considered in relative terms, more as indices with which to help compare alternatives than as real numbers in and of themselves.

It should be noted that the manner in which the recreation use projections were dore imparted an implicit bias in favor of current land use patterns on the Forest, and in favor of current tastes and preferences of the Puget Sound population. This is not necessarily bad. It helps to keep the use (demand) projections from being pulled along by the supply side. As timber is harvested and lands are roaded, the recreation supply on the Forest outside wilderness is going to convert quite rapidly from unroaded to roaded recreation. The manner in which the projections were done continues to display a recreationist interest in unroaded recreation, even if the supply is dwindling. Some earlier modeling efforts on other Forests inadvertently applied the old economic principle called "Say's Law" that was once espoused by many. Say's Law simply says that supply creates its own demand. In those other modeling efforts, it was assumed that because roaded recreation capacity increased as timber harvest and road building progressed, so would demand for roaded recreation increase. Conversely, as the unroaded recreation capacity decreased, so would demand for unroaded recreation. On this Forest, that assumption was avoided with our recreation modeling approach

The projected use figures by ROS category are shown below for the first five decades. To minimize compounding errors, projected use was leveled out from the sixth decade through the rest of the planning horizon.

Thousand RVD's Annually

Recreation Class	Decade 1	Decade 2	Decade 3	Decade 4	Decade 5
Rural Developed	3149.0	4275.9	4939.5	6240.4	7464.1
Rural Dispersed	489.1	635 3	790.2	933.1	1077.6
Roaded Natural/Modified	1935 0	2517.1	3116.6	3693.3	4273.5
Semi-primitive Motorized	44.4	57.6	71.1	84.6	97.7
Semi-primitive Nonmotorized	342 5	445.5	551 1	653.0	755.7
Primitive	12.3	16 1	20.0	23.8	27.5
Wilderness (all classes)	407.5	539.5	671.4	802.8	933.9

Two-step demand curves were built to keep the model from valuing recreation capacity in a given ROS class that was in excess of the estimated use in that decade The figures above were input as the first step of the two-step demand curve, along with weighted average values of the recreation activity types (hunting, fishing, general dispersed, etc.) making up that class, based on historical use patterns. The second step of the demand curve for each class was set at a very large (maximum) width with a value of zero attached.

The theory behind use of the demand curves was that the model would fill the demand step with RVD's of capacity from that ROS class, valuing them up to the point that they completely filled the first step of the demand curve. The rest of the RVD's of capacity would be zero valued.

The FORPLAN demand curve "quality differentials" option was used. With quality differentials, the model carries a base benefit value input with the demand curves for all RVD's up to the point that the demand step is filled. (This value was the activity type weighted average benefit value referred to above). The model then calculates a "quality differential," which is the difference between the base value in the demand curve section and the economic value by ROS/activity type. The latter value is found in the common economics section

This quality differential is carried in the objective function coefficients for all capacity RVD's, regardless of the demand curves. The hope is that the quality differentials, which are both positive and negative around the base value, depending on activity type, will generally sum to zero so that the objective function will not be particularly affected, either positively or negatively. Indications were that this formulation was consistently affecting the objective function of the runs by 1% to 1-1/2%, well within the overall error bounds of the value estimates.

The demand section of FORPLAN had little close examination until early 1986 Earlier in the process, there was poor understanding of the way the model filled the demand steps with different types of recreation, and how that affected the overall objective function and model solution. However, because the model formulation carried acres of ROS as the yields and split activity-type RVD's off these acres through dependency functions in the activity-output relationships section of the model, the chances for aberrant results were minimized This was substantiated by the small differences between the objective function value from the LP solution and that reported by the Report Writer, as noted above.

7. Sediment

Coefficients for sediment production were derived for harvest-related activities, road construction, and natural background levels. The original data developed by the Forest soil scientist were much more detailed, and included breakdowns by North and South slope class and soil stability class, by logging system, and type of road construction.

For the first AMS, the original coefficients were broken out into figures for ground and aerial systems, for new arterial/collector and new local road construction, and for background, by Slope Classes A, B, C1, C2, and C3. For the second AMS and the alternatives, and after the IDT decided not to attempt to model road construction by slope class, the coefficients were reduced to natural background and activity-related sediment for new arterial/collector and new local road construction, for ground systems for timber harvest Forest-wide on Slope Classes A and B, for ground systems North and South on Slope Class C, and for aerial systems for timber harvest Forest-wide on all slope classes. The sediment coefficients used in the model were as follows:

	Tons of Sediment		
	Background	Activity	
		Dec 1	Dec.2
*Arterial/Collector Roads	7.39	17 38	0.0
*Local Roads	7.12	18.41	0.0
#Harvest - Ground - Topog A	0.0107	0 0324	0.0
#Harvest - Ground - Topog B	0 0360	0.1102	0.0
#Harvest - Ground - Topog C - North	1.22	0.7	0.1
#Harvest - Ground - Topog C - South	1 04	0.6	0.1
#Harvest - Aerial - All Topog	0.25	0.05	0 01

*Coefficients are tons/mile/year
#Coefficients are tons/acre/year

The sediment coefficients represent the estimated sediment that would actually make its way into a watercourse. Note that most activity sediment production tapers off to background after the first decade, with the exception of the harvest systems on Slope Class C, and with aerial systems.

8. Old Growth

In 1981, the IDT decided that mature large sawtimber as mapped in the 1976 NFI would be considered old growth in Forest planning In 1989, the acreage and average ages were updated through 1988. The average age of mature large sawtimber is 250 years. There were 643,500 acres of old growth in the Forest planning base when the alternatives were run - 276,600 acres in tentatively suitable lands, 232,500 acres in wilderness, and 134,400 acres in other unsuitable (see Planning Record file 74, 10/8/86 for details). From this base, the change over time in old growth acres was determined manually for each alternative. It was assumed there would be no change in old growth acres over time, except in suitable lands. FORPLAN report F10.8 "Acres by Age Class Before Harvest at the Midpoint of Each Decade" was used to determine the change in old growth acres in suitable lands (ages 240 and 260 in Decade 1) for each decade over the planning horizon.

9. Softwood and Hardwood Sawtimber

The timber yield tables only give the net green volumes of "sawtimber" They do not differentiate between softwoods and hardwoods. This becomes a problem only with the mixed conifer stands. In these stands, the NFI plot data indicate that, by volume, about 67% of the average mixed conifer stand is softwood; 33% is hardwood. The activity-output relationships section of the model splits the sawtimber yields from the yield tables out into the softwood and hardwood components so that they can be valued properly.

When a mixed conifer stand is regenerated after final harvest, if normal regeneration occurrs, it is assumed the stand will retain its mixed conifer character in the same proportions as the existing stand However, if the model selects a timber management intensity to convert the mixed conifer stand to a regenerated pure conifer stand (intensities XF, SP, XC, XB or XE), the regenerated stand would yield 100% softwood (conifer) sawtimber. (Refer back to section E for the discussion of the range of timber options considered.)

Conversely, if the model selects (or is constrained to select) management intensity YF to convert the mixed conifer stand to pure hardwood, the regenerated stand will get its volumes from the pure hardwood yield table, and the sawtimber outputs will be ascribed 100% to hardwood sawtimber. No constraints for conversion to hardwoods were applied in alternative runs and intensity YF was not selected by FORPLAN, because other intensities contributed more to the run objective function of Max PNV or Max Timber.

10. Other Wood Product Outputs

Three other wood product outputs were tracked through FORPLAN. These were firewood, nonchargeable live ("per acre") material 15/, and salvable dead material.

Firewood. Firewood was assumed to be available primarily as a result of timber harvest activities, specifically, from nonchargeable live material (nonmerchantable cull material with breakage, high defect, etc.) It was assumed that the firewood use of precommercial thinnings would be insignificant because of small size, often difficult access, and rapid decay. It was assumed that approximately 70% of the per acre material would be actually utilizable as firewood. At approximately 95 cubic feet of solid wood per cord, this would yield approximately 7.4 cords/MCF of nonchargeable live material.

Nonchargeable Live ("Per Acre") Material. This is the material nonmerchantable because of size or defect left after timber harvest. This currently accounts for about 20% of the volume on an average timber sale acre. However, with the major increase in emphasis on improved utilization of both merchantable volumes and residues, this figure is expected to drop to 8% of net green volume on a sale area by 1995, and down to 2% by the year 2035. Thus, the per acre material output was calculated as a percentage of sawtimber harvest by decade: Decade 1 = 8%; Decade 2 = 7%; Decade 3 = 6%; Decade 4 = 4%; and Decades 5 to 15 = 2%. It can be seen that the firewood output would drop accordingly over time, as it is calculated from the amount of per acre material available.

Salvable Dead. This is merchantable material that is dead but can still be harvested and sold by the timber purchaser. Past timber sale experience and timber inventory plot data indicate that there is an average of 301 cubic feet per acre of salvable dead material in stands of pole and larger timber.

11. Other Timber-Related Activities

A number of activities modeled in the activity-output relationships section are carried out in support of, or in conjunction with, timber harvest. Local road construction has already been discussed. Most of these activities occur on a 1:1 basis with timber harvest, either in terms of acres or MCF. Others occur at a greater or lesser ratio. All the data for these coefficients were derived from actual sale activity experience, samples of sale activity experience supplemented by professional judgment, or by best professional judgment.

15/ Although labeled live material a very small percentage may be from dead material present in the harvested unit.

Listed below are the coefficients which were modeled on a 1:1 basis with either final timber harvest acres or MCF:

Activity	Per
Visual and Cultural Resources Inv/Plng	Acre
Fish and Wildlife Planning	Acre
Soil and Water Planning/Monitoring	Acre
Sale Preparation	Acre
Sale Administration	Acre
Fuels Inventory	Acre
Fuels Treatment	Acre
Logging Costs (Set-up/down, road changes)	Acre
Logging Costs (Fell, buck, yard, load, haul)	MCF
Timber Purchaser Road Maintenance Cost	MCF

Other timber harvest-related coefficients were greater, lessor, or varied from time period to time period:

Activity	Coefficient	Per
Stand Exam		
At precommercial thin	1.25	Acre of PCT
At commercial thin	1.0	Acre of CT
At final harvest	4.6	Acre of Final Harv.
At reforestation	4.25	Acre of Planting
At reforestation	1.25	Acre of Nat. Regen
Planting		
For planting regimes	0.87	Acre of Final Harv.
For natural regeneration regimes	0.2175	Acre of Final Harv.

Activity	Coefficient	Per
Precommercial Thinning		
All stands except exist Seeds/Saps (Age 2, existing or regen stand)	0.80	Acre of Stand
Existing Seeds/Saps (Age 2)	0.20	Acre of Exist Stand
Road Reconstruction (miles)	0.0018207	MCF of Final Harv.
Boundary Location (miles)		
Decade 1 - 2	0.01	Acre of Final Harv.
Decade 3	0.05	of Existing Stand
Decade 4 - 15	0.0	Only

12. Anadromous Fish

Anadromous fish outputs, benefits, and costs were developed offline by the Forest fish biologist and economist. Estimates of fish output by investment level (see Part D) were made based on fry and smolt survival levels, average fish size in pounds, and catch-to-escapement ratios. These production estimates were incorporated into a spreadsheet program along with the estimated proportioning of the fishery catch among Indian and non-Indian fisheries (assumed to be 50-50 in line with the Boldt decisions); and within the non-Indian fishery, among the commercial, ocean sport, and river sport sectors. Also included in the spreadsheet program were the values associated with the commercial and recreational uses of the fish and the estimated angler days associated with the proportion of fish going to the recreational sport fishery.

For the DEIS, a total of 21 spreadsheet scenarios were run for combinations of the three investment levels and the associated estimated production for each of the five species of salmon (chinook, coho, pink, chum, and sockeye), for steelhead trout, and for other sea-run trout. Total costs, benefits, commercial pounds caught, and RVD's of angling (ocean and river) were summarized from the spreadsheet runs. Total costs and benefits were input directly for the investment level specified for a particular alternative. The related commercial pounds and angler days were also included for information. All the values were carried through with one of the one-acre "dummy" analysis areas

For the FEIS, the same process was followed, with the exception that sockeye salmon and sea-run trout were dropped from the analysis. The Forest did a major review and revision of the fish production and harvest estimates in response to public comment on the DEIS. In consultation with the State, it was determined that the sockeye salmon run originating on the Forest is too small to provide significant commercial or sport fishing opportunities; thus, there is little information on current production and harvest, and no estimates of potential production and harvest are made. Sea-run cutthroat trout provide a significant sport fishing opportunity, but there are simply no data for harvest or production on which to base future potential.

13. Summary

This part of Chapter III has recounted in detail the development and use of most of the physical/biological coefficients used in the FORPLAN model. The economic costs and benefits will be discussed in detail in Chapter IV. The reader is encouraged to read the Forest planning process records for additional details and discuss any questions with the Planning staff.

G. Timber Sale Program Quantity for Alternatives

The Forest Plan allowable sale quantity plus an estimate of annual sale volume to be added is displayed in Table B-14a. The total for RPA attainment is termed Timber Sale Program Quantity. The TSPQ is greater for all alternatives, except A, than the figures found in the FEIS tables (such as II-7a), because of the addition of volume from unsuitable lands in Management Area 19.

Table B-14a

Forest Plan Allowable Sale Quantity and Estimate of Annual Volume to be added to the Allowable Sale Quantity

Outputs	Alternatives							
	NC (No Change)	A (No Action)	I	B (RPA)	H	J (Pref)	G (Mod)	C
				Million Cubic Feet.				
I. Forest Plan Chargeable Volume Allowable Sale Quantity 1/	41.7 2/	31 0	26.6	26.3	24 1	22.4	18.3	13.8
II. Nonchargeagle Volume 3/								
A. Salvage								
1 Volume meeting utilization standards		1.2	1.0	1 0	0.9	0.9	0.7	0.6
2. Volume not meeting utilization standards	2 9	2.4	2.1	2.1	1.9	1 8	1.4	1.1
B. Volume from lands where timber is not programmed	0.4	0.4	0.4	0.4	0.4	0.4	0 4	0 3
C. Volume of other convertible products, eg., firewood, posts and poles 4/	0.0	0.0	0 0	0.0	0.0	0.0	0.0	0.0
Total for RPA Attainment (Timber Sale Program Quantity)	45 0	35.0	30.1	29.8	27.3	25 5	20.8	15.8

1/ Based on timber meeting Regional utilizatin standards, growing at the time of inventory and included in growth and yield projections used in Forplan.

2/ Potential yield differs from ASQ: it includes both net live (green) and dead (salvage) volume.

3/ Nonchargeable Volume All volume that is not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity.

4/ Less than 0.1 MMCF Most potential firewood volume is in II.A 2. above.

CHAPTER IV - ECONOMIC EFFICIENCY ANALYSIS

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER IV

There are no significant changes in Chapter IV between the DEIS and FEIS.

* * * * * * * * * * * *

Since Alternative NC (No Change) was not modeled in FORPLAN, economic measures comparable with benchmarks and other alternatives were not determined.

A. Present Net Value

Present net value (PNV) is the economic criterion maximized by the linear program algorithm of FORPLAN in most of the benchmark and alternative runs PNV is the difference between the sum of the total discounted benefits of a course of action over some time period, and the total discounted costs of carrying out that course of action over the same time period. Benefits and costs used to calculate PNV are those which have a market price or which can be assigned a market price equivalent.

PNV measures the net gain or loss to society of adopting a particular course of action. PNV will be positive if the total discounted benefits are greater than the total discounted costs. It will be negative if the converse is true. A positive PNV indicates that, from an economic efficiency standpoint, the course of action analyzed will result in a net gain to society and can legitimately be implemented. A negative PNV indicates that, from an economic efficiency standpoint, society would be worse off if the alternative were adopted. All other things being equal (i.e. all relevant costs and benefits are actually quantified in the analysis, there are no other competing societal goals, there are no policies requiring the alternative to be chosen, etc.), an alternative with a negative PNV should not be implemented.

The present net values of a series of alternatives can be compared to determine which one will result in the highest gain to society. Again, with all other things being equal, the alternative with the highest PNV should be the alternative chosen from an economic efficiency standpoint. (As will be discussed below, in Forest planning all other things are generally <u>not</u> equal, and other nonquantifiable factors and societal goals have to be taken into account before making a final decision).

In planning for this Forest, the PNV of an alternative reflects the total discounted value of priced outputs resulting from management of the Forest for a 150-year period, minus the total discounted Forest Service management and investment costs over the same period. Priced outputs are those that are, or potentially could be, exchanged in the market place. Management and investment costs are those dollar costs incurred by the Forest Service, directly or indirectly, in the management of the Forest. The PNV for an alternative did not include non-priced outputs, nor did it include non-Forest Service costs, values added to forest resources after their removal from the Forest, or income and employment effects of the alternative The definitions and derivations of priced and non-priced outputs and management and investment costs are discussed later in this section. Employment and income effects are discussed in Chapter V.

For modeling purposes, the value added and non-Forest Service costs were carried in FORPLAN for timber. Mill pond value was used for timber, and stump-to-mill logging costs were included. However, since mill pond value represents stumpage value plus stump-to-mill costs, this was equivalent to having the stump-to-mill costs added into both the benefit and the cost sides of the equation. Mathematically, the PNV would have come out the same if those extra costs and benefits had not been included They drop out when the costs are subtracted from the benefits.

1. Discounting

Discounting is the process used in financial and economic analyses to account for the effect of time on the real value of money. People generally prefer, if given a choice, to have money available to spend now rather than later, preferring immediate consumption to deferred consumption. However, if they receive a premium to defer consumption that is at least sufficient to offset the desire for use of their money right now, they may choose to put the money aside and wait. The premium they receive is known as "interest".

Interest is paid for some given time period. If a person puts $1000 into a savings account or some other instrument in return for a 6% interest rate paid annually, at the end of the first year the person would receive $60 interest. If that interest is left in the account along with the original principle of $1000, at the end of the second year, another 6% interest is due. But the second year the 6% will be due on $1060, a total interest of $63.60. Each year the $1000 principle plus interest is left in the account, the interest payment due at year's end will be larger. This process is called "compounding."

The important point is that at the end of two years, the original $1000 will be worth $1123.60. So $1000 today will be worth $1123.60 after two years at 6% interest. Conversely, $1060 a year from now is worth $1000 today, and $1123.60 two years from now is also worth $1000 today, if the interest rate is still 6%.

Because of the general propensity people have to consume today rather than wait, the passage of time has an effect on the value of money as seen from today. Thus, when costs and benefits are projected into future years while analyzing planning alternatives, it must be taken into account that those nominal values occurring in the future have a smaller real value in today's terms, just as the $1123.60 anticipated two years from now is actually worth today only the $1000 needed to put in the savings account. In fact, the $1000 today will have a different value every year in the future because of the compounding effect of the interest rate.

Discounting is the reverse of the compounding process. It allows taking values occurring at different times in the future and converting them to a common base, adjusting for the effects of time, so that the values can be compared on an equal basis. A "discount rate" is used to do this, which is the same rate as the interest rate used for compounding. For instance, today's value, or the "present value", of $1123.60 occurring two years from now is $1000, when discounted at 6%. The present value of $1060 occurring one year from now is also $1000 when discounted at 6%. By discounting both values by the same discount rate back to today from the years they occur, one can see that they are equivalent.

Just as $1000 today gets larger as it is compounded into the future, so does the present value of $1000 get smaller as that $1000 occurs farther into the future. The present value of $1000 occurring one year from now is $943.40; occurring five years from now, the present value of $1000 is $747.26; at 10 years, the present value is $558.39.

This relationship has major significance in economic efficiency analysis. It means that values occurring in the near term carry more weight than values occurring farther out in time, when all values are discounted back to the present and summed. Thus, any program that requires an investment in the near term in order to produce benefits farther out in the future will have its costs weighted more heavily than the benefits because of the effects of discounting.

When FORPLAN maximizes PNV (total discounted benefits minus total discounted costs), it will strive to put costs off as long as possible and to pull in benefits as soon as possible in the planning horizon. Thus, if given the latitude, it will put off road building for timber harvest as long as possible and pull roaded areas into solution for timber harvest first. (This is a simplified approach, as the discount rate, the existing and regenerated stand growth rates, the timber values, real price appreciation factors, non-declining yield constraints, and other factors all combine to complicate the actual solution. But the principle is the same)

2. Net Public Benefit

If all factors considered to be of value to society could be incorporated into an economic analysis as costs or benefits, the alternative with the highest PNV would be the best overall for society. But that kind of totally encompassing holistic analysis is not possible. There are values to society, such as preservation of endangered species or protection of American Indian religious and cultural areas, which the Forest does not have the capability to measure in quantitative terms so that they can be compared directly with other values

There are also societal goals other than economic efficiency that are difficult to measure in terms of costs or benefits. These relate primarily to economic equity (distribution of jobs, income and wealth) and to stability of the economic system: monetary and fiscal policy goals, such as budget reductions.

Although these other goals cannot be incorporated in the economic efficiency analysis done for the alternatives, they must still be incorporated into the decision process that selects the Preferred Alternative. To include these other societal goals in the decision-making process, the Forest Service uses the concept of the "net public benefit" (NPB). Net public benefit is defined in the NFMA regulations as "...the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index..." (36 CFR 219.3).

NPB is used to measure the overall value to society of the planning alternatives, including both priced and non-priced outputs and costs. The assessment of net public benefits is in the end a qualitative process, using the results of the economic analysis (PNV), analysis of the distributive effects of an alternative, evaluation criteria, and informed judgment. The alternative chosen as the preferred alternative for the Land and Resource

Management Plan is that alternative judged by the Regional Forester to have the highest net public benefit of all alternatives considered.

3. Benefits and Costs

Priced Outputs (Benefits). Priced outputs are those that can be exchanged in the market place. For this analysis, they included: timber, firewood, wilderness use, hunting, recreational fishing, other dispersed recreation, developed site recreation, and commercially harvested anadromous fish. In the planning effort on this Forest, the value of water from the Forest and the in-ground value of minerals were not included as priced benefits Water is considered to have a marginal value at or near zero in this region. Specific mineral deposits, their size and grade, are poorly known for the Forest; only broadly defined areas of mineral potential are known. The small probability of actual mineral extraction, plus poor data, resulted in omitting any mineral values as priced benefits. Consideration of potential mineral values was made in the context of the broader NPB criterion.

Values of priced outputs were determined from actual market transaction information or from estimation procedures that produced prices considered to be comparable with market transaction prices Timber and commercial fish prices were based on regional and local market transaction data. Recreation values were those specified in the 1985 Draft RPA Program for recreation areas managed at standard, as required by the Regional planning direction, November, 1983. RPA recreation values were based on a variety of studies, including market transaction data where available and applicable, and indirect value estimation studies, predominantly travel cost and contingent valuation

Values for recreation on national forests are not very comparable with existing market transaction data, because the type of recreation supplied by the national forests is generally much different in character and quality than that provided by the private sector. This is particularly true of dispersed and wilderness recreation. Developed recreation data may be somewhat more comparable, though private developed sites often vary significantly in character (location, visual quality, geographic and vegetation attributes) and in amenities provided (site spacing, accessibility, toilet/shower facilities, on-site services) from those on the national forests. This is particularly true on the Mt. Baker-Snoqualmie.

In spite of the difficulties of doing benefit valuation without market transaction data for some priced outputs, the values of priced outputs for both market- and nonmarket-based goods and services are as comparable as possible in terms of what is being measured and at what point in the production process the value measurement is being made.

Non-priced Outputs. Non-priced outputs are those for which there is no market in which they could be exchanged for money or something else of value. Further, because of the nature of the outputs, there are no potentially comparable markets and there is little likelihood of a market ever developing. Many of these outputs are provided for or required by law or policy, a not unusual outcome in situations where scarce values and valuable resources are not amenable to being handled by a market system in a way deemed appropriate and desirable by society.

Non-priced outputs include two mentioned earlier (endangered species and American Indian religious and cultural areas), plus viable populations of wildlife, vegetation diversity, quality water and air, wild and scenic rivers, and others. Non-priced outputs were usually provided for in the modeling process by setting constraints requiring production or maintenance of certain levels of output or certain areas of land. For instance, bald eagle nesting areas are off-limits to timber harvest and are assigned a specific management prescription, but no value is actually placed on the land around the nests, on the nests themselves, or on the eagles. Congress has simply said through the Endangered Species Act that the species is to be protected at all costs, and everything possible is to be done to bring it back to a viable population.

It is possible to estimate an "opportunity cost" of providing for a non-priced output, even if it is not valued directly. An opportunity cost is the value given up (or gained) by pursuing one course of action over another. For instance, if the bald eagle nest area could be used for timber management instead, the opportunity cost of making it a bald eagle nest area would be the present net value of the timber management program foregone on that area. But conducting such opportunity cost, or tradeoff, analyses requires care and skill. It is often the case on the Forest that provision for one non-priced output will also contribute toward another In economic jargon, they are "joint products." Therefore, calculating an opportunity cost and ascribing it solely to one or the other benefitting output would be a misstatement, as both are benefiting and should share the cost (generally to some unknown degree). For instance, if the eagle nest area is also part of a Research Natural Area that has been designated and would be protected anyway, it would be inappropriate to attribute all the opportunity cost of protecting the site to the eagle or to the RNA Because of these problems it is generally not desirable or appropriate to calculate the opportunity cost of a non-priced output and try to label that the "value" of that output.

Priced Activities (Costs). Priced activities are the direct management and investment costs incurred by the Forest Service in the process of protecting and maintaining the resource base and providing for the production of various outputs of goods and services from the Forest. Included in the planning process were costs of timber harvest activities, silvicultural practices, other resources management activities carried out in conjunction with the timber sale program (cultural, visual, wildlife and watershed planning, and inventory in the sale area), road construction, recreation management, recreation site construction, anadromous fish habitat improvement, and fixed management costs The dollar costs were derived from historical accounting data, budget data, contract records, work orders, and judgment by resource specialists.

Non-Priced Activities. Non-priced activities are really externalities of Forest management and use that are not amenable to valuation. They could probably be better considered as non-priced negative benefits, as they generally stem from negative effects or undesired outputs coming from various production processes. The two best examples are sediment loading of streams, and particulate input to the air. The former occurs naturally to some degree, but increases dramatically for a number of years as a result of road building and/or timber harvest It has not been possible to quantify what effects this has on fish populations (particularly anadromous fish) on the Forest and nearby areas. The subject is one of considerable controversy among fisheries scientists and among a number of other interested parties. To the extent sediment output has a negative but unquantifiable effect on fisheries, it can be considered a non-priced activity (or a negative non-priced output).

Smoke production from prescribed burning may in the future contribute to air pollution problems along the western side of the Cascades as urban growth moves east closer to the mountains. It is similar to sediment: the negative effects in terms of economic and health damage are as yet non-quantifiable. Until they are, particulate production from smoke can be considered a potential non-priced activity (or a negative non-priced output).

4. Distributive Effects and Impacts.

The distributive effects associated with the mix and level of outputs is also a national concern. These effects can be either positive or negative, and can be of local, regional, or national in scope. Some distributive effects, such as changes in consumer prices or taxpayer costs, have impacts at the national level. Others, such as changes in employment opportunity or payments to local governments, are more local or regional in nature. These concerns are more related to questions of equity rather than questions of efficiency, and are not assessed in the context of the efficiency criteria associated with PNV and net public benefits. However, these positive and negative distributive effects need to be assessed in conjunction with net public benefit measures, since equity objectives often influence efficiency objectives as well as vice versa. These effects will be discussed in more detail in Chapter V "Social and Economic Impact Analysis".

B. Parameters Used for Economic Efficiency Analysis

1. Discount Rate

The discount rate used for the economic analysis of the benchmarks and alternatives on the Mt. Baker-Snoqualmie is 4%, as prescribed by Forest Service Manual 1971.71. The 4% rate is a calculated real rate, net of inflation. It reflects the real marginal rate of return on investment in the private sector, which is appropriate to use as the cut-off rate for long-term government investment (any alternative yielding less than 4% net return would have a PNV less than zero). (See Clark, Kaiser and Sessions, 1981, paper for a full discussion of the adoption of the 4% interest rate).

An analysis of the sensitivity of the Preferred Alternative to the discount rate was performed by solving FORPLAN using both the 4% and the 7 1/8 % discount rates. For all other benchmarks and alternatives, the PNV, costs, and benefits were merely recalculated using the 7 1/8 % rate (FSM 1971.21). All costs and benefits were discounted from the midpoint of the decade in which they incurred.

Inflation is not incorporated in Forest Service land management planning economic analyses. Instead, costs and benefits are assumed to be net of inflation, as is the discount rate used. It can be shown mathematically that using inflated costs and benefits and a nominal discount rate that includes the same inflation assumptions will yield the same net results as using no inflation. The inflation in the values and that in the discount rate cancel.

2. Base Year Dollars

In order to compare costs and benefits on an equivalent basis, all values had to be taken to the same base year. For this Forest, the base year in which all dollars are expressed in the economic efficiency analyses is 1982. Historical data from different years used to derive costs and benefits were adjusted to 1982$, as were all analytical results. The Gross National Product Implicit Price Deflator series was used to make adjustments of values to the base year.

3. Real Price Appreciation (Trend) Factors

After considerable discussion and debate, the Regional Office directed that Region 6 Forests use a 1% real price trend on timber stumpage for the first 50 years of the planning horizon. A real price trend means that the value of the timber stumpage rises during the first five decades relative to all other costs and benefits in the model. Using a 1% annual trend results in timber price increases of 65.4% over the beginning prices by the end of five decades. The 1% trend reflects a belief that timber prices will continue to rise in real terms and relative to other prices in the economy, as they did for almost 100 years prior to 1980. The historical real price increase was actually closer to 2-3% annually, and some parties wanted to use at least a 2% real price trend. Others, though, argued that a fundamental restructuring of the wood products industry was taking place, and that imports, increased utilization, and changing technology would tend to hold down future real price increases. The 1% trend factor was essentially a compromise between these two positions.

Sensitivity runs were made during the benchmark analysis with real price trends on timber of 0%, 2%, and 3%, and were compared with the base 1% trend. For the Mt. Baker-Snoqualmie, there was only a change of a few percentage points in long-term sustained yield, first decade allowable sale quantity, and PNV when going to either 0% or 2% trends. The results of the analysis are displayed and documented in the Forest's AMS and in Chapter VI of this Appendix.

Real price appreciation factors are not applied to any other benefits in the planning process. No real price trends are applied to management or investment costs.

4. Demand Curves

As was discussed under recreation in Chapter III, demand curves for recreation were used only to force the model to stop valuing recreation capacity at the point where estimated demand was met. For planning purposes, it was assumed that the Forest faces a horizontal demand curve for its stumpage. This means that no matter how much timber the Forest puts up for sale (at least within the long run sustained yield capacity) it would not, on the average, significantly affect the price of stumpage in the market area into which it sells.

An estimation of the demand function was made during the development of the AMS. The point elasticity at the current price and production levels at that time was -13.52. This indicates that a 13.5% change in quantity offered on the market would be required to bring about a 1% change in stumpage price.

In light of this, no downward sloping demand curve for timber was assumed or used in FORPLAN. All quantities of timber harvested of a given type and diameter were valued at the same rate with no changes in price.

C. Costs

1. Costs in FORPLAN

FORPLAN Cost Listing. Following is a listing of all costs used in FORPLAN. Each cost, or category of costs, is discussed briefly, and the sources used to develop the cost(s) are highlighted. This section, and the one on benefits that follows, describe the economic ties between the prescriptions with their physical/biological yield coefficients described in Chapter III and the economic objective function which was used for most of the benchmark and alternative analyses.

Table B-15
FORPLAN Costs (1982$)

1. Timber Management-related Costs	
a. Timber Sale Support	
Visual and cultural res. planning/inv. (VIS1)	16.41 per acre
Fish and wildlife res. planning/inv. (C01)	37.84 per acre
Water and soil res. planning (F01)	38.70 per acre
Water and soil res. monitoring (F03)	8.73 per acre
Property boundary location (J06)	3,500.00 per mile
b Fuels Management	
Fuels inventory (P10)	
Commercial thin	6.25 per acre
Final harvest	11.80 per acre
Fuels treatment (USFS cost) (P11A)	
Commercial thin	75.00 per acre
Final harvest - existing	
Accessible w/roads	237.00 per acre
Inaccessible and/or aerial sys.	285.00 per acre
Final harvest - regen. stand	
Accessible w/ roads	158.00 per acre
Inaccessible and/or aerial sys.	190.00 per acre
Fuels treatment (Purchaser's cost) (P11B)	
Commercial thin	112.00 per acre
Final harvest - existing	
Accessible w/roads	411.00 per acre
Inaccessible and/or aerial sys.	493.00 per acre
Final harvest - regen. stand	
Accessible w/roads	161.00 per acre
Inaccessible and/or aerial sys.	193.00 per acre
c. Timber Harvest Activities	
Sale preparation (E06)	
Commercial thin	108.00 per acre
Final harvest	230.00 per acre
Sale administration (E07)	
Commercial thin	83.00 per acre
Final harvest	165.00 per acre
Stand exam (E03A)	7.10 per acre
Road reconstruction (L29R)	15,000.00 per mile
Road reconst. - engineering costs (L1QR)	10,000.00 per mile
Road maintenance (Purchaser's cost) (L19P)	54.00 per MCF 1/
Logging costs (per acre) (LOG1)	
Commercial thin	125.00 per acre
Final harvest	
Accessible w/roads	156.00 per acre
Inaccessible and/or aerial sys.	98.00 per acre

1/ This represents the average of a range $49.00/MCF for sales with large average stand diameters to $60.0/MCF for those with small average stand diameters.

Table B-15 Page 2 of 3

Logging costs (per MCF) (LOG2)		2/
Commercial thin and final harvest		
Accessible, Slope Class A		
7 - 9" dia., <2 MCF/ac	1,343.86	per MCF
11 - 13" dia., 4 - 6 MCF/ac	837.71	per MCF
17 - 19" dia., 6 - 7 MCF/ac	612.20	per MCF
21 - 23" dia., 7 - 9 MCF/ac	489.00	per MCF
25" + dia., 12 + MCF/ac	461.97	per MCF
Accessible, Slope Class B		
7 - 9" dia., <2 MCF/ac	1,524.28	per MCF
11 - 13" dia., 4 - 6 MCF/ac	942.15	per MCF
17 - 19" dia., 6 - 7 MCF/ac	682.79	per MCF
21 - 23" dia., 8 -10 MCF/ac	539.18	per MCF
25" + dia , 12 + MCF/ac	509 99	per MCF
Accessible, Slope Class C		
7 - 9" dia., <2 MCF/ac	1,717.71	per MCF
11 - 13" dia , 4 - 6 MCF/ac	1,054 12	per MCF
17 - 19" dia., 7 - 8 MCF/ac	755.28	per MCF
21 - 23" dia., 8 - 9 MCF/ac	595.72	per MCF
25" + dia., 12 + MCF/ac	561.49	per MCF
Inaccessible lands and/or aerial sys.		
(All diameters and volumes)	1,395.07	per MCF
d. Silvicultural Activities		
Planting (E04)		
Accessible w/roads	292 00	per acre
Inaccessible and/or aerial sys.	317 00	per acre
Stand exam after planting (E03B)	7.10	per acre
Precommercial thinning (E05A/E05B)		
Accessible w/roads	259.71	per acre
Inaccessible and/or aerial sys.	299.48	per acre
Stand exam after PCT (E03C)	7.10	per acre
e. Genetic tree improvement program (E09)		
1st decade	299,990.00	per year
Remaining decades	229,000 00	per year
2. New Road Construction Costs		
a. Arterials and Collectors		
Preconst. and const. engineering (ACN1)	30,000.00	per mile
New construction (A&CN)	250,000.00	per mile
b. Locals		
Preconst. and const. engineering (L10/L11)	20,000 00	per mile
New construction (LOCC/LOCN)	125,000 00	per mile

2/ This is a sampling of the full range of logging costs used in the FORPLAN data set. The first and last values in each set are the minimum and maximum costs used, respectively Commercial thin and final harvest costs are implicitly differentiated by the average stand diameters and volumes per acre harvested. Diameters and volumes will be smaller for commercially thinned material, resulting in higher logging costs, as shown by the table

Table B-15

3	Road Maintenance	
	a. Arterials and Collectors (L19A/L19B)	300.00 per mile/year
	b. Locals (L19L/L19M/L19N)	300.00 per mile/year
	c. Cost Share (USFS portion)	200.00 per mile/year 3/
4.	Recreation	
	a. Developed Site O&M	
	Campground and picnic areas (A07J)	0.58 per PAOT-day/yr
	Ski areas (A07K)	0.03 per PAOT-day/yr
	Other (rec. residences, org. sites, etc.)	0.11 per PAOT-day/yr
	b. Developed Site Construction (A07M)	
	Campground	11,020.00 per unit
	Picnic site	6,914.00 per unit
	c. Dispersed Nonwilderness O&M	
	Rural (A08A)	13.83 per acre/year
	Roaded Modified (A08F)	0 31 per acre/year
	Roaded Natural (A08B)	0.31 per acre/year
	Semi-primitive Motorized (A08C)	0.60 per acre/year
	Semi-primitive Nonmotorized (A08D)	0 13 per acre/year
	Primitive (A08E)	0.06 per acre/year
	d Wilderness O&M	
	Transition (B03A)	0 65 per acre/year
	Trailed (B03B)	0.35 per acre/year
	General Trailless (B03C)	0.14 per acre/year
	Dedicated Trailless (B03E)	0.14 per acre/year
	Special (B03D)	0.50 per acre/year
5.	Anadromous Fish Habitat 4/	
	a. Level I (FSH1)	
	1st decade	37,600.00 per year
	Remaining decades	40,000.00 per year
	b. Level II (FSH2)	
	1st decade	143,000.00 per year
	Remaining decades	80,000 00 per year
	c. Level III (FSH3)	
	1st decade	324,000.00 per year
	Remaining decades	200,000.00 per year
6.	Fixed Costs	6,200,000.00 per year

3/ The non-USFS portion of cost share road maintenance was not carried anywhere in the model. Unlike the timber purchaser's road maintenance costs (L19P), the non-USFS portion of cost share road maintenance is not related to any Forest Service activities.

4/ These are the total annual costs for each fishery investment level. In the FORPLAN data set, the figures for Levels II and III are the increments above Level I. In FORPLAN, Level I is added to the increment for Level II or Level III to get total costs for the level

Per acre costs shown in the table for timber-related activities are the actual costs developed. In the FORPLAN data set, one will also find the per acre costs shown reduced by 1% and 4% on Roaded and Unroaded lands, respectively, for the regenerated stand harvest. This is to proxy the additional reductions made for lands going into roads, as discussed in Chapter III.F.3.c Reductions in the per MCF costs were not needed, since the appropriate reduction had already been made in the volume yields.

FORPLAN Cost Development

a Timber Sale Support Costs

Resource protection, maintenance, and enhancement costs related to timber sale activity were developed by the various resource specialists (watershed, visual, cultural, fish and wildlife, and lands). These costs reflect the input required by the nontimber resource areas in the process of developing and implementing timber sales. Costs were generally developed on a per acre basis from project records, contract records, and budget estimates. Property boundary location costs were developed on a per mile basis. The model converted the acres of final harvest into miles of boundary line to be located at a rate of 0.01 miles per acre of final harvest in the first and second decades of the planning horizon; 0.005 miles/acre in the third decade; and 0.0 thereafter. The lands staff estimated that by the fourth decade, the boundary line location program will have been completed.

b. Fuels Management

Fuels management (residue management) costs, including inventory and treatment costs, were estimated by the fire and fuels specialists from project records and contract records. Fuels treatment costs are divided between the Forest Service and the timber purchaser. Based on data available, costs vary by commercial thin and final harvest, and by whether the lands are accessible by roads or are inaccessible and harvested by aerial system. The acre costs shown in the table are lower than the averages actually incurred by each party. Actually, the acres of a sale area treated by each party may be separate, with corresponding costs per acre higher than those shown in the table above, but applied to fewer acres than they were in the model. For modeling convenience, each party's cost was converted to an average cost across the entire sale area, and then applied to all acres harvested. The result was a lower average cost per acre, but the costs were applied to all acres harvested. With either approach, the total cost attributable to each party is the same.

c. Timber Harvest

Sale preparation and administration costs, stand exam costs, and road reconstruction and purchaser's road maintenance costs were all developed from project and contract records, supplemented by timber sale appraisal records (2400-17 and the timber sale appraisal handbook). Sale prep and administration costs vary by commercial thin or final harvest. The road maintenance costs included here are only those required of the purchaser as part of the timber sale contract. Road reconstruction is that done as part of a timber sale; other construction and maintenance costs are discussed below.

Logging costs (more correctly, stump-to-mill costs) are those incurred by the timber purchaser to get the timber cut, yarded, loaded, and trucked to the mill, along with associated environmental protection costs for which the purchaser is responsible. (The purchaser's road maintenance costs are tracked separately, as are the purchaser's fuel treatment costs). Even though logging costs are not Forest Service costs, they were used in the model because the values used were mill pond values i.e., the value of the log on the mill deck waiting to be processed. Carrying the logging costs allowed reduction of the number of benefit values required for timber.

Logging costs vary according to a number of factors: the size of the material handled, the volume per acre harvested and processed, the topography of the harvest area, distance from roads, logging system type, distance from the mill, special resource conditions such as unstable soils, etc. Because the regional wood products wholesale market generally sets prices of the material at the mill, values of logs of similar species, size and grade are similar at the mill, regardless of where they came from. Thus, the more it costs to get a log to the mill, the less the timber purchaser will be willing to pay for that tree while it is still standing in the forest. So as logging conditions get more difficult, the logging costs rise, and the stumpage values decline accordingly (assuming demand for stumpage and other factors remain constant).

These relationships allowed using a mill pond value for timber in the model, and application of logging costs that varied as shown in the table against the mill pond value, in order to arrive at a net stumpage figure. Although the net stumpage figure never showed up directly in the model, it was calculated internally, as the model calculated PNV by subtracting costs from benefits. Depending on what land type, average stand diameter, and volume per acre the model chose to harvest, the appropriate logging cost was subtracted from the mill pond value to get a stumpage value that reflected both timber size and quality and the ease or difficulty of getting the log to the mill.

Logging costs were originally developed using individual sale (2400-17) records, timber sale appraisal handbook guideline costs, and estimates by the Forest logging system engineer. Costs were defined for all ground systems (tractor, hi-lead, short-span and long-span skyline), by topograhic class, and on a per acre or per MCF basis. Because of the difficulty in forecasting what systems would be applied in future years, particularly on regenerated stands, and to keep down the size of the model, a weighted average value of all ground systems was calculated. The cost for logging using aerial systems was kept separate. These costs were used in the Forest's first AMS process.

As discussed in Chapter III, part C, a paper by Fight, LeDoux, and Ortman (1984) on logging cost in second growth coastal Douglas fir was used as the basis for redeveloping the logging system costs for the second AMS and the alternatives analysis. This paper detailed equations for each component of the stump-to-mill process; use of these equations resulted in costs that varied by average stand diameter and volume per acre. (The first set of costs developed on the Mt. Baker-Snoqualmie did not have these variables.) Costs for ground systems were developed from these equations for each of the Forest's three major topographic types (A, B, and C). Aerial system costs continued to be derived directly from Forest data and estimates.

The logging costs developed from the equations were significantly lower than the initial figures developed directly from the Forest data; not surprising, as the paper was written for much less difficult terrain than on the Mt. Baker-Snoqualmie. Also, harvesting in second growth forests should be relatively less expensive than harvesting in wild stands. Although the costs were lower, the relative spread of costs in terms of diameter and volume per acre seemed reasonable from the limited data available on the Forest. Therefore, the equation-based costs were indexed up to the Forest historical figures developed for the first AMS, maintaining the proportional spread across diameter and volume per acre. This allowed maintenance of a direct link with the Forest's actual experienced costs, but at the same time gave a reasonable estimate of how those costs varied over diameter of material handled and volume per acre harvested, information not available from past records.

The costs shown in Table B-15 above are on a per MCF basis for those that vary by volume harvested, and on a per acre basis for those that tend to vary more by the area harvested, such as rig-ups and rig-downs, road changes, etc. The costs shown in the table are just a sample of the range of the entire set of costs used in the model For more specific information on the development of the logging costs and the data and equations used, refer to the planning process records and the FORPLAN data set.

d. Silvicultural Activities

Planting costs, precommerical thinning costs, and stand exam costs were developed from project/contract records, budget estimates, and estimates by Forest silvicultural specialists. Planting and precommercial thinning costs vary by whether areas are accessible by road or are inaccessible.

e. Genetic Tree Improvement Program

The Forest geneticist calculated the expected costs of the genetic tree improvement program for future years. The estimate includes the costs of seed collection and management of the evaluation plantations and seed orchards. The costs were estimated to be about 30% higher in Decade 1 than in subsequent decades because of the higher costs of plantation and seed orchard establishment.

f. Road-related Costs

New road construction costs, including preconstruction and construction engineering, were estimated for arterial and collector roads and for local roads by the Forest's transportation planning engineer Cost estimates were based on historical data with some adjustments made for the recent trend toward building local roads to a lower standard, (a result of reduced budgets and recognition that, with proper design, locals can be built at lower cost while still protecting basic resource values and adequately serving the timber management areas).

Road maintenance costs were estimated by the Forest's engineering staff, based on past budgets and experience An average figure for all road types was used. In an average year, it was estimated that 90% of the Forest's permanent road system receives some kind of maintenance; this may range from a driving check, to culvert cleaning, to full-scale blading or resurfacing.

The Forest Service share of maintenance on "cost share" roads (roads in which the Forest Service has legal interest but are on lands not within the National Forest System) was estimated by the engineering staff to be about 2/3 of the annual total maintenance costs for the roads. The actual FS share will vary widely from road to road, but as more of the proportion of timber volume moving over those roads is from National Forest lands, the Forest Service is picking up a larger percentage of the maintenance cost, in accordance with the share cost agreements. The engineering staff estimate this share to be in the neighborhood of 2/3 throughout the planning horizon.

g. Developed Site Recreation

Developed site recreation management costs were developed from a combination of historical data, budget estimates, and information developed as part of the Recreation Information Management System. The RIM system information was developed to estimate the budget that would be required to manage recreation sites, both dispersed and developed, to standard. The IDT decided to use the costs required to manage to standard as the basis for recreation management costs, in order to avoid building underfunding into the future program.

Developed site O&M costs are tied to the capacity of the developed sites on the Forest in terms of "persons at one time" for one day (PAOT-days). The annual capacity can be measured by the total persons at one time the area can handle times the length of time during the year the site is open. The Forest's recreation staff felt that it was more accurate to tie the developed site management costs to capacity (PAOT-days), rather than visitation (RVD's). Many campground costs are incurred whether the campground visitation is at 40% or 80% capacity. Therefore, for modeling purposes, the total budget estimated as needed to manage to standard was divided by the total Forest developed site capacity in PAOT-days, getting a cost per PAOT-day for developed site management. These are the costs shown in Table B-15.

Construction costs for campground units and picnic units were developed from engineering estimates and converted into 1982$. The costs shown in the table are per unit, but can easily be converted to cost per PAOT if it is desired to model additional capacity construction on that basis.

h. Dispersed Recreation Management

Dispersed recreation O&M costs were also based on the RIM estimates of costs required to manage to standard. The Forest's recreation staff felt that the most meaningful cost connection for dispersed recreation was with acres of ROS experience level for which the Forest would manage, rather than RVD's of visitation. Management based on experience levels requires that areas of ROS be managed and maintained in such a manner as to provide the desired experience level for the recreationists that do come to the area. This is true whether visitation is heavy or light.

Because the RIM costs were developed prior to the time that RIM tracked ROS, the estimated total costs by activity type and area had to be converted to costs per acre of ROS. This was done by calculating estimated current RVD's by ROS class as a percentage of total RVD's of dispersed recreation. The total estimated budget to manage to standard was multiplied by these percentages to get the required budget for managing for each ROS class. These figures were then divided by the acres in the respective ROS classes to attain dollar figures for managing each acre of the ROS classes to standard. These are the figures shown in the cost table Again, it was recognized that tying the dispersed recreation management costs to acres of ROS, rather than RVD's, did not completely reflect the actual management situation, but was preferable to tying those costs just to RVD's.

i. Wilderness Management

Wilderness management costs were developed in the same manner as dispersed recreation costs. The costs for the first AMS were developed on the basis of the original ROS classifications After the change was made to the WROS system, the wilderness management costs were adjusted accordingly.

j. Anadromous Fish Habitat

Costs for fish habitat investment levels carried in FORPLAN were developed by the Forest fisheries biologist. For Level I, the costs are for maintaining the existing fisheries habitat (primarily spawning habitat) currently on the Forest. Costs would be for stream protection and for habitat structures and improvement, all done primarily for mitigation purposes.

For Level II, costs would be incurred to restore anadromous fish habitat lost or degraded by major modifications of watercourses by dam-building and resource extraction activities. Removal of barriers to upstream fish migration, creating improved pool:riffle ratios, placing log wiers, and similar activities would be included in the costs for Level II.

The intent of Level III is to improve fish habitat to its maximum potential, beyond that which historically existed under natural conditions. This investment level would involve removals of natural migration barriers, intensive management of streams by placement of structures (wiers, gabions, etc.) to maximize fish spawning and rearing habitat, and stocking of juvenile fish if necessary to meet production goals. For both Levels II and III, the initial costs for structural and nonstructural improvements occur in the first decade. Costs thereafter are primarily for maintenance and replacement. For Level I, costs rise somewhat after the first decade as increased mitigation measures are required to protect streams from increased pressures of road-building, timber harvest, and other development activities.

k. Fixed Costs

Other Forest management costs not discussed above were considered to be essentially fixed across all alternatives. Modeling fixed costs is difficult since they don't change on a continuum along with changes in program levels, outputs, or budgets. Fixed costs include the fire pre-suppression and suppression program, overhead, general administration, basic resource protection, minerals and special use permits processing and administration, and a variety of other activities not expected to change significantly until large

increases or decreases in current program levels are made. Total fixed costs were developed from budget figures for 1981-1983.

2. Costs Outside of FORPLAN

Monetary costs for alternative implementation outside of FORPLAN were not dealt with. Use of Version 2 of FORPLAN made it possible to carry nearly any activity and cost within the model, even if it was carried as a lump-sum cost that did not affect the model solution, such as the costs of the genetic tree improvement program. The approach was to keep as much of the economic information as possible within the model, even if simply running values through to get them calculated into PNV. This avoided doing extra spreadsheet calculations outside the model, and negated the concern that some economic values might actually have an effect on the model solution that would not be noticed if they were dealt with outside the model

3. Real Cost Trends

Real value appreciation (trend) factors were discussed above (part B). Use of real cost trends would have indicated that the expected value of one or more particular costs would rise at a rate faster than that of the general price level for all other goods and services in the economy. Under Washington Office and Regional Office planning direction, the Mt. Baker-Snoqualmie did not use any real cost trends in the analysis of the benchmarks or alternatives. All costs were assumed to stay even with the general price level, rising only along with all other goods and services at the general rate of inflation. This resulted in an effective real increase of zero for all costs.

4. Capital Investment vs. Operations and Maintenance Costs

According to FSM 1970.5, an investment (or capital) cost is "A cost of creating or enhancing capital assets, including costs of administrative or common-use transport facilities and resource management investments." Operations and maintenance costs are those costs incurred in the process of producing goods and services from the Forest for protection of the resource base, and for maintenance of capital assets

Investments in road construction, including all the preconstruction and construction planning and engineering costs, are capital investments. So are investments in facilities such as campgrounds, administrative buildings, water systems, trails, etc.

In a technical sense, any cost incurred in the production of timber stands or the creation of fish and/or wildlife habitat is a capital investment if it is expected to last more than a year and will produce future benefits, either regularly or as a one-time shot. Standing timber is a capital asset that will yield a return years or decades in the future, and which therefore has a current value which can be lost if not maintained and protected. Similarly, the mosaic of vegetation types and ages making up deer and elk winter range represents a capital asset that regularly yields a return in deer and elk produced, whether for consumptive use (hunting), nonconsumptive use (observation), or for ecological benefits (gene pool, diversity, etc.). This value produced at regular intervals is reflected in the capital asset value of the habitat, and can be lost if the habitat is not maintained and protected.

For display purposes in the DEIS and the FEIS, the more traditional definition of capital investment costs was used: those costs incurred to construct facilities such as roads, campgrounds, trails, and so forth. It seemed that this breakdown was more illuminating than one in which all timber management and habitat improvement costs were also included That decision may be debatable. If the reader so desires, all timber management costs incurred to produce the next crop of timber can be considered to be investment costs. This would include the costs of planting, stand exams, precommercial thinning, and even the net cost of commercial thinning, as this activity is generally done in order to increase the size and quality of the stand for final harvest. Costs of the genetic tree improvement program could also be considered part of the investment in the timber crop. Likewise, costs of wildlife and fish habitat improvements, including direct structural and nonstructural work as well as the net costs of timber harvest done to achieve age class distribution, can be considered to be investment costs.

5. Costs Relatively Constant Across Alternatives

The unit costs as shown in Table B-15 do not vary across alternatives; however, the total costs will change depending on the amount of each activity that occurs in a given alternative. In general, all the timber management-related costs can potentially vary widely across alternatives, depending on the timber sale program quantity for that alternative. Road construction costs vary by the amount of new construction in each alternative. Road maintenance costs are relatively constant, varying only at the margin by the differences in new roads built among alternatives.

Because of the way developed site capacity and expected use were modeled, those management costs stay almost constant across all alternatives In dispersed recreation, the management costs vary by the acres going into each ROS category by alternative. Costs for wilderness management stay relatively constant, with some variation among alternatives as acreages change among the five wilderness management intensities. Anadromous fish investment level costs are the same for any alternative with the same level assigned. They differ accordingly if different investment levels have been assigned The genetic tree improvement program costs were assumed to be the same across all alternatives, as were the cost categories included in the Fixed Costs, as discussed in part C, above.

D. Benefits

1. Priced and Non-priced Benefits

Priced Benefits. Outputs that are, or potentially could be, exchanged in a market place were given dollar prices in the planning process and in FORPLAN. Those benefit values that are actually based on market transaction data are called "market" values. Benefit values for goods and services that could potentially be traded in markets, but for which no markets or market transaction data actually exist, are called "nonmarket" or "assigned" values. These values were developed from estimation procedures that generated prices considered comparable to market transaction prices.

Market values used in FORPLAN were for timber (both softwood and hardwood) and commercially-caught anadromous fish. As was discussed earlier in the costs section, the timber values actually were the value of the log at the mill deck waiting to be processed. However, after incorporating logging costs, the effective value used was timber stumpage. Anadromous fish commercial values were integrated with the recreational values of the fishery to derive a total value expected from the anadromous fishery for each investment level used.

Assigned values used in FORPLAN were for developed recreation, dispersed recreation (including hunting, fishing, wildlife observation, and general dispersed activities), wilderness use, and firewood. Again, the recreational and commercial values for the anadromous fishery were combined into one for modeling purposes. (For more detail on the process used to calculate total anadromous fishery outputs and benefits, see the planning records.)

Two of the assigned values used actually have a "real" dollar price associated with them. Some developed campgrounds have overnight fees ranging up to $7 per night, depending on the amenities and services available at the campground. Also, firewood is now sold on the Forest at up to $10 per cord (for people collecting dead and down material for firewood, including yarded unusable material and residue from precommercial thins, as long as it is for personal use and not for resale) In both these instances, it is recognized that the administrative prices set by the Forest Service generally do not match the prices of similar goods and services sold in private markets. The on-site average value of firewood cut by commercial suppliers is about $15-$20 per cord, depending on the quality of the wood and its location relative to the nearest market. 1/

According to Washington Office and Regional Office direction, Forests are to use assigned prices in those instances where the market price is administratively set and does not fully reflect the market-clearing price that would be found in a "free" market. Therefore, we used assigned prices for both developed site recreation and for firewood.

Non-priced Benefits. Outputs that have no market for exchange because of their particular characteristics, but which still have value and benefit to society, are called "non-priced" outputs or benefits. The nature of these outputs is such that no economic markets are expected to materialize for their exchange, and there are no comparable economic markets from which to deduce prices. These benefits cannot be incorporated into the cost efficiency analysis of the planning process. Rather, they have to be considered qualitatively and incorporated into the estimate of overall net public benefits for each alternative (see the NPB discussion, part A).

1/ Based on perusal of classified ads and knowledge of what the Forest Service charges for firewood sales to commercial suppliers.

Non-priced benefits used in the planning process on the Mt. Baker-Snoqualmie included maintenance and enhancement of wildlife habitat; maintenance and protection of riparian vegetation; maintenance of old growth stands for wildlife, visual, esthetic, and genetic reasons; maintenance and protection of American Indian traditional religious and cultural areas; maintenance and protection of special ecological, cultural, historical and recreational areas; maintenance of air and water quality; effects of Forest management on area jobs and incomes, effects of Forest management on area lifestyles; maintenance of ecosystem diversity; visual quality; maintenance of opportunities for development and use of energy sources; and maintenance and restoration of threatened and endangered species populations.

It is evident that these benefits are extremely difficult to measure other than in some subjective, qualitative sense. The amount of at least some of them can be measured: acres of old growth remaining, acres of American Indian sites protected; changes in ecosystem diversity. But the overall benefits from even those amounts that are measured are qualitatively assessed, at best.

2. Point of Valuation

In cost-efficiency analysis, benefits should be calculated as close to the point of production as possible, to avoid double-counting benefits The economic analysis in the Forest planning process is trying to show the net benefits to society from the goods and services produced from the Forest by management activities. The value of timber from the Forest is not the wholesale price of lumber. The wholesale price of lumber includes not only the value of the tree in the forest, but also the cost to get it to the mill and the cost of processing it into wood products. These latter stages of production include labor, capital and entrepreneurial costs, which all contribute to the value added to the original raw material value.

In the planning process, timber was valued as stumpage in the forest (although as discussed previously, the actual values that show up in FORPLAN are the mill pond values and the logging costs; the two combined yield a stumpage value); firewood was valued at the point it was gathered from the Forest; commercially-caught anadromous fish were valued at the point of capture (ex-vessel price at the dock minus the average cost of harvest by the fishing boats), and recreation was valued at the point where the recreation was experienced - i.e., on the Forest.

In the last case, the value of recreation on the Forest represents what people would be willing to pay if they were required to do so to use the Forest's resources (scenery, streams, mountains, roads, etc.). The value represented by the recreation benefits is not the value of the recreationist's total recreation experience (which begins from the time the person leaves home until returning home), but that portion of the value of the recreation experience or activity contributed by the availability and use of the Forest's land and resources. Benefits valued as described here represent the net contribution made to society by the existence and management of the natural resources on the Forest.

3. Benefit Values in FORPLAN

FORPLAN Benefit Listing. Table B-16 lists the benefit values actually used in FORPLAN. Each benefit, or benefit category, is discussed briefly, and the sources used to develop the benefit(s) are highlighted. This section and the previous section on costs together describe the economic ties between the prescriptions with their physical/biological yield coefficients described in Chapter III and the economic objective function which was used for most of the benchmark and alternative analyses.

Table B-16 Page 1 of 3
FORPLAN Benefits (1982$)

1. Market Values	
a. Softwood Sawtimber (X06) [Mill Pond Value]	1/
North, Upper Working Group	
7" - 9" dia.	919.00 per MCF
13" - 15" dia.	1,176.00 per MCF
19" - 21" dia.	1,364.00 per MCF
23" + dia.	1,429.00 per MCF
North, Principal Working Group	
7" - 9" dia.	867.00 per MCF
13" - 15" dia	1,172.00 per MCF
19" - 21" dia	1,418.00 per MCF
23" + dia.	1,501.00 per MCF
North, Inaccessible Lands (Agg. Wrk. Grp)	
7" - 9" dia.	876.00 per MCF
13" - 15" dia.	1,167.00 per MCF
19" - 21" dia.	1,395.00 per MCF
23" + dia.	1,472.00 per MCF
South, Upper Working Group	
7" - 9" dia.	859.00 per MCF
13" - 15" dia.	1,110.00 per MCF
19" - 21" dia.	1,296.00 per MCF
23" +	1,358.00 per MCF

1/ This is a sampling of the full range of timber values used in the FORPLAN data set. The first and last values in each set are the minimum and maximum values used, respectively. Values are taken at the mill pond (deck) and vary by diameter of material harvested. See text for discussion of mill pond values, logging costs, and resulting stumpage values.

Table B-16 Page 2 of 3

South, Principal Working Group	
7" - 9" dia.	825.00 per MCF
13" - 15" dia.	1,124.00 per MCF
19" - 21" dia	1,367.00 per MCF
23" + dia.	1,449.00 per MCF
South, Inaccessible Lands (Agg. Wrk. Grp.)	
7" - 9" dia.	834.00 per MCF
13" - 15" dia	1,108.00 per MCF
19" - 21" dia	1,319.00 per MCF
23" + dia.	1,391 00 per MCF
North and South, Mixed Conifer Wrk. Grp.	
7" - 9" dia.	767.00 per MCF
13" - 15" dia.	1,115.00 per MCF
19" - 21" dia.	1,421 00 per MCF
23" + dia.	1,531.00 per MCF

b. Hardwood Sawtimber (X09) [Mill Pond Value]

North and South, Mixed Conifer Wrk. Grp.	
7" - 9" dia.	327.00 per MCF
13" - 15" dia.	476.00 per MCF
19" - 21" dia.	606.00 per MCF
23" + dia.	653.00 per MCF

c. Salvable Dead Material (X15) [Mill Pond Value]

North, Upper Working Group	
All diameters	1,218.00 per MCF
North, Principal Working Group	
All diameters	1,233.00 per MCF
North, Inaccessible Lands (Agg. Wrk. Grp.)	
All diameters	1,221 00 per MCF
South, Upper Working Group	
All diameters	1,151.00 per MCF
South, Principal Working Group	
All diameters	1,185.00 per MCF
South, Inaccessible Lands (Agg. Wrk. Grp.)	
All diameters	1,157.00 per MCF
North and South, Mixed Conifer Wrk. Grp.	
All diameters	1,001.00 per MCF

d. Anadromous Fish Commercial Harvest

Commercial ocean fishery	1.05 per pound
Indian fishery	1.05 per pound

2. Assigned (Nonmarket) Values

a. Firewood (X08) 20.00 per cord

b. Developed Site Recreation

Camping and picnicking	7 56 per RVD
Alpine (downhill) skiing	8.47 per RVD
Rec. residences, org. sites, etc.	7.56 per RVD

c. Dispersed Recreation

Wildlife observation/photography	
All ROS classes	25.00 per RVD

Table B-16 Page 3 of 3

Big and small game hunting	
All ROS classes	26 15 per RVD
Resident fish angling	
All ROS classes	15.00 per RVD
Primitive ROS other disp. rec.	11.25 per RVD
Semi-primitive nonmotor ROS other disp. rec	13.25 per RVD
Semi-primitive motor ROS disp. rec.	12 13 per RVD
Roaded Natural ROS other disp. rec.	9.38 per RVD
Roaded Modified ROS other disp. rec.	9.38 per RVD
Rural ROS other disp. rec.	8.92 per RVD
d. Wilderness Recreation	
All WROS classes	17.50 per RVD
e. Anadromous Recreational Fishing	
Ocean sport	33.00 per RVD
River sport	33.00 per RVD

Sources and Development of Benefit Values

a. Sawtimber Values

Sawtimber values were derived from the Timber Sale Statement of Accounts Cut and Sold Reports for April, 1977, through September, 1983, indexed to 1982$ The values used were the "cut" values - those prices actually paid by the purchaser at the time the harvested logs were scaled and billed to the purchaser by the Forest Service. Use of "cut" rather than "bid" values gives a much better representation of the market at the time the timber is actually harvested and eliminates much of the futures speculation found in bid prices.

Weighted average values by North and South by working group were calculated from the quarterly Cut and Sold Reports. Added to these base values were an average road construction cost per MCF and average stump-to-mill costs per MCF. The result was an average pond value by North and South by working group. This pond value, though, represented primarily logs 22" and greater in diameter. Based on a study done at the Pacific Northwest Experiment Station, the Regional Office provided a process to the Forests to develop a spread of timber values by diameter from the original timber value calculations The process used estimated the decrease in value experienced as log diameters decreased. The timber values shown in Table B-16 are the results of that benefit development process. They are average mill pond values. Site-specific stumpage prices were derived internally in the model by subtracting the site-specific logging costs (which vary by diameter and volume per acre) from the average mill pond value.

Hardwood sawtimber (X09) values required somewhat more general estimates, as much less data was available for that working group. Sawtimber values for salvable dead (X15) were not broken out by diameter for lack of data. The values shown are arithmetic averages of all the values by diameter for each group. Salvable dead material is all valued as softwood.

Some concern has been expressed by various interest groups during the Forest planning process that Forests developed their timber values right at the peak of the bidding frenzy in the late 1970's. The concern is that the resulting prices used in FORPLAN would be too high and distort the model solution in favor of increased timber allocations and outputs. The IDT felt that the timber values developed on the Mt. Baker-Snoqualmie do not have that bias. While the early part of the historical data period does cover the time of high bids, the values used are "cut" values, not "bid" values. So the data showing up from the late 1970's are based on contracts bid and sold earlier in that decade before bid prices skyrocketed. The values that show up in the early 1980's reflect only a portion of the results of the high bidding period, because many purchasers ended up not harvesting the sales bid and purchased during that time. They either did not harvest anything, or harvested as much low-cost timber as they could, mixing it in with the higher cost stumpage. Thus, use of the Cut and Sold Reports gave us a good basis to develop timber values representative of the longer-term market.

b. Anadromous Fish Commercial Harvest Values

The values per pound of anadromous fish commercially harvested were developed by the Washington Office for the draft 1985 RPA Program, and were specified for use in Region 6 Forest planning by RO planning direction. The value per pound represents the ex-
vessel price of the fish minus average costs of fishing off the NW coast.

c. Firewood

Firewood was carried in the model at its assigned price, even though it does have an administratively set market component. The Mt. Baker-Snoqualmie charges up to $10 per cord for personal use firewood collected on the Forest. As mentioned before, the real on-Forest value of firewood when sold through the market is closer to $15-$20 per cord. The administratively set price for personal use firewood is not capturing the total value of the resource as reflected in the marketplace.

d. Developed Site Recreation

Developed site recreation values were taken from the draft 1985 RPA Program, as required by the Regional planning direction. These values were developed to be as comparable as possible to similar private sector developed recreation prices. However, as noted earlier, there are few situations where that comparison can be made directly because of differences in location, environment, and amenities provided. The values used were those identified in the RPA document as values per RVD when areas and facilities are managed to standard.

The developed recreation values often have an administratively set market component in the form of user fees charged at various developed recreation sites As with firewood, the administrative price is not capturing the full market value that people would be willing to pay to use those, or similar, facilities. The assigned price reflects as much as possible that full market value, which should be the value of the contribution that National Forest lands and facilities are making to people's overall recreation experience.

e. Dispersed Recreation

Dispersed recreation values are also assigned values taken from the draft 1985 RPA Program, in accordance with Regional planning direction. The RPA values were developed from a number of sources, primarily travel cost and contingent valuation studies, and adjusted to proxy marginal values for incremental planning purposes, rather than the average values most studies produce. The values used were those identified in the RPA document as values per RVD enjoyed when areas are managed to standard.

The FORPLAN model carried, within each ROS class, wildlife observation, hunting, and fishing RVD's separately from other dispersed RVD's. The reason for this was to capture the significantly different values associated with those activities compared with the values for general dispersed activities. It was decided that the higher values for these types of activities would be the appropriate ones to use, no matter in what ROS class the activity took place. Therefore, the wildlife observation, hunting, and fishing RVD's carry the same value in all ROS classes, while the general dispersed recreation activities change according to ROS.

Dispersed recreation values were applied to RVD's of capacity, rather than to actual estimated use. As discussed in Chapter III.F.6, these values were used in combination with weighted average dispersed recreation values by ROS class in the demand curves section to provide a cut-off of valuation when the ROS capacity exceeded expected use in that class.

e. Wilderness Use

Values for all classes of wilderness use were taken from the draft 1985 RPA Program. The value was constant across all WROS classes and reflected value of wilderness managed to standard.

f. Anadromous Sport Fishing

The anadromous sport fishing value in the draft 1985 RPA Program included only the value for river sport fishing. All previous studies of recreational anadromous fishing values have indicated that ocean sport fishing has a higher average value than river sport fishing. Data from the 1980 RPA Program on values for ocean sport fishing were used in conjunction with the river sport fishing value from the draft 1985 document to develop a weighted average value that *includes both facets of the anadromous sport fishing experience.*

4. Benefits Considered Outside FORPLAN

No priced benefits were incorporated into the overall PNV of an alternative outside of those in FORPLAN. As mentioned in the costs section, the use of Version 2 allowed running through FORPLAN all the quantifiable benefits used, even if carried through on a simplistic basis just to get them added into the PNV, rather than having to do so outside the model afterwards. (Non-priced benefits were incorporated into the net public benefits assessment outside the model).

5. Non-cash Values and Cash Receipts

The Forest Service receives part of the economic value of the goods and services produced from the Forest in cash payment for the use and/or purchase of those goods and services. The rest of the economic value is enjoyed by users as "non-cash" benefits. The only payment required of users for those benefits is that required to "capture" the benefit: travel costs to get to the Forest to recreate, acquisition of a chainsaw to be able to cut firewood, etc.

The Forest Service receives cash for timber, for part of the value of firewood, and for part of the value of developed site recreation. (The Forest Service also receives some cash for various special use permits, but the amounts are insignificant and were not modeled).

Non-cash benefits to users are those accruing from the portion of firewood and developed site recreation not actually charged, and for nonwilderness dispersed and wilderness recreation. (Hunting and fishing license payments go to the appropriate State agency to pay for management of the fish or wildlife population. The State has authority over the populations; the Forest Service has authority over the habitat. No payment is currently made by the hunter or angler to access the habitat in order to hunt or fish).

Non-priced benefits are part of non-cash benefits, but are not shown anywhere in quantitative terms. They are discussed qualitatively.

Anadromous fish benefits are a special problem. Part of the anadromous fish population originating on the Forest is caught in the ocean and provides cash benefits to the fishers when they sell the fish to processors at the docks. None of this cash makes its way back to the Forest Service or the U.S. Treasury (except perhaps, in the latter case, as taxes). Ocean and river sport fishing for salmon and steelhead provide non-cash benefits to users; again, these benefits occur almost completely off National Forest System lands. All the anadromous fish values, both cash and non-cash, can be considered economic value to society and are included in PNV calculations. But they are more difficult to identify as cash and non-cash benefits, particularly in relation to the other resource goods and services produced from the Forest.

6. Real Price Trends

Real value appreciation (trend) factors were discussed in part B of this chapter. Real price trends on benefits were applied only to timber stumpage, in accordance with Washington Office and Regional planning direction. Stumpage was appreciated in real terms at 1% per year for 50 years. At the end of that time, real prices of stumpage are 64 5% above their beginning levels and above the base levels of all other prices in the model. After 5 decades, the price trend reverts to zero, and the timber prices stay at the appreciated level throughout the rest of the planning horizon. In FORPLAN, the 1% trend was applied both to the timber (mill pond) values and to the logging costs, in order to get a mathematically correct 1% real stumpage price increase

CHAPTER V - SOCIAL AND ECONOMIC IMPACT ANALYSIS

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER V

- Socioeconomic data have been updated to late 1980's information
- Estimated changes in employment and income by alternative have been updated to reflect changes in alternative output levels and the final set of alternatives carried in the FEIS.

* * * * * * * * * * * *

A. Social and Economic Overview

The Forest Service has always tried to make its forest management decisions consistent with the needs and concerns of the populations affected by those decisions Socio-economic effects, or impacts, are simply those changes that happen to people because of the way a forest is managed.

1. Forest Area of Influence Zone As Established for Economic Analysis

Assessment of the relationship between the Mt. Baker-Snoqualmie National Forest and the social and economic environment surrounding it requires identification of a relatively homogeneous unit for the analysis. This was not a simple task, because the social and economic structure of the region is diverse, not lending itself to precise categorization, and the data available for the analysis are gathered according to administrative boundaries (e.g. counties) which do not correspond with meaningful analytical units such as economic status or geographic location.

For the purpose of forest planning, a five county zone of influence was defined This zone includes Whatcom, Skagit, Snohomish, King, and Pierce counties. In addition, information was gathered on Canadian use, since the Mt. Baker-Snoqualmie National Forest is an important recreation resource for the residents of Vancouver, B.C.

This region is one of the faster growing areas in the United States. The population, although far from uniform, tends to be young and well-educated, with incomes above the national average. The economy is highly diversified Manufacturing is led by the aerospace industry. While that industry does not dominate the region quite so much as it has in the past, a recent study showed that one out of six jobs in the State of Washington is still dependent, directly or indirectly, on spending by the aerospace industry (Pascall and others, 1989) Linkages with the Pacific Rim countries make the wholesale and retail trade industry an important employer. Other major sources of employment include the forest products industry, the tourist industry, and the broadly-based service industry sector.

The region is composed of residents with varied values and lifestyles who exercise different demands on both the region's economic and natural resources. Economic opportunities, amenity considerations, and the "Northwest lifestyle" all influence institutions and organizations throughout the region.

The Mt. Baker-Snoqualmie National Forest both influences and is influenced by social and economic activities in the area.

2. Population

Over one-half of Washington State's population resides in this five-county area, a total of over 2.6 million people. King, Pierce and Snohomish Counties are, respectively, the first, second and third most populated in the state. Population density is high in urban areas: 600 up to 1,500 persons per square mile. In the rural areas, especially in Skagit and Whatcom counties, the population density is well below the State average of 67 persons per square mile.

Population Composition. The three more heavily urbanized, industrial counties (King, Pierce, and Snohomish), have younger populations with fewer people in the over-65 age group than the State average. Skagit and Whatcom counties have a large number of residents over 65 years of age, reflecting the in-migration of retirees and a number of communities declining in population.

Minority Populations. The population of the Forest's Zone of Influence is predominately white; in 1980, 12 percent of the area's population was non-white. The majority of the State's Black and Asian populations live within the Seattle-Tacoma metropolitan area. Just under half of the State-wide Hispanic population lives in the metropolitan area. Slightly less than half of the State's Native American population live within the 5 counties.

Projected Population Growth. The Washington Office of Financial Management projects that the State population will increase from 4,132,400 in 1980 to almost 5,400,000 by the year 2000. The five-county area is expected to grow somewhat faster than the State over the same time period, reaching over 3,100,000 by 2000. At that rate, nearly 60 percent of the State's population would live in the five-county area by the year 2000.

3. Income

When adjusted for inflation, real per capita personal income increased 27.3 percent statewide, compared with about a 29 percent increase in the five-county area between 1970 and 1978 (Table B-17). From 1978-1987, the real increase for both the State and the five-county area dropped to about 10%, although King and Snohomish Counties were significantly above that (15.9% and 21.6%, respectively). Income in the area is expected to increase within this range of rates through the year 2000, averaging 1.7 percent increase per year, as compared to 2.7 percent from 1960 to 1980. (PSCOG, 1984)

Table B-17
Per Capita Personal Income
1970-1987

	1970 (1970 $)	1978 (1978 $)	1987 (1987 $)	Nominal % Change 1970-78	Real % Change 1970-78	Nominal % Change 1978-87	Real % Change 1978-87 1/
King	$4,601	$10,064	$19,511	118.7	31.0	93.9	15.9
Pierce	3,923	7,881	14,008	100.9	20.4	77.7	6.2
Skagit	3,653	8,269	14,301	126.4	35.6	72.9	3.4
Snohomish	3,649	7,625	15,511	109.0	25.2	103.4	21.6
Whatcom	3,599	7,773	13,595	115.4	29.4	74.9	4.5
Washington State	3,997	8,494	15,642	112.5	27.3	84.2	10.1

1/ Income deflated by implicit price deflator for personal consumption expenditures. Inflation by this measure was 66.9% from 1970-1978, and 67.3% from 1978-1987

4. Employment

The five-county study area accounts for over half of all economic activity in the State. As shown in Table B-18, manufacturing, especially aerospace, lumber and wood products, trade, government, and the service sector are the major components of the area's economy.

Table B-18
Wage and Salary Employment By Sector - Five-County Area 1/

	Persons Employed		
Sector	1979	1984	1988
Agriculture, Forestry, Fisheries 2/	9,475	12,488	16,142
Mining	694	634	804
Construction	56,686	47,682	63,001
Manufacturing	196,436	184,055	228,421
Food and Kindred Products	15,556	14,546	15,171
Lumber and Wood Products	18,850	15,644	16,116
Transportation Equipment	87,110	78,502	88,316
All Other Manufacturing	74,920	75,363	108,818
Transportation, Communication, Utilities	54,576	60,525	69,783
Trade (Wholesale and Retail)	228,298	249,780	298,660
Finance, Insurance, and Real Estate	61,380	67,942	79,799
Services	165,865	206,699	270,319
Government	148,981	156,401	177,464
TOTAL	922,391	986,206	1,204,393

1/ Employment covered by Washington Employment Security Act, which covers in excess of 85% of total employment in the State. Does not include self-employed.
2/ Fewer than 5% of jobs in this sector are in the Forestry Services SIC Group.

Manufacturing is a relatively recent major activity; the State and the Puget Sound area have a long historical dependence upon resource-based industries. Transportation equipment manufacturing - primarily the aerospace industry - employs about 7 percent of the total wage and salary workforce in the area. The forest products industry is the second largest manufacturing component in the regional economy. Lumber production has the greatest local significance in Skagit County, where it provided 4 percent of all wage and salary jobs in 1988.

The Seattle metropolitan area is the dominant commercial center in the State and the Pacific Northwest and functions as a hub for transportation, trade, finance, administration, and government. It is the location of Regional headquarters of many Federal agencies.

The two remaining industries which have major significance throughout the study area are tourism and travel, and agriculture and food processing. Jobs supported by tourism are somewhat hidden in the data for trade, services, and other sectors. It is likely the third largest industry in sales and employment generated within the study area. The type and amount of agriculture, forestry, fishing and food processing employment varies by county.

5 .Employment Growth

The Puget Sound area economy is quite diverse today, although it is still relatively dependent on aerospace employment and spending (Pascall and others, 1990). National economic trends have and will continue to affect the area. Housing starts are now up from the slump of the early 1980's, but are expected to stay fairly level over the next decade. The trade and services sectors are expected to continue growing. The forest products industry has already experienced major changes over the last decade. A shakeout of marginal mills and more extensive modernization, coupled with new products and expanding markets, have led to high levels of wood products outputs in the past three years, but with about 25 percent fewer employees than required for similar output levels in the late 1970's.

Future manufacturing growth will likely be in the high-technology industries. Aerospace employment has begun to stabilize and is expected to stay slightly below its historic high for the next several years. Basic industries - food products, lumber and wood products, etc. - and government are projected to grow relatively little through the year 2000. In fact, forest products employment is expected to continue to decline over time as modernization and productivity gains continue to be made (NWPPC, 1989). Non-manufacturing jobs should increase about 2.5 percent per year, compared to manufacturing, with projected annual employment growth of about 1.3 percent. However, the output of the manufacturing sector will continue to grow due to greater labor productivity and new technology (PSCOG 1984).

The areas location, lifestyle amenities, educated work force, and the many land and water resources should provide the base for continued economic growth in the future, though likely at a more modest rate than in the late 1980's, which has been a period of fairly rapid economic expansion.

6. Forest Payments to Counties

By law, 25% of the revenues collected by the Forest Service from timber sales, recreation, minerals, land uses and other charges is returned to the counties within which those National Forest acres lie. The funds are used for public schools and roads. Table B-19 shows returns to the five counties for 1980 through 1989.

Table B-19
Returns To Counties

County	FY80	FY81	FY82	FY83	FY84	FY85	FY86	FY87	FY88	FY89

7. Future Trends - Lifestyle, Values

While most of the 5-county region's population is concentrated in the low-land areas along Interstate Highway 5, growth in the entire area reflects the national trends. Migration into the area is expected to continue. Most residents will live in urban-suburban areas, although growth in smaller towns and "bedroom" communities - reverse migration - is occurring, and people regularly commute to jobs in Everett-Seattle-Tacoma from Carnation, Duvall, North Bend, Enumclaw, and others. Rural population centers like Sedro Woolley are growing at a faster rate than the area as a whole.

The spread of knowledge, technology, and new values has shifted the metropolitan part of the Puget Sound area from an economy based on resource extraction to one based more on diversified manufacturing, trade, finance, tourism, and government. This same shift is now beginning to take place in the more rural portions of the area. The shift from resource extraction to services tends to place increasing emphasis on public goods such as developed and undeveloped recreation resources, clean air and water, and preservation of scenery. 2/

Darrington, Granite Falls, Concrete, Skykomish, Sedro Woolley and a few others are the remaining towns close to the Forest with residents who place more value on resources than amenities, though the environment and lifestyle of the area are important to them. But with mass communication, the up-river areas are exposed to modern technology, knowledge, and values. Many new residents of the smaller, less urban communities have had little direct experience with resource extractive uses of the Forest. A growing group of these "exurbanites" has already become a major source of opposition to active, visible environmental manipulation; herbicides in Index and Issaquah, and wilderness protection around Glacier are two examples of issues on which rural groups do not espouse wholly traditional values.

In the future, the decline of the traditional rural community is expected to continue, though overall population will increase. The changing local population composition, including greater numbers of people over age 65, a diverse regional economic base, and growth of regional industrial areas is likely to change the occupational patterns and value structures of many smaller towns.

As this occurs, traditional lifestyles in the smaller rural communities will be more and more challenged by new, more urban values and lifestyles. The Forest can expect to see increasing demands for recreation-oriented outputs and increasing challenge to ground and vegetation disturbing management activities as the traditional rural areas continue to evolve. The rate of change can be expected to be faster in towns closer to the metropolitan area, including Sedro Woolley, North Bend, and Enumclaw. Those towns further away, such as Darrington, will experience this change more slowly.

Refer, also, to Table B-67, in Chapter VIII.

B. Economic Impact Analysis

The result of the resource assignments and management prescriptions made in Forest Plan alternatives involve important links with the economies of an area. A computer based system, known as IMPLAN 3/, was developed by the Forest Service to assist planning efforts involving economic impact assessment. This system incorporates input-output analysis and enables Forest planners to develop non-survey based inter-industry models, and apply them to the evaluation of alternative management actions.

1. Input-Output Models

Input-output analysis is based upon the interdependence of the producing sectors of an economy. Industries must purchase inputs from other industries, as well as from primary sources, such as the employment of households for use in the production of products, which, in turn, are sold to other industries and final consumers.

Basically, an input-output model is an accounting device which depicts the structure of an economy. Flows of inputs can be traced through the model to show linkages between the industrial sectors of the economy. These linkages are represented by a system of simultaneous equations and the effect of a sale on total production in an economy is derived by solving this system of equations. In short, each purchase from a particular sector by a firm or by a final consumer initiates a series of reverberations throughout the economy. The input-output model traces through the maze of reverberations or interactions to show, when the rounds of spending have come to an end, what the total output of each sector will be given the initial increase or decrease in one of the final demand categories Employment, income, population, and other economic indicators which have a quantifiable relationship with the producing sectors can be estimated based on the level of production or resources made available in an economy.

IMPLAN. The IMPLAN data base consists of two major parts: 1) a national level technology matrix and 2) estimates of sectorial activity for final payments, gross outputs, and employment for each county in the nation. The software component consists of a set of linked programs that utilize the data base and user input to construct influence area input-output models. The approach used to build the regional set of accounts is the supply-demand pooling technique. This approach is based upon the assumption that if an industry is located in an area, and if there is demand for its output, this demand will first be met to the extent possible by the local industry. The IMPLAN system is well suited for economic impact analysis of national forest plans. Given the output levels of a particular forest allocation, input-output analysis indicates likely changes in area income and employment

3/ Gregory S. Alward and Charles S. Palmer, Implan: An Input-Output Analysis for Forest Service Planning

2. Analysis of Economic Impacts

Since changes are based on the economic ties between the Forest and the local economic system, the first step toward assessing any probable changes is to identify the output levels which result from a Forest Service activity and have significant impact or importance to an areas economy. Output levels for 13 different resources were examined and included in the input-output analysis. The resources were chosen based on: 1) their market effects, 2) data available to analyze trade flows within the area of influence, and 3) their ability to reflect the primary differences in the resource production levels between alternatives. Based on the above, the following resources were used as a basis for analyzing the potential economic impacts of each alternative:

Output	Unit of Measure
Developed Recreation:	RVD
General developed recreation	
Camping	
Downhill skiing	
Dispersed Motorized Recreation	RVD
Dispersed Nonmotorized Recreation	RVD
Wilderness Recreation	RVD
Wildlife Recreation:	WFUD
Fishing	
Hunting	
Non-consumption	
Commercial Fish Production	Lbs.
Timber	MBF
Lumber and Wood related	
Pulp and Paper	
Fuel wood	Cords

Forest Service land management activities impact the economy not only through the production of Forest outputs, but also through money paid to counties and annual Forest Service expenditures. Because the expenditures will vary depending on the intensities and outputs of each alternative, they were translated into changes in final demand and included into the analysis.

The procedure for converting changes in forest outputs into changes in final demand involves: 1) determining the per unit expenditure for each of the resources; 2) allocating the per unit expenditures to appropriate sectors; 3) adjusting values to constant dollars (1982); and 4) identifying the changes in output flows. In general, an average per unit market price or value is calculated for each resource, and sectors which have direct impacts are identified. The average value is then margined 4/ throughout these sectors to reflect per unit expenditures in 1982 dollars. In this way, when output flows from various alternatives are input into the IMPLAN system, both the sectors which are influenced and their proportional impacts (changes in final demand) can be determined.

4/ Determining Changes in Final Demand for Implan Economic Impact Analysis, Jay Sullivan.

The input-output model is now capable of tracking the effects of the various output and expenditure levels as they ripple through the area's economy. It allows prediction of the overall changes in income and employment that are likely to result from the land-use decisions made on the Forest.

The model was used to estimate how much of an impact, in terms of employment and income generated, each unit of output would have upon the economy. Table B-20 presents the income and employment response coefficients that would result from an output change of one unit for each resource. For example, for every 1 MRVD of developed recreation which is produced from the Forest, there would be 6.2 jobs and 0.1 $MM added to the area of influence's economy.

Table B-20
Employment and Income Response Coefficients, By Resource

Output	Units	Response Employment 1/ (# of Jobs)	Income ($MM)
Developed Recreation	MRVD	6.2	.1
Dispersed Motorized	MRVD	2.1	.04
Dispersed Nonmotorized	MRVD	1.4	.03
Wilderness Recreation	MRVD	1.4	03
Wildlife Recreation	MWFUD	2.7	.05
Commercial Fish	Mlbs	.1	.003
Timber	MMBF	13.9	.4
Fuelwood	MCORDS	1.2	.03

1/ Direct, indirect and induced employment

Given the output levels for the particular forest land-use assignments of each alternative, the model predicted the likely changes in employment and income. The potential economic impacts, in the form of employment and income, shown in Table B-21 reveal that alternatives which produce commodity based outputs will tend to have more positive impacts on an area's economy. These effects are typical of input-output models. Since the model is based on a linear system, it assumes perfect elasticity of supply, or no resource constraints, and thus ignores the normal forces of supply and demand.

For example, new industries may grow to meet the needs of new technologies and new resource use opportunities on the forest. The model measures benefits and costs as pure monetary transactions. Thus, an economic impact analysis can only reveal the best alternative if the goals are closely specified, such as maximizing employment. Moreover, the conclusions drawn from the economic impacts are bound by the assumptions of input-output analysis Although these assumptions in general do not reduce the usefulness of the analysis, they are reminders of the obvious point that the model and its outputs should not be applied mechanically.

Table B-21
Changes in Employment and Income by Alternative

	Alternatives							
Dec.	NC	A	I	B (RPA)	H	J (Pref)	C	G-Mod.
	Jobs Supported by Alternatives - Thousands of Jobs Per Year							
1st	30.1	29.3	29.1	29.1	28.9	28.8	28.0	28.4
2nd	39.6	39.3	38.9	38.9	38.7	38.6	37.6	38.0
5th	59.1	59.0	63.2	58.0	60.1	59.0	55.6	53.7
	Percent Change in Employment - 5 County Area of Influence							
1st	0	0	0	0	-0.1	-0.1	-0.2	-0.2
	Income Generated by Alternatives - Millions of Dollars Per Year							
1st	559	537	532	531	526	522	501	512
	Percent Change in Income - 5 County Area of Influence							
1st	0	-0.1	-0.1	-0.1	-0.1	-0.1	-0.2	-.02

Forest management decisions affect people in ways that do not pass through the economy or local governments. Recreationists' satisfaction can be directly influenced by changes in recreation opportunities and qualities on the forest. Management practices that change the perceived environmental quality of an area change the attractiveness of that area for its users. The amount and type of activity affects how people feel, particularly if they have always seen the forest as a place to get away from man's interventions and regulations.

Within the zone of influence, local economies have changed. The role of the traditional primary industries, such as timber production, have diminished in recent years. The area now has a broader economic base, which is more stable and adaptable to change and future growth. Social patterns have also changed as discussed above.

The diversity of lifestyles, values, and economic activity in the five county zone of influence makes the overall social-economic analysis a difficult task. In assessing the major tradeoffs between alternatives, one must reach a balance between values associated with preservation and those associated with meeting the need and demand for production.

CHAPTER VI - ANALYSIS PRIOR TO DEVELOPMENT OF ALTERNATIVES

A. Introduction

1. Requirements for and Purposes of Pre-alternative Analysis

The implementing regulations of the National Forest Management Act of 1976 require that an "analysis of the management situation" (AMS) be done prior to the development and analysis of Forest Plan alternatives (36 CFR 219.12 (e). The AMS process was described in Chapter I. Part of the required AMS process are the benchmark analyses. Benchmark runs are done primarily in FORPLAN, although a few (e.g., minimum level management) may be estimated outside the model. The purpose of the benchmarks is to:

help define the maximum economic and biological resource production opportunities on the Forest;

assist in evaluating the compatibilities and conflicts between market and nonmarket objectives;

define the range within which integrated alternatives will be developed;

estimate the schedule of management activities, resource outputs, discounted costs and benefits, present net value, and acres of prescription assignments appropriate for achieving the purposes of the benchmarks; and,

analyze the implications and opportunity costs of legal and policy constraints.

In other words, the benchmarks are used to define the "decision space" within which implementable alternatives must lie (the physical/biological production limits); to assess the opportunity costs of legal and policy constraints applied in the planning process; and to test the sensitivity of final results to major assumptions about activities, outputs, costs, and benefits.

A special note: the timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. As a result the timber output level lies beyond the timber outputs decision space defined by the benchmarks. The No Change alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER VI

This section describes the benchmark runs done for the Analysis of the Management Situation (AMS) completed in 1985 and carried forward to the Draft Environmental Impact Statement (DEIS) completed in 1987. As discussed above, the benchmark runs help define the Forest Plan decision space, as well as provide a structure within which to test the opportunity costs of applying management requirements (MR's) and to test the sensitivity of PNV and output results to changes in costs, prices, and price trends.

The benchmark analysis done for this Forest was thorough, as required by the Regional and Washington Offices, because of the status of the Mt. Baker-Snoqualmie as a "significant timber Forest." However, as described earlier in Chapter III, there were significant changes made in the FORPLAN model between the AMS and the DEIS, and some additional changes made between the DEIS and FEIS. Additionally, other factors such as the scope and definition of MR's changed significantly as the planning process moved ahead. As a result of these changes, all of the benchmarks originally done would have to be reformulated and rerun to make them match closely to the current model formulation, resource definitions, and constraint

The benchmarks have not been reformulated and rerun between the DEIS and FEIS because of the large amount of time and cost that would be involved. Though the model and other factors have changed, the indications of relative magnitude and direction of opportunity costs and sensitivities derived from the original benchmark analyses are still valid. These analyses helped define the development of alternatives for the DEIS. The FEIS builds on that initial process, as well as on what was learned from public input and additional analysis after the DEIS was published.

While the benchmarks were not rerun in their entirety, we did recalculate the decision space (reflected by Benchmark Run #7) in terms of ASQ and PNV, based on the most recent planning parameters as of the time this FEIS and Plan were developed. We also recalculated the opportunity costs of the major constraint sets based on these latest parameters, looking particularly at the effects of the revised spotted owl habitat areas (SOHA's) and the constraints applied as a result of the hydrologic cumulative effects (HCE) analysis. These results can be seen in FEIS Chapter II, Tables II-4 and II-5, Table B-23 of this chapter also displays the same material.

This chapter, then, contains an updated description of the development of the MR's and the constraints used to model these updated MR's. Benchmark results, opportunity cost analysis and sensitivity analysis results do not change from those displayed in the DEIS, except for the sensitivity of the alternative PNV's to varying discount rates. The latter have been updated to reflect the final set of alternatives carried in the FEIS.

* * * * * * * * * * * *

Decision Space Definition. Some benchmark runs are made to indicate the maximum amount of production that could be expected if all available lands and resources were concentrated on producing a single Forest output, such as timber, primitive recreation, or high visual quality. Benchmarks can also indicate the land-use assignments and resource scheduling patterns that would result if cost-efficiency (PNV) were maximized, or if budgets were minimized. Results of several benchmark runs can indicate the decision space within which any implementable alternative must lie. An actual alternative will have multiple objectives and constraints, with the result that all the Forest output and activity levels will lie within the maximums defined by the benchmarks.

Constraints Analysis. Benchmark runs are used for "with and without" comparisons of land-use assignment and scheduling patterns that are the same except for one particular constraint, such as nondeclining yields or wildlife management requirements (MR's). When just one factor is changed from one run

to the next, the changes in PNV and other outputs can be observed, and the opportunity cost of that constraint determined.

Although a simple concept, analysis of the opportunity costs of constraints becomes more complex when a series of interdependent constraints are analyzed. For instance, riparian areas by extended rotation management or no harvest also provide habitat to achieve wildlife MR's. Benchmark runs can be done that show the costs of applying each constraint set, individually, to an otherwise unconstrained land-use base. The results will be one set of opportunity costs for wildlife MR's and another set for riparian area protection. However, if the constraints are applied sequentially, the total effect of both constraint sets will be less than the sum of the two individual opportunity costs.

Sequential application of constraint sets can yield misleading results. It is not appropriate to apply the riparian constraint and calculate the opportunity cost of the riparian constraint, and then apply the wildlife MR constraint on top of the riparian constraint and calculate the incremental opportunity cost, calling the later the opportunity cost of the wildlife MR's. In this case, the riparian opportunity cost would be overstated and the wildlife constraint opportunity cost understated, because the riparian constraint would actually be serving to fulfill some of the wildlife needs as well. If the constraints were applied in the other order, the reverse would hold true.

In general, any time interdependent constraint sets are applied sequentially, the first set applied will show the largest opportunity cost and the last set will show the smallest Changing the order by which the constraint sets are applied can change the relative magnitudes of the respective opportunity costs.

In 1983, the Washington Office issued direction that required more rigorous analysis of the opportunity costs of constraints used in the Forest Planning process (Cargill's memo to Regional Foresters, dated 5/31/83). This memo was in response to dissatisfaction in the Secretary's Office over the quality of analysis in Forest plans seen up to that point. Part of the reason for the "planning pause" discussed in Chapter I was the content of this memo relating to additional requirements for constraints analysis.

Sensitivity Analysis. A number of major assumptions about production functions, costs, and benefits were made in the process of building FORPLAN and setting the base for the analysis of alternatives. A number of the assumptions selected came from a distribution of probable assumptions; there is uncertainty surrounding the actual value or form the assumption will take in the future.

On the Mt. Baker-Snoqualmie, the benchmarks were used to analyze three major economic assumptions in the planning process. One was the assumption that the real price trend for timber would be 1% instead of zero or 2%. Another concerned the level of timber management costs used in FORPLAN models. The third was the effects of using market prices only versus market plus assigned prices in the model The results of these sensitivity analyses are discussed later.

Benchmark runs with FORPLAN can be used to test the sensitivity of any desired factor, whether it be price trends, price levels (e.g., change recreation prices up or down by 50% and see what difference it makes in outcomes), production functions, yield coefficients, etc. Generally, sensitivity analysis runs are limited only by time, budget, and numbers of possible outcomes that can actually be comprehended in the decision-making process.

Benchmark Runs Completed. In order to accomplish the analysis required prior to development of the alternatives, 24 benchmark runs were made with FORPLAN; one benchmark (minimum level management) was done off-line. The results of these benchmarks will be discussed in the rest of this Chapter.

B. Management Requirements (MR's)

1. Development of MR's

The Planning Regulations (36 CFR 219.27) contain certain minimum requirements that must be met in accomplishing the goals and objectives of the National Forests. They cover requirements for resource protection, vegetative manipulation, silvicultural practices, even-aged management, riparian areas, soil and water, and diversity.

Region 6 developed direction to ensure that the minimum requirements were applied consistently across the Region. This direction is contained in letters dated February 9 and April 16, 1983, Land and Resource Management Planning (1920), both letters are available in the Planning Process records.

In response to direction by Deputy Assistant Secretary MacCleery in March, 1985, Region 6 reviewed all of its MR direction. As a result of this review, certain MR's were dropped, and others were modified. That information is reviewed in the June, 1986, Region 6 document "A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region." New direction was issued to Forests in Region 6 by the memo of July 25, 1986, entitled "A Revision to Appendix 2 of the February 9, 1983, MMR Direction."

Again, note that the TM Plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. As a result, Alternative NC does not meet the MR direction.

The Regional direction recognized that some of the minimum requirements were procedural in nature, could not be incorporated in the analysis, or were not likely to have an impact on analysis These requirements have been incorporated into the standards and guidelines, either Forestwide or those unique to a specific management area prescription. Other minimum requirements in the Regulations that impose substantive standards, can be incorporated in the analysis and are significant to the analysis are discussed in detail below.

This section discusses in abridged fashion the development of the MR's. For a detailed discussion of their development and modeling, see Appendix H.

Wildlife

Spotted Owls. To the extent possible, the Forest chose to develop 3 pair SOHA's. SOHA's were initially located on a Forest map on a 12 mile grid, within areas below 4,200 feet in elevation. This initial screen was adjusted to place as many SOHA's as possible in areas not suited for timber production due to wilderness, RNA's, unstable soils, or regeneration difficulty. This second screen was compared against timber size class mapping (a proxy for old

growth) and adjusted to assure as many of the SOHA's were placed in suitable habitat as possible The existence of verified owl pairs from previous field checking was also utilized.

The office map of the SOHA's was reviewed by District personnel, using on-the-ground knowledge of timber productivity, harvest and blowdown since preparation of the data base, and status of preparation investments for sales on the 5 year timber sale program. This review resulted in some minor changes, where SOHA's conflicted with proposed sales. The maintenance of the SOHA took precedence and, if necessary, the sale was dropped or modified to assure that suitable habitat would remain at the time of plan implementation. Sub-Regional coordination was conducted to assure that dispersal was still possible to adjacent Forests. Existing information on status of owls was also reviewed for adjacent National Parks.

This formulation resulted in the establishment of 84 SOHA's necessary to meet the distribution and dispersal requirements contained in Regional Direction, and maintain a minimum viable population.

Efficiency analysis was conducted for a managed versus dedicated strategy for SOHA's. This analysis indicated that the dedicated formulation was more efficient than managed in terms of effect on timber outputs.

Pileated Woodpecker and Marten. Utilizing the mapping done for spotted owls, habitat areas were located between SOHA's to meet the dispersion requirements for these two species. The assumption was made that each pileated woodpecker habitat area would also provide habitat for marten. The same sub-regional coordination described for spotted owls was conducted for these two species The same procedure to assure that suitable habitat was being selected with the least impact on timber harvest programs was used. Again, where conflicts were identified, they were resolved in favor of the wildlife species

Efficiency analysis was conducted for a managed versus dedicated strategy for pileated woodpecker and marten habitat areas utilizing the methodology developed by the Siuslaw National Forest. This analysis indicated that a dedicated strategy was more efficient than a managed strategy in terms of timber outputs In addition, an economic evaluation was conducted for marten habitat areas, comparing managed and dedicated strategies; it confirmed that dedicated was more efficient in terms of PNV at a 4% discount rate.

Mountain Goat The Forest has limited information on the location of winter range utilized by goats. Generalized mapping of winter range was conducted by Ranger District personnel several years ago. It consisted of the general areas where goats were observed during the winter, and areas identified as suitable habitat but not verified to determine goat occupancy. This effort did not precisely identify all goat winter range boundaries. There likely were areas of occupied winter range that were not identified because of the remoteness of the area, and the difficulty in visiting these areas during the winter months.

Based on this information, an estimate of 124 family units was made for the Forest, including some within wilderness. Forty-five acres per family unit were dedicated to goat winter range, and this was modeled as the management requirement level for goats. Of the total 5,580 acres modeled, 1,900 acres are in tentatively suitable timber land base

Subsequent to this initial identification, additional information has been developed by Ranger District field personnel and WDW hunter kill location data. If it is assumed that location of hunter kills is closely correlated with family units, 108 family units are identified outside of wilderness. The identification of family unit locations from hunter kill location data can provide the basis for inferring generalized locations of winter range, but not exact boundaries.

A degree of uncertainty exists as to the exact location of goat winter range and the amount necessary to maintain viable populations. There is general agreement among knowledgeable professionals that goat winter range is unlikely to be reduced at a rate that would threaten viability of the population during the next 10 years, the life of this proposed Plan. This is based on knowledge of the physical characteristics of goat winter range, its proximity to existing road systems, timber volumes per acre, and the economics of timber harvest and roading necessary to support that harvest.

Forest-wide Standards and Guidelines were established as one means of dealing with the uncertainty involved. They provide that, during project design, surveys to determine the presence or absence of goat winter range shall be conducted. When winter range is identified during project design, the Standards and Guidelines included in the mountain goat winter range management strategy shall be followed.

Primary Cavity Excavators. "Wildlife Habitats in Managed Forests, the Blue Mountains of Oregon and Washington" was used to determine the numbers and sizes of snags necessary to maintain populations at 20% of their potential. This information was compared with timber yield tables and it was determined that a 1.5% decrease would be needed to provide the required number and size of hard snags. Timber yield tables have been reduced by 1.5%. It was assumed that sufficient numbers and sizes of snags would remain in areas not suited for timber production to meet the management requirements for these species.

Bald Eagle. Only one eagle nest site is known to exist on the Forest, although suitable habitat is known to exist over a larger area. The known nest site will be protected through Standards and Guidelines following the criteria developed by the Fish and Wildlife Service. Because of the very small acreage involved, nesting sites are not modeled.

A considerable amount of winter feeding occurs within the Forest, but most of it is outside the Forest boundary. It is assumed that winter forage requirements are adequately provided for by the riparian MR as far as modeling is concerned. Therefore, winter foraging is not directly modeled

Peregrine Falcon. Aerial surveys for peregrine falcon nest sites have been conducted by the Department of Game, but none have been located Habitat requirements for this species have not been modeled.

Grizzly Bear. Historical sighting data have been plotted on the Forest. Most of these sightings occur within dedicated wilderness; there is no known occupied habitat. Habitat requirements for this specie have not been modeled, but will be covered under Standards and Guidelines. These will reflect the Grizzly Bear Recovery Plan for the North Cascade Ecosystem.

Fish

The MR for anadromous fish is to maintain the existing smolt production level (Investment Level 1). The MR will be met through compliance with the Clean Water Act of 1977, associated Best Management Practices, and application of the harvest limits associated with the water quality MR (see below).

Water Quality.

The process used by the Forest to complete its hydrologic cumulative effects analysis consisted of two separate parts. These were 1) Watershed Sensitivity Analysis - a preliminary analysis of the sensitivity of all watersheds and the assignment of each watershed to one of three categories of sensitivity and 2) Watershed Condition and Management Requirement Analysis - a three step site-specific analysis of each watershed in the two most sensitivity categories from the Watershed Sensitivity Analysis. The first step of this second analysis further examined the stream channel conditions and upslope conditions for each watershed. The next step was to determine, based on the above conditions and other considerations, whether the watershed was in an acceptable or unacceptable condition. The final step in the second analysis was to establish a maximum level of harvest on National Forest lands that will maintain a watershed in an acceptable condition or will improve an unacceptable watershed to acceptable conditions.

Watershed Sensitivity Analysis.. A preliminary analysis was made of the sensitivity of all watersheds on the Forest using the following set of watershed condition factors: 1) management history, 2) climatic conditions, 3) presence of landslides, 4) inherent soil stability, 5) stream channel stability, and 6) off-site impacts. A team of the Forest's Soil Scientist, Hydrologist, Fishery Biologist, and Geotechnical Engineer made the first-cut analysis based on information at hand and their extensive field experience. This analysis was based on the planning guidance found on pages 8-9 of the "Process for Cumulative Effect Analysis" (RO letter 9/24/84) As a result of this analysis, watersheds were placed in one of three categories defined as follows:

> Category I: watersheds where there has been little or no effect on water quality or quantity values The existing natural and geomorphic features produce stable watershed conditions within the watershed and off-site. Of the total on the Forest, 8 watersheds were rated as Category I.
>
> Category II: watersheds with recent management activity (over the last 30 to 40 years) that, together with some natural events, have caused adverse impacts to water quality - quantity values within and/or outside the Forest's watershed boundaries. The existing natural and geomorphic features can and have produced unstable conditions in some areas of the watershed. There are 53 Category II watersheds on the Forest

Category III: watersheds with a very high frequency of management activities over the past 30 to 40 years. The magnitude of these activities has been significant within the watershed (large areas with activity occurring in a very short time period - 5 to 15 years). The existing natural and geomorphic features have produced and can continue to produce highly unstable and dynamic watershed conditions (within the watershed and off-site). Significant impacts have occurred within and outside the Forest's watershed boundaries. Of the total, 17 watersheds were rated as Category III. All of these lie north of Highway 2.

Watershed Condition and Management Requirement Determination. After the watershed sensitivity analysis, it was determined that an additional, more site-specific, analysis of the Category II and III watersheds would be necessary because of past level of management activities in most of these watersheds. The results of this additional analysis would identify limits of activity necessary to protect or allow recovery of these watersheds. The sensitivity of the Category I watersheds was determined to not be as critical, and normal silvicultural created opening constraints would mitigate any unacceptable adverse cumulative effects.

The Forest organized individual District Interdisciplinary (ID) teams to conduct the watershed condition and management requirement analysis for Category II and III watersheds.

The ID teams were composed of the most experienced personnel (with up to 25 years experience on the Forest) from the Supervisor's Office and each District, many of whom could offer insight from their personal experience over the years of working on the Mt. Baker-Snoqualmie. The team reviewed in-place empirical data and developed historical perspectives on watershed conditions from examination of aerial photos taken over the past 30 to 40 years This process was applied to every Category II and III watershed on the Forest (a total of 70 watersheds).

The Regional Hydrologist worked with the Forest in developing a format for a worksheet for documenting the process in each watershed. That format required the IDT to direct their analysis and answer questions about stream channel conditions. Analysis and discussion were kept separate for upper watersheds (1st and 2nd order streams) and lower watersheds (3rd and 4th order streams). For both the upper and lower watershed areas, the ID teams looked at present and past in-channel stability, streambank stability, status of large woody debris, and channel pattern (lower watershed only).

The teams also looked at upslope conditions by reviewing past harvest rates, road density and condition, presence of landslides, amount of unstable soils, and ability to revegetate and recover.

Some other considerations were incorporated, such as: 1) expectations of the effect of new or improved Best Management Practices (BMP's), 2) what the estimated effects of mitigation measures would be if prescribed, 3) the relationship of the mature sawtimber left in a watershed to streams and unstable soils, 4) the amount of roading necessary to harvest the remaining timber and potential location to streams and unstable soils, and 5) the practicability of helicopter logging.

All of the above analysis and documentation was summarized in order to provide an overall evaluation of the existing watershed conditions. It was also used to reach an agreement on a desired future condition measured at the Forest boundary. Thus, extensive state and private logging outside the National Forest was not considered. Depending upon the consensus of the ID team on the magnitude of the past cause and effect relationships projected to the future, each watershed was rated as being in an acceptable or unacceptable condition. Of the 70 Category II and III watersheds analyzed in detail, 51 were rated acceptable and 19 were rated unacceptable. The preponderance of the unacceptable watersheds -- 15 out of 19, or approximately 80% -- were found on the more geological sensitive north end of the Forest (see Chapter III of the EIS for a description of the geology of the Forest).

Based on the results of their analysis, the ID teams assigned a maximum harvest acreage per decade for each Category II and III watershed. The harvest rate assigned to a watershed is meant to maintain an acceptable condition, or improve an unacceptable condition within the National Forest The harvest rate was developed based on the tentatively suitable acres identified in the EIS and became a management requirement applied to all alternatives.

The consequence of a watershed being rated in an unacceptable condition is the application of a tighter harvest level in that watershed for some period -- usually at least the first two decades of the Plan. This allows for hydrologic recovery to take place before resuming what could be a higher harvest level and still avoid adverse hydrologic cumulative effects.

Only one unacceptable watershed (AZ #31, Deer Cr. SE) was assigned a no-harvest management requirement because of the seriousness of the watershed condition. No harvest will take place for the first two decades of the Plan; harvest will then resume at an acceptable level in the third and subsequent decades.

All of the other unacceptable watersheds showed some level of harvest. In most cases, the level was reduced for the first two decades, then increases in the third and fourth decades. The ID team's rationale was that some harvest could take place in a watershed while recovery was taking place if the harvest activity would be conducted using improved BMP's and located in the less sensitive portions of the watershed.

The documentation and results of the watershed condition and management requirement analyses were reviewed by a Forest Supervisor's Interdisciplinary (ID) team and a Regional ID team to assure consistency in application of the principles of this analysis strategy (See Appendix H and the Forest's planning records for further details of the hydrologic cumulative effects analysis process.)

Riparian Areas

Class I and II streams have been inventoried on the Forest, but Class III and IV have not. Because stream miles are linear, it is difficult to show them in R2MAP. To calculate acres within the streamside area, on-the-ground sampling was conducted to determine actual widths of management areas and treatment that occurred. This sampling was used to arrive at Forest-wide average widths. Sampling was also conducted to determine the densities of class III and IV streams, which was again utilized to calculate Forest-wide mileages.

The average width of SMU's was estimated by reviewing timber sale maps for a two year period on four Ranger Districts. The actual widths of leave strips and individual tree marking areas were measured from the maps. SMU strip widths averaged 225 feet on each side for Class I and II streams and 125 feet on each side for Class III and IV streams. Since these widths represented what was currently being implemented, it was assumed that they exceeded the MR necessary to protect riparian values. They were therefore reduced to 200 feet for Class I and II streams, and 100 feet for Class III and IV.

Based on professional judgment and experience, it was determined that all Class III streams did not require the same degree of protection as the 100 foot width might indicate. The lightly incised Class III stream width was reduced to 10 feet each side of the stream.

Based on the above estimates of stream width and length, acreages of SMU were calculated. For modeling purposes, the SMU acres were modeled as 25% with no timber yield, 50% as extended rotation yield (160 year minimum rotation and harvest entry rate not to exceed 6.25% per decade), and the remaining 25% the same as the adjacent land as if the SMU were not present. SMU acres were modeled only in management areas where the timber intensity prescribed rotations of less than 150 years. The assumption was that riparian areas would be adequately protected by standards and guidelines in areas with longer rotations or no scheduled timber harvest.

The SMU prescription does not apply to Class IV streams. These streams are provided protection through the Forest-wide Standards and Guidelines. The increased cost of implementing Best Management Practices on Class IV streams is reflected in the logging costs calculated by soil stability class.

Timber

The generalized approach for modeling harvest dispersion outlined in Regional Direction was utilized to develop a theoretical starting point. This approach resulted in a harvest dispersion factor of 16-23%, depending on the number of years required to close an opening. On this Forest, the time required for trees to reach 4 1/2 feet in height following regeneration harvest varies by elevation and reforestation method. When reforestation is accomplished by planting, the estimated time for trees to reach 4 1/2 feet in height is 11 years at lower elevations and 13 years at higher elevations. When reforestation is accomplished by natural seeding, the time estimate is 12 years at lower elevations and 16 years at higher elevations.

As a check, some of the theoretical sale layout work completed for unroaded and undeveloped drainages was reviewed and it was estimated that a 30% dispersion factor was appropriate. As a further check, the Gifford Pinchot National Forest was consulted. Their preliminary evaluation indicated that a 28-32% harvest dispersion factor was appropriate for their Forest. A Forest-wide harvest dispersion factor by AZ of 30% for Decades 1 and 2; 20% for Decades 3 and 4; and 20% by North and South for Decades 5 through 15 was used for all Benchmark Runs.

2. Modeling Constraints for MR's

The following constraints were used in FORPLAN to model the MR's:

Wildlife MR's (except Primary Cavity Excavators). All wildlife MR acres, both tentatively suitable and unsuitable, were assigned to a "no-harvest" MR prescription. As noted earlier, analysis showed it was more cost-efficient on this Forest to dedicate somewhat smaller land areas to non-harvest to achieve the MR's, rather than managing larger land areas under extended rotation. The wildlife MR prescription did not allow tentatively suitable acres assigned to it to be available for timber harvest; they could not become part of the suitable acres in solution for that alternative.

Primary Cavity Excavators. As discussed above, the per acre timber yield tables were reduced by 1.5% for each 20% of primary excavator populations maintained by an alternative. It was assumed that there would be sufficient numbers and sizes of snags to meet the management requirements for primary cavity excavators in areas not suited for, or not subject to, timber management.

Fish. No special modeling was developed to meet MR's; Best Management Practices are implicit in the modeling of silvicultural practices and sediment yields, and the harvest constraints for the water quality MR provide additional assurance that watersheds will not be degraded below levels necessary to maintain adequate water quality and viable fish populations.

Water Quality

The water quality management requirement developed by the watershed condition assessment ID teams is incorporated into the Forest's FORPLAN model as a set of constraints. Accessibility constraints applied by allocation zone set a maximum on the amount of an area that can be scheduled for harvest in a decade. The accessibility constraints for the water quality MR were developed by zone for the first decade by calculating the percent of the area that can be entered in the next ten years while maintaining cumulative effects in the watershed at or below the threshold of unacceptable damage. The maximum harvest acreage limits by watershed in the first decade developed by the ID teams form the basis for these accessibility constraints.

For the second and subsequent decades, the water quality MR was modeled by flow constraints on acres of final harvest Forest-wide (by North and South). Accessibility constraints were not used in these decades because of insufficient information available from the model to track the vegetation condition class by zone after management is implemented in the first decade. The flow constraints were developed in concert with the Forest's resource specialists to reflect the continuing need to manage in order to keep cumulative hydrologic effects below the unacceptable damage threshold. The flow constraints allow final harvest acres in the second decade to increase by 4% over the first decade final harvest acres; by 10% in decade 3 over decade 2; by 4% in decade 4 over decade 3; and 0% increase thereafter -- a total increase in final harvest acres of approximately 18% over the first decade levels. (See the Forest's planning records for the detailed calculations involved in developing the FORPLAN harvest constraints for the water quality MR.)

Riparian Areas. Analysis by Forest watershed specialists led to the conclusion that up to 200 feet each side of Class I and II streams, up to 100 feet each side of deeply-incised Class III streams, and up to 10 feet each side of lightly-incised Class III streams will need special management consideration if subject to vegetation manipulation, particularly timber harvest. This area was

designated as Streamside Management Unit (SMU), and a specific prescription (13A) was written to govern its management.

For modeling purposes, 25% of the SMU was allocated to a non-harvest minimum-level intensity; 50% could be harvested on minimum 160-year rotation; and the other 25% was left in the original allocation choice assignment. (In other words, this last 25% would generally be allocated to the same management activity as that adjoining the SMU.) The extended rotation of the SMU had all silvicultural options available to it. The SMU prescription did not apply to Class IV streams; they are protected under the Forest-wide Standards and Guidelines.

Harvest Unit Dispersion. Silvicultural guidelines and NFMA vegetation management and diversity specifications (36 CFR 219.27(d),(g)) required the use of a constraint on the maximum area the model could be allowed to schedule for harvest in any given decade. In order to meet these guidelines and specifications, at least one decade of regeneration growth (on the average) would be required on a harvest unit before the adjacent stand could be harvested. Analysis on the Forest and within the Region indicated that approximately 30% of an area could be cut in Decades 1 and 2 of the planning horizon without violating the adjacency requirements. Because of the cumulative effects of adding harvest units, that percentage was dropped to 20% in the third and fourth decades. Thus, after four decades an entire area could be cut over without violating the guidelines and requirements.

In FORPLAN, these requirements were proxied by applying accessibility constraints to the coordinated allocation choices for each AZ by decade for the first four decades. Acres assigned to full timber management were limited to a maximum of 30% harvest in the first decade, an additional 30% in the second, another 20% in the third, and final 20% in the fourth. Thereafter, a general relational constraint was applied to the north part of the Forest and to the south part of the Forest, respectively. This constraint allowed a maximum of 20% of the acres assigned to timber management on each of those parts of the Forest to be harvested in any given decade.

It is important to note that the percentages used are maximums. There were many instances when FORPLAN chose to harvest fewer acres than allowed by the constraint. The accessibility constraints, though, are cumulative constraints. That is, the model could theoretically not cut anything for two decades, then cut 80% of an area in the third decade. We did not observe this actually happening when analyzing the benchmark and alternative runs.

The modeling results of the accessibility constraints were tested by actually plotting units as scheduled for harvest in a benchmark run onto an AZ/AA map. The resulting pattern indicated that the adjacency requirements could be met in most instances, though not with a lot of leeway. The constraint level proxied the desired result quite well. (In actual implementation, more flexibility would be allowed between AZ's to move harvest units away from problem areas into areas that can absorb higher than the 30/30/20/20 entry rate modeled in FORPLAN).

3. Constraint Overlap

As discussed above, constraints are often interdependent. Standing alone, each constraint set developed will provide for the particular management requirements for which it is designed. However, when applied in the same benchmark or alternative run, one constraint set will often, additionally, provide for some of the management requirements covered by a separate constraint set. For instance, spotted owl habitat areas are often located along streams. If the spotted owl area is dedicated to non-harvest, it would be redundant to also designate and constrain for a SMU through the same area. By constraining for the spotted owl area, the riparian area protection requirements are already met.

Overlaps were calculated among the various constraint sets to avoid such double counting (which is a particular problem when constraints are applied to AA acres, rather than to AZ's or other specific geographic areas). Where constraint sets overlapped, only the most limiting was applied. Therefore, total acres affected by all constraints are fewer than the sum of the acres in each individual constraint set.

4. Additional MR Analysis

Additional discussion on the description, background, development and analysis of the MR's is included in Appendix H. The appendix describes MR's with potentially significant effects on resource outputs or environmental consequences, and presents the results of testing the sensitivity to varying the MR levels.

C. Benchmark Analysis

1. Constraint Analysis

Three major constraint sets were used in the benchmarks and alternatives (wildlife MR's, riparian area MR's and dispersion/accessibility constraints) for the AMS and DEIS. They were analyzed to determine their individual maximum opportunity costs, and the opportunity cost for all three applied concurrently. These analyses were based on Benchmark Run #3 (all the benchmark runs are discussed in detail later in this chapter), the basic "maximize PNV" run with no minimum management constraints, but with nondeclining yield and 95% CMAI applied. (The constraints were not analyzed separately against each of the other benchmark runs).

Between the DEIS and FEIS, the harvest constraints for water quality resulting from the hydrologic cumulative effects analysis were incorporated into the Forest planning process and into FORPLAN. This constraint set was also analyzed to determine its individual maximum opportunity cost, as well as the opportunity cost when applied along with the other three major constraint sets.

The individual constraint sets were added one-at-a-time to Run #3. In this way, they were considered individually without overlap of the other constraint sets in the model, and the maximum opportunity cost associated with each constraint set was calculated separately. The four constraint sets were applied concurrently in Run #7. The differences between Run #3 and Run #7 represent the opportunity costs of the four sets together.

Table B-23 shows the difference between Run #3 and each constraint set individually, and then in combination, as represented by Run #7. In all cases, an interdependence between the individual constraint sets is indicated. The difference between Run #3 and Run #7 is less than the sum of the four constraint sets individually. The full output/effects tables, Tables B-27, B-28, and B-29, for the initial three constraints analysis benchmark runs are found in part D of this chapter. (Because of the modeling changes between the AMS benchmark runs and the FEIS, as discussed at the beginning of this chapter, the harvest limts for water quality constraint set was not run in a full-blown benchmark run with all outputs and effects calculated.)

A significant reduction in harvest figures (both LTSY and ASQ) as well as harvest acres is observed when MR's are applied. Less intensive timber management prescriptions are also selected, which accounts for the much lower decrease in PNV (14%) compared to the decrease in first decade ASQ (approximately 41%) or the decrease in total harvest acres over the first five decades (approximately 37%).

Table B-23
Opportunity Costs of MR's (NDF)

2. Required Benchmarks

There were seven benchmark runs required by NFMA regulations and the Region 6 planning direction (36 CFR 219.12 (e) (1) and memo of November 10, 1983, respectively). The required benchmark runs were:

Minimum Level Management - specifies the minimum level of management which would be needed to maintain the Forest as a part of the National Forest System, and to manage uncontrollable outputs and uses. (This benchmark was estimated outside of FORPLAN) See Table B-24 in this chapter.

Biological Timber Potential - specifies the management, outputs, costs, and effects that would occur to produce the biological timber potential with no constraints such as nondeclining yield (NDY), 95% CMAI, MR's, etc. (Run #1) See Table B-25 below

Maximum Present Net Value based on Assigned Prices (without MR's) - specifies the management which will maximize the present net value of those outputs that have assigned and market prices, NDY, 95% CMAI, with no MR's applied. (Run #3); see Table B-26.

Maximum Present Net Value based on Assigned Prices with MR's - specifies the management which will maximize PNV of those outputs that have assigned and market prices, NDY, 95% CMAI, with MR's applied. (Run #7) See Table B-37.

Maximum Timber Resource - specifies the management which will maximize timber outputs given NDY, 95% CMAI, and with MR's applied. See Table B-44.

Maximum Primitive and Semiprimitive Nonmotorized Recreation Opportunities - specifies the management which will maximize dispersed recreation in the Primitive and Semiprimitive Nonmotorized ROS classes. See Table B-45.

Current Direction - specifies the management most likely to be implemented in the future, and the resulting outputs, costs, and effects, if current plans and existing direction are followed. Three versions of this run were done. The first was current direction without the MR's required by NFMA, the truest representation of currently approved management direction for the Forest, and the reason why a new planning action is required. The second included MR's and the current first decade timber output requirement, to do this the NDY constraint had to be dropped. The third included MR's but no first decade timber harvest requirement, so NDY was maintained See Tables B-46, B-47 and B-48.

3. Other Benchmark Run

Variations of Runs #3 and #Z - Using Different Harvest Flow and Rotation Length Requirements.

a. Maximum PNV, assigned prices, no MR's, harvest allowed to fluctuate up or down by 20% compared to the harvest in the previous decade (known as 20% sequential upper and lower bounds), and final harvest allowed when trees reach utilization standards (7" DBH, 4" tops). This is the same as Run #3, Table B-26, except that nondeclining yield is replaced by harvest flows allowed to fluctuate by 20% from decade to decade, and harvest at 95% CMAI is replaced by harvest at utilization

standards -- a shortening of the minimum rotation by as much as 40 years. (Run #2) See Table B-30.

b. Maximum PNV, assigned prices, MR's included, 20% harvest fluctuations allowed, rotations based on utilization standards - same as Run #2 above, except that the MR constraint sets were added. (Run #4) See Table B-31.

c. Maximum PNV, assigned prices, MR's included, 20% harvest fluctuations allowed, 95% CMAI - same as Run #4, except using 95% CMAI instead of utilization standards. (Run #5) See Table B-33.

d. Maximum PNV, assigned prices, MR's included, nondeclining yields, rotations based on utilization standards; same as Run #4, except using nondeclining yields instead of fluctuating harvests. (Run #6) See Table B-35.

Variations Using Market Prices Only

a Maximum PNV, market prices, MR's, 20% harvest fluctuations allowed, rotations based on utilization standards - same as Run #4, except market prices only, rather than market plus assigned prices, used. (Run #8) See Table B-32.

b. Maximum PNV, market prices, MR's, 20% harvest fluctuations allowed, 95% CMAI - same as Run #5, except market prices only. (Run #9) See Table B-34

c. Maximum PNV, market prices, MR's, NDY, rotations based on utilization standards - same as Run #6, except market prices only. (Run #10) See Table B-36.

d. Maximum PNV, market prices, MR's, NDY, 95% CMAI - same as Run #7, except market prices only. (Run #11) See Table B-38.

Sensitivity Analysis Runs - See Tables B-39 through B-43 in part D for results of these five sensitivity analysis runs.

a. Same as Run #7, except that real timber price trends of 0% used.

b Same as Run #7, except that real timber price trends of 2% used.

c. Same as Run #7, except that real timber price trends of 3% used.

d. Same as Run #7, except that timber management-related costs (not including road construction and logging costs) were decreased 20%.

e. Same as Run #7, except that timber management-related costs (not including road construction and logging costs) were increased 20%.

Constraints Analysis Runs - The output results from the three initial constraint set runs (wildlife MR's, riparian area MR's and dispersion constraints) are shown in Tables B-27, B-28 and B-29 in part D of this chapter. Selected results of these three constraint analysis runs, along with those from the set of harvest limits for the water quality MR added between the

Draft and Final, are used in Table B-23 to show the opportunity costs of the constraint sets.

a Same as Run #3, except that full wildlife MR's constraint set added.

b. Same as Run #3, except that full riparian MR's constraint set added.

c. Same as Run #3, except that full dispersion/accessibility constraint set added.

D. Benchmark Detail

This section describes in detail the objectives, the assumptions incorporated, and the results of the required benchmark runs. Output tables are also given for benchmark runs that are primarily versions of the required benchmark runs, as shown above. A discussion is presented of the major differences between and among the various benchmark runs.

1. Minimum Level

Description and Purpose. The minimum level benchmark, Table B-24, specifies the level of management which would be needed to maintain the Forest as part of the National Forest System; provide for the protection of the life, health, and safety of the incidental Forest user, prevent environmental damage to lands or resources on adjacent or downstream lands of other ownerships; prevent significant impairment of the productivity of the land; and administer unavoidable non-Forest Service permits and leasable minerals. This benchmark was developed outside the FORPLAN model.

Assumptions and Constraints. 1) The transition costs of moving from the current situation to minimum level management were not included. 2) A minimum organization and a low level of management are needed to protect the life, health, and safety of incidental users; prevent environmental damage to adjacent non-Forest Service lands; and administer uncontrollable outputs and uses.

Results. Dispersed and developed recreation occur at levels far below current use, primarily because facilities such as roads and campgrounds are no longer maintained. In fact, recreation declines in future decades as non-maintained facilities become less and less useable. However, some use will still occur on the Forest, primarily along the periphery and by trail.

No timber sales are programmed in this alternative; therefore, ASQ and LTSYC are zero. No new roads are constructed; road reconstruction takes place only to the extent necessary to provide access for protection purposes. Sediment production overall decreases over time toward background levels as roads are closed. Some small localized areas of sediment increase may occur where areas in need of revegetation or stabilization do not receive that treatment.

Returns to the Treasury are minimal, coming primarily from salvage and sanitation sales made in response to resource protection needs. Some receipts may accrue where resource extraction activities such as gas, oil, and geothermal development take place under auspices of other laws.

As the environment returns to a more natural state, resources requiring low or no vegetation disturbance are favored. These would include archaeological,

2. Biological Timber Potential (Run #1)

Description and Purpose. This run establishes the highest possible level of timber outputs that can be sustained given a policy of non-declining flow, 95% CMAI, and in the absence of MR's. The run is initially made with a maximize timber in the Decade 1 objective function. Utilizing first decade timber harvest outputs as a constraint, a second run is made to maximize timber harvest for 15 decades. This second run is then rolled over using the first and 15th decade harvest levels as constraints to a maximize PNV objective function. The results of the third run are those shown in Table B-25.

Another purpose of this run is to calibrate the FORPLAN model in terms of timber information.

Assumptions and Constraints

- All lands identified as tentatively suitable are available for assignment to a timber prescription.
- The ending inventory constraint is applied.
- The non-declining flow constraint is applied.
- Rotation is based on 95% CMAI.
- Ending inventory constraint is applied.
- No budget constraint is applied
- Tentatively suitable lands within the Alpine Lakes and Skagit Wild and Scenic River are available for timber production, regardless of their current allocation in the approved plans.

Results. The average productivity from Run #1 was compared to the average productivity indicated in the current Timber Management Plan and also the average productivity in the 1979 Draft Timber Management Plan. The comparison was made using board foot values, since the current plan does not contain cubic foot information.

Source	Board Feet/Acre/Year
Run #1	551
Current Plan	373
1979 Draft Plan	660

The potential yield figure expressed in the current Timber Management Plan was developed utilizing the Hanzlik Formula and an area volume check. Any adjustments made to this are unknown. Because of the age (1963) and volume derivation methods used in this plan, it was decided to compare Run #1 outputs to the 1979 Draft Timber Management Plan.

	Draft TM Plan (1979)	Run #1
CFL/Tentatively Suitable (Acres)	770,781	604,800
Average Annual Production (MMBF)	508.6	333.3 1/
Board/Feet/Acre/Year	660	551
Average Site Index (100 Years)	133	113
Yield Generator	DFIT	DFSIM

Run #1 shows approximately a 17% decrease in board feet per acre productivity from the biological potential calculated in the 1979 Draft Timber Management Plan. A major portion of this difference is explained by the average site index used for the Forest between the two calculations. The difference between a site index of 133 and 113 would account for a difference in productivity of approximately 13%. In addition, the 1979 Draft Timber Management Plan assumed a genetics gain of 10% while a refined method of calculating the genetics increase for Run #1 shows only a 6.6% increase. The 1979 Draft Plan also assumed more acres would be available for precommercial and commercial thinning than are available in the existing current planning effort.

Based on the above evaluation, it was determined that the model was reasonable in terms of timber information provided.

1/ Reduced from benchmark output (334.5) proportional to approved tentatively suitable acres.

3 Maximum Present Net Value Based on Assigned Prices, No MR's (Run #3)

Description and Purpose. This is the first Benchmark Run that maximizes PNV utilizing both market and assigned values, rotations restricted to 95% CMAI, non-declining flow, and in the absence of MR's. This run will be utilized later to determine the opportunity costs associated with including the MR constraints.

Assumptions and Constraints. This Benchmark Run is formulated according to Regional Direction. The constraints that apply are:

- Objective function - maximize PNV for 15 decade
- Land base - tentatively suitable lands.
- Ending inventory constraint is applied.
- MR's are not included.
- NDF constraint is applied.
- Rotations are based on 95% CMAI.
- Budget is not constrained

Results. The results of this run (and its variations) by selected outputs and effects are shown in Tables B-26 through B-29. With the absence of MR's, this run has the highest level of suitable acres, with the exception of Run #1, Table B-25. It also has the second highest LTSYC and PNV.

A major portion of the required new road construction is being deferred until the second decade when timber values have increased slightly due to price trending, and when some discounting has occurred. This would tend to concentrate timber harvesting more in those areas that already have some roads in place, and have already been heavily harvested. The addition of MR's which includes a dispersal requirement tends to moderate this situation as can be seen by comparing road construction in this run to Run #7, Table B-37.

Recreation capacity for roaded modified increases with time and decreases in the SPNM and P Classes as timber harvest occurs.

Nearly all of the harvest in the first decade occurs in the old growth component of the suitable acres.

4. Maximum Present Net Value Based on Assigned Prices with MR's (Run #7)

Description and Purpose. This Benchmark Run forms the basis for the development of most of the alternatives to be developed in detail, in that it contains the minimum policy and legal constraints. It is also used as a basis for conducting sensitivity analysis for timber price trends and timber cost assumptions.

This run will also be used as a basis for analyzing the opportunity costs for including MR's.

Assumptions and Constraints. This run is formulated according to Regional Direction. The constraints that apply are:

- Objective function - Maximize PNV for 15 decades.
- Land Base - tentatively suitable lands
- Ending inventory constraint is applied.
- MR's are included.
- NDF constraint is applied.
- Rotations are based on 95% CMAI.
- Budget is not constrained.

Results. Results of this run (and its variations) by selected outputs and effects are shown in the run output Tables B-37 and B-39 through B-43.

This run differs from Run #3, Table B-26, in that MR's are included. Suitable acres drop to 528,800 acres or approximately 87% of the tentatively suitable acres.

Road construction increases in the first decade when compared to Run #3 which is primarily a function of the harvest dispersal factor included in this run.

A larger portion of the harvested acres are assigned to a natural regeneration prescription in this run than in Run #3. This appears to be a result of the MR's and in particular the dispersion constraint

This run does not harvest the suitable old growth quite as rapidly in the first decade as in Run #3, but by the fifth decade the remaining suitable old growth is approximately the same in both runs.

5. Maximum Timber Resource

Description and Purpose. This run is designed to determine the maximum timber outputs that can be produced on the Forest, given that legal and policy constraints are met. It is used as a basis for analyzing opportunity costs when other resource and economic objectives are met.

Assumptions and Constraints. This run is formulated according to Regional Direction. The one exception is that the run is first made to maximize timber for the first decade. The first decade harvest level is then used as a constraint in a run that maximizes timber outputs for 15 decades. The timber outputs from this second run are then used as constraints for a third run that maximizes PNV. This variation to Regional Direction was suggested by the Regional Timber Economist.

This run was formulated using the following constraints:

- Objective function - Maximum timber for 1 decade; maximum timber for 15 decades; maximize PNV.
- Land base - tentatively suitable lands.
- Ending inventory constraint is applied.
- MR constraints are applied.
- NDF constraint is applied.
- Rotations are based on 95% CMAI.
- Budget is not constrained.

Results. The results of this run are shown in the accompanying run output Table B-44.

This run has the highest LTSYC of any of the runs that meet legal and policy constraints. It is also has the lowest PNV of all the runs that use market and assigned values, except Maximum Primitive and Semi-Primitive Nonmotorized Recreation.

Timber outputs are above those of recent years, and approximately 37% above those in the current timber management plan after it was amended for the 1984 Wilderness Act. The main reason for this increase is the increase in the suitable land base.

The objective function drives timber management intensities to a higher level than occurs with a maximum PNV objective function, but it also accounts for the lower PNV value.

Suitable acres are also relatively high, exceeded only by Runs #1, Table B-25, and #3, Table B-26, which do not included MR's.

Arterial and Collector road requirements are very similar to those in Run #7, Table B-37, but are more evenly distributed between the first and second decade.

Nearly all of the timber harvest occurs in the old growth component in the first decade. Suitable old growth declines steadily through the fifth decade, when 14,000 acres remain.

6. Maximum Primitive and Semi-Primitive Nonmotorized Recreation Opportunities

Description and Purpose. This run was designed to maximize Primitive and Semi-Primitive Nonmotorized recreation opportunities on the Forest, and to determine the economically efficient level of outputs of other resources. It is used as a basis for responding to the major public issue of maintaining as much of the Forest in an unroaded and undeveloped condition as possible. It is also used as a basis for establishing the decision space for responding to Regional Planning Direction to develop an alternative where 12-16% of the total recreation demand is met in a Primitive or Semi-Primitive Nonmotorized setting.

Assumptions and Constraints. This benchmark was developed based on a number of assumptions. These include:

- 217 miles of existing collector roads and 34 miles of existing arterial roads would be closed. These closed roads are those that make long intrusions into areas that are currently mapped as Primitive or Semi-Primitive Nonmotorized. This includes areas that are designated wilderness as well as released roadless areas.

- 214 miles of planned collector roads would not be constructed These are roads that are similar in character to the existing roads described above.

- 111 miles of trail would be constructed within wilderness to increase carrying capacity. Affected acres would be managed at Semi-Primitive trailed level.

- Acres currently in Roaded Natural or Roaded Modified, and affected by road closures, would become Semi-Primitive within 5 decades.

- No scheduled timber harvest will occur on Primitive or Semi-Primitive Nonmotorized lands.

Constraints that apply to this Benchmark are as follows:

- Objective function - Maximize Primitive and Semi-Primitive Nonmotorized RVD's, rolled over to a maximize PNV

- Land base - All lands currently assigned, or with the potential to become, Primitive or Semi-Primitive Nonmotorized are considered suitable. Lands classified as tentatively suitable for timber production are reduced to reflect the P and SPNM acres.

- Ending inventory constraint is applied.
- MR's are applied.
- NDF is applied.
- Rotations are based on 95% CMAI.
- Budget is not a constraint.

Results. The results of this run are displayed in the accompanying run output Table B-45.

In keeping with the objectives of this benchmark, Semi-Primitive Nonmotorized and Primitive RVD capacity is approximately 37% higher by the 5th decade than in Run #7, Table B-37, then decreases only slightly thereafter, whereas the *other benchmarks show a rapid decline in Semi-Primitive Nonmotorized acres.* The five-decade display in the table does not include the transition of lands currently in a roaded state (approximately 62,500 acres of tentatively suitable lands) that will revert to a Semi-Primitive Nonmotorized ROS state after 5 decades.

Roaded recreation capacity grows only about 1.4% over the first five decades in this run, compared with an 8% increase in Run #7 This is a result of fewer acres being managed for timber and few miles of roads being constructed.

Hunting and fishing recreation capacity are at about the same level in the first decade as Run #7 and the Current Direction run, but increase only slightly thereafter. This reflects more lands staying in a Semi-Primitive Nonmotorized and Primitive status, with correspondingly lower capacity coefficients than roaded lands.

Suitable acres, timber harvest, and the LTSYC are respectively, 43% and 45% and 44% lower in this benchmark than in Run #7. Timber management intensity is slightly lower in this run than in Run #7, with a lower proportion of suitable acres precommercially thinned and reforested by planting.

As would be expected with a significantly lower timber harvest, PNV for this benchmark is about 14% lower than in Run #7, but the annual budget is also significantly lower.

7. Current Direction

Description and Purpose. This Benchmark specifies the management, resource outputs, and economic and environmental effects most likely to occur in the future if current plans and direction are followed

Those current plans and direction that have the most effect on resource outputs and environmental and economic effects were modeled in FORPLAN. These include the Alpine Lakes Area Management Plan, the Skagit Wild and Scenic River Plan, the 1963 Timber Management Plan as amended, and the Ranger District Multiple Use Plans Direction that was modeled includes retention of old growth habitat for protection of 49 pairs of spotted owls (1,000 acres per pair), cavity excavators at 40% of their potential population on commercial forest lands, and rotations based on culmination of mean annual increment. No dispersion or accessibility restrictions are required.

The only plan that actually specifies resource outputs is the Timber Management Plan, which has a potential yield of 203.8 MMBF The plan does not contain cubic foot data, so the RPA conversion factor of 4.89 was used, which results in a potential yield of 41 7 MMCF

This Benchmark was extremely hard to model because of the lack of compatibility between the Timber Management Plan, the Alpine Lakes Area Management Plan, the Skagit Wild and Scenic River Plan, and the Ranger District Multiple Use Plans.

Amendments to the Timber Management Plan never reduced the potential yield to meet direction in the Alpine Lakes and Skagit River Plans to protect 49 pairs of owls, nor to maintain cavity nesters at 40% of their potential population.

The task was further complicated by the fact that the current Timber Management Plan was amended several times to reflect declining land bases. These reductions were most frequently made on lands containing old growth (higher standing volumes) and plan amendments were not based on a new timber inventory. The most recent amendment reflected the Washington Wilderness Act, where essentially all acre reductions were old growth. Because of RARE II restrictions on a major portion of these lands and the fact that in recent years harvests were concentrated on the roaded portions of the Forest, this resulted in a forest structure that contains a much higher proportion of young stands than the structure used in the original development of the Timber Management Plan.

This Benchmark was run under an objective function that maximized timber volume for 5 decades The results were rolled over twice: first to maximize timber volume for 15 decades; second to maximize PNV for 15 decades, to force the solution toward economic efficiency The non-declining yield constraint was applied, and an absolute constraint of 41 677 MMCF average annual harvest was set as floor for the first decade. Budget was constrained to $27.0 MM annually for the planning horizon (The budget constraint was based on the indexed average for Fiscal Years 1982, 1983, and 1984 This is a slight variance from the Regional Direction of using Fiscal Year 1980-1982 However, it was felt that the more recent budget levels are a much better reflection of the dollars that are available in the future for managing the Forest at current levels). No dispersion or accessibility constraints were applied.
The run as formulated above is feasible; it is able to meet about 108% of the first and subsequent decade harvest level specified in the current Timber

Management Plan, while satisfying the spotted owl, cavity excavator, 100% CMAI, and non-declining requirements. Of the estimated tentatively suitable land available under current direction, approximately 97% is considered suitable in this run.

Assumptions and Constraints. The major assumptions and constraints finally selected for this run are described above.

Results. The results of this run are displayed in the accompanying Table B-46.

Suitable acres are approximately 97% of tentatively suitable estimates. The difference is primarily spotted owl habitat. The low tentatively suitable acre figure is partially a reflection of the Ranger District Multiple Use Plans which place resource management restrictions on the upper forest zone for landscape management, soils, and other special areas.

This run results in higher levels of roaded natural recreation capacity because of the lower level of timber harvest when compared to Run #7, Table B-37. Roaded modified capacity starts out lower in this run, when compared to Run #7, but increases at a similar rate through decade 5. The decline in Semi-Primitive Nonmotorized is very similar to Run #7.

Total road construction (arterial and collectors) is approximately 13% lower in this run than in Run #7 because of the lower suitable land base.

Nearly all of the harvest in the first decade occurs in the old growth stands. This heavy harvesting of old growth continues through the fifth decade when the old growth is nearly depleted (in suitable lands).

Spotted owl populations are not as well distributed across their range as in the other Benchmarks. The loss of a single habitat area may cause the establishment of "islands" of these species.

Populations of pine marten and pileated woodpecker are not specifically supported over their existing range, and populations would decline over time.

Cavity excavators would be provided for at 40% of their potential population levels.

8. Current Direction, Implementable with Specified Timber Targets

Description and Purpose. This Benchmark specifies the management, resource outputs, and economic and environmental effects most likely to occur in the future if current plans and direction are followed, including the requirements of the National Forest Management Act of 1976 and its implementing regulations. The timber harvest target (potential yield), as specified in the amended Timber Management Plan, is met in the first decade.

Those current plans, direction, and NFMA management requirements that have the most resource output, environmental, and economic effects were modeled in FORPLAN. These include the Alpine Lakes Area Management Plan, the Skagit Wild and Scenic River Plan, the 1963 Timber Management Plan as amended, the Ranger District Multiple Use Plans, NFMA regulations (FSM 1920), and the 11/83 Region 6 Planning Direction Specific modeling is discussed below. The same difficulties experienced in modeling the original Current Direction Benchmark were also experienced here, compounded by the additional constraints required to meet NFMA.

The only plan that actually specifies resource outputs is the Timber Management Plan, which has a potential yield of 203.8 MMBF The plan does not contain cubic foot data, so the RPA conversion factor of 4 89 was used, which results in a potential yield of 41 7 MMCF.

Assumptions and Constraints. This Benchmark was formulated and run along the same lines as the original Current Direction Benchmark, with some notable changes. Modifications were made to incorporate the management requirements to meet NFMA These are the same MR's used in all the other Benchmark Runs except Runs #1, 2, 3, and Current Direction The same accessibility/dispersion constraints were used as in the other Benchmark Runs to meet silvicultural guidelines, harvest unit size limitations, unit dispersion, and vegetation diversity. Habitat for 40% of the potential cavity nester population is maintained, as in the original Current Direction run (in contrast to the 20% level used as the MR level in the other Benchmarks). Rotations are based on culmination of mean annual increment

As in the original Current Direction Benchmark, the objective function was to maximize timber for 5 decades, rolled over to maximize timber for 15 decades, then rolled over once more to maximize PNV for 15 decades to force the solution toward economic efficiency.

The non-declining yield and ending inventory (perpetual harvest) constraints were applied. An absolute constraint of 41.677 MMCF average annual harvest was set as a floor for the first decade Budget was constrained to $27 0 MM annually for 150 year planning horizon.

Results. The initial run resulted in an infeasible solution. Timber harvest in the first decade could only reach about 40.7 MMCF instead of the required 41.7 MMCF. The budget constraint of $27.0 MM in the first decade could also not be met, probably because of increased intensities of timber management chosen to try to reach the required timber harvest level.

A second run relaxing the budget constraint by $5 MM annually cleared up the budget infeasibility in the first decade, but did not bring the first decade timber harvest up to 41.7 MMCF

A third run replacing non-declining yield with a 20% sequential upper and lower bounds (departure) formulation was made. First decade harvest was required to be equal to 41.7 MMCF, with departure allowed thereafter. This run was feasible.

The results of the third run are shown in the accompanying output Table B-47.

ASQ climbs to 54.6 MCF in the 3rd decade, drops to a low of 23 5 MCF in the 7th decade, and then again increases to 101.2 MCF by the 15th decade.

Road construction requirements increase in the 1st decade compared to the original Current Direction run, because timber harvest figures are slightly higher, but primarily because the harvest dispersion constraint is forcing harvest into the unroaded portion of the Forest.

Slightly higher levels of PCT are selected to meet the required ASQ in the 1st decade.

PNV is somewhat lower in this formulation as compared to the original Current Direction Benchmark because of the higher costs of increased timber management intensities and roading costs being incurred earlier in the planning horizon.

Suitable acres are approximately 89% of tentatively suitable as compared to 97% in the original formulation. This is due primarily to the effect of MR's.

9 Current Direction, Implementable With No Specified Timber Targets

Description and Purpose. This Benchmark specifies the management, resource ouputs, and economic and environmental effects most likely to occur in the future if current plans and direction are followed, including the requirements of the National Forest Management Act of 1976 and its implementing regulations.

Those current plans, direction, and NFMA management requirements that have the most effect on resource outputs and environmental and economic effects were modeled in FORPLAN. These include the Alpine Lakes Area Management Plan, the Skagit Wild and Scenic River Plan, the 1963 Timber Management Plan as amended, the Ranger District Multiple Use Plans, NFMA regulations (FSM 1920), and the 11/83 Region 6 Planning Direction Specific modeling is discussed below. The same difficulties experienced in modeling the original Current Direction Benchmark were also experienced here, compounded by the additional constraints required to meet NFMA.

The only plan that actually specifies resource outputs is the Timber Management Plan, which has a potential yield of 203.8 MMBF The plan does not contain cubic foot data, so the RPA conversion factor of 4 89 was used, which results in a potential yield of 41.7 MMCF.

Assumptions and Constraints. This Benchmark was formulated and run along the same lines as the original Current Direction Benchmark, with some notable changes. As the title indicates, modifications were made to incorporate the management requirements to meet NFMA. These are the same MR's used in all the other Benchmark Runs, except Runs #1, 2, 3, and Current Direction The same accessibility/dispersion constraints are used as in the other Benchmark Runs to meet silvicultural guidelines, harvest unit size limitations, unit dispersion, and vegetation diversity. Habitat for 40% of the potential cavity nester population is maintained, as in the original Current Direction run (in contrast to the 20% level used as the MR level in the other Benchmarks). Rotations are based on culmination of mean annual increment

As in the original Current Direction Benchmark, the objective function was to maximize timber for 5 decades, rolled over to maximize timber for 15 decades, then rolled over once more to maximize PNV for 15 decades to force the solution toward economic efficiency

The non-declining yield and ending inventory (perpetual harvest) constraints are applied. In contrast to the original Current Direction benchmark, no timber harvest target is set Budget is constrained to 27.0 $MM annually for the 150-year planning horizon.

Results With no first decade timber harvest target, this run was feasible. The results of the run are shown in the accompanying output Table B-48.

Most notable is the low first decade annual harvest of 20.9 MMCF, followed by a second and subsequent decade annual harvest of 43 1 MMCF. This is about 3.4% higher that the potential yield of 41 67 MMCF specified by the amended Timber Management Plan. In the 9th decade, the ASQ climbs to 46.9 MMCF and then rises to the LTSY level of 52.3 MMCF in the 10th decade through the end of the planning horizon

Road construction requirements increase in the 1st decade compared to the original Current Direction run, primarily because of the dispersion constraint is forcing harvest earlier onto the unroaded portion of the Forest.

Silvicultural intensity is slightly lower for this benchmark than for the original Current Direction benchmark, especially in the first three decades.

PNV is somewhat lower than for the Current Direction benchmark, reflecting primarily the low first decade harvest and roading costs incurred earlier in the planning horizon.

Suitable acres are approximately 89% of tentatively suitable, compared to 97% in the original Current Direction. This is primarily the result of applying the MR's.

E. Opportunity Costs Analysis

The analysis of opportunity costs of legal and policy constraints incorporated in the Forest planning process and in FORPLAN was conducted in accordance with Washington Office and Regional planning direction. In this section, the opportunity costs of the MR's 95% CMAI, and non-declining yield are analyzed and discussed. For the 95% CMAI and NDY policies, the analyses are done singly and then in combination with each other.

1. MR's in Combination

The opportunity costs of individual MR's were examined earlier in this section. The analysis below examines the costs of MR's in combination.

Given maximum PNV, assigned values, sequential upper and lower bounds, and rotations set at utilization standards:

Table B-49 shows the results of comparing Run #4, Table B-31, with Run #2, Table B-30.

Table B-49
MR's in Combination
(Maximum PNV, Assigned Values, Seq. U+L, Utilization Standards)

Comparison Factor	Unit of Measurement	Run #2 w/o MR's	Run #4 with MR's	% Change
LTSYC	MMCF	46.3	36.3	-22
1st Decade Harvest	MMCF	105 7	56.0	-47
Total 15 Decade Harvest	MMCF	820 7	643.7	-22
Planted Acres 5 Decade Total	M Acres	11.5	7.2	-37
PCT (5 Decade Total)	M Acres	7.4	4.6	-38
Suitable Acres	M Acres	597.7	515.0	-14
PNV	MM$	2796	2409	-14

The addition of MR's causes a substantial reduction in values of all selected comparison factors. Suitable acres are reduced which drives LTSYC and harvest levels downward. The timber management intensity level is also reduced with less acres going to a planted prescription and considerably less acres assigned to a PCT prescription.

Although PNV drops significantly, the percent decrease is much less than the percentage decline in timber harvest levels. This is due to the less intensive management practices selected and the assignment of more acres to non-timber prescriptions which results in higher levels of other resource outputs, primarily recreation.

Given maximum PNV, NDF, and 95% CMAI:

Table B-50 shows the results of comparing Run #7, Table B-37, with Run #3 Table B-26.

Table B-50
MR's in Combination
(Maximum PNV, Assigned Values, NDF, 95% CMAI)

Comparison Factor	Unit of Measurement	Run #3 w/o MR's	Run #7 with MR's	% Change
LTSYC	MMCF	66.2	49.6	-25
1st Decade Harvest	MMCF	63.9	48.8	-24
Total 15 Decade Harvest	MMCF	960.8	688.3	-28
Planted Acres 5 Decade Total	M Acres	29 5	17.1	-42
PCT (5 decade total)	M Acres	21 4	13.1	-39
Suitable Acres	M Acres	606 9	528.8	-13
PNV	MM$	2569	2381	- 7

When NDF and 95% CMAI are introduced, the opportunity costs of MR's in combination are very similar to those above where a departure and utilization standard are used except first decade harvest decreases less The cost to PNV is not as great, percentage wise, as when departure was allowed

2. Rotations at 95% CMAI

Given maximum PNV, assigned values, MR's, sequential upper and lower bounds, and rotations set at utilization standards:

Table B-51 shows the results of comparing Run #5, Table B-33, to Run #4, Table B-31.

Table B-51
Rotations at 95% CMAI
(Maximum PNV, Assigned Values, MR's, Seq U+L)

Comparison Factor	Unit of Measurement	Run #4 Util Standard	Run #5 95% CMAI	% Change
LTSYC	MMCF	36 3	40.8	+12
1st Decade Harvest	MMCF	56 0	52 9	- 6
Total 15 Decade Harvest	MMCF	643 7	653.8	+ 2
Planted Acres 5 Decade Total	M Acres	7 2	9 2	+28
PCT (5 decade total)	M Acres	4 6	7 0	+52
Suitable Acres	M Acres	515 0	513 9	- 0.2
PNV	MM$	2409	2406	- 0.1

The 95% CMAI constraint causes a significant increase in LTSYC because harvest is deferred until the trees are larger The 95 CMAI rotation also causes a reduction in first decade harvest, but total harvest in 15 decades increases slightly Timber management intensities increase, but PNV shows a very slight decrease which is not considered significant

Given maximum PNV, assigned values, MR's and NDF:

Table B-52 displays the results of comparing Run #7, Table B-37, to Run #6, Table B-35.

Table B-52
Rotations at 95% CMAI
(Maximum PNV, Assigned Values, MR's, NDF)

Comparison Factor	Unit of Measurement	Run #6 Util. Standard	Run #7 95% CMAI	% Change
LTSYC	MMCF	48.3	49.6	+ 3
1st Decade Harvest	MMCF	48.9	48.8	- 0.2
Total 15 Decade Harvest	MMCF	733.5	688.3	- 6
Planted Acres 5 Decade Total	M Acres	16.5	17.1	+ 4
PCT (5 decade total)	M Acres	13.1	13.1	0
Suitable Acres	M Acres	522.4	528.8	+ 1
PNV	MM$	2384	2381	- 0.1

When NDF is introduced, first decade harvests and total 15 decade harvests are very close regardless of the rotation. LTSYC does increase slightly, but not as much as when departure was permitted. Acres assigned to a planted prescription are about the same, and no increase in PCT is observed. PNV remains unchanged.

Given maximum PNV, market values, MR's and sequential upper and lower:

Table B-53 displays the results of comparing Run #9, Table B-34, with Run #8, Table B-32.

Table B-53
Rotations at 95% CMAI
(Maximum PNV, Market Prices, MR's, Seq. U+L)

Comparison Factor	Unit of Measurement	Run #8 Util. Standard	Run #9 95% CMAI	% Change
LTSYC	MMCF	37.2	41.2	+11
1st Decade Harvest	MMCF	54.5	52.9	- 3
Total 15 Decade Harvest	MMCF	658.1	659.1	+ 0.15
Planted Acres 5 Decade Total	M Acres	7.0	9.0	+29
PCT (5 decade total)	M Acres	5 1	7.6	+49
Suitable Acres	M Acres	523.1	513.3	- 2
PNV	MM$	1510	1507	- 0 2

Because departure is again introduced in this comparison, LTSYC increases and first decade harvest decreases. Total harvest for 15 decades is almost the same regardless of the rotation age. Acres planted increases, and PCT acres increase. Suitable acres and PNV remain constant regardless of the rotation selected.

Given maximum PNV, market values, MR's, and NDF:

Table B-54 shows the results of comparing Run #11, Table B-38, with Run #10, Table B-36.

Table B-54
Rotations at 95% CMAI
(Maximum PNV, Market Prices, MR's, NDF)

Comparison Factor	Unit of Measurement	Run #10 Util. Standard	Run #11 95% CMAI	% Change
LTSYC	MMCF	48.2	49.6	+ 3
1st Decade Harvest	MMCF	48.9	48.8	- 0.2
Total 15 Decade Harvest	MMCF	733.5	732.8	- 0.1
Planted Acres 5 Decade Total	M Acres	16 3	17.5	+ 7
PCT (5 decade total)	M Acres	12.9	13.4	+ 4
Suitable Acres	M Acres	523 7	524.3	+ 0.1
PNV	MM$	1486	1483	- 0.2

The introduction of NDF causes a increase in LTSYC, but little change in harvest levels. Harvest levels are at LTSYC with utilization standards, but are about 2% below LTSYC with 95% CMAI. The utilization standards constraint allows harvest of stands at an earlier age and more of the existing younger age stands are available now.

Suitable acres and PNV remain unchanged regardless of the rotation selected.

Summary - Rotations at 95% CMAI. In summary, the rotation age selected has virtually no effect on PNV. Rotations at utilization standards does allow harvest levels to equal LTSYC when NDF is utilized

3. Non-declining Flow

Given maximize PNV, assigned values, MR's, and rotations based on utilization standards:

Table B-55 shows the results of comparing Run #6, Table B-35, with Run #4, Table B-31.

Table B-55
Non-declining Flow
(Maximum PNV, Assigned Values, Utilization Standards)

Comparison Factor	Unit of Measurement	Run #4 Seq. U+L	Run #6 NDF _	% Change
LTSYC	MMCF	36.3	48.3	+33
1st Decade Harvest	MMCF	56.0	48.9	-13
Total 15 Decade Harvest	MMCF	643 7	733.5	+14
Planted Acres 5 Decade Total	M Acres	7 2	16.5	+129
PCT (5 decade total)	M Acres	4.6	13.1	+185
Suitable Acres	M Acres	515 0	522.4	+ 1
PNV	MM$	2409	2384	- 1

The NDF constraint displays the typical characteristics of increased LTSYC, lower 1st decade harvest, increased 15 decade harvest, more intensive timber management prescriptions, and a slight decrease in PNV.

Given maximize PNV, assigned values, MR's and 95% CMAI:

Table B-56 shows the results of comparing Run #7, Table B-37, with Run #5, Table B-33.

Table B-56
Non-declining Flow
(Maximum PNV, Assigned Values, MR's, 95% CMAI)

Comparison Factor	Unit of Measurement	Run #5 Seq. U+L	Run #7 NDF _	% Change
LTSYC	MMCF	40.8	49.6	+22
1st Decade Harvest	MMCF	52.9	48 8	- 8
Total 15 Decade Harvest	MMCF	653 8	688.3	+ 5
Planted Acres 5 Decade Total	M Acres	9.2	17.1	+86
PCT (5 decade total)	M Acres	7.0	13.1	+87
Suitable Acres	M Acres	513 9	528.8	+ 3
PNV	MM$	2406	2381	- 1

With rotations at 95% CMAI, the imposition of the NDF constraint again exhibits the characteristic pattern of increased LTSYC and 15 decade total harvest with a significant decrease in first decade harvest. The model selects higher harvest levels in the early portion of the planning horizon to satisfy the objective function before discounting has the opportunity to reduce PNV. When NDF is added, the harvest is spread over the planning horizon. The loss in PNV is partially regained by increased investments in timber management intensities.

Given maximize PNV, market prices, MR's and rotations based on utilization standards:

Table B-57 displays the results of comparing Run #10, Table B-36, with Run #8, Table B-32.

Table B-57
Non-declining Flow
(Maximum PNV, Market Prices, MR's, Utilization Standards)

Comparison Factor	Unit of Measurement	Run #8 Seq U+L	Run #10 NDF	% Change
LTSYC	MMCF	37.2	48.2	+30
1st Decade Harvest	MMCF	54.5	48.9	-10
Total 15 Decade Harvest	MMCF	658.1	733.5	+11
Planted Acres 5 Decade Total	M Acres	7.0	16 3	+133
PCT (5 decade total)	M Acres	5.1	12.9	+153
Suitable Acres	M Acres	523.1	523.7	+ 0.1
PNV	MM$	1510	1486	- 2

With the introduction of market prices only the typical characteristics of NDF are still exhibited. There is a reduction in PNV because recreation is not contributing.

Given maximize PNV, market prices, MR's, 95% CMAI:

Table B-58 displays the results of comparing Run #11, Table B-38, to Run #9, Table B-34.

Table B-58
Non-declining Flow
(Maximum PNV, Market Prices, MR's, 95% CMAI)

Comparison Factor	Unit of Measurement	Run #9 Seq. U+L	Run #11 NDF	% Change
LTSYC	MMCF	41.2	49.6	+20
1st Decade Harvest	MMCF	52.9	48 8	- 8
Total 15 Decade Harvest	MMCF	659 1	732.8	+11
Planted Acres 5 Decade Total	M Acres	9.0	17.5	+94
PCT (5 decade total)	M Acres	7.6	13.4	+76
Suitable Acres	M Acres	513 3	524.3	+ 2
PNV	MM$	1507	1483	- 2

Again the non-declining flow pattern for this Forest is exhibited. The percentage changes are not as large for LTSYC and the same total for 15 decade harvest, but this is primarily the introduction of market prices only, which increases the suitable acres. The value of PNV is considerably below that when

assigned values were used, but the NDF constraint reduces it only 2% when compared to the departure option.

Summary - Non-declining Flow. In summary, NDF causes reductions in first decade harvest, but increases in LTSYC and total harvest. NDF results in limited reductions in PNV, because of the higher investments in intensive timber practices in the early decades When only market prices are used, there is little increase in suitable acres.

4. NDF and 95% CMAI in Combination

Given maximize PNV, assigned values, no MR's:

Table B-59 displays the results of comparing Run #3, Table B-26, to Run #2, Table B-30.

Table B-59
NDF and 95% CMAI in Combination
(Maximum PNV, Assigned Values, No MR's)

Comparison Factor	Unit of Measurement	Run #2 Seq. U+L Utl. Stan.	Run #3 NDF 95% CMAI	% Change
LTSYC	MMCF	46.3	66.2	+43
1st Decade Harvest	MMCF	105 7	63.9	-40
Total 15 Decade Harvest	MMCF	820.7	980 8	+20
Planted Acres 5 Decade Total	M Acres	11.5	29 5	+157
PCT (5 decade total)	M Acres	7.4	21 4	+189
Suitable Acres	M Acres	597.7	606.9	+ 2
PNV	MM$	2796	2569	- 8

This comparison reveals the characteristics pattern of the NDF constraint for this Forest, where LTSYC and total 15 decade harvest increase substantially, but 1st harvest decade declines dramatically. The NDF constraint requires harvest schedules to be evened out over the planning horizon rather than concentration of harvest in the early decades as is observed under a departure option. The reduction in early decade harvest is at the expense of the objective function because of the effect of discounting. Dramatic increases in investments in more intensive timber management on higher levels of suitable acres tend to increase the LTSYC.

Given maximum PNV, assigned values, and MR's:

Table B-60 displays the results of comparing Run #7, Table B-37, with Run #4, Table B-31.

Table B-60
NDF and 95% CMAI in Combination
(Maximum PNV, Assigned Values, MR's)

Comparison Factor	Unit of Measurement	Run #4 Seq. U+L Utl Stan	Run #7 NDF 95% CMAI	% Change
LTSYC	MMCF	36.3	49.6	+37
1st Decade Harvest	MMCF	56 0	48.8	-13
Total 15 Decade Harvest	MMCF	643 7	688.3	+ 7
Planted Acres 5 Decade Total	M Acres	7.2	17.1	+137
PCT (5 decade total)	M Acres	4.6	13.1	+185
Suitable Acres	M Acres	515.0	528.8	+ 3
PNV	MM$	2409	2381	- 1

The introduction of MR's in this comparison drives the timber values downward, but the characteristic pattern associated with NDF is again observed The opportunity cost in terms of PNV is minor, but significant decreases in first decade harvest occur along with substantial increases in LTSYC and total harvest for 15 decades. Again when NDF is used, investments in timber management intensity increase.

Given maximize PNV, market values, and MR's:

Table B-61 displays the results of comparing Run #11, Table B-38, with Run #8, Table B-32.

Table B-61
NDF and 95% CMAI in Combination
(Maximum PNV, Market Values, MR's)

Comparison Factor	Unit of Measurement	Run #8 Seq U+L Utl Stan	Run #11 NDF 95% CMAI	% Change
LTSYC	MMCF	37 2	49 6	+33
1st Decade Harvest	MMCF	54 5	48 8	-10
Total 15 Decade Harvest	MMCF	658 1	732.8	+11
Planted Acres 5 Decade Total	M Acres	7 0	17.5	+150
PCT (5 decade total)	M Acres	5 1	13.4	+163
Suitable Acres	M Acres	523 1	524 3	+ 0.2
PNV	MM$	1510	1483	- 2

This comparison is again typical of other runs where NDF is imposed. The introduction of market values drives PNV downward sharply, but the opportunity cost of imposing NDF and 95% CMAI results in only a 2% reduction. There is little change in the amount of suitable acres as the market price constraint had already driven them as high as possible

F. Sensitivity Analysis

This section details the sensitivity analyses done around the 1% real timber price trend, and around the level of timber management-related costs used in FORPLAN.

1. Timber Price Trends Analysis

The use of timber price trends and the correct ones to use is a major Regional issue. All Benchmark Runs utilized a timber price increase of 1% per year for 5 decades and then a 0% trend thereafter.

The sensitivity of the price trend was analyzed utilizing a 0%, 2%, and 3% trend. Benchmark Run #7, Table B-37, was selected as a base for this analysis as it includes MR's. The results of the sensitivity runs are displayed in the table, B-62, below.

Table B-62
Timber Price Trend Sensitivity
(NDF MR s 95% CMAI)

Comparison Factor	Measure Unit	0% Trend	% Change From Base	Base (Run #7)	2% Trend	%Change From Base	3% Trend	% Change From Base
LTSYC	MMCF	46 3	- 1	49 6	51 2	+3	60 7	+22
1st Decade Harvest	MMCF	48 9	+ 0 2	48 8	47 2	-3	40 8	-16
Total 15 Decade Harvest	MMCF	820 7	+ 7	688 3	718 0	+4	784 0	+14
Planted Acres								
5 Decade Total	M Acres	16 6	- 3	17 1	18 0	+5	23 8	+39
PCT 5 Decade Total	M Acres	11 0	-16	13 1	14 1	+8	18 3	+40
Suitable Acres	M Acres	529 7	+ 0 2	528 8	525 4	-1	529 7	+ 0 2
PNV	MMS	2217	₣ 7	2281	2604	+9	2919	+23

In general, the results of this sensitivity analysis are what one would expect. When a 0% trend is compared to the base (1% trend), less intensive timber prescriptions are selected and PNV declines by 7%. With a 0% price trend, 1st decade harvest is equal to LTSYC, while with a 1% trend, annual harvest does not reach LTSYC until sometime after the 15th decade.
With a 2% trend, LTSYC increases by about 3% from the base, but 1st decade harvest is slightly lower than with a 0% or 1% trend. Acres selected for planting increase 5% over the base with a 2% trend, but acres assigned to a PCT prescription increase 8%. With the 2% price trend, PNV increases 9%.

When a 3% trend is utilized, LTSYC increases 22% over the base, but first decade harvest decreases 16%. A significant increase in the number of acres assigned to a more intensive timber management intensity is observed when prices are trended at a 3% rate, with the increased intensities and higher timber values, a 23% increase in PNV is observed.

The highest number of suitable acres actually occurs within 0% and 3% and decreases slightly with the base and 2% trends. All of these changes are 1% or less and not considered significant

The most significant conclusions that can be drawn from this analysis is that the first decade ASQ decreases with an increase in timber price trend and PNV shows significant change with a change in timber price trend.

2. Timber Costs Assumptions and Analysis

Timber Industry has expressed concerns about the sensitivity of timber costs utilized in the FORPLAN model.

The Forest made two cost sensitivity runs by increasing and decreasing timber-related costs by 20%. Benchmark Run #7, Table B-37, was used as a base for this analysis, since this run includes MR's which respond to several issues on the Forest. The results of this analysis are displayed in Table B-63.

Table B-63
Timber Cost Sensitivity

Comparison Factor	Measurement Unit	20% Cost Decrease	% Change From Base	Base (Run #7)	20% Cost Increase	% Change From Base
LTSYC	MMCF	57 3	+16	49 6	42 1	-15
1st Decade Harvest	MMCF	54 0	+11	48 8	38 8	-20
Total 15 Dec Harvest Planted Acres	MMCF	820 7	+19	688 3	582 0	-15
5 Decade Total	M Acres	25 9	+51	17 1	7 7	-55
PCT 5 Decade Total	*M Acres*	*20 0*	+53	13 1	*6 1*	-53
Suitable Acres	M Acres	529 7	+ 0 2	528 8	519 0	- 2
PNV	MMS	2668	+12	2381	2127	-11

The above data indicates that as timber-related costs decrease by 20%, the LTSYC and timber harvest increase and the suitable timber land base remains relatively unchanged The higher timber management intensities scheduled in this run along with the lower costs result in a higher (12%) PNV

As timber-related costs are increased 20%, reductions in the comparison factor values for 1st decade harvest and total 15 decade harvest and planted acres decrease more significantly than they increase with the 20% decrease All other comparison factor values decrease with the 20% cost increase approximately the same amount as they increase with the 20% cost decrease Because of the increased costs, less acres are intensively managed for timber, resulting in less timber outputs and a corresponding decrease in PNV of 11%.

This analysis indicates that the model and the forest structure are more sensitive to cost increases, in timber-related costs, than to cost decreases, *although both bring about significant changes in all factors except suitable* lands.

G. Analysis of Assigned Price Runs vs. Market Price Runs

On some Forests, assigning prices to recreation use can have significant effects on the amount of lands allocated to timber management. If higher prices are assigned to Primitive and Semi-primitive Nonmotorized recreation than to road-related recreation, the value of keeping the lands unroaded and available for more primitive types of recreation experience can outweigh the value of roading and harvesting the lands, particularly if the timber values are fairly low, and the recreation opportunity is high quality.

That situation was apparently not the case on the Mt. Baker-Snoqualmie. There was very little difference in outputs and land allocations in the benchmark runs that were identical except for assigned prices being used in one and market prices only being used in the other. For comparison see runs #4 vs. #8 (Table B-31 vs. B-32); #5 vs. #9 (Table B-33 vs. B-34); #6 vs. #10 Table B-35 vs B-36; and #7 vs. #11 (Table B-37 vs. B-38). The PNV in these paired runs averages 38% lower in the "market price only" runs (#'s 8, 9, 10, & 11).

Part of this result is undoubtedly a reflection of large timber values on this Forest When the model can harvest 40,000 BF/Ac at an average stumpage price of about $125/MBF in Decade 1, it gets a benefit of $5000 per acre. If that same acre yields about 0.6 SPNM RVD's per year at a value of $13 25 per RVD, in Decade 1, that acre would yield a gross value of $79.50. It would take almost 70 years for that acre to provide as much benefit as the timber does in the first decade. Even if the net benefit from timber after all management costs were accounted for was only half the gross timber value per acre, it would still take more than 30 years for the recreation to catch up

The discounting process has an effect here as well. If the timber is harvested in the first or second decade, it is not affected significantly by the discount rate. But as the recreation is trying to catch up over a space of 30-60 years, it is more affected by the discount rate. Even if the recreation value does catch up over the time it takes to grow another timber stand, the present value of those recreation benefits will be substantially below that of the early period timber harvest If the model is maximizing PNV, it will tend to choose timber over recreation more often than not. If that is the case, it becomes relatively immaterial whether or not assigned values are used for recreation.

The other major factor involved is that there is very little potential to make major increases in Semi-primitive Nonmotorized and Primitive recreation capacity on this Forest. Much of the land providing these experiences is not suitable for timber anyway The benchmark maximizing this type of recreation only managed to get a capacity of about 200,000 RVD's annually by the end of the fifth decade. The maximum timber potential run, on the other hand, is still experienced by the end of five decades. So at the extremes, there was only about a 50% gain in capacity. In absolute terms, which is what the model will pay attention to when it maximizes on PNV, there is very little that can be gained, even by putting a high price on the unroaded recreation, because there is so little room within at least a five-decade span for expansion in capacity. Increases in roaded recreation, which go along with timber harvest, can easily outweigh losses in unroaded recreation, even if priced significantly lower, because of the much larger absolute amount of capacity and demand. These two factors combine to make little difference in outputs and land allocations between the assigned price runs and the "market price only" runs. There is apparently not enough absolute value that can be associated with increasing unroaded, primitive recreation to pull any significant amount of land away from assignment to timber management.

H. Sensitivity of Alternatives to the Discount Rate

To help determine the sensitivity of the benchmarks and alternatives to varying discount rates, present net value, costs, and benefits were calculated using both the 4% and 7 1/8% discount rate (FSM 1971.71) In addition, an analysis of the sensitivity of the preferred alternative to the discount rate was performed by solving the FORPLAN model using both of the discount rates. Table B-63a displays the results of the calculating present net value, discounted benefits, and costs using the 4% discount rate vs. the 7 1/8% discount rate.

Table B-63a
Comparison of Present Net Value, Discounted Costs, and Discounted Benefits by Alternative for Discount Rates of 4% vs. 7 1/8% - in Million 1982 $

Rate = 4%

Alternative	PNV	Discounted Benefits	Discounted Costs
Max PNV Benchmark	2590.7	4287 6	1696.9
B (RPA)	2343 2	3434 7	1091.5
I	2342 9	3438.3	1095 4
A	2283.5	3557 2	1273.7
H	2260.0	3291.3	1031.3
J (Pref)	2258.8	3243 2	984 4
G-Mod	1997.0	2825.1	828.1
C	1970.9	2695.2	724.3
NC 1/	NA	NA	NA

Rate = 7.125%

Alternative	PNV	Discounted Benefits	Discounted Costs
Max PNV Benchmark	1305.9	2161 2	855.3
B (RPA)	1215.4	1790 9	575.5
I	1221.8	1796.9	575 1
A	1187 1	1858 1	671.0
H	1174.3	1717 1	542.9
J (Pref)	1170.2	1689.2	519.0
G-Mod	1055.3	1493.6	438 3
C	1029.6	1417 9	388.3
NC 1/	NA	NA	NA

1/ The TM Plan upon which the Alternative NC is based was developed in 1963 It was not an integrated resource plan, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable with the Max PNV Benchmark and other alternatives were not determined.

Across all the alternatives, lower PNVs, discounted costs and benefits resulted from using the higher discount rate; however, the magnitude of the change was not constant for all alternatives In one case, the rankings between alternatives (B and I) was changed. Under a 4% rate, B has a slightly higher PNV than I When recalculated at 7 1/8%, the rankings switch, with the PNV for I almost $6 million higher than B. The reason for the differences, caused from using the 7 1/8% discount rate, is a function of the point in the planning horizon at which the benefits and costs of the alternative occur as well as the magnitude of the costs and benefits themselves

To test the sensitivity of the preferred alternative to the discount rate, the FORPLAN solution was resolved using the 7 1/8% discount rate. The analysis revealed that when the objective function values are discounted using this discount rate, the optimal solution will include more intensive silvicultural management prescriptions As a result, both ASQ and LTSY increased. The model is optimizing on these prescriptions to generate shorter rotation ages, and therefore perform a final harvest twice within the planning horizon (natural regeneration usually uses a rotation of 120 years compared to a 70 year rotation for more intensive practices) By doing so, the model is taking advantage of the higher discount rate and the effect of discounting any costs associated with later harvest activities, since in general, the changes in discounted benefits are more than compensating for increases in discounted costs. Although these benefits minus the costs did produce a positive PNV, the total discounted PNV for this run was still only about 50% of the prior 4% PNV.

I. Summary of Benchmark Results

The outputs and associated PNV for each benchmark run are shown in the output and effects tables in Part D. Runs without MR's had the highest PNV's because of additional lands available for timber management. Runs allowing fluctuating harvest and harvest utilizations standards instead of 95% CMAI tended to have higher PNV's than comparable runs with non-declining yield and 95% CMAI The market price only runs had uniformly lower PNV's than those for the assigned price runs. Valuing recreation added around $800 million to the 15-decade PNV.

All of the benchmarks with MR's had the same acres going to the MR management emphasis After accounting for overlaps, about 99,600 acres were assigned for wildlife MR's, of which about 70,400 acres were tentatively suitable Another approximately 19,500 acres were assigned to SMU, with 25% non-harvest, 50% harvest at 160-year rotation, and the remaining 25% available for full management. Slightly over 700,000 acres were assigned in all cases to wilderness. The balance of the tentatively suitable acres were available for assignment to timber management. The "suitable acres" line in the results tables indicates how many acres in each run actually went to timber management. With a little over 600,000 acres of tentatively suitable lands in the data base for the benchmarks, for most runs almost all of the available lands not assigned to MR's went to timber, usually within 10,000 acres. Acres not chosen for timber management (generally inaccessible lands with high harvest costs), acres assigned to MR's and all unsuitable acres went into essentially a minimum level state However, they still produced recreation opportunities and had recreation management costs charged against them.

CHAPTER VII - FORMULATION OF ALTERNATIVES

CHANGES BETWEEN DRAFT AND FINAL - APPENDIX B, CHAPTER VII

- o The "Process Used to Formulate Alternatives" section has been updated to describe the process up through the development of the preferred alternative for the FEIS.

- o Reference to the water quality MR and associated harvest acreage limitations by watershed has been added.

- o Discussion of the availability and application of commercial thinning has been updated to reflect review and revision of commercial thinning criteria between the Draft and Final.

- o Alternative descriptions have been updated to encompass the final set of alternatives carried in the FEIS.

- o Discussion of constraints to meet NFMA management requirements has been updated to include the water quality MR constraints resulting from the hydrologic cumulative effects analysis.

- o Two additional alternatives are developed for consideration in detail in the FEIS. Alternative I was developed in response to strong public support and comment. Alternative J was developed by the Forest Management Team as the new Forest Service Preferred Alternative.

- o One alternative considered in detail in the DEIS, Alternative G, was significantly modified in response to public comment and to better meet its stated management objectives.

- o Alternatives D, E, E-Departure, F, and H-Departure, which were considered in detail in the DEIS, were dropped from further consideration in the FEIS. They received very little support or comment during the DEIS review. They are not needed to provide a full range of alternatives for analysis.

- o Alternative H is carried forward to the FEIS as an alternative considered in detail, but is no longer the Forest Service Preferred Alternative.

* * * * * * * * * * * *

A. Introduction

A Forest Plan alternative is a mix of management prescriptions applied in specific amounts and locations of the Forest to achieve a desired management goal and objectives. As a result, each alternative would generate a different mix of goods, services, and environmental effects. The planning regulations (36 CFR 219,12(f)) require that an alternative must:

- o Be within the maximum and minimum resource potential of the Forest to provide a full range of major commodity and environmental resource uses and values.

- Reflect a range of resource outputs and expenditure levels.
- Be formulated to facilitate analysis of opportunity costs, resource use, and environmental tradeoffs among alternatives.
- Be formulated to facilitate evaluation of present net value, benefits, and costs of achieving various outputs and nonpriced benefits.
- Address and respond differently to major public issues, management concerns, and resource opportunities.
- Be formulated to require changes in existing laws and policies, to implement if reasonable and necessary, to address major public issues, managementconcerns, or resource opportunities.
- Respond to and incorporate the RPA Program tentative resource objectives for the Forest in at least one alternative.
- Reflect the level of goods and services provided by the unit, and the highest level of goods and services that would be provided in the future if current management direction continues in at least one alternative (the "no action" alternative pursuant to NEPA).
- Represent, to the extent practicable, the most cost-efficient combination of management prescriptions to meet the objectives of the alternative.
- State the condition and uses that will result from long-term implementation.
- State what goods and services will be produced, including timing and flow of outputs, and the costs and benefits generated.
- State the resource management standards and guidelines.
- State the purposes of the proposed management direction.

The formulation of alternatives for the DEIS (planning step five) was based on information gathered during the first four steps of the planning process: identification of issues, concerns, and opportunities; development of planning criteria; inventory and data collection; and Analysis of the Management Situation.

The benchmarks from the Analysis of the Management Situation defined the range within which alternatives could be developed. In addition, the planning team developed several alternatives that are required by regulation, Regional and *National direction*.

The choice of alternatives to develop and present in detail in the FEIS built on the information developed up through publication of the DEIS, public response, and additional analysis conducted prior to the preparation of the FEIS. For the FEIS, two additional alternatives are presented: one in response to strong public support and comment, and the other the new Preferred Alternative. Significant modifications were made to another alternative presented in the DEIS, and three alternatives and two departure schedules were dropped from further consideration in the FEIS.

Several alternatives are required by regulation, Regional, and National direction; these required alternatives are listed and briefly described below.

No Change.

This alternative, developed in response to a 1986 appeal, is designed to represent the existing direction in approved plans. The No Change Alternative represents the 1963 Timber Management Plans (as amended); coordination with other resources is guided by the Ranger District Multiple Use Plans and the Forest Service Directives System. It does not comply with the provisions of the National Forest Management Act. **In this FEIS, Alternative NC is the No Change Alternative.**

Current Direction (No Action)

This is the alternative of "No-Action" required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14) and the NFMA regulations (36 CFR 219.12(f)(7)). This alternative will continue the management of the Mt. Baker-Snoqualmie as defined by existing direction in approved management plans; continuation of existing policies, standards, and guidelines; management requirements; current budget updated for changing costs over time; and, to the extent possible, production of current levels and mixes of resource outputs. **In this FEIS, Alternative A is the "No-Action" Alternative.**

Emphasis on the RPA Program

This alternative will determine how the 1980 RPA Program distributed to the Forests through the Regional Guide can best be implemented. **In this FEIS, Alternative B is the 1980 RPA Program alternative.**

Emphasis on Nonmarket Opportunities

This alternative puts an emphasis on water, fish and wildlife, recreation, and other amenity values. Management for other resources will be consistent with the emphasis on amenity values. **Alternative C is the alternative which emphasizes nonmarket opportunities in this FEIS.**

Emphasis on Market Opportunities

This alternative has an emphasis on outputs that have an established market price (timber, livestock range forage, commercial fish, developed recreation opportunities, and minerals). Management for other resources will be consistent with the emphasis on market-oriented outputs. **In this FEIS, Alternative I is the alternative which emphasizes market opportunities.**

B. Process Used to Formulate Alternatives

The process used to derive alternatives, first for the DEIS and then for the FEIS, is outlined below as a series of steps. Some of these steps took place concurrently; some were repeated in whole or in part.

1. Identify Major Issues, Concerns, and Opportunities (ICO's)

Major public issues, management concerns, and opportunities were identified through public and internal meetings and Forest Plan Reports. See Appendix A for additional detail.

2. Develop a Forest Planning Base

A comprehensive multi-resource data base was formed based on the identified issues and concerns; it was stored in a computer mapping system R2MAP.

3. Identify and Map Analysis Areas

Analysis areas which represent lands having similar physical and biological attributes were identified and mapped. The capability, suitability, and management opportunities of specific areas of the Forest were considered in this step.

4. Prepare a Set of Possible Management Prescriptions to Respond to ICO's

A set of management prescriptions was prepared to represent a variety of possible ways and intensities to manage the Forest in response to the issues, concerns, and opportunities. These prescriptions include the most cost efficient set of activities which meet the goals and objectives of each prescription.

5. Determine Management Prescriptions Applicable to Each Analysis Area

6. Estimate Cost, Yield, and Value Coefficients from Applying Management Prescriptions

The costs of applying management prescriptions to analysis areas, and the outputs and resource values which would result, were estimated.

7. Estimate Demand for Various Forest Outputs

8. Develop a FORPLAN Model for the Forest

A FORPLAN model was developed for the Forest incorporating the information developed in the preceding steps. A detailed description of the FORPLAN model is found in Chapter III of this Appendix.

9. Analysis of the Management Situation

During the AMS, supply potentials were determined using the FORPLAN computer model and other techniques. Various assumptions, constraints, and objectives were used to establish benchmarks for supply potentials of each resource. A benchmark was established for maximum present net value. Existing resource supply and projected demand were compared. Opportunities to resolve issues and management concerns were explored by comparing existing and projected demand to potential production levels. These potentials, when compared to the Current Direction, indicate opportunities and/or need for change.

10. Establish a Broad Range of Alternative Goals and Objectives to Respond to ICO's

Alternative goals and objectives were established to provide a broad range of options for future management of the Forest and to provide a broad range of responses to the Forest's planning problems.

11. Map Feasible Land-Use Assignments For Alternative Goals and Objectives Established in Step 10.

Feasible alternative land-use assignments were mapped by the Forest Management Team, using the goals and objectives identified for these DEIS alternatives: RPA Alt. B, nonmarket emphasis Alt. C, and market emphasis Alt. I. The No Action, Alternative A, land allocations were identified from existing plans and adjusted where necessary to reflect current direction, such as NFMA regulations.

12. Map, Utilizing Forest Planning Data Bases, Land-Use Assignments Made by the Conservation Liaison Group

The land-use assignments for the Conservation Liaison Group were developed by that group, utilizing the multi-resource data base, AA's, and management prescriptions developed by the Forest. They were analyzed as Alternative G.

13. Check to Ensure Estimated Outputs of Mapped Alternatives Had a Good Distribution Over the Decision Space Determined in Step 9

Based on the information developed in the AMS and the results of the various benchmark runs, estimates of resource outputs and effects were made for the alternative land-use assignments to determine if a good distribution of outputs within the decision space would result.

14. Formulate Another Alternative

Based on this evaluation, an additional alternative land use assignment was made to fill some gaps identified in the decision space. This alternative was designated Alternative F.

15. Model Alternative Land-Use Assignments in FORPLAN

These land-use assignments were modeled in FORPLAN. Additional objectives were modeled as constraints. FORPLAN computer runs were made utilizing the alternative land-use assignments, the appropriate constraints and, an objective function of maximization of present net value. For the No Action Alternative A, a maximize timber objective function was utilized to be consistent with the goals of these alternatives. These runs were then "rolled over" with a maximize PNV objective function to, ensure that the objectives could be realized in the most cost efficient manner.

16. Cost Efficiency in FORPLAN Runs

Economics played an important role in selecting the mix of timber management intensities which were available in each alternative. Prior to making FORPLAN runs, an intensive examination of alternative silvicultural practices was made, considering the many possible combinations of reforestation method, precommercial thinning, commercial thinning, and rotation lengths. Cost efficiency as well as volume production were also examined prior to selection of the prescriptions to be carried forward into FORPLAN.
Utilization of DP-DFSIM permitted the examination of approximately 100 different timber management intensities. Of those examined, 23 were eventually carried forward to the FORPLAN model. The full range of management intensities was not appropriate, given the desired future condition of the Forest. In those cases, only the intensities that met the multiple use objectives of the alternative were available. The possibility of not managing for timber

production was available in all alternatives. FORPLAN solutions provided the most cost efficient method of meeting the objectives of the alternative.

17. Analysis of the RPA Alternative

An examination of the results of the RPA Alternative revealed that the RPA targets could not be met simultaneously given the current management situation. Several additional FORPLAN runs were made by relaxing discretionary constraints and examining departure options. It was finally concluded that meeting the RPA targets simultaneously was infeasible.

18. Analyze FORPLAN Run Solutions to Determine if the Range of Alternatives were Responsive to ICO's

The results of FORPLAN solutions to these alternatives were analyzed to determine if a broad range of alternatives that were responsive to the issues had been achieved. This analysis identified the need to develop an additional alternative that was more responsive to some of the ICO's.

19. Formulate a Preferred Alternative for the DEIS

An additional alternative (J) was developed, modeled in FORPLAN, and analyzed. This alternative was selected by the Regional Forester as the Preferred Alternative.

20. Publish the DEIS

21. Receive and Analyze Public Comment

22. Revise Mix of Alternatives for FEIS in Response to DEIS Review and Comment

A new market-oriented alternative supported strongly by the Public Land Users Society (PLUS) was developed, mapped, modeled and analyzed. This was designated Alternative I, and replace Alternative D as the required alternative emphasizing market opportunities.

The Conservation Liaison Group Alternative (G) was modified in response to public comment, and to more closely reflect the objectives of the alternative. Some areas originally assigned to timber production were re-designated and mapped as Semi-primitive Nonmotorized areas. Trails proposed under "Trails 2000" were added. This alternative is shown as G-Modified in the FEIS.

In addition to Alternative D, Alternatives E, E-Departure, and H-Departure were dropped from further consideration because of a lack of interest and public comment. The new and revised alternatives, along with the other alternatives carried forward from the DEIS, provided the full range required for analysis in detail in the FEIS.

23. Develop a New Preferred Alternative for the FEIS

After consideration of the revised mix of alternatives, public input, and other factors such as changes in the wildlife management requirements and application of a timber harvest constraints for a water quality management requirement, the Forest Management Team and ID Team developed a new Preferred Alternative, designated Alternative J. This is the culmination of the alternative formulation, assessment, and review process, and reflects the Forest Service estimation of the best mix of activity and output levels, costs and benefits,

and environmental effects that will maximize net public benefits. Alternative J is the basis for the Forest Plan.

C. Constraints Common to All Alternatives

A number of constraints were used in the FORPLAN model for all alternatives to reflect conditions that had to be met by any implementable alternative. These conditions are legal and policy requirements set at the Regional and National level (non-declining yield, MR's, etc.), as well as requirements established in the Forest's Prescriptions, Standards and Guidelines for the Forest Plan (rotation lengths, commercial thinning criteria, etc.). Each common constraint, its purpose and rationale are listed below. Most of the tradeoffs are discussed in general terms, as the constraints used were not analyzed individually on an alternative-by-alternative basis. The major constraints (wildlife MR's, riparian MR's, water quality MR's, and dispersion/diversity) were analyzed using benchmark runs during the AMS process (see Chapter VI of this Appendix).

1. Ending Inventory Constraint

Purpose and Description. The ending inventory constraint was applied without exception in all alternative runs. The purpose of the ending inventory (or perpetual harvest) constraint was to assure that the model had enough timber inventory at the end of the planning horizon to enable it to maintain growth and harvest at long term sustained yield levels indefinitely into the future. This constraint is built into FORPLAN and can be specified or not.

Rationale. NFMA regulations require that "Each sale schedule shall provide for a forest structure that will enable perpetual timber harvest which meets the principle of sustained-yield and multiple-use objectives of the alternative" (36 CFR 219.16(a)(2)(iv)). Without the ending inventory constraint, the model would have no incentive to hold stands to meet long term sustained yield past the end of the 150-year planning horizon. It would tend to cut increasing amounts of timber in the latter decades of the planning horizon until the standing inventory was at or near zero by the end of the 15 decades.

Tradeoffs. Use of the ending inventory constraint was necessary to proxy reality in forest management. It is unforeseeable that future managers would allow the standing volume in suitable timber stands to be reduced to near zero, resulting in a gap of 60-70 years before harvest could once again take place. The tradeoff in applying the constraint was a reduction in the total timber outputs available over the 15 decade horizon.

2. Long-term Sustained Yield (LTSY) Link

Purpose and Description. The LTSY link was used in all the alternatives. The constraint was set so that the harvest in the last period of the planning horizon could not be greater than the Long-term Sustained Yield Capacity (LTSYC) calculated by the model. NFMA regulations require that allowable sale quantity (ASQ) not be above LTSYC except when considering departure options from the base sale schedule (36 CFR 219.16(a)(1)). The LTSY link is a constraint built into FORPLAN which may be specified or not at the user's choice.

Rationale. Without the LTSY link constraint, set at "Maximum", the model could have cut at rates higher than the LTSYC in the final decade of the planning

horizon, as long as there was still sufficient standing inventory to meet the ending inventory constraint, and the non-declining yield constraint was met.

Tradeoffs. The LTSY link constraint potentially reduced the timber outputs available from the latter decades by keeping ASQ in the last decade at or below LTSYC. When non-declining yield is also applied, ASQ prior to the final decade would have to be at or below LTSYC, since non-declining yield keeps ASQ from declining from one period to the next. Thus, ASQ could not rise above LTSYC at any point in the planning horizon as long as non-declining yield applied.

3. Tentatively Suitable Lands

Purpose and Description. Although in some ways a data base determination, the specification of tentatively suitable lands also acted as a constraint on the model. Tentatively suitable lands were defined to meet the requirements of 36 CFR 219.14 (timber resource land suitability), and indirectly to meet 36 CFR 210.27(a) (management requirements for resource protection) and 36 CFR 219.27(c) (*management requirements for vegetative manipulation*). *Refer to* Chapter II, A for details. Tentatively suitable lands were identified through the AA delineations in the data base.

Rationale. Without the restriction that only tentatively suitable lands were available for harvest, the NFMA regulations would have been violated and, if implemented, irreversible resource damage would occur.

Tradeoffs. The restriction of timber harvest to tentatively suitable lands resulted in a lower timber output than would have otherwise occurred. The reduction in harvest came from timber lands taken out of the suitable base because of extremely unstable soils or regeneration problems.

4. Management Requirements

Purpose and Description. MR's were discussed in detail in Chapter VI, B. The MR's were designed to meet NFMA requirements for maintaining viable wildlife and fish populations (36 CFR 219.27(a)(6)); for providing "special attention" to management of riparian areas (36 CFR 219.27(e)); for meeting harvest opening size limitations in even-aged management regimes (36 CFR 219.27(d)); for meeting vegetation diversity requirements (36 CFR 219.27(g)); and for soil and water conservation (36 CFR 219.27(a)(1)). MR's were incorporated in the model as follows:

a. As discussed in Chapter VI, C., all acres determined as required to maintain viable populations for spotted owls, pileated woodpeckers, pine martens, mountain goats, and bald eagle were assigned to non-harvest MR prescriptions, effectively dedicating those acres to the wildlife MR's. In some alternatives, a prescription for enhanced mountain goat habitat was applied. When that prescription was applied to areas including, but larger than, the management requirement acres, the entire area was given the enhancement prescription and was subject to vegetation manipulation in accordance with the standards and guidelines for that prescription. It was assumed that the larger area being managed for the wildlife species in conjunction with the practices specified by the prescriptions would be sufficient to, at the minimum, maintain the viable population, if not substantially increase it.

b. Viable populations of primary cavity nesters were provided for by providing sufficient numbers and sizes of hard snags per acre to meet the nesting

requirements of the species. This was done in the model by reducing the timber yield tables by 1.5% for each 20% of the potential primary excavator populations maintained. (See Chapters III.F and VI.B.2.) A viable level of primary cavity excavator species was determined to be 20% of their maximum potential population.

c. Viable populations of resident and anadromous fish will be maintained by retaining at least the level of fish production currently experienced. This was modeled by applying Level I fisheries investments at the minimum, to all alternatives, following Forest-wide Standards and Guidelines, and applying the water quality management requirement in terms of harvest acreage limitations by watershed across all alternatives.

d. Maintenance of acceptable water quality and watershed condition was modeled by the application across all alternatives of the harvest acreage limitations by watershed developed through the hydrologic cumulative effects analysis process. Accessibility constraints on acres available for harvest are applied by allocation zone for the first decade to limit the harvested acres to the maximum determined by the ID teams for each watershed. In the second and subsequent decades, Forest-wide flow constraints were applied (by North and South) to limit the amount of increase in harvest acres allowed from decade to decade. The total increase allowed over the first decade levels is approximately 18%; no additional increase is allowed after the fifth decade. (See Chapter VI.B or Appendix H for additional details.)

e. Riparian area management was modeled by providing a mix of harvest and non-harvest activity in Streamside Management Units. In the model, 25% of the acres assigned to SMU were given a non-harvest intensity; 50% of the acres were allowed an extended rotation with a minimum rotation age of 160 years and a corresponding harvest entry rate not to exceed 6.25% of the suitable acres per decade; and 25% of the acres stayed in the adjoining prescription, including those providing for full-scale timber management.

f. Harvest opening size limitations and vegetation diversity requirements were modeled in two ways. For the first four decades, accessibility constraints were applied to the acres subject to any timber harvest. The maximum constraint (i.e., that allowing the greatest entry per decade) was applied to those acres going to full-scale timber management (Management Area 17).

This constraint was set to allow up to 30% of the acres assigned to MA 17 within an AZ to be harvested in Decade 1, up to 60% in Decade 2, up to 80% in Decade 3, and up to 100% in the fourth decade. The accessibility constraints are maximum and cumulative; that is, the percentage specified is the maximum that can be harvested in a decade, but the decadal constraints are cumulative. So if the entire 30% is not harvested in the first decade, the balance of the 30% plus the 30% allowed in the second decade can all be harvested in the second decade; and so on up through the fourth decade.

For other MA's with longer rotation lengths specified to meet the objectives of the area (Scenic Viewshed, Deer and Elk Winter Range, etc.), accessibility constraints were also used, with the accessibility proportions set to achieve the desired rotation length. For instance, the Scenic Viewshed prescription specifies a minimum rotation of 200 years to meet the foreground retention objective. Thus, the accessibility constraint is set at 5% for each decade. These accessibility constraints

are designed to meet the objectives of the prescription, not for achieving MR's for diversity and harvest size limitation, but in effect, they more than provide for the MR's in those areas.

After the fourth decade, the harvest size limitation and diversity requirements are modeled using a general relational constraint. This constraint is applied separately to the North and South halves of the Forest. The constraint is specified so that only 20% of all acres assigned to a prescription allowing full-scale timber management can be harvested in any given decade for decades 5-15. See Chapter IV, B for additional discussion.

Where the water quality MR harvest acreage limitations were limiting in a watershed (as represented by one or a combination of allocation zones), the accessibility constraints for harvest opening size and vegetation diversity requirements were adjusted downward to reflect those harvest acreage limits.

Rationale. The MR constraints were required to meet NFMA regulations and Regional planning direction. Had these constraints not been used, the alternatives analyzed would not have been implementable. They would have represented courses of action in violation of law and policy.

Tradeoffs. The MR constraints were analyzed in the AMS through the benchmark process. Additional analysis of the tradeoffs from applying the MR constraints was done after the hydrologic cumulative effects analysis process was completed and a water quality MR was developed. This tradeoff analysis is discussed in detail in Chapter VI, C. The combined effect of applying the MR constraints (except for the primary cavity excavators) was a reduction of about 42% in LTSYC and ASQ, a 24% reduction in tentatively suitable acres going into solution (because of the dedication of acres to non-harvest to meet the MR's), and a 14% reduction in PNV (Chapter VI, Table B-23).

These tradeoffs can be considered maxima, as they were analyzed against a relatively unconstrained benchmark. For any given alternative, otherwise implementable, the constraint sets would show lower overall effect on timber outputs and PNV because of other objectives being met by the alternative (e.g., visual corridors or wild and scenic rivers) which allow less than full-scale timber harvest. On the other hand, institution of the MR constraints maintained some additional area that supported unroaded recreation; although, because of the relatively small size of the individual MR areas, the increment of unroaded recreation was not very large.

The timber yield reduction for primary cavity excavators was 1.5% for the MR level. This was a direct reduction in timber output and associated benefits.

5. Rotation Length

Purpose and Description. Constraints on rotation length were necessary to achieve the objectives of the various management prescriptions, as specified by the prescription standards and guidelines. Rotation length constraints were designed to require rotations to meet a minimum age. For example, enhanced deer and elk winter range required that regenerated stands not be cut until they were at least 160 years old; regenerated stands in the Skagit Wild and Scenic River management area had to be at least 200 years old to harvest.

Appendix B
Chapter VII

The rotation length constraints were specified in two ways. First was a harvest entry per decade control, along with a combination of accessibility and general relational constraints. The minimum rotation length was converted to an equivalent percentage of area that could be harvested in one decade. If a minimum rotation of 200 years was required, only 5% of an area could be harvested in any one decade (5% for 20 decades = 100% of the stand harvested). The percent entry was specified for the applicable prescription as an accessibility constraint by AZ for the first four decades and as a general relational constraint Forest-wide with the appropriate entry percentage for decades 5-15.

The second constraint specified the rotation length as the minimum age at which the model could access the stand for harvest. This was done through the "common prescription harvest/implementation periods" ("harvest source") section of FORPLAN. In this section, the user specifies at what ages the model can enter the existing and regenerated stands for harvest. The rotation length was set as the minimum age for entry for both existing and regenerated stands.

The two types of constraints to achieve a minimum rotation length might seem redundant, but both were necessary to achieve the desired result. If only the percent entry per decade constraint were used, the model could make the appropriate cuts for 6-7 decades, then start over harvesting the regenerated stands which are growing faster and potentially giving more volume and value than the stands left uncut. This would result in an area in which only one-third to one-half of the original stands were cut and then harvested again as regenerated stands at age 60-70, while the balance of the stands in the area would remain unharvested. This would not meet the desired objective of achieving a desired rotation length before harvest. Conversely, if only a minimum rotation age were specified in the "harvest source" section of the model, the model could cut an entire area at once and then let it all sit until it once again met the minimum rotation age. So both types of constraints were necessary.

The following minimum rotation lengths and maximum harvest entry percentages were used in FORPLAN:

Prescription	Minimum Rotation Length	Maximum % Entry per Decade
Scenic Foreground (2A)	200 years	5.00%
Mt. Baker NRA (4)	200 years	5.00%
Potential Scenic River (5B)	200 years	5.00%
Skagit Wild & Scenic River (6)	200 years	5.00%
Enhanced Goat Winter Range (15B)	200 years	5.00%
Riparian & Fish Hab. Emph. (13)	160 years	6.25%
Enhanced Deer/elk Wntr Range (14B)	160 years	6.25%
Potential Recreation River (5A)	155 years	6.50%
Scenic Forest (Alpine Lakes) (27)	150 years	6.68%
Roaded Natural Recreation (1D)	125 years	8.00%
Scenic Middleground (2B)	100 years	10.00%

Rationale. These constraints were necessary to meet the intent of the management prescriptions, as stated in the standards and guidelines. (Rotation lengths were stated either directly, or inferred from the visual quality objectives specified for the prescription. In the latter case, the rotation lengths were calculated using the Timber Management volume of the Visual Resource Management Handbook (USDA-Forest Service, Agric. Handbook No. 559).

Tradeoffs. Any minimum rotation length set that is greater than the normal rotation length will cause a reduction in overall timber yields and LTSYC. The amount of the reduction depends on the ages set, the working groups to which applied, and the other constraints affecting the model.

6. Commercial Thinning Availability and Application

Purpose and Description. For the alternatives considered and modeled in detail for the Draft EIS, a constraint was set to limit the lands on which commercial thinning could be carried out. Analysis by the Forest Silviculturist and Timber Planner, plus District input, showed that commercial thinning was physically and biologically viable only in the Principal and Mixed Conifer working groups. Thinning in the Upper working group (primarily true firs) results in too much damage to the residual stand with resulting unacceptable loss from physical damage and disease, particularly root rot. Thinning in the inaccessible working group is not feasible since commercial thinning relies on roads, and no roads are built in the inaccessible lands.

Analysis also showed that commercial thinning yields worthwhile results in terms of increased yields only where a predominant portion of a stand is Douglas fir and western hemlock. This occurs only in the principal and mixed conifer working groups. After adjusting for the amount of those lands actually suitable for Douglas fir management in the future, the analysis showed an estimated 42.25% of the principal and mixed conifer working groups in the north and 48.75% of those working groups in the South to be suitable and available for commercial thinning. Refer to planning records for details.

The commercial thinning constraint was set in two ways. First, in the "common prescriptions specifications" section of the model ("prescription source file"), all upper and inaccessible working group lands were excluded completely from availability for commercial thinning by not connecting the commercial thinning intensity to these lands. Second, a set of general relational constraints was used that applied to the principal and mixed conifer working groups by slope class (A, B, and C) on the North and the South. These constraints specified that no more than 42.25% of the A, B, and C topographic lands in the North, and no more than 48.75% of the A, B, and C topographic lands in the South, could receive a commercial thinning intensity. (The rest of the lands would be treated with a timber management intensity that did not include commercial thinning.) The only purpose of applying the constraints across the topographic classes was to spread out the application of commercial thinning. Otherwise, the model would tend to group up the commercial thinning intensities all on one type of land, probably A or B. Applying the constraints in this way kept the commercial thinning spread out in a more realistic manner.

A thorough review of the commercial thinning situation for the Forest was made between the review of the DEIS and the release of the FEIS. Of particular concern was the possibility that FORPLAN was not recognizing commercial thinning opportunities in existing stands within the first decade or two of the planning horizon.

A review of stands on the Forest by the District silviculturists indicated approximately 200 acres that could be commercially thinned each year over the next decade after meeting criteria for commercial thinning such as percent Douglas fir, age, distance from existing roads, etc. (see Chapter III.E.2 of this appendix). As a result of this review, the Standards and Guidelines for Management Area 17 (timber production emphasis) were rewritten to allow more flexibility for initiating commercial thinning based on site-specific

assessments by the silviculturists, within specified criteria such as those noted above. Because the acreages were so small, and because data in FORPLAN lack the level of resolution to model these commercial thinning opportunities effectively, the estimated acres and values of commercial thinning opportunities were calculated outside the model and incorporated later. The model itself continues to allow only those commercial thinning opportunities meeting the model specifications discussed above, usually occurring later in the planning horizon.

Rationale. The constraint was required for all alternatives to restrict commercial thinning to those lands on which it actually could or would be applied. Lack of the constraint would have allowed commercial thinning to be scheduled and applied where it would not be physically or biologically appropriate to do so.

Tradeoffs. The tradeoffs are likely only on paper. If the constraint had not been used, additional timber volume might have been made available from commercial thins. However, commercial thinning is not particularly viable from an economic standpoint, as discovered during the development of the timber management intensities (Chapter III, E.). Any run made without the commercial thinning constraint under an economic objective function would probably have not added much by way of thinning.

7. Non-declining Yield

Purpose and Description. The non-declining yield constraint was applied to meet the requirements of the NFMA regulations that any sale schedule for a decade be equal to, or greater than, the sale schedule for the previous decade (36 CFR 219.16(a)(1). The exception to this is when departures from the base schedule are analyzed. Regional planning direction required a non-declining yield constraint for all alternatives, including those analyzed additionally with a departure from the base sale schedule. Every alternative was run with the non-declining yield constraint. An attempt was made to analyze Alternative B under a departure regime in order to meet the RPA Program targets, but even with a change from 95% CMAI to utilization standards in the timber yield tables, the model could only achieve about 70% of the required targets. There was no feasible solution to achieving the RPA Program timber targets while meeting the other Program requirements, such as high investments in wildlife habitat enhancement.

The non-declining yield constraint is built into the FORPLAN model. It can be specified or not, at the user's choice. If NDY is not specified, the user will usually specify "sequential upper and/or lower constraints" or "absolute" constraints on timber harvest instead.

Rationale. The non-declining yield constraint was invoked to meet NFMA and Regional planning direction.

Tradeoffs. The non-declining yield constraint generally has fairly major effects on the scheduling of timber harvest over time and the amount of timber actually made available for harvest in each decade. The magnitude and direction of the effects of the NDY constraint depend on whether a Forest is deficit or surplus in old growth timber (has more old growth or less old growth than that necessary for the mix of stand ages allowing harvest at LTSYC).

The Mt. Baker-Snoqualmie appears to be an old growth surplus Forest, so the ASQ for the Forest could actually be above LTSYC for a few decades, then below

LTSYC while the regenerated stands were getting older, and finally just at LTSYC in a fully managed state. The result would be a higher timber output than under NDY, particularly in the early decades of the planning horizon.

Because it schedules timber harvest on a Forest-wide basis, FORPLAN has built into it what is known as the "allowable cut effect", or ACE. The allowable cut effect raises early decade harvests over what they would be on a solely per acre basis by taking credit on a forest-wide basis for the higher per acre future volumes from regenerated stands in the calculation of the Forest's LTSYC. This LTSYC based on regenerated stand volumes is then used to calculate the harvest volumes by decade. The ACE allows the model to schedule harvest on more acres of existing stands than would otherwise be the case, based on the anticipation of higher volumes of regeneration growth forest-wide.

The non-declining yield flow constraint tends to intensify the allowable cut effect because, as a harvest constraint, it overrides the economics of the problem in order to satisfy the constraint. It tends to pull more acres into solution than would otherwise be the case, but manages them less intensively to keep costs down (and PNV up). Having more acres in solution provides a larger acreage base and inventory pool to keep future period harvests equal to or greater than the previous decades' harvest, and still allow the higher early decade harvests that the model chooses because of the effects of discounting.

8. Demand Curves

Purpose and Description. The demand curves were used in the model to limit the amount of recreation capacity actually valued to the amount of estimated use in that decade. See Chapter III, B regarding use of demand curves in the model.

Rationale. Without the demand curves, recreation would have been valued to capacity whether or not actual use of that magnitude was expected. If expected use were actually less than capacity, this would have overstated the recreation value of the alternative and possibly affected land-use assignment and scheduling solutions in the model.

Tradeoffs. Without the demand curves constraining valuation of recreation capacity to expected use, recreation benefits and PNV would have been overstated.

9. Budget Constraint

Purpose and Description. A budget constraint row was built into all alternative runs to facilitate calculation of the Forest Service budget for an alternative. It was set very high, $100,000,000 per year budget, so that it would be non-constraining but still accumulate budget costs and show them in the LP solution rows.

Rationale. The budget constraint was included in all alternatives for ease of tracking total budget costs.

Tradeoffs. There were no tradeoffs for any alternative. Alternative A did not require a budget restraint. Incorporation of MR's and the concomitant reduction in harvest levels, associated timber management and road building resulted in a budget level about $5 million below FY year 1982-1984 average.

10. 95% CMAI Timber Tables

Purpose and Description. NFMA regulations require that "...all even-aged stands scheduled to be harvested during the planning period will generally have reached the culmination of mean annual increment of growth..." (Part 219.16(a)(2)(iii)). Washington Office and Regional direction have interpreted "generally" to mean that harvest should be allowed when stands have reached at least 95% of CMAI. The use of timber yield tables based on 95% CMAI was in response to this direction.

Rationale. NFMA and implementing regulations were definitely written to exclude using timber yield tables and rotations based on financial rotations or rotations based on stand age and size just meeting utilization standards. The word "generally" was interpreted, though, to leave a little room for shortening rotations below full 100% CMAI, which had been the harvest standard up to that time for the Forest Service. The interpretation agreed on was 95% CMAI.

Tradeoffs. Tradeoffs of the 95% CMAI were either positive or negative. From the financial rotation viewpoint, the tradeoff was a loss in timber volume, though with some gain in average diameter and unit value, because the rotations were extended anywhere from 10 to 40 years. However, compared to 100% CMAI, the 95% CMAI tables allowed the rotations to be shortened by 10 to 20 years, thus making more volume available, although slightly smaller in size. From a non-timber perspective, shortening rotations can have a deleterious effect on habitat for wildlife, as there is less time to gain hiding and thermal cover characteristics before the stand is entered once again for harvest. See Chapter VI, E for more detail on effects of 95% CMAI and Utilization Standards.

D. Development of the Alternatives

Benchmarks defined the minimum and maximum output levels of the Forest under a given set of constraints. The maximum PNV benchmark with MR's (Run 7) identified the most efficient land-use assignment and schedule of activities and outputs, given the information modeled in FORPLAN. This provided a starting point for formulation of alternatives developed in detail. However, benchmarks do not consider the spatial feasibility of implementation. In order to incorporate the feasibility of implementation into the FORPLAN model the management team mapped alternative land allocations (coordinated allocation choices) consistent with the goals and objectives of the alternatives.

The following is a description of each alternative, including the design elements common to all alternatives Detailed descriptions of the alternatives are included in Chapter II of this DEIS.

Elements Common to All Alternatives

A number of resource management programs are treated the same in all the alternatives considered in detail. These are described below and are **not** included in the alternative descriptions which follow.

- The Alpine Lakes Area Management Plan,implemented in 1981, is incorporated into all alternatives except Alternative NC.

- The Skagit Wild and Scenic River Plan, implemented in 1984, is incorporated into all alternatives except Alternative NC.

- The Mt. Baker National Recreation Area, established in 1984, is the same in all alternatives.

- The three existing Research Natural Areas - North Fork Nooksack River, Lake Twenty-two and Long Creek - are retained in all alternatives.

- The foreground of the Mather Memorial Parkway, designated in 1931, is managed to retain its scenic quality in all alternatives.

- The management requirements necessary to integrate the requirements of law and regulation are incorporated in all alternatives except Alternative NC.

- The rights established by the various Indian Treaties are retained in all alternatives. Consultation with Indian Tribal leaders will continue on any proposed projects within sites inventoried in response to the American Indian Religious Freedom Act.

- The acres of designated wilderness are the same in all alternatives. Acres assigned to classes of the Wilderness Recreation Opportunity Spectrum (WROS) do vary by alternative; however, there are no WROS classes in Alternative NC.

- Even-aged management and regeneration harvest through clearcutting are assumed in estimating timber outputs in all alternatives; the use of other systems, however, is not precluded. Refer to Appendix F for a discussion of those situations where other harvest methods are acceptable.

- All alternatives would make full use of vegetation management techniques including herbicides and fire. In 1988, the Pacific Northwest Region, USDA Forest Service completed a final EIS on managing competing and unwanted vegetation (USDA 1988b). That final EIS, the Mediated Agreement, and accompanying implementation direction is incorporated by reference into this FEIS. It will guide vegetation management activities as the Forest Plan is implemented.

- All existing utility corridors, electronic sites, and administrative sites are retained in all alternatives.

Alternative NC (No Change)

The No Change Alternative has been developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's.

The No Change Alternative is designed to continue the level of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1963 Timber Management Plans. This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA; the alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

Alternative NC: does not use the most up-to-date inventories for assessing effects and estimating outputs; does not use current yield projection methods; its harvest schedule was not developed according to the concepts and philosophy of non-declining flow; and it does not incorporate management requirements, including those designed to maintain viable plant and animal populations.

Design Criteria for Alternative NC (No Change)

Timber: the 1963 Timber Management Plans are the basis for the alternative

Roads: the Naches Pass road would not be constructed.

Roadless Areas: an estimated 60% of the roadless areas would remain undeveloped; this estimate is based on the acres of commercial forest land assumed to be in the roadless areas.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: no provision for study or protection of potential rivers is included in the TM Plans.

Research Natural Areas: no potential areas recommended.

Spotted Owls: no provisions made to protect old-growth habitat for wildlife.

Big Game Habitat: no provisions made for protection of big game habitat.

Cavity Excavators: no provisions made for protection of habitat.

Anadromous/Resident Fish: no provisions made for protection of fish habitat.

Municipal Watersheds: all are managed under current agreements, memoranda of understanding.

Alternative A (No Action)

Alternative A was developed to continue management direction as set out in plans formulated and approved prior to the passage of the National Forest Management Act. The alternative incorporates the requirements of the National Forest Management Act of 1976 (36 CFR 219.12 through 219.27). The goal of Alternative A is to provide maximum timber outputs while maintaining or exceeding existing recreation, wildlife, fisheries, and visual resource outputs.

The plans approved prior to NFMA, plus current laws, regulations, and directions - including MR's - were used to assign management direction to different parts of the Forest. The most recent inventories were used to identify land base features, such as riparian zones and different timber condition classes. The NFMA process of land stratification for timber production was applied to commercial forest lands identified in the 1963 TM Plans. The latest technical processes were utilized to develop growth and yield projections for existing and regenerated timber stands. See the discussion below for more about the relationship of Alternative A (No Action) and the No Change Alternative.

This is the No Action Alternative required by the Council on Environmental Quality Regulations for implementing the National Environmental Policy Act (NEPA).

Design Criteria for Alternative A (No Action)

Timber: an exception to "Elements Common to All Alternatives", in FORPLAN, Alternative A was run with an objective of maximize timber volume for the first five decades, then was rerun to maximize PNV for 15 decades with the same timber outputs as in Decades 1-5. This resulted in some timber prescriptions having less than maximum economic efficiency. Approximately 70 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 26 miles of arterial and collector roads would be built. During that same period, about 330 miles of local roads would be constructed. The Naches Pass road would not be constructed.

Roadless Areas: would be managed under the direction contained in the Ranger District Multiple Use Plans; approximately 82 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: the 15 rivers included in the National Park Service Nation-wide Inventory are recommended for designation as part of the National Wild and Scenic River System. These fifteen rivers include a total of 375 miles, of which 142 miles are within the national forest boundary.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat is provided for viable populations at the MR levels; additional habitat for some species in wilderness, RNA, and areas not suited for timber production.

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of their potential population levels.

Anadromous/Resident Fish: current populations are maintained through habitat maintenance or improvement at the MR level (low investment, MA 13A; see below.)

Municipal Watersheds: are managed under current agreements, memoranda of understanding.

Alternative B (RPA)

The goal of Alternative B is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation, as specified in the 1980 RPA Program.

The RPA targets specified are:

Timber: annual programmed timber sales (TSPQ)
Decade 1 - 66 MMCF; Decades 2,3 - 69 MMCF; Decades 4, 5 - 70 MMCF
Developed Recreation: in thousand RVD's
Decade 1 - 2,381; Decade 5 - 2,660
Dispersed Recreation (includes hunting, fishing): in thousand RVD's
Decade 1 - 2,910; Decade 5 - 3,930
Wildlife Habitat Improvements: in acre equivalents
Decade 1 - 7,278; Decade 5 - 3,068

Design Criteria for Alternative B (RPA)

Timber: is produced at the highest level possible, while meeting the other goals of the alternative. Approximately 64 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 28 miles of arterial and collector roads would be built. During that same period, about 280 miles of local roads would be constructed. The option to construct Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 87 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic designation.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 79,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on land suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of their potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

Alternative C

The goal of Alternative C is to emphasize primitive and semi-primitive nonmotorized recreation (accomplished through retention of existing roadless areas and, over time, reversion of some roaded areas to unroaded condition); protect scenery, fish, and wildlife habitat; and protect sites and areas important to American Indians for religious and cultural use.

Design Criteria for Alternative C

Timber: no production goals set; suitable acres and harvest level will be the lowest of all alternatives considered in detail. Approximately 43 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 300 miles of existing arterial and collector roads. In the first two decades, about 15 miles of arterial and collector roads would be built, and about 180 miles of local roads would be constructed. Construction of the the Naches Pass road is precluded by management of surrounding lands for unroaded dispersed recreation.

Roadless Areas: nearly all (97%) of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: high to moderately-high protection of the foreground and middleground of all inventoried primary and secondary viewsheds.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers included is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat provided to maintain cavity excavators at 60% of their potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, with stipulation that habitat be maintained as old growth when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - closed watershed, exchange NF lands; Others - no timber harvest, limited recreation use.

Alternative G-Modified

The goal of Alternative G-Modified is to emphasize maintenance of natural ecosystems and diversity of native plants and animals, emphasize providing uses not found on private lands, and produce timber in a way that is consistent with the other goals and is non-damaging to soils.

Design Criteria for Alternative G-Modified

Timber: timber production will occur on currently accessed sites first. Maintenance or development of old growth, especially at lower elevations, is emphasized. Approximately 41 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 65 miles of existing arterial and collector roads. In the first two decades, approximately 13 miles of arterial and collector roads would be built, and about 145 miles of local roads would be constructed. Construction of the Naches Pass road is precluded by management of surrounding lands for undeveloped recreation.

Roadless Areas: approximately 96% of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: the foreground of selected corridors is protected, including the upper end of Mt. Baker Highway, portions of the Cascade River and North Fork of the Cascade, portions of the Mt. Loop Highway, the upper Sauk, lower Sultan, and Mather Memorial Parkway. Integral vistas within and from Class I airsheds and other wildernesses (not yet designated Class I) are protected.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers include is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Twin Sisters, Monte Cristo, Baker Lake, Naches Pass, and along the Mather Memorial Parkway.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide with additional habitat areas being protected to meet the objectives of the alternative. Approximately 113,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat provided for viable populations at the MR levels; some additional habitat for some species in wilderness, RNA.

Cavity Excavators: on lands suitable for timber production, habitat is provided for cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - managed to retain old-growth habitat with stipulation that it be maintained when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - managed for a full range of outputs, timber production on suitable lands.

Alternative H

The goal of Alternative H is to provide an increased emphasis on unroaded recreation; protection of scenic values in the foreground and middleground of heavily traveled highway corridors; increasing big game populations; plus emphasis on timber production on tentatively suitable acres not assigned to other objectives.

Design Criteria for Alternative H

Timber: about 60 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. About 20 miles of existing roads, located in areas assigned to unroaded dispersed recreation, will be closed. In the first two decades, approximately 11 miles of arterial and collector roads would be built. During that same period, about 250 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 88 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways.

Wild and Scenic Rivers: the five rivers determined in the DEIS to be eligible for Wild and Scenic River designation are recommended for designation - North

Fork Nooksack, North Fork Skykomish, South Fork Skykomish, Tye, and Middle Fork Snoqualmie Rivers, a total of 154 miles, of which 71 miles are within the national forest boundary.

Research Natural Areas: five potential are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 61,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - current direction (exchange NF lands to City of Seattle, no old-growth habitat maintained); Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

Alternative I

The goal of Alternative I is to emphasize those resources with an established price in the market place: timber production, anadromous fish, developed recreation, and minerals. Emphasis is also placed on enhancement of big game wildlife and fish habitat, and developing/maintaining an extensive trail system to accommodate a wide variety of users on a year-round basis. Other resources are managed at levels that do not reduce the outputs from the market resources.

Design Criteria for Alternative I

Timber: timber production is emphasized. Approximately 65 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed, to meet timber production goals. In the first two decades, approximately 34 miles of arterial and collector roads would be built. During that same period, about 290 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 86 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual: the foreground of heavily-traveled highways are managed for scenic quality (I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways).

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic River designation.

Research Natural Areas: no potential areas are recommended for designation.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. About 93,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.
Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous fish populations are increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

Alternative J (Preferred)

This is the Preferred Alternative. It is a new alternative and was not displayed in the DEIS. Beginning with the draft EIS Preferred Alternative (H), Alternative J was developed to respond to public comment and new information. Differences between the draft and this Preferred Alternative include: a considerable increase in trail mileage; an increase in the number of rivers recommended for addition to the National Wild and Scenic Rivers System; allocation of three Special Areas (Botanic, Scenic, and Recreation/Education); an increased emphasis on unroaded recreation; and greater protection of scenic values within travel corridors. Timber production is emphasized on suitable acres assigned to a timber harvest prescription. Other resources will be managed at levels commensurate with the objectives of the alternative.

Design Criteria for Alternative J (Preferred)

Timber: about 58 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. Roads to be closed include about 25 miles of existing roads, located in areas assigned to unroaded dispersed recreation. In the first two decades, approximately 15 miles of arterial and collector roads would be built, and about 240 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 91 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways.

Wild and Scenic Rivers: 30 of the 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for inclusion in the National Wild and Scenic Rivers System. A total of 452 miles are recommended, with 276 of those miles located within the national forest boundary. This recommendation is a preliminary administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Mather Memorial Parkway, Heather Meadows, and Sulfur Creek.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 54,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - initiate negotiations on a new Cooperative Agreement to reestablish goals and management for the watershed; until then, do not enter into land exchanges affecting National Forest lands; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

E. Alternative Constraints

This section discusses the constraints applied to each alternative to meet the goals and objectives of the particular alternative. The constraints applicable to all alternatives (with exceptions noted) have been discussed above in Part B of this Section. Some general comments applicable to all alternatives will be made first, and then constraints specific to each alternative discussed.

Constraints to Meet NFMA Management Requirements (36 CFR 219.27). Part 219.27 of the NFMA regulations sets forth "minimum specific management requirements" to be met in accomplishing goals and objectives for the National Forest System. The following listing shows the constraints applied to all alternatives used to meet the management requirements of Part 219.27. The purpose, rationale, and tradeoffs associated with each constraint applied was discussed in part C of this Chapter, as well as in Chapter VI, parts B and C.

NFMA Regulation	Constraint (Discussed in Part)
219.27(a) - Resource protection	Tentatively suitable lands (C.3) Wildlife MR's (C.4.a-b) Fish MR's (C.4.c) Riparian MR's (C.4.d) Water quality MR's (C.4.e)
219.27(b) - Vegetative manipulation	Tentatively suitable lands (B.3) Riparian MR's (C.4.c) Harvest unit size limit (C.4.f) Dispersion constraint (C.4.f)
219.27(c) - Silvicultural practices	Ending inventory constraint (C.1) LTSY-Link (C.2) Tentatively suitable lands (C.3) Riparian MR's (C.4.d) Harvest unit size limit (C.4.f) Dispersion constraint (C.4.f) Commercial thinning (C.6) Non-declining yield (C.7) 95% CMAI (C.10)
219.27(d) - Even-aged management	Harvest unit size limit (C.4.f) Dispersion constraint (C.4.f) Rotation length (C.5)
219.27(3) - Riparian areas	Riparian MR's (C.4.d) Rotation length (C.5)
219.27(f) - Soil and water	Tentatively suitable lands (C.3) Riparian MR's (C.4.d) Water quality MR's (C.4.e)
219.27(g) - Diversity	Wildlife MR's (C.4.a-b) Fish MR's (C.4.c) Riparian MR's (C.4.d) Harvest unit size limit (C.4.f) Dispersion constraint (C.4.f)

Cost efficiency was considered in the development of the constraint sets to meet the wildlife, riparian, and dispersion/diversity constraints. This process was discussed in Chapter VI of this Appendix, as well as in the AMS document. For the constraint developed after the hydrologic cumulative effects assessment process to meet soil/water and resource protection management requirements, cost-efficiency was considered to the degree possible. While there were no viable options other than limiting harvest in the affected watersheds, harvest acre limitations were set as low as possible while still meeting the necessary threshold for watershed disturbance. Also, the constraint is structured so that it can be filled first with first with large and small sawtimber before accessing pole stands. If the small sawtimber returns a higher benefit than the poles (true in almost all situations), then, within the total acre constraints, the small sawtimber will be brought into solution for harvest before poles are scheduled.

The constraints required by Washington Office and Regional planning direction were applied without further analysis of cost efficiency, although the opportunity costs of applying non-declining yield and 95% CMAI were calculated (see Chapter VI, E). The cost efficiency of the commercial thinning constraint was analyzed through the use of DP-DFSIM and off-line calculations done by the Forest Silviculturist and Timber Planner. Rotation length constraints were determined by the Forest Management Team to be the best way to meet the overall desired objectives of the alternatives, after considering a number of factors, including implementability and relative cost-efficiency.

These constraints were not analyzed on an alternative-by-alternative basis, either individually or together, in terms of their effects on PNV and total discounted benefits and costs. The opportunity costs of the major constraint sets for the management requirements can be seen in Chapter VI. The total effects of all the constraints, including management area acre assignments, can be seen in Chapter VIII.

Constraints Unique to Each Alternative

Coordinated Allocation Choices. The constraints common to all alternatives described above were invoked primarily to meet legal or policy directives, or to force the model to act similar to the way things would happen in the "real world". The major changes among alternatives came from the different acre assignments made to various management prescriptions by the Forest Management Team in the course of developing the alternatives. These acre assignments, as represented in the coordinated allocation choices (one for each alternative), reflected the Management Team's best judgment about how the objectives of each alternative could best be met. In that way, the acre assignments (coordinated allocation choices) acted as major constraint sets applied to each alternative to achieve the goals and objectives of that alternative.

Because of the use of coordinated allocations choices and varying acre assignments to prescriptions to achieve the goals of each alternative, the coordinated allocation choices were just about the only difference among alternatives. Table B-64 shows the acres assigned to each management area by alternative.

Yield Reductions for Primary Cavity Excavators. Aside from the coordinated allocation choices, only one other factor varied as a constraint with some alternatives. Primary cavity excavators were carried at a level of 20% of potential population in all alternatives, with a corresponding 1.5% reduction in timber yields. However, in some alternatives, a higher than minimum level was stated as an objective. The following alternatives had goals of maintaining primary cavity excavators at greater than minimum levels:

Alternative	% Population	% Timber Yield Reduction
A	40%	3.0%
C	60%	4.5%
H	40%	3.0%
J	40%	3.0%

As mentioned in part B, the timber yields and associated benefits were reduced 1.5% for every additional 20% cavity excavator population maintained.

Departure Alternatives (DEIS Only)

Two alternatives were included in the DEIS that examined a departure in timber harvest scheduling from the base sale schedule, as provided for in the NFMA regulations (36 CFR 219.16(a)(3)). These departure options were based on DEIS Alternatives E and H. In the departure alternatives, the basic land-use pattern stayed the same. The departure, however, was run with the harvest flow constraints set to allow a fluctuation in harvest up or down by a maximum of 20% from one decade to the next. Thus, the harvest patterns toward the end of the planning horizon rose near the 20% rate per period for both departure runs, resulting in last decade harvests above LTSYC. (However, if the planning horizon were extended, the harvest levels would cycle down again in the future, as they can't stay above LTSYC indefinitely.)

As discussed in Chapter II of this Appendix, the departure schedules were dropped from further consideration in the FEIS because of lack of public comment and support. The remaining alternatives, along with new ones developed, were sufficient for the necessary full range of alternatives for analysis.

F. Summary of Alternative Development Process

DEIS

The alternative development process involved the Forest ID Team, the Forest Management Team, and the Regional Forester and his staff. It began during the Analysis of the Management Situation, when the Planning Staff and Management Team roughed out the broad outlines of the alternatives originally thought needed to provide a broad range of forest management options and to respond to the Forest ICO's.

The completion of the Prescriptions, Standards, and Guidelines by the Forest ID Team and Management Team set the stage for the development of the full alternatives. With the prescriptions, their standards and their intent freshly in mind, the Forest Management Team and ID Team spent several days initially mapping out the management areas necessary to meet the objectives of the alternatives which had been established. They took into account the requirements for assigning various portions of the roadless area base to development and nondevelopment in different alternatives. Also considered were

1/ Total acres in each alt. vary due to rounding MA 9 not used, MA 24 Min Mgt not assigned in any alternative

2/ Applies only to Alt A, includes mostly unroaded, but some roaded recreation, from exisitng Multiple Use Plans

3/ Parcels of the 1926 area that remain outside of wilderness and the Mt Baker NRA are included here

4/ Acres are protected, at varying levels, in the alternatives, but not shown to protect confidential nature

5/ Includes Cultural-Historic, Geologic, Biologic, Botanic, and Scenic Special Areas.

6/ Many acres of riparian zone fall within other MA's and are protected through those management prescritptions

7/ Management Areas 16B Grizzly Bear, 16C American Peregrin Falcon, and 16D Gray Wolf have no acres assigned at this time, because no specific habitat has been identified or evaluated

8/ Acres of existing or proposed RNA located within wilderness are included in MA 10, not here.

9/ These acres overlap other MA's

10/ Includes acres within the congressionally designated Alpine Lakes Management Unit that are not otherwise assigned to other, compatible management areas (Compatible MA's include 5, 11, 12, 14, 15, and 16)

ranges of potential wild and scenic rivers to be included as candidates for further study for inclusion in the wild and scenic rivers system; ranges of research natural areas to add; ranges of American Indian Religious and Cultural Use sites to be protected; ranges of wildlife enhancement to assign; and so on.

With the completion of the initial mapping, the process of transferring the polygon maps into grid format for input to R2MAP began. As the process went along, numerous questions and inconsistencies had to be clarified with the Management Team members. The process was fluid and dynamic with refinements and improvements made as the group moved ahead.

Along with the alternatives mapped by the Forest Management Team, the Conservation Liaison Group alternative (G) was also completed and input.

Finally, the initial results of all the alternatives were taken before the Forest Management Team. The group chose to create one more alternative that they felt would complete the broad range of alternatives required under NEPA and NFMA for the Forest Plan EIS. The results of those alternative runs and subsequent analysis of effects by the Forest ID Team and Management Team are found in Chapters II and IV of the DEIS. They are also be discussed more briefly in Chapter VIII of Appendix B to the DEIS.

FEIS

After publication of the DEIS, public response, and the analysis of that response, the Forest Management Team and the ID Team again engaged in a series of exercises to determine new alternatives needed to respond to public comment, what alternatives could be dropped from further consideration, and what modifications were needed in the remainder of the existing alternatives. As a result of this process, a new Alternative I was developed in response to strong public support, particularly from the Public Land Users Society (PLUS). This alternative replaced Alternative D as the market-emphasis alternative. Alternatives E and F were dropped for lack of public interest and support. Alternative G was modified significantly to better meet its objectives. The two departure schedules were dropped. And finally, after considering all of these changes, the Forest Management Team developed Alternative J, which the Regional Forester chose as the new Forest Service Preferred Alternative on which the Forest Plan for the Mt. Baker-Snoqualmie National Forest is based.

The results of the alternatives included in the FEIS and the analysis of their environmental effects are discussed in Chapters II and IV of the FEIS. They are also discussed more briefly in Chapter VIII of this Appendix.

The reader interested in more detail of the development, use and analysis of constraints discussed in this Chapter, or in the process of developing the alternatives, is referred to the planning process records on file in the Land Management Planning section at the Supervisor's Office.

CHAPTER VIII - ESTIMATED EFFECTS OF BENCHMARKS, CONSTRAINTS, AND ALTERNATIVES

A. Introduction

This section provides a detailed discussion of the outputs and effects of the planning alternatives. The focus is on the tradeoffs among the alternatives as they provide different levels and mixes of goods and services, and as they address in different ways the ICO's guiding the Forest planning process.

The purpose of this chapter, including discussion of the consequences of the constraints used to help formulate alternatives, and the relationship of the alternatives to the benchmarks, is to facilitate the identification of the alternative that contributes the most to net public benefit. To accomplish this objective, there must be an understanding of the abilities of the Forest to produce different goods and services in response to the ICO's, and of the tradeoffs involved with the decisions to produce one mix of outputs and effects as opposed to another. As such, this comparative analysis provides the basis for selecting a preferred alternative for the Forest Plan. This process of estimating effects, evaluating the alternatives, and selecting the one that contributes the most to net public benefit is the process prescribed by Steps 6, 7, and 8 of the NFMA planning process (see Chapter I discussion).

B. Evaluation of Significant Constraints

The resource objectives of a benchmark or alternative were represented in FORPLAN as a combination of constraints, a coordinated allocation choice (which serves as a large constraint set), and an objective function. In most cases, the objective function for the linear program was Maximize PNV for 15 Decades. In some cases (timber biological potential benchmark, maximize timber with MR's, and Alternative A) an objective function maximizing timber output over some time period (generally five decades) was used; the results were then rolled over into a maximize PNV run to force the initial solution to be achieved as cost-efficiently as possible.

The objective function "drove" the solution of the linear program. Where the objective function was to maximize PNV, the model chose the most cost-efficient combination of management prescriptions, harvest and other output schedules, and levels of outputs within the ranges allowed by the constraints and the coordinated allocation choice. Generally (when running under a maximize PNV objective function), whenever a constraint was added to the model, it resulted in a lower PNV than the same run without the constraint. The reason: the model must meet the constraint first. Meeting that constraint essentially carries an infinite value; from the model's standpoint, it must be done at all costs or the run won't proceed - an infeasible run will result. If the constraint added is truly constraining, it will keep the model from reaching the PNV achieved in the previous run without the constraint. The difference in PNV and in outputs between the two runs, all other things being equal, is the incremental opportunity cost of the constraint and the tradeoff involved from applying it.

During the benchmark analysis, the maximum opportunity costs of the major constraint sets required to meet MR's were analyzed. Also analyzed were the opportunity costs and tradeoffs of the two major policy constraints used in the model: non-declining yield from timber harvest one decade to the next, and timber harvest at 95% of culmination of mean annual increment (95% CMAI).

These results are discussed in detail in the AMS document (May, 1985) and in Chapter VI of this Appendix. In addition, sensitivity analyses were performed to provide information about the effects on modeling of the levels of real price trends on timber that were and could be applied, and the effects on the modeling results of alternative levels of timber management costs (see Chapter VI, Section F of this Appendix). Those results are also detailed in the AMS document. Since all of this analysis is discussed elsewhere in this Appendix and in the AMS, the results will not be repeated here.

The opportunity costs and tradeoffs of some of the constraints applied commonly across all, or almost all, alternatives (e.g., non-declining yield, MR's, 95% CMAI) were analyzed during the AMS process with benchmark runs. Other common constraints (e.g., ending inventory constraint, LTSY link, commercial thin applicability) were <u>not</u> analyzed through FORPLAN, but were taken as givens going into FORPLAN. The relative opportunity costs of the commercial thin applicability constraint and the rotation length constraint were analyzed during the process of developing the timber management intensities through the use of DP-DFSIM (see Chapter III, Section E of this Appendix, and "Documentation of the Development of Managed and Empirical Yield Tables," September 1989 (revised), Forest planning records).

Other than a direct reduction in timber yield tables for varying levels of primary cavity nester populations supported by each alternative, the major constraint sets applied unique to each alternative were the coordinated allocation choices (CAC's) that specified land-use assignment patterns needed to meet the goals and objectives of the alternative, as decided by the Forest Management Team. Overall changes in the coordinated allocation choices indicated the tradeoffs and opportunity costs of moving from one alternative, with its mix of goods, services, and responsiveness to ICO's, to another alternative.

None of the common constraints or the alternative-specific constraints were analyzed on an incremental or sequential basis for each alternative. To do so would have been prohibitively expensive and time consuming. As pointed out in Chapter VI, Section A, the order by which constraints are added changes the apparent opportunity cost of each constraint, unless the constraints are <u>totally</u> independent, which is rarely the case. Any analysis of constraints, constraint by constraint and alternative by alternative, would have left the decision makers with masses of confusing information that would not have been resolvable to some more simple common denominator.

The constraints analysis information from the benchmarks was used to guide the IDT and Management Team in developing the alternatives. The general effects of the constraints and their estimated magnitude of effect in the more constrained situation of the alternatives were kept in mind, in order to achieve the objectives of each alternative in the most cost-efficient and productive manner possible.

The effects of changing the major constraint sets - the coordinated allocation choices - among alternatives are seen by observing the outcomes and effects from each alternative. These total changes represent the opportunity costs and tradeoffs of the alternative-specific constraint sets, i.e., of the alternatives themselves. No attempt was made to disaggregate each CAC and add or subtract various parts sequentially; the run time and costs would have been enormous, with little useful data provided. The level of change having value for the decision-making process was represented by the changes among the goals, objectives, and formulation of the entire alternatives. The information on these comparisons, and the estimated contributions to net public benefit, are discussed in detail in Chapters II and IV of the FEIS. An abbreviated display and discussion of this information comprises the balance of this chapter.

C. Analysis of Tradeoffs Among Alternatives

This section discusses the consequences of each alternative, including response to the Forest ICO's, resource outputs, environmental consequences, social, and economic effects. Economic tradeoffs are analyzed in some detail, including reasons for differences in costs, benefits, and PNV among alternatives. Factors affecting net public benefit that were not carried quantitatively in the model are discussed for each alternative. Alternative objectives and effects are compared and contrasted, with the similarities, differences, and their reasons discussed. The tables and discussion below repeats much of Chapter II of the FEIS; refer to that document for more detailed discussion.

1. Consequences of the Alternatives

The major reason that alternatives differ is that they represent different ways of responding to issues, concerns, and opportunities. In the following Table B-66, the response of each alternative to the major ICO's is displayed.

Inputs, Yields, and Effects of Various Resources and Activities by Alternatives

The following Tables, B-67a through B-67g show the inputs, yields, and effects of various resources and activities, by alternative. The numbers are derived either from analysis completed in the FORPLAN model, or in a few cases, from analysis done outside of the model.

The alternatives are displayed, from left to right across the top, in order of decreasing acres of land suitable for timber production. Total suitable acres are strongly correlated with the goals and objectives of each alternative. For example, Alternative I, with an emphasis on timber and other resources with an established market price, has a high number of suitable acres and also a high ASQ. Alternative C, with a goal of emphasizing primitive and semi-primitive dispersed recreation, has the fewest suitable acres and the lowest ASQ.

This order - by decreasing suitable acres - is useful in understanding how the environmental consequences and effects will vary by alternative. The sequence is strongly correlated to the amount of vegetative management in the alternatives.

Outputs and effects that are generally related, such as timber/roads/sediment or recreation/wilderness/scenery, are grouped and displayed together. There are narratives preceeding each table in Chapter II of the FEIS; they will not be repeated here.

Table B-66
Response, By Alternative, to Major Issues and National Concerns

	National Concerns			Development Vs. Nondevelopment Issue 1/			Timber Supply Issue

C	1970.9	-2.1/14.1	60.7/78.8	93	375.8	23.1	15.8	(75)	19.9	256	28.0	2.6
NC 3/	N/A	N/A	N/A	NA	NA	NA	45.0	(220)	N/A	547	30.1	9.5

1/ Roadless Areas refer to the 402,930 acres of remaining RARE II parcels.

2/ This is an approximate figure. Alternative A is unique because an unspecified amount of development is permitted in the Upper Forest Resource Zone See description of Management Area 1E.

3/ The TM Plans upon which Alternative NC is based were developed in 1963; they are not integrated resource plans, and consequently did not address all resource uses and outputs. Missing data in this table (NA) cannot be reasonably estimated, since the TM plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect standards in the NFMA regulations, or are otherwise inappropriate.

4/ Includes wilderness and non-wilderness acres of old growth located below 3,000 feet elevation. Indicator species for mature and old-growth habitats are Northern spotted owl, pileated woodpecker, and pine marten.

5/ Acres given include deer and elk winter range, management areas with compatible goals and which will incorporate winter range standards and guidelines, and some mountain goat habitat.

6/ Protection is afforded by those management areas that preclude or limit ground disturbing activities. Differences between "high" and "moderate" derived from expected frequency of human encounters. See Table II-9o.

7/ No management areas assigned in Alternative NC and the above information cannot be reasonably estimated. The TM Plans, upon which the No Change Alternative is based, were developed in 1963.

1/ The TM Plans upon which the No Change Alternative is based were developed in 1963. The outputs and effects are generated from previous inventories All other alt. outputs and effects were calculated using updated inventories and yield tables and the latest method of calculating timber harvest levels. For Alt. NC, tentatively suitable lands were not determined and standard plus special commercial forest land is shown as lands suitable for timber production.

2/ ASQ: Quantity of timber that may be sold, from suitable land. Includes only chargeable, live (green) not salvage, fuelwood or other non-industrial wood. Potential yield from the TM Plan is shown for Alternative NC.

3/ Potential yield is a ceiling on amount of chargeable timber volume that can be sold; includes both net live and salvage volume. Current potential yield equals 203.8 MMBF/yr. Potential Yield 1975-1979 = 240.9 MMBF/yr.; 1980-1983 = 259 4 MMBF/yr.; 1984-1988 = 203.8 MMBF/yr. See Table BI-11 for further explanation on potential yield values.

4/ Includes ASQ, nonchargeable mortality volume, volume not meeting utilization standards, and volume used for other than board products from lands suitable for timber production, and volume from unsuitable lands. Includes PY and all other volume for NC.

5/ The fuelwood conversion is 95 cubic feet per cord. Volumes are estimated as a % of submerchantable timber outputs associated with regeneration harvest. This volume is included above in Timber Sale Program Quantity and in 1975-84 Cut and Sold It is not included in ASQ or PY.

Research Natural Areas Recommended for Designation	No. of Areas	0	0	0	0	5	5	5	5

5/ Includes 721,600 acres of preservation VQO in wilderness, which is the same in all alternatives.

6/ The visual quality terms here were not in use in 1963. Modified cutting areas termed "Landscape Management Areas (LMA) were managed to protect other resource values. These LMA's included "Present Occupency Areas" (e.g Mather Memorial Parkway and developed recreation sites); "Proposed Occupancy"; and roadside, streamside, lakeside, and buffer zones where reduced timber harvest was part of the regulated PY. Terminology amendment to the 1963 Plan termed the CFL in LMA's as Special or Unregulated. Actual acres assigned to VQO cannot be reasonably estimated, but would be similar to Alternative A.

7/ VQO for these acres was assigned by the 1981 Alpine Lakes Land Management Plan. These acres vary by alternative depending upon the amount of wildlife habitat assigned in that alternative.

8/ RARE II roadless areas released by the 1984 Washington Wilderness Act.

9/ System roads tentatively closed to all travel are not included.

1/ The Timber Management Plans upon which the No Change Alternative is based were developed in 1963 They are not integrated resource plans, and consequently did not address all resource uses and outputs *The missing information in this table cannot reasonably be calculated However based on the existing* vegetation, it is unlikely that more than 50% of the total roadless area acres would be developed in the foreseeable future

2/ Estimate Alternative A is unique because an unspecified amount of development is permitted in Upper Forest Resource Zone See the description of MA 1E, earlier in this chapter

1/ Values for wildlife species other than bald eagle and primary cavity excavators are population estimates based on maximum habitat potential.
2/ The TM Plans upon which the No Change Alternative is based were developed in 1963. They are not integrated resource plans and consequently did not address all resource uses and outputs
3/ Populations would be expected to decline at a rate faster than Alternative A because no specific provision is made in Alt. NC to maintain viable populations and more of the old growth is suitable for timber harvest and will be fragmented.

C	232,500	173,393	134,400	103,245	91,396	77,180	33,134
G-Mod.	232,500	195,946	134,400	80,692	66,491	47,228	7,824

1/ The total acres of old growth, at the starting point, wilderness and non-wilderness = 643,538. No reasonable estimates for Alt. NC.

2/ Other resource objectives include allocations such as wildlife MR's, riparian MR's, or non-motorized dispersed recreation, etc. These vary by alternative, depending upon the objectives or goal of the alternative.

1/ The 1963 TM Plans, upon which Alternative NC is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated because, except for cemeteries, the percentages were developed by overlaying inventoried areas with MA's; no MA's were assigned in Alternative NC.

Qualitative Resource Outputs, Environmental Effects, by Alternative

The previous Tables B-67a through B-67i, displayed the quantitative resource outputs, environmental effects, activities and costs by alternative. Not all the outputs and effects can be quantified. In the following Table B-68, those outputs and effects that cannot be adequately covered quantitatively are discussed.

Alternative NC (No Change) is based on the 1963 Timber Management Plans; they were not an integrated resource plans and consequently did not address all resource uses and outputs. Data for this alternative is presented, or estimated, as available.

Note: although the outputs and effects occur over the long-term, the results of this planning process will apply for only 10 to 15 years, the life of this Forest Plan.

Refer to Chapter IV, Environmental Consequences, for a complete discussion of the effects of implementing the alternatives on the physical, biological, social, and economic environments.

Table B-68 Page 1 of 6
Qualitative Resource Outputs and Environmental Effects

Archaeological and Historical Properties

NC (No Change)	Estimated to be similar to Alternative A (No Action), by highest frequency of resource damage.
A (No Action)	High frequency of resource damage in developed areas, with high mitigation costs. Information gained through site discovery and recovery.
I	Intermediate frequency of resource damage in developed areas, with high mitigation costs. Some information gained.
B (RPA)	Similar to Alternative I in developed areas.
H	Similar to Alternative I in developed areas.
J (Pref)	Similar to Alternative I, with more potential for information gain and interpretation.
C	Has the fewest adverse effects on cultural and historic resource, but also fewer opportunities for information gained through site discovery and interpretation
G-Mod	Only Alternative C has fewer adverse effects. Somewhat less opportunity for gaining information.

Visual Quality

Same in All Alternatives: Visual quality in Alpine Lakes Management Area (which includes Snoqualmie Pass and Stevens Pass Highways) and Skagit Wild and Scenic River will be managed as prescribed in approved plans, except where overridden by wildlife MR's. Wilderness is Preservation in all alternatives.

NC (No Change) The foreground of Mather Memorial Parkway is managed as a scenic corridor; timber harvest permitted but not scheduled. Effects of NC on other areas of the Forest are estimated to be similar to Alternative A.

A (No Action) With emphasis on timber harvest at low elevations, coinciding with many heavily used rec. areas, there would be some conflict between commodity production and scenic quality. The cumulative effect of Alt. A would be a "moderately" altered character even in highly scenic areas. Only the foreground of Mather Memorial managed as scenic corridor.

I With an emphasis on managing tentatively suitable lands for timber production, only the foreground of heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Parkway, Mtn. Loop Highway, Mt. Baker Highway, Baker Lake Highway, and North Cascades Highway 20. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily-altered state.

B (RPA) With high emphasis on managing all tentatively suitable lands for timber production, scenic quality will deteriorate for almost all lands accessible by road. Only the foreground of Mather Memorial Pkwy will be managed as scenic area; only sites unsuitable for timber production will remain roadless.

H The foreground and middleground of five heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Pkwy, Mtn. Loop Hwy, Mt. Baker Hwy, Baker Lake Hwy, and North Cascades Hwy 20. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily altered-state.

J (Pref) The foreground and middleground of 7 heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Pkwy (MA 8, Special Area), Mtn. Loop Hwy, Mt. Baker Hwy, Baker Lake Hwy, North Cascades Hwy 20, Cascade River road, and Crystal Mtn. Hwy. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily altered-state. Wild and scenic river recommended (30 rivers) will add to visual quality.

G With low level of timber harvest and emphasis on retaining old growth and wild and scenic rivers, many foreground areas will be visually unaltered. Some scenic acres assigned: upper end of Mt. Baker Hwy, portions of Cascade and N. Fk. Cascade R., portions of Mtn. Loop Hwy, upper Sauk, lower Sultan, and Mather Memorial Pkwy. Middleground views will be "moderately altered". Roadless areas will be undisturbed.

C Nearly all existing roadless areas will remain roadless and be visually undisturbed. Both primary and secondary recreation corridors will be managed as scenic viewsheds. Opportunities for roaded and remote scenic viewing are high.

Table B-68 Page 3 of 6

Water and Riparian Resources

NC (No Change	Emphasis for water quality similar to Alt. A. Some riparian values protected via land stratification in TM Plan (no regulated harvest on Marginal). Mitigation measures - similar to Alt. A.
A (No Action	Emphasis on maintaining water quality. Riparian values managed at MR level. Intensive mitigation measures needed to mitigate effects of high road construction and vegetation disturbance from timber harvest.
I	Water quality maintained or improved slightly from Alternative A. Riparian values managed with special emphasis on enhancement. More intensive mitigation measures than in Alternative A, required to mitigate direct effects of roads and timber harvest on soils which result in sedimentation.
B (RPA)	Water quality will improve slightly over Alt. A due to longer harvest rotations in large areas managed for wildlife habitat improvement. Riparian values managed with special emphasis on enhancement. Fewer acres harvested and miles of road constructed/reconstructed than in Alt. A require less mitigation of direct effects of road construction and timber harvest.
H	Water quality improved over Alt. A due to fewer acres harvested and fewer new roads. Management of riparian values and mitigation measures needed are similar to Alt. I.
J (Pref)	Water quality improved over Alt. A due to fewer acres harvested and fewer new roads. Management of riparian values and mitigation measures needed are similar to Alt. I.
G-Mod	Water quality will improve significantly over Alt. A due to fewer developed areas, reduced road construction and timber harvesting, and closure of about 65 miles of existing road. Riparian values managed with special emphasis on enhancement. Lowest mitigation costs except for Alt. C.
C	Water quality will improve significantly over Alt. A due to reduced timber harvest, road construction, plus closure of 300 miles of existing road. Riparian values managed with the highest emphasis on enhancement of any alternative. Least mitigation required.

Diversity of Plant Communities

Same in All Alternatives: Timber harvest or the lack of timber harvest, will have a great effect on the kinds and distributions of plant communities found on the Forest. On those areas where timber harvest is precluded, natural processes will continue uninterrupted and more late successional communities will prevail. These areas will be dominated by large diameter trees of advanced age and other plant species associated with this condition.

In those areas where timber harvest occurs, there will be a transformation from the late successional communities to early successional communities. These areas will be dominated by small to medium size trees of relatively younger ages, less than 160 years old, and other plant species associated with this condition. These plant communities will take on a mosaic appearance because of the schedule of harvest activities and their distribution across the landscape. In addition, there will be intermingled areas of late successional communities. The amount and distribution of these intermingled older communities will depend on the theme of the individual alternative.

NC (No Change	There will be an increase in early successional plant communities on all commercial forest lands. By the end of the 5th decade, approximately 435,000 total forested acres will be in successional stages 100 years or less in age.
A (No Action	Late successional plant communities will be found on 739,000 forested acres (480,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 147,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 370,000 total forested acres in successional stages 100 years of age or less.
I	Late successional plant communities will be found on 744,000 forested acres (486,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 128,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 351,000 total forested acres in successional stages 100 years of age or less.
B (RPA)	Late successional plant communities will be found on 744,000 forested acres (486,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 130,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 353,000 total forested acres in successional stages 100 years of age or less.
H	Late successional plant communities will be found on 757,000 forested acres (450,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 117,000 acres will have been converted to earlier successional stages. This combined with the starting acreage

of stands in successional stages under 50 years of age (223,000 acres) produces a total of 340,000 total forested acres in successional stages 100 years of age or less.

J (Pref) Late successional plant communities will be found on 763,000 forested acres (503,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 108,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 331,000 total forested acres in successional stages 100 years of age or less.

C Late successional plant communities will be found on 806,000 forested acres (540,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 70,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 293,000 total forested acres in successional stages 100 years of age or less.

G-Mod Late successional plant communities will be found on 832,000 forested acres (563,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 73,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 296,000 total forested acres in successional stages 100 years of age or less.

Civil Rights

Same in All Alternatives: Various Civil Rights, Affirmative Action, and Equal Employment Opportunity Acts require that Forest Service hiring, supervisory, and contracting practices be conducted in a manner conducive to meeting established Regional and Nation-wide goals in these areas. In all alternatives, positive steps are included to ensure that facilities, sites, and activities will not be denied to any individual on account of race, color, creed, religion, sex, marital status, age, handicap, or National origin.

Social Environment

Same in All Alternatives: There is no measurable effect on urban communities. See Table II-9n for the economic effects. Jobs lost/gained will often affect residents in the rural and agricultural communities east of the Interstate Highway 5 corridor.

NC (No Change) Lifestyle and minority employment: estimated to be similar to Alternative A (No Action).

A (No Change) No apparent changes in lifestyle. Some of the employment generated in Decade 1 will be filled by minorities.

I Opportunities increases for individual pursuing roaded recreation experiences, although these people will encounter strong evidence of altered landscapes. The most favorable alternative for minority employment.

B (RPA) Similar to Alt. D; less favorable than the current situation for minority employment.

H No apparent changes in lifestyle would occur. Less favorable than the current situation for minority employment.

J (Pref) No apparent changes in lifestyle would occur. Less favorable than the current situation for minority employment.

G-Mod Opportunities are enhanced for those who seek leisure or work in a more natural environment, and diminished for those pursuing roaded recreation experiences. Less favorable than the current situation for minority employment.

C Opportunities increase for those pursuing activities in a natural setting and decrease for those pursuing roaded recreation experiences. Least favorable for minority employment.

2. Benchmark PNV Summary

A detailed discussion of the benchmarks, their outputs, and the opportunity costs of the major constraint sets is given in Chapter VI of this Appendix. That information is used here to develop a summary of the benchmark PNV's and the reasons for the differences among them. Rather than display present net values for all 25 benchmarks analyzed, only those for the required benchmarks, plus the Max PNV with Market Prices Only, will be used. Table B-69 summarizes differences in PNV between these benchmarks. The output table number in this Appendix for each benchmark is referenced in parenthesis. These benchmarks represent the range of benchmark analysis; for additional tradeoffs and opportunity costs of changing individual constraints, non-declining yield, or 95% CMAI, the reader is referred to Chapter VI or the AMS document.

In order to calculate the Discounted Costs and Benefits for Table B-69a, PNV figures from the back of the report file had to be used. There is a difference of approximately 1% in the reported PNV figures.

Following the completion of the benchmark analysis and prior to the development of the alternatives, several improvements were made in the FORPLAN model to better account for road building and recreation related activities and their resulting costs and benefits. Fixed costs and the fish investment levels and benefits were also added to the model. These model improvements resulted in several of the alternatives producing a higher PNV than the max PNV benchmark.

In this FEIS where a comparison is made between the max PNV benchmark and the alternatives, the PNV for the benchmark has been increased from $2,403.1 to $2,590.7 to place it on a comparable basis with the alternatives. This increase was estimated using a least-squares regression. Linear equations were developed to make statistical inferences about revenues and costs, based on timber sale program quantities in each of the alternatives. Given the timber sale program quantities of each decade for the benchmark, these models were then used to predict a more comparable PNV for the max PNV benchmark (7).

Table B-69
Summary of Benchmark PNV's

Benchmark	PNV 1/	Change	Objective Function	Differences/Comments
Maximum PNV with No MMR's (Table B-26)	2630.9	-31 2	Max PNV for 15	Maximum unconstrainted economic benchmark
Biological Timber Potential (Table B-25)	2599.7	-216.3	Max Timber for 1 Max Timber for 15 Max PNV for 15	To achieve max timber, run uses more intensive silvicultural practices such as commercial thin that have negative PNV
Maximum PNV with MMR's (Table B-37)	2381 4	-61.6	Max PNV for 15	Major decrease in PNV caused by holding lands out of timber harvest and using extended rotations for MMR's
Current Direction w/1st Decade Timber Target: no NFMA MMR's (Table B-46)	2319.8	-17.5	Max Timber for 5 Max Timber for 15 Max PNV for 15	Although not having MMR's, 49 owl pairs were supported and cavity nesters were maintained at 40% of their potential population. In addition, there are about 55,000 fewer acres of land available for timber mgmt. because of the current direction land allocations. This offsets the gains from no MMR's resulting in a lower PNV.
Maximum Timber with MMR's (Table B-44)	2302 3	-109.6	Max Timber for 1 Max Timber for 15 Max PNV for 15	Higher cost silvicultural practices and those having negative PNV such as commercial thin are used to achieve max timber.
Current Direction with MMR's and 1st Decade Timber Target (Departure formulation) (Table B-47)	2192.7	-34.2	Max Timber for 5 Max Timber for 15 Max PNV for 15	95,000 fewer acres of suitable land for timber management because of MMR's and the current direction land allocations. NDY constraint dropped for departure formulation to achieve feasible run. Departure allows higher cutting in early decades and higher PNV than would occur under NDY.
Current direction with MMR's; no 1st Decade Timber Target (Table B-48)	2158.5	-108.0	Max Timber for 5 Max Timber for 15 Max PNV for 15	PNV slightly lower because of low 1st decade harvest allowed without timber target. NDY applied, also lowering PNV.
Maximum Primitive and Semi-Primitive Recreation Opp. (Table B-45)	2050.5	-567.6	Max P/SPNM Rec for 15 Max PNV for 15	Suitable acres for timber mgmt. down about 225,000 reflecting land allocations designed to preserve Prim. and SPNM dispersed rec. opportunities. Lower benefits offset somewhat by lower mgmt. and road construction costs.
Maximum PNV with MMR's Market Prices Only (Table B-38)	1482.9		Max PNV for 15	No recreation values included. About $900 MM difference from run with assigned prices.
Minimum Level Management (Table B-24)	Not Estimated		N/A	

1/ PNV objective function value from the LP solution in benchmark runs (See III.F.6.)

3. Comparison of the Economic Effects of the Alternatives

Present Net Value (PNV) is an estimate of the potential economic effectiveness of managing the Forest. Since each alternative is a different way of managing the Forest, each alternative has its own PNV. By comparing PNV of the alternatives, the economic effectiveness of the alternatives can be compared.

PNV is defined as the discounted dollar value of all priced outputs, less the discounted cost of all expenditures for management and investments. Discounting is a way of combining current and future values to show them in todays terms; values are expressed in terms of 1982 dollars and the discount rate used is 4%.

Priced outputs include resource outputs with a market price and those non-market resource outputs that have an assigned price (commensurate with market prices). Market resources include: timber, developed recreation, commercial anadromous fish, minerals, and special uses for which fees are collected. The displayed economic benefits for market resources include actual dollar receipts plus additional assigned dollar benefits for developed recreation. Non-market resource benefits are dollar benefits assigned to dispersed recreation, wilderness, and wildlife and fish-dependent recreation. The purpose of assigning dollar benefits is to reflect the full economic benefit, even though none, or only part, of that benefit associated with particular resources is actually collected as fees under current laws and policies. Economic benefits associated with market and non-market resources are displayed in detail in Appendix B, Table B-16.

As discussed in the text preceding Table B-73, an assumption made concerning the relationship between recreation capacity and use has a significant effect on the economic benefits of recreation discussed here. It was assumed that recreation use will be limited to estimated capacity. Under this assumption, no use would occur above capacity levels; therefore, no economic benefits were assigned above that level.

If this assumption is incorrect and recreation use occurs to the level of predicted demand, recreation benefits have been underestimated by $698 million

to $801 million, depending on the alternative. This potential underestimation would increase PNV by approximately one-third.
Since projected demand in Decade 1 is below estimated capacity for all classes of recreation - except non-wilderness unroaded dispersed, 6 percent of total demand - the possible underestimated economic benefits would not occur until after the first decade, or beyond the life of this plan.

Costs

Two types of costs are included in Forest management: operation and maintenance, and capital investment.

Operation and maintenance costs are the costs of activities required to plan and manage outputs, and maintain existing capital assets at standard levels. These include fixed costs such as general administration, and variable costs which vary with different levels of outputs. Fixed costs are constant across all alternatives, while variable costs differ among the alternatives.

Capital investment costs are the costs of creating or enhancing capital assets, such as roads, trails, or fish habitat improvement structures. Road construction costs are a main component of capital; they are a direct function of the timber program. Other capital investment costs, such as fish and wildlife, vary independently of the timber program.

Table B-70: PNV, Discounted Costs and Benefits of Alternatives

Table B-70 summarizes the economic information used to determine PNV for each alternative, except Alternative NC, and for the Maximum PNV, with MR's Benchmark. This benchmark is not considered to be a viable alternative for the reasons discussed earlier in this chapter; it is shown as a reference point. The alternatives are ranked in order of decreasing PNV.

Discounted costs are the sum of all the costs which would be incurred to implement the alternative, discounted to their present value at a four percent interest rate. Discounted benefits are the sum of all the benefits produced by an alternative, discounted to their present value using a four percent interest rate.

The "change" is the difference in either PNV, discounted costs, or discounted benefits between successionally ranked (in descending order of PNV) pairs of alternatives. The incremental changes in PNV are a measure of the net economic benefits of the priced resources that would be foregone if a lower ranked alternative were to be selected over the preceding one. These priced resources that would be foregone would have to be weighed against the response to public issues and any net difference among the non-priced outputs.

As a general rule, PNV declines because benefits decline faster than costs, mainly due to a decline in timber benefits, although recreation benefits also fall. There are, however, some exceptions to this general rule.

When comparing Alternative A (No Action) to Alternative J (Preferred), Alternative A has markedly higher discounted costs (30%) and benefits (10%) than Alternative J (Preferred) but only slightly higher (1%) PNV. The objective function (in FORPLAN) for Alternative A is to maximize timber outputs in the first five decades. As a result, Alternative A has higher timber outputs with accompanying increased benefits, but these increased outputs are achieved at the cost of less efficient investments in timber management

practices, which increases cost. Alternative A has the highest road construction program of any of the Alternatives, which also increases costs.

Another general trend: as roaded dispersed recreation use declines, so does PNV. Again, there are some minor exceptions. All alternatives have the same roaded dispersed recreation use in Decade 1, as capacity exceeds demand, thus limiting the benefits of roaded recreation to actual use.

Although there is a strong correlation between roaded dispersed recreation and PNV, this relationship is attributable to timber outputs and the accompanying road construction program. Thus, timber outputs are the real driver of PNV.

Table B-70

Present Net Values and Discounted Costs and Benefits of Alternatives

Alternative/Benchmark	PNV	Change	Discounted Costs	Change	Discounted Benefits	Changes
Benchmark	..... Millions of Dollars.....					
Max PNV with MR's (run #7)	2590.7	1/				
		-247.5				
Alternatives						
B (RPA)	2343.2		1091.5		3434.7	
		-0.3		3.9		3.6
I	2342.9		1095.4		3438.3	
		-59.4		178.3		118.9
A (No Act.)	2283.5		1273.7		3557.2	
		-23.5		-242.4		-265.9
H	2260.0		1031.3		3291.3	
		-1.2		-46.9		-48.1
J (Pref.)	2258.8		984.4		3243.2	
		-261.8		-156.2		-418.0
G-Mod.	1997.0		828.1		2825.1	
		-26.1		-103.9		-130.0
C	1970.9		724.3		2695.2	
NC (No Change)2/	NA	NA	NA	NA	NA	NA

1/ Revised for comparison with alternatives (see Appendix B. VIII. C.2.).

2/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable with the Max PNV Benchmark and other alternatives were not determined.

Comparison by Costs. Table B-71 shows the same data as the previous table, but it has been rearranged to show the ranking of the alternatives according to increasing total discounted costs. In general, the costs increase as PNV increases. This indicates that as constraints are relaxed, primarily the amount of timber harvest allowed, it is possible to increase the investments made in management of the Forest and get a return greater than the amount of the additional investment.

For instance, an additional $104 million in discounted costs going from Alternative C to G results in a total gain in discounted benefits of $130 million, or a net gain in PNV of about $26 million. From an economic standpoint, the incremental benefits are greater than the incremental costs. As long as that is the case, it is justifiable (all other things being equal) to increase the amount of the investment up to the point that the incremental benefits just equal the incremental costs.

Table B-71
Present Net Value, Discounted Costs, and Discounted Benefits By Alternative
Million 1982$

Alternative	Discounted Costs	Change	Discounted Benefits	Change	PNV	Change
Alt. NC 1/	NA	NA	NA	NA	NA	NA

		178.3		118.9		-59.4
Alt. A (No Action)	1273.7		3557.2		2283.5	
		422.0		729.2		307.2
Max PNV Benchmark (Run #7)	1695.7		4286.4 2/		2590.7 2/	

1/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable with the Max PNV Benchmark and other alternatives were not determined.

2/ Revised for comparison with alternatives (see Appendix B. VIII. C.2.).

Comparison by Benefits. Table B-72 again displays the information in the previous two tables, but this time ordered according to declining total discounted benefits. Here again, except for the two runs done under a maximize timber objective function, the total benefits decline along with PNV, timber harvest, road building, and roaded recreation. The two runs done under a maximize timber objective function (A and E-Departure) both display benefits out of line with the normal pattern. This is because a larger amount of timber was harvested, but at an even proportionately larger cost. For instance, E-Departure invested $229.9 million more than Alternative E, but got only $212.3 million more in benefits. In this case the incremental benefits were less than the incremental costs, and PNV declines.

Table B-72
Present Net Value, Discounted Costs, and Discounted Benefits By Alternative
Million 1982$

Alternative	Discounted Benefits	Change	Discounted Costs	Change	PNV	Change
Max PNV Benchmark 1/	4286.4 1/		1695.7 1/		2590.7 1/	
		-729.2		-422.0		-307.2

		-129.9		-103.8		-26.1
C	2695.2		724.3		1970.9	
NC 2/	NA	NA	NA	NA	NA	NA

1/ Revised for comparison with alternatives; see Appendix B, VIII, C.

2/ The TM Plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable with the Max PNV Benchmark and other alternatives were not determined.

Table B-73: Average Annual Cash Flows, Non-cash Benefits

In Table B-73, the alternatives are ranked in order of decreasing net receipts; all alternatives show a positive cash flow (net receipts) to the treasury in Decade 1 except Alternative C. Alternative A has the highest cash flow, with $6.5 million, while Alternative C has the lowest with a ($2.4) million negative flow. There is an almost identical ranking of the alternatives in terms of cash flow and ASQ, because timber receipts make up nearly all of the total receipts on the Forest.

All of the alternatives have a positive cash flow in the fifth decade. Again the ranking of the alternatives in terms of cash flow mirrors the ranking of alternatives by ASQ.

Net receipts increases from Decade 1 to Decade 5 in all alternatives. In the first decade, the water quality and riparian management requirement result in reduced acres of harvest in some watersheds and thus lower receipts than in later decades when the HCE management requirement allows increased harvest. Alternative A net receipts increase most ($23.1 million) and Alternative G-Modified the least ($8.9 million) between the first and fifth decade.

From Decade 1 to Decade 5, total receipts in Alternative J (Preferred) increase approximately 121%. At the low end, Alternative G-Modified total receipts increase approximately 67%, and at the high end Alternative C total receipts increase approximately 182%.

Non-cash benefits increase from first to fifth decades in all alternatives. This is a function of increased recreation benefits that are valued as demand increases in Decade 5. By the fifth decade, development will have converted more lands from nonmotorized recreation opportunity to motorized recreation. Motorized recreation is more valuable on a per acre basis than nonmotorized. This also explains why Alternative C has the lowest non-cash benefits, as it maintains more land in a nonmotorized condition than any of the other alternatives.

Table B-73

Average Annual Cash Flows and Non-cash Benefits
Decades 1 and 5, By Alternative

Alternatives	Decade 1 Net Receipts	Decade 1 Total Costs	Decade 1 Total Receipts	Decade 1 Non-Cash Benefits to Users	Decade 5 Net Receipts	Decade 5 Total Costs	Decade 5 Total Receipts	Decade 5 Non-Cash Benefits to Users
	Millions of Dollars Per Year							
A (No Action)	6.5	15.3	21.8	60.9	29.6	16.7	46.3	85.2
I	5.8	14.3	20.1	61.3	25.6	15.4	41.0	85.5
B (RPA)	5.3	14.4	19.7	61.0	24.8	15.4	40.2	86.8
H	4.8	13.6	18.4	60.5	24.1	14.9	39.0	83.8
J (Preferred)	3.4	13.6	17.0	61.2	23.1	14.6	37.7	85.5
G-Modified	2.1	12.4	14.5	60.6	11.0	13.2	24.2	80.2
C	-2.4	11.8	9.4	60.7	14.1	12.4	26.5	78.8
NC (No Change) 1/	NA	NA	NA	NA	NA	NA	NA	NA

1/ The 1963 TM Plans, upon which the No Change Alternative is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable to the other alternatives were not determined.

Table B-74: PNV, Discounted Benefits and Costs By Resource Group

In Table B-74, the total costs and benefits for each alternative are assigned to selected major accounting or budgeting categories. A complete and exact relationship between the dollar benefits associated with a particular priced output and the cost figure assigned to it should not be assumed. Forest-wide production of any specific priced output is generally supported by complex combinations of input costs. As an example, some recreation and wildlife benefits are joint outputs of timber management.

In Table B-74 the total discounted costs and benefits have been disaggregated into the broad resource groups of timber, recreation, and other. "Timber" benefits include sawtimber and fuelwood. "Recreation" benefits include dispersed and developed recreation, and wildlife and fish use. Benefits for commercial fish are included under "other." Discounted costs for roads are shown as a separate entry, since it is very difficult to accurately separate these costs into the resource groups. Costs shown under "other" include fish habitat improvement investments, share-cost road maintenance, and fixed costs.

Table B-74 indicates that almost all of the variation in PNV discounted costs and discounted benefits is due to the variation in timber outputs of the alternatives. First decade timber outputs vary by 125% between Alternative C (13.8 million cubic feet) and Alternatives A (31.0 million cubic feet). The discounted costs and discounted benefits for timber follow the same general trend as timber outputs with some minor exceptions: as timber outputs decline, so do discounted costs and benefits.

Discounted costs and benefits for recreation change very little from one alternative to another. This is partly due to the fact that current recreation use is very close to capacity on the forest for most types of recreation except roaded dispersed. There is little opportunity to significantly increase recreation supply in wilderness or primitive, semi-primitive nonmotorized, or semi-primitive motorized outside of wilderness. Although there is some variation between alternatives in these dispersed recreation capacities, it is a very small percentage of the current capacity and affects discounted recreation benefits only about 6% between the alternatives. Discounted recreation benefits exceed discounted timber benefits in all alternatives.

Alternative C has the lowest discounted recreation benefits of all the alternatives but the highest levels of primitive and semi-primitive nonmotorized recreation capacity. This inverse relationship is true throughout all the alternative rankings. Although primitive and semi-primitive nonmotorized recreation use has a higher value per RVD than motorized use, it has a lower RVD per acre coefficient. The result is that on a per acre basis, motorized use is more valuable than nonmotorized use.

Table B-74

D. MAJOR TRADEOFFS AMONG ALTERNATIVES

This section summarizes the relationships among the economic values (discussed in detail above) and the differing responses of the alternatives to selected issues, concerns, and opportunities (ICO's). The purpose is to highlight major economic tradeoffs and public issue-response tradeoffs and non-economic trade-offs (or combinations of differences) that can be quantified, through the use of indicators of responsiveness to ICO's, as a means of comparing the alternatives. However, a complete understanding of differences among alternatives requires reading all of this chapter and Chapter IV. The ICO's are discussed in detail in Chapter I and Appendix A.

To provide a partial framework for assessing tradeoffs, the long-term resource demands of the nation, region, and local economic area are briefly summarized. In part two, selected economic values and quantified indicators of responsiveness to major ICO's are tabulated (Table B-75). Finally, differences and similarities among individual alternatives are summarized in terms of major tradeoffs among competing objectives or responses to expressed public issues, management concerns, and resource use and development opportunities.

1. National, Regional, and Local Overview

National (RPA) planning estimates that total national demands will rise for all outputs of the National Forest. At the same time, there is a strong demand to protect and enhance the quality of the environment. Many people view the production of goods and services from the National Forests as competing with protection and enhancement of a quality environment.

Demands and prices for commodity products are generally determined in regional and national markets. The nation benefits most when supplies are provided from the most efficient sources of production

The Mt. Baker-Snoqualmie National Forest is an efficient supplier of timber products. The 1980 RPA program assigned approximately 2.5 percent of the total projected timber outputs for the National Forest System in 1990 to the Mt. Baker-Snoqualmie National Forest. The Forests' share of the projected Regional outputs in 1990 is approximately 6 percent. The Mt. Baker-Snoqualmie produces about 15 percent of the logs consumed in the Puget Sound area; forest industry and other private owners are the major producers of logs consumed in the area. Nearly all (97%) of the logs produced on the Forest are processed in the local economic area (Larsen and others 1983). The resulting products are consumed primarily in the Western U.S. market.

The Forest has extremely low capability to produce economically efficient forage for commercial grazing of domestic livestock.

Demands on the Forest for outdoor recreation uses are more localized than the regional and national demands for timber. Most of the Forest recreation users reside in the major population centers along the Interstate 5 highway corridor.

Recreation use and the demand for recreation of many types is growing, and at a rate faster than the population growth of the Puget Sound area. Total recreation use increased approximately 40 percent on the Forest in the 10 year period from 1975-1984. In a similar time period, the population of the five county area of the Forest increased approximately 20 percent. The fastest

growing segment of the recreation spectrum is wilderness use: + 145 percent, compared to an increase of 65 percent in developed recreation use. Wilderness use represents approximately 4.5 percent of the total recreation use on the Forest for the period 1975 to 1984.

The Mt. Baker-Snoqualmie National Forest is a major supplier of National Forest wilderness in the Pacific Northwest and the nation. The Forest contains 16 percent of the National Forest wilderness in the Pacific Northwest Region and 2.2 percent of the total National Forest wilderness system. Available data collected in the late 1970's and early 1980's indicates that 82-94 percent of wilderness use on the Forest originated from Washington State, and 49-65 percent of the users are from the Puget Sound area. Several of the Forest wildernesses are among the most heavily used in the nation.

Salmon, by a large margin, is the most valuable fish or wildlife species, as measured by the market value of the harvest. An estimated 50 percent of the harvest of naturally produced (as opposed to hatchery produced) salmon for the Puget Sound area are produced from Mt. Baker-Snoqualmie National Forest water systems.

2. Economic Values and Responses to Major ICO's

The main reason that alternatives differ is that each alternative is designed to respond differently to the major issues, concerns, and opportunities (ICO's) identified for this Forest. The following section and Table B-75 summarize many of those differences in response by defining indicators of those responses that can be quantified. In addition, indicators of central concern to the nation as a whole are discussed. Appendix A fully discusses each of the ICO's; also refer to Chapter I. Additional information about the effects and tradeoffs is displayed earlier in this chapter and in Chapter IV. The ICO's and indicators of responsiveness found in Table B-75 include:

- **Development versus Nondevelopment of the Forest Issue:**
  - Existing Roadless Areas Allocated to Nondevelopment
  - Roadless Areas Assigned to a Roaded Management Prescription, But Not Developed in the Next 15 Years

- **Timber Supply Issue:**
  - Timber Harvest Level
  - Long-term Sustained Yield Capacity
  - Lands Suitable for Timber Production
  - Employment: Jobs Supported by the Alternative
  - Payments to Counties

- **Old Growth Ecosystems and Fish/Wildlife/Plant Diversity Issue:**
  - Total Old Growth Remaining, at the end of Decades 1 and 5
  - Old Growth Remaining on Suitable Acres, at the end of Decades 1 and 5
  - Anadromous Fish Production
  - Low-Elevation Old Growth Habitat for Wildlife
  - Suitable Winter Range for Deer and Elk, Decade 1

- **American Indian Religious and Cultural Use Issue:**
  - Percent of Inventoried Use Areas with High or Moderate Protection

- **Recreation Opportunities Issue:**
  - Demand Satisfied for Wilderness, Primitive and Semi-Primitive Nonmotorized Recreation, Decades 1 and 5

Roads Open to Public Use, Passenger Car
Trail Construction, Reconstruction, Decade 1
Lands Managed for High Visual Quality Level, Meeting a Visual Quality Objective of Retention, Partial Retention

- **Wild and Scenic Rivers Issue:**
  Recommended for Designation as Wild and Scenic River

- **Management of Municipal Watersheds Issue:** (see note below)
  Timber Harvest Level (see note below)

- **Effects of Timber Management and Related Activities Issue:**
  Timber Harvest Level (see note below)
  Old Growth Remaining on Suitable Acres, Decades 1 and 5 (see note below)
  Annual Road Construction, Decade 1
  Sediment Produced from All Sources, Annually, Decade 1

- **Adjacent and Intermingled Lands Issue:** (see note below)
  Timber Harvest Level (see note below)

Note: Two issues - Management of Municipal Watersheds and Adjacent and Intermingled Lands - are not listed separately in the table, but their indicators are included in other ICO's. When an indicator is used to measure responsiveness for more than one ICO, the indicator is displayed only once.

In addition, the indicators of national interest include the following; they are listed in the first three columns of Table B-75:

- **National Concerns:**

  Present Net Value
  Net Receipts
  Noncash Benefits

Table B-75
Response, By Alternative, to Major Issues and National Concerns

NC 3/	N/A	N/A	N/A	NA	NA	NA	45.0	(220)	N/A	547	30.1	9.5

1/ Roadless Areas refer to the 402,930 acres of remaining RARE II parcels

2/ This is an approximate figure. Alternative A is unique because an unspecified amount of development is permitted in the Upper Forest Resource Zone. See description of Management Area 1E.

3/ The TM Plans upon which Alternative NC is based were developed in 1963; they are not integrated resource plans, and consequently did not address all resource uses and outputs. Missing data in this table (NA) cannot be reasonably estimated, since the TM plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect standards in the NFMA regulations, or are otherwise inappropriate.

Table B-75
Response, By Alternative, to Major Issues and National Concerns

	Old Growth Ecosystems and Fish, Wildlife, & Plant Diversity Issue					American Indian Religious & Cultural Use Issue

7/ From all sources, including timber harvest, new road construction, old roads, and background (which includes sediment from previously disturbed ground and natural sedimentation).

3. Economic Benefit and Issue Response Tradeoffs Among Alternatives

The alternatives were designed to respond to specific major issues, or a combination of issues. In responding to one set of issues, some potential benefits or responses to other issues may be limited or "traded off". This section discusses the incremental changes in indicators of response of the alternatives as economic efficiency (PNV) declines. This is only one systematic way of examining tradeoffs. It should be noted that there are tradeoffs among indicators of response to the issues as well as with economic benefits.

The alternatives are discussed in order of highest PNV to lowest. Following the discussion of the changes in each alternative from the one with the next highest PNV, is a display that shows which indicators increase in value and which decrease, and the magnitude of the change. These indicators of response *are also displayed in Table B-75.*

Alternative B

The goal of this alternative is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation as specified in the 1980 RPA Program. With this goal, this alternative results in the highest PNV of all alternatives: $2343.2 million. Net receipts of $5.3 MM in the first decade increase to $24.8 MM by the fifth decade, reflecting the increase in ASQ between the first and fifth decade.

Noncash benefits (primarily dispersed recreation) of $61.0 MM in the first decade increase to $86.8 MM in the fifth decade, as more roaded recreation is valued as a result of increasing demand.

As a result of the emphasis of this alternative, a timber sale program quantity (TSPQ) of 29.8 MMCF is provided on a suitable land base of 380,000 acres. The long-term sustained yield capacity (LTSYC) is approximately 33.4 MMCF. An average of 16 miles of road construction annually is required in the first decade to support the timber harvest level. This high harvest level results in one of the three highest levels of jobs, income, and payments to counties of all the alternatives.

Of the 447,000 acres inventoried for American Indian Religious and Cultural Use, 43% are afforded a high level of protection (no timber harvest or road construction) and 7% are afforded a moderate level of protection (no timber harvest or road construction, but increased probability of human contact). The acres afforded high protection change very little among alternatives; there is more change between alternatives in percent of acres afforded moderate protection.

This alternative would satisfy 76% of the primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation demand anticipated in the first decade and 34% of anticipated demand in the fifth decade, based on currently defined standards for capacity. This decline over time is a result of increasing demand and slower increases in supply, as more of the currently undeveloped areas become developed. There is little change among the alternatives in the Forests ability to meet this demand, due to low per acre yield of this type of recreation. This indicator is not further discussed in the other alternatives.

Alternative B has 287,000 acres assigned to a management prescription that meets the Visual Quality Objectives (VQO) of retention; another 285,000 acres will meet partial retention VQO. The amount of acres managed to meet retention is in the lower part of the range of all alternatives reflecting less emphasis on managing the scenic foreground along travelways. However, the amount of land managed for partial retention is in the higher part of the range for all alternatives reflecting a recognition of the need to maintain a relatively high level of scenic quality forest-wide.

Effective acres of wildlife habitat for mature and old growth management indicator species are reduced by 82,000 acres, or 26% during the first five decades. A total of 225,000 acres of inventoried big game winter range is managed to provide an optimal mix of thermal and forage habitat.

Total old growth remaining at the end of Decade 5 is 513,000 acres, a reduction of approximately 20% over the five decades. This reflects the relatively high level of harvest in this alternative.

Alternative B has a high level of investment in anadromous fish habitat improvements (MA 13C); 8,874 M pounds of fish will be produced.

Alternative I

The PNV for Alternative I is $2342.9 or $0.3 MM lower than PNV for Alternative B. Annual net receipts in Decade 1 are $0.5 MM higher than those in Alternative B, primarily because of the higher timber outputs. Net receipts in Decade 5 are $0.8 MM higher than those of Alternative B, again because of the higher timber outputs.

Alternative I has 6,000 acres more land suitable for timber production than Alternative B, primarily attributable to the emphasis of the alternative on those resources with an established price in the market place. The higher number of suitable acres result in a Decade 1 TSPQ that is 0.3 MMCF above that of Alternative B; LTSYC is 0.8 MMCF higher.

The slightly higher timber harvest levels in Decade 1 in Alternative I also requires a small increase (over Alternative B) in road construction of 1 mile annually. This alternative provides essentially the same levels of jobs, income, and payments to counties.

The acres of American Indian Religious and Cultural Use afforded high levels of protection remain the same in Alternative I while those acres afforded a medium level of protection decrease by 5%. This change reflects an increased probability of human contact as a result of the additional access provided in Alternative I.

Alternative I would satisfy 18% more of the first decade demand for primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation and 11% more of the fifth year demand than Alternative B. This reflects a higher emphasis on dispersed recreation than in Alternative B

Alternative I has 79,000 fewer acres than Alternative B that will meet a VQO of retention, but 26,000 acres more that meet a VQO of partial retention. The shift in VQO is due to the slight increased in acres suitable for timber production.

Alternative I has about the same amount of roadless areas remaining in a roadless condition as Alternative B.

Since there is less emphasis on management of deer and elk habitat in Alternative I, old growth available for indicator species in the fifth decade is 3,000 acres more than in Alternative B; however, there are 28,000 fewer acres managed for big game winter range.

Alternative I has essentially the same amount of old growth included in the land base suitable for timber harvest. The rate of old growth harvest is approximately the same so that at the end of the fifth decade, about the same amount of old growth suitable for timber production will be left in both alternatives.

Alternative I has the same level of investment in anadromous fish habitat improvements and therefore provides the same level of fish production as Alternative B.

Summary of Alternative I

Indicators That Increase From Alternative B

- Decade 1 annual net receipts, +$0.5 MM
- Decade 5 annual net receipts, +$0.8 MM
- Decade 1 annual noncash benefits, +$0.3 MM
- Decade 1 annual TSPQ, +0.3 MMCF
- LTSYC, +0.8 MMCF
- Lands suitable for timber production, +6,000 acres
- Decade 1 annual road construction, +1 miles
- Acres meeting VQO of partial retention, +26,000
- Acres of Old Growth for indicator species in Decade 5, +3,000

Indicators That Decrease From Alternative J (Preferred)

- PNV, -$0.3 MM
- Decade 5 annual noncash benefits, -$1.3 MM
- Acres meeting a VQO of retention, -79,000
- Acres managed for deer/elk winter range, -28,000

Alternative A (No Action)

The PNV for Alternative A is $2283.5 or $59.4 MM lower than PNV for Alternative B. Although Alternative A has a high level of timber outputs, timber harvest prescriptions were selected on the basis of their volume contribution, rather than their contribution to PNV. The high cost of these prescriptions offsets the high timber output contribution to PNV. Annual net receipts in Decade 1 are $0.7 MM higher than those in Alternative I, primarily because of the higher timber outputs. Net receipts in Decade 5 are $4 MM higher than those of Alternative I, again because of the higher timber outputs.

Alternative A has 26,000 acres more land suitable for timber production than Alternative I, primarily attributable to the maximize timber objective function used in the formulation of this alternative. The higher number of suitable acres plus the higher timber production prescriptions result in a Decade 1 TSPQ that is 4.9 MMCF above that of Alternative I; LTSYC is 4.6 MMCF higher.

The higher timber harvest levels in Decade 1 in Alternative A also require an increase (over Alternative I) in road construction of 2 miles annually.

Compared to Alternative I, Decade 1 jobs are 200 higher, income is $5 MM higher, and payments to counties are $0.5 MM higher in Alternative A, also a result of the higher timber harvest levels.

Alternative A has 88,000 fewer acres than Alternative B that will meet a VQO of retention, but 31,000 acres more that meet a VQO of partial retention. The shift in VQO - from retention to partial retention - is due to the emphasis on visuals in the upper resource management zone of the current multiple use plans, along with the protection of all rivers included in the National Rivers inventory, both of which have a VQO of partial retention.

Alternative A has 7% more roadless areas allocated to nondevelopment than Alternative I.

Since there is little emphasis on management of wildlife habitat in Alternative A, old growth available for indicator species in the fifth decade is 22,000 acres less than in Alternative I. There are 112,000 fewer acres managed for big game winter range.

Alternative A has 3,000 acres more old growth remaining in the suitable land base after the first decade. Old growth is harvested at a faster rate than in Alternative I, resulting in Alternative A having 19,000 fewer acres of total old growth in the fifth decade.

Alternative A maintains the current level of investments in anadromous fish habitat improvements (MA 13A), resulting in a production of 1,065 M fewer pounds than Alternative I.

Summary of Alternative A (No Action)

Indicators That Increase From Alternative I

- Decade 1 annual net receipts, +$0.7 MM
- Decade 5 annual net receipts, +$4.0 MM
- Decade 1 annual TSPQ, +4.9 MMCF
- LTSYC, +4.6 MMCF
- Lands suitable for timber production, +26,000 acres
- Decade 1 annual road construction, +2 miles
- Decade 1 annual jobs, +200
- Decade 1 annual income, +5 MM
- Decade 1 annual payments to counties, $0.5 MM
- Acres meeting VQO of partial retention, +31,000
- Acres of old growth in suitable lands end of Decade 1, +3,000

Indicators That Decrease From Alternative I

- PNV, -$59.4 MM
- Decade 1 annual noncash benefits, -$0.4 MM
- Decade 5 annual noncash benefits, -$0.3 MM
- Acres meeting a VQO of retention, -88,000
- Acres of old growth in suitable lands in decade 5, -14,000
- Total acres of old growth in decade 5, -19,000
- Annual anadromous fish production, -1,727 M pounds
- Acres of old growth for indicator species in Decade 5, -22,000

- Acres managed for deer/elk winter range, -112,000

Alternative H

The PNV of Alternative H is $23.5 MM less than Alternative A. While the TSPQ is 7.7 MMCF lower than Alternative A, the timber prescriptions were selected on the basis of their contribution to PNV rather than to volume (as in Alternative A), so the decrease in PNV is not large. In addition fewer miles of road construction in H compared to A result in cost savings that mostly offset the benefits foregone from the reduced timber harvest.

First decade net receipts are $2.3 MM less and fifth decade net receipts are $5.5 MM less than Alternative A primarily as a result of reduced timber sale harvest levels.

Alternative H has 53,000 acres less land suitable for timber production than ALternative A. This reduction in suitable land is the result of increased emphasis on dispersed recreation, Wild and Scenic River recommendations, and more more emphasis on scenery and diversity. The TSPQ in the first decade is 7.7 MMCF lower than Alternative A and the LTSYC is 6.8 MMCF lower. The reduced timber harvest and the emphasis on dispersed recreation results in 5 miles less road construction per year in decade one compared to Alternative A.

Compared to Alternative A, there are 400 fewer jobs, $11 MM less income, and $1 MM less in payments to the counties in this alternative.

Alternative H has 287,000 more acres that will be managed to meet the VQO of retention and 161,000 less acres managed to meet the VQO of partial retention. This shift from partial retention and addition of retention reflect the increased concern of Alternative H for scenic values.

Alternative H has 3,000 more acres of old growth remaining after the first decade, and the total old growth remaining on all lands at the end of the fifth decade is 29,000 acres more than in ALternative A.

Anadromous fish habitat improvement investments are increased with a resultant increase in production of 1,065 thousand pounds per year more than Alternative A.

Summary of Alternative H

Indicators That Increase From Alternative A

- Acres meeting VQO of retention, +287,000
- Total acres of old growth at the end of Decade 1 and 5, +3,000/29,000
- Annual anadromous fish production, +1,065 M Lbs.

Indicators That Decrease From Alternative A

- PNV, -$23.5 MM
- Decade 1 annual net receipts, -$2.3 MM
- Decade 5 annual net receipts, -$5.5 MM
- Decade 1 annual noncash benefits, -$0.4 MM
- Decade 5 annual noncash benefits, -$1.4 MM
- Lands suitable for timber production, -53,000 acres
- Decade 1 TSPQ, -7.7 MMCF

- Decade 1 annual road construction, -5 miles
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$11 MM
- Decade 1 payments to counties, -$1.0 MM

Alternative J (Preferred)

The PNV for Alternative J (Preferred) is $1.2 MM lower than Alternative H. Annual net receipts are $1.4 MM less in the first decade and $1.0 MM less in the second decade. These reductions are all a result of the reduced timber harvest levels of Alternative J (Preferred) compared with Alternative H. The reduced levels of timber harvest also results in a reduction of road construction of 1 mile per year.

Noncash benefits increase in the first decade by $0.7 MM and in the fifth decade by $1.7 MM. These increases reflect the increased emphasis on non market resources from Alternative H.

Alternative J (Preferred) has 13,000 acres less land suitable for timber production than Alternative H. This reduction is primarily the result in increased emphasis on dispersed recreation, Wild and Scenic Rivers, and scenic values.

Compared to Alternative A, there are 400 fewer jobs, $11 MM less income, and $1 MM less in payments to the counties in this alternative.

Alternative J (Preferred) would satisfy 12% more of the first decade demand for primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation and 7% more of the fifth year demand than Alternative H. This reflects a higher emphasis on dispersed recreation than in Alternative H

Alternative J (Preferred) has 10% more roadless areas remaining in a roadless condition than Alternative H. Again this reflect a higher emphasis on dispersed recreation.

Alternative J (Preferred) has 3,000 less acres of old growth included in the suitable land base for timber production and the total old growth remaining on all lands at the end of the fifth decade is 10,000 acres more than in Alternative H.

Summary of Alternative J (Preferred)

Indicators That Increase From Alternative H

- Decade 1 annual noncash benefits, +$0.7 MM
- Decade 5 annual noncash benefits, +$1.7 MM
- Total acres of old growth at the end of Decade 5, +9,000

Indicators That Decrease From Alternative H

- PNV, -$1.2 MM
- Decade 1 annual net receipts, -$1.4 MM
- Decade 5 annual net receipts, -$1.0 MM
- Lands suitable for timber production, -13,000 acres
- Decade 1 TSPQ, -1.8 MMCF
- Decade 1 annual road construction, -1 miles

- Decade 1 annual jobs, -100
- Decade 1 annual income, -$4 MM
- Decade 1 payments to counties, -$0.3 MM
- Acres of old growth on suitable lands, Decade 1, -3,000 acres
- Acres of old growth for indicator species in Decade 5, -0,000 acres

Alternative G-Modified

Alternative G-Modified has a strong emphasis on the maintenance of natural ecosystems and diversity of native flora and fauna. The retention of existing ecosystems reduces the acres suitable for timber production and the TSPQ. Although less road construction is required than in Alternative J (Preferred), PNV is reduced by $261.8 MM.

The reduction in TSPQ of 5.1 MMCF from Alternative J (Preferred) results in net receipts declining by $1.0 MM in the first decade. Fifth decade net receipts decrease by $12.1 MM over Alternative J (Preferred).

Noncash benefits decline by $0.6 MM in the first decade and by $5.3 MM in the fifth decades.

Lands suitable for timber production decline by 99,000 acres from Alternative J (Preferred). Alternative G-Modified has 21% more roadless areas remaining in a roadless condition than Alternative J (Preferred). This reflects the objectives of maintaining natural ecosystems and diversity.

The reduced timber harvest in the first decade of Alternative G-Modified results in 400 fewer jobs than in Alternative J (Preferred), $10 MM less income, and $0.8 MM lower payments to the counties than in Alternative J.

Due to the emphasis on retention of natural ecosystems and the management of larger acres of currently developed lands in an undeveloped condition, the acres meeting a VQO of retention will increase by 178,000 over those in Alternative J (Preferred). Acres meeting a VQO of partial retention will be 148,000 less than in Alternative J (Preferred).

The emphasis on maintaining the natural diversity on the Forest will result in an increase of 25,000 acres of old growth for management indicator species in Decade 5; 167,000 fewer acres would be managed for big game winter range compared to Alternative J (Preferred).

Alternative G-Modified would have 56,000 acres less old growth in the suitable timber land base and 36,000 acres more total old growth by Decade 5 than would Alternative J (Preferred).

Summary of Alternative G-Modified

Indicators That Increase From Alternative J (Preferred)

- Acres meeting a VQO of retention, +178,000
- Acres of old growth for indicator species, +25,000
- Total acres of old growth at the end of Decade 5, +35,000

Indicators That Decrease From Alternative J (Preferred)

- PNV, -$261.8 MM
- Decade 1 annual net receipts, -$1.0 MM
- Decade 5 annual net receipts, -$12.1 MM
- Decade 1 annual noncash benefits, -$0.6 MM
- Decade 5 annual noncash benefits, -$5.3 MM
- Decade 1 annual TSPQ, -5.1 MMCF
- LTSYC, -6.8 MMCF
- Lands suitable for timber production, -99,000
- Decade 1 annual road construction, -5 miles
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$10 MM
- Decade 1 annual payments to counties, -$0.8 MM
- Acres meeting a VQO of partial retention, -148,000
- Acres of old growth in suitable lands in Decades 1/5, -56,000/-24,000
- Acres managed for deer/elk winter range, -167,000

Alternative C

The emphasis of Alternative C includes the non-market outputs of undeveloped dispersed recreation, visual quality, and fish and wildlife habitat. As a result, it has the lowest PNV of all the alternatives: $26.1 MM below that of Alternative G-Modified.

Alternative C has 9,000 more acres of land suitable for timber production than Alternative G-Modified. However, 62% of the total suitable acres produce timber at less-than-full yield to provide for visual quality and wildlife habitat. In combination, these result in a first decade TSPQ that is 4.6 MMCF lower than Alternative G-Modified.

The low level of timber outputs and the constraints on the rate of harvest of the available old growth result in first decade net receipts that are $0.3 MM less than Alternative G-Modified. A 15% increase in the TSPQ by the fifth decade, along with a higher percentage of the harvest coming from old growth stands results in an increase in net receipts of $4.1 MM over that of Alternative G-Modified.

The reduced timber harvest level in the first decade results in 400 fewer jobs, $11 MM less income, and $1.2 MM lower payments to the county than Alternative G-Modified.

The strong emphasis on visuals in Alternative C results in 46,000 more acres meeting a VQO of retention and 88,000 more acres meeting a VQO of partial retention than in Alternative G-Modified.

Habitat available for old growth management indicator species is the same in Alternative C as in Alternative G-Modified. There are 168,000 more acres of deer and elk winter range managed in Alternative C.

Alternative C has 25,000 acres more old growth in the suitable land base than Alternative G-Modified. Alternative C will have 2,000 acres more total old growth in Decade 5 than Alternative G-Modified.

Summary of Alternative C

Indicators That Increase From Alternative G-Modified

- Decade 5 annual net receipts, +$4.1 MM
- Decade 1 annual noncash benefits, +$0.1 MM
- Lands suitable for timber production, +9,000 acres
- Decade 1 annual road construction, +2 mile
- Acres meeting a VQO of retention, +46,000
- Acres meeting a VQO of partial retention, +88,000
- Acres of old growth in suitable lands Decade 1 and 5, +25,000 and +25,000
- Total acres of old growth in Decade 5, +2,000
- Acres managed for deer/elk winter range, +168,000

Indicators That Decrease From Alternative G-Modified

- PNV, -$26.1 MM
- Decade 1 annual net receipts, -$0.3 MM
- Decade 5 annual noncash benefits, -$1.4 MM
- Decade 1 annual TSPQ, -4.6 MMCF
- LTSYC, -3.7 MMCF
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$11 MM
- Decade 1 annual payment to counties, -$1.2 MM

Alternative NC (No Change)

Alternative NC is based on the Timber Management Plans developed in 1963. The Plans are not integrated resource plans and consequently do not address all resource uses and outputs. The data applicable to this alternative was not incorporated into a FORPLAN model; therefore, PNV was not calculated.

The No Change Alternative emphasizes the timber resource. As a result, the acres of land suitable for timber harvest and first decade TSPQ are the highest among the alternatives: an increase of 291,000 acres and 29.2 MMCF per year over that of Alternative C.

The harvest level involves more road construction, increases employment and income, and generates more payments to counties in Decade 1.

Recreation demand satisfied decreases. In addition, the total acres of old growth remaining in Decade 5 decrease from 573,000 in Alternative C, to 432,000 acres in Alternative NC.

Alternative NC continues the current level of investments in anadromous fish habitat capability; production is similar to Alternative A, which is 7,809 M pounds of fish per year, a decrease of 12% from Alternative C.

Summary of Alternative NC

Indicators That Increase From Alternative C

- Decade 1 annual TSPQ, +29.2 MMCF
- Lands suitable for timber production, +290,000 acres
- Decade 1 annual road construction which is +19 miles over Alternative C.
- Acres of old growth in suitable lands in Decade 1, +129,000 acres

Indicators That Decrease From Alternative C

- Total acres of old growth remaining in Decade 5, -141,000
- Annual anadromous fish production, similar to Alt. A, -1,065 pounds

INTRODUCTION

Appendix C includes a site-specific analysis of roadless areas on the Mt. Baker-Snoqualmie National Forest. Changes and modifications made since the release of the DEIS include:

- o adjusted acres, text for new wildlife MR's;
- o updated acres to reflect any timber harvest activities;
- o for clarity, dropped the second map for each parcel and included the information in a table;
- o for each parcel, added a table displaying the acres allocated to each management area prescription, by alternative;

Background

During the second Roadless Area Review and Evaluation (RARE II), about 786,339 acres of roadless, undeveloped land on the MBS were evaluated. In 1984, the Washington State Wilderness Act designated 341,000 acres of these roadless areas as additions to the National Wilderness Preservation System. Appendix C describes the remaining roadless area, which total about 402,930 acres.

The 1984 Act found that these remaining acres "... do not possess outstanding wilderness attributes or which possess outstanding energy, mineral, timber, grazing, dispersed recreation, and other values and which should not now be designated as components of the National Wilderness Preservation System but should be available for nonwilderness multiple uses under the land management planning process..."

The 1984 Act further stated: "...the Department of Agriculture shall not be required to review the wilderness option prior to revisions of these [Forest] plans, but shall review the wilderness option when the plans are revised..."; "... such areas need not be managed for the purpose of protecting their suitability for wilderness designation prior to or during revision of the initial land management plans."

The roadless areas on the MBS are not considered for wilderness designation in this round of forest planning. Prior to any ground-disturbing activity in any roadless area parcel, a site-specific, project-level environmental analysis (with NEPA documentation) will be completed.

Portions of all the original roadless areas remain. Some are large, contiguous areas but many are small parcels, a result of the 1984 wilderness designations. There are 101 separate parcels (compared to the original 25 roadless areas), ranging in size from 21 to 50,400 acres. The original RARE II name and number is used to identify each parcel. For ease of analysis, the Mt. Baker roadless parcels are grouped into five geographic blocks.

Appendix C Organization

Appendix C is divided into two sections. The first section (pages C-1 through C-15) summarizes the individual roadless area facts and figures. One map (page C-3) and five tables provide for rapid review of the individual roadless parcel narratives. Table C-1 displays, by alternative, roadless area acres remaining

unroaded by the end of decades 1, 2, and 5. Table C-2 provides a summary of resource information for the roadless areas as a whole. Table C-3 shows all of the roadless areas, parcel identifier, acres, and the pages where they are described in detail. Table C-4 lists each area's acreage and denotes changes, if any, from the inventoried (RARE II) roadless area boundary. Table C-5 summarizes each area's attributes.

In the second section, each roadless area parcel is described in detail. Maps of each area are found in this section. Each roadless area description will include the following information; details for each varies depending on size of area, resource complexities, and concerns expressed through public involvement.

- General description and overview
- Wilderness capability
- Availability for wilderness
- Wilderness evaluation
- *Environmental consequences*

Table C-1
Acres of Roadless Areas Remaining at End of Decades 1, 2, and 5, by Alternative 1/

Alternative	Acres Remaining End of Decade 1	2	5	Percent Remaining
A (No Act)	361,665	329,773	293,305	73%
B (RPA)	371,619	347,041	317,728	79%
C	397,854	393,564	387,257	96%
G-Mod.	392,421	383,715	375,470	93%
H	377,058	354,602	328,498	82%
I	370,878	344,998	313,914	78%
J (Pref)	382,587	365,565	344,730	86%

1/ No Management Areas are assigned in Alternative NC (No Change). Indirect comparisons between Alternative NC and the other alternatives can be made. This must be done understanding that the 1963 Timber Management Plans, as amended, stratified lands by their availability and suitability for timber harvest, while land in the other alternatives is stratified by its suitability for timber harvest and management strategies, which when combined equate to Management Areas.

Table C-2
Summary of Roadless Area Resource Information

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	402,930

Table C-4
Summary of Roadless Area Acreage and Change from Inventoried Roadless Area

RARE II Name	RARE II Number	RARE II Net Acres	Net Acres Revised	Reason for Change
Mt. Baker (Total Area)	6041	271,900	149,224	Area reduced 122,676 acres due to wilderness designation (Mt. Baker Wilderness, Washington Wilderness Legislation, 1984)
[Mt. Baker (Canyon Creek)]	6041	25,046	25,046	No change.
[Mt. Baker (North)]	6041	16,636	16,425	Area reduced 207 acres Nanny Goat TS (1985); 4 acres mapping discrepancy.
[Mt. Baker (West)]	6041	26,820	26,818	Two acre reduction due to mapping discrepancy.
[Mt. Baker (South)]	6041	6,690	6,375	Area reduced 188 acres by harvest activity from the Hi Boy Timber Sale (1984). Area reduced 139 acres by harvest activity from the Tip Top Timber Sale (1985). Area increased 12 acres due to mapping discrepancy.
[Mt. Baker (Noisy Diobsud)]	6041	54,654	50,367	Area reduced by 3252 acres by harvest from three timber sales since 1982 (Scarface, Shan, and 3-Mile). Area reduced by 1,035 acres due to harvest activity from the Bacon Rind Timber Sale (1988) and the Silvertone-Welker Timber Sale (1987).
Oakes Peak	6043	1,200	1,604	Area increased by 404 acre mapping discrepancy.
Alma Copper	6044	8,300	8,193	Area reduced by 107 acre mapping discrepancy.
Hidden Lake	6045	7,000	6,652	Area reduced 73 acres due to harvest activity from the Kincade Timber Sale (1983). Area reduced by 275 acres mapping discrepancy.
Glacier Peak H	H6031	12,483	7,939	Area reduced 3109 acres due to wilderness designation (Glacier Peak Wilderness, Washington Wilderness Legislation, 1984). Area reduced 1286 acres due to harvest activity from the LaRush Timber Sale (1984). Area reduced 149 acres due to mapping discrepancy.

Table C-4
Summary of Roadless Area Acreage and Change from Inventoried Roadless Area
(continued)

Glacier Peak I	I6031	18,397	12,755	Area reduced 1208 acres due to wilderness designation (Glacier Peak Wilderness, Washington Wilderness Legislation, 1984). Area reduced 1625 acres due to harvest activities from the Yellow Timber Sale and White Creek Skyline Timber Sale (1984). Area reduced by 2,387 acres due to harvest activity from the Upper Slope Timber Sale (1987) and the Indian Point Timber Sale (1987). Area reduced by 422 acres due to mapping discrepancy.
Glacier Peak G	G6031	59,755	8,737	Area reduced by 51,018 acres due to wilderness designation (Glacier Peak Wilderness, Washington Wilderness Legislation, 1984).
Glacier Peak J	J6031	31,604	25,971	Area reduced by 1,498 acres due to wilderness designation (Glacier Peak Wilderness, Washington Wilderness Legislation, 1984). Area reduced by 2,065 acres due to harvest activity from the Circle Creek, Pugh Blend, Sloan Creek, and Bowser Timber Sales. Area reduced by 1,158 acres in mapping discrepancy. Area reduced by 912 acres due to harvest activity from the Harriet Creek (1988), Box Mountain II (1986), and Big Creek (1987) Timber Sales.
Glacier Peak M	M6031	1,539	1,055	Area reduced by 483 acred due to wilderness designation (Glacier Peak Wilderness, Washington Wilderness Legislation, 1984). Area reduced by one acre mapping discrepancy.
Glacier Peak A	A6031	11,110	443	Area reduced 10,667 acres due to wilderness designation (Henry M. Jackson Wilderness, Washington Wilderness Legislation, 1984).
Glacier Peak L	L6031	55,220	14,227	Area reduced by 40,993 acres due to wilderness designation (Henry M. Jackson Wilderness, Washington Wilderness Legislation, 1984).
Glacier Peak B	B6031	43,186	18,646	Area reduced by 24,540 acres due to wilderness designation (Henry M. Jackson Wilderness, Washington Wilderness Legislation, 1984).

Table C-4

Glacier Peak K	K6031	45,745	45,509	Area reduced by 64 acres due to timber harvest activity from the Timbuktu Timber Sale. Area reduced by 172 acres due to mapping discrepancy.
Pressentin	6048	16,000	15,057	Area reduced by 802 acres due to timber harvest activity from the O'Toole Timber Sale (1986). Area reduced by 141 acres due to mapping discrepancy.
Higgins Mountain	6049	12,800	13,177	Area increased by 377 acres due to mapping discrepancy.
Prairie Mountain	6060	5,500	3,822	Area reduced by 1,668 acres due to harvest activity from the Black Diamond Timber Sale. Area reduced by 10 acres mapping discrepancy.
White Chuck Mountain		6051	6,000	5,723 Area reduced by 211 acres due to harvest activity from the Black Diamond Timber Sale. Area reduced by 66 acres due to mapping discrepancy.
Boulder River	6050	83,700	32,307	Area reduced by 50,274 acres due to wilderness designation (Boulder River Wilderness, Washington Wilderness Legislation, 1984). Area reduced by 1,119 acres due to harvest activity from the Goodbye (1986), Iron Mountain and Goodman Ridge (1988) Timber Sales.
Eagle Rock	6054	33,100	33,176	Area increased by 76 acres due to mapping discrepancy.
Tolmie Creek	6056	650	274	Area reduced by 274 acres due to harvest activity from the Poch Peak West Timber Sale (1982). Area reduced by 102 acres due to mapping discrepancy.
Clearwater	6055	24,900	8,803	Area reduced by 15,951 acres due to wilderness designation (Clearater Wilderness, Washington Wilderness Legislation, 1984). Area reduced by 123 acres due to harvest activity from the McGilvary Salvage Timber Sale and the West Line Salvage Timber Sale (1982). Area reduced by 23 acres due to mappind discrepancy.
Lonesome Lake	6057	1,850	295	Area reduced by 1,440 acres due to harvest activity from the High Mule, Liver Camp, High Mule Resale (1986), and Lower Mule (1988) Timber Sales. Area reduced by 115 acres due to mapping discrepancy.

Table C-4
Summary of Roadless Area Acreage and Change from Inventoried Roadless Area
(continued)

Sun Top	6058	5,200	2,386	Area reduced by 2,850 acres due to harvest activity from the Skookum Doe Timber Sale. Area increased by 36 acres due to mapping discrepancy.
Silver Creek	6059	1,000	1,055	Area increased by 55 acres due to mapping discrepancy.
Norse Peak	6034	28,200	10,093	Area reduced by 15,713 acres due to wilderness designation (Norse Peak Wilderness, Washington Wilderness Legislation, 1984). Area reduced by 2,639 acres due to harvest activity from the One Mile Salvage, High Minnie, Dry Ranger, Snoquera (1986), and Snoquera #2 (1988) Timber Sales. Area increased by 245 acres due to mapping discrepancy.

TOTAL: 402,930 acres

Key to Attributes Ratings used in Table C-5.

Manageability and Boundaries - Ability to manage and protect the area's natural character considering such factors as size, shape, and position (including boundary location) relative to external influences.

High - Inherently protected through excellent topographic positioning, favorable external influence (i.e. land allocation, physical conditions), or very limited hazards/risks to natural character.

Mod - Part of area subject to external influences, or overall positioning and physical conditions are at some risk.

Low - Considerable portions at risk or subject to external influences; manageability highly dependent on degree of protection provided in areas outside unroaded part.

0 - Protection largely unattainable due to present activities and conditions that are not inherently mitigated. Risks to natural character and processes high.

Natural Integrity - Extent to which long-term ecological processes are intact and operating, or are free of disturbances; consideration of extent to which human influences have altered natural conditions and are apparent to user.

High - Extremely limited, or not apparent.

Mod - Small portions of area affected by human activity, or recovery of past impacts approaching natural state and not perceived by user.

Low - Considerable area impacted, or perceived recovery of past change incomplete or apparent to user.

0 - Much of present ecosystem is primarily a result of recent or past activity by man; or major portion is directly or indirectly (from periphery) influenced by human activity; readily noticed by user.

Opportunities for Solitude - Area's feeling of solitude (how it provides for remote and backcountry setting).

High - Most of area free of external influence and provides a strong feeling of remoteness and solitude.

Mod - Fringes influenced by sight and/or sound of human activity; solitude aided by vegetative or topographic conditions.

Low - External influences persist over much of area; vegetation and topography generally only aid to providing solitude.

0 - Most of area within sight or sound of human activity; topography and vegetation provides only limited relief.

Opportunities for Primitive Recreation - Opportunities for primitive and unconfined types of recreation activities; how well the area provides outstanding opportunities for unusual adventures or excitement.

High - Varied type (more than those associated with foot travel only); unique experience, or experience of adventure/excitement.

Mod - Varied type (good mix of foot travel associated activity); potential for adventure exists.

Low - Limited type; adventure or challenge related to topographic difficulty and distance from nearest roaded access.

0 - Type and adventure not different than much of adjacent lands.

Special Features - Unique, abundant, or varied flora, fauna, historic, scientific, and physiographic features; where protection from nonconforming activities would enhance management of unusual or sensitive species or features.

High - Existence over much of area or very unique.

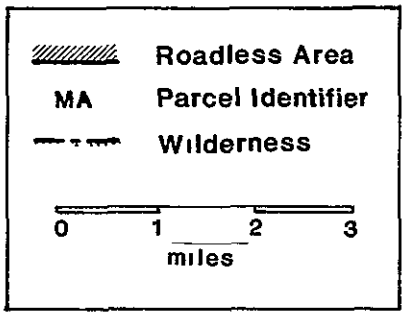
Mod - Existence of species or features over much of area that would be enhanced; limited extent of unique or sensitive elements.

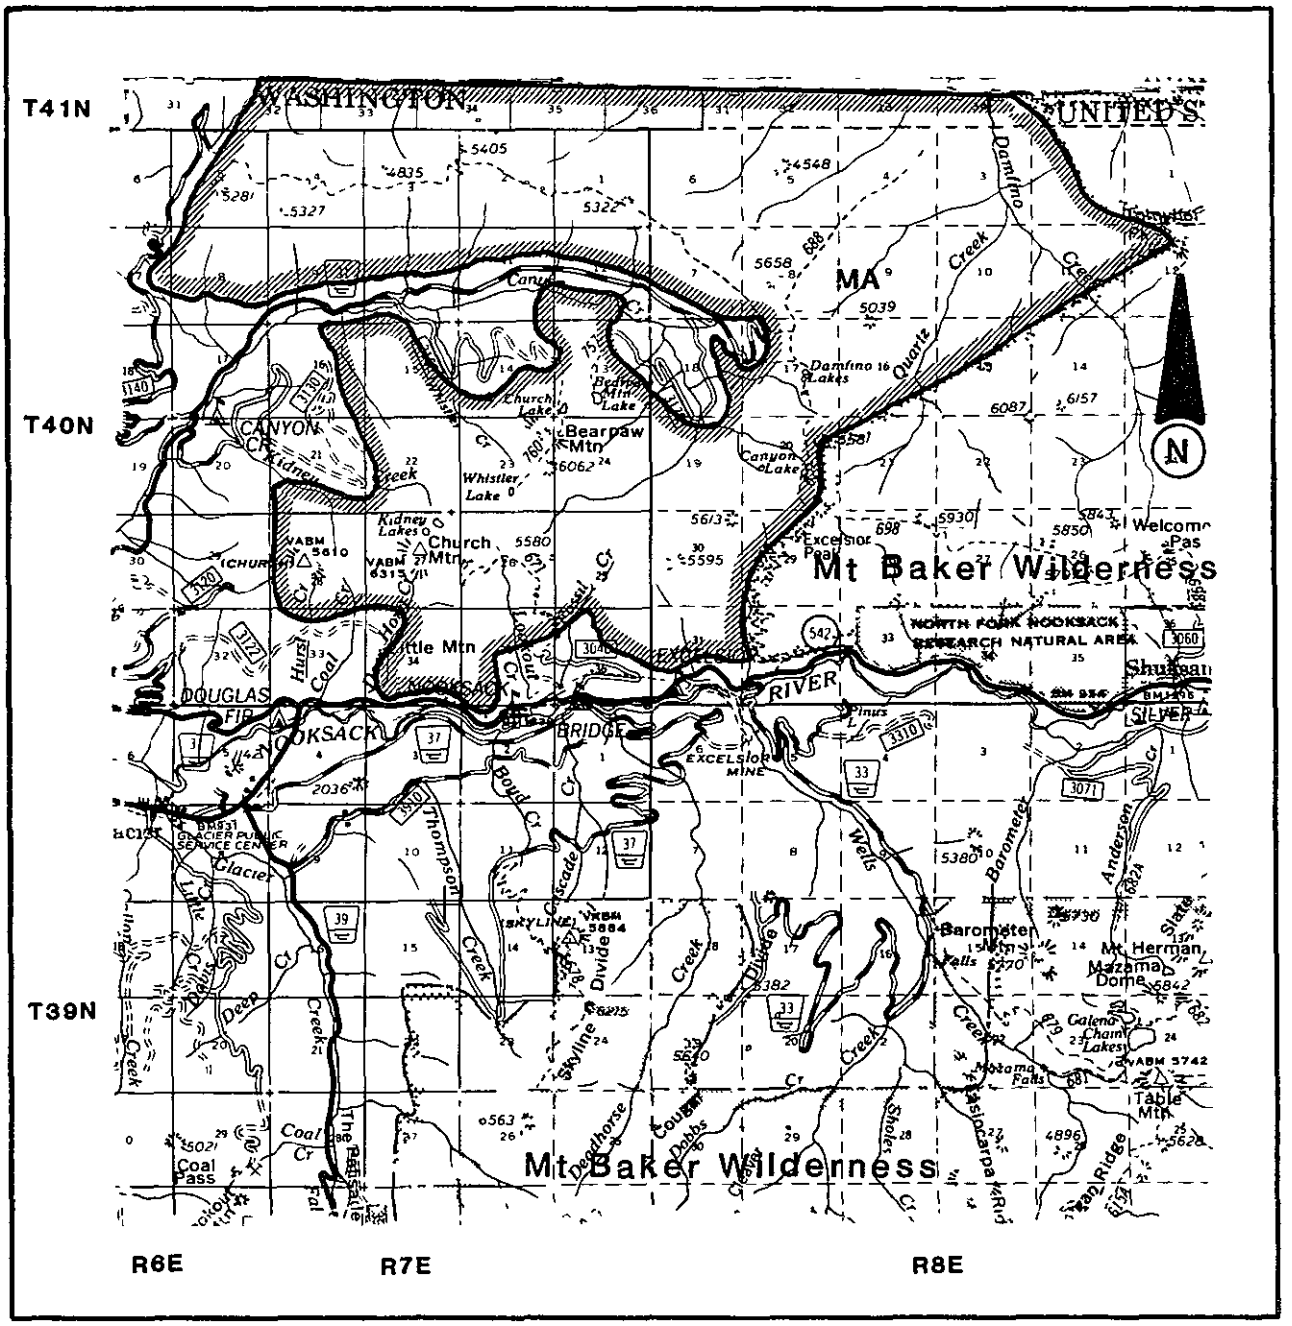
Low - Limited enhancement opportunity; unique or sensitive elements limited to very small areas, or other allocations, standards or guidelines afford adequate protection.

0 - Species and features not different than surrounding areas.

Mt. Baker (Canyon Creek Block)

Roadless Area 6041





Mt. Baker (CANYON CREEK BLOCK) **Roadless Area 6041 (MA)**

The original Mt. Baker RARE II Roadless area contained 271,900 acres. The 1984 Wilderness Act established the Mt. Baker Wilderness (117,528 acres) and the Noisy Diobsud Wilderness (14,133 acres); the remaining parcels of Mt. Baker Roadless Area total 126,201 acres. As mentioned above, for the Appendix C evaluation, the parcels have been grouped into five blocks.

The first block to be discussed - Canyon Creek - consists of one parcel totaling 25,046 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II final EIS assigned Area 6041 to nonwilderness uses. The following shows the disposition of acres within the Canyon Creek Block roadless area:

Canyon Creek	Net Acres
1984 RARE II	25,046
updated 1988	25,046
Change	0

OVERVIEW

Canyon Creek Block is located north of the Mt. Baker Highway, west of Mt. Baker Wilderness. The Canadian border forms the northern boundary of the area. Canyon Creek drains south into the North Fork Nooksack; Quartz and Damfino Creeks drain north into Canada. As shown on the map (opposite page), Canyon Creek may be accessed by road from the south via the Mt. Baker Highway #542, the West Church Road (#3120), and the East Church Road (#3040) and from the west via the Canyon Creek Road (#31), the Kidney Creek Road (#3130) and the Canyon Ridge Road (#3140).

Two east-west ridges dominate the area: Church Mountain (and associated ridges) and Canyon Ridge. The entire area is steep and highly dissected. Elevation ranges from 2,200 feet near Canyon Creek, to 6,315 feet at the summit of Church Mountain. Other peaks over 5,000 feet elevation are: Bearpaw Mountain (6,062 feet) and West Church (5,610 feet). The parcel also contains a number of small lakes.

Vegetation varies from forested slopes and valleys at lower elevations to rocky peaks, ridges, and meadows at higher elevations. Below 2,800 feet, the predominant cover types are Douglas-fir and western hemlock, with some western red cedar on wetter sites. Above 2,800 feet, predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,500 feet).

Soils are variable, with shallow residual soils on the steep, rocky ridgetop areas and deep glacial tills in the valley bottoms. There is some underlying bedrock instability (inactive faults) in the Church Mountain area and scattered unstable soils in the steep sideslope draws south of Canyon Ridge.

There is a variety of recreational use of the area, particularly in the vicinity of Damfino Lakes, Church Mountain, and Canyon Ridge. Several trails are located here.

WILDERNESS CAPABILITY

Manageability and Boundaries: The Canyon Creek Block is of sufficient size to make it a viable wilderness area and manageable for roadless primitive recreation. The north and east boundaries (adjacent to Canada and Mt. Baker Wilderness) are well-defined; those to the south and west are not. Areas near existing roads experience some motorcycle and snowmobile use, particularly along the Canyon Creek Road which extends into the middle of the area.

Natural Integrity and Appearance: The vast majority of the area has a natural appearance and is free from human disturbances, except for those portions associated with roads.

Opportunities For Solitude: Opportunities for solitude are numerous in those portions associated with peaks, ridges and lakes. These provide interaction between users, closeness to nature, and require self-reliance.

Opportunities For Primitive Recreation: Opportunities exist for high lake fishing, alpine mountaineering, backpacking, and nordic skiing. Parties on extended trips will likely experience minimal interaction with other users.

Challenging Experiences: There is opportunity for challenging experiences such as mountaineering and cross-country skiing.

Special Features: Several peaks of prominence include Church Mountain (6,315 feet elevation), Bearpaw Mountain (6,062 feet), and West Church Mountain (5,610 feet). About eight small lakes are located in Canyon Creek Block.

AVAILABILITY FOR WILDERNESS

Availability for wilderness is covered in two parts a summary table and a discussion of other resource potential of Canyon Creek Block.

Availability - Other Resource Potential

Recreation: The Mt. Baker Canyon Creek parcel is large, and has a variety of recreation opportunities, associated with the many peaks, small lakes, and other attractions in the area. Segments or entire trails include Canyon Ridge #639, Boundary Way #688, Damfino Lakes #625, Church Mountain #671, Church Lake #760, and Bear Paw Lake #757 Heaviest use is in the vicinity of Damfino Lakes and Church Mountain. The Canyon Ridge Trail is open to ORV's. Church Mountain is a notable viewpoint to Mt. Baker, Mt. Shuksan, and the Picket Range Little recreation use occurs in the Quartz Creek drainage or on the slopes draining into Canada. Damfino Trail #625 provides access to High Divide and the Mt Baker Wilderness. Total recreation use of the parcel is estimated to exceed 150 persons per week from July to September.

Fish and Wildlife: Pine marten and pileated woodpecker habitat is located within this parcel. A Spotted Owl Habitat Area (SOHA) occupies most of the Damfino Creek drainage. Critical mountain goat winter range can be found on south-facing slopes below Church Mountain east to the Wilderness boundary. The lower south-facing slopes along the N. Fork Nooksack River and Canyon Creek (below 3,000 feet) provide most of the winter range for resident blacktailed deer. Some elk may be using Canyon Creek for summer range. Higher elevations

provide mountain goats with summer range; winter range occurs along the south slopes of Canyon Creek.

Lower Canyon Creek and the North Fork Nooksack River support several species of salmon and anadromous trout (steelhead, cutthroat, and dolly varden) and provide spawning and rearing habitat.

Due to the size of this parcel and the diversity of topography and vegetation, habitat is also afforded for cougar, lynx, bobcat, black bear, golden eagles, elk, goat, deer, grouse, ptarmigan, and many other animals.

Summary Table - Mt. Baker (Canyon Creek Block) #6041 (MA)

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	25,046
Primitive/Semi-Primitive Recreation ROS	Acres	17,464
Timber		
Tentatively suitable	Acres	6,504
Tentatively suitable inaccessible	Acres	1,583
Tentatively suitable standing volume	M bdft	254,482
"Old Growth", Total Acres	Acres	14,181
0-2,500 Feet Elevation	Acres	401
2,500-4,000 Feet Elevation	Acres	7,940
4,000 + Feet Elevation	Acres	5,840
Management Indicator Species (MIS)		
Spotted owl MR	Acres	3,568
Pileated woodpecker and pine marten MR	Acres	2,069
Elk-deer Winter Range	Acres	527
Goat habitat MR	Acres	485
Bald eagle habitat (nests, forage, roost area)	Acres	84
Locatable Mineral Development Potential		
High	Acres	1,372
Moderate	Acres	253
Low	Acres	23,420
Claims	# of	40
Leasable Energy Minerals (Moderate Potential)		
Oil, Gas, Geothermal	Acres	2,703
Geothermal	Acres	22,343

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Water: Canyon Creek is a major tributary to the North Fork Nooksack River. Tributaries to Canyon Creek include Whistler Creek, Kidney Creek and several other unnamed creeks. Other tributaries to the N. Fork Nooksack include Hurst, Coal, Deer Horn, Lookout, and Fossil Creeks. There are several creeks north of Canyon Ridge that flow north into Canada, including Quartz Creek and Damfino Creek. Small lakes include Bearpaw Mountain Lake, Damfino Lakes, Canyon Lake, Whistler Lake, Church Lake, and Kidney Lakes.

Livestock Operations: None.

Ecology: Most of the area north of Canyon Creek supports forest species typical of the west Cascades (as discussed in the above description). The subalpine crest of Canyon and Boundary Way Ridges, and Damfino Lakes area are steep and rocky, with meadows.

Timber: "Old growth" forested lands are found mainly below 3,500 feet elevation in drainage bottoms. Above this elevation are scattered subalpine forests, rock outcroppings and alpine forest. Considerable logging has occurred outside of the roadless area along the Canyon Creek road

Minerals/Oil and Gas: The Canyon Creek Block is underlain by sedimentary and volcanic rocks of Jurassic, Cretaceous and Permian age, and by both glacial drift and alluvium of Quaternary age. The area is reported to have occurrences of lode gold, placer gold, limestone, copper and quartz, but none of the occurrences are known to have been developed beyond the prospect stage. The entire area is classified "prospectively valuable" for geothermal resources; a small portion of the northwest portion is classified "prospectively valuable" for oil and gas. Forty mining claims have been located within the area, but there are no leases or pending lease applications. The U.S. Geological Survey and U.S. Bureau of Mines have not studied the area's mineral resources, but based upon available data, it appears that the area has a relatively low to moderate potential for the occurrence of mineral resources.

Cultural: Sites along the North Fork Nooksack River and near Church Mountain and Whistler Lake are important for American Indian religious use.

Land Use Authorizations: The Forest Service maintains a Memorandum of Understanding to manage the Canyon Ridge Trail #689 for off-road vehicle use.

Non-Federal Lands: None. The parcel adjoins Canada.

Fire: In the past 100 years, large fires have occurred on the lower south-facing slopes of Church Mountain and Canyon Creek. Fire incidence at higher elevations has been low and limited to isolated lightning strikes.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The Canyon Creek Block of Mt. Baker Roadless Area adjoins Mt. Baker Wilderness to the east. Bellingham is 35 miles west and Vancouver, B.C. is 90 miles to the northwest. Many of the recreationists using the area are from B.C., Canada.

Public Interest: This parcel was identified in RARE I and RARE II as part of the Mt. Baker Roadless area. Local and national public response about the entire roadless area at that time (1972 and 1979) was divided between favoring wilderness and development of commodity resources.

In 1984, Congress did not include this area in the Mt. Baker Wilderness.

Following release of the DEIS and Draft Forest Plan, the entire Mt. Baker Roadless Area, plus specific geographic sites and features within the Canyon Creek Block of Mt. Baker Roadless Area received considerable public comment.

The Mt. Baker Roadless Area was mentioned 214 times. The majority of the comments urged the agency to keep the area roadless (mentioned 63 times); protect from logging (27); preserve the forest ecosystem (20); and add more SOHA's (17). Other respondents mentioned the importance of the entire roadless area to American Indian religious and cultural use and for wildlife habitat.

Damfino Creek was one of 15 areas Forest-wide that received the greatest amount of site-specific response. It was mentioned 496 times. Most respondents wanted the area protected from timber harvest (mentioned 118 times), to remain roadless (77), or the old growth ecosystem preserved (65). Other respondents favored protecting Damfino Creek for recreation, for wildlife, or for the scenic value. Several wanted the trail protected from logging. Five respondents favored more roads; one comment said Damfino Creek should be open to multiple use. 1/

Church Mountain was mentioned 301 times; most respondents favored protection from logging (66 comments), keeping the area roadless (41 comments), and saving the old growth ecosystem (30 comments). Protection of wildlife habitat (for spotted owl and mountain goat) was also mentioned. Two respondents wanted the area kept open for snowmobile use; one felt it was a top priority for timber harvest.

Damfino Lakes were mentioned 53 times; most respondents wanted the area added to wilderness or protected from logging.

Bearpaw Mountain was mentioned 40 times. Nearly all of these comments favored keeping the area open to snowmobiles.

Quartz Creek was mentioned 28 times: "no logging" "preserve low-elevation old growth" and "add to wilderness/keep roadless" were the comments most stated.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

MT. BAKER (CANYON CREEK BLOCK)
PARCEL MA

Significant Effects

Recreation: Current roadless recreation opportunities would not be significantly affected by implementation of most of the alternatives. Alternative C would leave the area entirely roadless through the end of the fifth decade. Alternative A, the alternative taking the greatest amount of area from roadless status, retains 93% of the area as roadless through the end of the fifth decade. Alternatives A, NC, B, H, I and J (Preferred) allocate acres to semi-primitive motorized recreation. Alternative A allocates 3% of the area to this prescription and alternative I allocates 49%.

Fish/Wildlife: Fish and wildlife would not be significantly affected by implementation of any of the alternatives. Alternatives B, H and I allocate the greatest area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement. Alternatives A, NC and J (Preferred) allocated the least.

Water: There are no adverse effects to the water resource of this area associated with implementation of any of the alternatives, due to the low level of proposed development activities

Ecology: The overall ecology of the area would not be significantly affected by implementation of any of the alternatives, due to the low level of proposed development activities.

Timber: Alternative C would have the least affect on the existing timber resource, as it allocates very minimal acreage to Management Area 17 (timber). Alternatives A, NC, B, G-modified and I would have the greatest effects. None of the alternatives would significantly affect the timber resource, as potential development activities would be minimal.

Minerals/Oil/Gas: None of the alternatives would have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC and H would provide a slightly higher amount of roaded access through the area for minerals development.

Cultural: Alternatives A, NC, B and I would have the greatest potential to adversely impact cultural resources within the area, due to development activities. Valuable sites would be protected via avoidance or conserved through data recovery. Alternatives C, H and J (Preferred) would have the least potential to adversely impact cultural resources.

Land Use Authorizations: Alternatives C and G-modified would dictate cancellation of the existing Memorandum of Understanding for off-road vehicle use of the Canyon Ridge Trail (#689).

Fire: None of the alternatives would significantly affect fire occurrence within the area.

Insect and Disease: None of the alternatives would significantly affect the occurrence of insects and disease within the area.

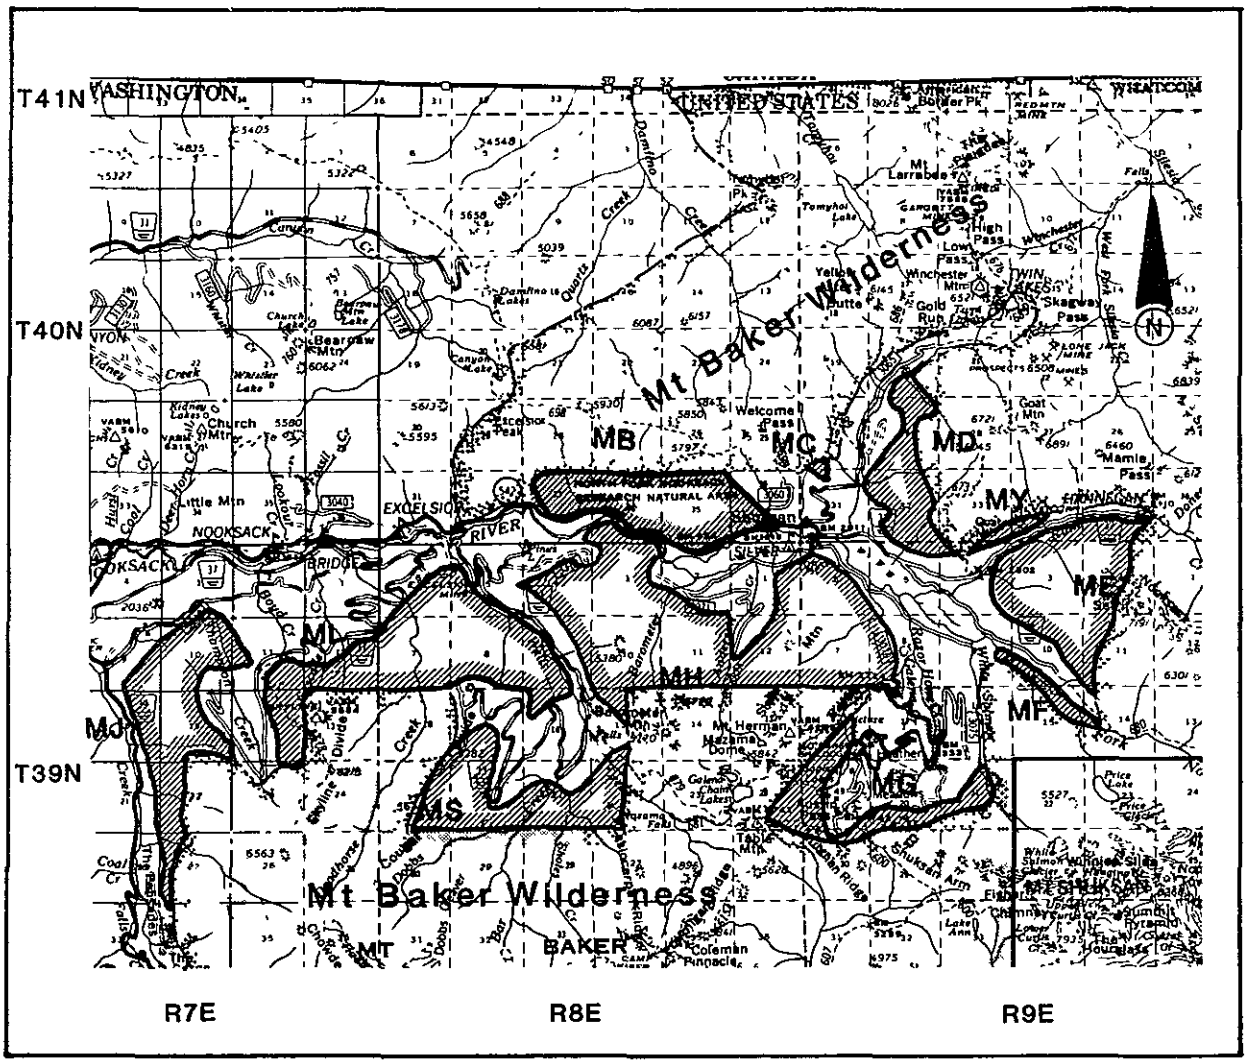
Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns approximately one-half of the area to the semi-primitive motorized management area and one sixth of the area to timber management. All alternatives would maintain over 93% of the area in a roadless condition through the end of the fifth decade. The wilderness potential would be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	24,311	23,855	23,411	93%
B (RPA)	24,737	24,423	24,116	96%
C	25,031	25,021	25,009	100%
G-Mod.	24,716	24,372	24,042	96%
H	24,611	24,055	23,526	94%
I	24,746	24,398	24,065	96%
J (Pref).	24,866	24,668	24,482	98%

Mt. Baker (North Block)

Roadless Area 6041



MT. BAKER (NORTH BLOCK) **Roadless Area 6041 (MJ, MI, MS, MB, MH, MG, MC, MD, MY, ME, MF)**

The second block of the Mt. Baker Roadless Area - North Block - consists of 11 parcels totaling 16,425 acres It was originally inventoried for study as potential wilderness during the RARE II process The RARE II decision assigned Area 6041 to nonwilderness uses. The following shows the disposition of acres within the North Block. One timber sale, Nanny Goat, was sold under contract in 1985; it removed 207 acres from roadless status. The area was reduced by four acres due to a mapping discrepancy. The following shows the disposition of acres within North Block:

Mt. Baker (North Block)	**Net Acres**
1984 RARE II	16,636
updated 1988	16,425
Change	**- 211**

OVERVIEW

As shown on the map, the North Block of the Mt. Baker Roadless area includes parcels on either side of the Mt. Baker Highway, adjacent to the wilderness, and on either side of the North Fork Nooksack River. Numerous roads provide access including: Mt.Baker Highway (#542), Thompson Creek Road (#3910), Wells Creek Road (#33), Razor Hone Road (#3070), Smith Basin Road (#3940), North Fork Nooksack Road (#34), Deadhorse Road (#37), and Hannegan Road (#32).

Portions of a number of creeks that drain into the North Fork of the Nooksack run through the eleven parcels, from Glacier Creek on the west to the mid-reaches of Ruth Creek on the east. Included are portions of Thompson, Upper Boyd, Cascade, Deadhorse, Bar, Wells, Barometer, and Anderson Creeks. The terrain is moderate in the valley bottoms and rugged on the higher slopes and ridges. Elevations range from 1,500 feet near Glacier Creek to 6,015 feet on an un-named peak in the eastern-most parcel.

Vegetation type varies from heavily forested slopes and valleys at lower elevations to meadowed ridges along Skyline Divide and adjacent to the Austin Pass-Heather Meadows area (parcel MG). The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, Pacific silver fir and western hemlock are predominant, with some mountain hemlock at the higher elevations of tne forested range (4,000-5,500 feet).

Soils vary with unstable portions adjacent to Thompson Creek and other tributaries to Glacier Creek, Wells Creek, Bar Creek, Barometer Creek, and on the sideslopes southeast of Ruth Creek. There are shallow, residual soils on the upper slopes of Slate Mountain and high elevation alpine soils (ranging from deep glacial till to shallow residual volcanic soil) in parcel MG.

The area provides a variety of recreation opportunity, with heavy use concentrated in parcel MG, which is adjacent to the Mt. Baker Ski Area and other developed recreation sites near Mt. Baker. Parcel MB is the North Fork Nooksack Research Natural Area. The North Block parcels contain a diversity of wildlife habitat and provides several areas of important mountain goat use.

WILDERNESS CAPABILITY

Manageability and Boundaries: The small size of the North Block parcels would not affect their manageability since all are adjacent to Mt. Baker Wilderness. Portions of parcels MJ and MS would be difficult to manage as wilderness since nearby logging spurs and flat terrain make vehicle trespass possible. The North Fork Nooksack Research Natural Area (parcel MB) would have little conflict with wilderness designation, but boundary locations could be difficult to establish due to lack of identifiable features.

Natural Integrity and Appearance: Most of the area has a natural appearance. Parcel MB shows evidence of little to no human disturbance.

Opportunities For Solitude: Opportunities for solitude in most of these parcels are low due to their proximity to existing roads, logging activity, and developed recreation sites.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are minimal due to overall proximity of existing roads and developed recreation sites. Opportunities increase closer to the existing wilderness boundary in the larger parcels such as parcel MH.

Challenging Experiences: The North Block parcels offer challenging experiences such as cross-country hiking, mountaineering, and nordic skiing.

Special Features: The 1,407 acre North Fork Nooksack River Research Natural Area is located within parcel MB. The RNA was set aside in 1934 to represent Douglas-fir and western hemlock forests in a 75 year old burn. Also included is a variety of subalpine, meadow communities. The new Artist Ridge trail crosses parcel MG; part of Phase I, Heather Meadows Capital Investment Program, the trail includes interpretive signs.

AVAILABILITY FOR WILDERNESS

Availability for wilderness is covered in two parts: the summary table on the next page and the following discussions of other resource potential in the North Block roadless area parcels.

Availability - Other Resource Potential

Recreation: There are a variety of recreational opportunities associated with Mt. Baker and the surrounding area. The Skyline Divide Trail #678 provides access to meadows and ridges of Mt. Baker. Parcel MG, near Mt. Baker Ski Area, is characterized by extensive recreational development, including the Artist Ridge Interpretive Trail. There is also very heavy dispersed recreation use (hiking, climbing, cross-country skiing) in Parcel MG. Most other areas are by-passed by recreationists on their way to wilderness.

Summary Table - Mt. Baker (North Block) #6041

Category 1/	Unit	Parcels MJ	MI	MS	MB	MH	MG	MC	MD	MY	ME	MF	Total
Acres (Minus water, private land)	Acres	1,901	2,533	1,668	1,456	4,688	1,204	84	718	168	1,752	253	16,425

1/ American Indian Religious and Cultural areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.
3/ Number of claims is not broken out by parcel.

Wildlife: Wildlife use of the 11 different parcels is quite diverse.

Parcel MJ contains important mountain goat winter range above the Palisades near Smith Basin. The cliffs and bluffs here are heavily used by goats during the winter and spring; the habitat is critical to the herds survival. Small tributaries to Glacier and Thompson Creeks support odd-year pink salmon runs. Thompson Creek provided spawning habitat for 10% of the total North Fork Nooksack River pink salmon run in 1983. Other salmonoid species include coho and chinook salmon, steelhead, cutthroat trout, and dolly varden charr. Duringruns of pink and coho salmon, bald eagles forage in lower Glacier and Thompson Creeks.

Spotted owl habitat exists in the eastern portion of parcel MI along Wells Creek. Lower portions of Deadhorse, Boyd, and Cascade Creeks provide important steelhead trout, coho, pink and chinook salmon spawning and rearing habitat. Resident rainbow, cutthroat trout, and dolly varden charr utilize the upper portions of most of these streams.

Some resident trout utilize the upper portions of Bar Creek and Wells Creek in parcel MJ.

Parcel MH contains critical winter and spring range for the Barometer Mountain goat herd. There are some resident trout in portions of Barometer, Anderson, and Bagley Creeks. Some of parcel MH lies in Spotted owl habitat.

Parcel MY includes steep, south-facing slopes below 4,000 in elevation which may be entirely mountain goat winter range.

Portions of parcel MB are a Spotted owl habitat.

Parcel MD includes blacktail deer winter range on southwest-facing slopes below 3,000 feet. It may also be excellent habitat for the peregrine falcon, an endangered species.

Water: The entire area is tributary to the North Fork Nooksack River. Included are portions of Thompson Creek and other tributaries to Glacier, Boyd Cascade, Deadhorse, Bar, Wells, Barometer, and Anderson Creeks.

Livestock Operations: None.

Ecology: Vegetation varies from heavily-forested slopes and valleys at lower elevations (including cedar, Douglas-fir, true firs, and hemlock) to subalpine, high-elevation meadows.

Timber: Substantial commercial forest exists at all but the upper elevations. The southwest portion of parcel MH was burned in the mid-1950's (Barometer Mountain fire) and has not yet produced commercial timber; the rest of this parcel supports old growth forest but is steep and inaccessible by road except for the Slate Mountain area. All of parcel MG is alpine.

Minerals/Oil and Gas: The geology of the area is dominated by Jurassic volcanics, Jurassic/Cretaceous sedimentary and volcanic rocks, Permian volcanics, Tertiary granitics and alluvium of recent age. The area is reported to have occurrences of lode gold, copper, iron, lead-zinc, and silver. Of these occurrences, the Wells Creek Gossan (Cu), the Great Excelsior gold-silver deposit, and Iron Cap and Tooker-Leshud iron-gold-silver deposits are of most interest. The Excelsior Mine receives extensive exploration work; a future operational mine is possible.

The entire area is classified "prospectively valuable" for geothermal, but only a very small part of the area is classified "prospectively valuable" for oil and gas resources. The area has had thirty-nine mining claims. The mineral resources of the area have not been inventoried by the U.S. Geological Survey and Bureau of Mines; but based upon available information the above mineralized areas are considered to have a moderate to high potential for future development.

Cultural: Various sites in the North Fork Nooksack River watershed are important for American Indian religious use.

Land Use Authorizations: There are no special land authorizations.

Non-Federal Lands: None.

Fire: There has been a low incidence of large fires in upper-elevation areas. Lower elevations in the vicinity of Thompson Creek, Boyd Creek, and Smith Basin show evidence of an extensive fire about 1885. The large Barometer Mountain fire occurred in the mid-1950's.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The Mt. Baker North Block parcels are adjacent to or contiguous with the Mt. Baker Wilderness. Several small communities are located along the Mt. Baker Highway. Bellingham is approximately 45 miles west, and Vancouver, B.C. is approximately 70 miles away.

Public Interest: These parcels were identified as part of the Mt. Baker roadless area in RARE I and RARE II. In 1984, much of the original area was designated as part of the Mt. Baker Wilderness.

Public comment to the DEIS and Draft Forest Plan included site specific comments about the north parcels of Mt. Baker Roadless Area. They were mentioned 144 times, with most people wanting the area to remain roadless (35 comments), be protected from timber harvest (34 comments), and the ecosystem preserved (21). Four letters stated it was a top priority for harvest.

Protection of American Indian religious use, fisheries habitat, wildlife, and mountain goats was also mentioned. Area MG is considered very sensitive due to its proximity to Heather Meadows Recreation Area and the Mt. Baker ski area. 1/

Areas adjacent to the Mt. Baker Wilderness were mentioned 35 times. Eight comments said to keep the area roadless, four wanted the forest ecosystem preserved, and three desired protection of the old growth ecosystem. The majority of the remaining responses said to manage the area for recreation and wildlife habitat.

Thompson Creek was mentioned 9 times; 2 recommended building more roads, the rest wanted the area protected from harvest, etc. Deadhorse Creek was mentioned 8 times: 2 "build more roads" comments plus others to protect old growth, recreation values, wildlife, and fisheries. Protection of mountain goat habitat near Barometer Creek was a concern for 3 respondents.

ENVIRONMENTAL CONSEQUENCES

The following tables display how each roadless parcel is assigned in the alternatives considered. An assignment represents long-term management.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternatives C and G-Modified will, effectively, leave the area roadless through the end of the fifth decade. Alternative I will allocate about one-fifth of the area to semi-primitive motorized recreation. Alternatives A and NC will designate about 10% of the area as the Mt. Baker Recreation Area.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B, H, I and J (Preferred) allocate the greatest amount of area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement. Alternatives A,NC and C allocate the least.

Water: There are no adverse effects to the water resource of the area associated with any of the alternatives.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives.

Timber: Alternatives A, NC, B and I will have the greatest affect on the existing timber resources, as these allocate the greatest acreage to management area 17 (timber). Alternatives C and G-Modified will have the least. None of the alternatives will significantly affect the timber resource, as potential development activities will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B and I will provide a greater amount of roaded access through the area that could be used for minerals exploration and development.

Cultural: Alternatives A, NC, B and I will have the greatest potential for adverse impacts to cultural resources within the area, due to development activities. Alternatives C and G-Modified will have the least potential. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns about one-fifth of the area to semi-primitive motorized recreation. Alternatives C and G-Modified would, effectively, maintain the area as roadless through the end of the fifth decade, maintaining wilderness potential. Alternatives A and NC, the alternatives which remove the greatest

amount of roadless area, will maintain 68% of the area in roadless status through the end of the fifth decade, thus losing wilderness potential on 1/3 of the acres in the roadless area.
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	14,850	13,090	11,180	68%

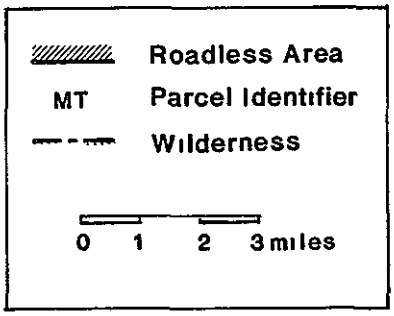
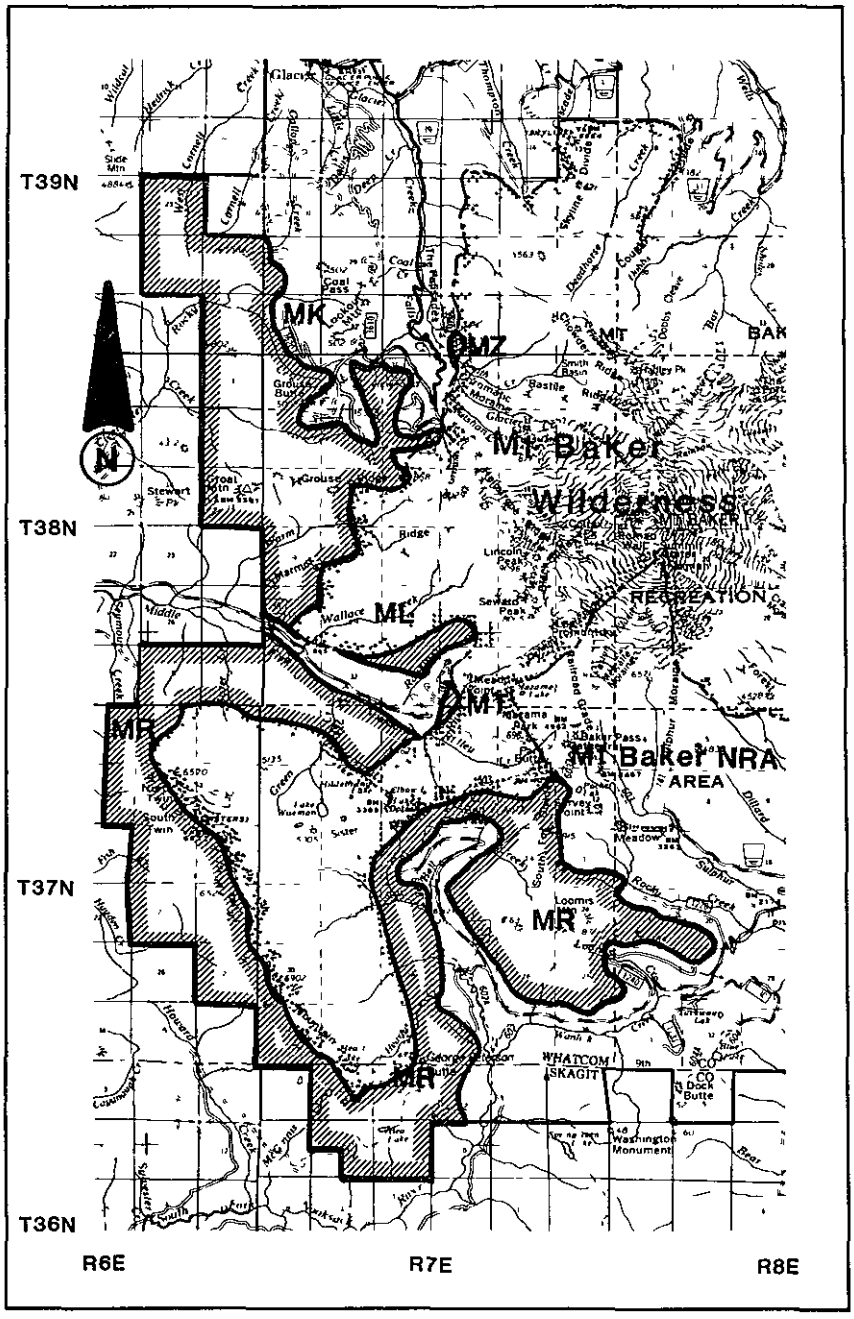
Mt. Baker (West Block)
Roadless Area 6041





MT. BAKER (WEST BLOCK) **Roadless Area 6041 (MK, MZ, ML, MT, MR)**

The third block of the Mt. Baker Roadless Area - West Block - consists of five parcels totaling 26,818 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6041 to nonwilderness uses. This area was reduced by two acres from its 1984 RARE II size due to a mapping discrepancy The following shows the disposition of acres within the Mt. Baker West Block roadless area:

Mt. Baker West Block	**Net Acres**
1984 RARE II	26,820
updated 1988	26,818
Change	- 2

OVERVIEW

These five parcels are located west of Mt. Baker Wilderness and southwest of the Mt Baker National Recreation Area Refer to the map on the next page. These lands include drainages to all three forks of the Nooksack River.

Access to the area is via several road systems: from the north by the Glacier Creek Road (#39), the Grouse Butte Road (#3600) and the Rocky Creek Road (#3620); from the west by the Middle Fork Nooksack Road (#38); and from the southeast by the Loomis-Nooksack Road (#12). Access from the west is also provided by several private logging roads.

The West Block parcels includes portions of Rocky, Clearwater, Warm, Rankin, Green, and Bell Creeks plus other tributaries to the Nooksack River system. Parcel MR wraps around the Twin Sisters Mountain range; on the west side, the ridgeline is the Wilderness boundary. Elevations range from 2,500 feet along the Middle Fork Nooksack River, to 6,932 feet at the summit of South Twin Mountain. Several peaks in the area exceed 5,000 feet - Groat Mountain (5,581 feet) and Loomis Mountain (5,587 feet) - and most of the area is located above 3,000 feet.

The predominant vegetative cover below 2,800 feet elevation is Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,500 feet).

To the north, there are unstable soils in the upper reaches of West Cornell Creek and adjacent to Clearwater Creek and Rocky Creek. Bedrock instability (inactive faults) occurs northwest of Wallace Creek and in the Warm Creek drainage adjacent to the Forest Boundary. There are also unstable soils adjacent to the lower reaches of Rankin Creek in parcel ML and on the steep lower slopes above the Middle Fork Nooksack River in parcel MT. To the south, there are localized occurrences of soil instability in the headwaters of Sisters, Green, Rish, Hayden, and McGinnis Creeks. There are also unstable soils south of Bear Lake adjacent to the Forest Boundary, on the sideslopes west of the South Fork Nooksack River, and adjacent to steep sideslope draws on the southwest side of Loomis Mountain.

This area contains a diversity of wildlife habitat, and provides important year-round range for elk and mountain goats.

WILDERNESS CAPABILITY

Manageability and Boundaries: In parcel MK, the meandering boundary adjacent to existing roads would be difficult to locate due to lack of definite landmarks. The north-south boundary of parcel ML lies on a midslope and would be difficult to locate. The Bell Creek parcel (MR) could experience vehicle trespass from elk hunters if designated wilderness or allocated to roadless recreation. The boundary west of the Sisters Range is well-defined.

Natural Integrity and Appearance: There is overall a natural appearance.

Opportunities For Solitude: Opportunities for solitude exist in the Warm Creek-Marmot Ridge parcel (MK), west of the Sisters Range parcel (MR), and in the vicinity of Loomis Mountain parcel (MR). Other parcels are close to existing roads where solitude is less likely.

Opportunities For Primitive Recreation: Parcels MK and MR provide the greatest opportunity for primitive recreation including hunting, cross-country hiking, camping, and mountaineering.

Challenging Experiences: Several peaks offer challenging mountaineering and cross-country skiing opportunities.

Special Features: The most prominent features are the Twin Sisters peaks on the border of the Mt. Baker Wilderness. Groat Mountain (5,581') is located in parcel MK and Loomis Mountain (5,587') is within parcel MR south of the NRA.

AVAILABILITY FOR WILDERNESS

Availability for wilderness is covered in two parts: the summary table on the next page and the following discussions of other resource potential in the Mt. Baker West Block parcels.

Availability - Other Resource Potential

Recreation: The Twin Sisters range is a popular mountain climbing area and a prominent visual attraction. The most often used climbing route is from the west. Elbow Lake Trail #697 receives moderate to low use, about 200 visitor use days per year The Bear Lake-Three Lakes area (accessible by cross-country routes) receives some use. South and southeast portions are heavily hunted for elk. Northern portions receive little recreational use.

Fish/Wildlife: In parcel MK Upper Warm Creek, Clearwater Creek and Rocky Creek are used in summer by elk. This use is expected to increase in the future. South slopes between Grouse Ridge and Warm Creek are heavily used by mountain goats as winter range. There are some resident trout in upper Clearwater and Rocky Creeks. Spotted owl habitat occupies a portion of this parcel.

In parcel MR the north slope forests above the Middle and South Forks Nooksack River contain elk summer range. During the winter the lower slopes along the Middle Fork Nooksack (below 2,300 feet) are used by these same herds. This habitat is important to survival of the herds The southwest-facing, old growth forest slopes of the Twin Sisters range (below 4,000 feet) are heavily used by mountain goats as winter range. This habitat is critical to this herds survival since much of their original winter range lies on private land and has been cut-over. This area may also be heavily used by elk during the summer.

Summary Table - Mt. Baker (West Block) #6041

Category 1/	Unit	Parcels MK	MZ	ML	MT	MR	Total
Acres (Minus water, private land)	Acres	8,468	42	591	127	17,590	26,818

Geothermal	Acres	6,757	42	591	126	14,085	21,601

1/ American Indian religious and cultural areas were analyzed. Site specific information is not disclosed due to its sensitivity
2/ Includes nest sites, forage areas, and roost areas
3/ *Number of claims is not broken out by parcel.*

Portions west of the South Fork Nooksack River are also heavily used by summering elk. Many of the small headwater drainages are important elk breeding sites, with elk licks and wallows scattered throughout. The lower slopes below 2,300 feet provide critical elk winter range and succulent forage throughout the dry summers.

The area south of Loomis Mountain (parcel MR also) is used by large herds of mountain goat and elk. It is one of the most important elk areas on the Mt. Baker District, providing elk with breeding areas, wallows, licks, hiding cover, thermal cover, and forage. The upper meadows are used as summer range by mountain goats. These goats winter on steep south and southwest-facing slopes below Loomis Mountain. The Loomis Mountain area also supports cougar, black bear, large deer herds, and may other species. A raptor migration route is apparent. Important salmon and anadromous trout habitat exists here as well.

Water: Drainages include portions of Rocky Creek, Clearwater Creek, Warm Creek, Rankin Creek, Green Creek, Bell Creek and other segments of the Nooksack system. Three Lakes and Bear Lake are located to the south. The Middle Fork Nooksack drainage furnishes a portion of the municipal water supply for the city of Bellingham.

Livestock Operations: None.

Ecology: The predominant forest community types below 4,000 feet are Pacific silver fir and western hemlock. There is a high proportion of mid to high-elevation land which does not support commercial timber. The Grouse Butte-Groat Mountain-Grouse Ridge portion is steep and rocky. The west slopes of the Twin Sisters Range support mountain hemlock/Pacific silver fir at lower elevations, subalpine vegetation on the midslope, and are steep and rocky near the crest. The rugged, upper slopes of Loomis Mountain feature subalpine forest and meadows.

Timber: Northern portions are primarily commercial forest except in the vicinity of Grouse Butte-Groat Mountain-Grouse Ridge. Southern portions have substantial commercial forest except for the slopes of the Twin Sisters Range. Timber harvest has occurred on nearly all the adjacent non-National Forest land.

Minerals/Oil and Gas: The geology of the area is dominated by pre-Upper Jurassic metamorphic rocks, Permian sedimentary and volcanic rocks, Tertiary dunite, Pleistocene to recent volcanics, and by alluvium and glacial drift of Quaternary age. The area has reported occurrences of chromite, asbestos, olivine, and limestone. Of most interest are the olivine and chromite occurrences. The olivine deposits are very large and will serve any foreseeable demand. The known chromite resources are small, and there is little present interest in this type of deposit.

Nearly the entire area is classified "prospectively valuable" for geothermal resources, however, only a small portion of the area is classified "prospectively valuable" for coal, oil, and gas. The area has had 365 mining claims, indicating a continuing interest in the area's potential for olivine and chromite. The area's mineral resources have not been inventoried by the U.S. Geological Survey and Bureau of Mines. But, based upon available data, localized portions of the area have a high potential for olivine development, and according to Lawson and Evarts (1983), the area has "high" potential for the occurrences of chromite resources.

Cultural: Various sites, including some near Bell Creek and Warm Creek, are important for American Indian religious use.

Land Use Authorizations: There are no special land authorizations.

Non-Federal Lands: A total of 320 acres of non-Federal lands are contained within these parcels.

Fire: Fire incidence is generally low. There is evidence of past fires on the south-facing slopes of the Sisters range. There is evidence of some large fires about 100 years ago in lower Cornell Creek.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to other Designated Wilderness and to Population Centers: These parcels are adjacent to the Mt. Baker Wilderness and Mt. Baker National Recreation Area Sedro Woolley is 30 miles away, Bellingham is 50 miles away and Vancouver, B.C. is 100 miles away.

Public Interest: Following release of the DEIS and Proposed Forest Plan, public comments were received on the Mt. Baker Roadless Area (West Block), as well as on specific geographic sites and features within this area, and on the area in a general sense.

Mt. Baker Roadless Area West was mentioned 18 times. Five comments said to make the area a top priority for harvest . Most of the remaining responses favored managing the area for nonmotorized recreation, and protection of wildlife habitat and visual quality. One comment wanted the area protected as an American Indian Religious Site. 1/

Mt. Baker parcel MR was mentioned four times. Two comments said to preserve the area as valuable low-elevation old growth. One favored designation at MA 1 AB (primitive/semi-primitive nonmotorized). One comment wanted protection for the old growth ecosystem.

The Mt. Baker Roadless Area, in it's entirety, was mentioned 214 times. Responses said to keep the area roadless (63), protect it from harvest (27), preserve the forest ecosystem (20), add more SOHA's in the area (17), protect it as an American Indian Religious Site (16), and protect the old growth ecosystem (15). The majority of the remaining comments favored managing the area for recreation, and protection of wildlife habitat, fisheries, and visual quality

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person **could** mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Areas adjacent to the Mt. Baker Wilderness Area were mentioned 35 times. Comments said to keep the area roadless (8), preserve the forest ecosystem (4), protect the old growth ecosystem (3), protect the area from harvest (2), and protect it as an American Indian Religious Site (2). Most of the remaining comments said to manage the area for recreation, and protection of wildlife habitat and visual quality. One response expressed the desire to have this area added to the National Park System.

Loomis Mountain was mentioned 226 times. Responses favored protecting the area for elk calving and Mountain Goat winter range (45), protecting it from harvest (42), preserving the forest ecosystem (35), keeping the area roadless (34), protecting wildlife habitat (13), and protecting the old growth ecosystem (10). The majority of the remaining comments said the area should be managed for recreation, and protection of wildlife habitat and scenic quality. One comment favored making this area a top priority for timber harvest.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

MT. BAKER (WEST BLOCK)

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternatives C and G-Modified will leave the area virtually unroaded through the end of the fifth decade. Alternative I will allocated about 40% of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B, H and I will allocate the greatest amount of acreage to old growth habitat, mature old growth, and mountain goat management requirement prescriptions. Alternatives A, NC, C and G-Modified allocated the least.

Water: There are no adverse effects to the water resources of this area associated with any of the alternatives, due to the low level of proposed development activities.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives B and I allocate the greatest acreage to timber management. Alternatives C, G-Modified and J (Preferred) allocate the least. None of the alternatives will significantly affect the timber resource due to the low level of harvest activity planned.

Minerals/Oil/Gas: None of the alternatives will significantly affect the availability of minerals, oil or gas for development. Alternatives B and I will provide greater roaded access through the area, which could be used for mineral exploration and development.

Cultural: Alternatives B and I have the greatest potential to adversely impact the cultural resources of the area, due to their level of development activity. Alternatives C and G-Modified will have the least potential. Valuable sites will be protected via avoidance or preserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

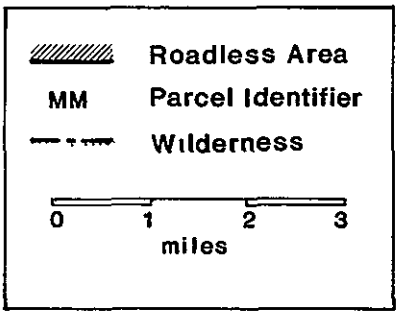
Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns approximately one-half of the area to semi-primitive motorized recreation and timber management prescriptions. Alternatives C and G-Modified will maintain the majority of the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained. Alternatives H and J (Preferred) will maintain approximately three-quarters of the area in a roadless condition through the end of the fifth decade. Alternatives A, B, and I will maintain approximately two-thirds of the area in a roadless condition through the end of the fifth decade.

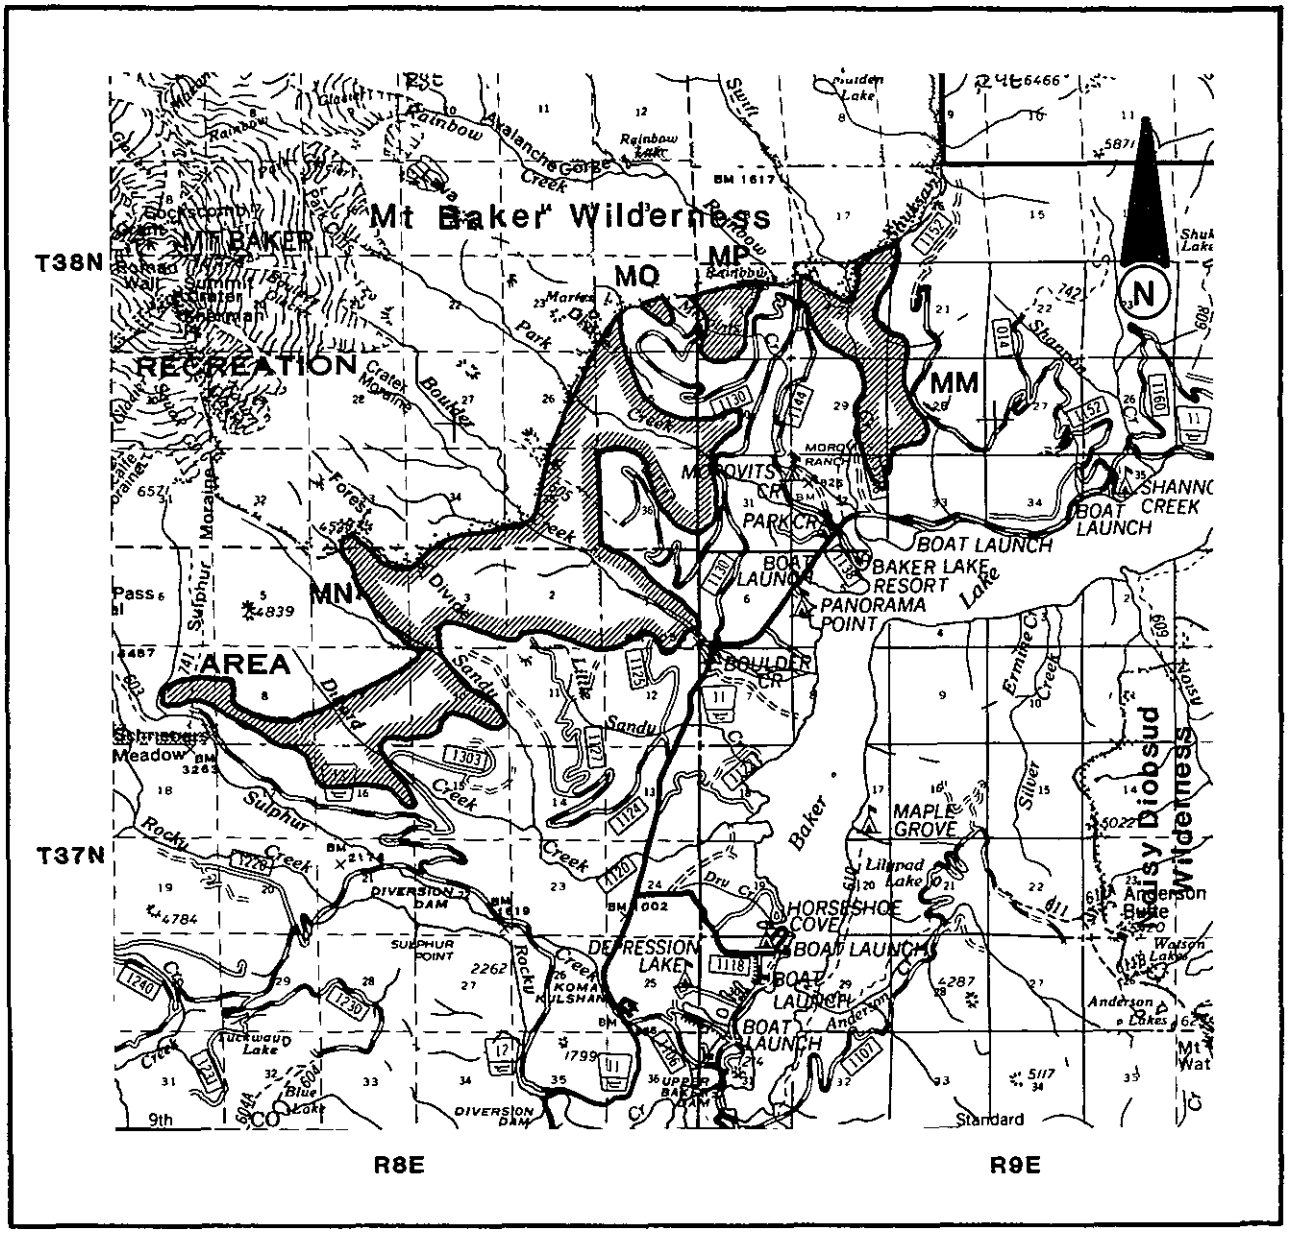
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	23,797	20,253	16,868	63%
B (RPA)	24,142	21,144	18,203	68%
C	26,620	26,454	26,237	98%
G-Mod.	26,359	25,949	25,487	95%
H	24,649	22,309	19,878	74%
I	24,073	20,959	17,901	67%
J (Pref)	24,898	22,896	20,803	78%

Mt. Baker (South Block)

Roadless Area 6041





MT. BAKER (SOUTH BLOCK) **Roadless Area 6041 (MN, MO, MP, MM)**

The Mt. Baker RARE II area originally contained 271,900 acres. Of this amount, 117,528 acres were legislated Mt. Baker Wilderness and 14,133 acres were legislated Noisy Diobsud Wilderness.

Remaining parcels of the RARE II Mt Baker Roadless Area consist of 126,201 acres This area was divided for ease of analysis into five blocks: Canyon Creek, Mt Baker North, Mt. Baker West, Mt. Baker South, and Noisy Diobsud. The following presents analysis of the Mt. Baker South Block.

This roadless area block consists of four parcels totaling 6,375 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6041 to nonwilderness uses.

In 1984, portions of the Hi Boy Timber Sale were sold under contract within this roadless area block. The sale removed 188 acres from roadless status. In 1985, the Tip Top Timber Sale removed 139 acres within the area from roadless status. The area was increased by 12 acres in 1988 due to a mapping discrepancy

The following shows the disposition of acres within the Mt. Baker South Block roadless area:

Mt. Baker (South Block)	**Net Acres**
1984 RARE II	6,690
updated 1988	6,375
Change	**- 315**

OVERVIEW

These parcels are located southeast of the Mt. Baker Wilderness and Mt. Baker National Recreation Area (NRA). The area includes lower and mid-reaches of several streams, all of which drain into the Baker Lake Reservoir.

Several roads provide access from the south and east: the Schriebers Meadows Road (#13), the Sandy Creek Road (#1124), the Marten Lake Road (#1130), the Boulder Ridge Road (#1131), the Morovitz Creek Road (#1144), and the Shuksan Creek Road (#1152).

These parcels include portions of Swift Creek, Morovitz Creek, Park Creek, Boulder Creek, and Dillard Creek. Elevations range from 1,200 feet to 4,500 feet with most of the area at less than 3,000 feet Soils are variable, with shallow, residual soils occurring on upper sideslopes and ridgetops. There are steep unstable soils adjacent to the Boulder Creek channel and sideslope draws, and adjacent to Morovitz Creek and the east side of Swift Creek.

The predominant cover types below 2,800 feet are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,500 feet).

Critical habitat is provided for several large herds of mountain goats.

WILDERNESS CAPABILITY

Manageability and Boundaries: These parcels are small, and boundaries would be difficult to locate due to lack of definable characteristics on the ground. Manageability would be difficult due to the proximity of several roads.

Natural Integrity and Appearance: These parcels are heavily forested and somewhat isolated by deep valleys and mountain streams.

Opportunities For Solitude: The greatest degree of solitude would be provided in brushy stream bottoms.

Opportunities For Primitive Recreation: There are few opportunities for primitive recreation activities due to adjacent roads.

Challenging Experiences: There are few opportunities for unusually challenging experiences.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: The Boulder Ridge Trail #605 receives moderate to heavy use for day hiking and as climbing access to Mt. Baker. The Swift Creek Trail #607 is moderately used. Other recreational attractions include Rainbow Falls, and stream fishing in Rainbow, Park and Boulder Creeks. Most areas are hunted extensively during deer season.

Fish/Wildlife: These parcels are very important to several large herds of mountain goats which spend each winter on southwest-facing slopes above Dillard Creek, Sandy Creek, Boulder Creek, and Park Creek. Each one of these drainages is used by a different herd of goats and provides steep-timbered slopes critical to the goats' winter survival. The lower, less steep portions of these same slopes are used by deer throughout the winter and may also be important to their survival.

Elk are becoming very common in the Baker Lake basin and have started wintering in this region. This herd is expected to increase in size and become an important component of the local wildlife. Currently, elk winter in the Baker Hot Springs region and in flat land old growth forest locations near Baker Lake parcel (MM). Swift Creek has important resident trout populations, and there are resident trout in portions of Dillard, Sandy and Park Creeks.

Other special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten.

Water: Drainages flowing into Baker Lake Reservoir include Swift Creek, Morovitz Creek, Park Creek, Boulder Creek, and Dillard Creek.

Livestock Operations: None.

Summary Table - Mt. Baker (South Block) #6041

Geothermal	Acres	5,321	63	147	844	6,375

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.

Ecology: Forest cover on these parcels is typical of the west Cascades, including cedar, Douglas-fir, true firs, and hemlock.

Timber: Seventy percent of the area supporting tentatively suitable commercial forest lands.

Mineral/Oil and Gas: The geology of the area is dominated by Permian aged sedimentary and volcanic rocks, and by volcanic rocks and glacial drift of Quaternary age The area has no reported occurrences of mineral resources, but it is classified "prospectively valuable" for geothermal resources. The area has no reported mining claims The mineral resources of the area have not been studied in detail by the U.S. Geological Survey and Bureau of Mines; but based upon available data the area has a relatively low potential for the occurrence of mineral resources other than geothermal.

Cultural Resources: Sites are located here which are important for American Indian religious use.

Land Use Authorizations: There are no special land authorizations here.

Non-Federal Lands: None.

Fire: There is a fairly high occurrence of small, isolated high-elevation lightning fires here.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are adjacent to the Mt. Baker Wilderness and Mt. Baker National Recreation Area The town of Concrete is about 20 miles to the south. Larger population centers include Sedro Woolley (40 miles away), Bellingham (60 miles away), Seattle (110 miles away), and Vancouver, B.C. (110 miles away).

Public Interest: Following release of the DEIS and Proposed Forest Plan, public comments were received concerning the Mt. Baker Roadless Area south block, and also on the area to the southeast of Mt. Baker.

Mt. Baker Roadless Area south block was mentioned 13 times. Three responses wanted the area made a top priority for harvest. Other comments favored protection of visuals (2) and old growth ecosystems (2). The remaining responses said to manage the area for recreation and wildlife habitat. 1/

The southeast side of Mt. Baker was mentioned 106 times. Comments said to protect the area for spotted owl habitat (33), protect the old growth ecosystem (23), protect from harvest (8), preserve the forest ecosystem (6), and keep the area roadless (6). Most of the other responses wanted the area managed for recreation, wildlife habitat and visual quality. One response said to to make the area a top priority for harvest.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be

tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative C will leave the greatest amount of acres in roadless status through the end of the fifth decade. Alternatives A and NC allocate about one-half of the area to the Mt. Baker Recreation Area. Alternative I assigns about 10% of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives, due to the low level of proposed development activity. Alternatives B, I and J (Preferred) allocate the greatest amount of the area to old growth habitat, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives A and C allocate the least.

Water: There will be no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of development activity planned.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives A, NC, B and I assign the greatest area to timber management. Alternatives C and J (Preferred) allocate the least. None of the alternatives will have a significant affect on the timber resource, as potential development activity is minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives B and I will provide a slightly greater amount of roaded access through the area, which could be used for mineral exploration and development.

Cultural: Alternatives B and I have the greatest potential to adversely impact cultural resources in the area. Alternatives C and G-Modified have the least. This is based on the planned level of development activity. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

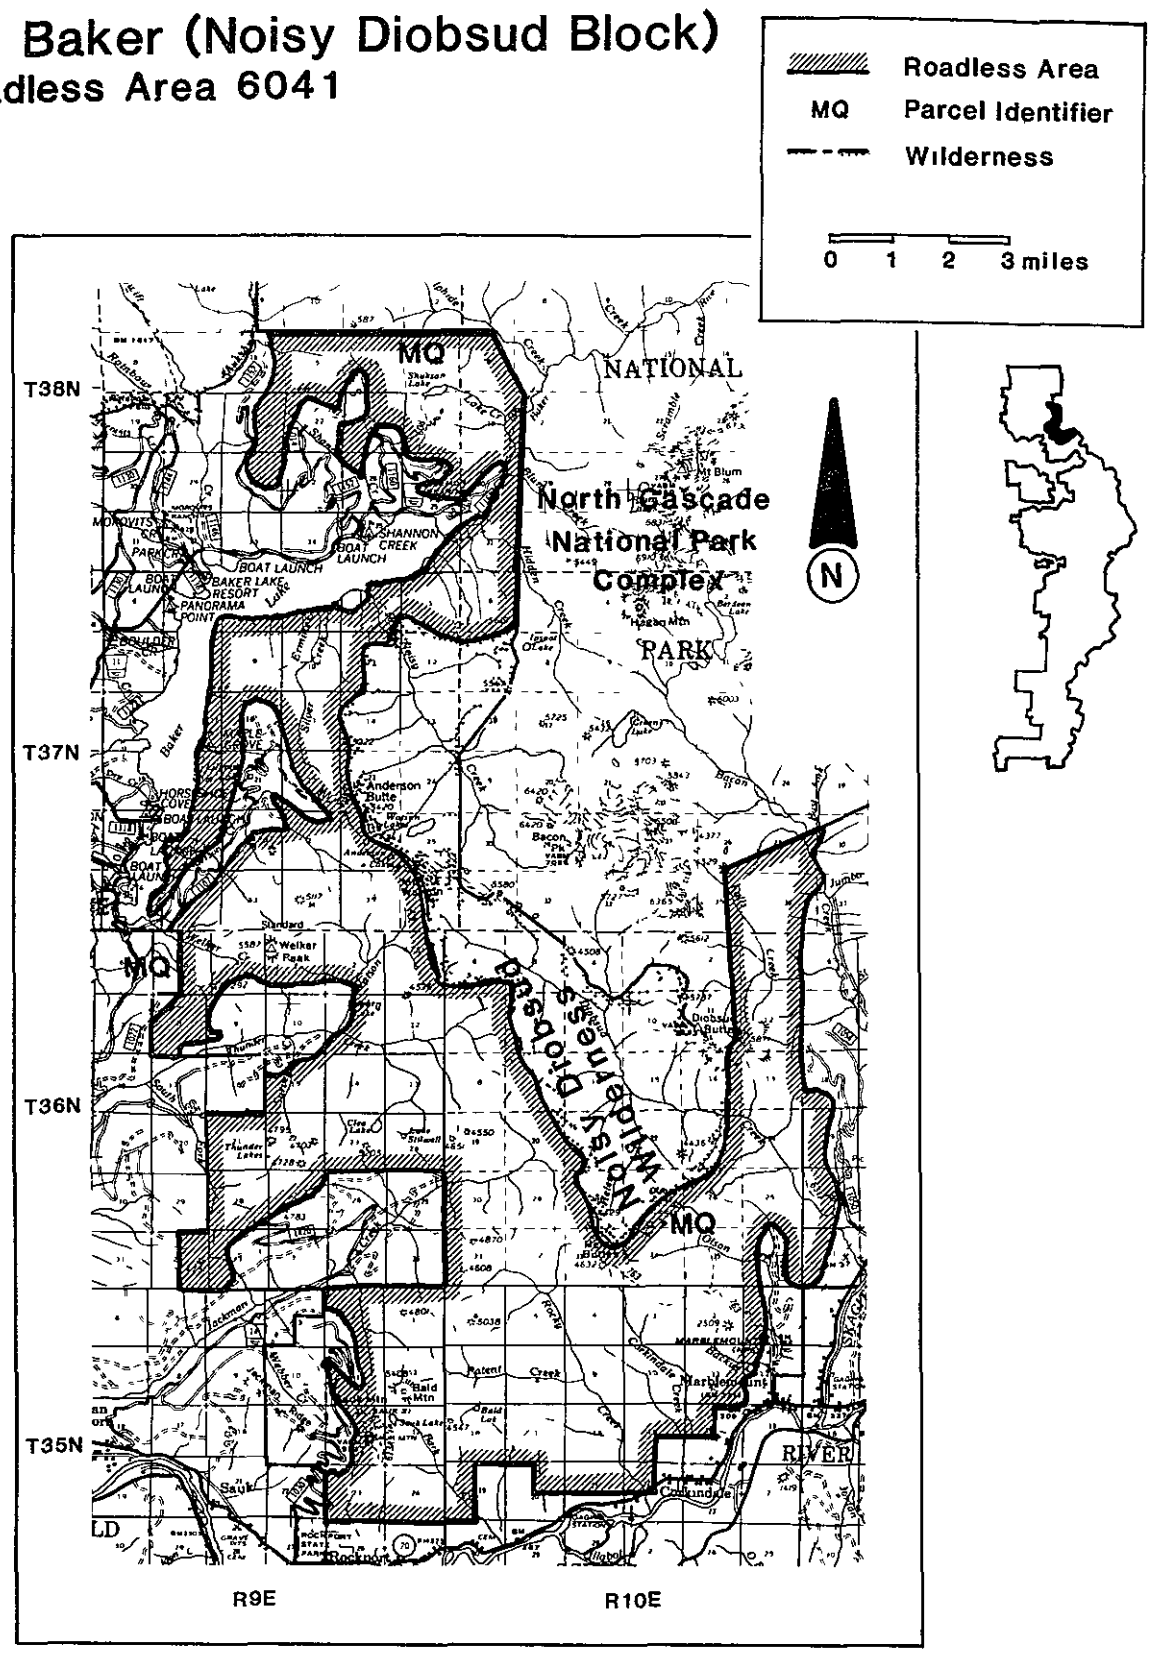
Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns about 10% of the area to semi-primitive motorized recreation and 40% of the area to timber management. Alternatives C and G-Modified will maintain the majority of the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained. Alternative J (Preferred) will maintain approximately 70% of the area in a predominately roadless condition through the end of the fifth decade. Alternatives A, NC, B, H, and I will

maintain approximately one- half of the area in a predominately roadless condition at the end of the fifth decade.
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	5,235	4,367	3,427	54%
B (RPA)	5,235	4,245	2,922	46%
C	6,228	6,076	5,934	93%
G-Mod.	6,024	5,870	5,509	86%
H	5,238	4,152	3,116	49%
I	5,196	4,148	2,739	43%
J (Pref).	5,736	5,274	4,591	72%

Mt. Baker (Noisy Diobsud Block)
Roadless Area 6041



MT. BAKER (NOISY-DIOBSUD BLOCK) **Roadless Area 6041 (MQ)**

The Mt. Baker RARE II area originally contained 271,900 acres. Of this amount, 117,528 acres were legislated Mt Baker Wilderness and 14,133 acres were legislated Noisy-Diobsud Wilderness. Remaining parcels of the RARE II Mt. Baker Roadless Area consist of 126,201 acres. This area was divided for ease of analysis into five blocks: Canyon Creek, Mt. Baker North, Mt. Baker West, Mt. Baker South, and Noisy-Diobsud. The following presents analysis of the Noisy-Diobsud Block.

This roadless area block consists of one parcel totaling 50,367 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6041 to nonwilderness uses.

Between 1982 and 1985, three timber sales were sold under contract within this roadless area block: Scarface, Shan, and 3-Mile Sales These sales removed 3,252 acres from roadless status The Bacon Rind Timber Sale (1988) and the Silvertone-Welker Timber Sale (1987) removed 1,035 acres within the area from roadless status. The following shows the disposition of acres within the Mt. Baker, Noisy-Diobsud Block, roadless area:

Mt. Baker (Noisy-Diobsud Block)	**Net Acres**
1984 RARE II	54,654
updated 1988	50,367
Change	**- 4,287**

OVERVIEW

This parcel is located north and east of Concrete, Washington in portions of Whatcom and Skagit Counties. For 35 miles it borders on North Cascades National Park and the Noisy-Diobsud Wilderness. The area is widespread, extending around Baker Lake to the north, and south and west to the Forest boundary. The entire area drains into the Skagit and Baker Rivers.

Several roads provide access, including the East Shannon Creek Road (#1160), Anderson Road (#1107), Jackman-Thunder Road (#14), Sauk Mountain Road (#1030), Thunder Lakes Road (#1420), Olson Creek Road (#1040), Diobsud Creek Road (#1050), and Bacon Creek Road (#1060)

Drainages include the Baker River system and the Diobsud, Olson, Corkindale, and Rocky Creek drainages (which flow south and east into the Skagit River). The terrain is rugged, with steep slopes and numerous ridges dissected by small streams. Elevation ranges from 500 feet to over 6,200 feet at the summit of Mt Watson. Other peaks include Welker Peak (5,587 feet), Sauk Mountain (5,537 feet), Bald Mountain (5,408 feet), and Diobsud Buttes (5,871 feet).

The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at higher elevations of the forested range (4,000-5,500 feet). Soils are variable, with steep and/or unstable areas occurring adjacent to many of the sideslope draws and stream channels.

There is a variety of recreational use, particularly in the vicinity of the Anderson-Watson Lake Trail (#611), the Sauk Mountain Trail (#613), and at several small lakes.

Important habitat is provided for a variety of wildlife species, including bald eagles, peregrine falcons, and mountain goats.

WILDERNESS CAPABILITY

Manageability and Boundaries: Most of this large parcel would be manageable as wilderness Some boundaries, particularly those in close proximity to existing roads, may be difficult to locate on the ground due to lack of definable features. The portion north of Baker River would be relatively easy to manage as wilderness due to its rugged topography and trail access. It would be very compatible with adjoining segments of Wilderness and National Park. It provides a logical extension of the Noisy-Diobsud Wilderness.

Natural Integrity and Appearance: Much of this parcel is visible from either Baker Lake or the North Cascades Highway (S.R. 20). It is free from disturbance except for trails and dispersed campsites. Adjacent clearcuts may be seen from ridgetops Location adjacent to the National Park and existing wilderness has aided in the long term continuation of ecological processes that are free of disturbances.

Opportunities For Solitude: Opportunities for solitude are many and greatly increase as one moves away from existing road systems. Portions situated away from the immediate vicinity of Baker Lake receive little recreation use.

Opportunities For Primitive Recreation: There are excellent opportunities for primitive recreation, including camping, hunting, fishing, mountaineering, ski touring, cross-country hiking, and photography.

Challenging Experiences: There are many excellent opportunities for challenging experiences in hiking, mountaineering, hunting, and fishing.

Special Features: Prominent peaks include Welker Peak, Bald Mountain, Diobsud Buttes, and Sauk Mountain

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: This extensive parcel has a large variety of recreational use associated with peaks, small lakes, and cultural attractions. Principal recreation activities center around Baker Lake,Anderson-Watson Lakes (Trail #611) and Sauk Mountain. The Sauk Mountain Trail #613 provides access to Sauk Lake and Sauk Mountain which are destinations for many hikers. This peak provides excellent views of the Skagit Wild and Scenic River. Other trails include: the Upper Baker Trail #606 at the north end of Baker Lake providing access into the National Park, the East Bank Trail #610 along the east side of Baker Lake provides a low elevation, year long recreation opportunity; the Shuksan Lake Trail #610, a popular climbing route to Mt. Shuksan; and the Cow Heaven Trail #763 south of Olson Creek.

There is a non-system trail to Welker Peak. Clear Lake receives moderate use, primarily for fishing. Other small lakes in the area (Shuksan, Thunder, Stillwell, Bald, Edgar) receive light use.

Hunting is heavy in the fall. Stream fishing in lower Noisy Creek is a low-to-moderate use activity.

Summary Table - Mt. Baker (Noisy-Diobsud Block) #6041 (MQ)

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	50,367

Bald eagle habitat (nests, forage, roost area)	Acres	1,604
Locatable Mineral Development Potential		
High	Acres	0
Moderate	Acres	0
Low	Acres	50,367
Claims	# of	73
Leasable Energy Minerals (Moderate Potential)		
Geothermal	Acres	19,555

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Fish/Wildlife: Special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten.

There is a bald eagle nest adjacent to salmon rearing ponds at the north end of the parcel. The adults breeding at this nest site forage along the southeast shore of Baker Lake and up Baker River. The undisturbed lakeshore and river habitat are important to the survival of this breeding pair.

There is also excellent peregrine falcon habitat and recently there have been several sightings of this endangered species here. There may be nesting on the cliffs above Baker Lake. These cliffs along Baker River near the rearing ponds are also critical goat winter range for 40 or more mountain goats.

The west-facing shoreline of Baker Lake provides excellent deer winter range for large herds of black-tail deer The lower slopes are mostly covered with old growth forest which is preferred winter forage and cover. The north-facing lower slopes along Baker Lake may also provide winter range. Many of the small streams which flow into Baker Lake provide spawning and rearing habitat for anadromous trout and salmon, as well as resident trout. The steep southwest-facing slopes above Welker Creek (below 3,500 feet) are important winter range for the Welker Peak mountain goat herd.

Forested slopes directly above the Skagit River are used by bald eagles as winter communal night roosts. This is critical habitat for this threatened species.

The lower portions of Barr, Rocky and Corkindale Creeks are used by spawning coho, chum, steelhead and pink salmon. The lower south-facing slopes provide excellent deer winter range

The area in the vicinity of Diobsud Creek was at one time known to be used by nesting peregrine falcons. Important mountain goat winter range lies below Diobsud Buttes on the steep south-facing bluffs above Diobsud Creek. Diobsud Creek is also one of the most important spawning and rearing tributaries in the Skagit River drainage

The Sauk Mountain portion is particularly rich in wildlife. The large open *meadows and forested slopes are known to be heavily used by black bear,* black-tailed deer, cougar, and mountain goats.

Water: The entire nine-mile eastern shoreline of Baker Lake reservoir borders this parcel. Tributaries to the Baker River system include Shannon Creek, lower Noisy Creek, Silver Creek, Anderson Creek, Welker Creek, and Thunder Creek. There are also several creeks that flow directly into the Skagit River, including Jackman Creek, Barr Creek, Rocky Creek, Corkindale Creek, Olson Creek, Diobsud Creek, and Falls Creek Several small lakes are also located within this parcel.

Livestock Operations: The head of Rocky Creek was at one time designated the Cow Heaven cattle allotment. The permittee discontinued this use several years ago, and the area is no longer used for livestock operations. The Cow Heaven area is accessed by the Cow Heaven Trail #763

Ecology: Most of this parcel is forested with species typical of the West Cascades, including cedar, Douglas-fir, true firs, and hemlock. Subalpine vegetation occurs at higher elevations and there are alpine meadows and talus slopes associated with several peaks. Most of the portion north of Baker River (except lower Shannon Creek) is steep and rugged, supporting subalpine vegetation. The portion between Noisy and Hidden Creeks is steep and non-commercial forest.

The portion south and east of Jackman Creek includes commercial forest interspersed with non-commercial sub-alpine vegetation. Upper Rocky Creek and Olson Creek are characterized by steep and rugged terrain supporting non-commercial sub-alpine vegetation.

Timber: Approximately half of this parcel is forested with commercial timber. There are major areas of undeveloped forest in the Thunder, Jackman, Patent, Corkindale, and Olson Creek drainages.

Minerals/Oil and Gas: The geology of the area is dominated by Permian sedimentary and volcanic rocks, mid-Jurassic metamorphics and glacial drift of quaternary age. Even though the area has few reported mineral occurrences, which are limited to limestone and diatomite, and is not known to contain mineral resources of significant interest, it has had 73 mining claims located within it. A large portion of the western part of the area is classified "prospectively valuable" for geothermal resources. The area has not been studied in detail by the U.S. Geological Survey and Bureau of Mines; but based upon available data it appears that, except for geothermal, the area has a relatively low potential for the occurrence of mineral resources.

Cultural: None known.

Land Use Authorizations: There are no special land authorizations. Several small hydro projects are under study on Noisy, Anderson and Rocky Creeks.

Non-Federal Lands: There are approximately 2,400 acres of non-Federal lands here including 640 acres of private land in Sections 4 and 5 (T.35N., R.10E.) and about 60 acres of State land in Section 16 (T.35N., R.10E.) have been helicopter logged. Congress recently appropriated funds for acquisition of these private lands.

Most of the non-Federal land outside and adjacent to the west and southern borders have been logged over or developed.

Fire: The upper Baker Lake basin, in the vicinity of Shannon and Noisy Creeks, has the highest incidence of lightning and human-caused fires on the Forest. Fires have generally been limited to under 350 acres. Most of the parcel east of Baker Lake has burned in large fires over the past 200 years.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The parcel is adjacent to North Cascades National Park and the Noisy-Diobsud Wilderness. The small communities of Marblemount, Rockport, and Concrete are located just a few miles to the south along S.R. 20. Larger population centers include Sedro Woolley (35-40 miles away), Bellingham (55-60 miles away), Seattle (110 miles away) and Vancouver, B.C. (110 miles away).

Public Interest: This parcel was identified as part of the Diobsud roadless area #504 during RARE I. It was then inventoried as part of the Mt. Baker roadless area #6041 during RARE II. Portions of these acres were subsequently designated in the Noisy-Diobsud Wilderness in 1984. The Anderson-Watson Lakes area and the east side of Baker Lake has been of high interest to environmental groups in the past. This area is also of interest for peregrine falcon, osprey, and bald eagle habitat. The Nature Conservancy and Washington State Wildlife Department have expressed interest in preserving old growth for bald eagle roosts above the Skagit River.

Mt. Baker (Noisy-Diobsud Block)
Appendix C

Following release of the DEIS and Proposed Forest Plan, public comments were received concerning the Noisy-Diobsud Roadless Area, as well as specific geographic features within the area and its adjacency to other areas.

The Noisy-Diobsud Roadless Area was mentioned 468 times. Responses said to keep the area roadless (125), preserve the forest ecosystem (64), protect the area from harvest (63), protect the old growth ecosystem (42), protect wildlife habitat (24), and protect the area for recreation (16). The majority of the remaining comments favored management of this area for recreation and the protection of wildlife habitat. Five comments wanted the area made a top priority for timber harvest. One comment said to keep the area trailless.

Areas adjacent to North Cascades National Park were mentioned 71 times. Comments favored keeping the area roadless (11), protecting it from timber harvest (9), protecting it for recreation (5), preserving the forest ecosystem (4), protecting the old growth ecosystem (4), and protecting visuals. Most of the other comments wanted the area managed for recreation. One comment said the area should be added to the National Park System. One favored making the area a top priority for timber harvest. 1/

Silver Creek was mentioned 108 times. Responses said to keep the area roadless (28), protect it from harvest (19), protect the old growth ecosystem (11), and preserve the forest ecosystem (11). The majority of the other comments favored managing the area for recreation, wildlife habitat and visual quality. One comment said to build more roads in the area.

Thunder Creek was mentioned 260 times. Comments favored protecting the area from harvest (50), keeping it roadless (45), adding it to wilderness (16), protecting wildlife habitat (14), protecting the old growth ecosystem (14), preserving the forest ecosystem (13), avoiding the building of roads on unstable soils (13), and protecting fisheries (12). Most of the remaining comments said to manage the area for recreation and wildlife habitat. Three comments favored making the area a top priority for harvest. Two comments wanted more roads built in the area.

Falls Creek was mentioned 86 times. Comments said to protect old growth ecosystems (38), preserve the forest ecosystem (8), protect the trail from logging (7), and protect the area from harvest (7). Five comments wanted the are to remain roadless. Most of the other responses said to manage the area for recreation and wildlife habitat. One comment said to add this area to the National Park System.

Rocky Creek was mentioned 22 times. Responses said to protect the area from harvest (3), keep it roadless (3), build more roads (2), and no new road construction (2). The majority of the other responses favored managing the area for recreation and wildlife habitat. One comment said to cut the old growth.

Shukson Lake was mentioned 8 times. Two comments said to add this area to the National Park System, two said to designate the area MA 1AB (primitive/semi-primitive nonmotorized), and two favored not improving the existing trail system.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be

tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The following table displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

MT. BAKER (Noisy-Diobsud BLOCK)

Significant Effects

Recreation: The majority of the current recreation opportunities will not be significantly affected by any of the alternatives. Alternatives C, G-Modified and J (Preferred) will leave the area effectively roadless through the end of the fifth decade. Alternative I assigns approximately one-quarter of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B and I allocate the greatest amount of the area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives C, G-Modified and J (Preferred) allocate the least, but effectively protect the most habitat through other more restrictive allocations.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of potential development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of potential development activity.

Timber: Alternatives A, NC, B and I will allocate the greatest amount of area to timber management. Alternatives C and J (Preferred) will allocate the least. None of the alternatives will significantly affect the timber resource, as potential development activities will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B, H and I will provide a slightly higher amount of roaded access through the area, and could be used for mineral exploration and development.

Cultural: Alternatives A, NC, B, H and I will have the greatest potential to adversely impact cultural resources within the area, due to development activities. Alternatives C, G-Modified and J (Preferred) will have the least potential. Valuable sites will be protected via avoidance or preserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease in the area.

Wilderness Potential: All alternatives, with the exception of I, A and NC, assign over 90 percent of this area to management prescriptions compatible with preserving its roadless character. The wilderness potential of a great portion of the area will be maintained by Alternatives C, G-Mod., and J (Pref). Alternative I assigns more than half the area to timber management and semi-primitive motorized recreation prescriptions.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	46,452	43,014	39,012	77%
B (RPA)	47,643	45,015	42,102	84%
C	50,250	50,166	49,982	99%
G-Mod.	50,151	49,995	49,740	99%
H	48,393	46,025	43,590	87%
I	47,598	44,662	40,728	81%
J (Pref)	50,019	49,673	49,293	98%

OAKES PEAK **Roadless Area 6043**

This roadless area originally consisted of 1,200 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6043 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation. This area was increased in 1988 by 404 acres, due to a mapping discrepancy. The following shows the disposition of acres within the Oakes Peak roadless area:

Oakes Peak	Net Acres
1984 RARE II	1,200
updated 1988	1,604
Change	**+ 404**

OVERVIEW

This parcel is located approximately 8 miles north of Marblemount, in portions of Skagit and Whatcom Counties. The area is drained by Bacon Creek, which is a tributary of the Skagit River. It borders North Cascades National Park. Access to the area is by the Bacon Creek Road (#1060) and the Oakes Peak Road (#1062).

The parcel includes Jumbo Creek, Oakes Creek, and other unnamed tributaries to Bacon Creek. Terrain is steep, rugged, and dissected by streams. Elevation ranges from 1,200 feet near Bacon Creek to 5,696 feet at the summit of Oakes Peak. Vegetation is typical of the west slope of the Cascades, and includes Douglas-fir, Pacific silver fir, western hemlock, and mountain hemlock.

WILDERNESS CAPABILITY

Manageability and Boundaries: This parcel is very small in size. Boundary locations would be difficult due to lack of definable characteristics on the ground.

Natural Integrity and Appearance: It is steep, natural appearing, and heavily timbered.

Opportunities For Solitude: There are few opportunities for solitude until one enters the National Park.

Opportunities For Primitive Recreation: There are few opportunities for primitive recreation other than hunting.

Challenging Experiences: There is limited opportunity for challenging experiences; Oakes Peak provides a moderately challenging climb.

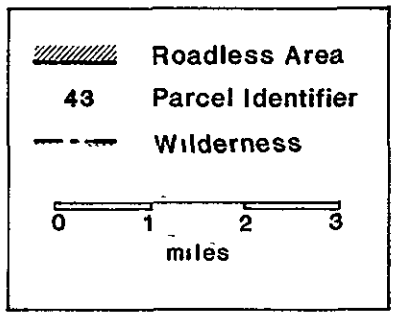
Special Features: Oakes Peak is the most prominent feature in this roadless area.

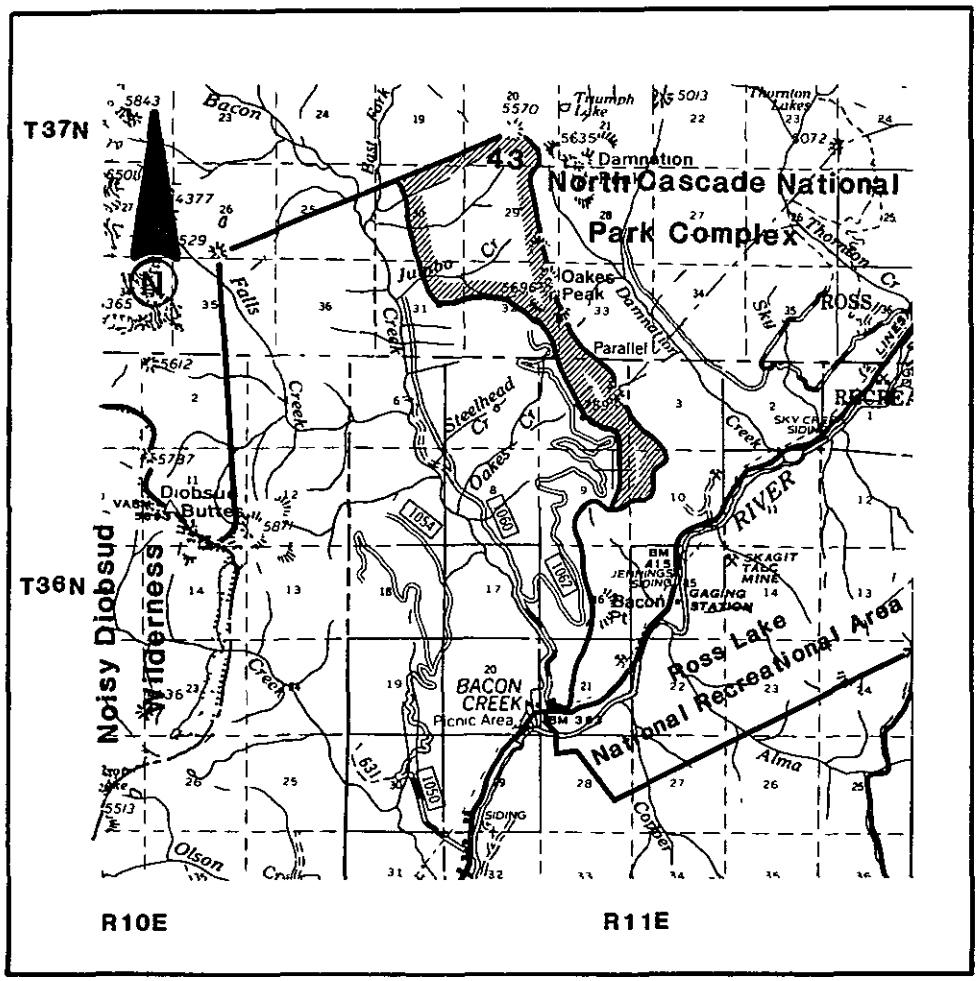
AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Oakes Peak

Roadless Area 6043





Summary Table - Oakes Peak #6043

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	1,604
Primitive/Semi-Primitive Recreation ROS	Acres	696
Timber		
Tentatively suitable	Acres	591
Tentatively suitable inaccessible	Acres	316
Tentatively suitable standing volume	M bdft	23,124
"Old Growth", Total Acres	Acres	506
0-2,500 Feet Elevation	Acres	0
2,500-4,000 Feet Elevation	Acres	359
4,000 + Feet Elevation	Acres	147
Management Indicator Species (MIS)		
Spotted owl MR	Acres	0
Pileated woodpecker and pine marten MR	Acres	0
Elk-deer winter range	Acres	1,562
Goat habitat MR	Acres	0
Bald eagle habitat (nests, forage, roost area)	Acres	0
Locatable Mineral Development Potential		
High	Acres	0
Moderate	Acres	0
Low	Acres	1,604
Claims	# of	3
Leasable Energy Minerals	Acres	0

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: There is very little recreational use due to steep, hazardous topography. The most common use is hunting.

Wildlife: Special wildlife habitats include habitat for deer and elk winter range. The steep north-west slopes of Jumbo Creek below 4,000 feet may be important goat winter range.

Water: Drainages include Jumbo Creek, Oakes Creek, and other unnamed tributaries to Bacon Creek, which drains into the Skagit River.

Livestock Operations: None.

Ecology: There is little commercial forest. Much of the upper area is steep and rugged, supporting sub-alpine vegetation.

Timber: Most of the commercial forest, 37% of the area is classified as tentatively suitable for timber management, would have to be harvested by helicopter. There has been considerable logging activity in the vicinity.

Minerals/Oil and Gas: The geology of the area is dominated by Tertiary granitic rocks. The area has no reported mineral resource occurrences, but 3 mining claims have been located within it or on immediately adjacent lands. The area is not classified "prospectively valuable" for any of the leasable mineral commodities, nor is it encumbered by any leases or pending lease applications. The mineral resources of the adjacent North Cascades National Park were inventoried by the U.S. Geological Survey and Bureau of Mines. Based upon their sampling of sediment along Bacon Creek, the copper and zinc content of the sediment was low and the molybdenum, lead, gold, and silver content was negligible. Considering the results of their sampling and other available data it appears that the area has a relatively low potential for the occurrence of mineral resources.

Cultural Resources: None.

Land Use Authorizations: None.

Non-Federal Lands: None.

Fire: There is a low incidence of fire.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to other Designated Wilderness and to Population Centers: This parcel is adjacent to North Cascades National Park, and Noisy-Diobsud Wilderness lies a few miles to the west. Several communities along the North Cascade Highway (S.R. 20) are located 15-30 miles away. Larger population centers include Bellingham (70 miles away), Sedro Woolley (50 miles away), and Seattle (120 miles away).

Public Interest: This parcel was not identified in RARE I. It was inventoried as roadless in the RARE II process (#6043). Public comments were few for this parcel during the RARE II process.

Following release of the DEIS and Proposed Forest Plan, Oakes Peak was mentioned 12 times in the public comments received. Two comments wanted the area made a top priority for timber harvest. Most of the remaining comments said to manage the area for recreation and wildlife habitat. 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Areas adjacent to North Cascades National Park were mentioned 71 times. Comments favored keeping the area roadless (11), protecting it from timber harvest (9), protecting it for recreation (5), preserving the forest ecosystem (4), protecting the old growth ecosystem (4), and protecting visuals. Most of the other comments wanted the area managed for recreation. One comment said the area should be added to the National Park System. One favored making the area a top priority for timber harvest.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

OAKES PEAK

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp Rec	971						
1B SPNM		654	1,583	1,119	992		950
1C SPM						908	
2B Midgrd.			21		570		591
14 D&E Enhanc		105		42	42		63
17 Timber	633	506		105		696	
19 Mtn. Hemlk		337		337			

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative I will allocate approximately one-half the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives, due to the low level of potential development activity.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of potential development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives A, NC, B and I allocate the most area to timber management. Alternatives C, H and J (Preferred) allocate the least. None of the alternatives will significantly affect the timber resource, due to the low level of planned development activity.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant affect on cultural resources, due to the low level of development activity planned.

Land Use Authorizations: None of the alternatives will have a significant affect on land use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns the area to semi-primitive motorized recreation and timber management prescriptions. All alternatives will maintain the area in a primarily roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	**Decade 1**	**Decade 2**	**Decade 5**	**Remaining**
A (No Act)	1,472	1,472	1,472	92%
B (RPA)	1,562	1,562	1,562	97%
C	1,604	1,604	1,604	100%
G-Mod.	1,604	1,604	1,604	100%
H	1,604	1,604	1,604	100%
I	1,577	1,577	1,577	98%
J (Pref)	1,604	1,604	1,604	100%

ALMA COPPER **Roadless Area 6044**

This roadless area originally consisted of 8,300 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6044 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation. This area was reduced by 107 acres in 1988 due to a mapping discrepancy. The following shows the disposition of acres within the Alma Copper roadless area:

Alma Copper	Net Acres
1984 RARE II	8,300
updated 1988	8,193
Change	**- 107**

OVERVIEW

This parcel lies northeast of Marblemount, adjacent to Ross Lake National Recreation Area and North Cascades National Park and extends south to the Forest boundary. To the south and west are the Cascade and Skagit Rivers. The nearest access is via the Cascade River Road to the south, and S.R. 20 to the west. Although close to main travel routes, access is difficult due to rugged terrain and relative lack of trails.

In the northern portion, Alma Creek and Copper Creek drain into the Skagit River, while the southern portion is drained by the Cascade River. The terrain is rugged, with steep slopes and finger ridges dissected by small drainages. Elevations range from 1,000 feet near the Skagit River to 5,719 feet at the summit of Lookout Mountain.

The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,500 feet). Soils vary, with steep, shallow residual soils along the south and west slopes of Lookout Mountain and adjacent to stream channels in upper Alma and Copper Creeks.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries could be easily identified since the area is located between the National Park, National Forest, State and private lands. The area could be easily managed as wilderness since it is relatively inaccessible with little risk of trespass from nonconforming uses.

Natural Integrity and Appearance: The western portion is readily visible from the North Cascades Highway (S.R. 20). It is also visible from Lookout Mountain. The area is natural in appearance, except for a hiking trail and a fire lookout. There have been heavy impacts by fire. The relative isolation due to topography and location adjacent to the National Park ensure continued ecological processes unhindered by the mans impacts.

Opportunities For Solitude: Opportunities for solitude are readily available because of proximity to the National Park and due to the rugged terrain. Encounters with other users are unlikely.

Opportunities For Primitive Recreation: Steep, rugged terrain and dense vegetation make any recreational activity an arduous undertaking. Lack of trails provide the opportunity for cross-country travel with a high degree of self-reliance.

Challenging Experiences: Steep rugged slopes provide challenging cross-country travel, although the terrain coupled with dense vegetation makes such use unlikely.

Special Features: An old fire lookout is located on Hidden Lake peak.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Alma Copper #6044

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	8,193
Primitive/Semi-Primitive Recreation ROS	Acres	7,328
Timber

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Recreation use is light, except for moderate use of the Lookout Mountain Trail #743 which accesses both an old Forest Service fire lookout, and the Monogram Lake portion of North Cascades National Park. Steep, rugged terrain and dense vegetation make the area inaccessible, severely restrict recreation use elsewhere.

Fish/Wildlife: Special wildlife habitats include habitat for spotted owl, pine marten and mountain goat. The south-facing slopes below 3,000 feet near Lookout Creek provide deer winter range. The entire area is rich in game such as black-tailed deer, black bear, and grouse.

Water: Alma Creek and Copper Creek flow northwest into the Skagit River. Taylor Creek, Day Creek, Lookout Creek and Monogram Creek flow south into the Cascade River.

Livestock Operations: None.

Ecology: Vegetation is typical of the west slope of the Cascades, including cedar, Douglas-fir, true firs, hemlock, and high elevation, alpine meadows.

Timber: The Alma and Copper Creek basins are heavily forested and very steep at lower elevations, with potential access expected to be difficult. Access for timber management would require use of helicopters. Approximately 50 present of the area is classified as tentatively suitable.

Minerals/Oil & Gas: The geology of this area is dominated by contact zones between Jurassic metamorphic rocks and Paleozoic intrusive rocks. The area has no reported mineral occurrences of interest, and no mining claims have been recorded for the area. The area is not classified "prospectively valuable" for any of the leasable minerals, nor is it encumbered by any leases or pending lease applications. The area has not been studied by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears that the area has a relatively low potential for the occurrence of mineral resources.

Cultural: There are sites important for American Indian religious and cultural use.

Land Use Authorizations: There are no special land authorizations.

Non-Federal Lands: There are 160 acres of State land in Section 3, which have been completely logged.

Fire: Fire occurrence is low to moderate; most are lightning-caused. Approximately 80 acres burned in the mid-1970's. There is evidence of larger fires at lower elevations within the past 100 years.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to other Designated Wilderness and to Population Centers: The parcel adjoins Ross Lake National Recreation Area and North Cascades National Park. Glacier Peak Wilderness is six miles to the south. It lies within a few miles of cross-state Highway 20. The small community of Marblemount is a few miles to the west; large population centers are 50-150 miles away.

Public Interest: This parcel was identified in RARE I as roadless area #505. It was also inventoried as roadless in the RARE II process (#6044). Following release of the DEIS and Proposed Forest Plan, no public comments were received regarding the Alma Copper Roadless Area. Comments were received regarding specific geographic sites and features included in the area, as well as on its proximity to other areas of interest.

The Copper Creek Basin was mentioned 228 times. Comments favored protecting the area from harvest (68), preserving the forest ecosystem (41), keeping the area roadless (34), and protecting the old growth ecosystem (12). Five responses said to make this area a top priority for timber harvest; four said to build more roads. Two wanted the area managed for multiple uses; one said to cut the old growth. The majority of the remaining comments said to manage the area for recreation and wildlife habitat. 1/

Alma Creek was mentioned 216 times. Responses said to protect the area from harvest (64), preserve the forest ecosystem (39), keep the area roadless (33), protect visuals (12), and protect the old growth ecosystem (10). The majority of the remaining comments favored management of the area for recreation and wildlife habitat. Five responses said to make this area a top priority for timber harvest; two wanted more roads built. Two comments said to add this area to the National Park System.

Lookout Mountain was mentioned 184 times. Comments favored protecting the area from logging (38), protecting it from harvest (25), keeping it roadless (25), avoiding road construction that will bisect the trail system (18), preserving old growth (14), and protecting the old growth ecosystem (12). Most of the other comments favored managing the area for recreation and the protection of wildlife habitat and scenic quality. Two comments said to make this area a top priority for timber harvest. One favored adding the area to the National Park System.

Areas adjacent to North Cascades National Park were mentioned 71 times. Comments favored keeping the area roadless (11), protecting it from timber harvest (9), protecting it for recreation (5), preserving the forest ecosystem (4), protecting the old growth ecosystem (4), and protecting visuals. Most of the other comments wanted the area managed for recreation. One comment said the area should be added to the National Park System. One favored making the area a top priority for timber harvest.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The following table displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

ALMA COPPER

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	4,012						
1A Prim.			675	675			
1B SPNM		527	7,454	7,496	5,385		6,082
1C SPM						3,357	
1D RN					21		42
2A Foregrd.			42				
2B Midgrd.					1,626		1,710
11 O-G Hab.	718	147	21	21	147	168	84
12 Mature O-G	126	253			253		274
14 D&E Enhanc		126				401	
15 Goat MR		907			84	337	
17 Timber	3,336	3,991			485	3,928	
19 Mtn. Hemlk		2,238			190		

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative I will assign approximately 40% of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B and I allocate the greatest area to mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives C and G-Modified assign the least.

Water: *There are no adverse effects to the water resource of this area* associated with any of the alternatives, due to the low level of proposed development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives C, G-Modified and J (Preferred) will have the least affect on the existing timber resource, as they do not allocate any area to timber management. Alternatives A, NC, B and I allocate the greatest amount of area to this designation. None of the alternatives will have a significant affect on the timber resource, due to the low level of proposed development activity.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant affect on the cultural resources of the area, due to the low level of planned development activity.

Land Use Authorizations: None of the alternatives will have a significant affect on land use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

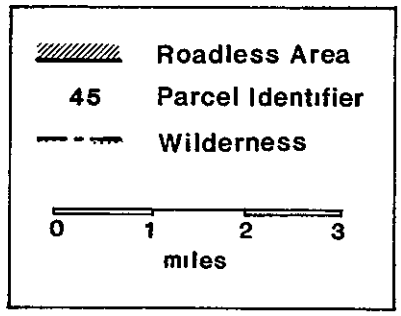
Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns 40% Of the area to semi-primitive motorized recreation and 48% of the area to timber management. Alternatives C, G-Modified and J (Preferred) will maintain the area in a totally roadless condition through the end of the fifth decade. The wilderness potential will be maintain.

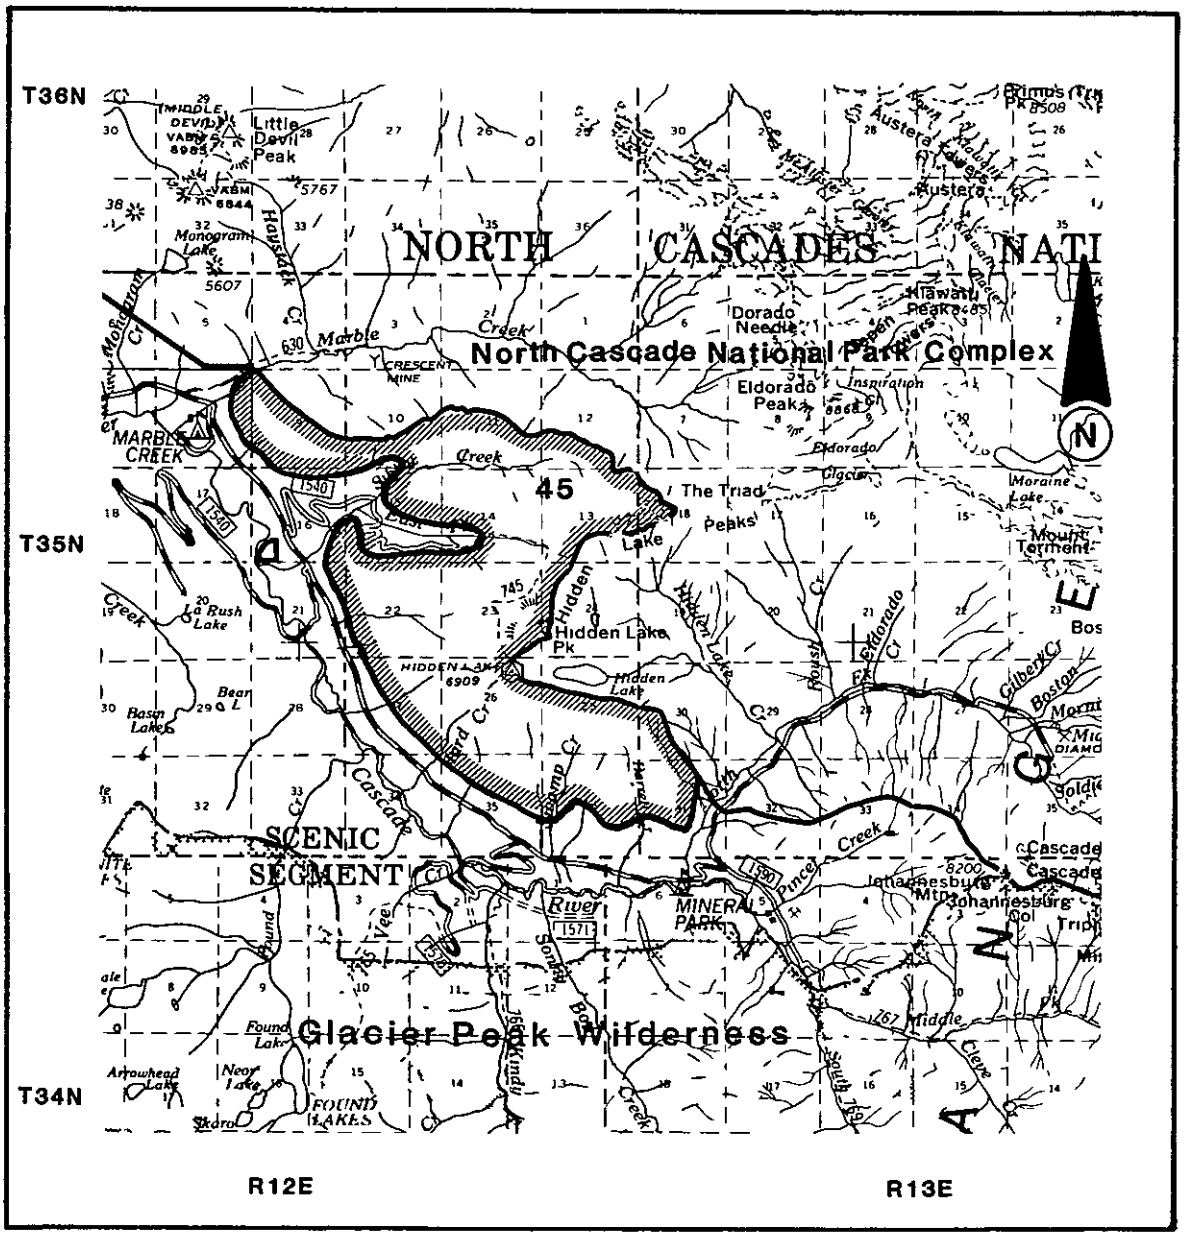
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	7,422	7,320	7,133	87%
B (RPA)	7,758	7,658	7,526	92%
C	8,184	8,170	8,162	100%
G-Mod.	8,193	8,193	8,193	100%
H	8,049	7,961	7,788	95%
I	7,845	7,743	7,546	92%
J (Pref).	8,193	8,193	8,193	100%

Hidden Lake

Roadless Area 6045





HIDDEN LAKE **Roadless Area 6045**

This roadless area originally consisted of 7,000 acres. It was originally inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6045 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation.

In 1983, portions of the Kincade Timber Sale were sold under contract within this roadless area block. The sale removed 73 acres from roadless status. In 1988, the area was reduced by 275 acres due to a mapping discrepancy. The following shows the disposition of acres within the Hidden Lake roadless area:

Hidden Lake	**Net Acres**
1984 RARE II	7,000
updated 1988	6,652
Change	**- 348**

OVERVIEW

This parcel is located approximately 9 miles east of Marblemount, between the North Cascades National Park and the Cascade River Road. Its namesake is located to the east, just inside the Park boundary. Included are several tributaries of the Cascade River.

Road access is via the Cascade River Road and the Sibley Creek Road (#1540).

Drainages include the headwaters of Sibley Creek, Hard Creek, and Swamp Creek. On the south is the Cascade River designated under the Wild and Scenic Rivers Act. The terrain is rugged, with steep slopes and dissecting drainages. Elevation ranges from about 1,100 feet to over 6,900 feet at Hidden Lake Peak.

The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,000 feet elevation).

Soils are variable, with steep and shallow residual soils on the sideslopes northeast of the Cascade River and unstable soils adjacent to Sibley Creek.

The Hidden Lake Peak Trail #745 is one of the most popular trails in the North Cascades, ending at a lookout with a panoramic view of the National Forest and North Cascades National Park.

The Cascade River area provides important habitat for wintering bald eagles.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries to the west may be difficult to locate on the ground. Management of some portions would be complicated due to proximity to existing roads.

Natural Integrity and Appearance: Elevation rises rapidly to high mountain meadows, glacially-scarred rock and small ponds.

Opportunities For Solitude: Opportunities for solitude are reduced due to the amount of recreational trail use associated with the lake and lookout. This opportunity is best north of Sibley Creek where terrain is rugged and brushy.

Opportunities For Primitive Recreation: There are excellent opportunities for primitive recreation, including hiking, hunting, mountaineering, and photography.

Challenging Experiences: Unusually challenging experiences are limited. Most use of the area is used for hiking and dispersed hunting.

Special Features: The Hidden Lake Peak lookout (which may have potential for historic register status) is an intact structure being maintained by a volunteer group. Both the trail and lookout provide panoramic views of surrounding peaks.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Hidden Lake #6045

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	6,652
Primitive/Semi-Primitive Recreation ROS	Acres	5,215

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Most recreation use is associated with the Hidden Lake Peak Trail #745, primarily hiking and climbing. Hunting is popular in the trailless high country.

Fish/Wildlife: This parcel along the Cascade River is used by as many as forty bald eagles in years when food resources on the Skagit River are scarce They feed on coho, chinook, and steelhead salmon which spawn in lower Sibley Creek, Marble Creek, and the smaller tributaries to the Cascade River.

The steep south-facing slopes above Sibley Creek and its east fork are known to be used by mountain goats as winter range. The south-facing slopes below Hidden Lake may be providing deer and goat winter range.

The old growth forested slopes above the Cascade River may be used by bald eagles as communal night roosts during the winter and as special wildlife habitat for spotted owl, pileated woodpecker and pine marten.

Water: This parcel includes the upper reaches of Sibley Creek, Hard Creek, and Swamp Creek.

Livestock Operations: None.

Ecology: Most of the parcel is forested with species typical of the west Cascades, including cedar, Douglas-fir, true firs, and hemlock. There are alpine meadows at higher elevations, and the portion north of Sibley Creek is generally non-forested, steep talus slopes. The northeast corner north of Hidden Lake Peak is heavily meadowed. Where Trail #745 crosses the east fork of Sibley Creek, there is a striking transition from metamorphic rocks supporting grassy-type flora to granitic rocks dominated by heather.

Timber: The lower elevations support commercial timber with only twenty-nine percent of the area classified as tentatively suitable.

Minerals/Oil and Gas: The geology of the area is dominated by Jurassic metamorphic rocks, Tertiary granitic rocks, and Quaternary aged glacial drift. Even though the area has no reported mineral resource occurrences of interest, it has 13 mining claims located within it. The area is not classified "prospectively valuable" for any of the leasable minerals, and it is not encumbered by any mineral leases or pending lease applications. Only a small part of the area has been studied by the U.S. Geological Survey and Bureau of Mines, and they have not identified the area as having a potential for the occurrence of mineral resources. However, adjacent areas on the south have been identified as having a high potential for the occurrence of base and precious metal resources. Based upon geologic inference, the subject area could have the same potential

Cultural Resources: Sites along Cascade River and other high-elevation sites are important for American Indian religious and cultural use.

Land Use Authorizations: There are no special land use authorizations.

Non-Federal Lands: None.

Fire: South facing slopes show evidence of considerable fire activity from mid-slope to timberline about 100 years ago. A fire burned the central portion of the parcel in the 1930's and 1940's.

Insect and Disease: There are no known insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The parcel adjoins North Cascades National Park. The small community of Marblemount is about 10 miles to the west. Bellingham is 65 miles away. Seattle and Vancouver, B.C. are each about 120 miles away.

Public Interest: This parcel was not identified during RARE I. It was inventoried as roadless in the RARE II process. The Fish and Wildlife Service is also interested in this parcel because of concern for bald eagle foraging and night roost spots along the Cascade River.

Following release of the DEIS and Proposed Forest Plan, public comments were received regarding Hidden Lake and, in a general sense, areas adjacent to North Cascades National Park

Hidden Lake was mentioned 204 times. Responses said to not log along the trail (33), keep the area roadless (27), avoid bisecting trails with new road construction (24), protect the area from harvest (17), preserve old growth (16) and no new road construction (15). The majority of the other comments favored managing the area for recreation, wildlife habitat and scenic quality. Four comments expressed the desire for this area to be made a top priority for timber harvest. 1/

Areas adjacent to North Cascades National Park were mentioned 71 times. Comments favored keeping the area roadless (11), protecting it from timber harvest (9), protecting it for recreation (5), preserving the forest ecosystem (4), protecting the old growth ecosystem (4), and protecting visuals. Most of the other comments wanted the area managed for recreation. One comment said the area should be added to the National Park System. One favored making the area a top priority for timber harvest.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The following table displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

HIDDEN LAKE

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	4,730

19 Mtn. Hemlk		1,964				316	

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives, due to the low level of planned development activity. Alternative I will allocate about one-half of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B, G-Modified and I allocate the greatest amount of area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives A, NC, C and J (Preferred) allocate the least.

Water: None of the alternatives will significantly affect the water resources of the area, due to the low level of development activity planned.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of development activity planned.

Timber: Alternatives A, NC, B and I will allocate the greatest area to timber management. Alternatives C and J (Preferred) will allocate the least. None of the alternatives will have a significant affect on the timber resource, as potential development activities would be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant affect on cultural resources, due to the minimal amount of development activity planned.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire in the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease in the area.

Wilderness Potential: All alternatives, with the exception of I, assigns the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns more than half the area to semi-primitive motorized recreation and timber management allocations. All alternatives will maintain the area in a primarily roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	*Undeveloped Acres* Decade 1	Decade 2	Decade 5	*Percent* Remaining
A (No Act)	6,397	6,355	6,319	95%
B (RPA)	6,562	6,528	6,501	98%
C	6,652	6,652	6,652	100%
G-Mod.	6,652	6,652	6,652	100%
H	6,652	6,652	6,652	100%
I	6,589	6,549	6,504	98%
J (Pref)	6,640	6,632	6,616	99%

GLACIER PEAK H Roadless Area H6031 (HA, HB)

This roadless area originally consisted of 12,483 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area H6031 to nonwilderness uses. In 1984, 3,109 acres from this area were designated as additions to Glacier Peak Wilderness by Congress as a result of the Washington Wilderness Legislation. Two parcels remain in roadless status.

In 1984, portions of the LaRush Timber Sale were sold under contract within this roadless area. The sale removed 1,286 acres from roadless status. In 1988, this area was reduced by 149 acres due to a mapping discrepancy. The following shows the disposition of acres within the Glacier Peak H roadless area:

Glacier Peak H	Net Acres
1984 RARE II	*12,483*
updated 1988	7,939
Change	**-4,544**

OVERVIEW

These parcels are located in the Cascade River watershed east of Marblemount. Southern portions are adjacent to the Glacier Peak Wilderness, and the Cascade River road is to the north. The eastern portion is adjacent to the North Cascades National Park.

Road access is from the north via the Cascade River Road, the Irene Creek Road (#1550), the Found Creek Road (#1570), and the South Fork Cascade Road (#1590).

Drainages include upper Irene Creek and the lower valleys of Found Creek, Kindy Creek, Sonny Boy Creek, and Pincer Creek. These drainages flow into the Cascade River which is a designated Wild and Scenic River. Topography is generally steep, ranging from extremely rough and precipitous in the Found and Pincer Creek drainages to fairly gentle in Irene Creek. Elevations range from 1,200 to 8,200 feet on Johannesburg Mountain.

There are unstable soils adjacent to lower Kindy and Sonny Boy Creeks. Steep, shallow residual soils occur in the upper Irene Creek drainage and on the slopes on the southwest side of the Cascade River channel. In the Pincer Creek parcel there are steep and shallow residual soils on the upper slopes.

The Cascade River area provides important habitat for wintering bald eagles.

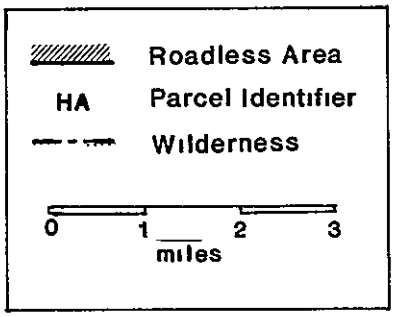
WILDERNESS CAPABILITY

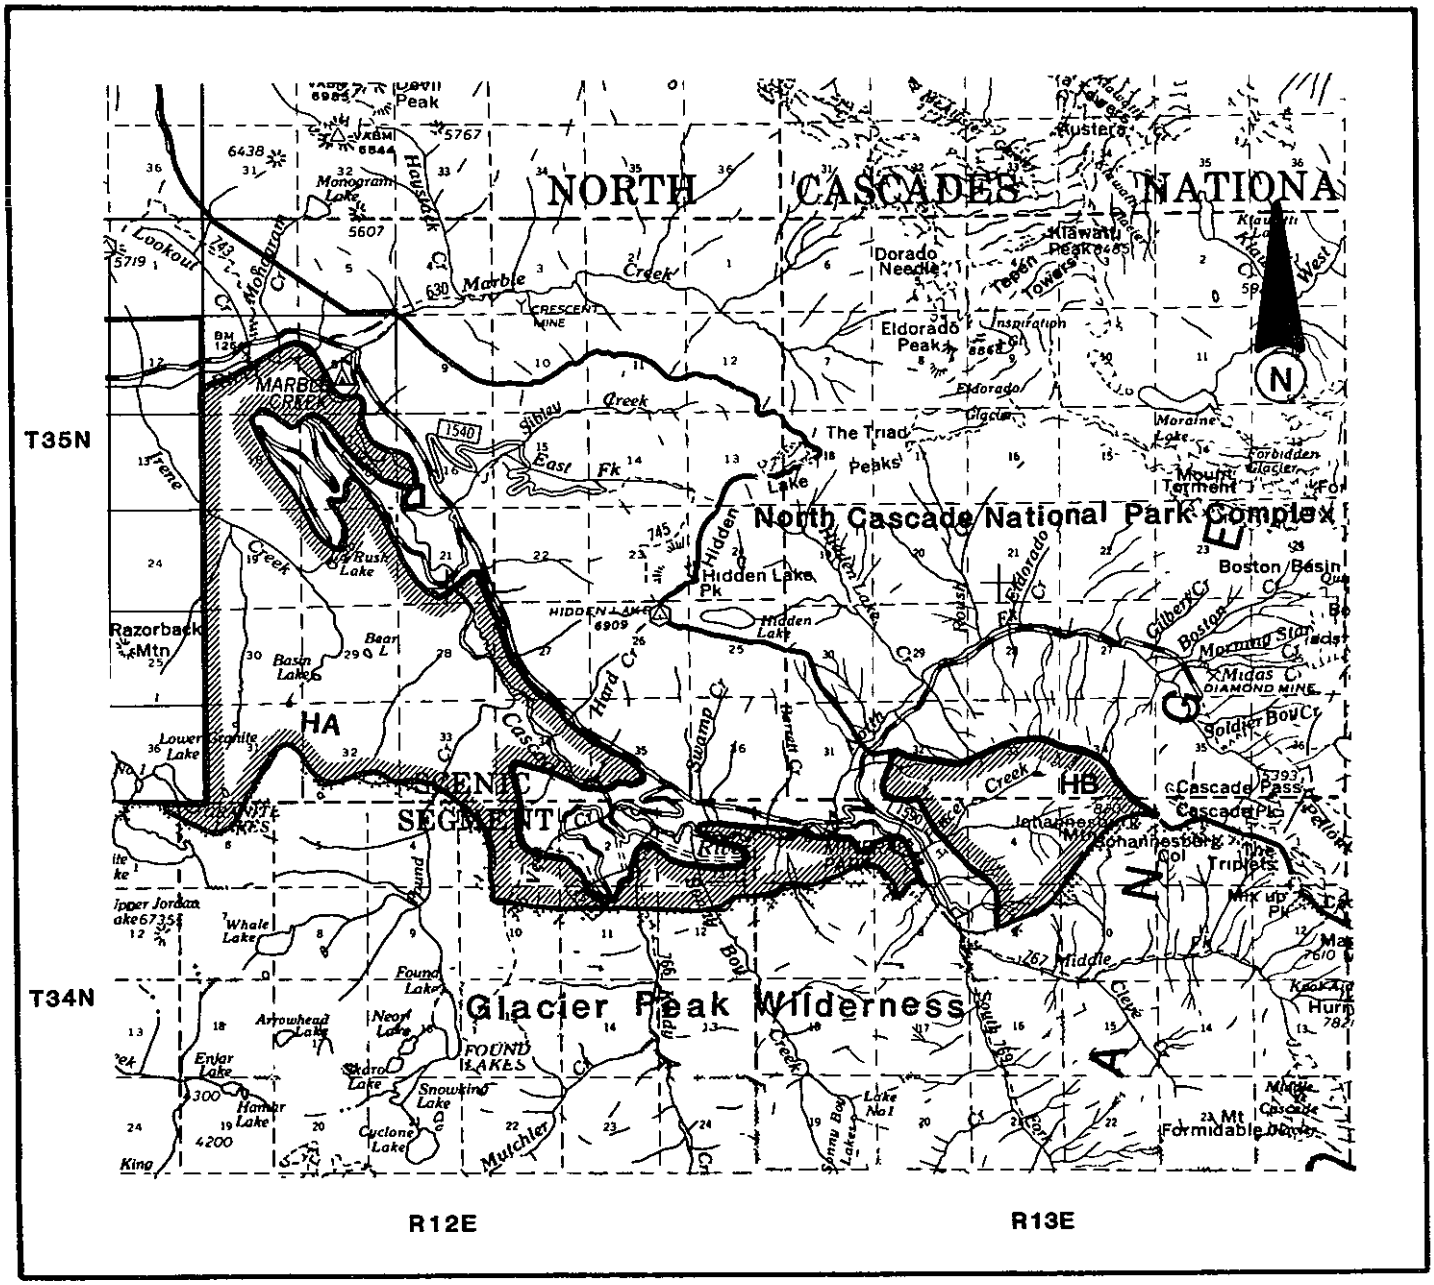
Manageability and Boundaries: Management as wilderness would be enhanced due to steep topography and arduous access. Location of the lower boundaries could be difficult due to proximity of existing roads and lack of definitive ground characteristics.

Natural Integrity and Appearance: Kindy Creek and Sonny Boy Creek are visible from the Cascade River Road. There is an overall natural appearance. The wilderness landscape of Johannesburg Mountain and the surrounding area is extremely rugged and scenic.

Glacier Peak H

Roadless Area H6031





Opportunities For Solitude: Excellent opportunities for solitude exist in upper Irene Creek in the western portion of the area and in the vicinity of upper Pincer Creek and Johannesburg Mountain. The remaining portions are in close proximity to existing roads and heavy recreation use.

Opportunities For Primitive Recreation: Primitive recreation opportunities include hiking, cross-county travel, hunting, fishing, mountaineering.

Challenging Experiences: Johannesburg Mountain offers challenging mountaineering experiences, with spectacular views of the surrounding Glacier Peak Wilderness and North Cascades National Park.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Glacier Peak H #H6031

Category 1/	Unit	Parcels HA	Parcels HB	Total

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.

Availability - Other Resource Potential

Recreation: Recreation use is light to moderate, with most use along user-built trail to LaRush and Bear Lakes. There is a scramble trail up Vee Creek accessing Found Lake, located in Glacier Peak Wilderness.

Fish/Wildlife: These parcels have a high probability of containing one or more bald eagle communal night roosts. Preliminary surveys determined that bald eagles make nocturnal use of the upper slopes of Irene Creek. Bald eagle forage and perching habitat exists all along the Cascade River, and it may be an important wintering area. Eagles have been observed perching and foraging as far up as Vee Creek. The lower reaches of Found Creek Hard Creek, Vee Creek, Kindy Creek, and Sonny Boy Creek provide spawning and rearing habitat for steelhead, chinook, and coho salmon.

Special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten. The low elevation, south facing slopes of Pincer Creek may provide winter range for deer and mountain goat.

The Cascade River is bordered by a large riparian area used by a variety of wildlife. It provides habitat for more wildlife species than any other type of habitat found on the District. The frequent meanders and side channels also provide spawning and rearing habitat for coho, chinook, and pink salmon and steelhead.

Water: Drainages include upper Irene Creek and the lower portions of Found Creek, Vee Creek, Kindy Creek, and Pincer Creek, as well as several smaller tributaries to the Cascade River. There are three small lakes (LaRush, Bear, and Basin) in the western portion.

Livestock Operations: None.

Ecology: The predominant cover type is Douglas-fir along the river, western hemlock along the midslopes, and Pacific silver fir on the upper slopes.

Timber: Timber harvest has occurred on non-National Forest land to the west; there has been little harvest activity north of the Cascade River Road. Approximately one-half of the area is classified as tentatively suitable for timber management.

Minerals/Oil an Gas: The geology of this area is dominated by Jurassic metamorphic rocks, Paleozoic granitic rocks, and glacial drift of Quaternary age. The area has reported mineral resource occurrences of significant interest and it does had 12 mining claims located within it. THe area is not classified "prospectively valuable" for any of the leasable minerals, nor is it encumbered by any leases or pending lease applications The east portion of the area was inventoried by the U S Geological Survey and Bureau of Mines. As a result of their investigation, they have concluded that the eastern 3 miles of the area has a high and medium potential for the occurrence of base and precious metal resources.

Cultural Resources: Sites along the Cascade River and selected high-elevation sites are important for American Indian religious use.

Land Use Authorizations: None.

Non-Federal Lands: There are approximately 150 acres of non-Federal land south of Marble Creek Campground.

Fire: Considerable lightning activity occurs in the Kindy Creek drainage every year. Approximately 125 acres burned in 1970.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are a few miles southwest of North Cascades National Park and adjoin the Glacier Peak Wilderness. The small community of Marblemount is about 15 miles away. Seattle and Vancouver, B.C., are each about 125 miles away.

Public Interest: Local and other public sentiment has been divided between favoring wilderness and development of commodity resources. There is interest in areas for bald eagle foraging and night roosting along the Cascade River. Following release of the DEIS and Proposed Forest Plan, public comments were received on Glacier Peak Roadless Area parcel H, as well as on subparcels, specific geographic sites and features within the area, and on it as being adjacent to other areas.

Glacier Peak parcel H was mentioned 26 times. Four comments each were received saying the area should be made a top priority for timber harvest and that it should be kept open for mining. Other responses included increasing the developed campgrounds (3), building more roads (3), and increasing the opportunity for motorized recreation (3). The majority of the remaining comments said to manage the area for wildlife habitat. 1/

Glacier Peak parcel HA received three comments. The responses said to preserve the forest ecosystem, protect old growth ecosystems, and to protect the area as a low-elevation trail.

Glacier Peak parcel HB was mentioned three times. Comments favored preserving the area as valuable low-elevation old growth, keeping it roadless, and preserving the forest ecosystem.

Irene Creek was mentioned 273 times. Responses said to preserve the forest ecosystem (54), protect the area from harvest (53), protect the old growth ecosystem (36), keep the area roadless (35), protect wildlife habitat (11), and protect the area for recreation (11). The majority of the remaining comments said to manage the area for recreation and wildlife habitat. Two responses said to add it to the National Park System. One said to make it a top priority for timber harvest.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

The Cascade River was mentioned 700 times. Comments favored protecting the area from harvest (141), keeping it roadless (83), preserving the forest ecosystem (75), protecting the old growth ecosystem (51), protecting it for recreation (37), opposing road construction that will bisect trails (28), and preserving the area as a corridor into the backcountry (28). Other comments included no new road construction (27), protecting trails from logging (26), and protecting the area for wildlife habitat (23) and scenic value (23). Most of the remaining responses favored managing the area for recreation and wildlife habitat. One comment said to make this area a top priority for timber harvest; one said to cut the old growth.

Areas adjacent to North Cascades National Park were mentioned 71 times. Comments favored keeping the area roadless (11), protecting it from timber harvest (9), protecting it for recreation (5), preserving the forest ecosystem (4), protecting the old growth ecosystem (4), and protecting visuals. Most of the other comments wanted the area managed for recreation. One comment said the area should be added to the National Park System. One favored making the area a top priority for timber harvest.

Areas adjacent to Glacier Peak were mentioned 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20). Other comments said to protect the area for wildlife habitat and recreation values.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative I allocates about 12% of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B, H, I and J (Preferred) allocate the greatest amount of acres to old growth habitat, deer and elk enhancement and threatened and endangered species (bald eagle nest and forage/roost areas). Alternatives C and G-Modified allocate the least.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives.

Timber: Alternatives A, NC, H and I allocate the greatest amount of area to timber management. Alternatives C and J (Preferred) allocate the least. None of the alternatives will significantly affect the timber resource.

Minerals/Oil/Gas: None of the alternatives will significantly affect the availability of minerals, oil or gas for development. Alternatives B, H, I and

J (Preferred) will provide a greater amount of roaded access through the area, which could be used for mineral exploration and development.

Cultural: Alternatives B, H, I and J (Preferred) will have the greatest potential to adversely impact cultural resources in the area. Valuable sites will be protected via avoidance or preserved through data recovery. Alternatives A/NC and C will have the least potential to impact cultural resources.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: Alternative I allocates about 38% of the area to semi-primitive motorized recreation and timber management prescriptions. Alternatives A/NC and C will leave the greatest amount of roadless area remaining at the end of the fifth decade. Alternatives H, I and B will leave the least. Alternatives A and C will leave the majority of the area in a roadless condition throughout the end of the fifth decade, most of the wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	7,657	7,447	7,277	92%
B (RPA)	5,797	3,965	1,536	19%
C	7,255	6,469	5,445	69%
G-Mod.	6,481	5,081	3,737	47%
H	5,401	3,187	3.140	40%
I	5,653	3,615	1,086	14%
J (Pref).	6,076	4,392	2,268	29%

GLACIER PEAK I Roadless Area I6031 (IA)

This roadless area originally consisted of 18,397 acres It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area I6031 to nonwilderness uses. In 1984, 1,208 acres from this area were designated as additions to the Glacier Peak Wilderness by Congress as a result of the Washington Wilderness Act.

Since the 1984 RARE II inventory, this area has been reduced by 5,642 acres. In 1984, the Yellow Timber Sale and the White Creek Skyline Timber Sale removed 1,625 acres from roadless status. In 1987, the Upper Slope Timber Sale and the Indian Point Timber Sale removed 2,387 acres from roadless status. The area was reduced 422 acres due to a mapping discrepancy.

The following shows the disposition of acres within the Glacier Peak I roadless area·

Glacier Peak I	**Net Acres**
1984 RARE II	18,397
Updated 1988	12,755
Change	**- 5,642**

OVERVIEW

This parcel lies several miles south of Marblemount, Washington with the Glacier Peak Wilderness to the east, the Forest boundary to the north, and existing road systems to the south and west. The northern portion drains into the Skagit and Cascade Rivers, while the southern portion is drained by the Sauk and Suiattle Rivers.

Road access is via the West Boundary Road (#1610), the Illabot Peak Road (#1620), and the Illabot Road (#16) which extends from west to east through the middle of the area)

Drainages include upper Jordan Creek, which drains into the Cascade River; Illabot Creek and tributaries, which drain into the Skagit River; upper Hilt Creek and White Creek, which drain into the Sauk River; and upper Grade Creek, which drains into the Suiattle River. Elevations range from approximately 1,000 feet to the summit of Illabot Peaks at 5,944 feet.

The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western redcedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher elevations of the forested range (4,000-5,500 feet).

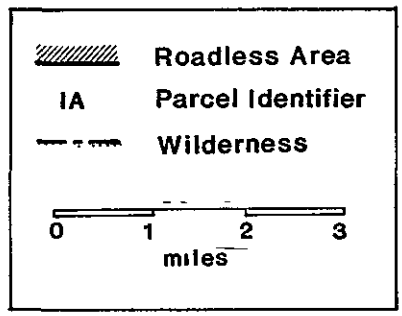
Soils vary, with primarily steep, shallow, unstable areas adjacent to steep sideslope draws in the upper reaches of Jordan Creek, adjacent to the Iron, Bluebell, Illabot, and Arrow Creek channels, at the headwaters of White Creek, and southwest of the White Creek channel.

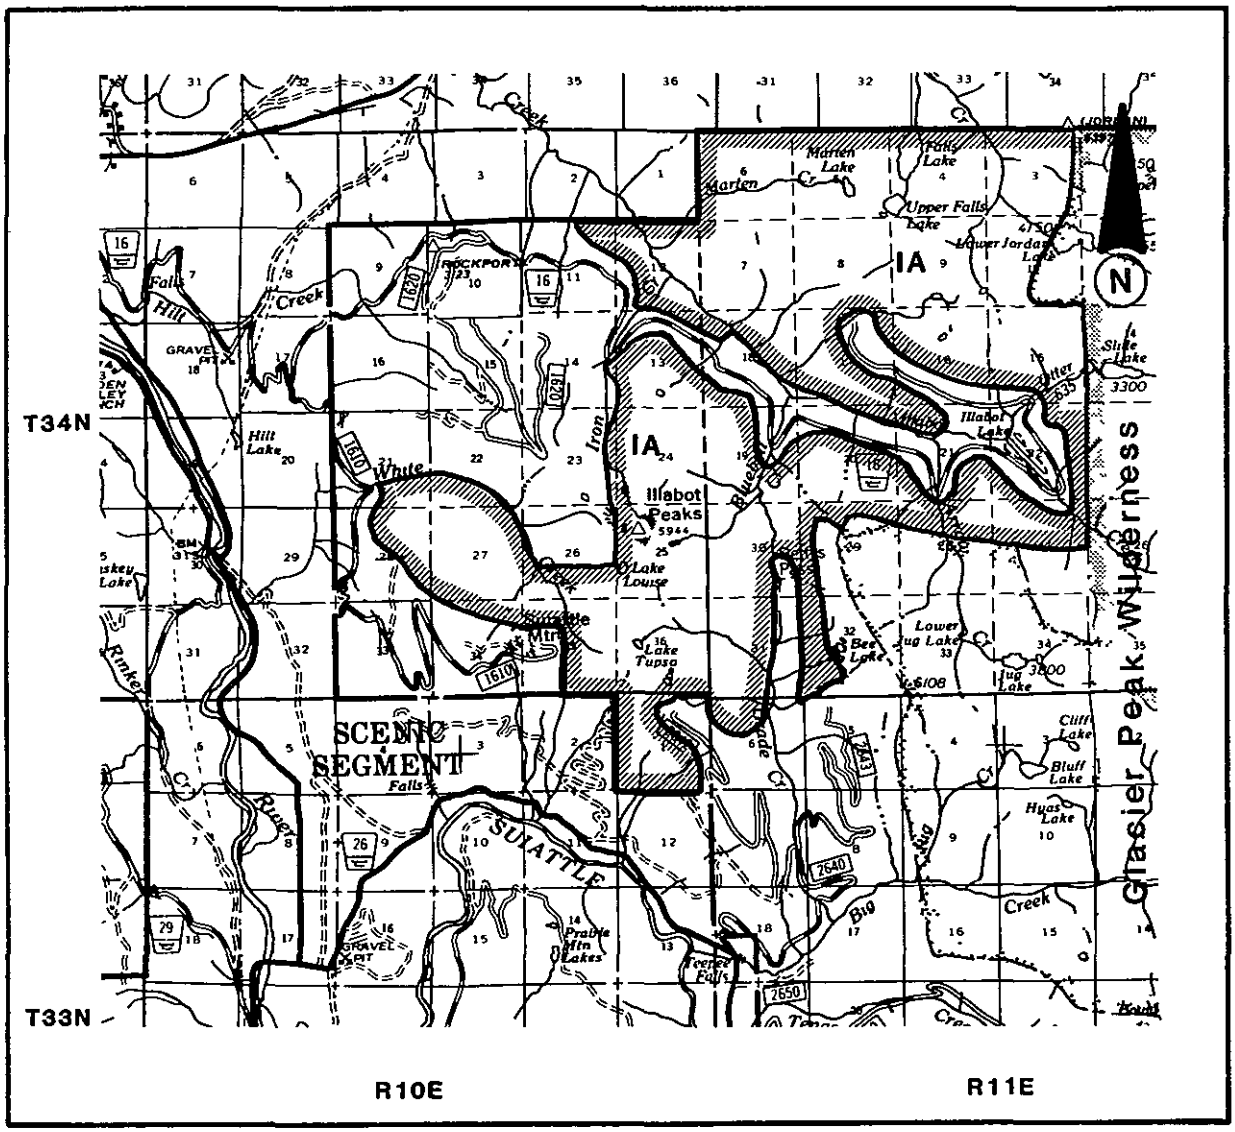
A variety of recreational use centers around high-elevation lakes.

Important habitat is provided for a variety of wildlife species.

Glacier Peak I

Roadless Area I6031





WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries in close proximity to existing roads may be difficult to manage and locate on the ground. Access in other parts of this parcel is by primitive trails, which would facilitate wilderness management.

Natural Integrity and Appearance: Overall appearance is natural. The portion around Lake Louise and Illabot Peaks is isolated, and the Falls Lake area is a pristine environment.

Opportunities For Solitude: Opportunities for solitude are very good due to large size and rugged terrain.

Opportunities For Primitive Recreation: There are excellent opportunities for primitive recreation activities such as hiking, camping, hunting, fishing, and photography.

Challenging Experiences: There is opportunity for cross-country travel.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: The Slide Lake Trail #635 is heavily used to access the Glacier Peak Wilderness. Marten Lake, Falls Lake, and Upper Falls Lake receive considerable use via trails off of private roads to the north. Lake Louise and Lake Tupso receive moderate cross-country use. Hunting and fishing use is moderate.

Fish and Wildlife: Special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten. A bald eagle night roost has been located on private land near Illabot Creek just downstream from the Forest boundary. Some eagles may head further up Illabot Creek and use some of the old growth stands as communal night roosts.

The low elevation southwest-facing slopes directly above Illabot Creek provide a large deer wintering area. The spacious riparian corridor along Illabot Creek is important to a wide variety of wildlife species. Mountain goats are known to summer on Illabot peaks.

Illabot Creek is used by coho, steelhead, chinook, and chum salmon. It is not clear how far up the creek the fish migrate. Lower White Creek is also used by spawning coho and chinook.

Water: This highly dissected parcel has tributaries into the Skagit, Cascade, Sauk, and Suiattle Rivers. There are several high-elevation lakes.

Livestock Operations: None.

Summary Table - Glacier Peak I #16031 (IA)

1/ American Indian Religious and Cultural areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Ecology: This is a large, heavily forested parcel divided by high, rugged mountain terrain containing lakes, meadows, and alpine timber. Species include cedar and Douglas-fir at lower elevations and Pacific silver fir and hemlock at higher elevations.

Timber: Most of the parcel supports commercial forest except for the central, high elevation Illabot Peaks portion. Less than half of the area, however, is tentatively suitable for logging.

Minerals/Oil and Gas: The geology of the area is dominated by Jurassic metasedimentary rocks and by Tertiary and Mesozoic granitic rocks. Data shows the area has no reported mineral resource occurrences of significance, and the area has only 4 mining claims recorded for it. The area is not classified "prospectively valuable" for any leasable mineral, nor is it encumbered by any leases or pending lease applications. A portion of the area was studied by the U.S. Geological Survey and Bureau of Mines. As a result of their studies, it is concluded that the southern portion of the area has a low potential for the occurrence of gold resources in hydrothermal quartz veins, and it has some potential for the occurrence of gold placer deposits.

Cultural: There are sites important for American Indian religious and cultural use.

Land Use Authorizations: There are no special land authorizations.

Non-Federal Lands: None.

Fire: There is a low occurrence of fire.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel adjoins the Glacier Peak Wilderness. The communities of Rockport, Marblemount, and Darrington are 10-20 miles away. Seattle is approximately 85 miles away.

Public Interest: Local and other public sentiment has been divided between favoring wilderness and development of commodity resources. There has been interest from American Indians in the Marten Lake area. Following release of the DEIS and Draft Forest Plan, the following specific geographic sites and features within Parcel I of the Glacier Peak Roadless Area, well as Parcel I itself, received public comment.

Illabot Creek was mentioned 766 times. Most responses (191) wanted Illabot Creek designated a Wild and Scenic River. Other responses desired protection of the area from timber harvest (77), protection of bald eagle habitat (56), protection of old growth ecosystems (56) and fisheries (50). The remaining comments, in general, favored protection of wildlife habitat, preservation of the forest ecosystem, no new road construction, and protection of the area for recreation. One response said that the old growth in the area should be harvested. 1/

Falls Lake was mentioned 198 times. Most responses said to protect the area from harvest (44), to have it remain roadless (44), to protect wildlife habitat in general (25), to preserve the forest ecosystem (19), and to preserve old growth (15). Other comments express the desire for enhancing the trail system in the area.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Jordan Creek received 45 comments. Most responses favored no logging in the area (14), and for the area to remain roadless (7). The remaining responses wanted the area to be protected for recreation purposes and wildlife habitat. One response said the area should be kept trailless; one response desired more trail construction in the area.

Glacier Peak I was mentioned twelve times. The majority of the responses (3) favored designation of this area for timber harvest. Other responses included a desire to increase the opportunity in the area for motorized recreation (2), manage the area for big game (2), protect the trail from logging, manage the area for nonmotorized recreation, protect the area from timber harvest, protect the area for wildlife habitat, and protect the area for spotted owl habitat (one response each).

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

17 Timber	3,695	1,964	1,626	612	2,090	2,639	1,795
19 Mtn. Hemlk		1,562	190	274	760	1,013	485

Significant Effects

Recreation: Current recreation opportunities would not be significantly affected by implementation of any of the alternatives. Alternative G-Modified would have the least impact on the roadless character of the area through the fifth decade. Alternative H, the alternative taking the greatest amount of area from roadless status, retains 86% of the area as roadless through the end of the fifth decade. Alternative I allocates 4,265 acres to semi-primitive motorized recreation and retains 96% of the area in a roadless condition through the end of the fifth decade.

Fish/Wildlife: Fish and wildlife would not be significantly affected by implementation of any of the alternatives. Alternative B would provide the greatest emphasis on wildlife, as it allocated the greatest amount of acres to old growth habitat, mature old growth, deer and elk enhancement, and mountain goat habitat areas. Alternatives C and H provide the least.

Water: There are no adverse effects to the water resource of this area associated with implementation of any of the alternatives, due to the low level of proposed development activities.

Ecology: The overall ecology of the area would not be significantly affected by implementation of any of the alternatives, due to the low level of proposed development activities.

Timber: Alternative G-Modified would have the least effect on the existing timber resource, as it allocates very minimal acreage to management area 17 (timber). Alternatives A, NC and I would have the greatest effects. None of the alternatives would significantly affect the timber resource, as potential development activities would be minimal.

Minerals/Oil/Gas: None of the alternatives would have a significant affect on the availability of minerals, oil, or natural gas for development. Alternative A, NC,H and I would provide a slightly higher amount of roaded access through the area for minerals development.

Cultural: Alternatives A, NC and I would have the greatest potential to adversely impact cultural resources within the area, due to development activities. Valuable sites would be protected via avoidance or conserved through data recovery. Alternatives C and G-Modified would have the least potential to adversely impact cultural resources. None of the alternatives would significantly affect cultural resources.

Fire: None of the alternatives would significantly affect fire occurrence within the area.

Insect and Disease: None of the alternatives would significantly affect the occurrence of insects and disease within the area.

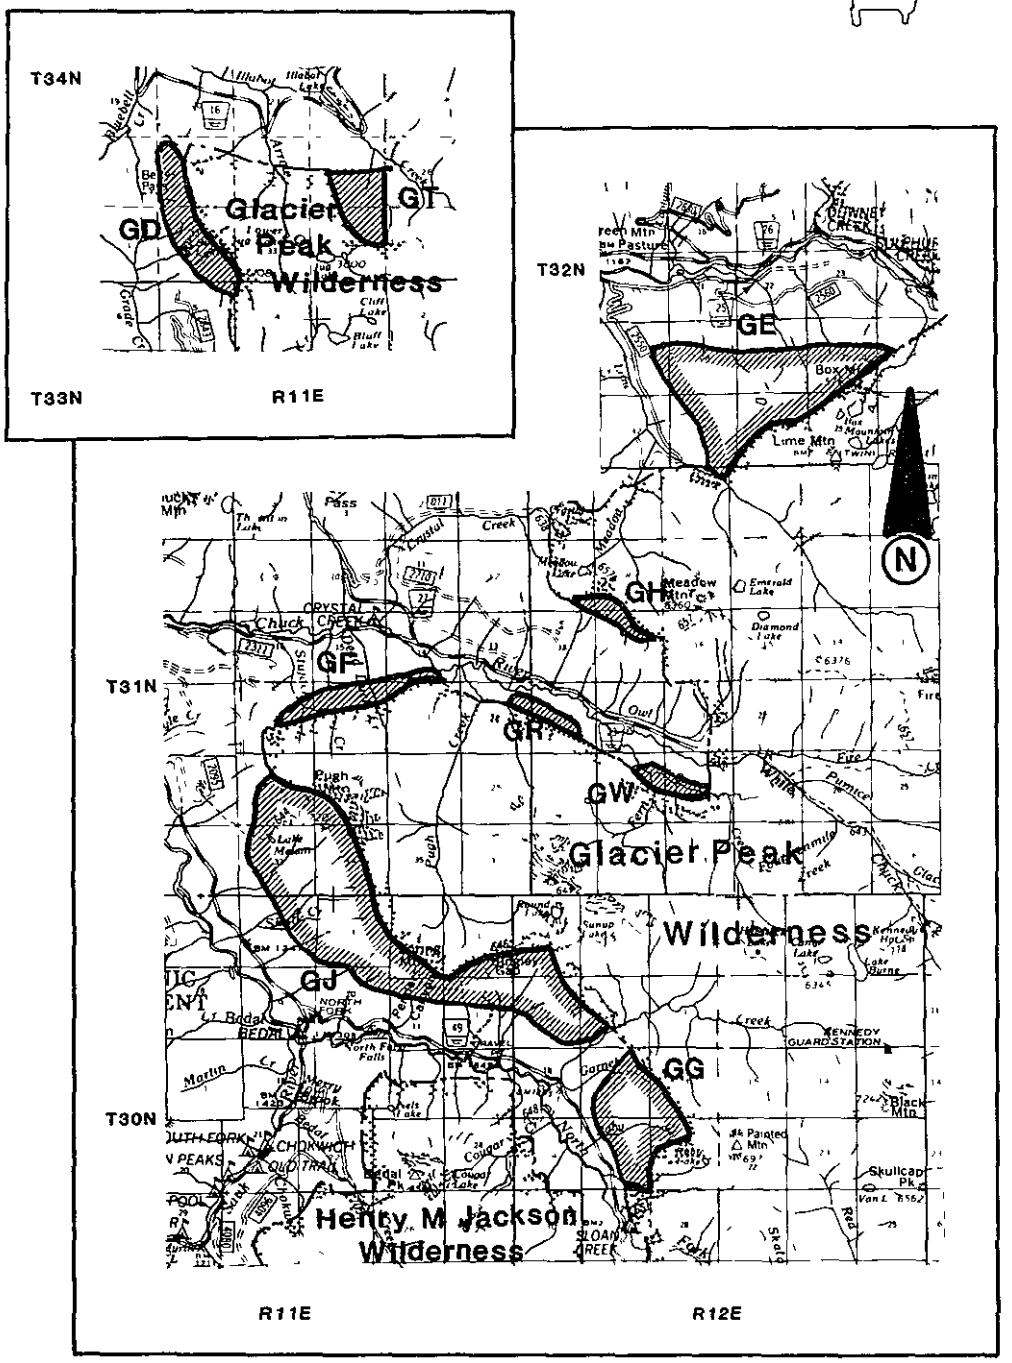
Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns approximately one-third of the area to semi-primitive motorized management area. All alternatives would maintain the area in a largely roadless condition through the end of the fifth decade. The wilderness potential would be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	12,518	12,308	12,111	95%
B (RPA)	12,557	12,393	12,234	96%
C	12,554	12,456	12,306	96%
G-Mod.	12,557	12,663	12,651	99%
H	12,209	11,613	11,016	86%
I	12,572	12,394	12,226	96%
J (Pref).	12,659	12,559	12,453	98%

Glacier Peak G

Roadless Area G6031



GLACIER PEAK G **Roadless Area G6031**

This roadless area originally consisted of 59,755 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area G6031 to nonwilderness uses. In 1984 51,018 acres from this area were designated as additions to the Glacier Peak Wilderness by Congress as a result of the Washington Wilderness Legislation. Nine parcels remain in roadless status.

The following shows the disposition of acres within the Glacier Peak G roadless area:

Glacier Peak G	Net Acres
1984 RARE II	59,755
updated 1988	8,737
Change	**-51,018**

OVERVIEW

These parcels are adjacent to Glacier Peak Wilderness. Topography is characterized by steep, rugged, forested, and rocky slopes. Many streams drain areas ranging in elevation from 1,600 to 7,200 feet. Collector and local roads provide access to within 1/4 to 1/2 mile of most of the parcels Trails cross some of the parcels.

Plant associations include the western hemlock, Pacific silver fir, and mountain hemlock mature conifer forests. Highest elevations are often bare rock. Mid-elevations are comprised of sparsely forested areas interspersed with brush fields and talus slopes. Alpine meadows are small in size and uncommon.

Soils have formed in coarse-textured, weathered gneiss bedrock that has been altered by glacial and stream processes. Soils are gravelly sandy loam. Steep slopes adjacent to stream courses are prone to earth slides under natural conditions.

WILDERNESS CAPABILITY

Manageability and Boundaries: The nine parcels could be added to adjust wilderness, but they would be illogical additions due to difficulty of managing boundaries on ill-defined features.

Natural Integrity and Appearance: Adjacent cutover lands provide the appearance of a modified landscape.

Opportunities For Solitude: Opportunities are low due to nearby roads and logging activity.

Opportunities Primitive Recreation: Opportunities are low.

Challenging Experiences: Opportunities for challenging experiences are low.

Special Features: None.

2/ Number of claims not broken out by parcel.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: the summary table below and a discussion of other resource potential.

Availability - Other Resource Potential

Recreation: Trails including the Meadow Mountain #657, Mt. Pugh #644, and Round Lake #646 each receive about 1,500 visits per year by hikers and horsemen who are passing through these areas to destination points in Glacier Peak Wilderness. Areas adjacent to trails are steep and generally unsuitable for recreation except by occasional big game hunters.

Wildlife: Special habitats include habitat for spotted owl, pileated woodpecker and pine marten. The steep slopes south of Mt. Pugh provide year round range for several herds of mountain goats. Habitat is afforded several species of native vertebrates. Streams provide habitat for native trout.

Water: There is little potential for water use.

Livestock Operations: There is no potential or current livestock use.

Ecology: The areas are generally heavily forested with silver fir, hemlock and redcedar. Steeper slopes have exposed rock.

Timber: About 28 percent of the area (2,426 acres) in the parcel is tentatively suitable for logging.

Minerals/Oil and Gas: The geology of these areas is dominated by Jurassic metamorphic rocks, Mesozoic granitic rocks, Tertiary volcanic rocks, and glacial drift of Quaternary age. According to MILS data, the area has no reported mineral resource occurrences of significance, however, five mining claims have been located in T.32N.,R.12E. Except for the two parcels lying within T.34N.,R11E., the entire area is classified "prospectively valuable" for geothermal resources. However, none of the parcels are encumbered by geothermal leases or lease applications. Much of the area has been inventoried by the U.S. Geological Survey and Bureau of Mines as part of their Glacier Peak study. Based upon that evaluation, they have concluded the following:

The parcels in T.34N.,R.11E. are underlain by a granitic pluton, and as a consequence they have a "probable" potential for the occurrence of gold deposits.

The parcels in T.32N.,R12E. may have a limestone deposit (Lime Mountain property) which has a potential for future use, but is presently noneconomic.

Parcels in T.31N.,R12E. may also have limestone deposits, which are presently subeconomic.

The southernmost parcel in T.30N.,R.12E. may have hot spring type deposits, but their potential is low. The same area has a low potential for the occurrence of base-metal (copper, lead, zinc with silver and gold) resources in hydrothermal veins. Little exploration work has been done in the area.

Cultural: There is little cultural significance.

Land Use Authorizations: There are no special land uses.

Non-Federal Lands: None.

Fire: There is a high occurrence of fires (4-5 per decade), with four major fires in the past 30 years.

Insects and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels adjoin the Glacier Peak Wilderness, and are about 70-100 miles from Seattle

Public Interest: There has been low public comment or interest in these parcels. Following release of the DEIS and Proposed Forest Plan, no public comment was received about this specific area Public comment did mention, in a generic sense, areas adjacent to Glacier Peak 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20). Other comments said to protect the area for wildlife habitat and recreation values. 1/

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

GLACIER PEAK G
PARCEL GD

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	612

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities would not be significantly affected by implementation of any of the alternatives. Alternatives C and G-Modified would leave the area roadless through the end of the fifth decade. Alternative A, the alternative taking the greatest amount of area from roadless status, retains 83% of the area as roadless through the end of the fifth decade. Alternatives B allocates minimal acres to semi-primitive motorized (21 acres). Alternative I allocates 3,061 acres to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by implementation of any of the alternatives. Alternatives B and I will allocate the greatest area to old growth habitat, deer and elk enhancement, and mountain goat management requirement. Alternatives A and J (Preferred) allocate the least.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of proposed development activity.

Ecology: The overall ecology of the area would not be significantly affected by any of the alternatives, due to the low level of development activity.

Timber: Alternatives C, H and J (Preferred) would have the least affect on the existing timber resource, as it allocates very minimal acreage to management area 17 (timber). Alternatives A, NC, and I would have the greatest effect. None of the alternatives will significantly affect the timber resource, as potential development activities will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or natural gas for development. Alternatives A, NC, B and I will provide a higher amount of roaded access through the area for minerals development through the fifth decade.

Cultural: Alternatives A, NC, B and I will have the greatest potential to adversely impact cultural resources within the area, due to development activities. Alternatives C, H and J(Preferred) would have the least potential to adversely affect cultural resources.

Land Use Authorizations: There are no current land use authorizations within the area.

Fire: None of the alternatives will significantly affect the fire occurrence within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

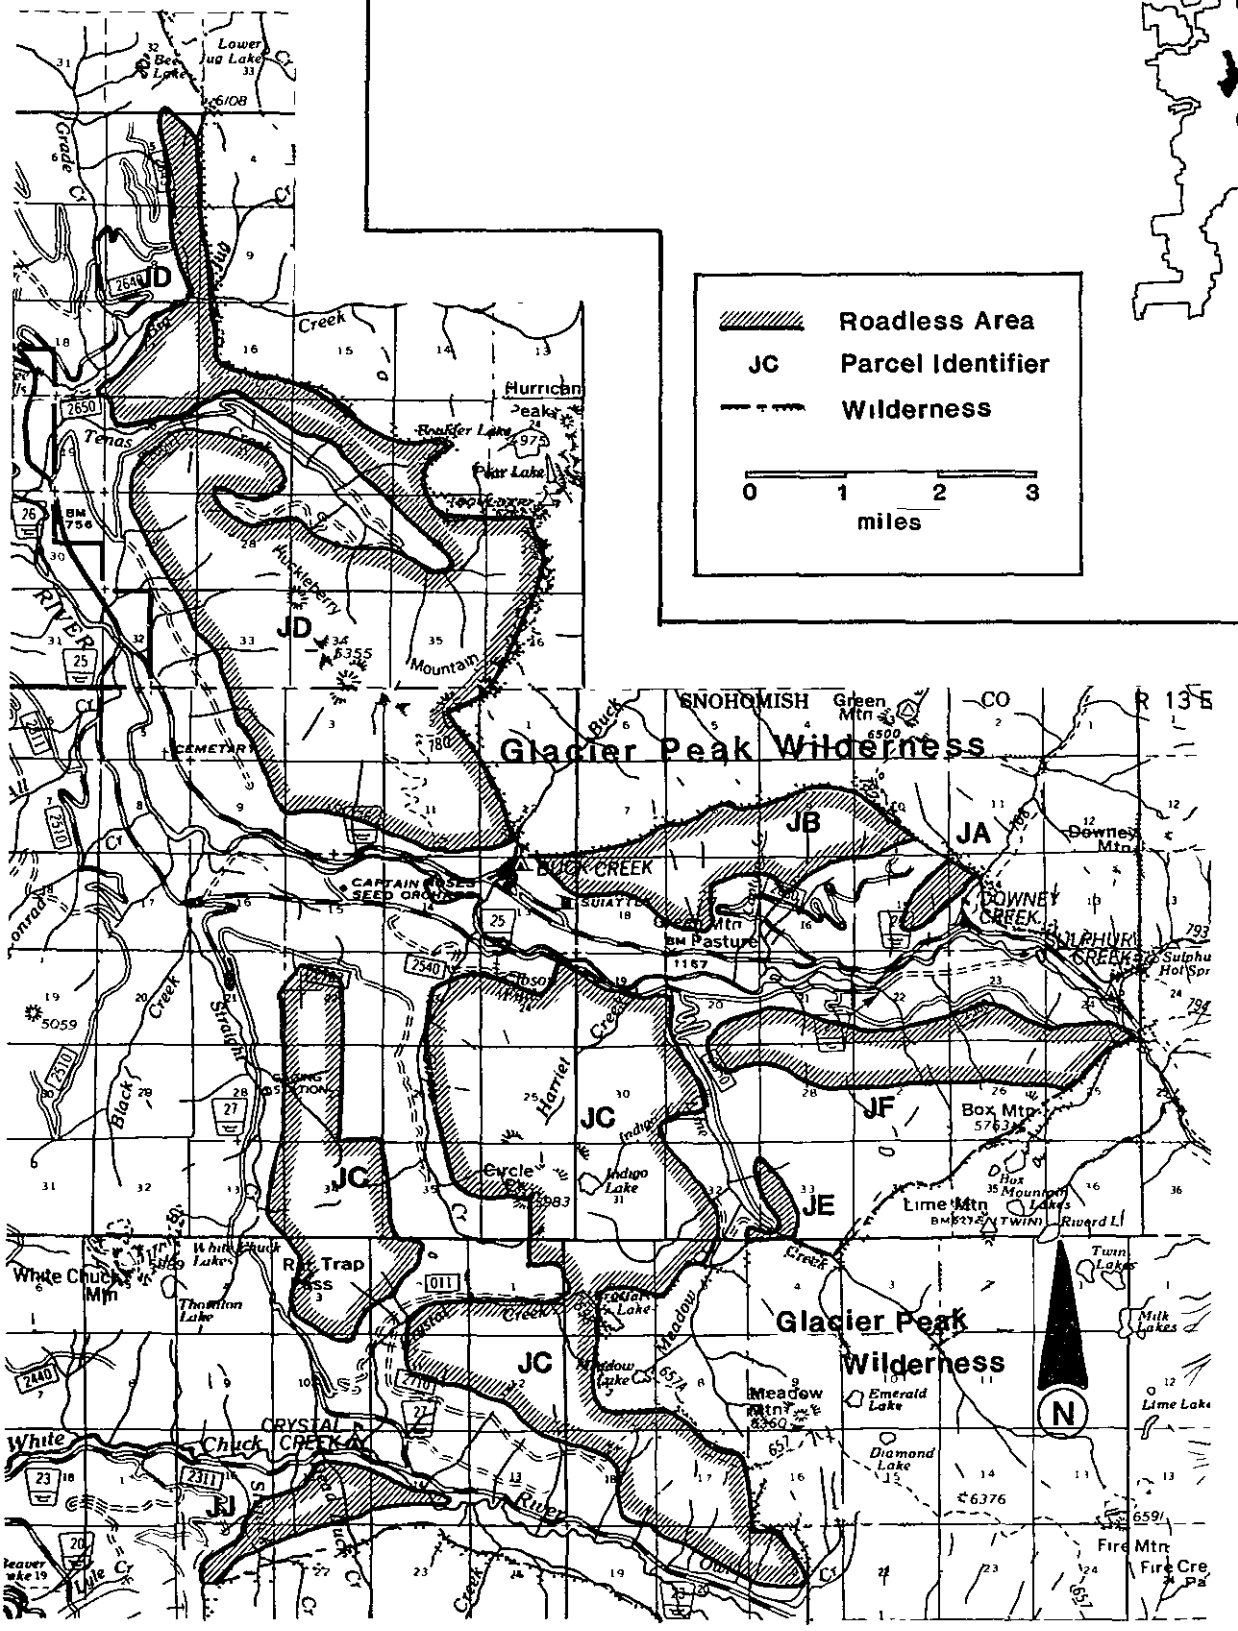
Wilderness Potential: All alternatives, with the exception of alternative I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternatives C and G-Modified do not remove any acres from roadless areas through the end of the fifth decade. Alternative A, which will remove the greatest amount of acres from roadless status, will still leave 83% of the area unroaded at the end of the fifth decade. Alternative I assigns approximately 35% of the area to the semi-primitive motorized management area and 25% of the area is allocated to timber management. Alternative I retains 95% of the area in a roadless condition through the end of the fifth decade. The wilderness potential of this area will be maintained in every alternative.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	7,780	7,642	7,283	83%
B (RPA)	8,533	8,395	8,312	95%
C	8,737	8,737	8,737	100%
G-Mod.	8,737	8,737	8,737	100%
H	8,467	8,335	8,179	94%
I	8,647	8,319	8,268	95%
J (Pref).	8,596	8,480	8,480	97%

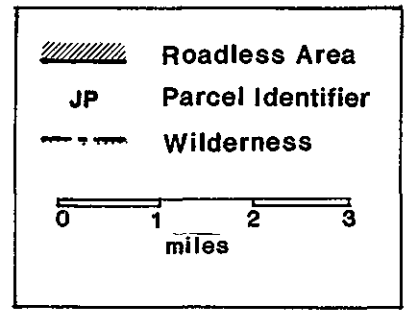
Glacier Peak J

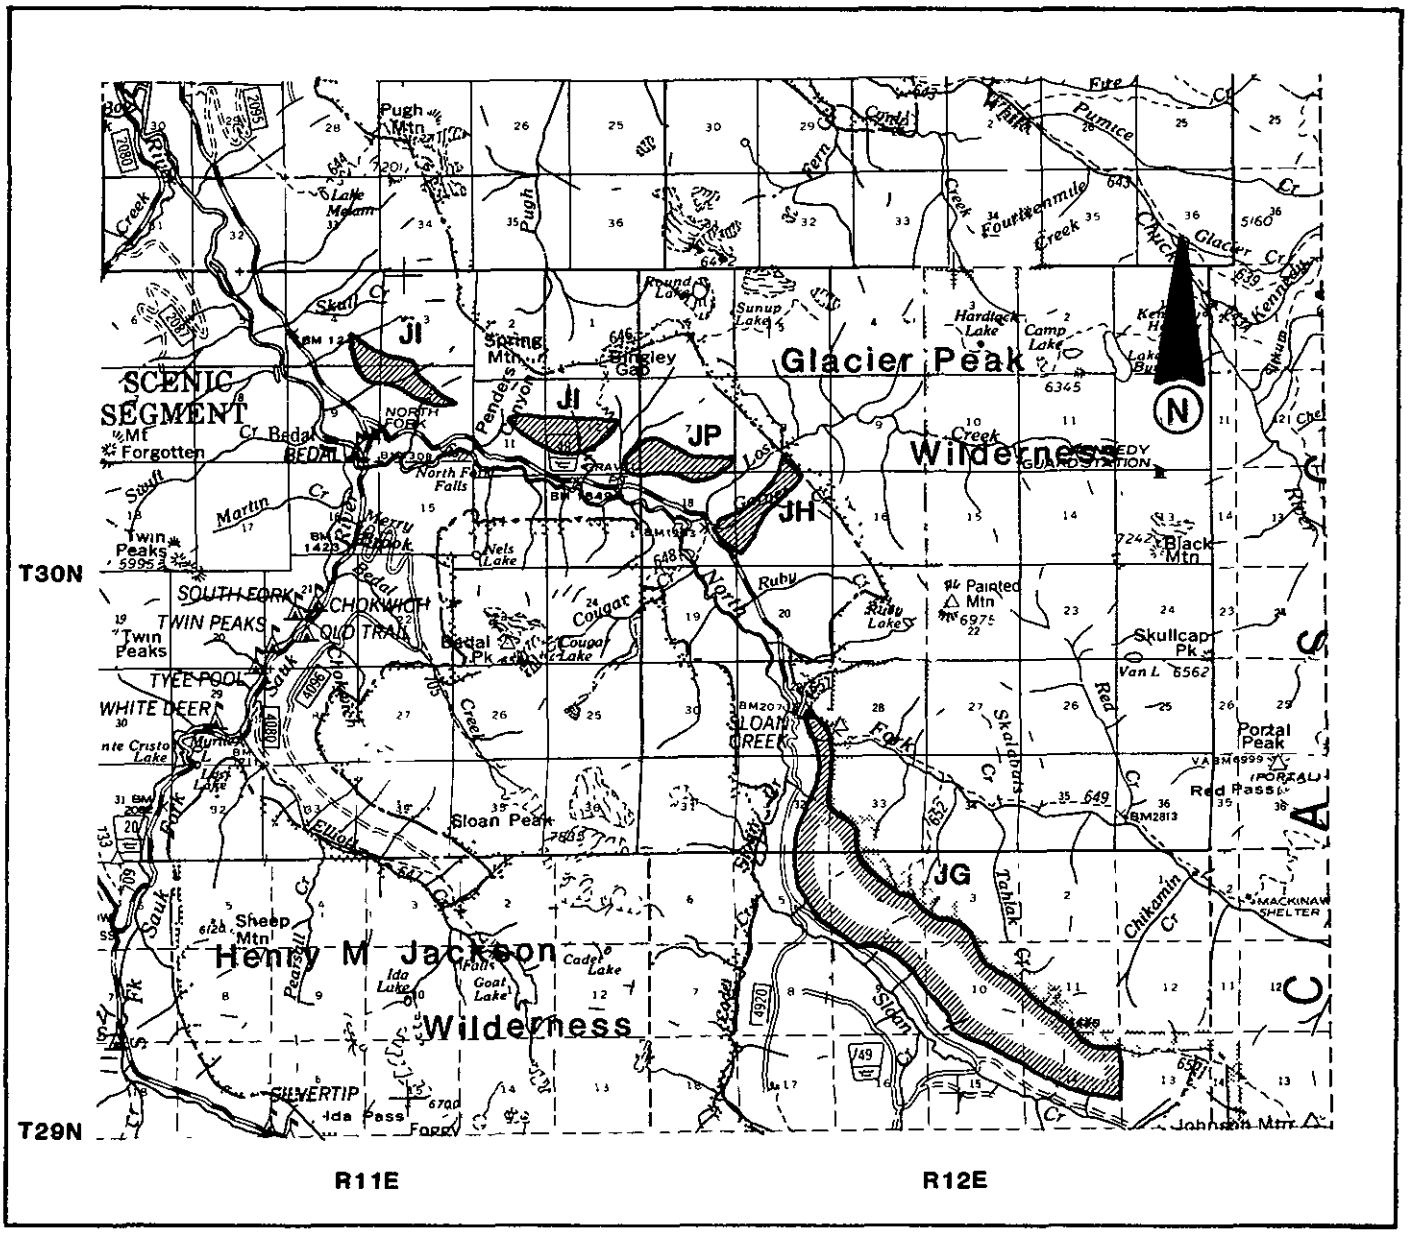
Roadless Area J6031



Glacier Peak J

Roadless Area J6031





GLACIER PEAK J **Roadless Area J6031 (JD, JB, JA, JF, JE, JC, JJ, JI, JP, JH, JG)**

This roadless area originally consisted of 31,604 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area J6031 to nonwilderness uses. In 1984 1,498 acres from this area were designated as additions to the Glacier Peak Wilderness by Congress as a result of the Washington Wilderness Act. Eleven parcels remain in roadless status.

Since the RARE II inventory, this area has been reduced by 5,633 acres. Four timber sales (Circle Creek, Pugh Blend, Sloan Creek, and Bowser Creek Timber Sales) removed 2,065 acres from roadless status. The area was reduced by 912 acres following the Harriet Creek, Box Mountain II, and Big Creek Timber Sales. Total acreage within the area was reduced 1,158 acres due to a mapping discrepancy.

The following shows the disposition of acres within the Glacier Peak J roadless area:

Glacier Peak J	**Net Acres**
1984 RARE II	31,604
updated 1988	25,971
Change	**- 5,633**

OVERVIEW

These eleven parcels are located adjacent to the Glacier Peak Wilderness. They generally have steep, forested, and rocky slopes, with elevations ranging from 1,600 to 6,000 feet. Arterial, collector, and local roads provide direct access to within 1/4 to 1/2 mile of all parcels. Trails cross several parcels including the Huckleberry Mountain trail in parcel JD, Green Mountain trail in parcel JB, and the Crystal Lake trail in parcel JC.

Plant associations include the western hemlock, Pacific silver fir, and mountain hemlock mature conifer forests. Highest elevations are comprised of bare rock and snow fields. Alpine meadows are small in size and uncommon.

Soils have generally formed in coarse-textured, weathered gneiss bedrock that has been altered by glacial and fluvial processes. Soils vary from shallow to moderately deep and consist of sandy loam to very gravelly sandy loam. Extremely steep slopes adjacent to drainages are prone to earth slides under natural conditions.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries for all parcels are not conducive to separate management, except as they may be added to adjoining wilderness.

Natural Integrity and Appearance: Most of the parcels adjoin timber harvest units. Generally the higher elevations appear undisturbed.

Opportunities For Solitude: Opportunities for solitude are low due to nearby roads or logging activities.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are low, except along low use trails to Huckleberry Mountain and Circle Peak.

Challenging Experiences: Opportunities for challenging experiences are low due to the proximity to the works of man.

Special Features: The potential Green Mountain Research Natural Area is partially in parcel JB. See a description under Other Management Considerations below.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: The Boulder Lake Trail (#675), Huckleberry Mountain Trail (#710), and Circle Peak Trail (#634) each receive about 500 visitor days use per year by hikers passing through on their way to destination points within the Glacier Peak Wilderness. The Green Mountain Trail (#782) receives about 3,500 visitor use days per year primarily by hikers passing through the area to the meadows and view points in Glacier Peak Wilderness. Indigo Lake, near Circle Peak, attracts less than 500 fishermen per year. Other than big game hunting, the steep topography of the area and dense understory vegetation discourage recreation use.

Wildlife: Special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten. Habitat also exists for several species of native vertebrates, and for native trout. Steeper slopes near Pendors Canyon and Lost Creek provide year round range for several herds of mountain goats.

Water: There is little potential for water use.

Livestock Operations: There is no potential or current livestock use.

Ecology: The southeast part of parcel JG contains steep alpine meadows. The rest of the area is steep, forested slopes with many exposed cliffs. Ecological communities include dense forests of tall evergreen trees with patches of shrubby undergrowth. Dominant species include Pacific silver fir, Douglas fir, subalpine fir and mountain hemlock.

Timber: About 49 percent of the parcels 12,834 acres are classed as tentatively suitable for logging.

1/ American Indian Religious and Cultural areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.
3/ Number of claims is not broken-out by individual parcel

Minerals/Oil and Gas: The geology of these parcels is dominated by Mesozoic granitic and metamorphic rocks and glacial drift of Quaternary age. The areas have no reported mineral occurrences of significance, however they do have 30 mining claims located within the parcels or on adjacent lands. Most of these claims are in T.32N.,R12E. All except that portion of the area located in T.33N.,R.12E. is classified "prospectively valuable" for geothermal resources, and parcels J-F are encumbered by 2 pending lease applications. A large part of the area has been inventoried by the U.S. Geological Survey and Bureau of Mines. Based upon their study, they have concluded the following:

> That portion of the area lying within T.33N.,R.11E. has a "probable" potential for the occurrence of gold deposits.
>
> That portion of the area lying within T 32N.,R.12E. has limestone deposits which are presently noneconomic.
>
> That portion of the area lying within T.30N.,R.12E. has reported placer garnet deposits of marginal interest, and it has a "probable" potential for the occurrence of precious and base-metal deposits (Au, Ag, Cu, Pb, Zn).

Cultural: There is little of cultural significance in these parcels.

Land Use Authorizations: There are no special land uses.

Non-Federal Lands: None.

Fire: The parcels have a history of 5-10 fires per decade. Four major fires occurred in the past 40 years. Average fuel accumulation is 40-50 tons per acre.

Insect and Disease: None.

Others: Alternatives G-Modified and H propose a Green Mountain Research Natural Area in Parcel JB. Approximately one-third of this 2,060 acre reserve is in the roadless area; the remainder is in the Glacier Peak wilderness. This RNA represents a subalpine parkland mosaic, heather-huckleberry communities, and subalpine lush herbaceous communities.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels adjoin or are adjacent to Glacier Peak Wilderness and are located about 70-100 miles from Seattle.

Public Interests: Following release of the DEIS and Proposed Forest Plan, areas adjacent to the Glacier Peak area, as well as specific geographic features within Parcel J, received public comment.

Areas adjacent to Glacier Peak were mentioned in public comments 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20).

Other comments said to protect the area for wildlife habitat and recreation values. 1/

Huckleberry Mountain was contained in 303 responses. Most comments expressed a desire to protect the old growth ecosystem (49), exclude timber harvest (49), have the area remain roadless (48), preserve the forest ecosystem (34), and protect the trail from logging (27). Other comments favored managing the area for the protection of recreation, wildlife, and visual quality.

Buck Creek was mentioned 98 times. Thirty-five comments favored Wild and Scenic River designation for the creek; fourteen responses said to protect the area from timber harvest. Other comments expressed a desire to protect the area for wildlife habitat, recreation and visual quality.

Crystal Creek was cited in 40 responses. The majority of the comments favored no logging (10), and no new road construction (6). Five responses said to close existing roads; three comments wanted more roads built.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternative G-Modified would leave the greatest amount of the area (91%) roadless through the end of the fifth decade. Alternative A, the alternative taking the greatest amount of area from roadless status, retains 79% of the area as roadless through the end of the fifth decade. Alternative I will allocate approximately one-fifth of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by implementation of any of the alternatives. Alternatives B, G-Modified and I allocate the greatest area to old growth habitat, mature old growth, and deer and elk enhancement. Alternatives A, NC, C and J (preferred) will allocate the least.

Water: There are no adverse effects to the water resource of this area associated with implementation of any of the alternatives, due to the low level of proposed development activities.

Ecology: *The overall ecology of the area will not be significantly affected by* implementation of any of the alternatives, due to the low level of proposed development activities. Alternatives G-Modified and H will designate the Green Mountain Research Natural Area.

Timber: Alternatives C, G-Modified and J (Preferred) will have the least affect on the existing timber resource, due to minimal allocations of acreage to management area 17 (timber). Alternatives A, NC, H and I will have the greatest effects. Alternatives A and NC allocate 47% of the area to timber management.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, H and I will provide a higher amount of roaded access through the area for minerals development.

Cultural: Alternatives A, NC, H and I will have the greatest potential to adversely impact cultural resources within the area, due to development activities. Alternative C will have the least potential. Cultural resources will not be significantly impacted by any of the alternatives.

Land Use Authorizations: None of the alternatives will significantly affect special land uses.

Fire: None of the alternatives will significantly affect fire occurrence within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives assign the majority of this area to management prescriptions compatible with preserving its roadless character, with the exception of alternative I. Alternative I assigns approximately one-fifth of the area to semi-primitive motorized recreation and nearly one-half of the area to timber management. All alternatives will maintain the

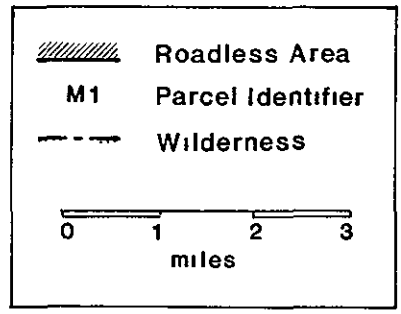
area in a primarily roadless condition through the end of the fifth decade. The wilderness potential of the area will be maintained.

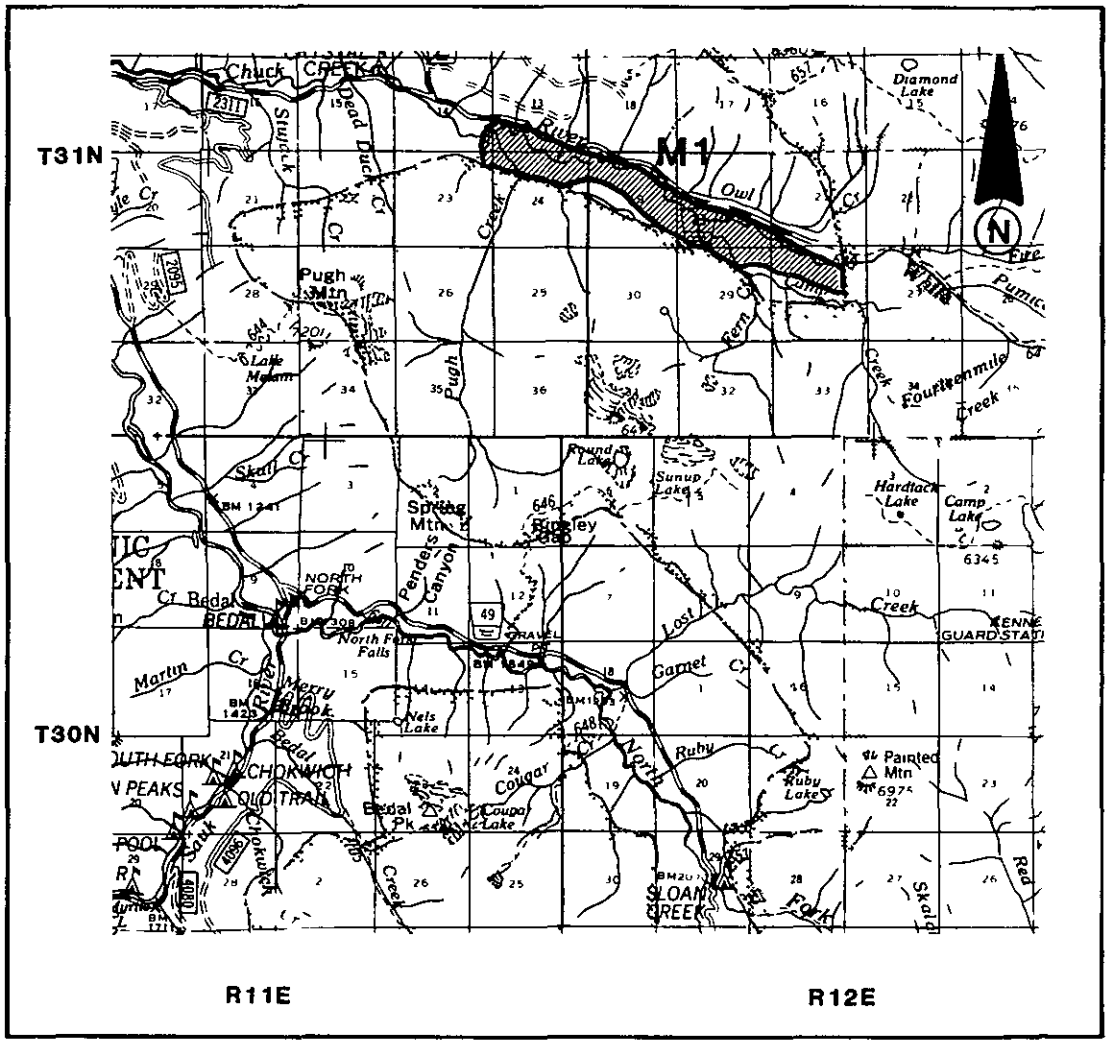
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	23,439	21,887	20,614	79%
B (RPA)	24,144	22,830	21,472	83%
C	25,221	24,733	23,851	92%
G-Mod.	24,738	24,096	23,555	91%
H	24,348	23,082	21,438	83%
I	24,174	22,804	21,229	82%
J (Pref).	24,525	23,375	21,929	84%

Glacier Peak M

Roadless Area M6031





GLACIER PEAK M **Roadless Area M6031 (M1)**

This roadless area originally consisted of one parcel totaling 1,539 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area M6031 to nonwilderness uses. In 1984, 483 acres from this area were designated as additions to the Glacier Peak Wilderness by Congress as a result of the Washington Wilderness Act. The area was reduced by one acre due to a mapping discrepancy. The following shows the disposition of acres within the Glacier Peak M roadless area:

Glacier Peak M	Net Acres
1984 RARE II	1,539
updated 1988	1,055
Change	**- 484**

OVERVIEW

This parcel is located along the south side of the Whitechuck River before it enters the Glacier wilderness. The terrain is gentle to steep over uneven terraces and slopes. Elevations range from 1,600 to 2,600 feet. There is no direct road or trail access to this parcel There is an arterial road along the north side of Whitechuck River.

Plant associations are confined to Pacific silver fir. Soils have formed from residual and colluvial rock material overlying intrusive igneous and gneiss bedrock. Much of the river terraces and lower sideslopes are overlain by pumice and mudflow from Glacier Peak. Glacial scouring and deposition processes produced the landforms. The steeper slopes are prone to earth slides of the unconsolidated coarse textured material.

WILDERNESS CAPABILITY

Manageability and Boundaries: This parcel has wilderness value only if added to the Glacier Peak wilderness. A boundary on the river would be easy to identify.

Natural Integrity and Appearance: An undisturbed appearance is influenced predominantly by natural processes.

Opportunities For Solitude: Opportunities are low due to its close proximity to Whitechuck River road.

Opportunities For Primitive Recreation: Opportunities are low.

Challenging Experiences: Opportunities for challenging experiences are low.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials

Summary Table - Glacier Peak M #M6031 (M1)

Category 1/	Unit	Total

Leasable Energy Minerals (Moderate Potential)		
Geothermal	Acres	1,055

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: This parcel is presently unsuitable for extensive recreation due to dense understory vegetation and lack of trail access. Occasional hunters and fishermen use the area.

Fish/Wildlife: Special wildlife habitats include habitat for spotted owl. Riparian valley bottom habitat is afforded to several species of native vertebrates, including deer winter range. The Whitechuck River and low gradient tributaries support anadromous fish, including spring chinook salmon. Other streams may provide some habitat for native trout.

Water: The Whitechuck River has potential for hydroelectric power development. It is also under study as a wild and scenic river.

Livestock Operations: There is no potential or current livestock use.

Ecology: The parcel is covered with dense and very tall evergreen trees. Dominant species include Douglas fir, western red cedar and western hemlock.

Timber: About 56 percent of the parcel (591 acres) is tentatively suitable for logging. A major bridge across the Whitechuck River would be necessary to manage this area for timber ,

Minerals/Oil and Gas: The geology of this area is dominated by pre-Tertiary metamorphic rocks and by pyroclastic and volcanic sedimentary deposits of Quaternary age. The area has no mining claims recorded for it. The entire area is classified "prospectively valuable" for geothermal resources, but it is not encumbered by any leases or pending lease applications. The mineral resources of adjacent areas have been inventoried by the U.S. Geological Survey and Bureau of Mines, but those areas lying immediately adjacent to the subject area were not identified as having a known mineral resource potential.

Cultural: The parcel has little cultural significance.

Land Use Authorizations: There are no special land uses.

Non-Federal Lands: None.

Fire: There has been one fire in the last decade in this parcel. A larger fire was recorded in the area about 30 years ago.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is adjacent to Glacier Peak Wilderness, and is about 65 miles from Everett. The nearest town is Darrington some 18 miles away.

Public Interest: Following release of the DEIS and Proposed Forest Plan, Glacier Peak Parcel M, as well as areas adjacent to Glacier Peak and specific geographic sites and features within Parcel M, received public comment. Glacier Peak parcel M was mention 21 times in public responses. Most of the comments favored preserving the area as valuable low-elevation old growth (4), designating the area as MA 1AB (primitive/semi-primitive nonmotorized) (3), adding the area to the adjacent wilderness area (2), and protecting the area from timber harvest (2). 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.Public comment did mention, in a generic sense, areas adjacent to Glacier Peak 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20). Other comments said to protect the area for wildlife habitat and recreation values.

The White Chuck River, which flows through a portion of Parcel M, was mentioned 516 times. Most comments favored Wild and Scenic River designation (176), protection from timber harvest (69), keeping the area roadless (43), preserving the forest ecosystem (28), and protecting the old growth ecosystem (25). Other comments favored managing the area for protection of wildlife habitat, fisheries, recreation and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

GLACIER PEAK M
PARCEL M1

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp Rec	401						
1B SPNM		211	1,055	1,055	295		316
2A Foregrd.							274
2B Midgrd.							63
5 Potent W&S							147
11 O-G Hab.		147			42	337	42
14 D&E Enhanc		359				422	
17 Timber	654	337			718	295	211

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternatives C and G-Modified will leave the area in a roadless status through the end of the fifth decade. All other alternatives will road the area, providing access to recreational opportunities.

Fish/Wildlife: *Fish and wildlife will not be significantly affected by* implementation of any of the alternatives. Alternatives B and I allocated the greatest area to old growth habitat and deer and elk enhancement. Alternatives A, NC, C, and G-Modified allocate the least

Water: *Alternatives A, NC and I would allow development of the White Chuck* River for hydroelectric purposes. All other alternatives will preclude development.

Ecology: The overall ecology of the area would be altered due to development with all alternatives except C and G-Modified.

Timber: Alternatives C and G-Modified would have the least affect on the existing timber resource, as they allocate no acres to management area 17 (timber) Alternatives A, NC and H would have the greatest affect.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. All alternatives,

with the exception of C and G-Modified, will provide improved roaded access through the area for mineral exploration and development.

Cultural: Alternatives C and G-Modified will have the least potential for adversely impacting the cultural resources of the area. Alternatives A, NC and H have the greatest potential for impacts. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect land special uses.

Fire: None of the alternatives will significantly affect fire occurrence within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease in the area.

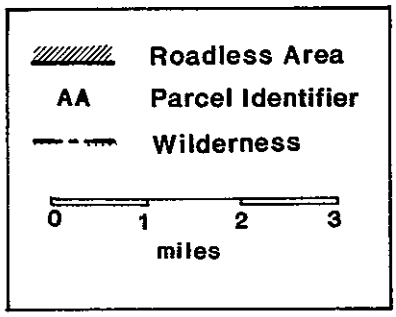
Wilderness Potential: Alternatives C and G-Modified will preserve this area in management prescriptions compatible with preserving its roadless character. These alternatives will retain the area in a roadless condition through the end of the fifth decade. The wilderness potential will be maintained. All other alternatives will retain zero acres in a roadless condition through the end of the fifth decade. These alternatives would preclude future wilderness consideration.

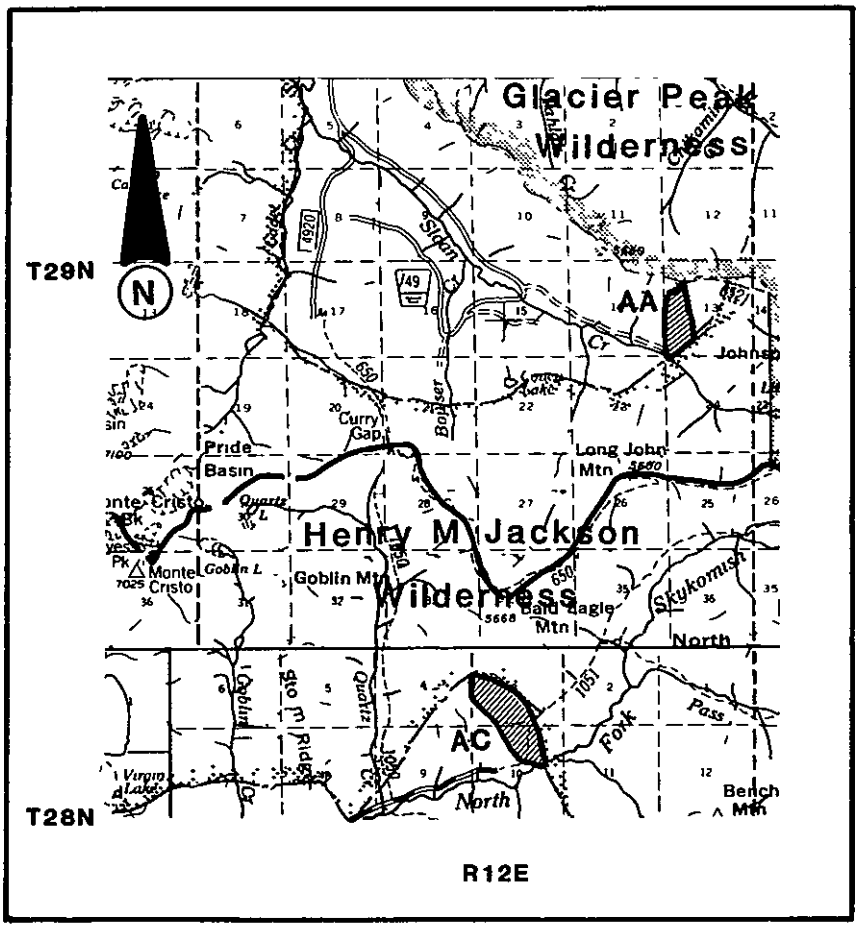
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	158	0	0	0%
B (RPA)	392	0	0	0%
C	1055	1055	1055	100%
G-Mod.	1055	1055	1055	100%
H	392	0	0	0%
I	260	0	0	0%
J (Pref).	392	0	0	0%

Glacier Peak A

Roadless Area A6031





GLACIER PEAK A **Roadless Area A6031 (AA, AC)**

This roadless area originally consisted of 11,110 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area A6031 to nonwilderness uses. In 1984 10,667 acres from this area were designated the Henry M. Jackson Wilderness by Congress as a result of the Washington Wilderness Act. Two parcels remain in roadless status. The following shows the disposition of acres within the Glacier Peak A roadless area:

Glacier Peak A	**Net Acres**
1984 RARE II	11,110
updated 1988	443
Change	**-10,667**

OVERVIEW

This roadless area consists of two parcels. One is located upslope from Sloan Creek at the juncture of Glacier Peak and Henry Jackson Wildernesses. The other parcel is immediately north of the end of Road #63 in the North Fork Skykomish River Basin adjacent to the Henry M. Jackson Wilderness. The terrain is uniformly steep with a south aspect. Elevations range from 3,600 to 5,200 feet. An abandoned logging road ends 1/2 mile to the west of the Sloan Creek parcel.

Plant associations include Pacific silver fir and mountain hemlock mature coniferous forest. Medium textured soils have formed from residual and colluvial rock material overlying glacially altered intrusive igneous gneiss and metasedimentary bedrock. There is an unpatented mining claim within the Sloan Creek parcel, which provides a source of crude garnets to recreationists.

WILDERNESS CAPABILITY

Manageability and Boundaries: The addition of these parcels to adjacent wilderness would have no significant impact on management activities.

Natural Integrity and Appearance: The parcels adjoin cutover areas, although interior slopes appear natural and undisturbed.

Opportunities For Solitude: Opportunities for solitude are low due to the close proximity of roads.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are low due to the proximity of roads.

Challenging Experiences: Opportunities for challenging experiences are low.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Glacier Peak A #A6031

Category 1/	Unit	Parcels AA	AC	Total
Acres (Minus water, private land)	Acres	253	190	443

Claims	# of	0	1	1
Leasable Energy Minerals (Moderate Potential)				
Geothermal	Acres	253	190	443

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Parcel AA receives incidental recreation use from big game hunters. Parcel AC is generally unsuitable for recreation use except the southwestern portion where the North Fork Skykomish trail (#1051) transects the parcel. Use on the trail averages 2,000 recreation visitor days per year.

Wildlife: Old growth forest provides habitat for spotted owls, pine marten, pileated woodpeckers, and native vertebrates. Habitat for native trout is also present in the North Fork Skykomish River.

Water: There is little potential for water use. A few Class III and IV streams exist.

Livestock Operations: None.

Ecology: This parcel is forested with species typical of the west Cascades including cedar, Douglas fir, true firs and western hemlock.

Timber: Only 84 acres (19%) of the 443 acres in this parcel are tentatively suitable for logging.

Minerals/Oil and Gas: These parcels are underlain by Cretaceous metamorphic and granitic rocks. They have no reported mineral occurrences, and have only one mining claim. They are classified prospectively valuable for geothermal resources, but they are not encumbered by any leases or pending lease applications.

Cultural: None.

Land Use Authorizations: There are no special land uses.

Non-Federal Lands: None.

Fire: Fire occurrence is moderate, about 3 fires per decade on the average. Two major fires have occurred in the last 50 years in the Sloan Creek area. Average fuel accumulation is 40-50 tons per acre.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are about 70 miles east of Everett They are adjacent to the Henry Jackson and Glacier Peak Wilderness Areas.

Public Interest: There is little public interest in these parcels. Following release of the DEIS and Proposed Forest Plan, public comments regarding this area were received. Glacier Peak AA was mention 8 times. Three responses favored making the area a top priority for timber harvest; two responses said to not use the area as a wilderness buffer. The other comments desired the area be managed for its recreation value. 1/

Public comment did mention, in a general sense, areas adjacent to Glacier Peak 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20). Other comments said to protect the area for wildlife habitat and recreation values.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person **could** mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The following table displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

GLACIER PEAK A
PARCEL AA

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternative I will allocate approximately one-half of the area to semi-primitive motorized recreation.

Fish/Wildlife: Alternatives A and NC allocate very minimal acres to old growth habitat. None of the other alternatives make specific fish/wildlife allocations. Fish and wildlife will not be significantly affected by implementation of any of the alternatives.

Water: THere are no adverse effects to the water resource of this area associated with implementation of any of the alternatives, due to the low level of development activity.

Ecology: The overall ecology of the area will not be significantly affected by implementation of any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives B and I allocated approximately one-quarter of this area to management area 17 (timber). All other alternatives have made no timber

allocation. None of the alternatives would significantly affect the timber resource, as potential development activity is minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: Alternatives B and I will have some potential to adversely impact cultural resources. All other alternatives, since they propose very minimal development activity, will have no potential to precipitate adverse impacts.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect fire occurrence within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

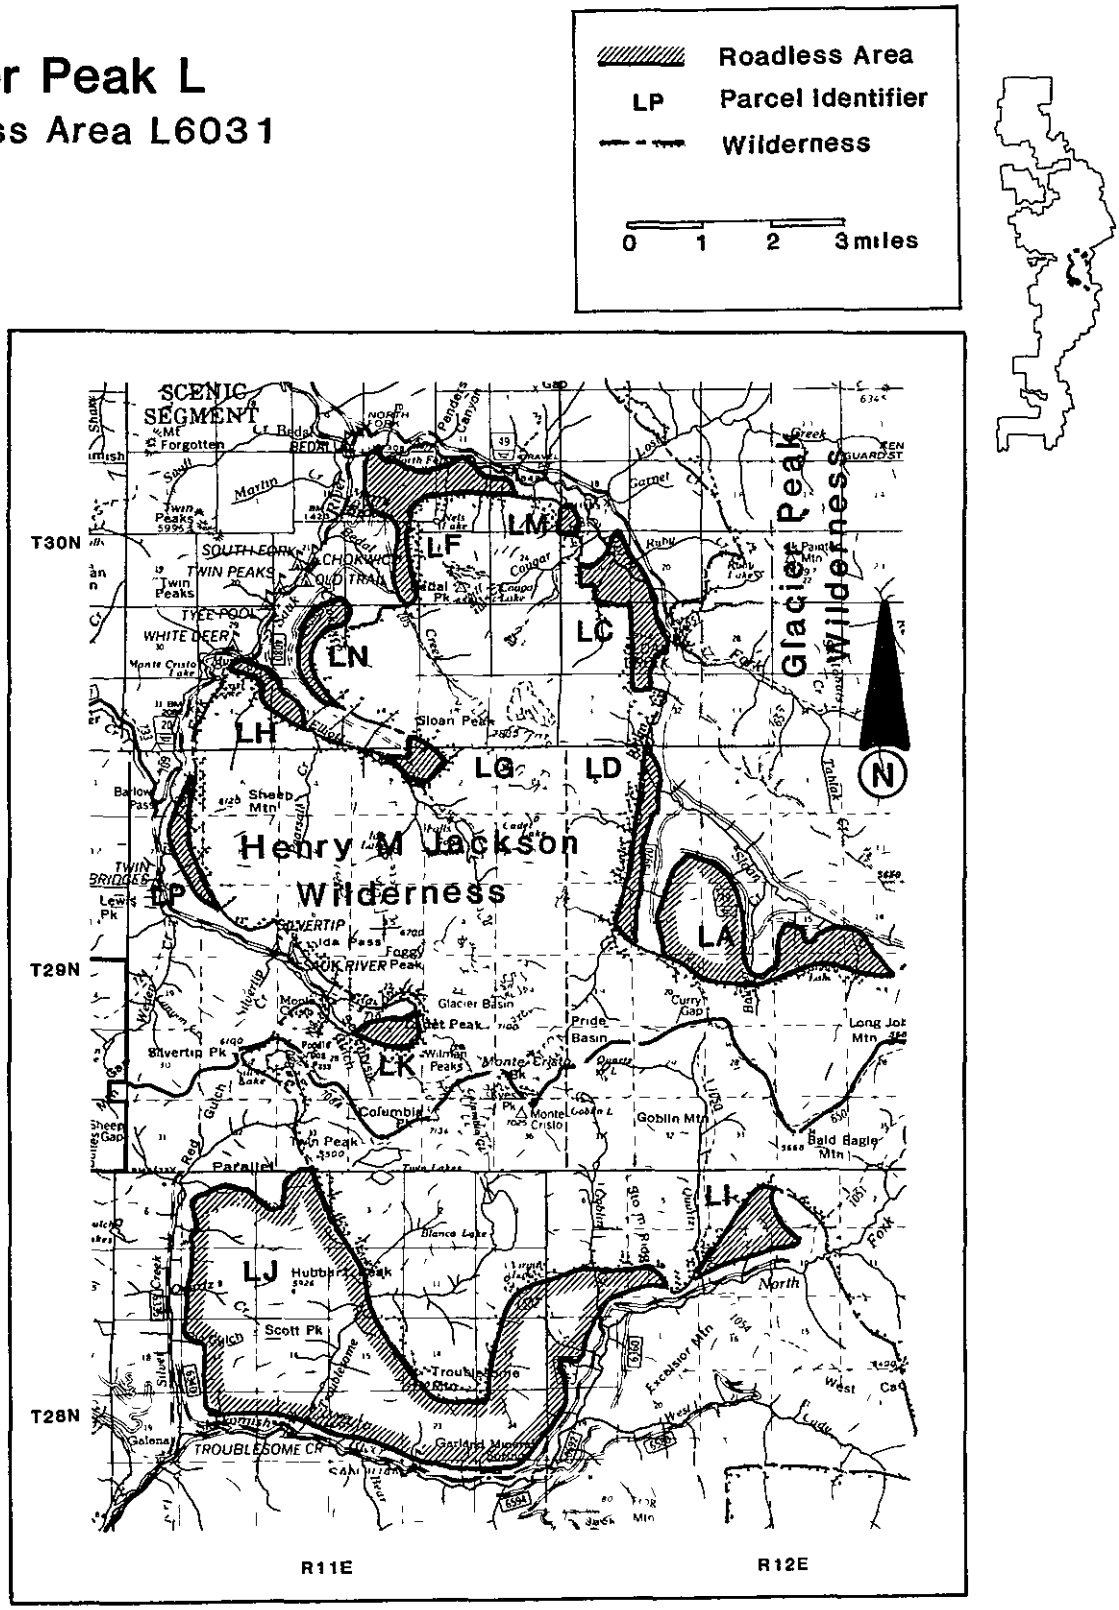
Wilderness Potential: Alternatives A, NC, C, G-Modified and J (Preferred) assign the majority of this area to management prescriptions compatible with preserving its roadless character. These alternatives leave 100% of the area in a roadless condition through the end of the fifth decade. The wilderness potential will be maintained. Alternative I would assign approximately one-half of the area to semi-primitive motorized recreation and one-quarter of the area to timber management. Alternative B allocates 28% of the area to timber management and retains 61% of the area in a roadless condition through the fifth decade.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	443	443	443	100%
B (RPA)	365	331	270	61%
C	443	443	443	100%
G-Mod.	443	443	443	100%
H	395	355	320	72%
I	362	350	274	62%
J (Pref).	443	443	443	100%

Glacier Peak L

Roadless Area L6031



GLACIER PEAK L **Roadless Area L6031 (LA, LD, LC, LM, LF, LN, LG, LH, LP, LK, LJ, LI)**

This roadless area originally consisted of 55,220 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision designated area L6031 to further planning. In 1984, 40,993 acres from this area were designated the Henry M. Jackson Wilderness by Congress as a result of the Washington Wilderness Act. Twelve parcels remain roadless. The following shows the disposition of acres within the Glacier Peak L roadless area:

Glacier Peak L	Net Acres
1984 RARE II	55,220
updated 1988	14,227
Change	**-40,993**

OVERVIEW

These parcels are located around the periphery of the Sloan Peak, Monte Cristo Peak, Kyes Peak, Columbia Peak, and Troublesome Mountain portions of the Henry Jackson Wilderness. Terrain is moderate to generally steep over forested and rocky slopes. Elevations range from 1,400 to 5,000 feet.

Road access is within 1/4 to 1/2 mile of these parcels. Parts of the North Fork Sauk River, the North Fork Skykomish River and many tributaries flow through these parcels.

Plant associations include the western hemlock, Pacific silver fir and mountain hemlock mature conifer forests. Brushfields are common features on some higher slopes and along Cadet Creek.

Soils along valley bottoms originated from glacial and stream transported local bedrock material, including: phyllite, gneiss and sedimentary rock. Soils are generally shallow to moderately deep gravelly, sandy loam. The soils of the upper Cadet Creek area are formed from residual, colluvial, and glacial materials from metasedimentary and medivolcanic rocks. Extremely steep dissected slopes along Cadet and Sloan Creeks are prone to earth movement under natural conditions.

Parcel LK is near the site of a short lived, but major gold mine, circa 1910. There are current mining claims and residents at the nearby former townsite of Monte Cristo. Patented mining claims covering several hundred acres as well as numerous unpatented claims exist in the Hubbart Peak area of parcel LJ.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries are not logical for separate management, but could be added to the Henry M. Jackson Wilderness.

Natural Integrity and Appearance: Most parcels adjoin cutover areas. Generally the upslope portions appear undisturbed. The portions along the North Fork Skykomish River are essentially undisturbed except for existing trails.

Opportunities For Solitude: Opportunities for solitude are low due to adjacent road corridors.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are very low for the northern most "L" parcels. Parcel LJ has the greatest opportunity for primitive recreation because of its size.

Challenging Experiences: The ten northern parcels have very minimal potential for challenging recreational experiences. Parcel LJ provides excellent opportunities for climbing and hiking in rugged terrain.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: Parcels LA, LG and LK have recreation trail corridors. The Bald Eagle trail in area LA accommodates about 1,000 hikers and horsemen per year who are travelling to destination points within the Glacier Peak and Henry M. Jackson Wildernesses. The Elliott Creek trail in area LG and LK accommodates about 5,000 hikers per year who are travelling to destination points within the Henry M. Jackson Wilderness.

Trout fishing occurs in Cadet Creek parcel LD and parcels LC, LM, and LF. It also occurs in the South Fork Sauk River in parcels LH and LP. Use is estimated to be relatively low in all areas, except the South Fork Sauk which receives greater use.

Area LN receives only incidental use by big game hunters. These parcels are generally unsuitable for recreation use except in trail corridors due to the steep, rugged terrain. Use on the Blanca Lake trail (#1052) in parcel LJ averages approximately 4,500 recreation visitor days annually. Use levels in remaining portions of this parcel are insignificant.

Fish/Wildlife: Old growth forest provides habitat for spotted owls, pine marten and pileated woodpeckers. Habitat is also afforded for several species of native vertebrates, and for native trout. The south side of Troublesome Mountain includes primary and secondary mountain goat range for three to four families.

Water: There is little potential for water use. Several streams feed the North Fork Skykomish River, an important anadromous fish river in the LJ parcel. There are several power withdrawals with FERC study permits.

Livestock Operations: None.

Ecology: The northern most parcels are brushfields of vinemaple and alder on higher slopes and along Cadet Creek. Steep slopes have cliffs and mature *conifer forests including hemlock, silver fir and mountain hemlock. The* southern half of parcel LJ is forested with species typical of the west Cascades including cedar, Douglas-fir, true firs, and western hemlock. The northern half is composed of numerous steep rock bluffs with scattered parcels of trees and other ground vegetation intermixed.

Summary Table - Glacier Peak L #L6031

Category 1/	Unit	Parcels LA	LD	LC	LM	LF	LN	LG	LH	LP	LK	LJ	LI	Total

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.
3/ Number of claims not broken out by parcel.

Timber: About 34 percent of these roadless parcels (4,791 acres) are tentatively suitable for logging.

Minerals/Oil and Gas: This area lies within or immediately adjacent to the Monte Cristo, Silver Creek, Troublesome Creek, and Goat Lakes mining districts. The geology of the area, in general, is dominated by Tertiary volcanic and granitic rocks and by Mesozoic metamorphic rocks. Of the subject lands, only LJ has reported mineral occurrences, but the districts in general have numerous occurrences. According to BLM records the subject lands have 159 mining claims. The southwest parcels are classified "prospectively valuable" for coal, but none of the area is encumbered by leases or pending lease applications. The area has been studied by the U.S. Geological Survey and Bureau of Mines, and they have concluded the following:

Parcel LK lies within an area identified as having "substantiated" or a high potential for the occurrence of copper (Cu), lead (Pb), zinc (Zn), gold (Au), and silver (Ag) resources.

Parcels LC, LD, and LA have a moderate potential for the occurrence of the same minerals.

Parcel LJ has numerous mineral resource occurrences and is identified as having a "substantiated" or high mineral resource potential. Not only does it have potential for the occurrence of Au, Ag, Cu, Pb, and Zn in vein type deposits, but it also has a high potential for the occurrence of large disseminated porphyry type copper deposits which includes two deposits that are large enough to employ lower-cost open pit or sub-level caving mining methods.

Cultural: These parcels have little cultural significance. Evidence of mining activity in parcel LJ can be found.

Land Use Authorizations: There are no land special uses.

Non-Federal Lands: None.

Fire: There is an average 2 fires per decade, with two major fires in the past 40 years. Average fuel accumulation is 60 ton per acre.

Insect and Disease: There have been no particular problems with insect infestations or disease.

Others: The Monte Cristo parcel LK has had proposals for mining and recreation development. Access is via a county road which is on National Forest lands and would require reconstruction to permit increased access.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are adjacent to the Henry Jackson Wilderness, and are about 85 miles from Seattle.

Public Interest: Following release of the DEIS and Proposed Forest Plan, no public comments were received on Glacier Peak parcel L specifically. This parcel received comments in a more general sense as part of other areas.

Lands adjacent to the Henry M. Jackson Wilderness were mentioned 175 times. Most of the comments favored the area remain roadless (57), protected from timber harvest (38), the forest ecosystem preserved (34), and old growth preserved (11). Most other comments desired to have the area managed for recreation, wildlife habitat and visual quality. 1/ Public comment did also mention, in a general sense, areas adjacent to Glacier Peak 293 times. Responses favored protecting the area from harvest (78), preserving the forest ecosystem (52), keeping the area roadless (44), and protecting old growth (20). Other comments said to protect the area for wildlife habitat and recreation values.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternatives C and G-Modified leave the greatest amount of unroaded acres at the end of the fifth decade (89% respectively). Alternative I leaves the least (74%). Alternative I allocates approximately one-fifth of the area to semi-primitive motorized recreation.

Fish/Wildlife: Alternatives B and I allocate the greatest area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives C, G-Modified and H allocate the least. Fish and wildlife will not be significantly affected by implementation of any of the alternatives.

Water: Hydroelectric development would be precluded under Alternatives B, C, G-Modified, H and J (Preferred), due to allocations of land to semi-primitive nonmotorized and wild and scenic river prescriptions. Development would be possible under alternatives A, NC and I.

Ecology: The overall ecology of the area would not be significantly affected by implementation of any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives C and G-Modified would have the least affect on the existing timber resource, as they allocate minimal acres to management area 17 (timber). Alternatives A, B and I would have the greatest affect. None of the alternatives will have a significant affect on the timber resource, as potential development activity is minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC and I will provide a higher amount of roaded access through the area for minerals exploration and development.

Cultural: Alternatives A, NC, B and I have the greatest potential to adversely affect cultural resources within the area. None of the alternatives will significantly affect cultural resources.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

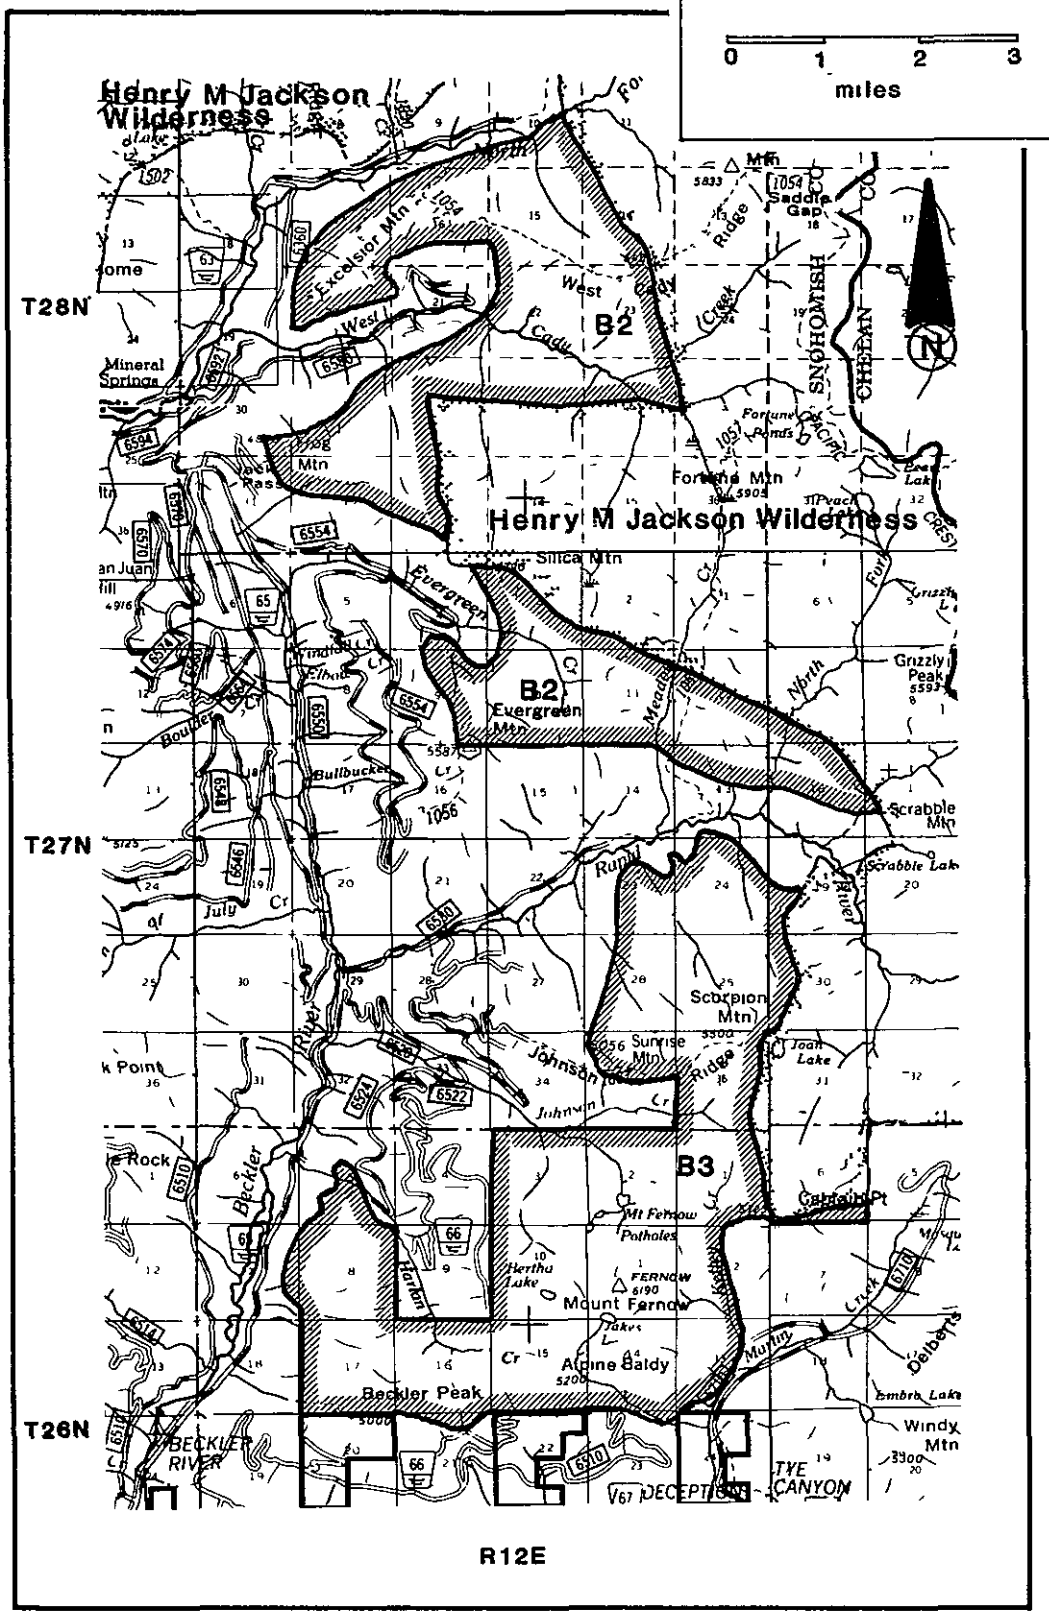
Wilderness Potential: Alternatives C, G-Modified, H and J (Preferred) assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns approximately one-fifth of the area to semi-primitive motorized recreation. All alternatives will maintain the area in a primarily roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	12,469	11,549	10,723	75%
B (RPA)	12,715	12,007	10,678	75%
C	13,750	13,244	12,681	89%
G-Mod.	13,543	13,017	12,632	89%
H	13,042	12,246	11,428	80%
I	12,658	11,976	10,598	74%
J (Pref).	13,480	12,994	12,220	86%

Glacier Peak B

Roadless Area B6031



GLACIER PEAK B **Roadless Area B6031 (B2, B3)**

This roadless area originally consisted of 43,186 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area B6031 to nonwilderness uses. In 1984, 24,540 acres from this area were designated the Henry M. Jackson Wilderness by Congress as a result of the Washington Wilderness Act. Two parcels remain roadless. The following shows the disposition of acres within the Glacier Peak B roadless area:

Glacier Peak B	Net Acres
1984 RARE II	43,186
updated 1988	18,646
Change	**-24,540**

OVERVIEW

These parcels are adjacent to the Henry M. Jackson Wilderness, extending from Beckler Peak and Alpine Baldy Mountain on the south, and north to the North Fork Skykomish River drainage. They include all currently undeveloped lands west to the Beckler River. Access is provided by Forest Service roads along the North Fork Skykomish and Rapid Rivers, Johnson Ridge, Beckler Peak, and West Cady, Evergreen, and Martin Creeks.

Elevations range from approximately 1,800 to over 6,000 feet. Peaks include Mount Fernow, Sunrise and Scorpion Mountains, Johnson Ridge, Evergreen and Frog Mountains, West Cady Ridge, and Excelsior Mountain. Steep sideslopes are characterized by rock outcroppings, and talus slopes. These parcels are comprised primarily of 30-100% slopes with northerly or southerly aspects along east/west drainages.

Soils on sideslopes are typically shallow sandy loams with moderate to high erosion potential and good drainage. Glacial deposits in valley bottoms provide deep, relatively well drained soils with a sandy loam surface. Bedrock is generally intrusive igneous and gneiss rock.

Vegetation varies with aspect, elevation, and site conditions. The primary cover is mixed Pacific silver fir and western hemlock stands. Higher elevations have Pacific silver fir and mountain hemlock. Typical ground cover is huckleberry, salal, and Oregon grape. Where soils support trees and fire has not disturbed ecological succession, old growth stands exceed 400 years of age. The largest proportion of forest cover is 200-400 years old. Areas on West Cady Ridge and Evergreen Mountain are still recovering from fire disturbances of the last 100 years. Wide variation in tree age classes provide an opportunity to view and study stages of ecosystem development.

Heavy recreation use occurs on trails up the North Fork Skykomish River, Cady Creek, and Meadow Creek. Fernow Potholes and Jakes Lake are regularly fished for trout. Northern Spotted Owl habitat abounds and three Spotted Owl Habitat Areas have been established. Pileated woodpecker, pine marten, and mountain goat are also found here. Some hydroelectric development is proposed, although no proposals have yet shown economic viability or have approved development plans.

The majority of lands in these parcels have the appearance of being in a natural state; however, most vistas are heavily modified by human impacts. The natural landscapes are high-mountain, low timber-producing sites with rock outcroppings and avalanche chutes. Extensive management activities have occurred in the Beckler River and North and the South Fork Skykomish drainages. West Cady Creek has received heavy logging activities.

WILDERNESS CAPABILITY

Manageability and Boundaries: These parcels could be included in the Henry M. Jackson Wilderness. Boundaries would not be easily recognizable or manageable. Sights and sounds uncharacteristic of a wilderness experience are present in approximately 60 percent of the area.

Natural Integrity and Appearance: The parcels are natural in appearance. Trail improvements are the only visible impacts within their borders.

Opportunities For Solitude: Opportunities for solitude are limited by activities on adjacent lands and by heavy recreation use within these parcels.

Opportunities For Primitive Recreation: Primitive recreational use centers on hunting and fishing. Fernow Potholes is the only known destination point.

Challenging Experiences: There is limited opportunity for challenging experiences. A "scrambling hike" requiring endurance rather than skill is available on the highest slopes.

Special Features: The primary feature is ecological succession. The variability of stand-age classes permits appreciation of a wide range of ecosystems. Other interest centers around wildlife, including mountain goats, spotted owls, and bald eagles

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: These parcels provide access to the Henry M. Jackson Wilderness. Use is generally restricted to the West Cady Ridge Trail (#1054), Johnson Ridge Trail (#1067), Meadow Creek Trail (#1057) and the Mt. Fernow area and averages approximately 3,000 recreation visitor days annually. The West Cady Ridge and Meadow Creek trails are suitable for pack and saddle stock use.

Wildlife: Old growth forest provides habitat for Spotted owls, pine marten, pileated woodpeckers, and mountain goats. Native trout species, both naturally occurring and introduced, are found in lakes and streams throughout these parcels.

Water: Drainages include Kelly, Johnson, Harlan, and Evergreen Creeks. All but Kelly Creek drain into the Beckler River. Kelly Creek feeds into Martin Creek. Both Beckler River and Martin Creek flow into the South Fork Skykomish which provides anadromous fisheries habitat. Streams with their headwaters in wilderness flow through the area and into these drainages, as well as into the North Fork Skykomish River. Some power withdrawals have been granted, and developers are in the process of gaining FERC permits.

Livestock Operations: None.

Ecology: Most of the parcels are forested with species typical of the west Cascades including cedar, Douglas fir, true firs, and western hemlock. There are alpine meadows in the Alpine Baldy vicinity

Summary Table - Glacier Peak B #B6031

Category 1/	Unit	Parcels B2	Parcels B3	Total

Bald eagle habitat 2/	Acres	0	0	0
Locatable Mineral Development Potential				
High	Acres	0	0	0
Moderate	Acres	0	0	0
Low	Acres	168	2,344	2,512
Claims	# of	0	2	2
Leasable Energy Minerals (Moderate Potential)				
Geothermal	Acres	8,700	9,946	18,646

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.
2/ Includes nest sites, forage areas, and roost areas.

Timber: Approximately 21 percent of this area or 3,905 acres is tentatively suitable for logging.

Minerals/Oil and Gas: The geology of the area is dominated by Mesozoic granitic rocks and Jurassic metamorphic rocks. According to available MILS data, the area has no reported mineral resource occurrences of significance, however, it does have two mining claims. The area is classified "prospectively valuable" for geothermal, but it is not encumbered by any leases or pending lease applications. The area has not been inventoried by the U.S. Geological Survey and Bureau of Mines, but based on available data it appears that the areas potential for mineral resource occurrences is low.

Cultural: There are old trapper's cabins and trails located here.

Land Use Authorizations: There are no land special uses.

Non-Federal Lands: None.

Fire: There is low to moderate fire occurrence. Fires start mainly from lightning or abandoned campfires, but they remain small.

Insect and Disease: Insects and diseases endemic to natural ecosystems are present.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are 60-80 miles from Everett. They are located west of the Henry M. Jackson Wilderness.

Public Interest: Following the release of the DEIS and Proposed Forest Plan, Glacier Peak parcel B, as well as specific geographic sites and features within this parcel and its more general location, received public comment.

Glacier Peak parcel B was mentioned 15 times. Three response said this area should be a top priority for timber harvest, three said to increase opportunities for motorized recreation there, and two comments wanted the area kept open for multiply use. The remaining comments favored keeping the area roadless, preserving the forest ecosystem, protecting wildlife habitat and managing the area for nonmotorized recreation. One comment expressed the desire to not use this area as a wilderness buffer. 1/

Glacier Peak parcel B2 (a portion of parcel B) was mentioned 4 times. Responses were split between making the area a top priority for harvest and preserving the forest ecosystem.

Glacier Peak parcel B3 (a portion of parcel B) was mentioned 5 times. Responses were split between making the area a top priority for harvest and preserving the forest ecosystem.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Cady Creek was mentioned 14 times. The comments favored protecting the old growth ecosystem (4), protecting the area from harvest (2), and designating it a Wild and Scenic River (2). One comment received expressed the desire to make this area a top priority for timber harvest.

Johnson Ridge was mentioned 11 times. Most of the comments said to keep the area roadless (3), restrict ORV use (2), and protect it from timber harvest (1). One comment was received that said to make this area a top priority for timber harvest.

Kelly Creek was mention 210 times. The comments expressed the desire to keep the area roadless (68), preserve the forest ecosystem (41), protect it from harvest (37), and protect the old growth ecosystem (16). The remaining comments favored managing the area for recreation and protecting wildlife habitat.

Lands adjacent to the Henry M. Jackson Wilderness were mentioned 175 times. Most of the comments favored the area remain roadless (57), protected from timber harvest (38), the forest ecosystem preserved (34), and old growth preserved (11). Most other comments desired to have the area managed for recreation, wildlife habitat and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

19 Mtn. Hemlk		3,632	147	591	2,534	3,125	2,766

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternative C and G-Modified would remove the fewest acres from roadless status through the end of the fifth decade. Alternative A, the alternative taking the greatest amount of area from roadless status, retains 90% of the area as roadless through the end of the fifth decade. Alternative I will allocate slightly over one-third of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by implementation of any of the alternatives. Alternatives B, H and I allocated the greatest area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives A, NC, C and G-Modified allocate the least.

Water: Hydroelectric development will be largely precluded under Alternatives B, C, G-Modified, H and J (Preferred), due to allocations to the semi-primitive nonmotorized and wild and scenic rivers prescriptions. Alternatives A, NC and I will allow development.

Ecology: The overall ecology of the area would not be significantly affected by implementation of any of the alternatives, due to the low level of proposed development activity

Timber: Alternatives C and G-Modified will have the least affect on the existing timber resource, as they allocate very minimal acreage to management area 17 (timber) Alternatives B and I will have the greatest affect. None of the alternatives will significantly affect the timber resource, as potential harvest activity will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B and I will provide slightly greater roaded access through the area for minerals exploration and development.

Cultural: Alternatives A, NC, B, I and J (Preferred) will have the greatest potential to adversely impact cultural resources in the area, due to development activities. Alternatives C and G-Modified will have the least. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect fire occurrence within the area.

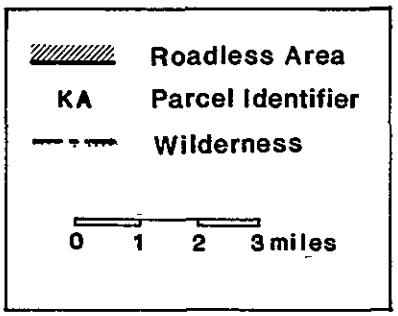
Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

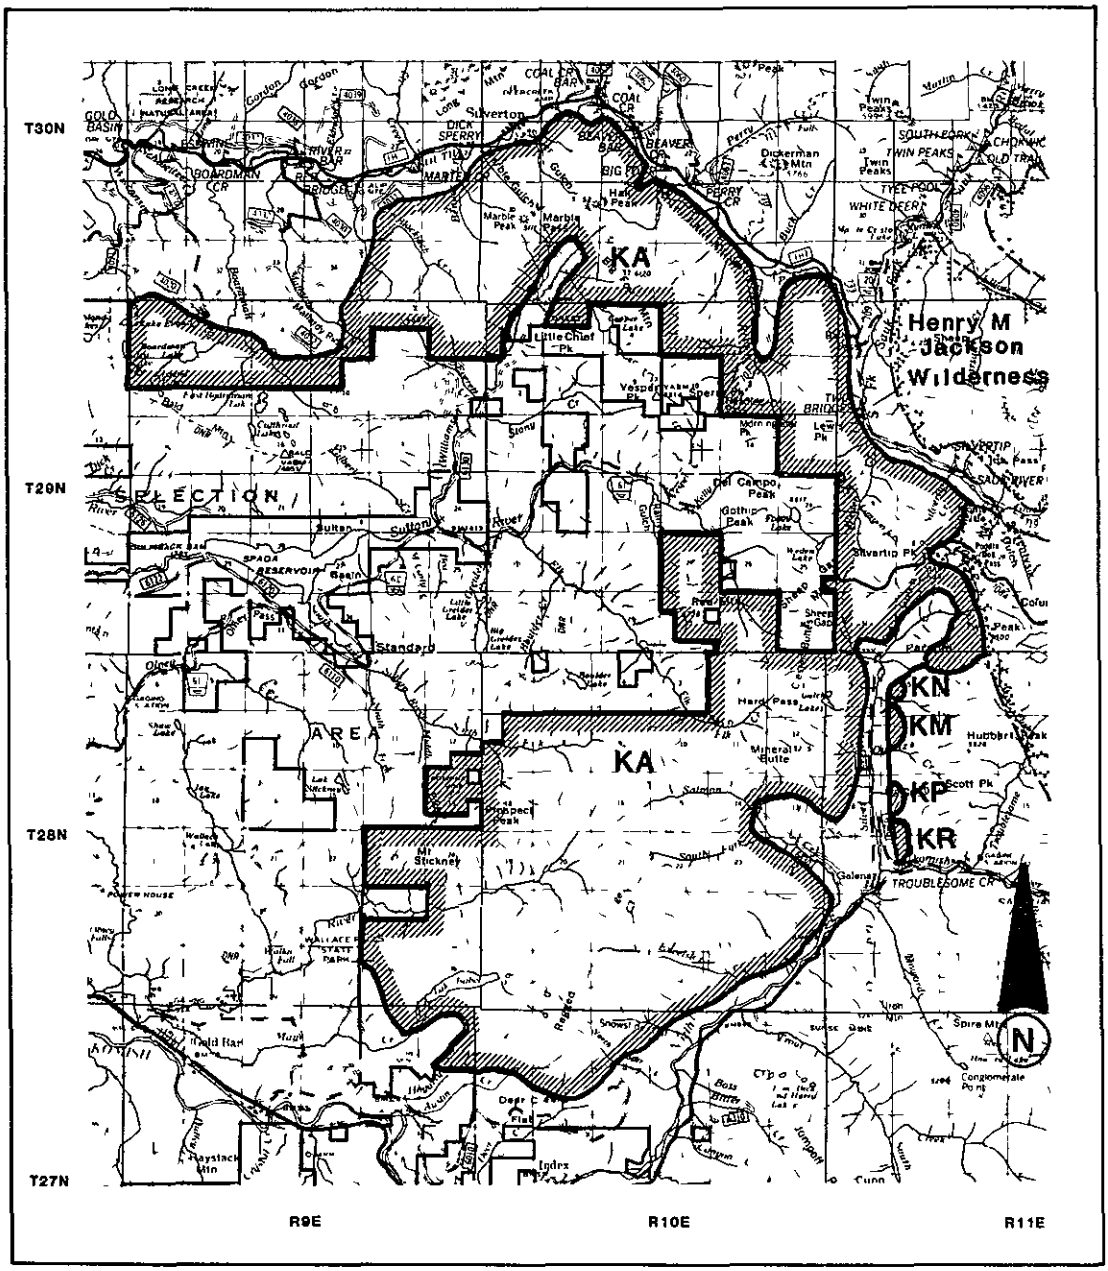
Wilderness Potential: All alternatives assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I allocates slightly over one-third of this area to semi-primitive motorized recreation. All alternatives will maintain the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	17,863	17,319	16,826	90%
B (RPA)	18,004	17,606	17,200	92%
C	18,589	18,555	18,513	99%
G-Mod.	18,478	18,382	18,294	98%
H	18,337	18,107	17,902	96%
I	18,193	18,011	17,661	95%
J (Pref)>	18,202	17,896	17,603	94%

Glacier Peak K
Roadless Area K6031





GLACIER PEAK K **Roadless Area K6031 (KA, KN, KM, KP, KR)**

This roadless area originally consisted of 45,745 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area K6031 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Act. Five parcels make up the Glacier Peak K roadless area.

The Timbuktu Timber sale contract has been awarded within this roadless area which removed 64 acres from roadless status. The area was reduced by 172 acres due to a mapping discrepancy. The following shows the disposition of acres within the Glacier Peak K roadless area.

Glacier Peak K	Net Acres
1984 RARE II	45,745
updated 1988	45,509
Change	**- 236**

OVERVIEW

These parcels are located along the southern boundary of the Darrington Ranger District (from Boardman Lake to Silvertip Peak), and on the Skykomish Ranger District (southwest from Silvertip Road to Lake Isabel). Terrain is moderate to generally steep over forested and rocky slopes. Elevations range from 1,600 to 6,100 feet. Road access to within 1/4 to 1/2 mile of these parcels occurs in many places. Parts of the South Fork Stillaguamish River and many tributaries comprise the watershed. Some lands are located in the City of Everett municipal watershed.

Plant associations include the western hemlock, Pacific silver fir, and mountain hemlock mature conifer forests. Highest elevations are comprised of bare rock and snow fields. Alpine meadows are small and uncommon.

Soils are shallow to moderately deep, formed in metasedimentary, and sedimentary rock. Soil and landscape formation was influenced by glacial scouring and deposition, weathering, and rock transport by streams and gravity. Extremely steep slopes and areas of lacustrine silty clays are prone to failure under natural conditions.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries are illogical and do not comprise a discrete, manageable area.

Natural Integrity and Appearance: Appearance is mostly natural. Long-term ecological processes are ongoing. Due to size, shape, and location of these parcels, it is doubtful they could remain unaffected by nearby activities.

Opportunities For Solitude: Opportunities for solitude are low due to adjacent travel corridors and timber management activities.

Opportunities Primitive Recreation: Lake Evans and Boardman Lake are popular destinations. Trails to Poodle Dog Pass, Headlee Pass, and Gothic Basin receive heavy use.

Challenging Experiences: Opportunities for challenging experiences are good. This is mostly a day-use area, with potential for longer excursions limited due to the rugged terrain of Ragged Ridge.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: The trails to Boardman Lake, Headlee Pass and Weden Creek each accommodate about 1,500 hikers per year. Fishing and viewing are the attractions at Boardman Lake. Viewing scenery and mountain climbing are the attractions at Headlee Pass and Weden Creek. The South Fork of the Stillaguamish River receives heavy pressure from sports fishermen due to easy access. In the southern portion of this parcel use is primarily centered on trail corridors leading to lakes and mountain tops, but use levels are very low due to steep, rugged topography.

Fish/Wildlife: Old growth forest provides habitat for spotted owls, pine marten and pileated woodpeckers. Mountain goats inhabit Headlee Pass. Anadromous fish reside in the South Fork Stillaguamish River; other streams support native trout.

Water: Several of the larger streams have potential for hydropower development.

Livestock Operations: None

Ecology: Generally, areas below 4,000 feet elevation are forested with species typical of the west Cascades including cedar, Douglas fir, true firs, and western hemlock. The higher elevations are typically steep rock and open slopes supporting snow a majority of the year.

Timber: Nineteen percent of this area is tentatively suitable for logging.

Minerals/Oil and Gas: The geology of the area is dominated by Jurassic metamorphic volcanic and sedimentary rocks and by Tertiary granitic and ultrabasic rocks. The area has numerous reported mineral resource occurrences, and there are 581 mining claims located within it. The northern part of the area lies within the Squire Creek and Silverton mineral resource areas, which are identified as having a moderate to low potential for the occurrence of copper, lead, zinc, gold and silver resources.

The eastern portion lies adjacent to the Monte Cristo mining district and is within the Silver Creek and Sultan areas, which have numerous reported mineral resource occurrences. The Silver Creek District has a history of past production and is considered to have a moderate to high potential for the occurrence of copper, lead, gold and silver.

Summary Table - Glacier Peak K #K6031

Geothermal	Acres	23,420	0	0	0	0	23,420

1/ American Indian Religious and Cultural areas were analyzed Site specific information is not disclosed due to its sensitivity

2/ Number of claims is not broken out by parcel.

Those parcels lying east of Silver Creek (KA, KN, KP, and KP) lie within an area identified by the U.S. Geological Survey and Bureau of Mines as having a "substantiated" or high potential for the occurrence of copper, silver, gold, lead and zinc in lode type deposits. That portion of KA lying within Section 33, T.29N.,R.11E. and in Section 4 and 5, T.28N.,R.11E. has been identified as having a high potential for the occurrence of large disseminated porphry-type copper deposits, which are large enough to employ lower cost open pit or sub-level caving methods of mining.

That portion of the area lying within T.28N.,R.9 and 10E. within the Sultan Mining District, which also has potential for the occurrence of gold, copper, iron and lead in the form of lode deposits. The area around Red Mountain has a potential for the occurrence of chromite deposit in the form of magmatic segregation type deposits.

A large portion of the area along the Stillaguamish and Sauk Rivers and along Silver Creek are classified "prospectively valuable" for coal, and all but that area lying west of R.10E. is classified "prospectively valuable" for geothermal resources. However, none of the area is encumbered by leases or pending lease applications.

Cultural: A few areas of significance are associated with former mines.

Land Use Authorizations: *There are no special land use authorizations.*

Non-Federal Lands: None.

Fire: There have been 3-4 fires per decade, with three major fires in the past 40 years. Average fuel accumulation is 60-80 tons per acre.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are approximately 60 miles from Everett. They are south and west of the Boulder River and Henry M. Jackson Wilderness Areas.

Public Interest: Following release of the DEIS and Proposed Forest Plan, Glacier Peak parcel K, plus specific geographic sites and features within the parcel and its adjacency to other areas, received public comment.

Glacier Peak parcel K was mention 17 times. The comments were split between making the area a top priority for timber harvest (3), keeping it open for mining (3), and building more roads (3), and managing it for recreation (3), *the protection of wildlife habitat (2), and retention of old growth (2).* 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Big Four Mountain was mentioned 31 times. Eight responses favored preserving the forest ecosystem, seven wanted the area to remain roadless, four wanted the area protected from timber harvest, and three said to protect the old growth ecosystem. The remaining comments expressed a desire for the area to be managed for recreation and added to the wilderness.

Mt. Stickney was mentioned 12 times. The comments favored expanding the trail system, protecting the area from harvest, keeping the area roadless, and managing the area for recreation.

Lands adjacent to the Henry M. Jackson Wilderness were mentioned 175 times. Most of the comments favored the area remain roadless (57), protected from timber harvest (38), the forest ecosystem preserved (34), and old growth preserved (11). Most other comments desired to have the area managed for recreation, wildlife habitat and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternative G-Modified would leave the area effectively roadless through the end of the fifth decade. Alternative I would remove the greatest amount of acreage from roadless status, but still leaves 82% of the area roadless at the end of the fifth decade.. Alternative I would also allocate slightly over one-third of the area to *semi-primitive motorized recreation.*

Fish/Wildlife: Fish and wildlife will not be significantly affected by implementation of any of the alternatives. Alternatives B and I allocate the greatest area to old growth habitat, mature old growth, deer and elk *enhancement and mountain goat management requirement.* Alternative G-Modified allocates the least.

Water: Hydroelectric development will be largely precluded under Alternatives B, C, G, H, and J (Preferred), due to the emphasis in these alternatives on semi-primitive nonmotorized recreation. Development could proceed under Alternatives A, NC and I.

Ecology: The overall ecology of the area will not be significantly affected by implementation of any of the alternatives, due to the low level of potential development activities.

Timber: Minimal acreage is allocated to management area 17 (timber) over all alternatives. Alternatives A, NC, B and I allocate the greatest amount of area to timber management. Alternatives C and G-Modified allocate the least. None of the alternatives will significantly affect the timber resource.

Minerals/Oil/Gas: Alternative G-Modified allocates approximately one-quarter of the area to management area 8 (special). This allocation will withdraw these designated acres from mineral entry. Alternatives A, NC and I will provide a slightly higher level of roaded access through the area for mineral exploration and development.

Cultural: Alternatives A, NC and I will have the greatest potential to adversely impact cultural resources in the area, as they are associated with the greatest development activity. Alternatives C and G-Modified will have the least potential for impact.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire in the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns slightly more than one-third of the area to semi-primitive motorized recreation. Alternatives C and G-Modified retain the greatest area in roadless status through the end of the fifth decade. Alternative A, NC,B and I retain the least. All alternatives, however, will maintain the area in a primarily roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	**Decade 1**	**Decade 2**	**Decade 5**	**Remaining**
A (No Act)	42,764	40,204	37,492	82%
B (RPA)	43,115	40,793	38,346	84%
C	44,792	44,048	42,960	94%

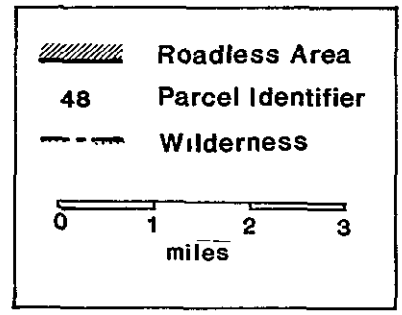
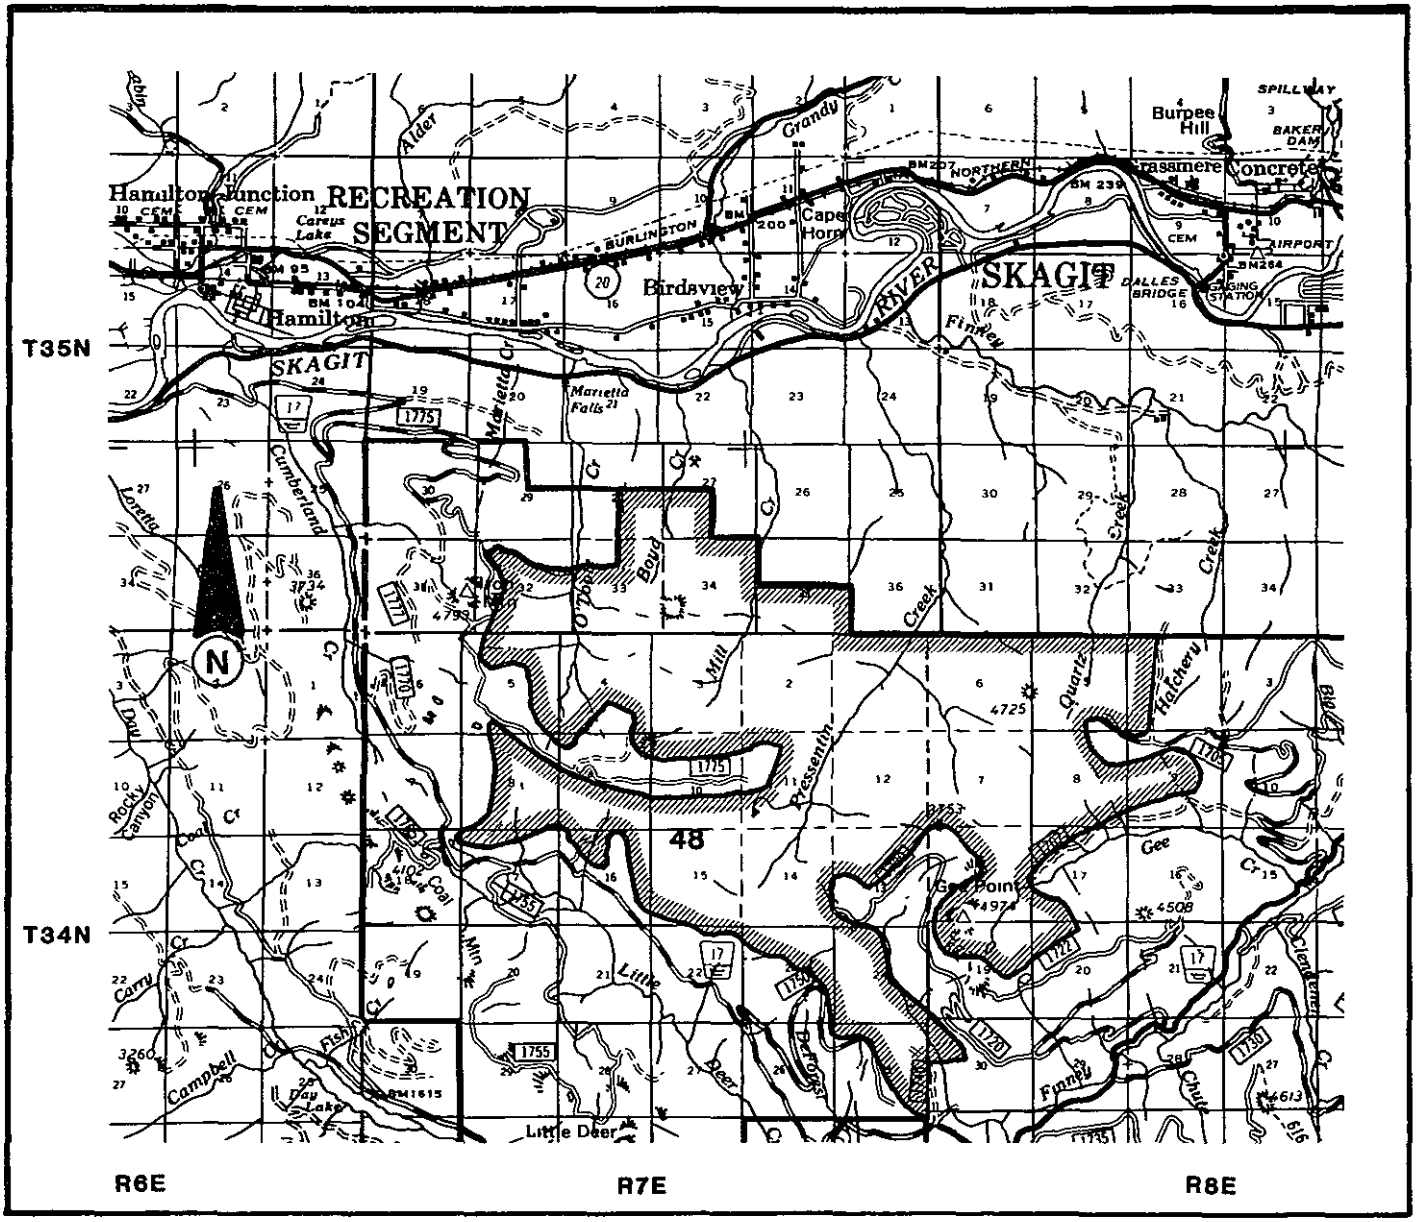
Pressentin

Roadless Area 6048





PRESSENTIN **Roadless Area 6040**

This roadless area originally consisted of 16,000 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6048 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation.

In 1986 the O'Toole Timber Sale was sold under contract within this roadless area. This sale removed 802 acres from roadless status. The area was reduced by 141 acres due to a mapping discrepancy. The following shows the disposition of acres within the Pressentin roadless area:

Pressentin	**Net Acres**
1984 RARE II	16,000
updated 1988	15,057
Change	**- 943**

OVERVIEW

This parcel is located southwest of Concrete, between the Forest boundary to the north and existing forest road systems to the south. The area drains into the Skagit River. Road access is provided via the Finney-Cumberland Road (#17), the Claims Road (#1775), the Gee Point-Pressentin Road (#1720), and the Gee Creek Road (#1705).

Drainages include the upper portions of O'Toole Creek, Boyd Creek, Mill Creek, Pressentin Creek, and Quartz Creek; the area is highly dissected by these drainages and terrain is moderately rugged. Elevation ranges from 2,000 to 5,080 feet.

The predominant cover types below 2,800 feet elevation are Douglas-fir and western hemlock, with some western red cedar on wetter sites. Above 2,800 feet, the predominant types are Pacific silver fir and western hemlock, with some mountain hemlock at the higher end of the forested range (4,000-5,500)

Soils are variable, with unstable soil adjacent to the steep sideslope along creeks. Scattered pockets of shallow soils on upper sideslopes and ridgetops.

WILDERNESS CAPABILITY

Manageability and Boundaries: This parcel lies in a relatively isolated block of National Forest land. Boundary location and manageability may be difficult due to irregular boundaries adjacent to existing roads, and State and private land located to the north.

Natural Integrity and Appearance: The parcel is heavily forested and natural in appearance.

Opportunities For Solitude: Opportunities for solitude are many due to large size and low recreation use.

Opportunities For Primitive Recreation: There are opportunities for cross-country hiking and hunting.

Challenging Experiences: Opportunities for unusually challenging experiences are minimal.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Pressentin #6048

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	15,057
Primitive/Semi-Primitive Recreation ROS	Acres	8,658
Timber		
Tentatively suitable	Acres	9,038
Tentatively suitable inaccessible	Acres	3,104
Tentatively suitable standing volume	M bdft	353,630
"Old Growth", Total Acres	Acres	11,867
0-2,500 Feet Elevation	Acres	1,034
2,500-4,000 Feet Elevation	Acres	8,933
4,000 + Feet Elevation	Acres	443
Management Indicator Species (MIS)		
Spotted owl MR	Acres	3,400
Pileated woodpecker and pine marten MR	Acres	654
Elk-deer winter range	Acres	527
Goat habitat MR	Acres	0
Bald eagle habitat (nests, forage, roost area)	Acres	0
Locatable Mineral Development Potential		
High	Acres	0
Moderate	Acres	0
Low	Acres	15,057
Claims	# of	6
Leasable Energy Minerals	Acres	0

1/ American Indian Religious and Cultural Uses areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Small amount of recreation use (other than hunting) occurs on the Gee Point Trail #612.

Fish/Wildlife: This parcel contains three spotted owl habitat areas and one pine marten management area.

Water: Several tributaries to the Skagit River include O'Toole Creek, Boyd Creek, Mill Creek, Pressentin Creek, and Quartz Creek.

Livestock Operations: None.

Ecology: Most of the parcel is relatively low elevation and forested with species typical of the west Cascades. The Gee Point vicinity is an island of non-commercial sub-alpine vegetation.

Timber: Timber harvest has occurred on private land adjacent to the northern boundary of this parcel. Some 60 percent of the area is classed tentatively suitable for harvest.

Minerals/Oil and Gas: The geology of the area is dominated by Jurassic aged metamorphic, pre-Tertiary ultrabasics, Tertiary aged nonmarine sedimentary rocks and by glacial drift of Quaternary age. The area has no reported mineral resource occurrences of significance, however, it does have 6 mining claims located within it. A large portion of the area along the west side is classified "prospectively valuable" for coal resources, but the area is not encumbered by any leases or pending lease applications. The area has not been inventoried by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears that the area has a relatively low potential for the occurrence of mineral resources.

Cultural: No areas of cultural significance are known within this parcel.

Land Use Authorizations: There are no special land authorizations.

Non-Federal Lands: There are 40 acres of non-Federal lands.

Fire: Approximately 300 acres on the northwest-facing slope of O'Toole Creek burned in the early 1950's. Evidence of isolated lightning strikes can be found on ridges in the Pressentin Creek drainage.

Insect & Disease: There are no insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The towns of Concrete and Sedro Woolley are each about 30 miles away, Bellingham is 50 miles away, and Seattle is 100 miles away. This parcel is nearly encircled on three sides by the Mt. Baker, Noisy Diobsud, Glacier Peak, and Boulder River Wilderness Areas.

Public Interest: Local and other public sentiment has been moderately to strongly in favor of multiple-use development of this parcel. Following release of the DEIS and Proposed Forest Plan, public comments mentioning geographic features within the Pressentin Roadless Area were received.

Pressentin Creek was mentioned 367 times. Most of the comments favored protection of old growth ecosystems (61), protection for spotted owl habitat (44), keeping the area roadless (43), protecting it from harvest (41), and preserving the forest ecosystem (41). Most of the remaining comments said to protect the area for recreation, wildlife habitat, fisheries, and scenic value. Five comments were received saying to build more roads in the area; five comments were received saying to make the area a top priority for timber harvest.

Quartz Creek was mentioned 28 times. The comments expressed a desire to protect the area from harvest (7), preserve old growth (4), add the area to wilderness (4), and keep it roadless (4). Other responses said to preserve the forest ecosystem and old growth ecosystem, protect visuals, and enlarge the size of SOHA's. One comment wanted the area closed to horse use. 1/

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

PRESSENTIN

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	6,905						
1B SPNM			13,959	9,693			
1C SPM						1,309	
1D RN							84
2B Midgrd.					886		865
11 O-G Hab.	1,900	3,400	295	1,224	3,273	3,357	3,231
12 Mature O-G	168	654		147	654	591	654
14 D&E Enhanc		42		84	84	42	126
17 Timber	6,082	6,863	633	2,808	6,251	6,546	6,082
19 Mtn. Hemlk		4,096	168	1,098	3,906	3,209	4,012

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by implementation of any of the alternatives. Alternative C will remove the least amount of acres from roadless status through the end of the fifth decade. Alternatives B and I remove the greatest amount. Alt. I will allocate approximately 10% of the area to SPM recreation.

Fish/Wildlife: *Alternatives B, H and J (Preferred) allocate the greatest area* to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement. Alternatives C and G-Modified allocate the least.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. *For example, "protect old growth" and "build a trail here" would be* tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Water: There are no adverse effects to the water resource of this area associated with implementation of any of the alternatives.

Ecology: The overall ecology of the area would not be significantly affected by implementation of any of the alternatives.

Timber: Alternative C will have the least affect on the existing timber resource, as it allocates very minimal acreage to management area 17 (timber). Alternatives A, NC, B, H, I and J allocate more than 40% of the area to timber.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B, H, I and J (Preferred) will provide greater roaded access through the area that could be used for minerals exploration and development.

Cultural: Alternatives A, NC, B, H, I and J (Preferred) have the greatest potential to adversely impact cultural resources within the area, due to development activity. Alternatives C and G-Modified have the least potential. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will have a significant affect on land special use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

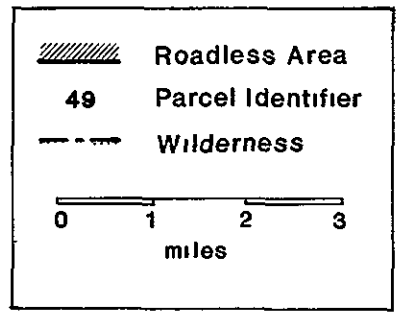
Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

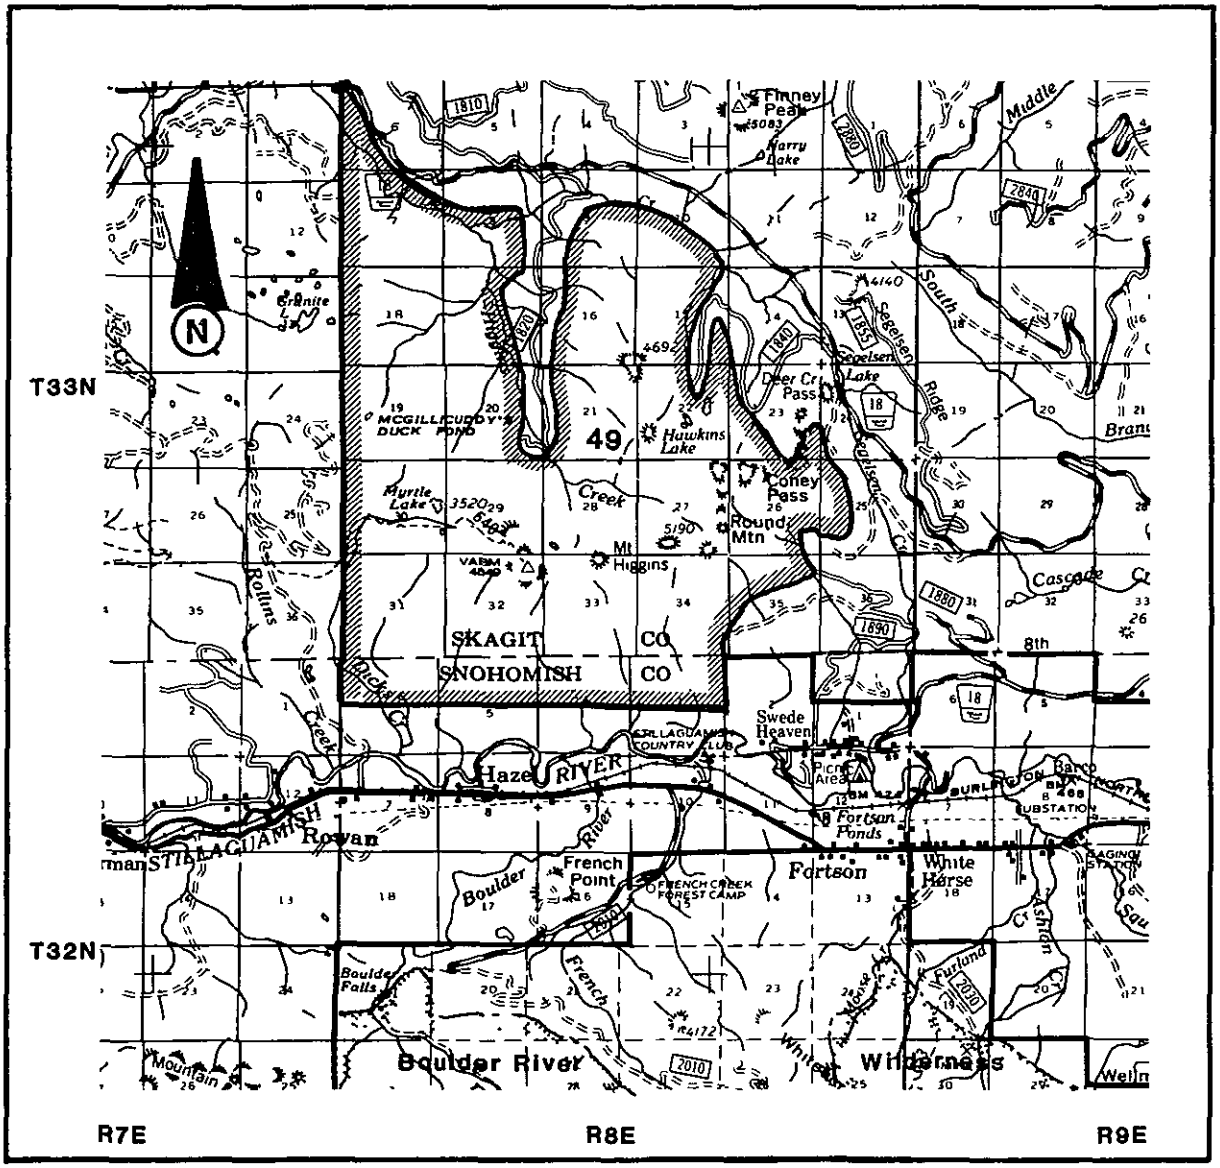
Wilderness Potential: Alternative C retains the greatest amount of roadless area at the end of the fifth decade. The wilderness potential will be maintained. Alternative I assigns approximately 10% of the area to the semi-primitive motorized prescription and approximately 40% to timber management. Alternatives A, NC and G-Modified leave less than 50% of the area in a roadless condition at the end of the fifth decade. Alternatives B, H and J (Preferred) leave just over 50% of the area in a roadless condition at the end of the fifth decade.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	11,706	7,722	4,004	27%
B (RPA)	12,357	11,507	7,720	51%
C	14,811	14,559	14,185	94%
G-Mod.	11,940	8,842	5,771	38%
H	12,825	10,381	7,929	53%
I	12,324	9,280	6,528	43%
J (Pref).	12,867	10,577	8,110	54%

Higgins Mountain
Roadless Area 6049





HIGGINS MOUNTAIN **Roadless Area 6049**

This roadless area originally consisted of 12,800 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6049 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation.

In 1988, this area was increased by 377 acres due to a mapping discrepancy. The following shows the disposition of acres within the roadless area:

Higgins Mountain	**Net Acres**
1984 RARE II	12,800
updated 1988	13,177
Change	**+ 377**

OVERVIEW

This parcel is located north of the North Fork Stillaguamish River, about ten miles northwest of the community of Darrington. It lies partly in Snohomish and Skagit Counties and is administered by both Darrington and Mt. Baker Ranger Districts. The Forest boundary skirts to the south and west, Deer Creek to the north, and existing Forest road systems to the east.

Road access is provided via Segelson Road (#18), the Hawkins Lake Road (#1840), and the Westside Higgins Road #1820, which extends south into the center of the area.

Drainages include the headwaters of Deer Creek and several tributaries which flow into the North Fork Stillaguamish River. Terrain is rugged, with steep slopes and numerous ridges dissected by tributary drainages. Elevations range from 2,000 to 5,000 feet. Higgins Mountain and Round Mountain are located astride the south boundary. Higgins Mountain has unusual tilted rock formations and a rock face which is visible from S.R. 530.

Heavy forest occurs throughout, except for subalpine areas in the immediate vicinity of Higgins and Round Mountains. Soils are variable with unstable glaciolacustrine soils on the west side of Higgins Creek and south side of Deer Creek. There are also unstable soils adjacent to the steep sideslope channels east of Higgins Creek.

WILDERNESS CAPABILITY

Manageability and Boundaries: This parcel is in a relatively isolated block of National Forest land, and boundary location and manageability would be fairly easy. There is potential for motorized access from adjacent road systems.

Natural Integrity and Appearance: Southern slopes are visible from S.R. 530. This route leads from Interstate 5 to Darrington, thus scenic qualities are experienced. The Higgins Mountain range is very rugged. This rugged topography and moderately large size of the parcel provide the area protection, allowing an unaltered, natural ecosystem to exist.

Opportunities For Solitude: Opportunities for solitude are excellent since the parcel is large and receives light recreation use.

Opportunities For Primitive Recreation: *Primitive recreation opportunities* include hiking, hunting, and mountaineering.

Challenging Experiences: Unusually challenging experiences are minimal.

Special Features: Higgins Mountain has unusual tilted rock formations and a striking slab face which is visible from S.R. 530. Fossils can be found high on Higgins Mountain.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Higgins Mountain #6049

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	13,177

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Myrtle Lake, the Higgins Mountain ridge, and the high pocket valley of Higgins Creek are accessed by the Mt. Higgins Trail #640; this trail receives moderate use. Other recreation use is limited primarily to hunting.

Fish/Wildlife: Special wildlife habitats include habitat for spotted owl, pileated woodpecker and pine marten. South-facing slopes below Higgins Mountain provide excellent deer winter range. Bear are seen here also. Mountain goats are found year round on northwest slopes of Higgins Mountain. Steelhead, coho salmon, and trout utilize Higgins Creek and Deer Creek.

Water: Drainages include the upper reaches of Deer Creek and all of Higgins Creek, a major tributary to Deer Creek. The southern portion includes several smaller tributaries to the North Fork Stillaguamish River, as well as Myrtle Lake and McGillicuddy's Duck Pond.

Livestock: None.

Ecology: This parcel is heavily forested, except for rocky sub-alpine portions of Higgins Mountain Ridge, which features meadows and tarns. Commercial species are those typical of the West Cascades at this elevation, and include Douglas-fir, Pacific silver fir, western hemlock, and mountain hemlock.

Timber: Most of the parcel is forested with commercial timber with 61 percent classed as tentatively suitable. There are scattered stands of mountain hemlock at the higher elevations. Most of the non-Federal lands adjacent to the south and west boundaries have been harvested.

Minerals/Oil and Gas: The geology of this area is dominated by Paleozoic metamorphics, Cretaceous volcanic rocks, Paleocene-Cretaceous nonmarine rocks and glacial drift of Quaternary age. The area has reported occurrences of lead, zinc, and copper but none are considered to be of significance. The area does have 29 mining claims located within it, most of which are located in Sections 22, 23, 25, 26, 27, and 28. Most of the area is classified "prospectively valuable" for coal, but it is not encumbered by any leases or pending lease applications. The area has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears the area's mineral potential is low.

Cultural: No areas of significant cultural interest are present.

Land Use Authorization: There are no special land authorizations.

Non-Federal Lands: There are 240 acres of non-Federal lands located within this parcel.

Fire: Fire incidence is low, and is limited to isolated lightning strikes.

Insect & Disease: There are no insect or disease concerns.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The towns of Concrete and Sedro Woolley are each about 40 miles away, Bellingham is 60 miles away, and Seattle is 110 miles. This parcel is nearly encircled by the Glacier Peak, Mt. Baker, and Boulder River Wilderness Areas.

Public Interest: Following release of the DEIS and Proposed Forest Plan, public comments on the Higgins Mountain Roadless Area, as well as geographic features within the area, were received.

Higgins Mountain was mentioned 373 times. The comments favored keeping the area roadless (75), protecting it from harvest (68), preserving the forest ecosystem (50), protecting the old growth ecosystem (23), and having the area added to the wilderness (15). The majority of the remaining responses said to manage the area for recreation, protection of wildlife habitat, and for its scenic value.

Three comments wanted the area to remain open for snowmobile use, three wanted it made a top priority for timber harvest, and three wanted the area kept open for mining. 1/

Higgins Creek was mentioned 12 times. Two responses favored building more roads, two said to protect the old growth ecosystem, two wanted protection from timber harvest.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

HIGGINS MOUNTAIN

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	5,786						
1B SPNM		3,484	12,713	12,755	3,695		3,928
1C SPM						2,745	
2B Midgrd.			42		3,463		3,590
5 Potent W&S				21			
11 O-G Hab.	950	1,140	21	232	1,055	1,330	696
12 Mature O-G	147	527	42	21	485	760	506
14 D&E Enhanc		2,998	126	21	168	2,660	147
17 Timber	6,293	4,434	232	105	3,843	5,342	3,780
19 Mtn. Hemlk		591		21	464	337	527

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by alternatives C and G-Modified which will leave the area predominately roadless through the end of the fifth decade. Alternatives A, NC and I leave no area roadless at the end of the fifth decade. Alternative I would allocate about 21% of the area to semi-primitive motorized recreation.

Fish/Wildlife: Alternatives B and I allocate the greatest area to old growth habitat, mature old growth, and deer and elk enhancement. Alternative C and G-Modified allocate the least.

Water: There are no significant adverse effects to the water resources of this area due to implementation of any of the alternatives.

Ecology: Alternatives A, NC, B and I have the greatest potential to affect the overall ecology of the area. Alternatives C and G-Modified have the least potential.

Timber: Alternatives C and G-Modified will have the least affect on the existing timber resource, as they allocate very minimal acreage to management area 17 (timber).

Alternatives A/NC and I allocate the greatest amount of area to timber. None of the alternatives will significantly affect the timber resource.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B and I will provide a greater amount of roaded access to areas that could be used for minerals exploration and development.

Cultural: Alternatives A, NC, B and I will have the greatest potential for adverse impacts to the cultural resources of the area, due to development. Alternatives C and G-Modified will have the least potential. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will have a significant affect on land special use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

Wilderness Potential: Alternatives C and G-Modified assign the majority of this area to management prescriptions compatible with preserving its roadless character, the wilderness potential will be maintained. Alternative I assigns about one-fifth of the area to semi-primitive motorized recreation. Alternative B leaves 3% and alternatives H and J (Preferred) leave approximately 15% in a predominately roadless condition at the end of the fifth decade. Alternatives A, NC,and I leave none of the area in a roadless condition at the end of the fifth decade. Wilderness potential will be lost should one of these five alternatives be implemented.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	6,850	2,898	0	0%
B (RPA)	8,467	5,461	349	3%
C	13,138	13,098	13,050	99%
G-Mod.	13,177	13,177	13,177	100%
H	9,244	6,520	2,107	16%
I	8,266	4,970	0	0%
J (Pref).	9,037	6,147	1,723	13%

PRAIRIE MOUNTAIN **Roadless Area 6060**

This roadless area originally consisted of 5,500 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6060 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation.

One timber sale contract has been awarded within this roadless area. The Black Diamond Timber Sale removed 1,668 acres from roadless status. The area was reduced ten acres due to a mapping discrepancy. The following shows the disposition of acres within the Prairie Mountain roadless area:

Prairie Mountain	Net Acres
1984 RARE II	5,500
updated 1988	3,822
Change	**-1,678**

OVERVIEW

This parcel is located on the summit and surrounding ridges of Prairie Mountain which dominates the river flats known as Sauk Prairie. Logging roads surround and intrude into the parcel. The Sauk and Suiattle Rivers are major drainages just outside the parcel. The terrain is generally steep with forested and rocky slopes. Elevations range from about 1,800 to 5,700 feet.

Forest cover is composed of western hemlock, Pacific silver fir, and mountain hemlock plant associations. There are scattered brushfields and talus slopes, and a few small subalpine meadows near the summit of Prairie Mountain.

Soils have developed from residual and colluvial rock material, glacial till and aerial volcanic deposits. Rock types are generally schist, gabbro, and other igneous rock, with minor areas of serpentine material. There are pockets of unstable soil and landforms adjacent to Conrad Creek and on the west-facing slopes of Prairie Mountain.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries do not follow natural land forms thus making them difficult to manage. The parcel is not adjacent to an existing wilderness and the acreage is marginal for wilderness consideration.

Natural Integrity and Appearance: Appearance is strongly influenced by extensive timber harvest surrounding the area.

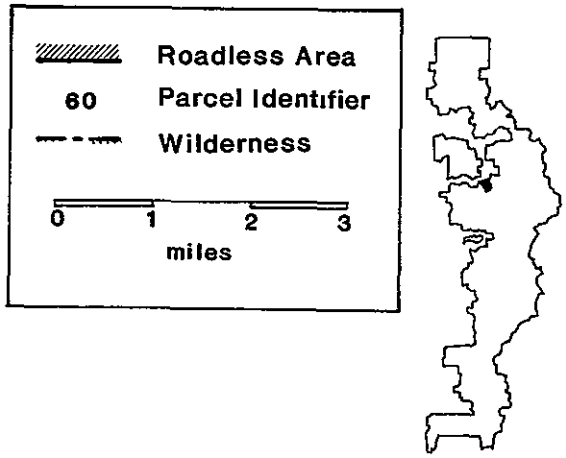
Opportunities For Solitude: Opportunities are low.

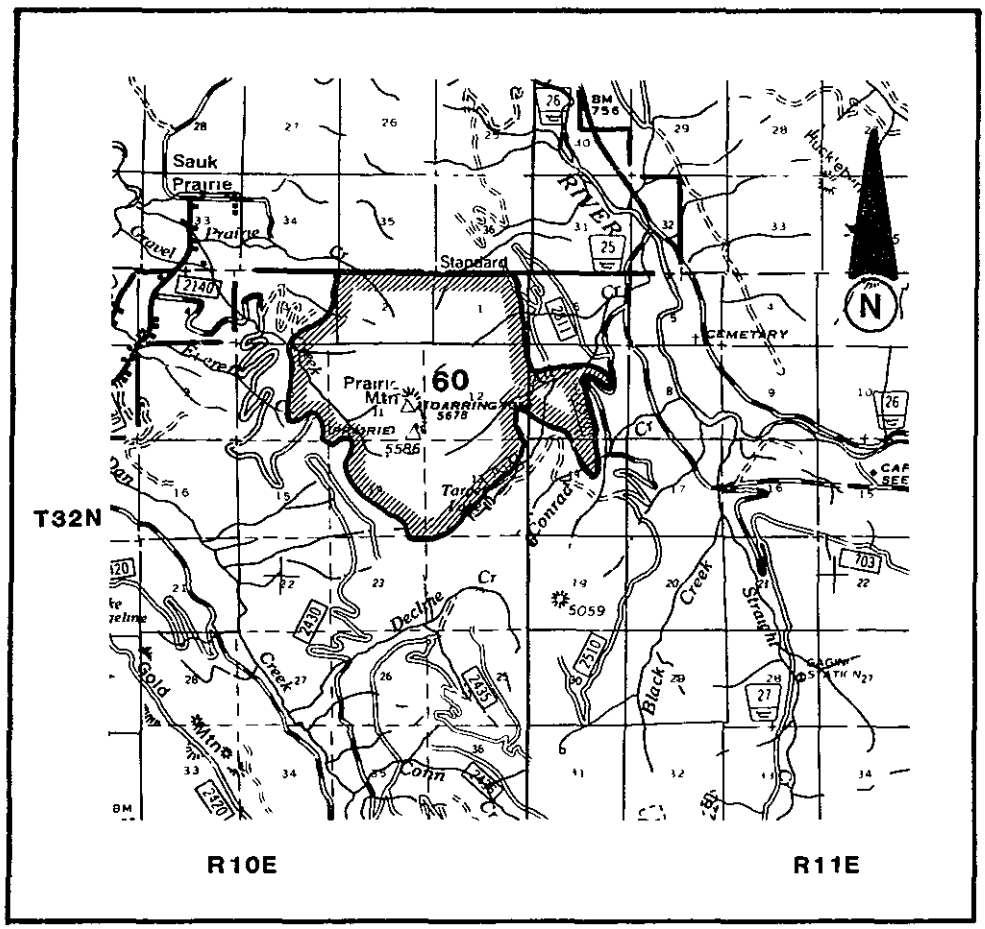
Opportunities For Primitive Recreation: Opportunities are low.

Challenging Experiences: There are few if any challenging experiences.

Special Features: None.

Prairie Mountain
Roadless Area 6060





AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Prairie Mountain #6060

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	3,822

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Resource values are considered low. Incidental big game hunting occurs in this area.

Fish/Wildlife: Special wildlife habitats include habitat for the pileated woodpecker, pine marten, spotted owl, and mountain goat. The area also supports blacktail deer seasonally.

Water: No power withdrawals are noted. One stream, Gravel Creek, W.R.I.A. #04-1071, provides domestic water for several households. No other special uses related to water are noted.

Livestock Operations: No potential or current livestock use noted.

Ecology: Dense evergreen forests occur on this area. Dominant species include Douglas fir, western red cedar, western hemlock, Pacific silver fir on the lower elevations. Higher elevations support subalpine fir and Mt. hemlock plant communities.

Timber: About 56 % of the area (2,154 acres) is tent. suitable for logging.

Minerals/Oil and Gas: There are no mining claims filed within this area and there is little potential for production of oil and gas.

Cultural: The area is considered to be of little cultural significance.

Non-Federal Lands: None.

Fire: The occurrence is approximately 2 fires per decade with no major fires in the past 30 years. Average fuel accumulation is 60-80 tons per acre.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is within 10 miles of the Boulder River, Glacier Peak, and Henry M. Jackson Wildernesses. Seattle is approximately 80 miles away.

Public Interest: Following release of the DEIS and Proposed Forest Plan, Prairie Mountain was mentioned 29 times in the public comments received. The responses said to make the area a top priority for timber harvest (5), manage it for big game (3), keep ORV's out of the area (2), protect the trail from logging (2), and protect the old growth ecosystem (2). Most of the remaining responses favored managing the area for recreation, wilderness, and wildlife habitat. One response desired roads in the area be left open for public use.1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

PRAIRIE MOUNTAIN

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	1,710						
1B SPNM			3,209				
1D RN		1,161			1,203		1,203
2B Midgrd.			211				
11 O-G Hab.		1,182	337	1,182	1,182	1,183	1,203
12 Mature O-G	21	168		168	168	168	190
14 D&E Enhanc		147	63			63	
15 Goat MR		84		84	84	84	84
17 Timber	2,090	971		2,027	1,077	1,964	1,034
19 Mtn. Hemlk		105		359	105	359	105

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternatives A, NC and H will provide a very slightly higher level of roaded recreation. The other alternatives will leave the entire area in a roadless state.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives, due to the low level of development activity proposed.

Water: None of the alternatives will significantly affect the water resource of the area, due to the low level of potential development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of potential development activity.

Timber: Alternatives B, H, and J (Preferred) will not significantly affect the existing timber resource, due to the low level of development activity. Alternatives A, NC, G-Modified and I allocate the greatest number of acres to timber management, approximately 53%.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant affect on the cultural resources of the area, due to the low level of potential development activity.

Land Use Authorizations: None of the alternatives will have a significant affect on land special use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

Wilderness Potential: Alternatives A, NC, C and H remove an extremely limited amount of area from roadless area by the end of the fifth decade. None of the other alternatives remove any area from roadless status by this time. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	**Decade 1**	**Decade 2**	**Decade 5**	**Remaining**
A (No Act)	3,786	3,732	3,680	96%
B (RPA)	3,822	3,822	3,822	100%

J (Pref).	3,822	3,822	3,822	100%

WHITE CHUCK MOUNTAIN **Roadless Area 6051**

This roadless area originally consisted of 6,000 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6051 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation. The Black Diamond Timber Sale has removed 211 acres from roadless status The area was reduced by 66 acres due to a mapping discrepancy. The following shows the disposition of acres within the White Chuck Mountain roadless area:

White Chuck Mountain	Net Acres
1984 RARE II	6,000
updated 1988	5,723
Change	**- 277**

OVERVIEW

This parcel is located on the summit and surrounding slopes of White Chuck Mountain, which is named for the glacial river at its base. Logging roads surround the parcel, which is dissected by many streams that feed into the White Chuck River and tributaries and the Suiattle River. Terrain varies from steep to very steep, mainly forested slopes below narrow rocky ridges. Elevations range from about 1,400 to 7,000 feet.

Plant associations include western hemlock, Pacific silver fir, mountain hemlock, and mature second growth riparian deciduous trees found along the White Chuck River. Upper elevations are comprised of bare rock and ice, including a 30 acre glacier. Mid-elevations are sparsely forested rocky areas interspersed with brush fields and talus slopes.

Soils have formed from residual and colluvial material and glacial till. Rock types are generally phyllite, sedimentary, and volcanic rock. Shallow soils cling to 75% slopes, which are prone to movement under natural conditions.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries are illogical and do not allow for a discrete, manageable area.

Natural Integrity and Appearance: Appearance is strongly influenced by adjacent cutover lands.

Opportunities For Solitude: Opportunities are low.

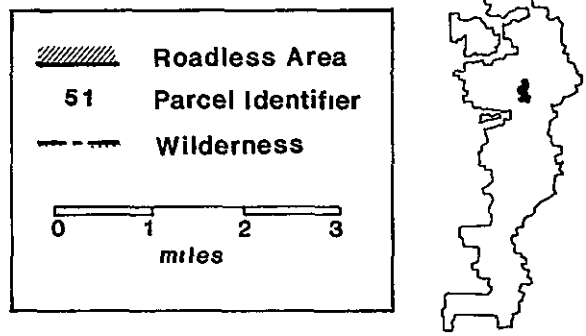
Opportunities For Primitive Recreation: Opportunities are low.

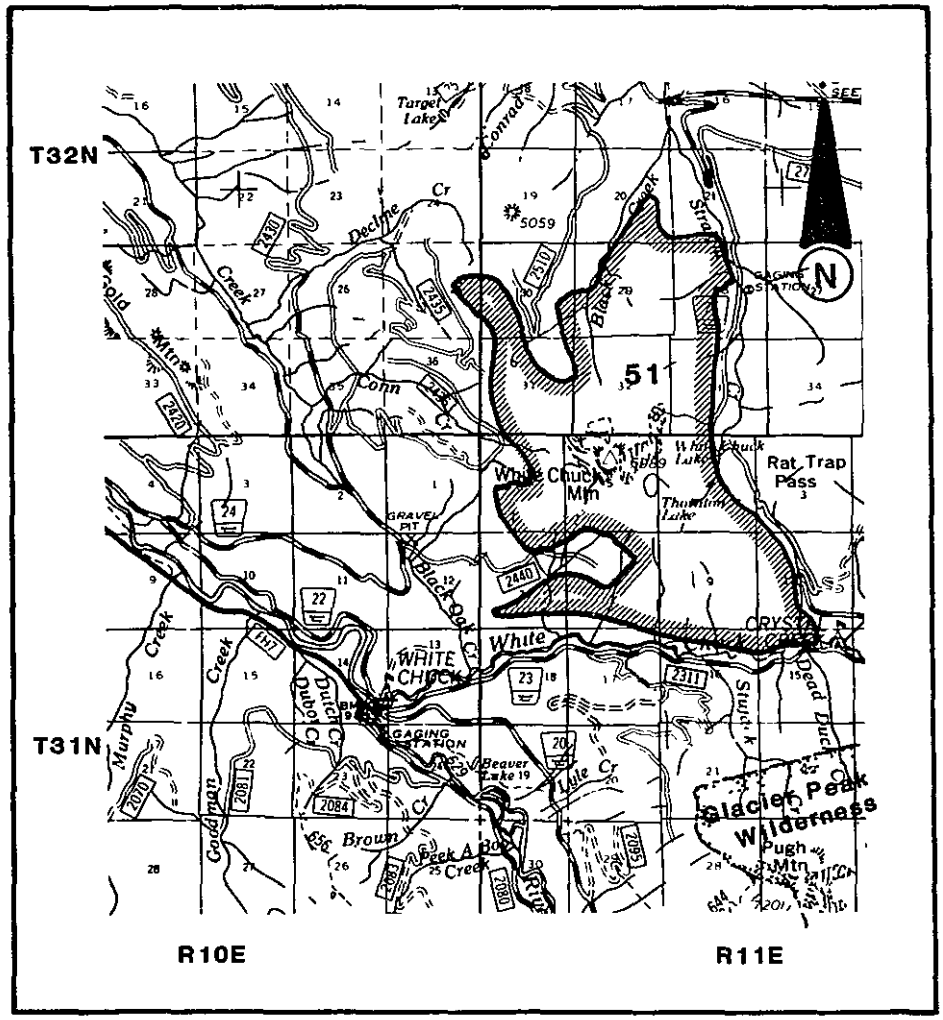
Challenging Experiences: The climb to the summit of White Chuck Mountain is considered by many to be challenging.

Special Features: None.

White Chuck Mountain

Roadless Area 6051





AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - White Chuck Mountain #6051

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	5,723
Primitive/Semi-Primitive Recreation ROS	Acres	2,787
Timber		
Tentatively suitable	Acres	1,647
Tentatively suitable inaccessible	Acres	211
Tentatively suitable standing volume	M bdft	64,442
"Old Growth", Total Acres	Acres	2,428
0-2,500 Feet Elevation	Acres	591
2,500-4,000 Feet Elevation	Acres	1,077
4,000 + Feet Elevation	Acres	760
Management Indicator Species (MIS)		
Spotted owl MR	Acres	0
Pileated woodpecker and pine marten MR	Acres	168
Elk-deer winter range	Acres	443
Goat habitat MR	Acres	929
Bald eagle habitat (nests, forage, roost area)	Acres	42
Locatable Mineral Development Potential		
High	Acres	0
Moderate	Acres	0
Low	Acres	0
Claims	# of	2
Leasable Energy Minerals (Moderate Potential)		
Geothermal	Acres	51

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: *An occasional mountain climber ascends White Chuck Mountain.* Use is estimated at less than 100 climbers. Big game hunters of approximately 500 each year use the area.

Wildlife: Special wildlife habitats include habitats for the pileated woodpecker, pine marten, mountain goat, and blacktail deer. Also present are blacktail deer. The Whitechuck and Suiattle Rivers provide anadromous fish habitat.

Water: No power withdrawals or special users related to water exist.

Livestock Operations: None.

Ecology: Dense evergreen forests occur on this area. Dominant species include Douglas fir, western red cedar, western hemlock, Pacific silver fir on the lower elevations. Higher elevations support subalpine fir and mountain hemlock plant communities. Many cliffs and brushfields of red alder occur on the north slope of White Chuck Mountain.

Timber: About 29 percent or 1,647 acres of this parcel is classed tentatively suitable for logging.

Minerals/Oil and Gas: The area is primarily underlain by Jurassic metamorphic rocks and Permian sedimentary rocks. It has no reported occurrences of mineral resources, but does have 2 recorded mining claims. The area is classified "prospectively valuable" for geothermal resources, but it has no leases or pending lease applications. It has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears the area has a low potential for the occurrence of mineral resources.

Cultural: Nothing of cultural significance is found within this parcel.

Land Use Authorization: There are no special land use authorizations.

Non-Federal Lands: None.

Fire: There have been two major fires in the last 40 years with an average 5-10 fires per decade. Average fuel accumulation is 40-50 tons per acre.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is about 80 miles from Seattle. It is nearly encircled on three sides by Henry M. Jackson, Glacier Peak, and Boulder River Wildernesses.

Public Interest: Following release of the DEIS and Proposed Forest Plan, White Chuck Mountain was mentioned 35 times in the public comments received. The responses favored protecting old growth ecosystems (6), preserving the forest ecosystem (5), making the area a top priority for timber harvest (4), and keeping the area roadless (2). Most of the remaining comments said to protect the area for wildlife habitat, visual quality and recreation. 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The following table displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

WHITE CHUCK MOUNTAIN

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	4,033						
1B SPNM		2,998	4,160	3,378	3,526		3,231
1C SPM						2,745	
2A Foregrd.			168				147
2B Midgrd.			591		527		675
5 Potent W&S				42			
11 O-G Hab.	760			211	63		
12 Mature O-G		63	42	84	63	126	42

17 Timber	929	1,034	126	1,119	950	1,689	781
19 Mtn. Hemlk		591		359		63	

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives, due to the low level of potential development activity. Alternative I allocates approximately one-half of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B and I allocated the greatest amount of acreage to mature old growth, deer and elk enhancement, and mountain goat management requirement prescriptions. Alternatives A, NC, C and H allocate the least.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of proposed development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternative C will have the least effect on the existing timber resource, as it allocates very minimal acreage to management area 17 (timber). Alternatives B, G-Modified and I allocate the greatest acreage. None of the alternatives will significantly affect the timber resource, as potential development activity will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant affect on the cultural resources of the area, due to the very low level of development activity proposed.

Land Use Authorizations: None of the alternatives will have a significant affect on the cultural resources of the area, due to the very low level of development activity proposed.

Fire: None of the alternatives will have a significant affect on the cultural resources of the area.

Insect and Disease: None of the alternatives will have a significant affect on the cultural resources of the area.

Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns three-quarters of the area to semi-primitive motorized and timber allocations. All alternatives will maintain the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	5,387	5,281	5,077	89%
B (RPA)	5,651	5,441	5,294	93%
C	5,657	5,621	5,525	97%
G-Mod.	5,600	5,488	5,366	94%
H	5,567	5,413	5,219	91%
I	5,567	5,411	5,223	91%
J (Pref).	5,606	5,512	5,367	94%

BOULDER RIVER — **Roadless Area 6050 (BA, BG, BF, B1, BE, BD, BH, BI, BL, BJ)**

This roadless area originally consisted of 83,700 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6050 to nonwilderness uses. In 1984, 50,274 acres from this area were designated the Boulder River Wilderness by Congress as a result of the Washington Wilderness Act. Ten parcels remain in roadless status. The Goodbye (1986), Iron Mountain (1988) and Goodman Ridge (1988) Timber Sales removed 1,119 acres from roadless status. The following shows the disposition of acres within the Boulder River roadless area:

Boulder River	Net Acres
1984 RARE II	83,700
updated 1988	32,307
Change	**-51,393**

OVERVIEW

These parcels are located along rugged peaks and ridges between the Boulder River and the Henry M. Jackson Wilderness, and between Clear Creek to the west and South Fork Sauk River to the southwest. Arterial and collector roads encircle the parcels, which are heavily dissected by many streams draining to the Sauk and South Fork Stillaguamish Rivers.

Terrain varies from gentle to quite steep, with elevations ranging from 800 to 6,000 feet.

Plant associations include western hemlock, Pacific silver fir, and mountain hemlock mature conifer forests. Upper elevations feature bare rock and snow fields, mid-elevations are sparsely forested areas interspersed with brush fields and talus slopes.

Soils have formed from phyllite, various other metasedimentary rock, and igneous rock altered by glaciation, stream cutting and gravity transport. Upper slope soils are very shallow residual or moderately deep glacial till deposits of loams and gravelly loams. The lower slopes of French and Clear Creeks, and the Sauk and Stillaguamish Rivers have deep deposits of poorly drained silty clay formed from glacial lake bed material. The lake deposit material is naturally unstable. Groundwater seepage and very steep slopes are factors effecting natural earth slides.

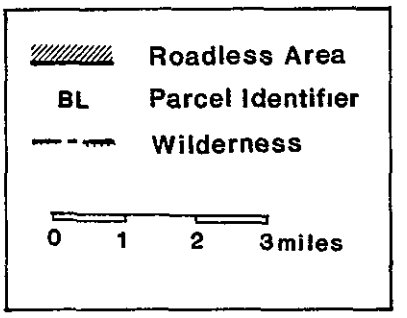
Many of the peaks and lakes are popular for hiking and scrambling with new ones being "discovered" every year. Well established trails lead to Forgotten and Dickerman Mountains. This back country is also used by hunters, anglers, and berry-pickers.

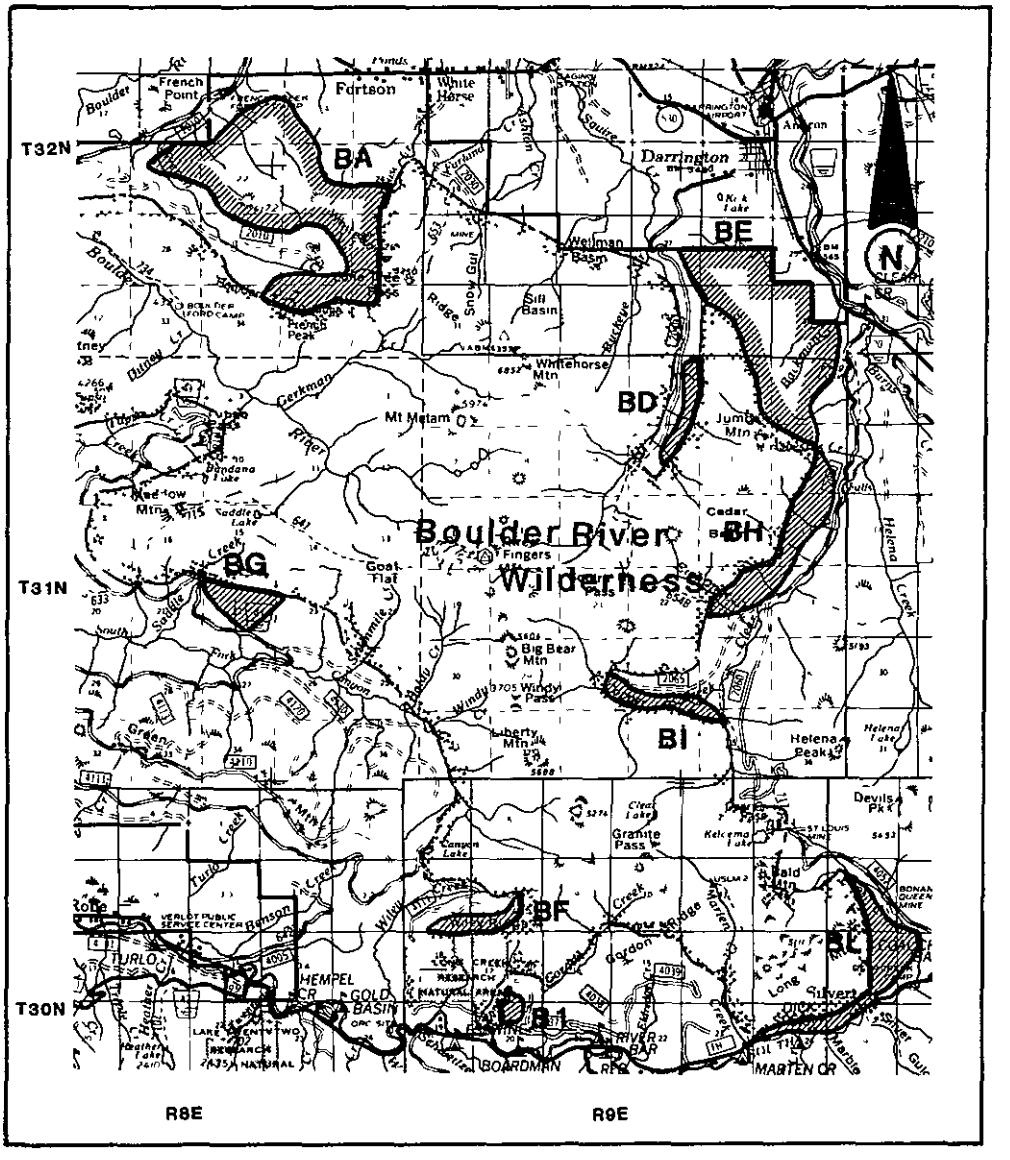
WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries of each of these parcels are generally illogical for separate management. Their addition to adjacent wilderness would not simplify management.

Natural Integrity and Appearance: Except for parcel BJ, adjacent cutover lands give the overall appearance of a modified landscape.

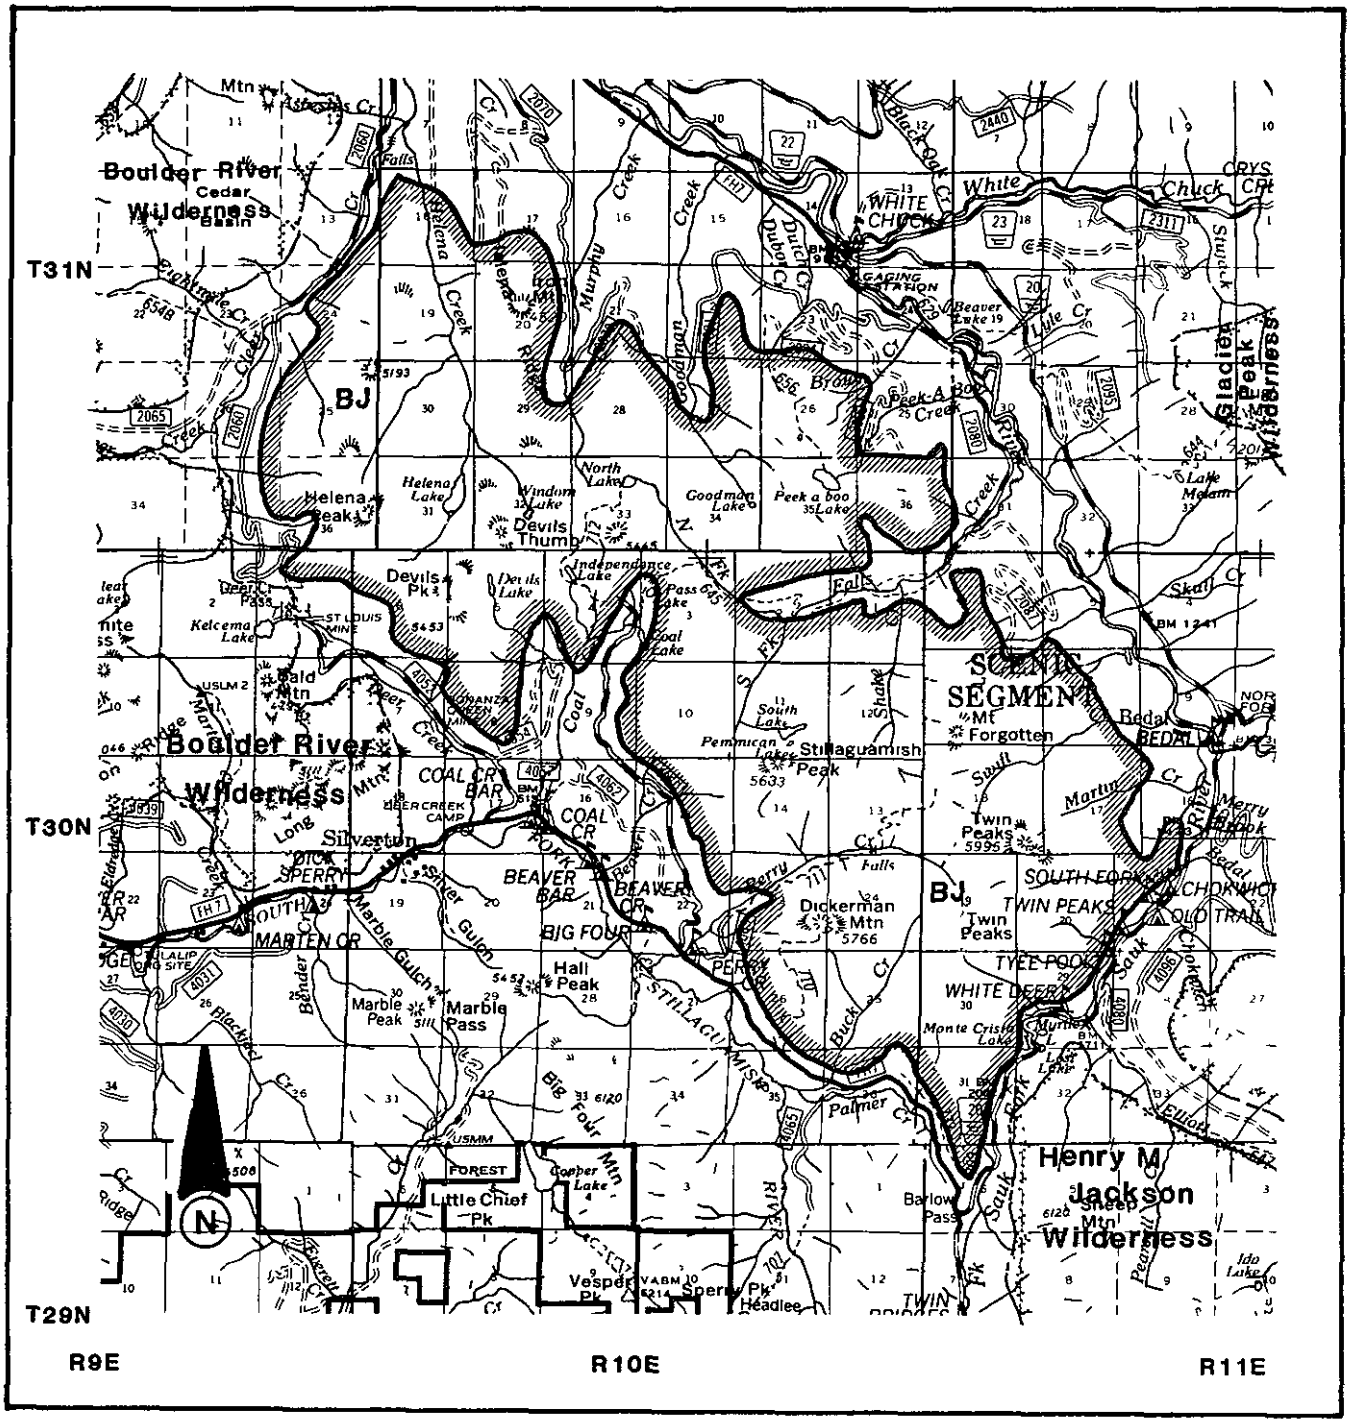
Boulder River
Roadless Area 6050





Boulder River

Roadless Area 6050



Opportunities For Solitude: Opportunities for solitude are low, except for portions of parcel BJ where potential is good.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are generally poor, except for parcel BJ where potential is good.

Challenging Experiences: Only parcel BJ provides good opportunities for challenging experiences.

Special Features: The potential Research Natural Area at Perry Creek is located in Parcel BJ. See description under Other Management Considerations below.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: Parcel BJ offers trail, fishing, hunting, primitive camping, and rockclimbing opportunities.

Fish/Wildlife: These parcels provide habitat for blacktail deer and mountain goats. Perry Creek and other streams support anadromous fish and native trout. Parcel BJ contains most of one SOHA and part of another. It contains all or part of three pine marten MR. It also contains acres allocated as pileated woodpecker MR. There are small parts of two other SOHA's in parcels BD and BF. Mountain goats are common throughout parcel BJ and some herds also live in parcels BH and BA.

Water: Several of the larger streams have potential for hydropower development.

Livestock Operations: None.

Ecology: Dense forests are interspersed with cliffs and brushfield. Dominant species include Douglas fir, western red cedar, western hemlock, and Pacific silver fir.

Timber: About 27 percent of the total acreage is classed tentatively suitable for logging.

Minerals/Oil and Gas: These parcels lie adjacent to the Boulder River Wilderness. Their geology is dominated by Jurassic metamorphic, Tertiary granitic rocks, pre-Tertiary volcanics, and glacial drift of Quaternary age. Only parcel BL is reported to have significant resource occurrences and is considered to lie within the Silverton and Squire Creek mineral resource areas. These have a moderate to low potential for the occurrence of copper, lead, zinc, gold and silver resources. The small parcels BA through BL are reported to have 15 mining claims. The eastern part of the area along Clear Creek and the Stillaguamish River are classified "prospectively valuable" for coal, however, the area is not encumbered by any leases or pending lease applications. Based upon the available data it appears the area has a relatively low potential for the occurrence of mineral resources.

The large BJ parcel has 196 mining claims. According to Lawson and Evarts (1983) the area may contain gold, silver, copper, and lead resources. Most of

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

2/ Number of claims is not broken out by parcel.

the area is classified "prospectively valuable" for geothermal resources and a large portion of the west side of the area is classified "prospectively valuable" for coal resources. However, none of the area is encumbered by leases or pending lease applications. Based upon available data it appears that the area's mineral potential is low.

Cultural: Nothing of cultural significance is present within these parcels.

Land Use Authorizations: There are no special land use authorizations.

Non-Federal Lands: None.

Fire: These parcels have a moderate fire occurrence which averages 3 fires per decade. There has been one major fire in the past 30 years. Average fuel accumulation is 40-50 tons per acre.

Insect and Disease: None.

Others: There are mining claims which are currently inactive. In addition, the proposed Perry Creek Research Natural Area is planned in Parcel BJ This 2,555 acre RNA represents a unique assemblage of rare fern species and Alaska cedar in a stand with mountain hemlock and subalpine fir, and a heather-huckleberry plant community.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: Each of the parcels are contiguous with the Boulder River Wilderness. They are roughly 75 miles from Seattle.

Public Interest: Following release of the DEIS and Proposed Forest Plan, public comments were received on the several parcels included in the Boulder River Roadless Area, as well as more general comments on areas adjacent to the Boulder River Wilderness.

Boulder River parcel BJ received 11 comments. Three responses wanted the area made a top priority for timber harvest, two wished to have it dedicated as a backcountry recreation area, two said it should be protected for recreation, and two favored protection of the area for winter habitat for deer and elk. 1/

Boulder River parcel BE received 6 comments. The responses favored protecting visual quality, preserving the forest ecosystem, and keeping the area roadless.

Areas adjacent to the Boulder River Wilderness were mentioned 18 times. The most common comments were to keep the area roadless (4) and to protect it from timber harvest (2) Most of the remaining responses favored managing the area for recreation and wildlife habitat

. ...

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives, due to the low level of proposed development activities. Alternative I allocated approximately one-half of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B and I allocate the greatest acreage to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives A, NC, C and G-Modified allocate the least.

Water: Hydroelectric development will be largely precluded under Alternatives B, C, G-Modified, H and J (Preferred), due to the emphasis on semi-primitive nonmotorized recreation. Development could proceed under Alternatives A, NC and I.

Ecology: The overall ecology of the area would not be significantly affected by any of the alternatives, due to the low level of potential development activity.

Timber: Alternatives A, NC, B and I would allocate the greatest area to timber management. Alternatives C, G-Modified, H and J (Preferred) allocate the least. None of the alternatives will have a significant affect on the timber resource, due to the low level of development activity planned.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B and I will provide a slightly higher amount of roaded access through the area, which could be used for minerals exploration and development.

Cultural: Alternatives A, NC, B and I have the greatest potential to adversely impact cultural resources, due to their higher development levels. Alternatives C, H, G-Modified, and J (Preferred) have the least. Valuable sites will be protected via avoidance or preserved through data recovery.

Land Use Authorizations: None of the alternatives will have a significant affect on special use authorizations.

Fire: None of the alternatives will have a significant affect on the occurrence of fire within the area.

Insect and Disease: None of the alternatives will have a significant affect on the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives, with the exception of I, will assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I assigns about two-thirds of the area to semi-primitive motorized recreation and timber management prescriptions. All alternatives will maintain the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	*Decade 1*	*Decade 2*	*Decade 5*	*Remaining*
A (No Act)	30,243	29,633	27,638	86%
B (RPA)	31,122	30,736	29,576	92%

EAGLE ROCK **Roadless Area 6054**

This roadless area originally consisted of 33,100 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision designated area 6054 to further planning. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation. This area was increased by 76 acres due to a mapping discrepancy. The following shows the disposition of acres within the Eagle Rock roadless area:

Eagle Rock	Net Acres
1984 RARE II	33,100
updated 1988	33,176
Change	**+ 76**

OVERVIEW

This parcel is located in the center of the Skykomish Ranger District. Access is from State Route 2 on the south, the Beckler River road on the east, and the Snohomish County/North Fork Skykomish Road on the northwest.

The North Fork Skykomish River borders on the north, with the South Fork Skykomish River on the south; the Beckler River borders on the east, with Heybrook Ridge on the west. It is dissected by several drainages including: Barclay, Trout, Howard, Bear, San Juan, Boulder, Fourth of July, and Eagle Creeks.

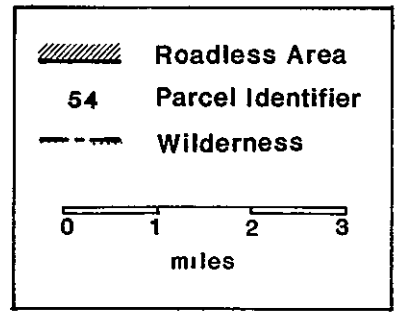
This parcel features numerous high, rugged peaks (including Eagle Rock, 5,612 feet; El Capitan, 5,100 feet; Spire Mountain, 6,065; Conglomerate Point, 5,200 feet; Gunn Peak, 6,245 feet; Merchant Peak, 5,827 feet; and Baring Mountain, 6,125 feet), and steep-sloped, deep valleys (including Barclay, Fourth of July, San Juan, and Boulder Creeks). Barclay, Tom, Dick, Harry, Gunn, Eagle, Grotto, Klinger, Stone, Simms, Sunset, Howard, and Boulder Lakes are within the area. Elevations range from 900 feet in Trout Creek to 6,245 feet on Gunn peak about three and one-half miles away.

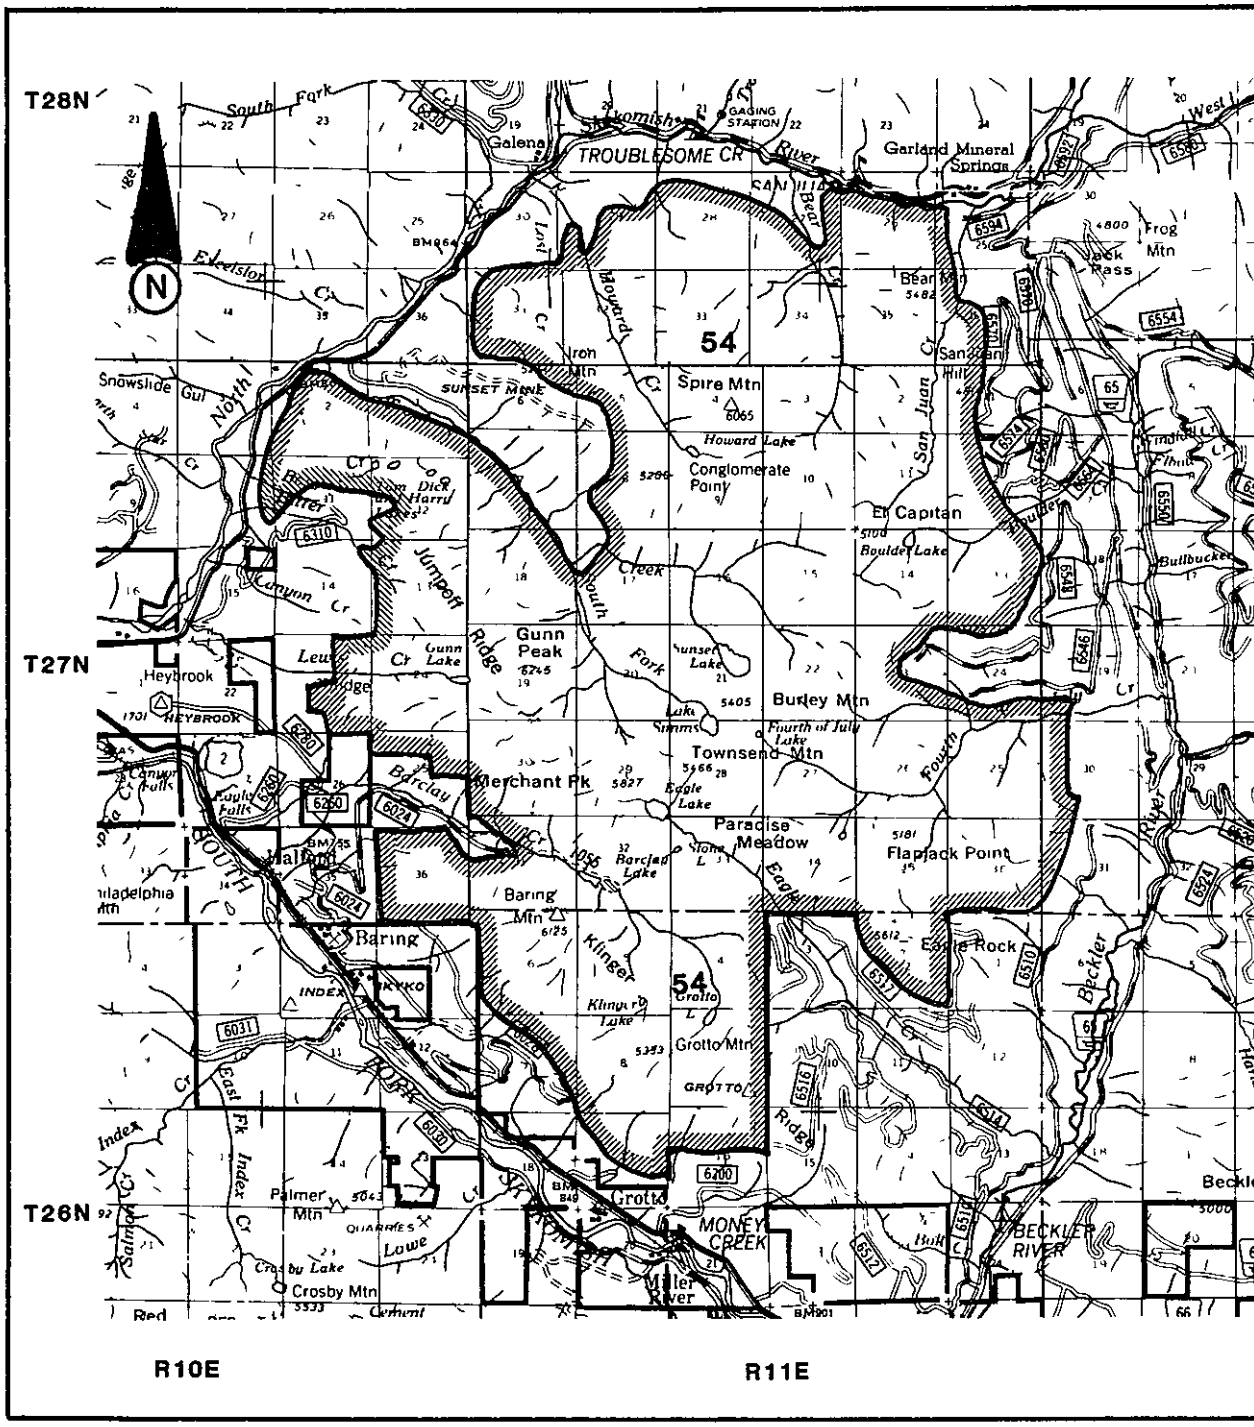
Soils vary from shallow, gravelly-stony, sandy loams, to loams on the slopes, to deep glacial tills in valley bottoms. The glacial tills are a mixture of silts and clays, with rock components ranging from lenses of gravel to scattered large boulders.

When present on the upper slopes, vegetation is typically scattered, low-growing trees and shrubs, including western hemlock, Pacific silver fir, Douglas-fir, Alaska yellowcedar, western redcedar, alder, willow, heather, huckleberry, and devil's club. Grasses and forbs create a few small meadows scattered throughout the area. Lower slopes have dense forest cover consisting of western hemlock, Douglas-fir, Pacific silver fir, and western redcedar. Alder, maple, and cottonwood trees are found in wet sites and previously logged areas. The most common shrubs are salal, vine maple, willow, salmonberry, elderberry, and devil's club.

Eagle Rock

Roadless Area 6054





Recreational use is heavy. Easy access to Barclay Lake, Eagle Lake, and Boulder Lake make them popular day hike destinations. The "easy" routes on Baring Mountain, Gunn Peak, and Merchant Peak attract technical rock and mountain climber use. There have been some logging and mining claim improvements in the Trout Creek and Bitter Creek drainages on privately owned land. In the Trout Creek drainage, several claims were developed for mining copper and gold.

Recently, much of the private acreage was added to the National Forest System through a land exchange.

This parcel has an appearance similar to the nearby Henry M. Jackson and Glacier Peak Wildernesses. It is largely undisturbed by human development. It has numerous high peaks, deep valleys, and small alpine lakes. Adjacent lands do display evidence of timber harvest, mining activities, roads, developed recreational facilities, and summer homes.

In addition to popular recreational destinations, five mountain goat families attract visitors to the area.

WILDERNESS CAPABILITY

Manageability and Boundaries: Due to the nature of the terrain, this parcel is of marginal size to make a viable wilderness. Sights and sounds uncharacteristic of a wilderness are present in 80 percent of the area. The boundaries are ill-defined by natural features.

Natural Integrity and Appearance: Disturbances include mining activity, timber harvesting (units are less than 200 acres), and several mining cabins (including Eagle Lake cabin). Long-range ecological processes are ongoing. Past activities are not readily apparent and would be unnoticed unless sites were actually visited.

Opportunities For Solitude: Opportunities for solitude are limited due to travel corridors and forest management activities outside the parcel.

Opportunities For Primitive Recreation: Primitive recreational use includes hiking, camping, fishing, hunting, backpacking, and mountain climbing. High avalanche hazards restrict backcountry skiing. Poor trails, as well as lack of trails limit horse use. Streams are too small to support rafting.

Challenging Experiences: There are outstanding opportunities for mountain climbing. Thirteen peaks over 5,000 feet require significant effort and a fair degree of skill and judgement.

Special Features: One Spotted Owl Habitat Area (SOHA) is located here. A bald eagle roost site has been identified adjacent to the parcel. Mountain goats are present during both summer and winter.

Most of the old mining claims were not worked after initial exploration, and therefore do not exhibit a full range of early era mining practices.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Eagle Rock #6054

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	33,176
Primitive/Semi-Primitive Recreation ROS	Acres	26,397
Timber		
Tentatively suitable	Acres	7,750
Tentatively suitable inaccessible	Acres	5,490
Tentatively suitable standing volume	M bdft	303,234
"Old Growth", Total Acres	Acres	13,451
0-2,500 Feet Elevation	Acres	2,323
2,500-4,000 Feet Elevation	Acres	8,869
4,000 + Feet Elevation	Acres	2,259
Management Indicator Species (MIS)		
Spotted owl MR	Acres	4,329
Pileated woodpecker and pine marten MR	Acres	802
Elk-deer winter range	Acres	359
Goat habitat MR	Acres	1,098
Bald eagle habitat (nests, forage, roost area)	Acres	21
Locatable Mineral Development Potential		
High	Acres	7,222
Moderate	Acres	8,447
Low	Acres	17,507
Claims	# of	69
Leasable Energy Minerals (Moderate Potential)		
Geothermal	Acres	29,269
Coal, geothermal	Acres	3,906

1/ American Indian Religious and Cultural areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: This parcel receives approximately 6,000 visitor days per year of hiker and fishing use. When compared to the Henry M. Jackson and Alpine Lakes Wildernesses, this parcel has a more restricted range of recreational attributes due to the lack of trails. The Barclay Lake trail is the only trail in this area.

Fish/Wildlife: One SOHA has been designated. This parcel is used as summer range and partial winter range by at least five separate mountain goat families. Planted fish are present in all lakes and most streams. Special wildlife habitats include habitats for the pileated woodpecker and pine marten.

Water: Drainages include Barclay, Trout, Howard, Bear, San Juan, Boulder, Fourth of July, and Eagle Creeks; all are tributaries to Beckler River and the South Fork and North Fork Skykomish Rivers.

There are several power withdrawals with FERC study permits.

Livestock Operations: None.

Ecology: Generally, areas below 4,000 feet elevation are forested with species typical of the west Cascades including cedar, Douglas-fir, true firs, and western hemlock. The higher elevations are typically steep rock and open slopes supporting snow a majority of the year.

Timber: Some 7,750 acres or 23 percent of this area is classed tentatively suitable for timber harvest.

Minerals/Oil and Gas: This area lies within the Index Mining District, and it is underlain by Tertiary aged granitic, volcanic and sedimentary rocks, and by Jurassic aged metamorphic rocks. The area has numerous reported mineral occurrences, and BLM records indicate that it has 69 mining claims. The area has been studied by the U.S. Geological Survey and Bureau of Mines and they have concluded that the west one-third of the area has a "substantial" or probable "potential" for the occurrence of copper, gold, silver, lead and zinc. However, the demonstrated resources are generally small tonnages, of low grade, and located in areas where access is difficult. Based upon the available data, the area is considered to have a moderate potential for the occurrence of copper and silver resources in vein type deposits.

A small portion of the area is classified "prospectively valuable" for coal and the entire area is classified "prospectively valuable" for geothermal. However, none of the area is encumbered by leases or pending lease applications.

There is no oil and gas potential.

Cultural: There are several mine shafts, mining cabins, trails, and tramways dating from the early 1900's.

Land Use Authorizations: None.

Non-Federal Lands: The Sunset Mines inholding was recently acquired by the National Forest System (except mineral rights).

There are 320 acres of private land in section 21, T.27N., R.11E., WM. There is also a potential mining claim in sections 11 and 12, T.27N., R.10E., WM.

Fire: There is low fire incidence. Large fires occur about once in a hundred years.

Insect and Disease: Insects and disease typical of nature and old growth timber stands are present at a low level. No control is anticipated.

Others: Private land in Section 21 has no road access. The Sunset Mines parcel is accessed by a County mine-to-market road. The patented claims in Sections 11 and 12 are accessed by a road. Acquisition of these inholdings would require a land exchange or condemnation by the federal government.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and Population Centers: The Henry M. Jackson, Alpine Lakes, and Glacier Peak Wildernesses are less than 10 miles away. It is approximately 40 miles to Everett and 50 miles to Seattle.

Public Interest: Following release of the DEIS and Proposed Forest Plan, the Eagle Rock Roadless Area, as well as specific geographic sites and features within the parcel, received public comments.

Eagle Rock Roadless Area was mentioned 313 times. Comments favored keeping the area roadless (76), expanding the trail system (40), protecting the area from harvest (39), preserving the forest ecosystem (39), and making it a backcountry recreation area (27). Most of the remaining comments favored managing the area for recreation, wildlife habitat and scenic quality. One comment said no new trails should be built. 1/

Eagle Rock was mentioned 236 times. Responses favored dedicating the area as a backcountry recreation area (68), expanding the trail system (22), keeping it roadless (17), preserving the forest ecosystem (17), building trails (16), and adding it to wilderness (12). Most of the remaining comments said to manage the area for recreation, wildlife habitat, and visual quality. Four responses favored keeping the area open to mining. One response wanted the area made a top priority for timber harvest.

Jumpoff Ridge was mentioned 121 times. Responses favored keeping the area roadless (36), protecting old growth ecosystems (23), preserving the forest ecosystem (13), expanding the trail system (13) and protecting the area from harvest (10). The majority of the rest of the comments said to manage the area for recreation, wildlife habitat, fisheries, and scenic quality.

Fourth of July Creek was mention 14 times. Comments said to protect the area as prime winter habitat for deer and elk (4), protect old growth ecosystems (4) and preserve the area as a scenic corridor into the backcountry (3).

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by most of the alternatives. The exception is alternative I which allocates 53% of the area to semi-primitive motorized recreation and 16% of the area to timber management.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives, due to the low level of proposed development activities.

Water: Alternatives B, C, G-Modified, H and J (Preferred) will largely preclude hydroelectric development, due to the emphasis each of these alternatives place on the semi-primitive nonmotorized management prescription. Alternatives A, NC and I would allow hydro development.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activities.

Timber: None of the alternatives will significantly affect the existing timber resource, due to the low level of harvest activity proposed over the next fifty years. Alternative I allocates the greatest amount of acreage to management area 17 (timber); this alternative dedicates about 16% of the area to timber. Alternatives C and G-Modified allocate the least acres (less than 2%).

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A, NC, B, and I will provide a slightly higher amount of roaded access through the area that could be used for mineral exploration and development.

Cultural: Alternatives A, NC, B and I will have the greatest potential to adversely impact cultural resources within the area, due to development activities. Alternative G-Modified will have the least potential. Valuable sites will be protected via avoidance or conserved through data recovery.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: All alternatives, with the exception of I, assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I allocates approximately one-half of the area to the semi-primitive motorized management prescription. All alternatives maintain the area in a predominately roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	31,850	30,944	30,066	91%
B (RPA)	32,042	31,228	30,572	92%
C	32,663	32,385	31,884	96%
G-Mod.	33,176	33,176	33,114	100%
H	32,504	32,060	31,595	95%
I	32,000	31,200	30,461	92%
J (Pref).	32,585	32,235	31,828	96%

TOLMIE CREEK **Roadless Area 6056**

This roadless area originally consisted of 650 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6056 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation.

In 1982, the Poch Peak West Timber Sale removed 274 acres from roadless status. In 1988, the area was reduced by 102 acres due to a mapping discrepancy. The following shows the disposition of acres within the Tolmie Creek roadless area:

Tolmie Creek	**Net Acres**
1984 RARE II	650
updated 1988	274
Change	**- 376**

OVERVIEW

This parcel is located adjacent to the northeast corner of Mt. Rainier National Park. Road access is via Mowich Lake Highway and the Forest Service Evans Creek Road System #7920. Terrain is mostly steep mountain sideslopes with Tolmie Creek forming the major drainage system. Two ridges extend northwest from Mt. Rainier National Park. Elevations range from 3,400 to 5,128 feet at the summit of Poch Peak.

Soils are shallow to moderately deep, non-plastic, silty sands, and silty gravels derived from andesite and pyroclastic rocks. Soils derived from weathered granite are moderately deep, slightly plastic, sandy silts, and sandy clays.

The predominant cover type is old growth Pacific silver fir, with minor components of western hemlock and Douglas-fir found at lower elevations. No threatened or endangered plants have been identified.

The parcel is bordered on the east by Mt. Rainier National Park, which is managed as primitive backcountry. The surrounding National Forest land is managed for multiple-use and appears heavily modified. There are no known special attractions within this area.

WILDERNESS CAPABILITY

Manageability and Boundaries: Boundaries do not follow natural features or contours. Due to its small size, it is not manageable as wilderness.

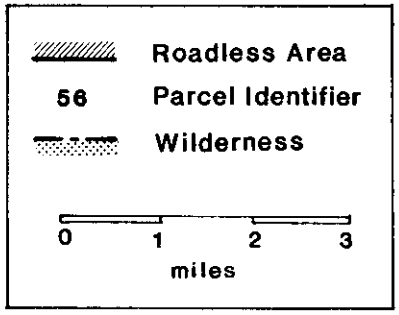
Natural Integrity and Appearance: The heavily modified appearance outside the area can be attributed to extensive logging and road building activities.

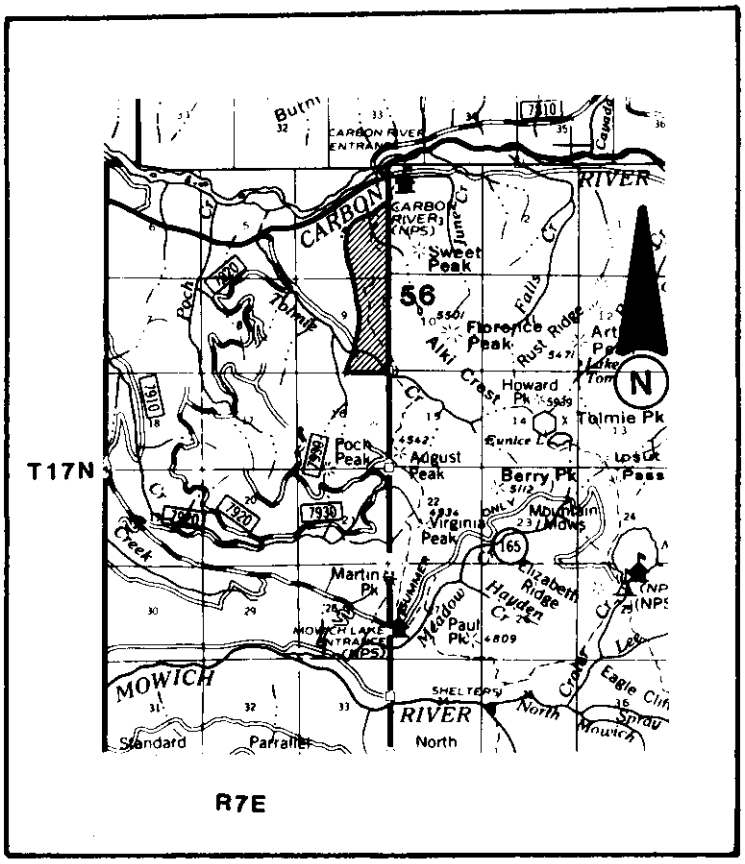
Opportunities For Solitude: Opportunities for solitude are very limited because of past management activities.

Opportunities For Primitive Recreation: Opportunities for primitive recreation are non-existent because of the small land area and existing forest developments.

Tolmie Creek

Roadless Area 6056





Challenging Experiences: None.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Tolmie Creek #6056

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	274

Leasable Energy Minerals (Moderate Potential)		
Oil, gas, coal, geothermal	Acres	274

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Recreational activity is mostly hunting. Use of the trail along the Park boundary is limited.

Wildlife: The entire parcel affords summer range for blacktail deer and a small herd of elk due to the elevations involved. No threatened or endangered species have been identified.

Water: There are no power withdrawals or domestic water users.

Livestock Operations: None

Ecology: This Pacific silver fir zone is characterized by cool, moist soils, persistent winter snowpack, a general lack of summer plant moisture stress, and a short, cool growing season.

Timber: Old growth forest on half this area is classed tentatively suitable for timber harvest.

Minerals/Oil and Gas: This area is underlain primarily by Tertiary volcanic rocks, and is reported to have occurrences of cooper, gold, lead and silver. However, only one mining claim is recorded to have been located within the area. The area is classified "prospectively valuable" for oil and gas and geothermal, but is encumbered only by one oil and gas lease. The area has not been studied by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears that the area has a relatively low potential for the occurrence of mineral resources.

Cultural: The potential for cultural resources is low due to the steep topography in the area.

Land Use Authorizations: None

Non-Federal Lands: None

Fire: Fire occurrence is rare.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: The Clearwater and Norse Peak Wildernesses and Mt. Rainier National Park are located within six miles of the parcel. Seattle and Tacoma are within 50-70 miles.

Public Interest: Following release of the DEIS and Proposed Forest Plan, the Tolmie Creek Roadless Area was mentioned 28 times in the public comments. Seven responses said to maintain the roadless area as a buffer to wilderness. Four wanted to have the area made a top priority for harvest. Three comments favored keeping the area open for multiple uses, and two desired the area be protected from logging. Most of the remaining comments favored managing the area for recreation, wildlife habitat, and scenic quality. 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

In a general sense, the area adjacent to Mt. Rainier National Park was mentioned 402 times. Responses said to protect the area from harvest (96), preserve the forest ecosystem (58), keep the area roadless (50), that the devastation (logging, clearcutting, road building) was appalling (30), protect old growth (22), maintain the roadless area as a buffer to wilderness (21), protect wildlife habitat (16), and protect the area for recreation (14). The majority of the remaining comments favored managing the area for recreation, and protecting wildlife habitat, fisheries, and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

TOLMIE CREEK

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	105						
1B SPNM			253	168			
1D RN		126					21
2A Foregrd.			21				
17 Timber	168	147		105	274	274	253

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives.

Water: The water resource of the area will not be significantly affected by any of the alternatives.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives.

Timber: The timber resource of the area will not be significantly affected by any of the alternatives, due to the low level of planned development activity.

Minerals/Oil/Gas: None of the alternatives will significantly affect the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will significantly affect the cultural resources of the area, due to the low level of proposed development.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: Alternatives H, I and J (Preferred) assign the majority of the area to management area 17 (timber). Alternatives A, NC, B and G-Modified assign about half of the area to timber. Alternative C assigns none of the area to it. All alternatives will maintain the area in a roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	274	274	274	100%
B (RPA)	274	274	274	100%
C	274	274	274	100%
G-Mod.	274	274	274	100%
H	274	274	274	100%
I	274	274	274	100%
J (Pref).	274	274	274	100%

CLEARWATER **Roadless Area 6055 (CI, CG, CH, CF, CB, CC, CE, CD)**

This roadless area originally consisted of 24,900 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6055 to nonwilderness uses. In 1984 15,951 acres from this area were designated the Clearwater Wilderness by Congress as a result of the Washington Wilderness Legislation. In 1982, the McGilvary Salvage and West Line Salvage Timber Sales were sold under contract which removed 123 acres from roadless status. The area was reduced by 23 acres due to a mapping discrepancy. Eight parcels remain in roadless status. The following shows the disposition of acres with the Clearwater roadless area:

Clearwater	**Net Acres**
1984 RARE II	24,900
updated 1988	8,803
Change	**-16,097**

OVERVIEW

These parcels are located along the north boundary of Mt. Rainier National Park adjacent to Clearwater Wilderness. The area extends north to the Forest Boundary. Soils are shallow to moderately deep silty sands and well graded gravels primarily from andesite and pyroclastic rock origin. Sideslope gradients range from 50% to 90%. Elevation ranges from 2,000 to 5,000 feet above sea level.

The predominant cover type is old growth Pacific silver fir and western hemlock above 3,000 feet, changing to Douglas-fir and western hemlock below this elevation. No rare and endangered plants have been identified.

Dispersed recreation is the primary use; amount of use is low to moderately high. The moderately high use is limited to the area around Coplay and Summit Lakes. Coplay Lake has road access. The Summit Lake trail system receives heavy use. The ROS classification is split between semi-primitive non-motorized, roaded natural, and roaded modified.

Mt. Rainier National Park borders on the south of these parcels and is managed as primitive backcountry. The area to the north is privately owned cutover land and appears heavily modified. The surrounding National Forest lands are managed for multiple-use and appears modified.

WILDERNESS CAPABILITY

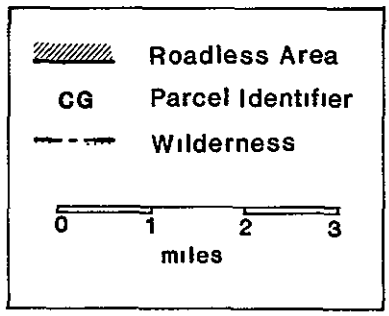
Manageability and Boundaries: The eight parcels are heavily influenced by adjacent logging and road building. No parcel could stand on its own, but would make logical additions to the Clearwater Wilderness.

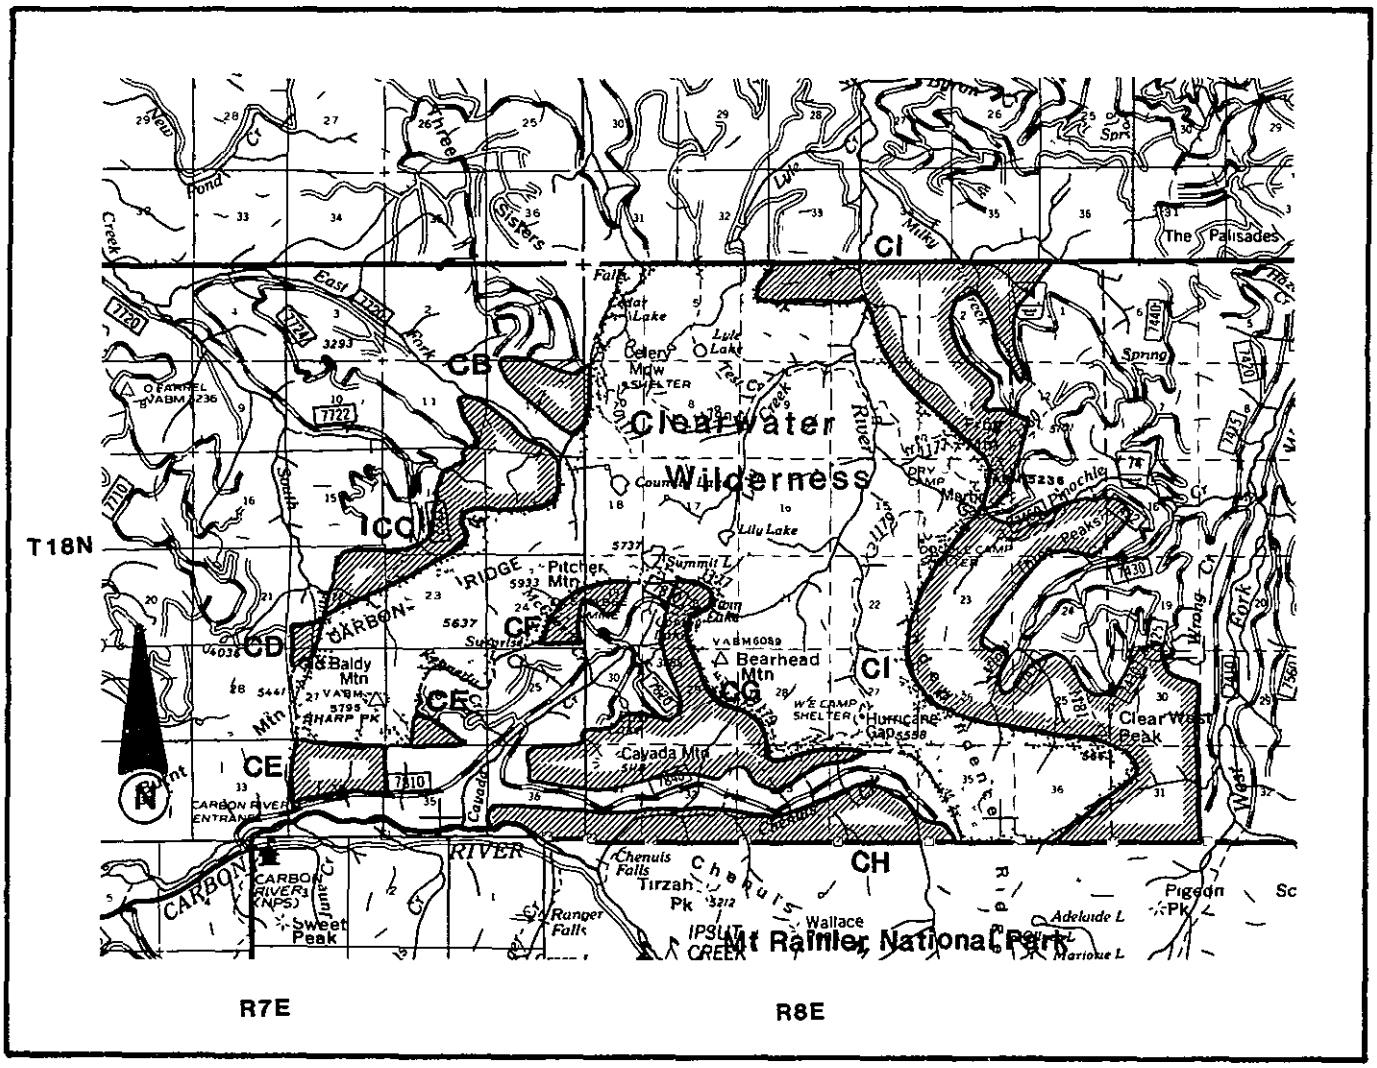
Natural Integrity and Appearance: Long-term ecological processes would be influenced greatly by existing forest management activities.

Opportunities For Solitude: None due to roads and past harvesting practices on lands outside the roadless area. No site within these parcels is more than one mile from an existing road.

Clearwater

Roadless Area 6055





Opportunities For Primitive Recreation: Few due to proximity of existing roads.

Challenging Experiences: None.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: Very little recreation use occurs except during hunting season. The trail to Clearwest lookout site receives approximately 100-200 visits annually. The Chenius Creek road system has dispersed recreation during the summer. The Coplay and East Lake areas receive heavy motorized use during the summer months.

Fish/Wildlife: These parcels provide summer range for approximately 100-150 elk. Portions also provide summer range for blacktailed deer. Mountain goat use has been identified along Carbon and Independence Ridges as well as on Cayada Mountain and Clearwest Peak. An adjacent area within the Clearwater Wilderness is being managed as mountain goat habitat. A spotted owl MR is present.

Water: These parcels have several streams with resident trout. These drainages flow into the glacial Carbon River, West Fork White River systems. The major streams include Chenuis, South Prairie, Milky, Pinochile, Viola, and Pigeon Creeks and the Clearwater River. All have documented resident fish use, and the East Fork of South Prairie Creek is a domestic water source for the City of Buckley. No power withdrawals exist on any of these streams.

Livestock Operations: None.

Ecology: The Pacific silver fir zone on these parcels is characterized by cool moist soils, persistent winter snow packs, and a short growing season. The lower elevation hemlock zone generally occurs up to 3,900 feet on warm aspects to 3,200 feet on cooler aspects.

Timber: Old growth forest stand volumes average 50-60 thousand board feet per acre; 80% of the area is classed tentatively suitable for timber harvest.

Minerals/Oil and Gas: This area is underlain primarily by Tertiary granitic and volcanic rocks, and by Quaternary aged alluvium. It lies partly within the Carbon River Mining District, and is reported to have 11 mining claims located within it. It has reported occurrences of copper, molybdenum, and silver. According to Lawson and Evarts (1983), the southern portion has high potential for occurrence of porphyry type copper deposits. It is classified "prospectively valuable" for geothermal. Based upon available data, it appears that the area has a moderate to high potential for the occurrence of copper deposits, which would presently be noneconomic.

Cultural: Nothing of cultural significance could be found in this parcel.

Summary Table - Clearwater #6055

1/ Includes nest sites, forage areas, and roost areas.
2/ Native American Religious Freedom areas were analyzed. Site specific information is not disclosed due to its sensitivity
3/ Number of claims not broken out by parcel

Land Use Authorizations: Mining claims are located within these parcels; geothermal testing has occurred in the Chenuis and Cayada Creek drainages. Apiary permits are issued on a yearly basis.

Non-Federal Lands: None.

Fire: Potential for fire from natural occurrences is low in this Pacific silver fir zone. Wildfire ignitions are twice as likely to occur in the lower elevation hemlock stands. There have been no large fires in recent times.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is adjacent to the Clearwater Wilderness and Mt. Rainier National Park. Seattle and Tacoma are within 50-70 miles.

Public Interest: Following release of the DEIS and Proposed Forest Plan, comments were received concerning the several parcels within the Clearwater Roadless Area, as well as responses on areas adjacent to the Clearwater Wilderness and specific geographic sites and features within the Clearwater Roadless Area.

Clearwater parcel CI was mentioned four times. The responses said to preserve the forest ecosystem, protect visuals, avoid road building on these unstable soils, and protect corridors of old growth linking SOHA's (one each). 1/

Clearwater parcel CE was mentioned twice. One response favored protecting the area for recreation; one said to preserve it as valuable low-elevation old growth.

Clearwater adjacent areas were mentioned 256 times. The responses favored keeping the area roadless (69), protecting it from harvest (49), and preserving the forest ecosystem (42). The majority of the remaining comments said the area was most valuable for recreation, and for protection of old growth, wildlife habitat, and scenic quality. Five comments said to make this area a top priority for timber harvest; three said to not use it as a buffer to wilderness.

Chenius Creek was mentioned 401 times. Responses favored protecting the area from harvest (118), adding it to the National Park System (60), preserving the forest ecosystem (44), keeping it roadless (44), making the road into a trail (29), and protecting old growth (17). Most of the remaining comments said to manage the area for recreation, wildlife habitat and scenic quality.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Clear West Peak was mentioned 11 times. Six comments said it should be a Wild and Scenic River.

Areas adjacent to Mt. Rainier National Park were mentioned 402 times. Responses said to protect the area from harvest (96), preserve the forest ecosystem (58), keep the area roadless (50), that the devastation (logging, clearcutting, road building) was appalling (30), protect old growth (22), maintain the roadless area as a buffer to wilderness (21), protect wildlife habitat (16), and protect the area for recreation (14). The majority of the remaining comments favored managing the area for recreation, and protecting wildlife habitat, fisheries, and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives B, I and J (Preferred) allocate the greatest area to old growth habitat, deer and elk enhancement and mountain goat management requirement management areas; Alternatives A, NC, C and G-Modified allocate the least.

Water: There will be no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of development activity.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of development activity.

Timber: Alternative C will have the least affect on the existing timber resource, as it does not allocate any acreage to management area 17 (timber). Alternatives A, B, H and I allocate the most. Alternatives G-Modified and J (Preferred) will not significantly affect the timber resource, as potential development activities will be minimal.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives A and NC will provide a slightly higher amount of roaded access through the area, which could be used for minerals exploration and development.

Cultural: None of the alternatives will significantly affect the cultural resources of the area.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: Alternatives C, G-Modified and J (Preferred) assign the majority of this area to management prescriptions compatible with preserving its roadless character. These alternatives will maintain the area in a predominately roadless condition through the end of the fifth decade, maintaining the wilderness potential. Alternatives A, NC, B, H and I maintain at least three-quarters of the area in a predominately roadless condition through the end of the fifth decade.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	**Decade 1**	**Decade 2**	**Decade 5**	**Remaining**
A (No Act)	7,834	7,232	6,617	75%
B (RPA)	8,107	7,715	7,244	82%
C	8,797	8,797	8,618	98%
G-Mod.	8,803	8,803	8,784	100%
H	8,269	7,865	7,503	85%
I	8,167	7,899	7,412	84%
J (Pref).	8,680	8,584	8,454	96%

LONESOME LAKE **Roadless Area 6057**

This roadless area originally consisted of 1,850 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6057 to nonwilderness uses. In 1984 no acres from this area were designated Wilderness by Congress as a result of the Washington Wilderness Legislation. Two timber sales are under contract within this roadless area. The High Mule and Liver Camp Timber Sales removed 1,440 acres from roadless status. The area was reduced by 115 acres due to a mapping discrepancy. The following shows the disposition of acres within the Lonesome Lake roadless area:

Lonesome Lake	**Net Acres**
1984 RARE II	1,850
updated 1988	295
Change	**-1,555**

OVERVIEW

This parcel is located along the north boundary of Mt. Rainier National Park, with access provided by the West Fork Roads #74 and #7530 and Huckleberry Creek Road #73. Soils are shallow to moderately deep non-plastic, silty sands and silty gravels primarily from andesite and pyroclastic rocks occurring on steep, high-elevation sideslopes. Terrain is steep, heavily dissected, with sideslope gradients ranging from 50 to 90 percent. Elevation ranges from 2,800 to 5,400 feet. A ridge system running north out of Mt. Rainier National Park forms the divide between the West Fork and Huckleberry Rivers.

The predominant cover type is old growth Pacific silver fir and western hemlock above 3,000 feet, changing to Douglas-fir and western hemlock below 3,000 feet. No threatened and endangered plants have been identified.

Dispersed recreation is the primary use. Moderate amounts of use occur during the fall hunting season. Lonesome Lake has road access to within several hundred yards from the north. No officially recognized trails exist. The ROS classifications are roaded modified and roaded natural. Mt. Rainier National Park on the south boundary of this parcel is managed as primitive backcountry. The surrounding National Forest lands are managed for multiple use; past harvesting and road development are readily apparent.

WILDERNESS CAPABILITY

Manageability and Boundaries: This parcel is too small to manage as Wilderness, but does offer roadless recreation potential.

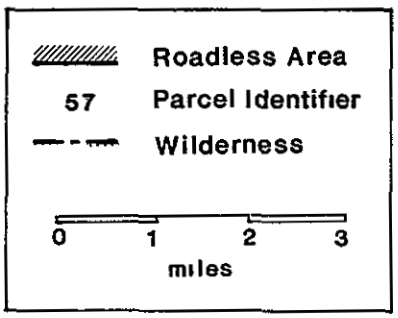
Natural Integrity and Appearance: Due to proximity to Mt. Rainier National Park, continuing long-term ecological processes can be assured. Appearances however are influenced by Forest practices to the north.

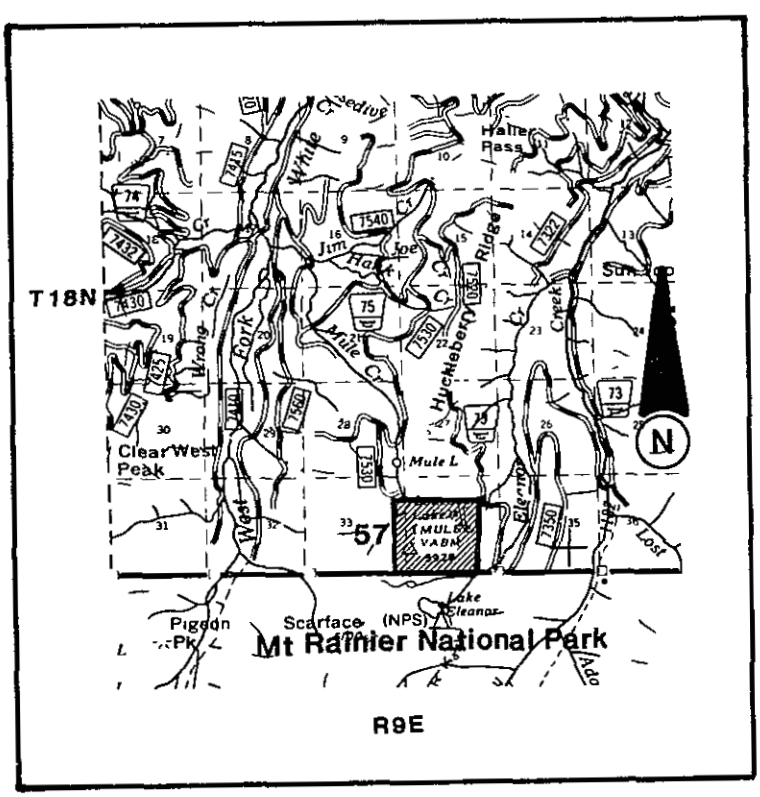
Opportunities For Solitude: None due to roads and past harvesting activities. No site within the area is more than 1/2 mile from an existing road.

Opportunities For Primitive Recreation: None because of minimal amount of unroaded area.

Lonesome Lake

Roadless Area 6057





Challenging Experiences: None.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Lonesome Lake #6057

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	295

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: This parcel receives predominately roaded dispersed use although some unroaded use occurs on a trail to Lake Eleanor in Mt. Rainier National Park.

Fish/Wildlife: This parcel affords summer-fall range for approximately 150 elk and numerous deer. It has a small amount of suitable habitat for mountain goats; sightings of single animals have been reported. No threatened or endangered animals have been identified.

Water: Drainages include intermittent streams which feed Huckleberry Creek and the West Fork River. No domestic use or power withdrawals exist.

Livestock Operations: None.

Ecology: This Pacific silver fir zone is characterized by cool moist soils, persistent winter snowpack, and a short growing season.

Timber: Twenty-eight percent of this area is classed tentatively suitable for timber harvest. Old growth stand volumes average 45 thousand board feet per acre with 20 percent defect from disease.

Mineral/Oil and Gas: This area is primarily underlain by Tertiary intrusive and volcanic rocks, and it is reported to have occurrences of copper and molybdenum. It, however, has no reported mining claims. The area is classified "prospectively valuable" for geothermal resources, but it is not encumbered by any leases or pending lease applications. The area has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears the area has a low potential for the occurrence of mineral resources.

Cultural: Nothing of cultural significance has been found in these parcels.

Land Use Authorizations: None.

Non-Federal Lands: None.

Fire: Potential for natural ignition fires is low. Stand age for the old growth is between 450 and 850 years.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: Within 4 miles of this parcel are located the Clearwater and Norse Peak Wildernesses. The southern boundary of this parcel adjoins Mt. Rainier. Seattle and Tacoma are approximately 50-70 miles away.

Public Interest: Following release of the DEIS and Proposed Forest Plan, the Lonesome Lake Roadless Area was mentioned 36 times in the public comments. Responses said to make the area a top priority for harvest (5), preserve the forest ecosystem (4), increase opportunities for motorized recreation (4), maintain the roadless area as a buffer to wilderness (4), and protect wildlife habitat (4). Most of the remaining comments favored managing the area for recreation and wildlife habitat. One comment said to add this area to the National Park System. 1/

In a general sense, areas adjacent to Mt. Rainier National Park were mentioned 402 times. Responses said to protect the area from harvest (96), preserve the forest ecosystem (58), keep the area roadless (50), that the devastation (logging, clearcutting, road building) was appalling (30), protect old growth (22), maintain the roadless area as a buffer to wilderness (21), protect wildlife habitat (16), and protect the area for recreation (14). The majority of the remaining comments favored managing the area for recreation, and protecting wildlife habitat, fisheries, and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

LONESOME LAKE

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp. Rec	232						
1B SPNM			232	211			147
1D RN			42				
2B Midgrd.							42
12 Mature O-G		84			84	84	84
15 Goat MR		21	21	21	21	21	21
17 Timber	63	190		63	190	190	

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of proposed development activities.

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person could mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

Ecology: *The overall ecology of the area will not be significantly affected by* any of the alternatives, due to the low level of proposed development activities.

Timber: Alternatives C and J (Preferred) do not allocate any acreage to management area 17 (timber). Alternatives B, H and I allocate 64% of the area to timber. Alternatives A, NC and G-Modified allocate 21% of the area to timber management. None of the alternatives will significantly affect the timber resource, as no harvest activity is planned through the fifth decade.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: *None of the alternatives will have a significant affect on the* cultural resources of the area, as no development activity is planned.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

Wilderness Potential: Alternatives B, H and I allocate 64% of the area to management area 17 (timber). Alternatives C and J (Preferred) do not allocate any of the area to timber. All alternatives will maintain the area in a roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres Decade 1	Decade 2	Decade 5	Percent Remaining
A (No Act)	295	295	295	100%
B (RPA)	295	295	295	100%
C	295	295	295	100%
G-Mod.	295	295	295	100%
H	295	295	295	100%
I	295	295	295	100%
J (Pref).	295	295	295	100%

SUN TOP **Roadless Area 6058**

This roadless area originally consisted of 5,200 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6058 to nonwilderness uses. None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Legislation. Since then, 2,850 acres have been removed from roadless status because of the Skookum Doe Timber Sale under contract. The area has been increased by 36 acres due to a mapping discrepancy. The following shows the disposition of acres within the Suntop roadless area.

Sun Top	Net Acres
1984 RARE II	5,200
updated 1988	2,386
Change	**-2,814**

OVERVIEW

This parcel is located adjacent to the northeast corner of Mt. Rainier National Park. Access is by the Huckleberry Creek Road (#73) on the north and west side, and the Buck Creek Road (#7160) on the east. Topography is varied, from flat river bottoms along the White River to the open flat ridges of Sun Top Lookout. Portions south of Sun Top Lookout include a prominent vertical rock face. Drainages include Huckleberry, Lost, Doe, Buck and Skookum Creeks, with all but Skookum Creek originating in Mt. Rainier National Park. Sun Top Lookout sits on a high ridge that extends north from the Park and divides Huckleberry Creek and the White River. Elevations range from 2,400 feet to 5,600 feet.

Rock types are andesite flows and andesite breccias with pyroclastic material. The andesite rocks are hard, moderately to highly fractured, and are competent. The volcanic sediments and pyroclastic materials are moderately hard to soft, highly fractured, and are moderately competent to incompetent.

Soils are shallow to moderately deep, non-plastic, silty sands and silty gravels. Soils derived from the pyroclastic material are moderately deep to deep, slighty plastic, sandy silts and sandy clays.

Vegetation ranges from large, old growth Douglas-fir in valley bottoms to Pacific silver fir-subalpine fir near ridgetops. East exposure ridges have several meadows and open slopes Mountain hemlock is found in the upper basins on north slopes. No threatened or endangered plants have been identified.

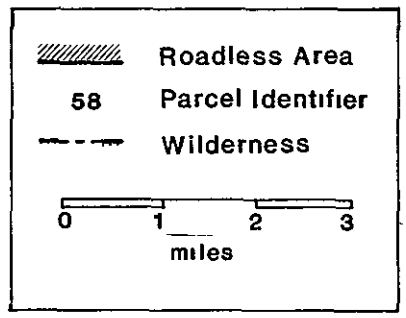
Dispersed recreation use ranges from fishing along Huckleberry Creek to hiking Sun Top Lookout ridges. There are approximately 8 miles of maintained hiking trails. The ROS classifications are: roaded natural, semi-primitive motorized, roaded modified and semi-primitive non-motorized.

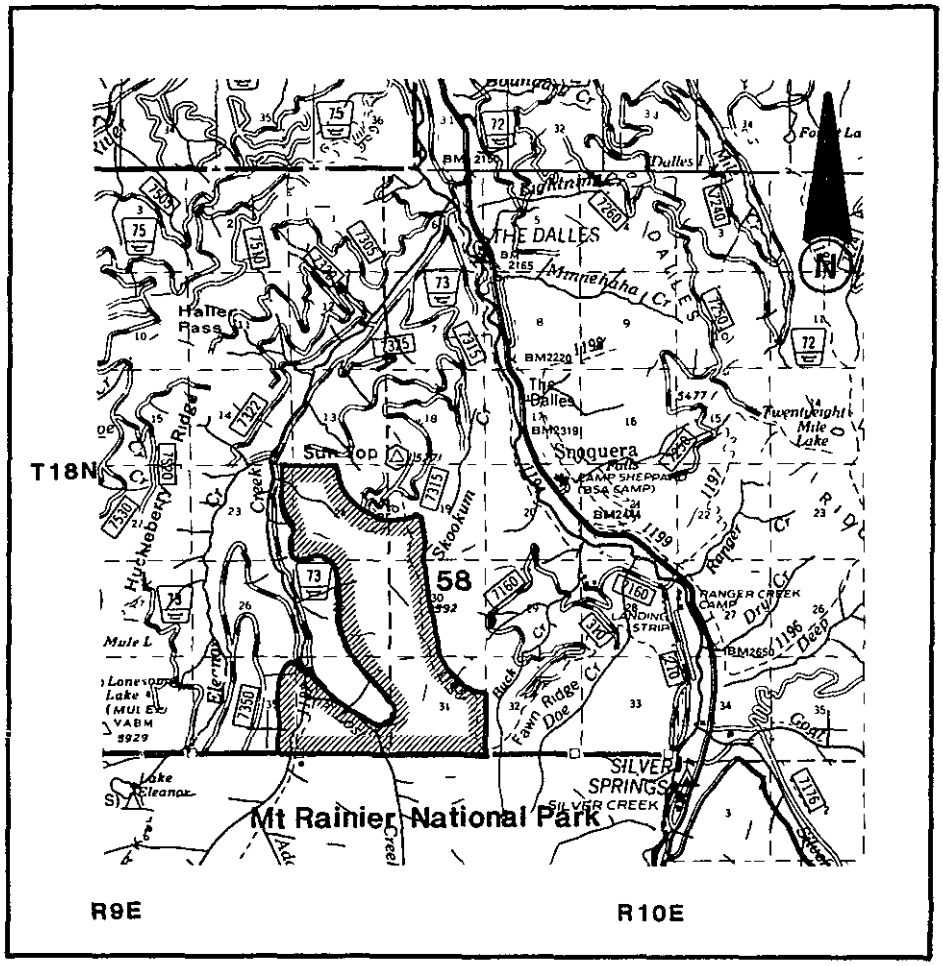
Mt. Rainier National Park forms the southern boundary. The surrounding National Forest land is managed as multiple use.

The major attraction is Sun Top Lookout.

Sun Top

Roadless Area 6058





WILDERNESS CAPABILITY

Manageability and Boundaries: This area is marginal in size as wilderness unless combined with Mt. Rainier National Park. Area is suitable for highly accessible roadless recreation. Some boundary adjustments are desirable to reduce the impact of adjacent roads.

Natural Integrity and Appearance: Long-term ecological processes can be maintained due to proximity to the Park. The appearance is a natural setting except near the boundaries where the influence of logging is readily apparent.

Opportunities For Solitude: Potential for solitude is low. The trail south from Sun Top provides a limited chance for solitude.

Opportunities For Primitive Recreation: The opportunity is low due to road accessibility.

Challenging Experiences: None.

Special Features: Sun Top Lookout.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Sun Top #6058

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	2,386
Primitive/Semi-Primitive Recreation ROS	Acres	0
Timber		
Tentatively suitable	Acres	2,048

Low	Acres	2,386
Claims	# of	0
Leasable Energy Minerals (Moderate Potential)		
Geothermal	Acres	1,626

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: This parcel receives high levels of dispersed recreational use, especially during hunting season. Several migration routes for elk leaving Mt. Rainier National Park are known. The Skookum Flats Trail along the White River receives approximately 3,000-4,000 annual visitors and the Suntop Trail receives approximately 1,000-2,000 annual visitors.

Fish/Wildlife: This parcel features a high diversity of wildlife. Approximately 13 mountain goats winter on the rock slopes south of Sun Top It affords summer range for blacktail deer and transition range for approximately 300 elk leaving the Park. Pileated woodpecker and pine marten MR habitat is present. Huckleberry and Lost Creeks have a resident trout populations.

Water: Buck Creek Lodge takes domestic water from its namesake (which originates in this parcel). The water intake is approximately 1 1/2 miles outside the parcel. There are no power withdrawals.

Livestock Operations: None.

Ecology: The Pacific silver fir zone here is characterized by cool, moist soils, persistent winter snowpacks, and a short growing season. The hemlock-Douglas-fir zone is found on lower elevations and warmer sites. Because of the vast elevation differential, this parcel has a diversity of ecosystems, ranging from large old-growth Douglas-fir to alpine meadows.

Timber: Forest stand volumes range from 90 thousand board feet per acre to 15 thousand board feet per acre near ridgetops Stand defect is 25 percent to 30 percent. Understory is limited mostly to north slopes. Harvest units adjacent to this parcel are well stocked with Douglas-fir and noble fir. Nearly all this area is tentatively suitable for timber harvest.

Minerals/Oil and Gas: This area is primarily underlain by Tertiary volcanics. It has no reported mineral resource occurrences, nor does it have any recorded mining claims. The area is classified "prospectively valuable" for geothermal resources. It has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data, it appears the area has a relatively low potential for the occurrence of mineral resources.

Cultural: Nothing of cultural significance is known to exist within this parcel.

Land Use Authorizations: Approximately 1,800 acres are designated as the Sun Top Recreation Area. This is along the ridgetop south of Sun Top Lookout.

Non-Federal Lands: None.

Fire: Fire occurrence is moderate. Lightning strikes occur every 4 or 5 years, and human caused fires occur frequently.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is within 7 miles of both the Clearwater and Norse Peak Wildernesses. It is also adjacent to portions of Mt. Rainier National Park managed as primitive backcountry. Seattle and Tacoma are within 50-70 miles.

Public Interest: Following release of the DEIS and Proposed Forest Plan, the Sun Top Roadless Area did not receive any public comments. However, in a more general sense, areas adjacent to Mt. Rainier National Park were mentioned 402 times. Responses said to protect the area from harvest (96), preserve the forest ecosystem (58), keep the area roadless (50), that the devastation (logging, clearcutting, road building) was appalling (30), protect old growth (22), maintain the roadless area as a buffer to wilderness (21), protect wildlife habitat (16), and protect the area for recreation (14). The majority of the remaining comments favored managing the area for recreation, and protecting wildlife habitat, fisheries, and visual quality 1/

1/ As discussed in the Summary of Public Response to the DEIS in Appendix A of this document: the number of times an area is "mentioned" does not equal the number of inputs mentioning a site, as one person **could** mention an area several times. For example, "protect old growth" and "build a trail here" would be tallied as "2" in the number of times an area is mentioned. However, most people only mentioned a specific area once.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management

23B Otr Wtsh.			359				

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected in most of the alternatives. Alternatives G-Modified and H leave the area unroaded. Alternatives B and I remove the largest amount of area from roadless status at the end of the fifth decade (67% and 73% remaining, respectively).

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives, due to the low level of proposed development. Alternatives B, H, I and J (Preferred) allocate the greatest amount of acres to old growth habitat, mature old growth, and mountain goat management requirement management areas. Alternatives A, C and G-Modified allocate the least.

Water: There will be no adverse effects to the water resource of this area associated with any of the alternatives, due to the low level of development activity proposed.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of proposed development activity.

Timber: Alternatives A, NC, B, H and I allocate approximately one-half of the area to management area 17 (timber) Alternatives C, G-Modified and J (Preferred) allocate very minimal acres to timber. None of the alternatives will significantly affect the timber resource, due to the minimal amount of harvest activity planned.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives B and H will provide a slightly higher level of roaded access, which could be used for *mineral exploration and development.*

Cultural: Alternatives B and H will have the greatest potential to adversely impact cultural resources within the area, due to development activities. Valuable sites will be protected via avoidance or conserved through data recovery. Alternatives C, G-Modified and H will have the least potential to impact.

Land Use Authorizations: None of the alternatives will significantly affect land special use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

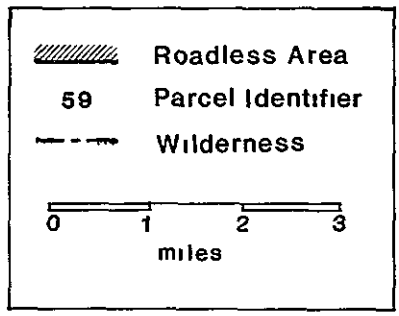
Wilderness Potential: Alternatives C, G-Modified, and J (Preferred), assign the majority of this area to management prescriptions compatible with preserving its roadless character. In the alternatives above the wilderness potential will be maintained. Alternative A, NC assigns 48% of the area to timber management. Alternative B assigns 45% of the area to timber management. Alternative H assigns 44% of the area to timber management and alternative I assigns 56% of the area to timber management.

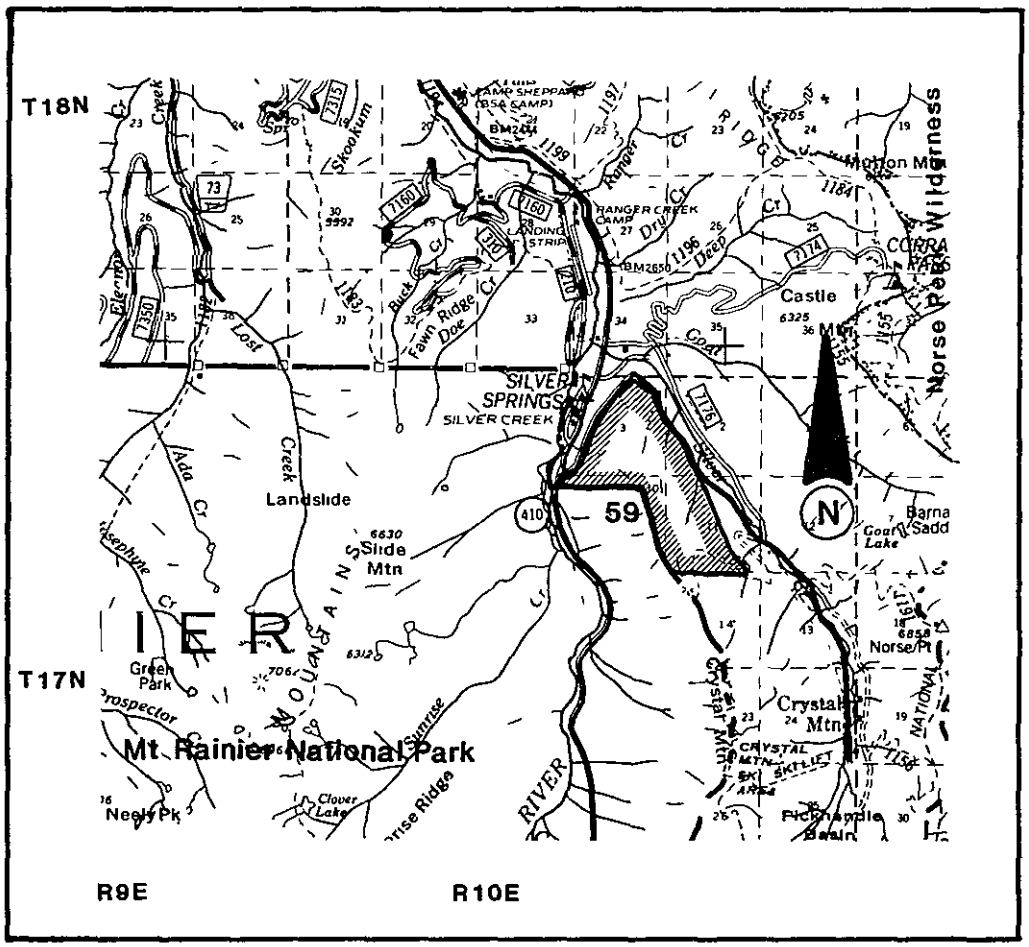
The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	2,278	2,254	2,073	87%
B (RPA)	2,038	1,970	1,590	67%
C	2,323	2,273	2,237	94%
G-Mod.	2,386	2,386	2,386	100%
H	2,386	2,386	2,386	100%
I	2,056	2,032	1,734	73%
J (Pref).	2,182	2,132	1,958	82%

Silver Creek

Roadless Area 6059





SILVER CREEK **Roadless Area 6059**

This roadless area originally consisted of 1,000 acres. It was inventoried for study as potential wilderness during the RARE II process. The RARE II decision assigned area 6059 to nonwilderness uses None of this area was designated Wilderness by Congress as a result of the 1984 Washington Wilderness Act. The area was increased by 55 acres due to a mapping discrepancy. The following shows the disposition of acres within the Silver Creek roadless area:

Silver Creek	Net Acres
1984 RARE II	1,000
updated 1988	1,055
Change	**+ 55**

OVERVIEW

This parcel is located adjacent to the northeast corner of Mt. Rainier National Park. The southern boundary borders on the Crystal Mountain Ski Area Access is via the Crystal Mountain Highway #33.

Rock types are andesite flows and andesite breccias with pyroclastic material. The andesite rocks are hard, moderately to highly fractured and are competent. The volcanic sediments and pyroclastic materials are moderately hard to soft, highly fractured, and are moderately competent to incompetent. Soils are shallow to moderately deep, non-plastic, silty sands and silty gravels. Soils derived from the pyroclastic materials are moderately deep to deep, slightly plastic, sandy silts and sandy clays.

Terrain is uniformly steep sideslopes which run to ridgetops extending north from Mt. Rainier National Park. Drainages include White River, Silver Creek, and tributaries. Elevations range from 3,000 to 6,100 feet. The west facing slopes support old growth western hemlock with Douglas-fir up to about 4,000 feet. The east facing slopes are colder and support Pacific silver fir. There are no threatened or endangered plants identified. No timber harvest has occurred.

Dispersed backcountry recreation is the primary use. There is one ridgetop trail (it is not currently maintained nor shown on Forest Service maps). The ROS classifications are roaded natural and semi-primitive non-motorized. There have been no previous management activities and overall appearance is of old growth forest.

The Mt. Rainier National Park adjoins on the south and east, and is managed as primitive backcountry. The surrounding National Forest land is managed as roaded natural and rural in the Silver Springs Summer Home Area

WILDERNESS CAPABILITY

Manageability and Boundaries: This small isolated parcel is not suitable for wilderness consideration unless combined with Mt. Rainier National Park.

Natural Integrity and Appearance: This area is highly influenced by road corridors and the nearby ski development. Its appearance is dominated by outside activities rather than the naturalness of its interior.

Opportunities For Solitude: Opportunities for solitude are limited due to the adjacent Crystal Mountain Highway, although the old, unmaintained trail offers a slight potential.

Opportunities For Primitive Recreation: None due to the close proximity of Highway 410, Crystal Mountain Highway, and the developed ski area.

Challenging Experiences: None.

Special Features: None.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Summary Table - Silver Creek #6059

Category 1/	Unit	Total
Acres (Minus water, private land)	Acres	1,055
Primitive/Semi-Primitive Recreation ROS	Acres	316
Timber		
Tentatively suitable	Acres	337
Tentatively suitable inaccessible	Acres	0
Tentatively suitable standing volume	M bdft	11,147
"Old Growth", Total Acres	Acres	211

Moderate	Acres	0
Low	Acres	1,055
Claims	# of	1
Leasable Energy Minerals	Acres	0

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

Availability - Other Resource Potential

Recreation: Current use is dispersed recreation.

Wildlife: This parcel affords summer range for blacktail deer and elk. There are no threatened or endangered species identified.

Water: There are no power withdrawals or domestic water uses; streams are all small and intermittent.

Livestock Operations: None.

Ecology: Cover type varies from old growth timber forest at lower elevations to small meadows on or near ridgetops. The entire parcel is characterized by cool, moist soils, persistent winter snowpack, and a short, cool growing season The understory is predominately Pacific silver fir as this is the climax species for most of this area of the Cascade Range.

Timber: Forest stand volumes vary from 50 to 15 board feet per acre with 32 percent classed as tentatively suitable for timber harvest.

Minerals/Oil and Gas: This area is primarily underlain by Tertiary aged volcanics, and it lies within the Silver Creek Mining District. It is reported to have occurrences of lead, zinc, gold, silver, and copper but it has only one recorded mining claim. It is classified "prospectively valuable" for geothermal resources, but it is not encumbered by any leases or pending lease applications. The area has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears the area has a moderate potential for the occurrence of mineral resources

Cultural: Potential for cultural resources is low due to the steep topography.

Land Use Authorization: None.

Non-Federal Lands: None.

Fire: Fire occurrence is low One documented lightning strike has occurred in the last 10 years.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: This parcel is within 2 miles of Norse Peak Wilderness, and about 10 air miles from the Clearwater Wilderness. Seattle and Tacoma are within 50-70 miles.

Public Interest: Following release of the DEIS and Proposed Forest Plan, Silver Creek was mentioned 29 times in the public comments received. Responses favored protecting visuals (6), keeping the area open for multiple uses (3), reducing logging in the area (3), managing for nonmotorized recreation (2), designating the area MA 1AB (primitive/semi-primitive nonmotorized) (2), keeping it roadless (2), and rebuilding the trail (2). The remaining comments were split between

making the area a top priority for harvest and building more roads, and managing it for recreation, building no new roads, and protecting it for wildlife habitat.

Areas adjacent to Mt. Rainier National Park were mentioned 402 times. Responses said to protect the area from harvest (96), preserve the forest ecosystem (58), keep the area roadless (50), that the devastation (logging, clearcutting, road building) was appalling (30), protect old growth (22), maintain the roadless area as a buffer to wilderness (21), protect wildlife habitat (16), and protect the area for recreation (14). The majority of the remaining comments favored managing the area for recreation, and protecting wildlife habitat, fisheries, and visual quality.

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management

SILVER CREEK

MANAGEMENT AREA NAME	A/NC	B	C	G-Mod.	H	I	J(Pref).
Disp Rec	865						
1B SPNM		654	105	190	84		760
1C SPM						359	
2A Foregrd	147	147	147	718	190	190	105
5 Potent W&S			42				
8 Special							190
11 O-G Hab.				147			
17 Timber		126					
23A Otr Wtsh.	42	126			781	506	
23B Otr Wtsh			760				

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative I allocates approximately one-third of the area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife would not be significantly affected by any of the alternatives, due to the very low level of development activity planned.

Water: There are no adverse effects to the water resource of this area associated with any of the alternatives, due to the no development activity planned.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to no development activity planned.

Timber: Only Alternative B allocates area to timber management. None of the alternatives will significantly affect the existing timber resources, as no harvest activity is planned.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development.

Cultural: None of the alternatives will have a significant adverse impact on the cultural resources of the area, due to no development activities planned.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

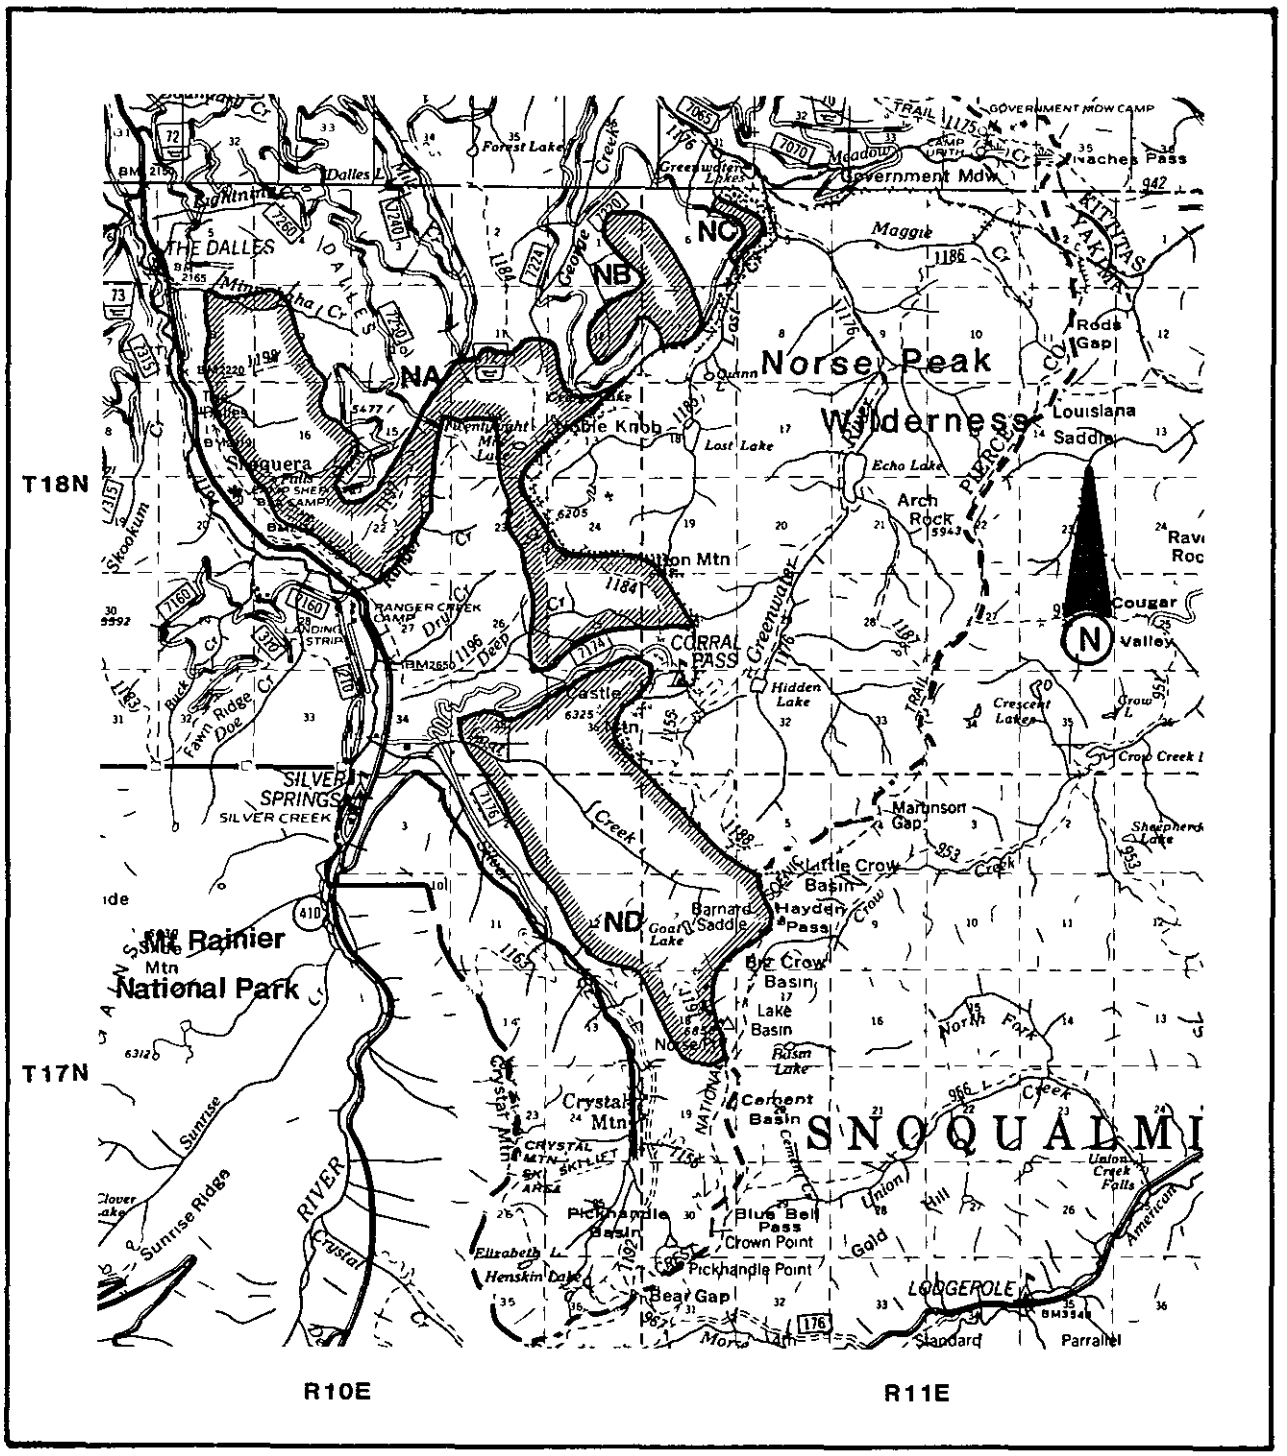
Wilderness Potential: All alternatives assign the majority of this area to management prescriptions compatible with preserving its roadless character. Alternative I allocates about one-third of the area to semi-primitive motorized recreation. All alternatives will maintain the area in a roadless condition through the end of the fifth decade. The wilderness potential will be maintained.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

Alternative	Undeveloped Acres			Percent
	Decade 1	Decade 2	Decade 5	Remaining
A (No Act)	1,055	1,055	1,055	100%
B (RPA)	1,055	1,055	1,055	100%
C	1,055	1,055	1,055	100%
G-Mod.	1,055	1,055	1,055	100%
H	1,055	1,055	1,055	100%
I	1,055	1,055	1,055	100%
J (Pref)	1,055	1,055	1,055	100%

Norse Peak

Roadless Area 6034



NORSE PEAK **Roadless Area 6034 (NC, NB, NA, ND)**

This roadless area originally consisted of 28,200 acres. It was inventoried for study as potential wilderness during the *RARE II* process. The *RARE II* decision assigned area 6034 to nonwilderness uses. In 1984, 15,713 acres from this area were designated the Norse Peak Wilderness by Congress as a result of the Washington Wilderness Legislation. Four parcels remain roadless.

Three timber sales have been sold under contract within this roadless area. The One Mile Salvage, The High Minnie and the Dry Ranger Timber Sales have removed 2,639 acres from roadless status. The area was reduced by 245 acres due to a mapping discrepancy. The following shows the disposition of acres within the roadless area:

Norse Peak	**Net Acres**
1984 RARE II	28,200
updated 1988	10,093
Change	**-18,107**

OVERVIEW

These parcels are directly east of Highway 410, and Crystal Mountain Highway #33. The eastern boundary is adjacent to the Norse Peak Wilderness. A small portion of the Pacific Crest National Trail is astride the southeastern boundary. Access is via the Corral Pass, 28 Mile Creek, George Creek, and Echo Lake road systems.

Rock types are andesite flows and andesite breccias with pyroclastic material. The andesite rocks are hard, moderately to highly fractured, and are competent. The volcanic sediments and pyroclastic materials are moderately hard to soft, highly fractured, and are moderately competent to incompetent. Soils are shallow to moderately deep, non-plastic, silty sands and silty gravels. Soils derived from the pyroclastic material are moderately deep to deep, slightly plastic, sandy silts and sandy clays.

Topography is varied, but is generally steep, dissected mountain sideslopes. Drainages include Goat Creek, Deep Creek, Dry Creek, Ranger Creek, Minniehaha Creek, plus several small unnamed tributaries. The portion on the eastern edge around Noble Knob and Mutton Mtn. through Corral Pass south is open meadow ridgetop. Elevations range from 2,300 to over 6,000 feet. Snoquera Creek Falls accents a large rock fence and is a notable feature.

Vegetation ranges from old growth trees on the lower two thirds of the slopes to bear grass meadows along the higher ridges. Pacific silver fir dominates the north slopes with western hemlock at lower elevations and subalpine fir at upper elevations. There is extensive evidence of large fires around 1890 - 1900, which created the subalpine fir - alpine parklands ecosystem. No threatened or endangered plants identified.

Current uses are varied. Activities range from sightseeing from roads to hiking the Pacific Crest National Trail. Corral Pass campground gets heavy day use along with the trails that lead from there to Castle Mountain and the Noble Knob Lookout site. The Mather Memorial Parkway skirts this area on the western edge. The ROS classifications are roaded natural, roaded modified, semi-primitive motorized and semi-primitive non-motorized.

Norse Peak Wilderness is adjacent to the east. The surrounding National Forest land is managed as multiple use.

Major attractions are Snoquera Falls, Castle Mountain, and the campground at Corral Pass. The Pacific Crest National Trail crosses a small portion of the southern boundary.

WILDERNESS CAPABILITY

Manageability and Boundaries: The NA and ND parcels are large enough to be managed for dispersed and primitive forms of recreation. The natural character can be maintained.

Natural Integrity and Appearance: Long-term ecological integrity can be assured with human influences minimal.

Opportunities For Solitude: Potential for solitude is low. No site within these parcels is more than one mile from an existing road.

Opportunity For Primitive Recreation: Opportunity is low due to road and trail accessibility.

Challenging Experiences: None.

Special Features: Snoquera Falls and the Castle Mountains area are noteworthy features.

AVAILABILITY FOR WILDERNESS

Availability is covered in two parts: a roadless area summary table and a discussion of various resource potentials.

Availability - Other Resource Potential

Recreation: These parcels have high dispersed recreation use. The trail system and Corral Pass Campground get moderate to heavy use. During hunting season, the general area is heavily impacted.

Fish/Wildlife: These parcels exhibit a high diversity of wildlife. Castle Mountain and environs afford mountain goat habitat, and summer range for blacktail deer and elk. A resident herd of elk summer in the general area. Northern spotted owls have been located and a management area has been established. Pileated woodpecker and pine marten MR habitat is present.

Water: Several summer home sites rely on Minnehaha, Dry, Deep, and Goat Creeks for water. However, these are not permanent water systems. The gradient of these streams is too great to support a resident fish population. There are no power withdrawals.

Livestock Operations: None.

Summary Table - Norse Peak #6034

Category 1/	Unit	Parcels NC	NB	NA	ND	Total
Acres (Minus water, private land)	Acres	84	570	5,089	4,350	10,093

Claims 2/	# of	-	-	-	-	1
Leasable Energy Minerals (Moderate Potential)						
Geothermal	Acres	84	570	5,089	549	6,292

1/ American Indian Religious and Cultural Use areas were analyzed. Site specific information is not disclosed due to its sensitivity.

2/ Number of claims not broken out by parcel.

Ecology: The Pacific silver fir zone is characterized by cool, moist soils, persistent winter snowpacks, and a short growing season. Old growth Douglas-fir is found at the lower elevations. Hemlock and true fir are found at mid-elevations. There are high elevation subalpine fir and alpine meadows. Understory is varied, occurring more frequently on the northern, wetter sites.

Ground cover is sporadic and ranges from small amounts of Oregon grape and salal to moderately heavy huckleberry.

Timber: Forest stand volumes range from 70 to 15 thousand board feet per acre. Fifty-one percent or 4,729 acres is classed tentatively suitable for timber harvest. Stand defect is 30 percent - 35 percent.

Minerals/Oil and Gas: This area is underlain primarily by Tertiary aged volcanics. The southern portion of the area lies in the Silver Creek Mining District, and it is reported to have occurrences of lead, zinc, silver, gold and copper. However, it only has one recorded mining claim. The area is classified "prospectively valuable" for geothermal. It has not been studied in detail by the U.S. Geological Survey and Bureau of Mines, but based upon available data it appears the area has a moderate potential for the occurrence of mineral resources.

Cultural: The potential for cultural resources is low due to steep topography.

Land Use Authorizations: None.

Non-Federal Land: None.

Fire: Fire occurrence is moderate. Lightning fires occur every 4 to 5 years and human-caused fires occur frequently.

Insect and Disease: None.

WILDERNESS EVALUATION

Proximity to Other Designated Wilderness and to Population Centers: These parcels are adjacent to the Norse Peak Wilderness. Mt. Rainier National Park is 4 miles away. Seattle and Tacoma are within 50-70 miles.

Public Interest: Following release of the DEIS and Proposed Forest Plan, the Norse Peak Roadless Area received no public comment. However, areas adjacent to Norse Peak Wilderness and geographic features within the Norse Peak Roadless Area did receive comment.

Areas adjacent to Norse Peak were mentioned 210 times. Responses favored keeping the area roadless (56), protecting it from harvest (50), preserving the forest ecosystem (32), and protecting old growth (10). Most of the remaining comments said to protect the area for recreation, wildlife habitat and visual quality. Two comments expressed the desire to make this area a top priority for timber harvest. One comment said to build more roads. One comment wanted the area added to the National Park System. 1/

ENVIRONMENTAL CONSEQUENCES

The table below displays how each roadless parcel is assigned in the alternatives considered. An assignment represents the long-term management.

PARCEL NA

Significant Effects

Recreation: Current recreation opportunities will not be significantly affected by any of the alternatives. Alternative C will leave the largest amount of area (90%) of this parcel unroaded through the end of the fifth decade. Alternative I allocates about 18% of this area to semi-primitive motorized recreation.

Fish/Wildlife: Fish and wildlife will not be significantly affected by any of the alternatives. Alternatives A, NC, B, C, H and I allocate the greatest amount of area to old growth habitat, mature old growth, deer and elk enhancement and mountain goat management requirement prescriptions. Alternatives G-Modified and J (Preferred) allocate the least.

Water: There will be no adverse effects to the water resource of this area associated with implementation of any of the alternatives, due to the low level of development planned.

Ecology: The overall ecology of the area will not be significantly affected by any of the alternatives, due to the low level of potential development activity.

Timber: Alternatives B and I allocate the greatest amount of acres to timber management. Alternatives C, G-Modified and J (Preferred) allocate the least.

None of the alternatives will significantly affect the timber resource, as potential harvest activity will be low.

Minerals/Oil/Gas: None of the alternatives will have a significant affect on the availability of minerals, oil or gas for development. Alternatives B, H and I would provide a slightly greater amount of roaded access through the area that could be used for mineral exploration and development.

Cultural: None of the alternatives will have a significant adverse impact on cultural resources in the area. Alternatives B, H and I will have the greatest potential for impact, as they propose the greatest amount of development activity. Alternative C will have the least potential for impact.

Land Use Authorizations: None of the alternatives will significantly affect special land use authorizations.

Fire: None of the alternatives will significantly affect the occurrence of fire within the area.

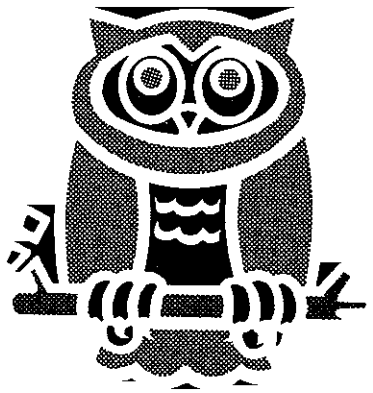
Insect and Disease: None of the alternatives will significantly affect the occurrence of insects and disease within the area.

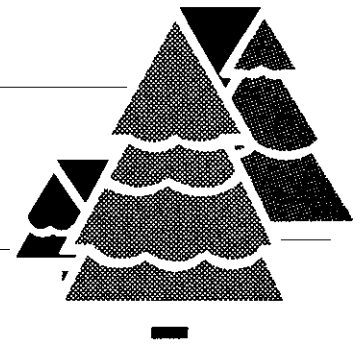
Wilderness Potential: Alternatives C, G-Modified, and J (Preferred) assign the majority of this area to management prescriptions compatible with preserving its roadless character. The wilderness potential in the above alternatives will be maintained. Alternative I assigns approximately 18% of the area to semi-primitive motorized recreation and maintains 60% of the area in a roadless condition through the end of the fifth decade. Alternatives A, B, and H maintain approximately two-thirds of the area in a roadless condition through the end of the fifth decade.

The following table provides an estimate of acres remaining unroaded at the end of specific decades by alternative.

	Undeveloped Acres			Percent
Alternative	**Decade 1**	**Decade 2**	**Decade 5**	**Remaining**
A (No Act)	8,068	7,024	7,047	70%
B (RPA)	7,942	6,798	5,805	58%
C	9,652	9,444	9,111	90%
G-Mod.	8,974	8,246	7,966	79%
H	8,479	7,361	6,472	64%
I	7,921	7,063	6,027	60%
J (Pref).	9,169	8,519	7,899	78%

Appendix D





APPENDIX D

STANDARDS AND GUIDELINES THAT DIFFER FROM THE FOREST PLAN

Standards and guidelines state the bounds or constraints within which all practices will be carried out in achieving the resource objectives of the alternatives The management of the Mt. Baker-Snoqualmie is subject to all applicable laws and regulations Standards and guidelines are intended to help the manager achieve the goals and objectives, while staying within constraints prescribed by law.

Some of the management activities on the Forest would cause significant environmental damage if they were practiced without a means of mitigating that potential harm Many potential, adverse effects can be anticipated. Measures can be designed and prescribed, in advance, to mitigate that damage. These mitigation measures consist of a broad scope of actions that avoid, minimize, rectify, reduce, or compensate for environmental impacts. The standards and guidelines provide those means of mitigating adverse environmental impacts.

There are two categories of standards and guidelines: Forest-wide, applying to all management areas; and standards and guidelines specific to individual management areas.

Development of Standards and Guidelines

The Forest-wide standards and guidelines and management prescriptions were developed according to Regional Direction, for the purpose of: 1) identifying anticipated potential direction for activities on the MBS, and 2) assist in directing formulation of the Forest's planning model and alternatives. Both Forest-wide and management area standards and guidelines were developed by the Forest Management Team, and Forest Plan Interdisciplinary Team.

Forest-wide standards and guidelines are applicable to all areas of the Forest unless specifically stated in the management prescriptions. Forest-wide standards and guidelines contain two parts: Management Requirements (MR's) and other important direction. The management prescriptions apply to specifically identified land areas.

Both the Forest-wide standards and guidelines and the management prescriptions contain a goal statement, reflecting the expected results for a forest resource, activity, or land area. They provide direction emphasis for the Mt. Baker-Snoqualmie, supplementing Forest Service manuals, handbooks, and the Regional Guide. Both respond to Forest ICO's, appropriate laws, regulations and existing direction, land capabilities, and professional judgement.

Standards and Guidelines for the Preferred Alternative

The standards and guidelines for the preferred alternative are found in Chapter 4 of the Forest Plan, accompanying this final EIS. Most of these standards and guidelines apply to all other Forest Plan alternatives with two exceptions: there are two MA prescriptions that only apply to Alternative A. Secondly, the Alternative NC (No change) would not adopt the Standards and Guidelines of the Forest Plan, as it is designed to represent the existing timber management plan and consequently, does not comply with all provisions of NFMA and its implementing regulations.

Standards and Guidelines Not Used in the Preferred Alternative

Several standards and guidelines were developed that were not used or were not appropriate in the Preferred Alternative. These standards and guidelines provide an opportunity for the public and the Forest Service to analyze other options for managing the Forest. The standards and guidelines described here are those which differ from, or are in addition to, those for the Preferred Alternative (Alternative J).

Below is a table of contents for the rest of this appendix. On the following page, Table D-1 shows the management prescriptions and intensities that apply in each alternative Refer to the management area acres table, Chapter II, FEIS for the acres allocated to each prescription/intensity, by alternative.

1 DISPERSED RECREATION

INTENSITY 1E: GENERAL DISPERSED RECREATION Goal Manage the Alpine Resource Zone and some of the Upper Forest Resource Zone in accordance with Ranger District Multiple Use Plans.

Description of the Lands Where Prescription Applicable: Alpine Resource Zones and some of the Upper Resource Zone as delineated on Ranger District Multiple Use Plan maps. Acres are designated to this management prescription only in Alternative A, Current Direction "No Action"

Desired Future Condition Setting varies from primitive to roaded natural with a wide range of dispersed recreation Roadless, dispersed recreation is the dominant use, but some roaded dispersed recreation use, including ORV's, may occur.

Management Practices, Standards and Guidelines: Overall management direction for these areas *is to protect the scenic, soil, watershed, and recreation values* In the Upper Forest Resource Zone, management for resource development may require modification to protect scenic, soil, and watershed values. In most of these areas, removal of trees will be done only for recreational development, public safety to control insect or disease epidemics, or salvage catastrophic forest losses

Timber utilization will be permitted in tentatively suitable lands where overall management direction can be met; however no scheduled timber harvest is planned. Any timber volume removed will be nonchargeable

Road construction is permitted provided overall management objectives are met. The area may be traversed by a number of roads to access developed areas in other management areas. Roads should be temporary except those needed for timber harvest or to access other management areas

---

INTENSITY 1F 1926 MT. BAKER RECREATION AREA Goal. Manage the Mt. Baker Recreation Area in accordance with the Secretary of Agriculture's 1926 designation order

Description of Lands Where Prescriptions Applicable: This area includes the remaining parcels of the Mt Baker Recreation Area, totaling approximately 6,005 acres. In 1926, the Secretary of Agriculture designated 74,859 acres as the Mt. Baker Recreation Area. The Washington State Wilderness Act of 1984 changed the designation of most of the Mt. Baker Recreation Area to the Mt. Baker Wilderness or the Mt Baker National Recreation Area. The Mt. Baker Ski Area is included in the Management Area 3C.

Acres are designated to this management prescription only in Alternative A (Current Direction, No Action).

Desired Future Condition: To be used and enjoyed by the general public for recreation purposes.

Management Practices, Standards and Guidelines: Overall management direction for this area emphasizes recreation for the use and enjoyment of the general public. Proper and orderly utilization of timber, forage, water power, and other economic resources is allowed; but such utilization shall not be permitted to impair the value of the area as a site for public camp grounds, municipal or health camps, sanitaria, club houses, hotels, summer homes, or public utilities requisite for the comfort and convenience of the people using the area for recreational purposes

B

Appendix D

In the sixty years since establishment, silvicultural practices have occurred on approximately 570 acres, less than 1% of the total area designated. Timber utilization is permitted, however, no scheduled timber harvest is planned Timber volume removed is nonchargeable

---

3 DEVELOPED RECREATION

Goal: Provide a wide variety of year-round recreation experiences and facilities at developed sites

Description of Lands Where Prescription Applicable: Developed recreation sites are usually located close to water bodies, or other areas of scenic or special interest Developed recreation sites include existing and potential campgrounds major trailheads, boating and swimming sites, picnic areas, alpine ski areas, and associated facilities, organization camps, recreation residences, and others Facilities will be provided at mostly recreation development scale 2 (semi-primitive) with little site modification, to scale 4 (rural) with the site heavily modified The areas allocated to developed recreation include the specific site on which existing or potential development takes place and a surrounding visual and noise screen Soils and vegetation should be able to absorb heavy use Except for winter recreation areas, developed recreation sites are usually located on land with slopes of 10 percent or less.

Desired Future Condition: Common to all Intensities

Developed recreation sites may appear mostly natural to rural in setting. Physical facilities may be evident; design and construction will repeat the color, shapes, and lines of the surrounding environment. Site controls and user interaction will vary with the setting There is no scheduled timber harvest and any vegetative management is done for the purposes of maintaining a safe, functional, and attractive site Openings exist to accommodate facilities and provide scenic views. Vegetation will vary widely in type, size, and age. Access is by road

Intensities in this Management Prescription·

3B POTENTIAL RECREATION SITES

This management intensity is applied to areas of the Forest that are suitable for a variety of developed recreation facilities Under this intensity selected areas will be reserved for future study and development

The type of facilities to be developed is dependent on user demand patterns and specific site suitability Sites to be developed will complement the existing areas as developed facilities and expand the Forest's capacity to accommodate additional use

Program Element		Standards and Guidelines
A Recreation		
1. Recreation Facility Planning	a	Potential sites will be developed when needed and programmed, that are appropriate to the forest environment, and will be maintained to provide only facilities for forest-type recreation such as camping, picnicking, hiking, canoeing, etc
	b	Sites shall be designed to ensure that the People At One Time (PAOT) capacity of the site is in proper relationship to the desired ROS class and the ability of the site to withstand use.

		c	Overcrowding and loss of privacy shall be prevented by strategically locating improvements, limiting their number, or designing facilities so as to limit the number of persons who can physically use or occupy them at one time.
		d.	A comprehensive and detailed site plan including needed roads to serve the site shall be developed prior to site construction in accord with requirements specified in FSM 2330.
		e.	Constructed structures should be architecturally compatible with the established landscape
		f.	Vegetative management plans are required prior to manipulation of vegetation
		g.	The area should be administered to protect its value for future development and use as a recreation site
	2. Visual Quality	a	Visual Quality Objective will range from preservation to partial retention.
	3. American Indian Religious and Cultural Use	a	Meet Forest-wide Standards and Guidelines
	4. Trail Planning	a	Trails are permitted.
		b	Maintain existing trails to a Level III Standard, within the developed site, providing resource protection, and visitor convenience
B.	Wilderness	a.	Not applicable
C	Wildlife and Fish		
	1. Habitat Improvement	a	Improvement of wildlife and fisheries habitat may be permitted as long as it is compatible with the potential future recreation use.
D.	Range	a	Not applicable.
E.	Timber		
	1. Timber Management Planning	a.	Timber shall be managed on a non-scheduled basis.
		b.	Logging practices shall be selected that protect the area in a manner consistent with the intended recreation use.
		c	Vegetative management prescriptions should be prepared to manage desired vegetation conditions for each site.

F	Water, Soil, and Air		
	1 Planning and Improvement	a.	Improvements are appropriate as long as visitor conflicts with future recreation development and use are minimized
G	Minerals and Geology	a.	Inventory and/or validate existing mining claims and initiate title clearance on sites planned for development.
		b	Removal of common variety minerals should not be permitted.
		c.	Recommend denial for application for leasable minerals
		d.	Sites not previously withdrawn shall be recommended for withdrawal from mineral entry.
		e.	Developed sites shall be protected by standard and special stipulations in any leasing actions.
		f	No on-site occupancy
		g.	Applications will include stipulations to protect existing and/or future uses Denial may also be recommended on a case-by-case basis
H	Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines
J	Lands		
	1 Special Use Management	a	Special uses compatible with future recreation development and use should be permitted.
	2 Land Ownership Planning	a	Place all these lands in Group II Retain or acquire when possible.
L	Facilities		
	1 Transportation System Planning	a	Provide and manage roads that are compatible with intended future recreation use
P	Protection		
	1 Fire Management Planning	a	Forest-wide Fire Protection Group C applies.
	2 Forest Pest Management	a.	Meet Forest-wide Standards and Guidelines

---

8 OTHER SPECIAL AREAS

Goal To protect and, to the extent possible, foster public use and enjoyment of areas with unique recreation, cultural, historic, or scientific values

Description of Lands Where Prescription Applicable: Areas that because of their unique cultural-historical, geological, botanical or biological features have been identified for special recognition and management.

Desired Future Condition The attributes which caused these areas to be recognized and classified are preserved and maintained for public study, use, or enjoyment.

Intensities in this Management Prescription: 8D Other Special Areas

Program Element	Standards and Guidelines
A. Recreation	
1. Recreation Planning	a. ORV use shall be restricted to designated route or within areas where use is compatible with Special Area purpose.
	b. Site development should generally be restricted and located outside of area to protect special features
	c Facilities may be provided for visitor use, environmental interpretation, safety of visitors, or to protect or enhance area values.
	d. ROS class may vary from semi-primitive to roaded natural
2. Visual Quality	a. Visual Quality Objectives are retention to preservation
3. American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines
	b. Visitor use and activities shall be managed to prevent degradation of Special Interest Areas
4. Trail Planning	a. Manage to prevent resource degradation and provide for public safety.
	b Minimize affects to biological community
B. Wilderness	a. Not applicable
C. Wildlife and Fish	a. Emphasis should be given to the maintenance and improvement of habitat for observable wildlife species
D. Range	a. Not appliable.
E. Timber	
1. Timber Management Planning	a. No scheduled timber harvest. Incidental timber harvest in response to implementation of vegetation management plans or to protect property and life, health and safety of area users is permitted
	b. Prepare vegetation management prescriptions to establish the short and long-term treatments necessary to maintain or enhance the unique or desired vegetation characteristics of areas.
F. Water, Soil, and Air	a. Meet Forest-wide Standards and Guidelines
G. Minerals & Geology	a Conduct mineral studies in conjunction with the mineral withdrawal process Areas should

			be withdrawn from mineral entry to ensure maintenance of area values.
		b	Common variety minerals should not be removed.
		c.	Conduct geologic mapping and studies to enhance interpretation of special geologic areas or features to the recreating public
		d.	In areas not otherwise withdrawn from entry protect or mitigate the unique or special features of areas by the development and enforcement of special lease or permit stipulations and requirements
H.	Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines
J	Lands		
	1 Special Use Management	a	Avoid locating transportation and utility corridors in these areas
		b	Special Use Permit are acceptable provided that values are protected and that permitted use support the goals and objectives established for individual areas
	2. Land Ownership Planning	a	Group II - retain or acquire when possible
L	Facilities		
	1 Transportation System Planning	a	Roads, trails, and other facilities may be developed and maintained to meet the objectives of Special Areas
P.	Protection		
	1 Fire Management Planning	a.	Forest-wide Fire Protection Group C applies
	2. Forest Pest Management	a	Only suppression work using biological, chemical or silvicultural methods consistent with management goals for the area

---

13 WATERSHED, WILDLIFE, and FISHERIES EMPHASIS IN RIPARIAN AREAS

Goal: To maintain or improve water quality and to produce various levels of potential habitat capability for various species of fish within designated riparian areas Also maintain or enhance habitat for riparian associated wildlife species

Descriptions of Lands Where Prescription Applicable This prescription is applicable to those lands adjacent to perennial and intermittent streams - Class I, II, and deeply incised Class III streams - lakes, wetlands, ponds, seeps, floodplains, and it includes the aquatic and the riparian ecosystems These lands also support a diversity of plant species, being dominated by species preferring or tolerating wet or moist site conditions.

Riparian areas contain a variety of resource values (water quality, fish and wildlife habitat, and soil productivity) This strategy is designed to maintain and/or improve these resource

values, with special emphasis on water quality and fish habitat. Actual area and boundaries of these riparian areas will be determined at the project level of planning.

Desired Future Condition: Meet or exceed State/Federal water quality standards. Maintain current (existing) levels of habitat capability of all fish species. In some areas, increase habitat capability for targeted fish species (habitat restoration or enhancement). Maintain, and in some cases, improve riparian vegetation diversity. Maintain, and in some areas improve, existing levels of habitat capability of all riparian dependent wildlife species through restoration and/or enhancement. A variety of plant and animal species are present, hardwood tree species are more common here than elsewhere A variety of dead trees, standing and downed, are common. Created openings are small and widely distributed The riparian area will include mature trees that may be managed on a normal rotation, as well as larger older trees to be managed on an extended rotation (160 + years). Some trees are not planned to be harvested, as they are needed for slope stability or large wood debris

Intensities in this Management Prescription:

13A Management Requirements
13C Level III Anadromous, Existing Resident Fish Habitat Capability

---

INTENSITY 13A: MANAGEMENT REQUIREMENT

Program Element		Standards and Guidelines	
A	Recreation		
	1 Recreation Planning	a	A broad range of developed recreation can be permitted, however, any planned development will be designed to minimize impact in riparian values
		b	ROS settings can range from primitive to roaded natural
	2. Recreation Use	a.	Ground or water channel disturbing activities will be minimized
	3. Visual Quality	a.	Visual Quality Objectives of retention to modification consistent with adjacent management areas
	4. American Indian Religious and Cultural Use	a.	Meet Forest-wide Standards and Guidelines.
	5 Trail Planning	a.	Trail construction and reconstruction, and maintenance are permitted
		b	Existing ORV use permitted on roads or trails designed for that use
		c	New ORV trail construction/reconstruction permitted, minimize impact to riparian values
B	Wilderness	a	Not appliable.

C. Wildlife and Fish

1. Planning

a. Habitat for primary cavity excavators will be managed to 80% of potential population levels.

b. If water temperature is an issue, created openings adjacent to a stream may be permitted, provided that 80% of the entire stream surface shading requirement is met. The length of stream is that included within the planning areas.

c. Trees of all age classes will be left adjacent to and leaning over perennial streams if they are needed for shading, slope, and bank protection, or future large organic debris recruitment.

d. Wetlands including bogs, seeps, and ponds, will be protected.

2. Habitat Improvement

a. Fish and wildlife habitat improvement and structures are permitted for mitigation. Maintain fish habitat capability (anadromous and resident) at present levels (Level I) by maintenance of existing spawning and rearing habitat. Maintain terrestrial wildlife habitat diversity.

D. Range

a. Not applicable.

E. Timber

1. Timber Management Planning

a. Silvicultural practices will be applied for the purpose of maintaining riparian habitat diversity and integrity. Timber Management Intensity (extended rotation) best meets the riparian values of Class I, II, and deeply incised Class III aquatic systems. Other timber management intensities A-G which meet the riparian values of Class I, II, and deeply incised III aquatic systems may also be considered.

2. Timber Sale Preparation

a. Yarding and skidding that maintains soil disturbance and vegetation standards are acceptable (see F1).

b. No more than 10% of the area may be compacted. A compacted area exists when there is an increase in soil bulk density of 15% or more over the undisturbed level, a macropore space reduction of 50% or more, and/or a reduction below the 15% level as measured by an air permeameter.

F. Water, Soil, and Air

1. Improvements

a. Improvement and maintenance activities are permitted. Use vegetative restoration methods to restore live root mat and reduce risk of slope failure when practical.

b. Flood damage restoration projects are permitted.

2. Soil Resource Monitoring	a.	Ground disturbing activities will result in no more than 10% mineral soil exposed within a project area after the first year
	b.	Small woody and herbaceous vegetation disturbance limited to 25% within the project area after the first year.
G. Minerals and Geology	a.	Extraction of common variety minerals may be conducted provided riparian values can be protected.
H. Rural, Community, Human Resources	a.	Meet Forest-wide Standards and Guidelines.
J. Lands		
1. Special Use Management	a.	Activity to be analyzed through NEPA process to determine its effect on riparian habitat. Only permitted if riparian habitat diversity and integrity is maintained.
2. Rights-of-Way Grants	a.	Meet Forest-wide Standards and Guidelines.
3. FERC License and Permits	a.	See a above. Also assure consideration and establishment of minimum flows.
4. Land Ownership Planning	a.	Lands critical to riparian management should be placed in a Group III classification. Federal and non-federal lands shall contain equal amounts of riparian habitat.
L. Facilities		
1. Transportation System Planning	a.	Locating roads in a riparian area can only be done if riparian values are protected.
2. Road Construction, Reconstruction and Operation	a.	Only those construction and reconstruction practices that protect riparian values will be allowed. Water quality and/or fish habitat problems caused by construction should be given a high priority for corrective action.
	b.	Road cut and fill slopes within riparian areas shall be protected with erosion and/or sediment control. Final stabilization practices shall include vegetation as well as structural
	c.	Road construction and design should stress maintenance of slope hydrology when routing surface water
	d.	All roads not receiving annual maintenance will have measures to control road surface and ditch water.
	e.	Temporary structures installed to impound water for road maintenance will be removed upon completion of use.

P. Protection		
1. Fire Management Planning	a.	Forest-wide Fire Protection Group D applies.
2. Forest Pest Management	a.	Integrated pest management is permitted following Forest-wide Standards and Guidelines except where use of pesticides conflicts with riparian values.

INTENSITY 13C: LEVEL III ANADROMOUS, EXISTING RESIDENT FISH HABITAT CAPABILITY

Program Element		Standards and Guidelines
A. Recreation		
1. Recreation Planning	a.	When planning any new development and a conflict exists, that conflict will be resolved in favor of the dependent riparian resources and values (soil, water, fish, and wildlife.)
	b.	ROS settings can range from primitive to roaded natural.
2. Recreation Use	a.	No ground or water channel disturbance from any ORV use.
3. Visual Quality	a.	Visual Quality Objectives of retention to modification consistent with adjacent management areas.
4. American Indian Religious and Cultural Use	a.	Meet Forest-wide Standards and Guidelines.
5. Trail Planning	a.	Nonmotorized trail facilities are permitted. Existing ORV use will be permitted on roads or trails designated for that use.
	b.	New ORV trail construction/reconstruction activities will be permitted in designated riparian areas only when stated riparian objectives can be accomplished. If ORV activities are allowed, they should be restricted to timing and/or access due to anadromous fish migration and/or spawning.
B. Wilderness	a.	Not applicable.
C. Wildlife and Fish		
1. Planning	a.	Emphasize maintenance and/or improvement of water quality; e.g. reduce turbidity, and bedload movement.
	b.	Retain instream woody material plus standing (live and dead) adjacent to the stream, needed for future debris recruitment plus bank and channel stability.
	c.	Maintain streamside vegetation so that at least 80% of the fish habitat stream surface has shade

during the summer low flows Maintain or restore 75% of other small woody and herbaceous vegetation.

d. Primary excavator habitat will be managed to 80% of potential population levels. All large dead and down logs will be left except for logs to be used as instream structures

e. For T & E species, follow Forest-wide Standards and Guidelines and Management Prescription 16 Standards and Guidelines. Manage wetlands to protect all bogs, swamps, and beaver ponds.

f. Consult with local state biologists to assure fish management objectives are compatible with state management objectives.

2. Habitat Improvement

a Emphasize improving and/or enhancing existing fish habitat for anadromous fish species Enhance existing or restored spawning and/or rearing habitat. This would include enhancing off-channel or terraced tributary juvenile rearing habitat. Habitat enhancement would include structural and non-structural activities Structural activities includes log weirs, gabions, deflectors, and digger logs, rock and boulder emplacement, and groins Non-structural activities include off-channel rearing pond construction, bank or channel stabilization and spawning area improvement Maintain the resident fish habitat capability at the current or existing production level

b Emphasize measures to improve wildlife habitat diversity and integrity

c Stocking of anadromous fish (adults or juveniles) permitted to help meet production level III requirements. Must be part of the overall restoration plan Maintain resident fish stocking program

D. Range

a. Not applicable.

E. Timber

1. Timber Management Planning

a A range of silvicultural treatments will be permitted only when riparian objectives can be accomplished Timber management intensity H extended rotation best meets the riparian values of Class I, II, and deeply incised Class III aquatic systems Other timber management intensities (A-G) which meet the riparian values of Class I, II, and deeply incised III aquatic systems may also be considered.

	2. Timber Sale Preparation	a. Yarding and skidding that maintains soil disturbance and vegetation standards are acceptable (see F2).
		b. Less than 10% of the area should be damaged. A damaged area exists when there is an increase in soil bulk density of 15% or more over the undisturbed level, a macropore space reduction of 50% or more, and/or a reduction below the 15% level as measured by an air permeameter.
F.	Water, Soil, and Air	
	1. Improvements	a. Watershed improvements and maintenance are permitted. Use vegetative restoration methods to restore live root mat and reduce risk of slope failure along stream channels as well as upper slope areas outside the riparian area.
	2. Soil Resource Monitoring	a. Ground disturbing activities will result in no more than 10% mineral soil exposed within a project area. Disturbance should be widely distributed over the area.
		b. Small woody and herbaceous vegetation disturbance limited to 25% and widely distributed over the project area.
G.	Minerals and Geology	a. Extraction of common variety minerals may be conducted provided riparian values can be protected.
H.	Rural Community and Human Resources	a. Encourage use of various human resource programs to be used in accomplishing pre-selected water quality or fish habitat restoration/rehabilitation projects.
J.	Lands	
	1. Special Use Management	a. Activity to be analyzed through NEPA process to determine its effect on riparian habitat. Only permitted if riparian habitat diversity and integrity is maintained.
	2. Rights-of-Way Grants	a. Meet Forest-wide Standards and Guidelines.
	3. FERC License and Permits	a. Assure consideration and establishment of minimum flows.
	4. Land Ownership Planning	a. Lands critical to riparian management should be placed in a Group III classification. Federal and non-federal lands shall contain equal amounts of mature riparian habitat.
L.	Facilities	
	1. Transportation System Planning	a. Roads should avoid riparian areas when possible. Locating roads in a riparian area can only be done if riparian values are protected.

		b Necessary crossings should use methods that minimize adverse impacts to water and fisheries resources.
	2. Road Construction, Reconstruction and Operation	a. Road construction/reconstruction activities will be permitted in designated riparian areas only when stated riparian area objectives can be accomplished. Such activities may be restricted to timing and/or access due to anadromous fish migration and/or spawning
		b Slopes adjacent to or within riparian areas will be protected with erosion and/or sediment control. Before the first wet season, vegetation or slope protection will be completed. Prior to the end of the normal operating season, final stabilization practices should include vegetation as well as structural.
		c Water quality and/or anadromous fisheries habitat problems caused by road construction/ reconstruction will be fully mitigated in kind, on site
		d All roads not receiving annual maintenance will have measures to control road surface and ditch water.
P	Protection	
	1. Fire Management Planning	a. Forest-wide Fire Protection Group D applies
	2 Forest Pest Management	a. Integrated pest management is permitted except where use of pesticides conflicts with riparian values.

---

15 *MOUNTAIN GOAT HABITAT*

Goal *Protect and manage habitat to maintain or increase mountain goat populations.*

Description of Lands Where Prescription Applicable: This prescription is applied to selected acres of current and historical mountain goat habitat. These areas characteristically contain diverse vegetation including mature and old growth stands, steep rocky cliffs, projecting pinnacles, ledges, and talus slides. Winter range is generally at lower elevations (tree-line and below) than summer habitat.

Desired Future Condition: Current and historically used mountain goat range is in the process of being identified and verified The winter range is maintained as a natural environment with little evidence of human activity

No new roads will be constructed to access winter range; existing roads and trails that would permit human encroachment and subsequent harassment to mountain goats on the winter or summer range will have use restricted No scheduled timber harvest. If timber management activities are conducted, practices shall be for purpose of maintaining mountain goat habitat

Intensities in this Management Prescription: 15B Emphasis on Habitat Improvement, Mtn Goat

INTENSITY 15B: EMPHASIS ON HABITAT IMPROVEMENT, MOUNTAIN GOAT

Program Element		Standards and Guidelines
A. Recreation		
	1. Recreation Planning	a. New trail and campsite construction shall not be located within 1,500 feet of key habitat features.
	2. Visual Quality	a. Visual Quality Objectives consistent with adjacent management areas.
	3. American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines.
	4. Use Administration	a. Roads that directly access spring, summer, and winter range shall have use restrictions where harassment to mountain goat has been identified. Consider road closures, primarily in spring transition range during the period May 15 - June 15.
		b. Existing trail and campsite use that is identified adversely effecting mountain goats shall be located 1,500 feet from the particular key habitat feature.
B. Wilderness		a. Not applicable.
C. Wildlife & Fish		
	1. Planning	a. Cooperate with the Washington Department of Wildlife in mountain goat census and refinement of winter range boundaries.
		b. Continue surveys and inventory of known and suspected mountain goat winter range to document critical habitat for protection.
		c. Monitor habitat components to insure planning objectives are being met.
		d. Reintroductions and transplant proposals will be evaluated to determine feasibility.
D. Range		a. Not applicable.
E. Timber		
	1. Timber Management Planning	a. No harvest scheduled. If timber management activities are conducted, practices applied shall be for the primary purpose of maintaining mountain goat winter habitat.
		b. A maximum of 5% of suitable lands within this prescription may be regeneration harvested per decade.

		c.	Generally, harvesting practices shall be applied for the purpose of maintaining or improving mountain goat habitat diversity.
	2. Reforestation and Timber Stand Improvement	a.	Reforestation and TSI plans should be designed for improving forage.
	3. Timber Sale Preparation and Harvest Administration	a	Small, long, and narrow units will be encouraged, maximum width shall be 400 feet but shall not increase avalanche frequency.
		b.	Harvest activities shall take place so as to avoid conflict with mountain goat.
		c.	Tree cover immediately adjacent to avalanche chutes shall be considered as very critical to optimum thermal cover needs and be maintained
F.	Water, Soil, and Air	a	Meet Forest-wide Standards and Guidelines.
G	Minerals and Geology	a	Mineral exploration and extraction, including common variety minerals will include requirements and mitigation measures needed to protect habitat and winter range objectives.
H.	Rural Community and Human Resources	a	Meet Forest-wide Standards and Guidelines.
J.	Land		
	1 FERC Licenses and Permits	a	Construction, maintenance, and operation is if mountain goat is minimally altered and any adverse effect can be mitigated.
	2 Land Ownership Planning	a	Identified critical habitat within forest boundary will be placed in Ownership Group III, available for exchange.
L.	Facilities		
	1. Transportation System Planning	a	Location of new roads shall not adversely impact mountain goat habitat
		b.	Existing open-road density in spring and summer range should average 2 miles per square mile of contiguous habitat
	2. Road Construction and Reconstruction	a.	Construction and reconstruction activities shall be timed to avoid conflict with mountain goat habitat use.
P.	Protection		
	1. Fire Management Planning	a	Forest-wide Fire Protection Group E3 applies.
	2. Forest Pest Management	a	Utilize integrated pest management techniques except where use of chemical pesticides conflicts with objectives of managing mountain goat habitat
		b	Use of pesticides that jeopardize desirable forage shall be discouraged.

20 CEDAR RIVER MUNICIPAL WATERSHED (CITY OF SEATTLE)

Goal: Provide raw water at a level of quality and quantity which, with treatment by the purveyor, will result in a satisfactory and safe water supply. Production of timber products is allowed to the extent that the water quality goal is met. There is varying emphasis on other uses.

Description of Lands Where Prescription Applicable: The Watershed is comprised of private, municipal and National Forest lands totaling 90,495 acres in King County. This strategy applies to National Forest lands within the watershed that are not allocated to other management areas. National Forest lands are intermingled with City of Seattle and private lands in a checkerboard ownership pattern in the eastern portion of the watershed.

City of Seattle and private lands within the watershed are closed to the public. National Forest lands are open to public use. However, because the Forest Service does not own public rights on roads off of National Forest lands, the public has no road access to interior National Forest parcels and is restricted to use of National Forest lands that lay along the exterior boundary of the watershed. Some private use of interior National Forest parcels takes place via helicopter.

Timber regeneration harvest, sanitation harvest (salvage), and reforestation are the only significant silvicultural practices performed in the area by the Forest Service.

The final E.I.S. for the Cedar-Tolt Watershed Management Plan of 1979 provides that wildlife populations will fluctuate with available food supplies which in turn are directly affected by timber harvest. Threatened and endangered species are protected by state and Federal laws. Except for occasional small and scattered unsuitable or non-commercial timber stands, no specialized wildlife habitat areas are left for old growth dependent species.

Desired Future Condition: Varies by Intensity.

Intensities in this Management Prescription:

20A Current Direction. Exchange all National Forest lands to the City of Seattle.
20B Exchange National Forest Lands, City of Seattle Maintains Old Growth Habitat.
20C Retain National Forest Lands, Maintain Old Growth Habitat.

Intensity 20A: CURRENT DIRECTION. EXCHANGE ALL NATIONAL FOREST LANDS TO THE CITY OF SEATTLE

Desired Future Condition:

The Forest Service's ultimate objective within the watershed is to exchange National Forest lands therein to the City of Seattle in order to consolidate National Forest holdings elsewhere.

All mature timber on available commercial forest lands, within Management Area 20A, will be sold within about 30 years. Land exchanges will periodically follow the harvest of mature timber, every 5 to 10 years as logical blocks occur. The entire watershed would be owned by the City of Seattle in about 35 years.

Program Elements		Standards and Guidelines	
A.	Recreation		
	1. Visual Quality	a	Visual Quality Objective is maximum modification except for areas seen from the Pacific Crest National Scenic Trail where the standard will be retention foreground.
	2. American Indian Religious and Cultural Use	a	Meet Forest-wide Standards and Guidelines
	3 Facility Construction, Reconstruction, and Management	a.	No existing or planned developed recreation sites.
	4. Use Administration	a.	Dispersed use is permitted unless otherwise restricted.
	5. Trails Planning	a	Use of the Pacific Crest National Scenic Trail (PCNST) in the far eastern part of the watershed will be allowed to continue. No relocation is planned.
		b.	No new trails are planned
B.	Wilderness	a	Not applicable.
C.	Wildlife and Fish		
	1. Planning	a	Wildlife and fish management practices will be provided as described in the 1979 Cedar-Tolt Watershed Management Plan Environmental Impact Statement. Wildlife populations are allowed to fluctuate as a product of available food supply and habitat.
		b	Snags are left in numbers and distribution to meet minimum viable habitat requirements.
		c.	Except for occasional small and scattered unsuitable or non-commercial timber stands, no specialized wildlife habitat areas are left for old-growth dependent species.
		d	Identified nesting sites of any osprey, spotted owl or heron will be protected according to applicable laws and recommended practices contained in the State Forest Practices Act
	2. Threatened and Endangered Species	a.	Meet Forest-wide Standards and Guidelines
D.	Range	a.	Not applicable
E.	Timber		
	1. Timber Management Planning	a.	Timber Management Prescription 17, Intensity A, C, D Program Element E is applicable.
F.	Water, Soil, and Air		

1. Soil Resource Inventory	a.	Continue to update, monitor and record S-8 classified soils. Maintain inventory of areas in the TRI/GIS system.
2. Planning	a.	Use soil information when locating roads and harvest units.
3. Improvement	a.	Emphasize maintenance and improvement of water quality over other resources.
4. Administration/Management	a.	All operations are conducted in compliance with the 1962 Coop Agreement with the City of Seattle which includes prohibition of manufacturing, use of uniform road construction standards, and compliance with sanitary regulations. No overnight camping is allowed (applies only to Industrial Operations). Industrial operations must provide chemical toilets.
	b.	Prescribed slash burning is discouraged to protect residual seedlings, soil, water, and air quality.
	c.	Roads will not be constructed across S-8 classified soils and timber harvest will not be done on S-8 or J-8 lands.
5. Soil Resource Monitoring	a.	Timber harvest activities will result in no more than 10 percent of the project area having mineral soils exposed within the riparian zone or 15 percent outside the riparian zone.
G. Minerals and Geology	a.	National Forest lands were withdrawn from locatable mineral and mineral leasing activities (which includes minerals, oil and gas, and geothermal) by Public Law 97-350, 96 Stat. 1661 dated October 18, 1982. Extraction of common variety rock for road development needs is acceptable where water quality is not degraded.
H. Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines.
J. Lands		
1. Special Use Management	a.	Approval will be recommended for only those special use authorizations compatible with over all management goals and direction for this area.
2. Rights-of-Way Grants	a.	Rights-of-Way and easements will be given or obtained as outlined in the 1962 Cooperative Agreement.
3. Land Ownership Planning	a.	Dispose of National Forest lands and timber toward meeting the municipal ownership goal for this area, following the land adjustment

			objective provided for this area in the 1962 cooperative agreement Accomplish exchange as rapidly as funding and other factors permit National Forest lands within the watershed fall in Group IV, dispose
		b	Retain right-of-way on Pacific Crest National Scenic Trail.
L	Facilities		
	1. Transportation System Planning	a	Road locations are jointly planned and reviewed in accordance with the 1962 Coop Agreement in order to minimize the miles of road constructed.
	2. Road Construction and Reconstruction	a	Road construction standards are used as jointly agreed, in accordance with the 1962 Coop Agreement
	3. Road Operation	a	Road maintenance operations, schedules, and standards are agreed to annually through cooperative meetings between Forest Service, municipal owner, and private owners
		b	The moratorium on herbicide use would continue to be honored.
		c.	Road maintenance is financed through cooperative maintenance agreements under Forest Service timber sale contracts, cost-share agreements, and haul permit charges.
		d.	Locked gates and gate watchmen services at main entries are provided to control access by road
P	Protection		
	1 Fire Management Planning	a.	All operations are subjected to fire regulations mutually developed by the City of Seattle and the Forest Service as provided by the 1962 Coop Agreement.
		b	Suppress all fires utilizing suppression strategies and resources compatible with fire intensity conditions and values.
		c	Prescribed fire has limited application Maintenance of vegetative cover is important to meeting resource objectives Some burning of piled debris may be done.
		d	Avoid the use of ground disturbing equipment within 100 feet of water courses Avoid the use of retardant within 200 feet of water courses. Firelines should be located away from streams, maintaining at least 50 feet

		between the stream course and fire lines if possible.
		e. Natural fuels shall normally be left in place for soil stability. Activity fuels shall normally be treated by utilization.
	2. Forest Pest Management	a. Integrated pest management permitted except where use of pesticides conflicts with water quality objectives.

INTENSITY 20B: EXCHANGE NATIONAL FOREST LANDS, CITY OF SEATTLE MAINTAINS OLD GROWTH HABITAT.

Desired Future Condition: Ownership of old-growth stands to be maintained as habitat for old-growth-dependent wildlife species would be transferred to the City of Seattle through land exchange with agreement that such conditions would be maintained. Land exchanges of other National Forest lands would proceed as in Intensity A after completion of the old growth exchanges. Because of the old growth wildlife habitat areas, less National Forest lands would be harvested and more wildlife habitat would be preserved. Objectives and commitments of the 1962 Cooperative Agreement would still be in effect except for modifications of the land exchange objective due to old growth wildlife habitat areas. Public recreation opportunities on National Forest lands would be unchanged from Intensity A.

Program Elements		Standards and Guidelines
A.	Recreation	
	1. Visual Quality	a. Visual management is applied only to those areas which can be viewed from the ground from areas outside the watershed.
	2. American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines.
	3. Facility Construction, Reconstruction, and Management	a. No existing or planned developed recreation sites.
	4. Use Administration	a. Dispersed use is allowed to continue but is not encouraged.
	5. Trails Planning	a. Use of the Pacific Crest National Scenic Trail (PCNST) in the far eastern part of the watershed will be allowed to continue. No relocation is planned.
		b. No new trails are planned.
B.	Wilderness	a. Not applicable.
C.	Wildlife and Fish	
	1. Planning	a. Specialized habitat areas for old-growth-dependent species are designated and precluded from timber harvest.

		b. No structural projects to enhance fish passage are planned.
	2. Threatened and Endangered Species	a Meet Forest-wide Standards and Guidelines
D.	Range	a. Not applicable.
E.	Timber	
	1. Timber Management Planning	a. Timber management intensity A or C (where applicable Timber is applicable
		b. The maximum size of created openings will be increased by 100% over regional standard 2-1 to 120 acres in Douglas fir type and 80 acres in all other types. This standard may be exceeded in accordance with the stated descriptions if any one of the exceptions in the regional standard is met A created opening under standard 2-2 will no longer be classified as a created opening once the area has been certified as a completed reforestation project (normally following the third-year exam). These standards were developed by the U.S.F S. and the City of Seattle in 1983 study entitled - "An analysis of the effects of Various Silvicultural Standards and Guidelines on National Forest Lands Within the Cedar River Watershed."
F	Water, Soil, and Air	
	1. Soil Resource Inventory	a Continue to update, monitor and record S-8 classified soils. Maintain inventory of areas in the TRI system
	2. Planning	a. Use soil information when locating roads and harvest units.
	3 Improvement	a. Emphasize maintenance and improvement of water quality over other resources.
	4. Administration/Management	a All operations are conducted in compliance with the 1962 Coop Agreement with the City of Seattle which includes prohibition of manufacturing, use of uniform road construction standards, and compliance with sanitary regulations. No overnight camping is allowed (applies only to Industrial Operations). Industrial operations must provide chemical toilets.
		b. Prescribed slash burning is discouraged to protect residual seedlings, soil, water, and air quality.
		c Roads will not be constructed across S-8 classified soils and timber harvest will not be done on S-8 or J-8 soils.

5. Soil Resource Monitoring	a.	Timber harvest activities will result in no more than 10 percent of the project area having mineral soils exposed within the riparian zone or 15 percent outside the riparian zone.
G. Minerals and Geology	a.	National Forest lands were withdrawn from locatable mineral and mineral leasing activities (which includes minerals, oil and gas, and geothermal) by Public Law 97-350, 96 Stat. 1661 dated October 18, 1982. Extraction of common variety rock for road development needs is acceptable where water quality is not degraded.
H. Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines.
J. *Lands*		
1. Special Use Management	a.	Approval will be recommended for only those special use authorizations compatible with over all management goals and direction for this area.
2. Rights-of-Way Grants	a.	Rights-of-Way and easements will be given or obtained as outlined in the 1962 Cooperative Agreement.
3. Land Ownership Planning	a.	Old-growth stands to be retained for wildlife would be exchanged to the City of Seattle with patents reserving the U.S. Government's right to grant approval before proceeding with any ground-disturbing activity on these lands including road construction, salvage logging, or regular timber harvest. If any of these old-growth habitat areas were destroyed by wildfire, blowdown, or other catastrophe, the land exchange program would be halted until a suitable substitute area was acquired by the City, if available. The reservation to grant approval for management activities would expire when all National Forest lands within the watershed have been acquired by the City of Seattle.
	b.	The rate of land exchange and timber harvest would proceed at a faster rate than with Intensity A, taking about 10 years less to accomplish. Because of the old-growth wildlife habitat areas, less total National Forest land would be harvested. Objectives and commitments of the 1962 Cooperative Agreement would still be in effect except for modification of the land exchange scheme due to old-growth wildlife habitat areas.
	c.	Retain right-of-way on Pacific Crest National Scenic Trail.

L. Facilities		
1. Transportation System Planning	a.	Road locations are jointly planned and reviewed in accordance with the 1962 Coop Agreement in order to minimize the miles of road constructed.
2. Road Construction and Reconstruction	a.	Road construction standards are used as jointly agreed, in accordance with the 1962 Coop Agreement.
3. Road Operation	a.	Road maintenance operations, schedules, and standards are agreed to annually through cooperative meetings between Forest Service, municipal owner, and private owners.
	b	The moratorium on herbicide use would continue to be honored.
	c	Road maintenance is financed through cooperative maintenance agreements under Forest Service timber sale contracts, cost-share agreements, and haul permit charges
	d	Locked gates and gate watchmen services at main entries are provided to control access by road.
P. Protection		
1. Fire Management Planning	a	All operations are subjected to fire regulations mutually developed by the City of Seattle and the Forest Service as provided by the 1962 Coop Agreement.
	b	Suppress all fires utilizing suppression strategies and resources compatible with fire intensity conditions and values.
	c.	Prescribed fire has limited application Maintenance of vegetative cover is important to meeting resource objectives Some burning of piled debris may be done
	d.	Avoid the use of ground disturbing equipment within 100 feet of water courses. Avoid the use of retardant within 200 feet of water courses Firelines should be located away from streams, maintaining at least 50 feet between the stream course and fire lines if possible
	e	Natural fuels shall normally be left in place for soil stability Activity fuels shall normally be treated by utilization
2. Forest Pest Management	a.	Integrated pest management permitted except where use of pesticides conflicts with water quality objectives

---

INTENSITY 20C: RETAIN NATIONAL FOREST LANDS, MAINTAIN OLD GROWTH HABITAT.

Desired Future Condition: Wildlife habitat for old-growth-dependent species and others would be maintained in accordance with the National Forest Management Act. The 1962 Forest Service objective of exchanging National Forest lands in the Watershed to consolidate National Forest ownership elsewhere would be terminated. Since National Forest holdings would be retained, the full range of silvicultural practices, including fertilization, would be utilized to emphasize timber production on those lands not being retained in an old-growth status. The Forest Service would pursue acquisition of public rights on roads leading to National Forest lands within the watershed. Objectives and commitments of the 1962 cooperative agreement would still be in effect except for and the acquisition of public rights on roads leading to National Forest lands.

Program Elements	Standards and Guidelines
A. Recreation	
1. Visual Quality	a. Visual Quality Objective is maximum modification.
2. American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines.
3. Facility Construction, Reconstruction, and Management	a. No developed sites exist and none will be planned for the area.
4. Use Administration	a. Dispersed use will be emphasized over other forms.
	b. No use of vehicles permitted off of roads.
	c. Water related recreation activities will be discouraged.
	d. Sanitation facilities will be provided at areas of concentrated public use such as public firewood cutting areas.
	e. Special signing and literature will be developed to inform public recreationists that they are in a domestic water supply watershed and of special precautions necessary to prevent pollution and/or contamination.
	g. Snowmobile use will be prohibited.
B. Wilderness	a. Not applicable.
C. Wildlife and Fish	
1. Planning	a. Specialized habitat areas for old-growth-dependent species are designated and precluded from timber harvest.
	b. No structural projects to enhance fish passage are planned.

2. Threatened and Endangered Species	a	Meet Forest-wide Standards and Guidelines.
D *Range*	*a.*	*Not applicable.*
E. Timber		
1. Timber Management Planning	a.	Program Element E Timber from Timber Management Prescription 17, Intensities A through H is applicable. Silvicultural prescription and economic analysis at the time an activity is planned will determine the appropriate intensity.
F. Water, Soil, and Air		
1. Soil Resource Inventory	a.	Continue to update, monitor and record S-8 classified soils Maintain inventory of areas in the TRI system.
2. Planning	a	Use soil information when locating roads and harvest units.
3. Improvement	a.	Emphasize maintenance and improvement of water quality over other resources.
4 Administration/Management	a	All operations are conducted in compliance with the 1962 Coop Agreement with the City of Seattle which includes prohibition of manufacturing, use of uniform road construction standards, and compliance with sanitary regulations. No overnight camping is allowed . Industrial operations must provide chemical toilets
	b	Prescribed slash burning is discouraged to protect residual seedlings, soil, water, and air quality
	c.	Roads will not be constructed across S-8 classified soils and timber harvest will not be done on S-8 or J-8 soils.
5. Soil Resource Monitoring	a	Timber harvest activities will result in no more than 10 percent of the project area having mineral soils exposed within the riparian zone or 15 percent outside the riparian zone.
G. Minerals and Geology	a.	National Forest lands were withdrawn from locatable mineral and mineral leasing activities (which includes minerals, oil and gas, and geothermal) by Public Law 97-350, 96 Stat. 1661 dated October 18, 1982. Extraction of common variety rock for road development needs is acceptable where water quality is not *degraded.*
H. Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines.

J. Lands		
	1. Special Use Management	a. Approval will be recommended for only those special use authorizations compatible with over all management goals and direction for this area.
	2. Rights-of-Way Grants	a. Rights-of-Way and easements will be given or obtained as outlined in the 1962 Cooperative Agreement.
	3. Land Ownership Planning	a. The 1962 Forest Service objective of exchanging out of National Forest lands to consolidate National Forest ownership elsewhere would be terminated.
		b. National Forest lands would be placed in Group III, available for land exchange.
L. Facilities		
	1. Transportation System Planning	a. Road locations are jointly planned and reviewed in accordance with the 1962 Coop Agreement in order to minimize the miles of road constructed.
	2. Road Construction and Reconstruction	a. Road construction standards are used as jointly agreed, in accordance with the 1962 Coop Agreement.
	3. Road Operation	a. Road maintenance operations, schedules, and standards are agreed to annually through *cooperative meetings between Forest Service,* municipal owner, and private owners.
		b. The moratorium on herbicide use would continue to be honored.
		c. Road maintenance is financed through cooperative maintenance agreements under Forest Service timber sale contracts, cost-share agreements, and haul permit charges.
		d. Roads on which the Forest Service owns public rights will be open to public use. Information signs will be used to inform the public of any use restrictions or precautionary measures.
P. Protection		
	1. Fire Management Planning	a. All operations are subjected to fire regulations mutually developed by the City of Seattle and the Forest Service as provided by the 1962 Coop Agreement.
		b. Suppress all fires utilizing suppression strategies and resources compatible with fire intensity conditions and values.

		c. Prescribed fire has limited application. Maintenance of vegetative cover is important to meeting resource objectives. Some burning of piled debris may be done
		d Avoid the use of ground disturbing equipment within 100 feet of water courses. Avoid the use of retardant within 200 feet of water courses Firelines should be located away from streams, maintaining at least 50 feet between the stream course and fire lines if possible.
		e. Natural fuels shall normally be left in place for soil stability. Activity fuels shall normally be treated by utilization.
2. Forest Pest Management	a	Integrated pest management permitted except where use of pesticides conflicts with water quality objectives

---

21 GREEN RIVER MUNICIPAL WATERSHED (CITY OF TACOMA)

Goal: Provide for the production of water at a level of quality which, with adequate treatment by the purveyor, will result in a satisfactory and safe water supply Timber production is emphasized to the extent that the water quality goal is met. There is varying emphasis on other uses

Description of Lands Where Prescription Applicable This prescription is applied to the approximately 36,000 acres of National Forest land within the Green River Watershed Such lands are located in an intermingled pattern in the eastern part of the Green River drainage About 9,000 acres of National Forest Land are currently being considered under the existing Memorandum of Understanding for land exchange

Intensities in this Management Prescription

21B TIMBER HARVEST PERMITTED, MOST RECREATION PROHIBITED.

Desired Future Condition Public recreation will be prohibited except for those persons authorized to participate in special controlled big game hunts and for recreation use of the Pacific Crest National Scenic Trail

Program Element		Standards and Guidelines
A. Recreation		
1. Visual Quality	a	Manage to a maximum modification visual quality standard except in areas seen from the Pacific Crest National Scenic Trail.
2. American Indian Religious and Cultural Use	a	Meet Forest-wide Standards and Guidelines.
3 Facility Construction, Reconstruction Management	a.	No developed recreation sites exist Construct no new sites

	4. Use Administration	a. Recreation use prohibited except for use of the Pacific Crest National Scenic Trail (PCNST) and persons authorized to participate in special controlled big game hunts by permit.
		b. No overnight camping allowed by participants in special controlled hunts.
B.	Wilderness	a. Not applicable.
C.	Wildlife and Fish	
	1. Planning	a. Meet Forest-wide Standards and Guidelines.
		b. Cooperate with the Washington State Department of Fisheries and Department of Game in restoration and enhancement of fisheries habitat and the stocking of resident and anadromous fish within the area.
D.	Range	a. Not applicable.
E.	Timber	
	1. Timber Management Planning	a. Program Element E from Timber Management Prescription 17, intensities A through H are applicable. Silvicultural prescription and economic analysis at the time an activity is planned will determine the appropriate investment level.
F.	Water, Soil, and Air	
	1. Soil Resource Inventory	a. Continue to update, monitor, and record S-8 classified soils. Maintain inventory of areas in TRI/GIS system.
	2. Planning	a. Use soil information when locating roads and harvest units.
	3. Improvement	a. Emphasize maintenance and improvement of water quality over other resources.
	4. Administration/Management	a. Industrial operations must provide a means of disposing of human wastes and litter and restoration of the site upon removal of overnight facilities.
		b. Cooperate with the Washington State Department of Social and Health Services and the City of Tacoma in providing data that would be helpful in the study of the watershed and water quality.
		c. Prescribed slash burning is discouraged to protect residual seedlings, soil, water, and air quality.
		d. Roads will not be constructed across S-8 classified soils and timber harvest will not be done on S-8 or J-8 soils.

		e.	Timber harvest activities will result in no more than 10 percent of the project area having mineral soils exposed within the riparian zone or 15 percent outside the riparian zone.
		f.	Meet at least annually with the City of Tacoma to review work plans, anticipated contractor or permittee work within the drainage, informational or educational materials referencing activities within the drainage, and other issues of mutual interest.
G.	Minerals and Geology	a.	National Forest lands were withdrawn from locatable mineral and mineral leasing activities (which includes minerals, oil and gas, and geothermal) by Public Law 97-350, 96 Stat. 1661 dated October 18, 1982. Extraction of common variety rock for road development needs is acceptable where water quality is not degraded.
H.	Rural Community and Human Resources	a	Meet Forest-wide Standards and Guidelines
J.	Lands		
	1. Special Use Management	a	Approval will be recommended only for those special uses compatible with overall management goals and direction for this area.
	2. Land Ownership Planning	a.	Applicable details are found in the Memorandum of Understanding between the Forest Service and the City of Tacoma, dated August 29, 1984, F.S. Control #84-06-58-5.
		b.	National Forest lands are in ownership Group III and IV. (Group III - available for land exchange and Group IV - available for disposal through land exchange).
L.	Facilities		
	1. Transportation System Planning	a.	Meet Forest-wide Standards and Guidelines.
	2. Road Construction and Reconstruction	a.	Perform and administer road construction/reconstruction activities to stay within the water quality goal for this area.
	3. Road Operation	a.	Road maintenance is financed through cooperative maintenance agreements under Forest Service timber sale contracts, cost share agreements, haul permit charges and appropriated funding.
		b	Refer to Forest Service-Corps of Engineers joint Memorandum of Understanding No. DA(S) 45-108-CIVENG-60-10 which describes administration and maintenance agreements on Road 54 from the west watershed entry to the end of the Corps of Engineers' ownership.

P. Protection		
1.	Fire Management Planning	a. Forest-wide Fire Protection Group E applies.
2.	Forest Pest Management	a. Integrated pest management is permitted except where the use of pesticides conflicts with water quality objectives.

---

22 SULTAN RIVER MUNICIPAL WATERSHED (CITY OF EVERETT)

Goal: Provide water at a level of quality and quantity which with treatment by the purveyor, will result in satisfactory and safe water supply. There is emphasis on providing for other uses.

Description of Lands Where Prescription Applicable: This prescription is applied to approximately 16,800 acres of National Forest land within the Sultan River watershed. It excludes the private and municipal ownership in the watershed.

Desired Future Condition: Varies by Intensity.

Intensities in this Management Prescription:

22A Closed Watershed, Except for Production of High Quality Water and Hydropower, Exchange National Forest Lands.

22C Retain National Forest Land, and Full Multiple Use.

INTENSITY 22A: CLOSED WATERSHED, EXCEPT FOR PRODUCTION OF HIGH QUALITY WATER AND HYDROPOWER, EXCHANGE NATIONAL FOREST LANDS.

Desired Future Condition: National Forest land will be owned and managed by another party, either private, state, or municipal. The Forest Service will relinquish all rights except those necessary for the Federal Power Withdrawal (FERC Project No. 2157). While lands remain in the National Forest system, they will be managed to protect the watershed, produce hydropower and provide high quality water, with an emphasis on improving water quality.

Program Elements		Standards and Guidelines
A.	Recreation	
1.	Recreation Planning	a. No recreation activities permitted.
2.	Visual Quality	a. Meet Forest-wide Standards and Guidelines.
3.	American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines.
4.	Facility Management	a. Close existing sites and facilities. No recreation activities permitted.
5.	Trail Planning	a. Abandon existing trails, no recreational activities permitted.
B.	Wilderness	a. Not applicable.

C	Wildlife and Fish		
	1 Habitat Improvement	a	No activities permitted. Natural processes will determine the habitat.
D.	Range	a	Not applicable.
E	Timber		
	1 Timber Management Planning	a.	No additional timber harvest permitted beyond completion of timber sales under contract
		b	Timber management intensities A-H should be applied if they meet the requirements of this management prescription.
		c.	Salvage harvest permitted.
	2. Timber Stand Improvement	a	No activities permitted
F.	Water, Soil and Air		
	1. Improvement	a	Meet Forest-wide Standards and Guidelines
		b	Emphasize maintenance and improvement of water quality No additional ground-disturbing activities Bank stabilization and erosion control of natural and existing bare areas is encouraged to reduce turbidity, bed load and sedimentation
G	Minerals and Geology	a	Meet Forest-wide Standards and Guidelines
H.	Rural Community and Human Resources	a	Meet Forest-wide Standards and Guidelines.
J	Lands		
	1 Special Use Management	a	Administer special use permit for FERC license
	2. Right-of-Way Grants	a	Grant right-of-way to access state, municipal, and private lands
	3 FERC License and Permits	a	Continue current FERC license, no new permits issued for hydroelectric projects
	4 Withdrawals, Modifications and Revocations	a	Withdraw all non-claimed lands from mineral entry. Revoke all power withdrawals not currently licensed.
	5 Land Ownership Planning	a	Group IV - available for disposal through land exchange.
L.	Facilities	a	No new roads, trails or facilities permitted except as needed for timber harvest administration of hydroelectric project, fire suppression, and right-of-way access.
P.	Protection		
	1. Fire Management Planning	a	Forest-wide Fire Protection Group E (2) applies

	2. Forest Pest Management	a. Integrated pest management permitted except where the use of pesticides conflict with water quality objectives.

INTENSITY 22C: RETAIN NATIONAL FOREST LAND, AND FULL MULTIPLE USE.

Desired Future Condition: The National Forest land will be retained. Lands will be managed to emphasize the output of timber products, the development of recreation potential, and to provide a range of other uses and outputs. Emphasis is on meeting Washington State minimum legal standards for water quality and producing high levels of fish/wildlife habitat, recreation, and timber outputs.

Program Elements		Standards and Guidelines
A.	Recreation	
	1. Recreation Planning	a. Recreation site development is encouraged. No restriction on activities such as swimming, motor boats, etc. Dispersed recreation is permitted.
		b. The applicable Standards and Guidelines for developed recreation are found in Management Prescription 3A, program element A, Recreation.
	2. Visual Quality	a. Meet Forest-wide Standards and Guidelines.
	3. American Indian Religious and Cultural Use	a. Meet Forest-wide Standards and Guidelines.
B.	Wilderness	a. Not applicable.
C.	Wildlife and Fish	
	1. Habitat Improvement	a. Meet Forest-wide Standards and Guidelines. Projects to improve habitat are encouraged.
D.	Range	a. Not applicable.
E.	Timber	
	1. Timber Management Planning	a. Program element E from Timber Management Prescription 17, intensities A through H are applicable. Silvicultural prescription and economic analysis at the time an activity is planned will determine the appropriate investment level.
F.	Water, Soil and Air	a. Meet Forest-wide Standards and Guidelines. Emphasis on enhancement of riparian habitats.
G.	Minerals and Geology	a. Meet Forest-wide Standards and Guidelines.
H.	Rural Community and Human Resources	a. Meet Forest-wide Standards and Guidelines.
J.	Lands	
	1. Special Use Management	a. Special use permits compatible with this intensity.

	2 Land Ownership Planning	a	Group III - available for land exchange.
L.	Facilities	a.	Meet Forest-wide Standards and Guidelines.
P.	Protection		
	1. Fire Management Planning	a	Forest-wide Fire Protection Group E (2) applies.
	2 Forest Pest Management	a	Integrated pest management permitted except where the use of pesticides conflict with water quality objectives.

---

23 OTHER MUNICIPAL WATERSHEDS

Goal: Provide water at a level of quality and quantity which, with treatment by the purveyor, will result in satisfactory and safe water supply with varying emphasis on timber production, recreation, and other uses.

Description of Lands Where Prescription Applicable This prescription is applied to the small municipal watersheds of the Forest not covered in Management Prescriptions 20, 21, and 22 Watersheds are found throughout the Forest and at varying elevations. Most are forested old growth, second growth, and plantations. Access is generally by road.

Desired Future Condition Common to all Intensities

A varying mix of timber, recreation, wildlife and other resource use The primary emphasis will be to meet the above stated goal for a municipal watershed.

Intensities in this Management Prescription

23B NO TIMBER HARVEST, LIMITED RECREATION OPPORTUNITIES.

Program Element		Standards and Guidelines
A.	Recreation	
1. Recreation Planning	a	Discourage water contact recreation activities.
	b	No developed recreation facilities unless they are needed to protect water quality
	c	No overnight use
	d	Closed to ORV use.
2. Visual Quality	a	Visual Quality Objective will range from retention to modification
3. American Indian Religious and Cultural Use	a.	Meet Forest-wide Standards and Guidelines.
4. Trail Planning	a.	Maintenance and reconstruction of existing trails may continue. No new trail development

B. Wilderness		a. Not applicable.
C. Wildlife and Fish		a. Meet Forest-wide Standards and Guidelines.
D. Range		a. Not applicable.
E. Timber		
	1. Timber Management Planning	a. No scheduled harvest.
F. Water, Soil, and Air		a. Meet Forest-wide Standards and Guidelines.
G. Minerals and Geology		a. Additional mitigation and rehabilitation measures may be required to protect water quality. These measures will be determined through the NEPA process.
H. Rural Community and Human Resources		a. Meet Forest-wide Standards and Guidelines.
J. Lands		
	1. Rights-of-way Grants	a. Meet Forest-wide Standards and Guidelines.
	2. FERC License and Permits	a. Activity to be analyzed through NEPA process to determine its effect on water quality. Only permitted if water quality and minimum flows are maintained.
	3. Land Ownership Planning	a. Acquire and/or dispose of land as needed. Lands are in Group III.
L. Facilities		
	1. Transportation System Planning	a. New roads will be limited to those required to access public or private lands beyond the watershed.
		b. Roads must be located to meet water quality objectives.
	2. Road Construction, Reconstruction and Operation	a. Only those construction/ reconstruction practices that meet water quality objectives will be allowed. Water quality problems caused by construction should be given a high priority for corrective action.
		b. Road cut-and-fill slopes that may adversely effect water quality will be protected with erosion and/or sediment control. Final stabilization practices should include vegetation as well as structures.
		c. All roads not receiving annual maintenance will have measures to control road surface and ditch water.
		d. Temporary structures installed to impound water for road maintenance will be removed after use.

P	Protection		
	1. Fire Management Planning	a	Forest-wide Fire Protection Group A applies.
		b	Rehabilitation needs should be evaluated for all sizes of fires.
		c	Temporary structures installed to impound pumper chance water sources will be removed immediately after use.
	2 Forest Pest Management	a.	Integrated pest management is permitted except where use of pesticides conflicts with water quality objectives.

---

24 MINIMUM MANAGEMENT — Goal: Manage National Forest lands to meet basic stewardship responsibilities at minimum costs.

Description of Lands Where Prescription Applicable: The prescription applies to identified lands throughout the Forest.

Desired Future Condition: *Provide for natural ecological processes compatible with meeting* the strategy goal.

Management is necessary to· Protect life, health, and safety of incidental users, prevent unacceptable environmental damage to National Forest lands or resources of adjoining ownerships and downstream areas administer non-Forest Service special uses leases, and permits, retain National Forest land in Federal ownership, and protect Federal property from theft and damage

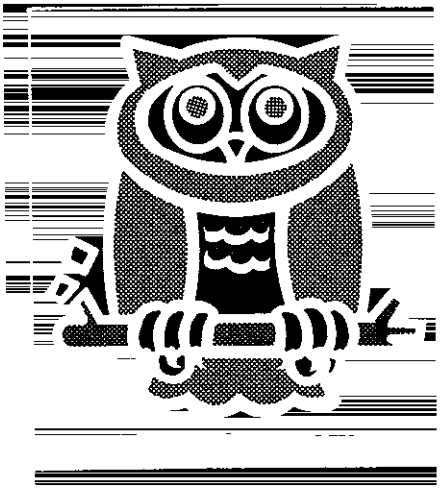
Intensities in this Management Prescription: None

Program Element		Standards and Guidelines
A.	Recreation	
	1. *American Indian Religious and* Cultural Use	a. *Meet Forest-wide Standards and Guidelines.*
	2 Trail System Planning	a Only that level of trail system management needed to protect the life health and safety of incidental users should be provided (e g signing trails).
B	Wilderness	a Not applicable.
C	Wildlife and Fish	
	1 Wildlife/Fisheries Cooperation with States and Other Agencies	a. Only the minimum level of cooperation with State and other Federal agencies and groups necessary to support regulation of incidental hunting and fishing use
	2. Threatened and Endangered Species	a Meet Forest-wide Standards and Guidelines
D	Range	a. Not applicable.

E. Timber		
1. Timber Management Planning	a.	Incidental harvest only to protect the life, health, and safety of incidental Forest users or to correct or prevent damage to Federal property or adjacent land and resources.
F. Water, Soil, and Air		
1. Soil and Water Resource Monitoring	a.	Meet Forest-wide Standards and Guidelines.
	b.	A level of soil monitoring commensurate with the need to prevent soil damage on the Forest or adjacent lands.
G. Minerals and Geology	a.	Level of activity necessary to protect surface resources and administer all privately held mineral rights for oil and gas, coal, energy and non-energy minerals.
H. Rural Community and Human Resources	a.	Meet Forest-wide Standards and Guidelines.
J. Lands	a.	Administer unavoidable non-Forest Service special uses. Inventory and resolve all new encroachments and only those existing encroachments that damage or threaten to damage resources on National Forest land. Boundary line location will be done to the extent necessary to carry out resolution of encroachment.
L. Facilities		
1. Road Maintenance	a.	Only that road system management needed to protect the life, health, and safety of incidental Forest users, such as signing, gating, or otherwise closing roads, and maintenance to the extent necessary for basic custodial care and the correction or prevention of damage to adjacent land and resources.
2. FA & O Maintenance	a.	All activities normally occurring under this code for those facilities necessary to carry out National Forest functions.
P. Protection		
1. Fire Management Planning	a.	Initial attack forces provide the level of fire detection and suppression activities needed to protect adjacent lands and the health and safety of nearby residents.
2. Law Enforcement	a.	Provide the level of law enforcement necessary to enforce existing rules relating to the incidental Forest user as well as laws applying to public land; e.g., posted road and trail closures, timber theft.
	b.	Provide the level of cooperative law enforcement activities with local authorities

		to enforce State and local laws applicable to incidental Forest users.
3.	Forest Pest Management	a. Provide the level of suppression needed to protect adjacent lands from insect and disease epidemics on National Forest land

Appendix



APPENDIX E

WILD AND SCENIC RIVERS

Introduction

Congress enacted Public Law 90-542 on October 2, 1968 known as the Wild and Scenic Rivers Act, which established a National Wild and Scenic Rivers System. The intent of Congress in establishing a national system of Wild and Scenic Rivers is stated in Section 1(b) of the Act:

> "The Congress declares that the established national policy of dam and other construction at appropriate sections of the rivers of the United States needs to be complemented by a policy that would preserve other selected rivers or sections thereof in their free-flowing condition to protect the water quality of such rivers and to fulfill other vital national conservation purposes."

More specifically, Congress established a policy:

> "It is hereby declared to be the policy of the United States that certain selected rivers of the Nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values shall be preserved in free-flowing condition, and that they and their immediate environments shall be protected for the benefit and enjoyment of present and future generations."

The Act named eight rivers as "instant" components of the National System and named "study rivers" for potential additions to the National System. Additional rivers not mentioned may be added to the System. The Act directs the Secretaries of Agriculture and Interior to: "make specific studies and investigations to determine which additional wild, scenic, and recreational river areas within the United States shall be evaluated in planning reports by all agencies as potential alternative uses of the water and related land resources involved "

Under this direction, the Heritage Conservation and Recreation Service (HCRS) in August 1980 released an inventory of rivers that were in a relatively natural, undeveloped condition. Eight rivers or portions of rivers on the Mt. Baker-Snoqualmie National Forest were listed. A revised inventory in 1982 published by the National Park Service listed an additional eight rivers as potentially eligible for designation.

In addition to NPS inventory rivers, the Regional Forester directed that all forests examine for eligibility any river that was requested by a public interest group or a large number of individuals. Thirty-one rivers or extensions of rivers were added for study as a result of environmental or recreation user group interest.

In summary, 47 rivers were studied for eligibility, covering approximately 765 miles of river. These were presented in the Draft EIS for the Forest Plan. Five of these rivers were determined to be eligible and were recommended in the Draft preferred alternative for designation into the Wild and Scenic River System.

Appendix E
Introduction

Table E-1

Eligibile Rivers Studied for Designation - In Miles

Inventoried River	Total Studied	USFS Inside Wilderness	Inside National Park	Private	Found Suitable, Recommended for Designation - Alt J
Silesia Creek	10.4	6.4	4.0	0.0	0.0

White River	37.7	0.0	13.3	15.9	37.7
Clearwater River	9.8	3.6	0.0	5.8	0.0
Greenwater River	21.4	8.4	0.0	4.5	0.0
	795.9	138.4	41.2	330.6	451.8

Public comment on the Draft EIS indicated overwhelming support for Wild and Scenic River designation. Almost 2,000 letters, response forms and petitions were received. Every river studied except Silesia Creek was mentioned by name by at least one respondent. The Pratt River was cited by 1,405 respondents. There was strong support from the public and other agencies to reevaluate rivers using a less strict criteria for eligibility, and to assess an additional four rivers not previously reviewed.

Eligibility was re-evaluated on 51 rivers. A group of Forest Service and non-Forest Service specialists were assembled to develop new eligibility definitions and to review additional resource data. As a result, 47 rivers were determined to be eligible for consideration as additions to the Wild and Scenic River System.

This report assesses the eligibility of these rivers, including river miles that are outside the forest boundary. For each river determined eligible, a determination is made of its suitability for inclusion into the National Wild and Scenic Rivers System and its recommended classification of wild, scenic, or recreational.

The 47 rivers listed in this Appendix total 795.9 miles. Table E-1, on the previous page, lists these rivers. Note that portions of these rivers are outside the National Forest boundary, thus requiring cooperative management agreements between the federal government and landowner or other governing body, should the river be designated. Also, there are many encumbered acres showing withdrawals or other private rights.

The Skykomish River System has been designated by the State of Washington as a Scenic River under provisions of the State Scenic River System Act (RCW 79 72). This designation only applies to city, county, and state lands; it does not apply to Federal lands or private property. This river features runs of anadromous fish, bald eagle feeding and perching areas, old growth habitat, and a variety of boating opportunities.

For convenience, some of the listed rivers have been combined for analysis. For example, the east and west forks of the Miller River are described along with the main stem of the Miller

Eligibility Determination

The initial phase of the Wild and Scenic River Study process is to determine if each river or segment of river is eligible for inclusion in the National Wild and Scenic Rivers System. In order to make this determination, it is necessary to interpret Section 1(b) of the Wild and Scenic Rivers Act (Public Law 90-542), as quoted above

Generally, a river must be free-flowing and possess one or more "outstandingly remarkable" resource values. Because the Act does not specifically define "outstandingly remarkable," the Forest developed definitions that would distinguish those "outstandingly remarkable values" that are exceptional, unique, or unusual from a national or regional perspective

Following are definitions of the outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural and ecological values as used in this analysis

Appendix E
Introduction

Outstandingly Remarkable Value - An outstandingly remarkable value is one which is significantly above average for the state, region or nation, even though it may be fairly common within the Mt. Baker-Snoqualmie National Forest.

1. Scenic Value - The area contains a wide variety of unusual or distinctive land or water forms or vegetation patterns, or it contains an impressive example of one particular land or water form or vegetative pattern.

2. Recreation Value - The area provides a diversity of high quality recreation opportunities, or one exceptionally high quality recreation opportunity.

3. Geologic Value - The area displays an individual, unusual or unique geologic feature or a combination of several distinctive geologic features.

4. Fisheries Value - The area contains unique resident or anadromous values for "rare", "relatively rare", or "unique genetic variant" species managed by the State, or high species diversity, very high fish production, or unique fishing experiences. For this Forest, "rare" fisheries values include spring run chinook salmon. "Relatively rare" include sockeye salmon, sea-run Dolly Varden, and summer run steelhead. "Unique genetic variants" for the MBS includes early run coho salmon.

5. Wildlife Value - Habitats for species identified by federal or state agencies as threatened or endangered; or critical habitats of species of concern.

6. Historic Value - Historical events of regional or national interest have occurred within the area, or the area contains physical remains of historical events.

7. Cultural Value - The area contains scientific, paleontological, archeological or cultural resources.

8. Ecological Value - The area contains a high quality example of an unusual ecological community or a plant species of special interest listed by the state or federal government.

In applying these criteria the Forest assembled an interdisciplinary group to evaluate river eligibility. This group studied the information presented under the description for each river. In addition to the ID Teams professional judgement, information and ratings from other sources were used, including: The Nationwide Rivers Inventory, River Recreation in Washington: An Initial Inventory and Assessment, the Pacific Northwest Rivers Study - Washington, and other similar assessments. The results of this evaluation are presented below, in Table E-2.

Forty-seven rivers are judged to possess "outstandingly remarkable" resource features and, thus, eligibility for Wild and Scenic River designation.

Note that the rating criteria listed above do not mechanically or automatically indicate which rivers are eligible and suitable. The Forest has to exercise judgment not only on the specific criteria as they apply to a particular river, but on the river as a whole, and on their relative weights. For this reason, the evaluation guidelines are not absolutes.

Table E-2

Classification of Eligible Rivers

The next step in studying potential Wild and Scenic Rivers was to evaluate eligible rivers and determine their classification. Classification was based on the relative level of development (existing land uses and access) within the river corridor. Each eligible segment qualified as one of three designation categories defined by the Wild and Scenic Rivers Act:

1. Wild river areas - These are rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.

2. Scenic river areas - These are rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

3. Recreational river areas - These are rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Applying these criteria the Forest exercised its judgment in determining the most restrictive potential classification of the rivers. The results of the analysis are displayed in Table E-3, Classification of Eligible Rivers, on the following pages.

Potential classification may differ from the Forest Service Recommended classification. For these differences see narrative for each rivers in this appendix.

Table E-3
Classification of Eligible Rivers

Inventoried River	Class	Length (mi.)	Description
Silesia	Wild	10.4	Headwaters in N Cascades National Park in NW 1/4 of Sec 3, T 39N , R 10E., to Canadian border
N. F Nooksack	Wild	3 5	Headwaters in N. Cascades National Park in SW 1/4 of Sec. 30, T.39N , R 10E. to Mt Baker Wilderness boundary.
	Scenic	9.9	Mt. Baker Wilderness boundary to Nooksack Falls diversion dam
	Rec	1.6	Nooksack Falls diversion dam to Nooksack Falls power plant
	Scenic	18.8	Nooksack falls power plant to the fish hatchery near Kendall, Washington.
	Rec	9.5	Fish hatchery to the confluence with the South Fork Nooksack River
Wells	Wild	2.6	Headwaters at Galena Chain Lakes to Rd. 33 bridge, E edge Sec. 16, T.39N , R.8E
	Scenic	3.4	Road 33 bridge to confluence with N. Fork Nooksack River.
M F. Nooksack	Wild	2.7	Headwaters on Deming Glacier in NW 1/4 of Sec. 35, T.38N., R.7E to Ridley Creek.
	Scenic	10.2	Ridley Creek to diversion dam in NE 1/4 of Sec 19, T.38N., R.6E.
	Rec	7.1	Diversion dam to confluence with N. F. Nooksack River
S F Nooksack	Wild	2 3	Headwaters in SW 1/4 of Sec 9, T.37N., R 7E. to Bell Creek.
	Scenic	24 3	Bell Creek to Saxon Bridge in SE 1/4 of Sec. 21, T.37N., R.5E
	Rec.	12.9	Saxon Bridge to confluence with N. F Nooksack River.
Bell	Scenic	3 0	Headwaters on Loomis Mtn in NE 1/4 of Sec. 23, T 37N., R 7E., to confluence with S. F Nooksack River

Appendix E
Introduction

Baker	Wild	11.2	Headwaters in North Cascades National Park near Perfect Pass in NE 1/4 of Sec. 28, T.39N., R.11E. to Blum Creek.
	Scenic	2.1	Blum Creek to Baker Lake.
Noisy	Wild	6.1	Headwaters on Bacon Peak in SE 1/4 of Sec. 29, T.37N., R.10E. to Baker Lake.
Diobsud	Wild	8.3	Headwaters on Mt. Watson in SE 1/4 of Sec. 36 T.37N., R.9E. to south section line of Sec. 24, T.36N., R.10E.
	Rec.	2.2	South section line of Sec. 24 to confluence with Skagit River.
Illabot	Wild	4.3	Headwaters in NW 1/4 of Sec. 32, T 34N., R.12E. to Glacier Peak Wilderness boundary.
	Rec.	11.0	Glacier Peak Wilderness boundary to confluence with Skagit River.
Buck	Wild	10.1	Headwaters in NE 1/4 of Sec. 4, T.33N., R.12E. to Glacier Peak Wilderness boundary.
	Scenic	1.0	Glacier Peak Wilderness boundary to confluence with Suiattle River.
Downey	Wild	10.0	Headwaters on Lizard Mtn. in NW 1/4 of Sec. 13, T.33N., R.13E. to Glacier Peak Wilderness boundary.
	Scenic	0.8	Glacier Peak Wilderness boundary to confluence with Suiattle River.
White Chuck	Wild	10.5	Headwaters in NW 1/4 of Sec. 6, T.29N., R.14E. to Glacier Peak Wilderness boundary.
	Rec.	12.0	Glacier Peak Wilderness boundary to confluence with Sauk R.
N. F Sauk	Wild	9.2	Headwaters in SW 1/4 of Sec 19, T.29N., R.14E. to the boundary of the designated Wild and Scenic Skagit River in SE 1/4 of Sec. 29, T.30N., R.12E. (Glacier Peak Wilderness Boundary)
S. F Sauk	Wild	1.0	Headwaters in SE 1/4 of Sec. 28, T.29N , R.11E. to Henry M. Jackson Wilderness boundary.
	Scenic	7.4	Henry M. Jackson Wilderness boundary to confluence with Elliot Creek (to existing W & SR designation).

N. F. Stillaguamish	Rec.	49 8	Headwaters in SE 1/4 of Sec 17, T.34N., R.9E. to confluence with N. F Stillaguamish River
North Branch	Rec.	5 1	Headwaters in NE 1/4 of Sec. 12, T.33N., R.8E. to confluence with N F. Stillaguamish River
Deer	Rec.	23.5	Headwaters near Coney Pass in SW1/4 of Sec. 23, T.33N., R.8E. to confluence with N. F Stillaguamish River.
Boulder	Wild	9.0	Headwaters in SW 1/4 of Sec. 7, T.32N., R.9E to Boulder River Wilderness boundary.
	Rec.	4.0	Boulder River Wilderness boundary to confluence with N F Stillaguamish R.
S F Stillaguamish	Scenic	36 6	Headwaters between Morning Star and Lewis Peaks in NE 1/4 of Sec 14, T 29N., R.10E. to Canyon Creek
	Rec	15 9	Canyon Creek to confluence with N. F Stillaguamish River.
Canyon	Rec.	11 9	Confluence of N. and S. Forks Canyon Creek to confluence with S. F Stillaguamish River
S F. Canyon	Wild	1 3	Headwaters in NE 1/4 of Sec. 5, T.30N., R.9E., to Boulder River Wilderness boundary.
	Scenic	7 1	Boulder River Wilderness boundary to confluence with N. F. Canyon Creek.
N F. Skykomish	Wild	8 2	Headwaters in NW 1/4 of Sec 30, T 29N., R.10E. to end of F S. Road 63 in NW 1/4 of Sec. 10, T.28N , R 12E.
	Scenic	8.4	Road end to Troublesome Creek
	Rec	12 0	Troublesome Creek to confluence with S F Skykomish River.
S. F. Skykomish (& mainstem)	Rec	48 6	Confluence of Tye and Foss Rivers to confluence with Snohomish River.
Troublesome	Wild	4 4	Headwaters at Blanca Lake to FS Road 63
	Scenic	0.1	FS Road 63 to confluence with N. F. Skykomish River.

Appendix E
Introduction

West Cady	Wild	4.8	Headwaters in NE 1/4 of Sec. 13, T.28N., R.12E. to bridge in Sec. 21, T.28N., R.12E.
	Rec	2.7	Bridge to confluence with N. F. Skykomish River
Tye	Rec	14.5	Headwaters in SE 1/4 of Sec. 14, T.26N., R.13E. to confluence with Foss River.
Miller	Scenic	3.7	Confluence of E. and W. Forks Miller River to confluence with S. F. Skykomish River.
W. F. Miller	Wild	2 1	Headwaters in SE 1/4 of Sec. 31, T.24 1/2 N , R.11E. to Alpine Lakes Wilderness boundary.
	Scenic	4.2	Alpine Lakes Wilderness boundary to confluence with E. F Miller River.
E. F. Miller	Wild	0.8	Lake Dorothy to Alpine Lakes Wilderness boundary.
	Scenic	6.0	Alpine Lakes Wilderness boundary to confluence with W. Fk Miller River
Foss	Rec.	4 4	Confluence of E. and W. Forks Foss River to confluence with Tye River.
W. F Foss	Wild	3 1	Delta Lake to Alpine Lakes Wilderness boundary.
	Rec	1 5	Alpine Lakes Wilderness boundary to confluence with E. F. Foss River.
E. F. Foss	Wild	6 7	Headwaters at Lynch Glacier in SW 1/4 of Sec. 11, T.24N., R.13E. to Alpine Lakes Wilderness boundary.
	Rec	1.2	Alpine Lakes Wilderness boundary to confluence with W F. Foss River.
Beckler	Rec	13.5	Headwaters at Jack Pass in NW 1/4 of Sec. 31, T 28N., R 12E. to confluence with S. F Skykomish River
Rapid	Wild	7 0	Headwaters upstream from Janus Lake in SE 1/4 of Sec 13, T.27N., R.13E. to Henry M. Jackson Wilderness boundary.
	Scenic	6 0	Henry M. Jackson Wilderness boundary to confluence with Beckler River.
Deception	Wild	9.8	Headwaters at Trico Lake in SW 1/4 of Sec. 5, T 24N., R.14E., to Alpine Lakes Wilderness boundary.

	Rec	0 5	Alpine Lakes Wilderness boundary to confluence with Tye River
S. F Tolt	Rec	5.4	Headwaters in SE 1/4 of Sec 33, T.26N., R 10E. to Tolt Reservoir.
N F. Snoqualmie	Wild	1.0	Headwaters at Lake Kanim in SE 1/4 of Sec 11, T.25N., R 10E to Alpine Lakes Wilderness boundary.
	Scenic	5.1	Alpine Lakes Wilderness boundary to Lennox Creek.
	Rec	8.0	Lennox Creek to Wagner Bridge in NE 1/4 of Sec 20, T.25N , R.9E.
	Scenic	12.1	Wagner Bridge to confluence with M. F. Snoqualmie River.
Lennox	Wild	0 3	Headwaters in NW 1/4 of Sec. 36, T 25N., R.10E. to Alpine Lakes Wilderness boundary
	Scenic	6 9	Alpine Lakes Wilderness boundary to confluence with N. F Snoqualmie River
M. F. Snoqualmie	Wild	6 4	Headwaters near Dutch Miller Gap in NW 1/4 of Sec. 29, T.24N , R 13E to Alpine Lakes Wilderness boundary
	Scenic	29.1	Alpine Lakes Wilderness boundary to near community of Tanner in NW 1/4 of Sec 13, T 23N , R.8E.
	Rec	4 2	Near community of Tanner to confluence with N. F. and M F Snoqualmie River
Taylor	Wild	6.6	Snoqualmie Lake to Quartz Creek Road
	Scenic	1 6	Quartz Creek Road to confluence with M. F Snoqualmie River.
Pratt	Wild	9.5	Headwaters at Melakwa Lake in NE 1/4 of Sec. 25, T 23N., R.10E. to confluence with M. F. Snoqualmie River.
S. F Snoqualmie	Rec	30 6	Headwaters at Source Lake in NE 1/4 of Sec. 30, T 23N., R.11E., to confluence with Snoqualmie River
Carbon	Wild	4.0	Headwaters at Carbon Glacier on NW slopes of Mt. Rainier to Ipsut Creek.
	Rec	28 4	Ipsut Creek to confluence with Puyallup River.

White	Scenic	20.0	Headwaters at Emmons Glacier on northeast slopes of Mt. Rainier to Huckleberry Creek.
	Rec	17.7	Huckleberry Creek to confluence with Clearwater River.
Clearwater	Wild	3.6	Headwaters in Clearwater Wilderness on Bearhead Mtn. in NW 1/4 of Sec. 28, T.18N., R.8E. to Clearwater Wilderness boundary.
	Rec	6.2	Clearwater Wilderness boundary to confluence with White River.
Greenwater	Wild	8.4	Headwaters in Norse Peak Wilderness on Castle Mtn. is SW 1/4 of Sec. 5, T.17N., R.11E. to Norse Peak Wilderness boundary.
	Rec	13.0	Norse Peak Wilderness boundary to confluence with White River.
TOTAL 47 Rivers		795.9 miles	

Suitability Determination

The last stage in studying potential Wild and Scenic Rivers is to evaluate eligible rivers and determine if the rivers are suitable. This step provides the basis for the decision to recommend designation or non-designation of the river. Factors used to determine suitability were:

1 The characteristics which do or do not make the area a worthy addition to the National System.

2. The current status of land ownership and use in the area, including the amount of private land involved and the uses on such land.

3 The reasonably foreseeable potential uses of the land and water which would be enhanced, foreclosed, or curtailed if the area were included in the Wild and Scenic Rivers System, and the values which could be foreclosed or diminished if the area is not protected as part of the system.

4. Public, State, and local government interest in designation of the river.

5 Other issues and concerns identified during the planning process

If a river was found to be eligible, its suitability, including a recommendation for river classification (wild, scenic, and recreation), was considered in the analysis of alternatives in the environmental impact statement accompanying this forest plan

Rational for the Inclusion of Rivers in Each Alternative:

Alternative A: Consistent with the current situation, this alternative includes 15 rivers listed in the 1982 National Park Service Nationwide Rivers Inventory on natural and free-flowing rivers. The only exception is Jim Creek, which was found not to be eligible.

Alternative B: The high timber goals of this alternative preclude recommending any eligible river segments within the National Forest boundary for wild and scenic designation.

Alternative C: Consistent with the goals of emphasizing primitive and semi-primitive recreation, scenery, and fish and wildlife habitat, in this alternative, all 47 rivers found to be eligible are recommended for designation as part of the National Wild and Scenic River system.

Alternative G: In keeping with the theme of maintaining natural ecosystems, this alternative recommends that all 47 rivers found to be eligible be recommended for designation as part of the National Wild and Scenic River system.

Alternative H: This alternative carries forward the five rivers found eligible and suitable at the Draft stage of this planning effort.

Alternative I: The designation of Wild and Scenic Rivers is not consistent with the goals and objectives of this alternative.

Alternative J: The Preferred Alternative includes the 30 rivers that were determined to be suitable, and that met the goals and objectives of this alternative. This decision was based on the criteria listed on page E-13.

The next pages include the list of suitable rivers, by alternative.

SILESIA CREEK

Whatcom County North Cascades National Park

Silesia Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters at Egg Lake, located in the North Cascades National Park in the NW 1/4 of Sec. 3, T.39 N., R.10 E. northward through the Mt. Baker Wilderness to the Canadian border. The entire length of the Creek is located either in the Mt. Baker Wilderness or North Cascades National Park.

Segment 1 - Headwaters in North Cascades National Park in NW 1/4 of Sec. 3, T.39 N , R 10 E. to the Canadian border (10.4 miles).

RIVER MILEAGE:

Study:	10 4 miles
Eligible:	10.4 miles
Forest Plan·	0.0 miles recommended for designation in preferred alternative

Note: This recommendation is pending evaluation by the National Park Service.

OUTSTANDINGLY REMARKABLE VALUES: Silesia Creek was found to possess "Outstandingly Remarkable" values for the following· wildlife.

The creek contains a large summer range for deer and bear as well as habitat for cougar, bobcats and mountain goats. A SOHA is also located in the drainage, with two nesting pairs of owls

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	10.4	None recommended	0.0

SUITABILITY DETERMINATION

Silesia Creek was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to lack of public and other agency support and few outstandingly remarkable values The remarkable value present for this river was wildlife, specifically a SOHA, which is already well protected by wilderness. River designation would not improve protection.

Appendix E
Silesia Creek

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
NPS, North Cascades National Park	4.0 miles	1,280 acres
Mt. Baker-Snoqualmie National Forest (Mt. Baker Wilderness-6.4 miles)	6.4 miles	2,048 acres
Total	10.4 miles	3,328 acres 1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: A large portion of this river segment has been identified by the BLM as an "area of critical mineral potential". According to the Bureau of Mines MILS data, two past-producing gold mines are located in Sec. 34, T.41 N., R.9 E. and in Sec. 3, T.40 N., R.9 E. (the Boundary Red Mountain and Gold Basin Mines, respectively). Based upon the available information, it appears that these mines lie outside the subject river boundary. However, any extension of mineralization could lie within the river corridor.

In addition to these two reported occurrences, the literature references the Silesia Placers (Sec. 2, T.40 N., R.9 E.). However, they have no reported production or development of any significance (Garrett, Jr., C.R., 1968). According to M.H. Staatz and others (1972), some sampling has been done in the area, but the sampling did not prove to be positive. BLM mining claim recordation data (1/19/89) indicates that at least 53 mining claims have been located in the vicinity of this river segment. Of the 53 claims, only 20 are considered to have not been abandoned or have not been declared to be null and void. Those 20 claims lie within Sec. 34, T.41 N., R.9 E. It is not known which, if any, lie within the river corridor.

The northern 6 to 7 miles are classified by the BLM as being prospectively valuable for geothermal resources. None of the area is considered to be prospectively valuable for other leasable mineral commodities. None of the area is encumbered by mineral leases or pending lease applications.

Based upon the available information, it appears that the northern portion of the area does have at least a low potential for the occurrence of precious and base-metal mineral resources and a potential for the occurrence of geothermal resources. However, it also appears that the area contains no known mineral resource of more than nominal value, and no serious interest in developing mineral resources in the river corridor has been recently expressed.

WATER RESOURCE DEVELOPMENT: A small hydroelectric dam near the Canadian border was used to power a mill for Boundary Red Mountain Mine. This dam has not been in use since the early 1900's. It is barely noticeable today and does not impede the free flowing character of the river. The Northwest Power Planning Council classified the Silesia River as "Protected" from hydropower development.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are no existing or planned roads, bridges, homes, farms or campgrounds along Silesia Creek.

Silesia Creek Trail #672 runs up and down the stream from the confluence of the West and Main forks. The downstream trail follows Silesia Creek to the Canadian border, but is difficult to find in places due to low use. The upstream trail ends at an old fire camp near Rapid Creek.

RECREATION ACTIVITIES: Dispersed recreation use of Silesia Creek is low due to limited access.

Recreation Activities (in RVD's, for National Forest system lands only):

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	25	40
Camping	110	170
Viewing (scenery, wildlife, driving for pleasure)	15	25
Misc. (hike, picnic)	25	50
TOTAL	175	285

WILDLIFE AND FISHERIES: Silesia Creek contains habitat for various wildlife species including cougar, bobcats, black-tailed deer, mountain goat and bear. A SOHA is located in the drainage with two nesting pairs of owls.

Silesia Creek contains populations of native rainbow trout and dolly varden. The creek flows into the Chilliwack River, a tributary to Canada's Fraser River. The Chilliwack is an important anadromous fishery.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Silesia Creek has a moderate stream gradient in its lower reaches. There are numerous small falls and rapids along its length. Small glaciers are found on Copper Mountain, located near the headwaters.

Water quality is excellent.

GEOLOGY: Silesia Creek passes through the steep and very rugged granitic mountains of the North Cascades. Continental and alpine valley glaciation has carved out a U-shaped valley and oversteepened the valley sidewalls. Lower sideslopes, dominated by stringers of conifers and brushy avalanche tracks, merge into massive, barren upper slopes where patches of snow often last through summer. Numerous side tributaries abound with waterfalls during spring runoff.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Silesia Creek and no prehistoric sites have been recorded. The lack of sites may be a result of the lack of survey of the drainage. During the historic period, the area was within the territory of the Nooksack Indians. No localities used for traditional religious practices are known within the potential wild and scenic river corridor.

During the historic period, the main use of the drainage was for trail access to adjacent areas. A historic mining trail followed the drainage for a short distance before turning east at the West Fork. In the early 1950's, Forest Service crews constructed a trail shelter on the West Fork, just upstream from its confluence with the main branch of Silesia Creek. The shelter is still present, but it has been determined ineligible for the National Register of Historic Places.

TIMBER: No timber harvesting activities have occurred along the United States side of Silesia Creek. However, extensive logging has taken place on the Canadian side of the border. The entire length of this segment is in the Mt. Baker Wilderness, thus it is not available for logging.

SOCIO-ECONOMIC EFFECTS: Silesia Creek can be accessed only by trail. The nearest community is Glacier, 33 miles away. This community, traditionally supported by logging and timber products, has been economically changed by an influx of retirees and Canadian vacation homeowners, as well as an increasing number of visitors to this scenic and recreation area.

CURRENT ADMINISTRATION: From its headwaters to the boundary of the Mt. Baker Wilderness, approximately 4 miles of Silesia Creek flow through North Cascades National Park Service Complex Wilderness administered by the National Park Service. The remaining 6.4 miles flow through the Mt. Baker Wilderness area before the river crosses the border into Canada. The wilderness is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Silesia Creek for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 500	
Costs of Implementation		$ 200
Development of Management Plan		3,900
Development Costs	72,000	
Operation and Maintenance Costs	1,000	
TOTAL - First Five Years	**$73,500**	**$4,100**

General administration and operation and maintenance costs are estimated to continue at $300 annually.

NORTH FORK NOOKSACK RIVER

Whatcom County — North Cascades National Park

The North Fork Nooksack River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The North Fork Nooksack River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters in the East Nooksack Glacier on Mt. Shuksan to the confluence with the South Fork of the Nooksack River.

Segment 1 - Headwaters in the North Cascades National Park in SW 1/4 of Sec. 30, T.39 N., R.10 E to the Mt. Baker Wilderness boundary in SW 1/4 of Sec 14, T.39 N , R.9 E (3.5 miles)

Segment 2 - Mt. Baker Wilderness boundary to Nooksack Falls diversion dam (9 9 miles).

Segment 3 - Nooksack Falls diversion dam to Nooksack Falls power plant (1.6 miles).

Segment 4 - Nooksack Falls power plant to the fish hatchery near Kendall, Washington (18 8 miles).

Segment 5 - Fish hatchery to the confluence with the South Fork Nooksack River (9.5 miles).

RIVER MILEAGE:

Study.	43.3 miles
Eligible:	43.3 miles
Forest Plan:	43.3 miles recommended for designation in preferred alternative

Note This recommendation is pending evaluation by the National Park Service portion of the river.

OUTSTANDINGLY REMARKABLE VALUES: The North Fork Nooksack River was found to possess "Outstandingly Remarkable" values for the following: scenic, recreation, fisheries, wildlife, and historical/cultural.

Scenic views of Mt. Shuksan and Mt. Baker can be viewed along the river. There are rapids near the confluence with Wells Creek and the 100-foot high Nooksack Falls.

The river sustains substantial boating use with a significant potential for increased use. Glacier run-off allows boating from early spring to August.

The river provides habitat for a number of anadromous fish species, including an important spring chinook salmon run.

R.9E.

R.10E.

Mountain goats, trumpeter and tundra swans, spotted owls, black-tailed deer and the federally listed Threatened and Endangered bald eagle all inhabit the North Fork drainage.

The early logging history in the North Fork Nooksack Watershed can be interpreted at many sites. A miner's cabin is listed on the National Register of historic places. Likewise, the Nooksack Falls hydroelectric plant is listed on the Register. It is the second oldest and smallest plant in Washington.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	3.5	Wild	3.5
Segment 2	Scenic	9.9	Scenic	9.9
Segment 3	Recreation	1.6	Recreation	1.6
Segment 4	Scenic	18.8	Scenic	18.8
Segment 5	Recreation	9.5	Recreation	9.5

SUITABILITY DETERMINATION:

The North Fork of the Nooksack River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the high number of outstandingly remarkable values, public support for designation, and interest of other public agencies. The North Fork of the Nooksack was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982. More recently, in 1988, the Washington State Scenic River Assessment included the North Fork as a river "possessing the natural, cultural, and recreational values that would make it a suitable addition to the Washington State Scenic Rivers System".

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
NPS, North Cascades National Park	2.2 miles	704 acres
Mt. Baker-Snoqualmie National Forest	1.3 miles	416 acres
(Mt. Baker Wilderness-1.3 miles)		
Segment 2		
Mt. Baker-Snoqualmie National Forest	9.9 miles	3,168 acres
Segment 3		
Nooksack Power Plant (Private)	1.6 miles	512 acres
Segment 4		
Mt. Baker-Snoqualmie National Forest	8.0 miles	2,560 acres
Private	7.4 miles	2,368 acres
State	3.4 miles	1,088 acres
Segment 5		
Private	9.5 miles	3,040 acres
Total	43.3 miles	13,856 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Even though the subject area has no reported mineral resource production of significance, a small portion of Segment 2, near Price Lake, has been identified by the BLM as an "area of critical mineral potential". The Bureau of Mines MILS data and Moen (1969) indicate a number of reported mineral resource occurrences within or immediately adjacent to the river corridor. Of these occurrence the following appear to be of most interest:

The Great Excelsior (T.39 N., R.8 E., Sections 5 and 6): major exploration is on-going to determine if mineralization extends north and south of the presently identified ore body, which is reported to contain 5.9 million tons grading 0.033 ounces of gold and 2.047 ounces of silver per ton.

The Glacier Mine (T 39 N., R.7 E., Sections 4, 5, 8, 9): It is reported to have potential for the occurrence of copper, but to date no ore deposits worthy of development have been identified.

The First Chance Mine (T.40 N., R.8 E., Section 31): It is reported to contain mineralized rock carrying up to 0.75 ounces of gold per ton, however, an economically viable deposit has not been identified.

The Tooker Mine (T.40 N., R 8 E., Section 31): It is reported to contain disseminated pyrite and marcasite in altered Mesozoic volcanic and sedimentary rocks, which carries as much as 2.9 ounces of silver and 0.103 ounces of gold per ton.

Other prospected occurrences of copper, silver, gold, lead, zinc and stone are reported for T.40 N., R.8 E., Section 32 and 33, T.39 N., R.9 E , Section 6, T.40 N., R.8 E , Section 33. None of these are reported to be mineral deposits of significance.

BLM mining claim data indicates 292 mining claims have been located within or adjacent to the river lying between T.39 N., R.7 E. Section 5 and T.40 N., R.8 E., Section 34. Of these claims, 161 have not been abandoned or declared to be null and void. It is not known which of these, if any, actually lie within the river corridor.

The western 20 to 24 miles have been classified as being prospectively valuable for oil and gas with the eastern 33 miles classified prospectively valuable for geothermal resources. An area from one mile east of the town of Glacier westward has been classified prospectively valuable for coal resources. None of the area has reported occurrences of such commodities.

Based upon the available information, it appears that the section of the river lying near Sections 4, 5 and 6, T.39 N., R.8 E. and Sections 31, 32 and 33, T.40 N , R.8 E. has at least a moderate potential for the occurrence of locatable mineral resources. Also a portion of the river lying outside the previously described lands but between Section 5, T.39 N., R.7 E. and Section 34, T.40 N., R.8 E. has at least a low potential for the occurrence of locatable mineral resources. Numerous unpatented mining claims have been located and maintained along that portion of the river corridor, which does indicate a continuing interest in the area. Most of the interest appears to be concentrated on the Excelsior mine area. The area also has potential for the occurrence of oil and gas, coal and geothermal resources. However, the pre-existing lease applications have been withdrawn and no serious interest in the leasable minerals of the area is currently being expressed.

WATER RESOURCE DEVELOPMENT: A diversion dam exists at Nooksack Falls in conjunction with the Nooksack Falls Hydroelectric Project facility. There are plans to rebuild or enlarge this facility. All facilities of this project with the exception of existing transmission lines are located on private land. A license application has been submitted.

Hydroelectric projects have been proposed for a number of tributaries to the North Fork Nooksack. Licenses for projects on Ruth and Swamp Creek were issued by the Federal Energy Regulatory Commission in 1986. License applications have been submitted for projects on Wells Creek, Boulder Creek, and Canyon Creek. License applications have also been submitted for projects on Deadhorse Creek, Bagley Creek and Glacier Creek, and the Forest Service has recommended licensing of these projects. Fossil Creek, Gallop Creek, Cornell Creek, West Cornell Creek, Thompson Creek, Cascade Creek and Barometer Creek all have preliminary permits issued. A summary is listed below:

Tributary	**Proposed Facilities Within Corridor**	**Megawatts**
Fossil Creek	Transmission lines	1.5
Deadhorse Creek	Transmission lines	7.9
Wells Creek	Transmission lines, powerhouse	15.3
Boulder Creek	Transmission lines	4.0
Canyon Creek	Transmission lines	12.2
Gallop Creek	Transmission lines	5.4
Cornell Creek	Transmission lines	5.4
W. Cornell Creek	Transmission lines	5.4
Thompson Creek	Transmission lines	3.6
Cascade Creek	Transmission lines	1.0
Nooksack Falls 1/	Transmission lines, powerhouse, diversion structure, penstock	8.0
Barometer Creek	Transmission lines	1.0
Bagley Creek	Transmission lines, powerhouse	1.5
Swamp Creek	Transmission lines	3.5
Ruth Creek	Transmission lines	2.8
Glacier Creek	Transmission lines	5 0

1/ *Nooksack Falls project is on the main Nooksack River, not a tributary.*

Nineteen miles of river are in power site classification.

The Nooksack River is listed by the Washington State Department of Ecology as a "River of Statewide Significance" based on its water volume. The river is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Mt. Baker Highway (State 542) parallels the river on the north side from Shuksan to Douglas Fir Campground. At Douglas Fir Campground it crosses the river and continues on the south side of the river to Warnick. At Warnick, the highway crosses the river again and continues on the north side of the river to its confluence with the South Fork Nooksack.

The North Fork Road (F.S Rd. #37) parallels the south side of the river from Nooksack Falls to the point that it meets the Mt. Baker Highway (just south of Douglas Fir Campground).

Bridges cross the river at: The Mt. Baker Highway crosses at Nooksack Falls, upstream from Silver Fir Campground, and at Warnick. F.S Rd. #3070 crosses upstream of Silver Fir Campground, F.S. Rd. #33 crosses at Douglas Fir Campground, and two logging roads cross upstream of Ruth Creek.

Five developed campgrounds are located along the river within the Forest boundary: Douglas-fir (30 sites), Nooksack (18 sites), Excelsior (a reservation-only group site), Silver Fir (21 sites) and Hannegan (6 sites). There are 3 campgrounds outside the Forest.

An old railroad grade parallels the river from Glacier to Kendall. It was used by Chicago, Milwaukee, St. Paul and Pacific Railways.

The Excelsior Pass Trailhead #670 is located on Mt. Baker Highway near Nooksack Falls. Goat Mountain Trailhead #673 is on Forest Road 32, 5 miles west of Hannegan Campground Horseshoe Bend Interpretive Trail is located across from Douglas-fir Campground.

A trail is proposed to run from Maple Falls to Glacier.

There is river access at Glacier, west of Maple Falls and below Nooksack Fish Hatchery.

The towns of Glacier, Kendall and Maple Falls are situated along the river. Farms and home sites are common downstream from the Forest boundary at Glacier Increased recreation home developments are occurring along some stretches of the river.

The Nooksack Fish Hatchery is located at Kendall Creek. Kendall Cemetery is located 1/16 mile from the river corridor, 1/4 mile below the fish hatchery.

Up Deadhorse Creek, there is an off-channel rearing pond for Chinook.

Planned fishery projects along the river include an acclimation pond on Deadhorse Creek, a hatchery project in Rutsatz Slough and a rearing and spawning channel 1 mile from Rutsatz Road.

Above the confluence with Canyon Creek, there is a solid waste transfer site.

There are 500 yards of riprap near the intersection of Highway 542 and Forest Road 3070, 1000 yards along the river adjacent to the Silver Fir Campground; 2000 yards along the Mt Baker Highway near Maple Falls and Bell Creek; and 2000 yards near the Highway 9 bridge crossing.

A powerline crosses the river .7 miles upstream from the confluence with the Nooksack River.

There are 2 sand and gravel quarries located within the river basin. In Sections 9 and 10, T.39 N., R.5 E. there is an active, 1 person operation. In Section 28, T.39 N., R.5 E., there is an inactive quarry.

The Puget Power Intake is located above Nooksack Falls.

There is a limited amount of prime agricultural farmland along the river. Most farmland is used for pasturing cattle and farm animals.

RECREATION ACTIVITIES: The North Fork Nooksack is a popular river for fishing enthusiasts and has a high potential for other boating use. Downstream from Nooksack Falls, fishing use is moderate to high. Rafting use, while presently low, has significant growth potential. Glacial run-off allows rafting into August, when other area rivers are already too low. From Nooksack Falls to the *Douglas-fir Campground, canoeing and kayaking use is light. Boating use* increases downstream from the campground, mainly by Canadian visitors. The river is viewed as above average to outstanding by kayak clubs due to its challenge and hydraulics. From time to time, there are commercial guided canoe and kayak trips.

The most popular attraction in the area is Mt. Baker. In the winter, the ski area draws skiers to the mountain. In summer, the Heather Meadows area at the base of the mountain, and numerous hiking, camping and picnicking opportunities attract visitors. Mt. Baker Highway is a designated Scenic Byway. Sightseeing by car is a very popular recreation activity.

Off-road recreation vehicle use is heavy on logging roads.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	500	825
Waterplay (swim, wade)	200	300
Fishing, Hunting	2,500	3,600
Camping	20,900	31,350
Viewing (scenery, wildlife, driving for pleasure)	1,500	2,280
Misc. (hike, picnic, berry picking, etc.)	3,000	5,880
TOTAL	28,600	44,235

WILDLIFE AND FISHERIES: Bald eagles, a federally listed Threatened and Endangered species, utilize the lower 3 to 5 miles of the river. A SOHA is located within the North Fork Nooksack Research Natural Area. The river corridor supports an extensive winter range for the black-tailed deer. Mountain goats can be seen from the upper reaches of the river, particularly in the Goat Mountain and Mt. Sefrit areas. Trumpeter and tundra swans are seen along the upper river during winter.

Spring chinook, coho, pink and chum salmon along with winter steelhead swim up river to the Excelsior Powerhouse, located below Nooksack Falls. The falls act as a total block to upstream migration. The spring chinook are native to the area and represent one of the better spawning runs in Puget Sound. Most *chinook spawning occurs in the North Fork, with juvenile populations rearing in* all accessible waters. Coho and some spring chinook have year round habitation. Pink and coho salmon use numerous North Fork tributaries.

Deadhorse Creek has a large population of pink salmon. The Nooksack Salmon Hatchery, located on Kendall Creek, produces coho, fall chinook, spring chinook and chum salmon. Resident cutthroat, rainbow trout and eastern brook trout are found in the upper reaches of the river.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: From its headwaters along its first six miles, the North Fork Nooksack River descends over very steep gradients with numerous cascades and falls. In the next five miles, the valley floor broadens, allowing moderate stream gradients with good pool-riffle balance. Below Nooksack Falls, the canyon narrows to form deeply incised cascades and rapids. Below Glacier Creek, the stream channel is unstable, which contributes to braiding of the stream.

From the headwaters to the confluence with the Middle Fork, the North Fork Nooksack drains a 293 square mile area with an annual runoff at more than 1,000,000 acre-feet. Streamflows reach a maximum in mid-June with up to 5000 cubic feet per second (cfs) at Deming stream. Another peak occurs in mid-December with 4400 cfs. The low flows occur in late August at a little less than 2000 cfs and in mid-winter when tributaries are frozen and precipitation falls as snow There are over 100 tributaries that contribute to the river's volume, with one-third of the total volume originating from Wells, Glacier and Canyon Creeks

A distinguishing feature of this river is the glacial runoff 6 to 8 months of the year. The glacial melt discolors the water. Four major glaciers, plus numerous smaller glaciers and perennial snow fields at the headwaters, help feed the river.

GEOLOGY: The upper Nooksack River area consists of ancient, uplifted and deeply dissected erosion surfaces cut into a complex series of granitic metamorphic rocks The surfaces are overlain by early tertiary sandstones, shales and coal The North Fork flows through a valley which was initially stream-cut and later modified by glaciation. Steep sideslopes rise to over 7,000 feet elevation. The Nooksack Falls area at the confluence of Wells Creek is a steep, narrow canyon.

Below Glacier Creek, the valley broadens then alternately narrows and widens for eight miles. The valley floors are underlain by a fill several hundred feet thick of glacial and stream sediments.

CULTURAL RESOURCES No systematic archeological survey has been made of the North Fork Nooksack River. Existing information comes from surveys made in conjunction with individual federal projects and published historical sources. No prehistoric sites have been recorded within the potential wild and scenic river corridor. The lack of sites is believed to reflect survey patterns rather than lack of use During the historic period, the area was within the territory of the Nooksack Indians. Locations used by the Nooksacks to practice their traditional religion exist within the river corridor.

During the late nineteenth and early twentieth centuries, thousands of mining claims were located in the North Fork watershed. Only the Lone Jack and Red Mountain lodes produced substantial amounts of ore, and neither is within the river corridor Further upriver, one of the early miners' cabins is still standing and is listed on the National Register of Historic Places.

Logging began in the upper Nooksack drainage during the first decade of the twentieth century, but did not make a significant impact on the valley above Glacier until about 1940. Logging and mining led to construction of a railroad to Glacier by 1910. In turn, the railroad facilitated construction of the Nooksack Falls hydroelectric project, the second oldest and smallest hydroelectric plant in Washington. The plant has been listed on the National Register of Historic Places.

Citizens of Bellingham were also promoting Mt. Baker as a recreation area during the early years of this century. Their efforts resulted in the extension of the road from Excelsior (Nooksack Falls) to Heather Meadows in 1921. Subsequent recreation developments, such as the Mt. Baker Lodge, occurred largely outside of the North Fork corridor, but the popularity of Mt. Baker did increase recreation use of the river below Excelsior.

The level of twentieth-century activity in the drainage necessitated an administrative presence on the part of the Forest Service, represented by the Glacier Ranger Station. The Station office is listed on the National Register of Historic Places as an unusually fine example of Civilian Conservation Corps construction.

TIMBER: Sideslopes away from the river have been logged extensively. To the west of the Forest boundary over 118,024 acres have been impacted by timber harvesting activities. Recent logging has concentrated in Ruth, Swamp and Razor Hone Creeks.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
183.5	2.946	2.870

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: None within the Forest boundary. Limited grazing on private land.

SOCIO-ECONOMIC EFFECTS: State Highway 542 runs along the North Fork of the Nooksack River, through the communities of Deming, Kendall, Maple Falls, and Glacier. These communities, historically supported by the timber industry, have been impacted by the creation of the North Cascades National Park, the Mt. Baker Wilderness, Mt. Baker ski facilities, and the recreation pursuits of the metropolitan populations of Bellingham and Vancouver, B.C. Canadians come in increasing numbers to the area acquiring vacation homes in the mountainous communities and using the recreation resources of the area. Between 1968 and 1975, over 5,000 home sites, trailer lots and condominiums were platted or constructed.

The great diversity of recreation opportunities include alpine skiing, hunting, fishing, hiking, camping, climbing and sightseeing.

Significant capital investments are planned for the Forest Service Glacier Public Service Center and Heather Meadows. River designation would add to the diversity of activities in the drainage and is expected to make it more economically viable for businesses catering to the recreation public.

The fisheries resource is considered significant on the North Fork Nooksack River The Nooksack salmon hatchery located 5 miles downstream of the town of Maple Falls helps maintain this important anadromous fishery.

CURRENT ADMINISTRATION: From the headwaters downstream 3.5 miles, the river flows within North Cascades National Park Service Complex Wilderness, administered by the National Park Service. From the park boundary downstream to the Forest boundary, the river corridor flows through the Mt. Baker Wilderness and thence through other National Forest lands administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, most of the shoreline of the North Fork Nooksack River has been classified as Conservancy by Whatcom County. The exception is a 1.5 mile section below Maple Creek, which is classified Natural. These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Natural designation denotes areas characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relatively intolerant of intensive human use.

Lands along the North Fork Nooksack, outside of federal jurisdiction, are mostly zoned for Forestry Use by Whatcom County. There are several developed areas along the river that are zoned for Rural Use, with 1 dwelling per 5 or 10 acre tracts

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Fork Nooksack River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 5,000	$ 50,000
Costs of Implementation		15,000
Development of Management Plan		78,600
Development Costs	600,000	50,000
Operation and Maintenance Costs	360,000	5,000
TOTAL - First Five Years	**$965,000**	**$198,600**

General administration and operation and maintenance costs are estimated to continue at $84,000 annually.

Appendix E
North Fork Nooksack River

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Trailled	296
		Wilderness-General Trailless	317
		Wilderness-Special	21
Segment 2	Scenic	Semi-Primitive, Non-Motorized Recreation	126
		Scenic Corridor (Foreground)	1,097
		Scenic Corridor (Middleground)	588
		Old Growth Habitat (spotted owl)	845
		Research Natural Area	422
		Developed Recreation	42
Segment 3	Rec	Old Growth Habitat (spotted owl)	21
		Scenic Corridor (Foreground)	357
		Scenic Corridor (Middleground)	147
Segment 4	Scenic	Scenic Corridor (Foreground)	1617
		Scenic Corridor (Middleground)	252
		Developed Recreation	84
		Goat Habitat	21
		T & E Species	105

WELLS CREEK

Whatcom County

Wells Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

Wells Creek was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters near Table Mountain on Ptarmigan Ridge to its confluence with the North Fork Nooksack River.

Segment 1 - Headwaters at Galena Chain Lakes to the Road 33 bridge, east edge of Sec. 16, T.39 N., R.8 E. (2.6 miles)

Segment 2 - Road 33 bridge to the confluence with North Fork Nooksack River (3.4 miles).

RIVER MILEAGE:

Study:	6.0 miles
Eligible:	6.0 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Wells Creek was found to possess "Outstandingly Remarkable" values for the following: wildlife.

Mountain goat winter range and a SOHA are located within the drainage.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	2.6	Not recommended	0.0
Segment 2	Scenic	3.4	Not recommended	0.0

SUITABILITY DETERMINATION:

Wells Creek was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to low recreation use, lack of anadromous fisheries, and high competing resource values. The remarkable value for this creek was wildlife, specifically a SOHA, located off of the river and already adequately protected.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Mt. Baker Wilderness-1.5 miles)	2.6 miles	864 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	3.3 miles	1,056 acres
Private (Nooksack Power Plant)	0.1 miles	32 acres
Total	6.0 miles	1,920 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Even though the subject area has no current reported mineral resource production of significance, a small portion of this river has been identified by the BLM as an area of "critical mineral potential". A portion of the area does have at least a moderate potential for the occurrence of gold and silver resources. Bureau of Mines MILS data and Moen (1969) indicate a number of mineral resource occurrences do occur within or immediately adjacent to the river corridor. Of these occurrences, the following are of interest:

> Great Excelsior (T.39 N , R.8 E , Section 6): Major exploration is on-going to determine if mineralization extends north and south of the presently identified ore body, which is reported to contain 5 9 million tons grading 0.33 ounce gold and 2.047 ounces silver per ton.
>
> The Wells Creek Gossan (T.39 N., R.8 E., Section 5)· Is reported to contain disseminated fine-grained pyrite in strongly sheared and altered Middle Jurassic andesite assaying up to 0.20 ounces of silver and 0 40% copper.

Other prospected occurrences of gold, silver and copper are reported for T.40 N , R.8 E., Section 31, 32 and 33.

BLM mining claim recordation data indicates that 154 claims have been located within or adjacent to the segment of the river lying in Sections 4,5 and 6, T.39 N., R.8 E., and in Sections 31 and 32, T. 40 N., R.8 E. Of these 154, 62 have been abandoned or declared to be null and void. What portion of those active claims lie within the river corridor is not presently known.

The entire river segment has been classified prospectively valuable for geothermal resources. However, none of it is classified "prospectively valuable" for other leasable mineral commodities. Sections 4, 5, 6, 8 and 9, T.39 N., R.8 E. have been encumbered by two geothermal lease applications. Both applications have been withdrawn.

Based upon the available information, it appears that the section of the river lying near Sections 4, 5 and 6, T.39 N., R.8 E. and Sections 31, 32 and 33, T.40 N., R.8 E. has at least a moderate potential for the occurrence of locatable mineral resources. Numerous unpatented mining claims have been located and maintained along that portion of the river corridor, which does indicate a continuing interest in the area with most interest being directed toward the Excelsior Mine and possible extensions of that ore body. The area also has some potential for the occurrence of geothermal resources, but the pre-existing lease applications have been withdrawn and no serious interest in the leasable minerals of the area is currently being expressed.

WATER RESOURCE DEVELOPMENT: Prior to the classification, a small hydroelectric project application was submitted to FERC. Proposed project facilities within the river corridor consist of a transmission line, a powerhouse, and a diversion structure and penstock. The project capacity will be 15.3 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: A gravel road (#33) parallels the lower 3.3 miles of the area. However, it is not visible from the creek for the first two miles. There is no road up stream of the confluence with Bar Creek.

One bridge crosses Wells Creek just above the fork with Bar Creek.

The Chain Lakes Loop Trail #682 begins at the Artist Point Parking Lot at the end of the Mt. Baker Highway. The trail passes near the headwaters of Wells Creek.

There are 300 yards of rip-rap along the river at river mile 5.5. There are also culverts at this location.

A stream gauge is associated with the small hydro project.

No homes or farms exist along Wells Creek.

RECREATION ACTIVITIES: The majority of recreation opportunities along the creek are nonwater oriented. Among these are driving for pleasure, with excellent vistas of Mt. Baker to the south. Hunting and hiking are also enjoyed in the drainage basin.

Wells Creek is unsuitable for rafting, canoeing and kayaking, or any other type of boating due to a low volume of water. No portion of the river is appropriate for swimming, and fishing use is only incidental due to few opportunities.

No developed campgrounds are present, and there is no opportunity for any development.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	100	144
Camping	10	15
Viewing (scenery, wildlife, driving for pleasure)	75	114
Misc. (hike, picnic, berry picking, etc.)	10	20
TOTAL	195	293

WILDLIFE AND FISHERIES: There are resident populations of rainbow trout and dolly varden. No salmon can use the creek due to a series of impassable cascades and falls located at the mouth. A SOHA and a critical mountain goat winter range lie adjacent to the creek.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: A 100-foot falls lies at the mouth of Wells Creek. Cascades and rapids occur for approximately 1 mile upstream. Mazama Falls is in the upper reaches.

The stream gradient is steep, falling some 4,300 feet in 7.7 miles. The stream bottom is mostly boulders and rubble.

Glaciers are present at the headwaters, especially from Mazama and Sholes Glaciers. The creek has discoloration due to glacial runoff 6-8 months of the year, which may limit fish production.

GEOLOGY: Wells Creek originates on the flanks of Mt. Baker and flows into the North Fork Nooksack River. Geology of the headwaters is composed of pyroclastics and andesitic flows associated with Mt. Baker. Extending downstream the stream passes through andesites and metasediments A unique geologic feature of Wells Creek is that the middle portion of the stream occupies a U-shaped valley that is underlain by glacial till and hard andesitic bedrock. This has restricted downcutting and as a result the stream through this section is very wide, shallow, and braided. As it flows past the contact from andesite to softer metasedimentary rocks, it has been rapidly downcutting since the glacial period and has formed a steep V-shaped canyon extending to the North Fork

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Wells Creek drainage. Available information comes primarily from published historical sources No prehistoric sites have been recorded within the potential wild and scenic river corridor. During the historic period, the area was within the territory of the Nooksack Indians. The area includes localities identified by the Lummi, Nooksack and Duwamish tribes for the practice of their traditional religion

In 1899, the Great Excelsior mine was located near the mouth of Wells Creek, which lead to further mineral discoveries up Wells Creek. Power was brought to the mine from the Nooksack Falls powerhouse in 1914. The development of these and other mines along the North Fork Nooksack facilitated the construction of a road along the Nooksack River. A wagon road provided access to Excelsior Mine. Mining interests along Wells Creek waned by 1920. Logging did not significantly impact the tributary drainages above Glacier until around 1940. None of the sites associated with these activities are listed on the National Register of Historic Places.

TIMBER: An old burn and logged-over land dominate the landscape for the first 3 miles upstream from the mouth of Wells Creek. The next 2 miles are in secon growth forest, pole size stands. The last 2 miles to the headwaters contain old growth forests.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
	Preferred	Preferred
Total	Alternative	Alt. with
Timber	w/o W&SR	Eligible W&SR
Volume	Designation	Designation
(MMBF)	(MMBF/yr.)1/	(MMBF/yr.)1/
44.1	.484	442

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: State Highway 542 is located at the confluence of Wells Creek and the North Fork Nooksack. The communities in the area were historically supported by the timber industry. However, the great diversity of recreation opportunities in the area have created a large tourist industry with Mt. Baker being the major draw.

CURRENT ADMINISTRATION: The upper 2 miles of Wells Creek are within the Mt. Baker Wilderness. The entire river is on the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Wells Creek for the next five years:

	Expenses Expected Independent of Designation	**Addit. Expenses with Designation**
General Administration	$1,000	$2,000
Costs of Implementation		2,000
Development of Management Plan		4,800
TOTAL - First Five Years	**$1,000**	**$8,800**

General administration and operation and maintenance costs are estimated to continue at $600 annually.

MIDDLE FORK NOOKSACK RIVER

Whatcom County

The Middle Fork Nooksack River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Middle Fork Nooksack River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters on the slopes of Mt. Baker to its confluence with the North Fork Nooksack River.

Segment 1 - Headwaters on Deming Glacier in the NW 1/4 of Section 35, T.38 N , R.7 E.to Ridley Creek (2.7 miles).

Segment 2 - Ridley Creek to the diversion dam in the NE 1/4 of Section 19, T.38 N., R 6 E. (10.2 miles).

Segment 3 - Diversion dam to the confluence with the North Fork Nooksack River (7.1 miles).

RIVER MILEAGE:

Study:	20.0 miles
Eligible:	20.0 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

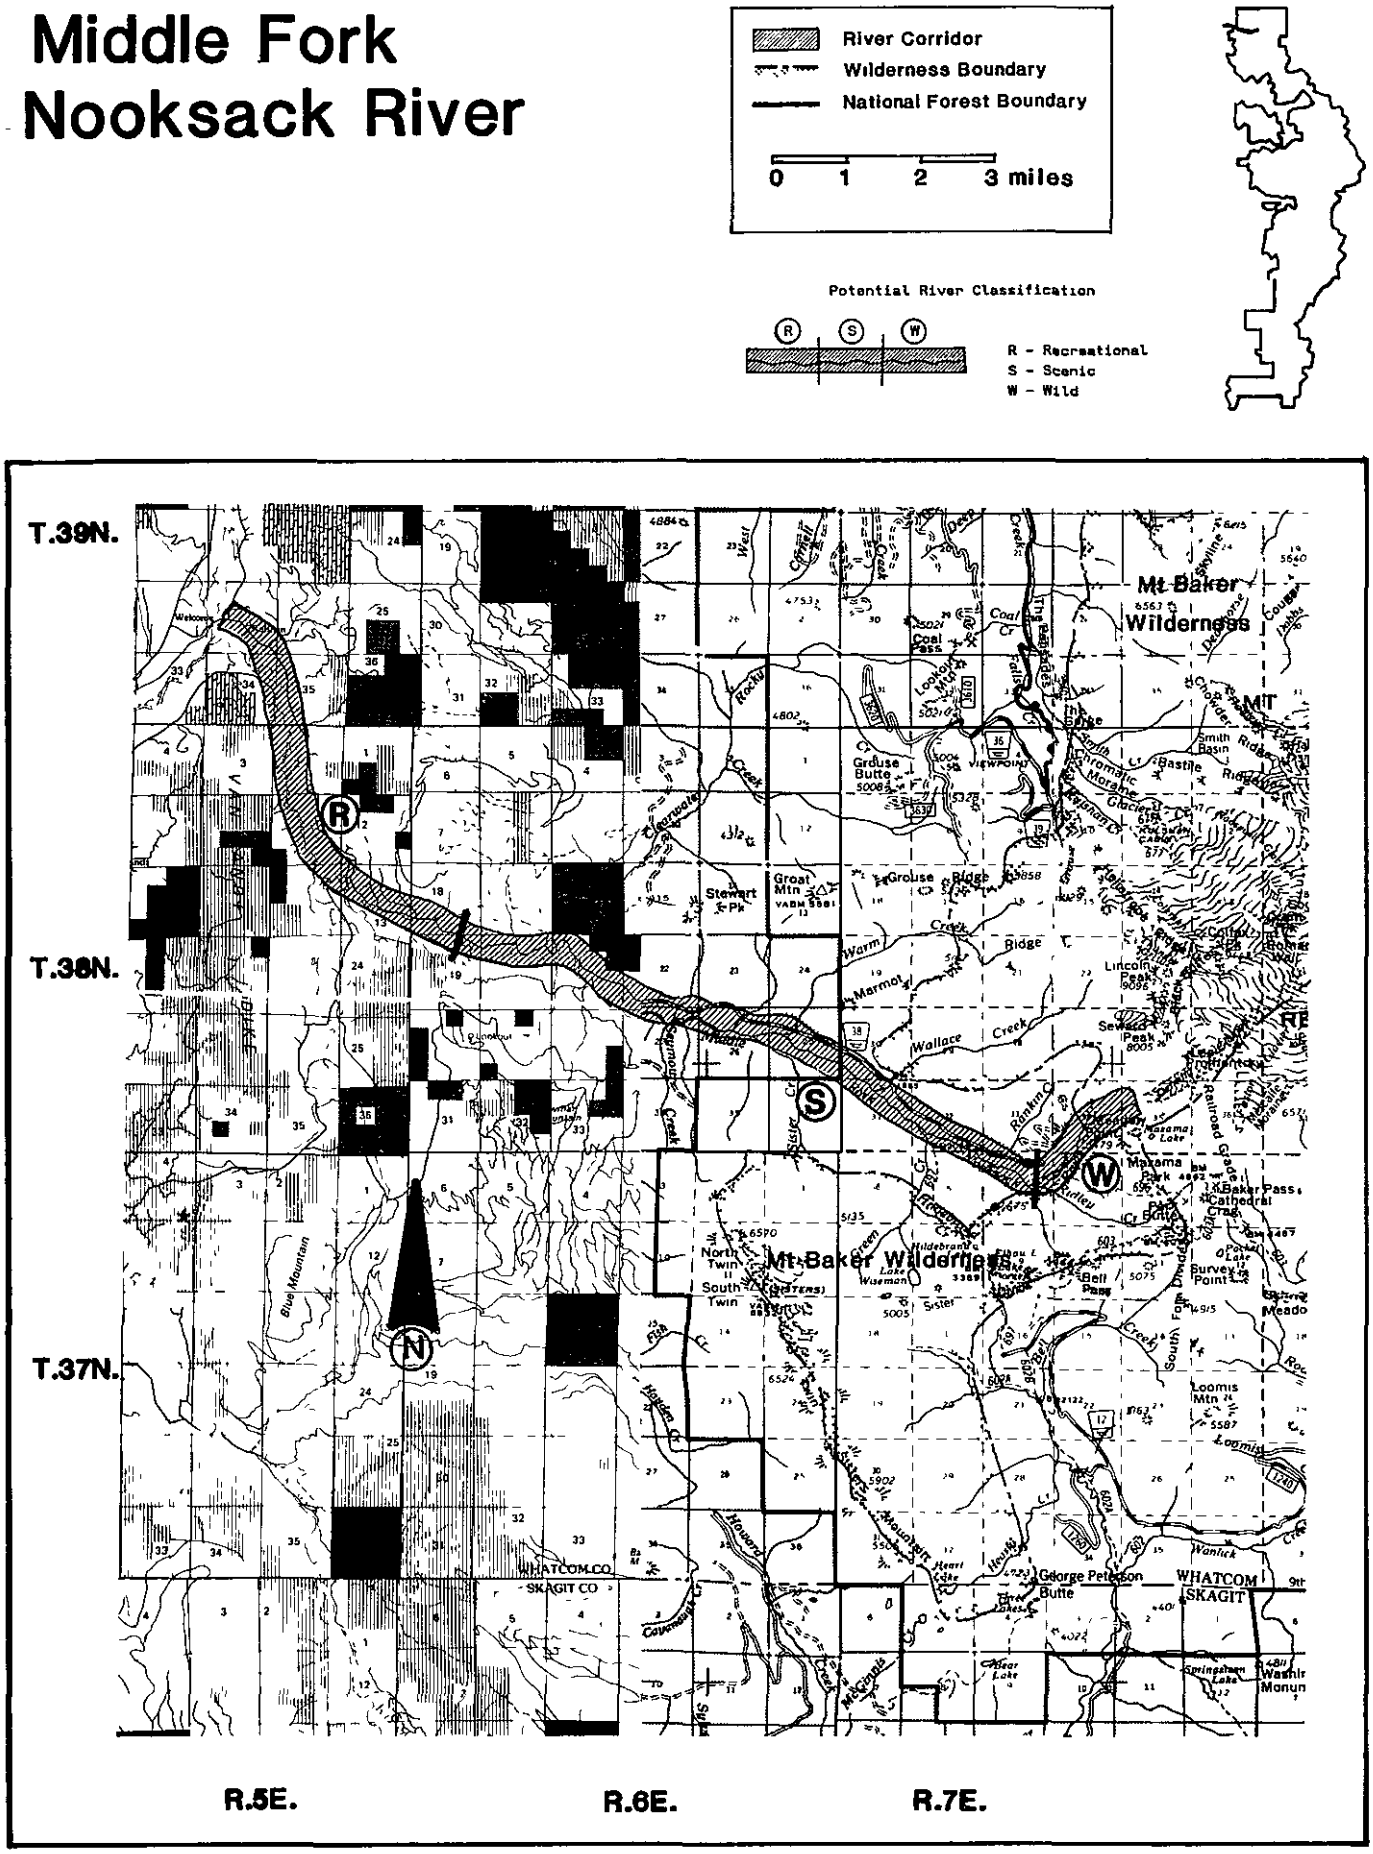
OUTSTANDINGLY REMARKABLE VALUES: The Middle Fork Nooksack River was found to possess "Outstandingly Remarkable" values for the following: wildlife.

Excellent black-tailed deer, Roosevelt elk and mountain goat winter range are found along the river corridor. A SOHA has been designated in the Middle Fork Nooksack drainage.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	2.7	Not recommended	0 0
Segment 2	Scenic	10.2	Not recommended	0.0
Segment 3	Recreation	7.1	Not recommended	0.0

Middle Fork Nooksack River



SUITABILITY DETERMINATION:

The Middle Fork of the Nooksack River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to a majority (70%) of the river being off of the Forest, in state or private ownership. The river received only moderate public support for designation and has high competing resource values within the National Forest. Low water flow and discoloration due to glacial runoff are limiting to fish production on the Middle Fork.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt Baker-Snoqualmie National Forest (Mt. Baker Wilderness-1.0 miles)	2.7 miles	864 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	3.4 miles	1,088 acres
Private	5.5 miles	1,760 acres
State	1.3 miles	416 acres
Segment 3		
Private	3.6 miles	1,152 acres
State	3.5 miles	1,120 acres
Total	20.0 miles	6,400 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified as areas of critical mineral potential. A review of available literature including Bureau of Mines MILS data indicates there are no reported occurrences of locatable mineral resources. BLM mining claim recordation data indicates that the area is not encumbered by any unpatented mining claims. The Bureau of Mines MILS data does indicate two occurrences of stone deposits in T 39 N., R.5 E., Section 28, one of which has provided for production in the past. However, it appears that they lie outside the river corridor.

The Bureau of Land Management has classified the western 14 miles as being prospectively valuable (PV) for oil and gas, the eastern 14 miles as being "PV" for geothermal resources, and the eastern 9 miles as being "PV" for coal resources. None of the area, however, has known occurrences of such resources. While the area or immediately adjacent areas have been encumbered by at least eight leases and 4 lease applications, all eight leases have terminated and the four applications have been withdrawn.

Based upon the available information, it appears the area has little if any potential for the occurrence of locatable minerals. It does have at least a low potential for the occurrence of geothermal, coal and oil and gas resources. However, it also appears that the area contains no known mineral resources of more than nominal value, and no serious interest in developing either leasable or locatable mineral resources in the river corridor is currently being expressed.

Appendix E
Middle Fork Nooksack River

WATER RESOURCE DEVELOPMENT: The Middle Fork Nooksack River is part of the Bellingham Municipal Watershed. A diversion dam exists at the 7.2 mile point, which feeds water to Lake Whatcom.

The Middle Fork Nooksack River is designated a power site. The river is listed by the State Department of Ecology as a "River of Statewide Significance" based on water volume.

The river is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A preliminary permit for a hydroelectric project has been issued by FERC on Clearwater Creek, a tributary of the Middle Fork Nooksack. Proposed facilities within the river corridor consist of the transmission line. Project capacity will be 1.2 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The Mosquito Lake Road takes off from the Mt. Baker Highway near the confluence of the Middle and North Forks of the Nooksack River. The road parallels the river to mile 5, crossing the Middle Fork Nooksack and proceeding south past Spring Lake, Mosquito Lake and Jorgenson Lake. Mine traffic occurs 3 months a year.

At Porter Creek a Forest Road forks south-east from Mosquito Lake Road and follows the Middle Fork Nooksack nearly to the Forest boundary.

Three bridges cross the river at: Mosquito Lake Road crossing (5 mile point), the diversion dam (7.2 mile point) and the section 21 mining road (9.5 mile point). A trail bridge crosses at mile post 11 on Forest Road 38. A road bridge is also planned at this location.

The Ridley Creek Trail #696 begins near the end of Forest Road 38. The trail parallels the Middle Fork for 1-1/2 miles to the junction with Ridley Creek. The trail crosses the Middle Fork near the creek mouth and continues up Ridley Creek. There is no bridge at the crossing.

The Elbow Lake Trailhead #697 is located on Forest Road 38. The trail crosses the Middle Fork and heads up Green Creek to Elbow and Dorene Lakes.

Farms, residences and the town of Kulshan are all located along the lower six miles of the river.

There is 6500 yards of rip-rap along the Mosquito Lake Road swamp, and 1000 yards on the mining road bridge.

An old railroad track and camp are located 12 miles upstream.

An old trail and ranger station site from the 1930's are located near the river between Warm and Wallace Creeks.

A fish passage is planned at the Middle Fork Dam, 7 miles upstream from the mouth of the river.

An aqueduct runs southwest from the diversion dam below Falls Creek. There is also river access at this point.

RECREATION ACTIVITIES: Public access to the river is limited by private ownership and geographical isolation. No developed trails or campgrounds are located along the river outside of the forest boundary. Hikers gain access to the Mt. Baker Wilderness from trails taking off from the end of Forest Road 38.

Hunters generally stay a distance from the river.

Boating and fishing occur along the lower three miles of the river where challenge and hydraulics are considered above average for canoeing and kayaking. There is currently little use of the river by rafters or swimmers.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	400	660
Waterplay (swim, wade)	200	300
Fishing, Hunting	2,000	2,880
Camping	3,000	4,500
Viewing (scenery, wildlife, driving for pleasure)	1,000	1,520
Misc. (hike, picnic, berry picking, etc.) berry picking, etc.)	1,500	2,940
TOTAL	8,100	12,800

WILDLIFE AND FISHERIES: Extensive winter range for black-tailed deer, Roosevelt elk and mountain goats are found along the river corridor. The upper reaches of the river contain an important spring calving habitat for elk. A SOHA has been designated in the Middle Fork Nooksack drainage.

Low water flows and discoloration due to glacial runoff are limiting to fish production on the Middle Fork. Anadromous fish spawn and rear upstream to the Bellingham diversion dam. Some of the better fish habitat is found near the mouth of the river. Species include Chinook, coho, pink, chum salmon and steelhead trout. Juvenile salmon rear throughout this section of the river and its accessible tributaries. Coho have year round habitation. Above the diversion dam, resident cutthroat, dolly varden and rainbow trout are found.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The Middle Fork Nooksack drains an area of 100 square miles. The river gradient averages 279 feet per mile. Precipitation is quite heavy. Snow and ice fields act as natural surface storage in the upper river basin.

The headwaters, consisting of the upper 10 miles, are characterized by mountainous terrain with a narrow, ravine-like valley. Stream gradient is very steep with numerous cascades and small falls. The bottom is mostly boulders and rubble. Stream width varies from 4 to 27 feet. The water is highly discolored most of the year due to glacial flour and high water scouring.

The lower half of the river starts out in fairly steep mountainous terrain. The river flows in a narrow, ravine-type valley. The course contains numerous rapids, cascades and small falls. The stream width is 18 to 45 feet. In the lower 5 miles of this section, the river breaks out of its narrow confined terrain into a broad valley floor. Stream gradient is moderate and characterized by meandering, riffle-type waters. Channel splitting and braiding is evident with stream widths of 30 to 75 feet.

GEOLOGY: Geology of the headwaters is composed of pyroclastic and lava flow associated with Mt. Baker. Extending downstream, the river passes through metasediments, metavolcanics, and extensive deposits of glacial till. While the valley has the characteristic U-shape of a glaciated valley. The stream has been actively downcutting and has produced a V-shaped channel within the broader valley. Steep forested side-slopes occur along most of the river's length.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Middle Fork Nooksack drainage. Available information comes primarily from published historical sources. No prehistoric sites have been recorded within the Middle Fork drainage; however, it is believed that this reflects the lack of survey rather than lack of use. During the historic period, the Middle Fork was within the territory of the Nooksack Indians. Several villages and fishing sites were reported to have been along the main river and at the mouths of creeks. The area includes localities identified by the Duwamish and Samish tribes for the practice of their traditional religion.

Historic sites are associated primarily with Forest Service Administration and are relatively recent. Some early logging took place, but it did not result in significant developments along the river. None of the sites have been identified as eligible for the National Register of Historic Places.

TIMBER: Outside of the Forest boundary, private clearcuts are located on both sides of the river. Large areas of blowdown occurred as a result of a high wind storm. These trees were salvaged logged in 1968.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest systems lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
40.2	1.629	1.462

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: Along the lower five miles of the river, cattle and horses graze along the river bank.

SOCIO-ECONOMIC EFFECTS: Although its headwaters are in the Mt. Baker Wilderness, the Middle Fork of the Nooksack River is accessible by road for much of its length. The communities of Deming and Van Zandt are near its confluence with the North Fork Nooksack. These communities, traditionally supported by the timber industry and agriculture, have been impacted by the creation of North Cascades National Park, the Mt. Baker Wilderness and the increasing population of nearby cities. Bellingham is 15 miles away and Vancouver, British Columbia is 60 miles away. Canadians are visiting the area in increasing numbers, acquiring vacation homes in the mountain communities and utilizing the recreation resources of the area. There are a great diversity of outdoor recreation opportunities in the area, which include kayaking, hunting, fishing, hiking, camping, climbing and sightseeing.

CURRENT ADMINISTRATION: The river flows through the Mt. Baker Wilderness and National Forest lands to the forest boundary administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, most of the shoreline of the Middle Fork Nooksack River has been classified as Conservancy by Whatcom County. The exception is a 1 1/2 mile section of shoreline just upstream from the Mosquito Lake Bridge. This section is classified as Natural. These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Natural designation denotes areas characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relatively intolerant of intensive human use.

The land along the Middle Fork from the forest boundary to Porter Creek, outside of federal jurisdiction, is zoned by Whatcom County for Forestry Use. From Porter Creek to the confluence with the Nooksack River, the corridor is zoned for Rural Use, with developments restricted to 5 or 10 acre tracts.

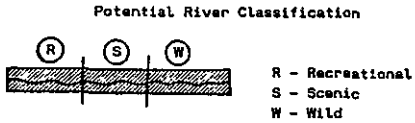
FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

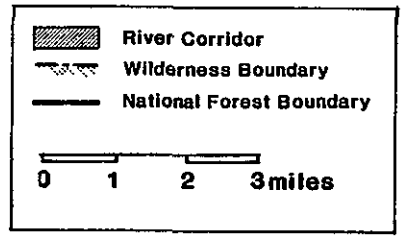
The following are expected funding requirements for the Middle Fork Nooksack River for the next five years:

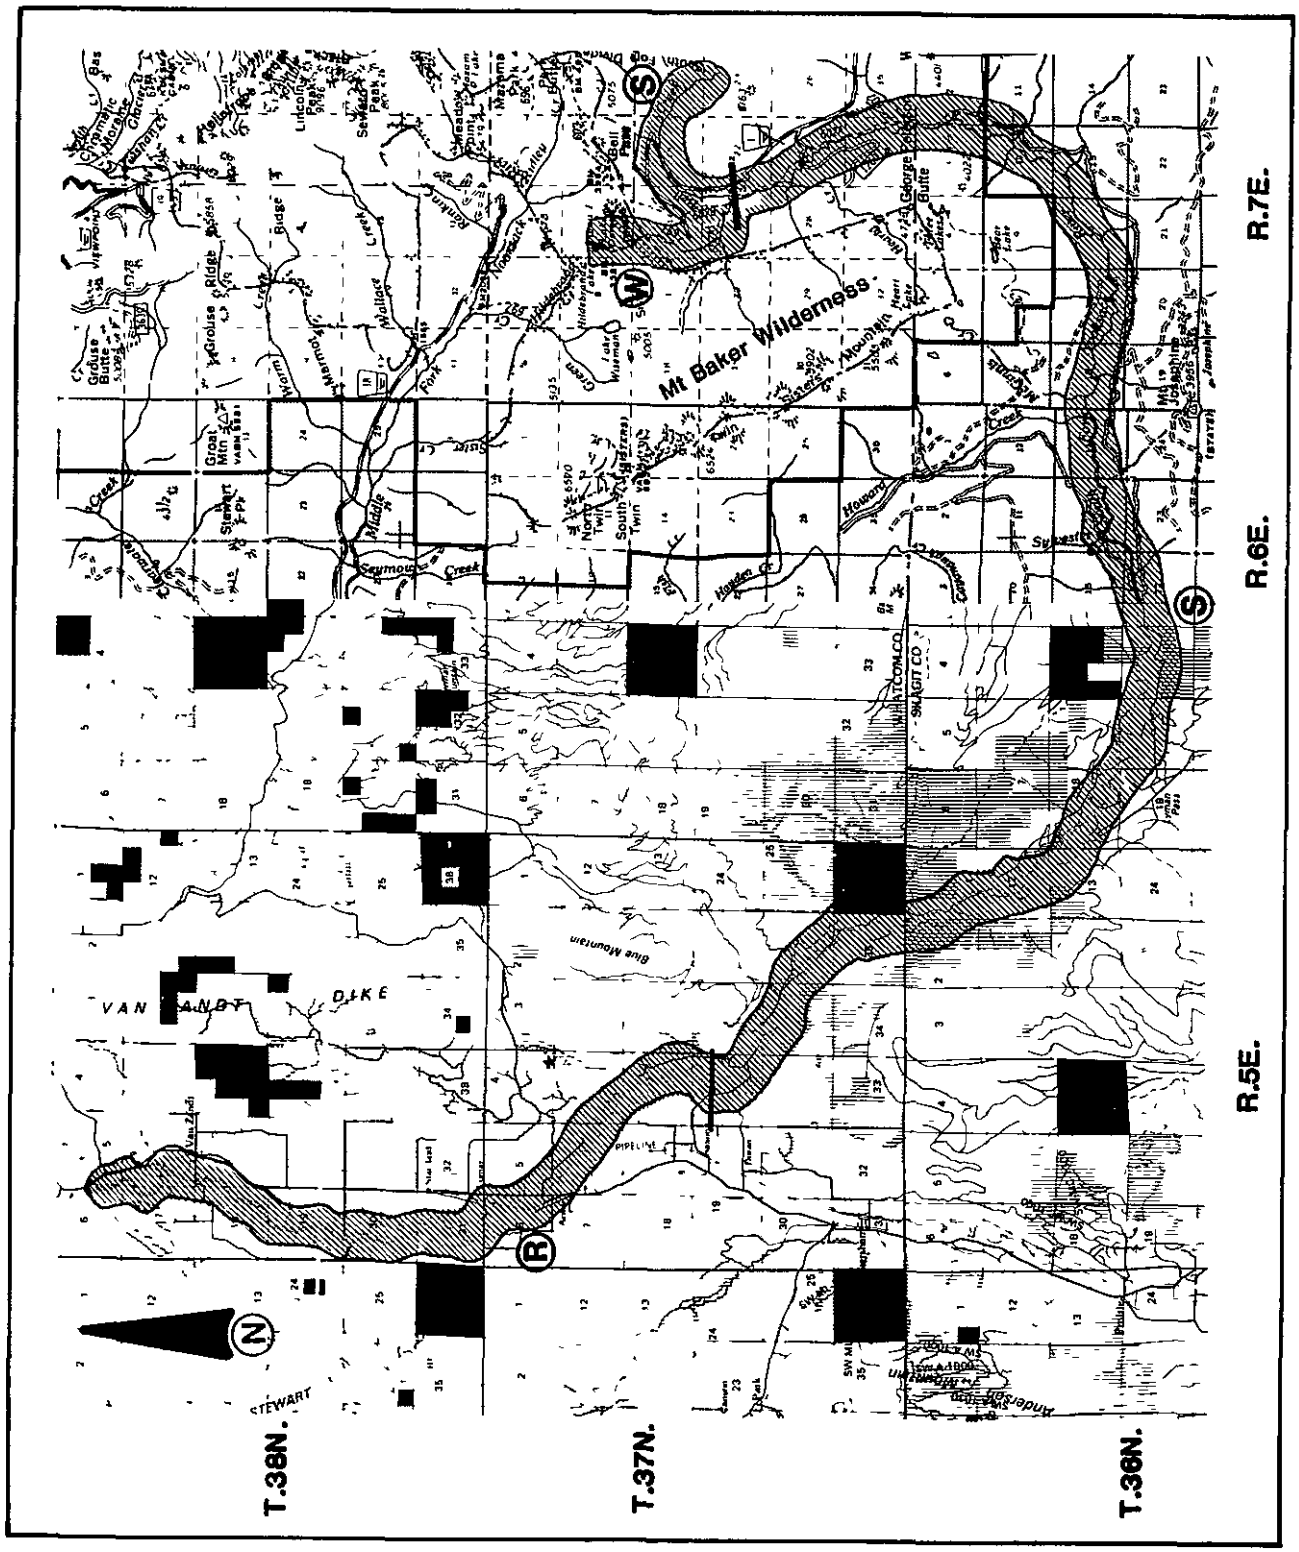
	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 20,000
Costs of Implementation		10,000
Development of Management Plan		35,500
Development Costs	0	50,000
Operation and Maintenance Costs		5,000
TOTAL - First Five Years	**$ 1,000**	**$120,500**

General administration and operation and maintenance costs are estimated to continue at $5,200 annually.

South Fork Nooksack River
Bell Creek







SOUTH FORK NOOKSACK RIVER
BELL CREEK

Whatcom and Skagit Counties

The South Fork Nooksack River and Bell Creek were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The South Fork Nooksack River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: The South Fork Nooksack flows from its headwaters at Lake Doreen and Elbow Lake and from tributaries flowing from the Twin Sisters mountain range to its confluence with the North Fork Nooksack River.

Bell Creek, a tributary, originates on the South Fork Divide and flows into the South Fork Nooksack River

Segment 1 - Bell Creek headwaters on Loomis Mtn. in NE 1/4 of Sec. 23, T.37N., R.7 E. to confluence with S. Fork Nooksack River (3.0 miles).

Segment 2 - Headwaters of the South Fork Nooksack in the SW 1/4 of Sec. 9, T.37N., R.7 E. to Bell Creek (2.3 miles).

Segment 3 - Bell Creek to Mt. Baker-Snoqualmie N.F. boundary (4.3 miles).

Segment 4 - Mt. Baker-Snoqualmie N.F. boundary to Saxon Bridge in SE 1/4 of Sec. 21, T.37N , R 5 E. (20.0 miles).

Segment 5 - Saxon Bridge to confluence with N. Fork Nooksack River (12.9 miles).

RIVER MILEAGE:

Study:	42.5 miles
Eligible:	42.5 miles
Forest Plan:	9 6 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The South Fork Nooksack River was found to possess "Outstandingly Remarkable" values for the following Fisheries and Wildlife

Bell Creek possesses values for Wildlife only.

Both river areas provide forage and cover for deer and elk. There is also spring elk calving in the drainage.

The South Fork Nooksack provides spawning and rearing habitat for chinook, coho, pink and chum salmon as well for resident rainbow and cutthroat trout, dolly varden and summer-run steelhead.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Scenic	3.0	Scenic	3.0
Segment 2	Wild	2.3	Wild	2.3
Segment 3	Scenic	4.3	Scenic	4.3
Segment 4	Scenic	20.0	None recommended	0
Segment 5	Recreation	12.9	None recommended	0

SUITABILITY DETERMINATION:

The upper 6.8 miles of the South Fork of the Nooksack was found to be suitable for inclusion in the preferred alternative of the Forest Plan. The Forest recommends that the State designate the lower sections of the river due to high private competing use outside of the Forest boundary. The South Fork had outstandingly remarkable values for fish and wildlife, and was one of the rivers listed in the Nationwide Rivers Inventory of the National Park Service in 1982. There is public support for designation of this river, as well as a recommendation for designation in the 1988 Washington State Scenic River Assessment.

Bell Creek was also found to be suitable as a logical extension of the South Fork of the Nooksack.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	3.0 miles	960 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest (Mt. Baker Wilderness-1.0 mile)	2.3 miles	736 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest	4.0 miles	1,376 acres
Private	0.3 mile	160 acres
Segment 4		
Private	18.9 miles	6,048 acres
State	1.1 miles	352 acres
Segment 5		
Private	12.9 miles	4,128 acres
Total	42.5 miles	13,600 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segment is classified as an area of critical mineral potential. However, a review of available literature including Bureau of Mines MILS data does indicate some reported magnesium, olivine and chromium occurrences. Those occurrences appear to be concentrated in Sections 3,4,9 and Section 16, T.37N., R.7 E., and Section 34, T.37N., R.7 E. BLM mining claim recordation data also indicates that Sections 16, 27, 28, 33 and 34, T.37N., R.7 E. and Sections 3,4 and 9, T.36N., R.7 E. are or have been encumbered by 144 unpatented mining claims. Of those 144 claims, 73 have either been abandoned or declared to be null and void. How many claims actually encumber the river corridor is not known.

The BLM has classified the northwest 7 miles as being prospectively valuable (PV) for oil and gas, has classified the eastern 12 miles "PV" for geothermal resources, and classified the northwest 7 miles "PV" for coal resources. However, only one occurrence of coal (Section 5, T.38 N., R.5 E.) and no known occurences of oil, gas or geothermal resources has been reported for the area. None of the area is encumbered by mineral leases or pending lease applications.

Based upon the available information, it appears that the segment of the river lying within Sections 27, 28, 34 and 35, T 37N., R.7 E. and in Sections 2,3 and 9, T. 36N., R.7 E. does have at least a low potential for the occurrence of magnesium, chromite and olivine. It is encumbered by numerous unpatented mining claims indicating a continuing interest in the area's locatable mineral resources. The area also has potential for the occurrence of coal, oil and gas and geothermal resources. However, none of the area is encumbered by mineral leases or lease applications, indicating that no serious interest in the leasable minerals of the area is currently being expressed.

WATER RESOURCE DEVELOPMENT: Two miles of the South Fork Nooksack are in power site classification. Some lands along the lower river reaches are under Nooksack Indian tribal jurisdiction. The South Fork of the Nooksack is classified as "Protected" from hydropower development by the NW Power Planning Council. Bell Creek is not classified for protection status.

A preliminary permit for a hydroelectric project has been issued by FERC on Howard Creek, a tributary to the South Fork. Proposed facilities located within the river corridor consist of the transmission line. The capacity of the project will be 4.2 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: State Highway 9 roughly parallels the river to Mosquito Lake Road. At Acme it crosses and continues south as the river veers to the east.

There are forest roads in the river corridor for most of its length, appearing just before the southern boundary of the national forest.

There is one bridge crossing over Bell Creek and one over the South Fork that occur inside the Forest boundary. Seven bridges cross downstream from the Forest boundary, including both State Highway 9 and the Burlington Northern railroad.

Potter Road crosses the river in SW 1/4 Sec. 8, T.38 N., R.5 E., Staud/Hillside Road crosses on the section line between 30 and 19, T.38 N., R.5 E., and Saxon Road crosses the river in SE 1/4 Sec. 21, T.37N., R.5 E.

Appendix E
South Fork Nooksack River and Bell Creek

The south end of the Elbow Lake Trail #697 takes off from the end of Forest Road 12, and parallels the South Fork Nooksack to its headwaters at Elbow and Dorene Lakes.

No developed campgrounds exist on the South Fork Nooksack or Bell Creek. A private recreation vehicle park is in Acme.

The City of Bellingham water pipeline crosses the river in SW 1/4 Sec. 9, T.37N., R.5 E. The Middle Fork pipeline dike lies at the mouth of Hutchinson Creek.

A reclaimed olivine quarry exists at the forest boundary.

2,000 yards of rip-rap was developed on the bridge of F.S. Road #1260, 500 yards of rip-rap at the Olivene Mire bridge, and extensive rip-rap outside of National Forest land.

The South Fork valley floor has been cleared and developed primarily in agriculture with scattered rural residences and the small communities of Saxon, Acme, Clipper and VanZandt.

A Lummi Tribal Residential Development is located in Sec. 19, T.38 N., R.5 E.

Fourteen log weirs were placed in the river to create pools for fish between the forest boundary and Saxon Bridge.

Near the mouth of Sylvester Creek there is a fisheries improvement project that allows salmon passage through a steep cascade - falls. Work consisted of blasting large boulders to allow passage. The river still appears natural and has no artificial structures.

RECREATION ACTIVITIES: The South Fork Nooksack River receives use by rafters, canoers, kayakers and swimmers. The majority of use is from Skookum Creek downstream. In summer, there is not enough water for canoes, but water levels are adequate for kayakers and rafters. There are scenic views, abundant wildlife and good gravel bars for resting. Swimmers enjoy the summer water temperature of 65 to 70 degrees. However, limited public access to the lower half of the river limits use.

The South Fork receives moderate use from fisherman for the resident Cutthroat and Rainbow Trout and low use for anadromous fish consisting of Coho Salmon and Winter Steelhead.

Sightseers enjoy the prominent view of the Twin Sisters Range and Mt. Baker from Forest Road 12. Along the lower portion of the South Fork, there are views of rock cliffs, distant waterfalls and a pastoral landscape.

Near the town of Acme, visitors enjoy views of Blue Mountain, beaches, wetlands and a high degree of vegetation and wildlife diversity. Sunny areas are ideal for picnicking, swimming, sunbathing, canoeing and boating.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	600	990
Waterplay (swim, wade)	200	300
Fishing, Hunting	3,000	4,320
Camping	4,200	6,300
Viewing (scenery, wildlife, driving for pleasure)	1,500	2,280
Misc. (hike, picnic, berry picking, etc.)	1,800	3,528
TOTAL	11,300	17,718

WILDLIFE AND FISHERIES: The entire South Fork Nooksack has important elk habitat. The upper reaches of the South Fork and Bell Creek contain important winter and summer habitat for elk and deer. The adjacent slopes of Sisters Mountain and Loomis Mountain contain mountain goat habitat. The lower reaches of the South Fork contain a high degree of vegetation and wildlife diversity. Marshes and a wetland habitats are found throughout this stretch.

The South Fork Nooksack provides spawning and rearing habitat for chinook, coho, pink and chum salmon. Spring chinook spawn in the 10 mile river stretch above the Saxon Bridge. Resident rainbow and cutthroat trout and dolly varden are found in the upper reaches of the South Fork and Bell Creek. The Lummi Indian Tribe operates a salmon production facility at Skookum Creek. The hatchery has produced good coho returns to the lower river tributaries Pink and chum production is limited. A remnant population of summer run steelhead remains on the South Fork.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The South Fork Nooksack River has excellent water quality and is listed by the State Department of Ecology as a "River of Statewide Significance" based on water volume.

The headwaters area of both rivers fall over steep mountain terrain through a shallow valley floor. Two miles down the South Fork, the valley deepens and remains narrow. The river contains numerous cascades and rapids. Fourteen miles downstream from the headwaters of the South Fork, there are large cascades which drop 20 to 25 feet in a very short distance.

The middle section of the South Fork flows through a very narrow canyon with sharply rising sideslopes. A large 20 to 50 foot waterfall occurs in the upper stretches of this section of the river. All tributaries along this stretch exhibit steep mountain characteristics with many cascades and falls.

The lower section of the South Fork starts as a narrow valley. Below Saxon Bridge, the valley opens abruptly into a broad, flat bottomland with sidehills rising steeply from the valley floor.

The river basins receive approximately 100 inches of precipitation annually. Low flows occur in late summer/early Fall. The low flows are extreme on the rivers because of the lack of augmentation from melting ice packs. Neither river has a glacial origin. In mid-winter, the low flow on the South Fork is less pronounced, due to the lower elevation of the South Fork and because most of the precipitation that falls in the basin is not stored as snow.

Appendix E
South Fork Nooksack River and Bell Creek

The South Fork Nooksack River gradient is 131 feet per mile. Below Skookum Creek, the river channel is braided. The stream bottoms are composed of large rock, boulders and rubble.

The South Fork Nooksack River has sixty small tributaries.

GEOLOGY: The bedrock geology is composed primarily of metasediments and metavolcanics. Extensive deep surficial deposits of glacial till and lacustrine materials occur within the valley bottom and toe slopes. Much of the valley has the typical U-shape resulting from past continental and alpine glaciation. As the South Fork reenters Whatcom County from Skagit County, a small gorge has been cut through phyllite and contains a unique kame moraine. It is an extremely fragile environment and is currently over-used.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the South Fork Nooksack River, and no prehistoric sites are recorded. The absence of sites probably reflects the lack of survey rather than lack of use. During the historic period the South Fork was within the territory of the Nooksack Indians. The South Fork was known as a good fishing river for eight miles above the forks. Several fishing villages were located at the mouths of tributaries. The potential wild and scenic river corridor includes areas identified by the Lummi, Nooksack and Samish tribes for the practice of their traditional religion.

The South Fork of the Nooksack does not appear to have played a significant role in regional development. There are no sites within the potential wild and scenic river corridor recognized on either State or National Historic Registers.

TIMBER: Logging presents a high to moderate influence along the entire length of the rivers.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
78.1	1.948	1.906

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The communities located along the lower South Fork Nooksack are traditionally supported by agriculture and timber. The regional plan supports a growing agriculture base, with any further commercial or residential development discouraged. The area has recently been impacted by the creation of the North Cascades National Park and the Mt. Baker Wilderness Area. The recreation needs of Bellingham (15 miles) and the metropolitan Vancouver B.C. area have brought economic change to the mountain towns. Canadians come in increasing numbers to the area, acquiring vacation homes and utilizing the recreation resources of the area. The resources include Alpine skiing, hunting, fishing, hiking, camping, climbing and sightseeing.

CURRENT ADMINISTRATION: National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. The lower reaches of the river pass along Lummi Tribal land.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the South Fork Nooksack River has been classified by Whatcom County as:

> Conservancy from the forest boundary to the Mosquito Lake Road, except for a narrow area in Sec. 35, T.37N , R.5 E., which is designated Natural.
>
> Rural from the Mosquito Lake Road to approximately 1 mile south of the confluence with the Nooksack River.

These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Natural designation denotes areas characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relatively intolerant of intensive human use. A Rural designation denotes shoreline areas characterized by agricultural uses, low density residential where most urban services are not available, and areas which provide buffer zones and open space between predominantly urban areas.

The Skagit County Comprehensive Plan has zoned the land along the South Fork Nooksack, outside of federal jurisdiction, for Forestry Use Whatcom County has currently designated land along the river as "GP" for General Provisions. This area will soon be rezoned

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the South Fork Nooksack River and Bell Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 20,000
Costs of Implementation		20,000
Development of Management Plan		78,300
Development Costs	160,000	50,000
Operation and Maintenance Costs		5,000
TOTAL - First Five Years	**$161,000**	**$163,300**

General administration and operation and maintenance costs are estimated to continue at $5,200 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

A portion of this river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Scenic	Semi-Primitive, Non-Motorized Recreation	316
		Old Growth Habitat (spotted owl)	380
		Deer and Elk Habitat Enhancement	21
		Timber Management	274
Segment 2	Wild	Old Growth Habitat (spotted owl)	21
		Semi-Primitive, Non-Motorized Recreation	275
		Wilderness-Transition	148
		Wilderness-General Trailless	127
		Wilderness-Trailled	42
		Deer and Elk Habitat Enhancement	168
		Timber Management	63
		Pine Marten/pileated woodpecker habitat	21
Segment 3	Scenic	Semi-Primitive, Non-Motorized Recreation	274
		Wilderness-Transition	168
		Wilderness-Trailed	21
		Wilderness-General Trailless	126
		Old Growth Habitat (spotted owl)	63
		Pine martin/pileated woodpecker habitat	21
		Deer and Elk Habitat Enhancement	1,308
		Timber Management	63

BAKER RIVER

Whatcom County North Cascades National Park

The Baker River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters in Mineral and Picket Creeks to Baker Lake.

Segment 1 - Headwaters in North Cascades National Park near Perfect Pass in NE 1/4 of Sec. 28, T.39 N., R.11 E. to Blum Creek (11.2 miles).

Segment 2 - Blum Creek to Baker Lake (2.1 miles).

RIVER MILEAGE:

Study:	13 3 miles
Eligible:	13.3 miles
Forest Plan:	13.3 miles recommended for designation in preferred alternative

Note: This recommendation is pending evaluation by the National Park Service.

OUTSTANDINGLY REMARKABLE VALUES: The Baker River was found to possess "Outstandingly Remarkable" values for the following: Scenic, Fisheries, and Wildlife.

The lower half of the river has occasional views of logging and roads, but Mt. Challenger dominates the view looking upstream. Mt. Blum can be viewed to the east. The upper third of the river has excellent views of Mt. Pugh, White Chuck Mountain and Glacier Peak.

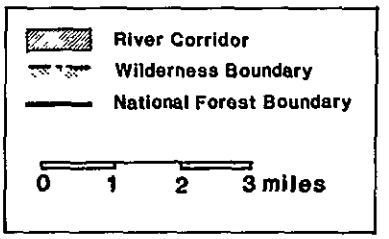
Excellent winter range for deer and elk, along with wintering and nesting habitat for bald and golden eagles are found along Baker River. The lower river flows through a SOHA and beaver habitat.

Sockeye, coho and summer and fall chinook are released into Baker Lake and swim up Baker River to seek their natural spawning grounds. Summer run steelhead are also transported.

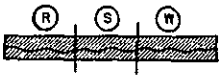
POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	11 2	Wild	11.2
Segment 2	Scenic	2.1	Scenic	2.1

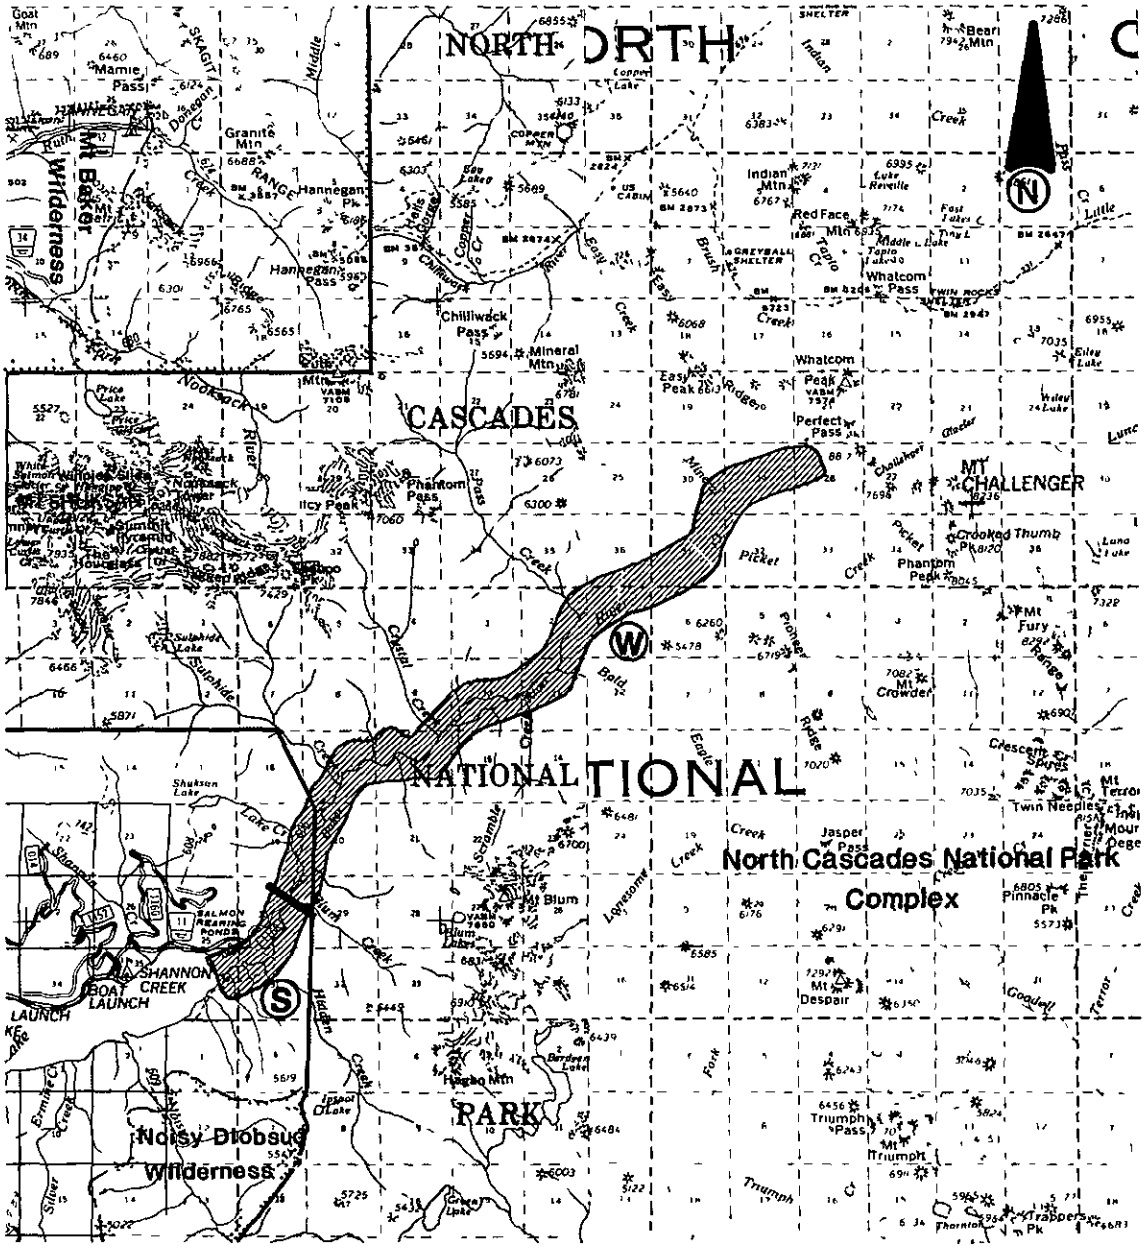
Baker River



Potential River Classification



R - Recreational
S - Scenic
W - Wild



SUITABILITY DETERMINATION:

Baker River was found to be suitable for inclusion in the preferred alternative of the Forest Plan. The entire river is in federal ownership, and there would be few resource conflicts on Forest Service land. Baker River was found to possess outstandingly remarkable values for scenery, fisheries, and wildlife, and there was public support for designation.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
NPS North Cascades National Park	10.0 miles	3,200 acres
Mt. Baker-Snoqualmie National Forest	1.2 miles	384 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	2.1 miles	672 acres
Total	13.3 miles	4,256 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has no reported occurrences of locatable mineral resources. None of the area is encumbered by unpatented mining claims, mineral leases or lease applications, and no part of the area has been classified by the BLM as being prospectively valuable for leaseable mineral resources.

Therefore, based upon the available information, it appears that the area has a relatively low potential for the occurrence of locatable and leasable mineral resources, and no serious interest in either the locatables or leasables has been expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along the river. The lower 9.7 miles of the Baker River are classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are no forest roads, homesites or farms bordering the river.

The Baker River Trailhead #606 is located on Forest Road 1168 near the end of the Baker Lake Highway. The maintained trail runs upstream to Sulphide Creek on the west side of the river. The trail continues unmaintained up to Bald Eagle Creek

There is a Park Service backcountry camp near Sulphide Creek.

Currently, no bridges span the river. An old abandoned road bridge 1 mile upstream washed out in the late 1960's. A proposed trail bridge would cross the river just above Blum Creek to access the east side of Baker Lake.

There is 1,000 yards of rip-rap 1/2 mile above the abandoned bridge, and 500 yard of rip-rap at the bridge.

The meandering nature of the river has caused unsuccessful attempts at channelization which was aimed at protecting sockeye spawning beaches.

A Washington Department of Fisheries artificial spawning beach lies at the head of Baker Lake and mouth of upper Baker River for chinook, coho and sockeye.

RECREATION ACTIVITIES: Dispersed recreation occurs along the drainage. The Baker River Trail provides access to a Park Service backcountry camp near Sulphide Creek.

Good dolly varden fishing is available as far as Bald Eagle Creek. There is some potential for kayaking from Sulphide Creek downstream, but boats must be portaged to the river. The river is not used for rafting or swimming.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	10	15
Waterplay (swim, wade)	20	30
Fishing, Hunting	500	720
Camping	1,500	2,250
Viewing (scenery, wildlife, driving for pleasure)	1,000	1,520
Misc. (hike, picnic, berry picking, etc.)	2,000	2,920
TOTAL	5,030	7,455

WILDLIFE AND FISHERIES: The drainage contains extensive winter range for the black-tailed deer and Roosevelt elk and wintering and nesting habitat for bald and golden eagles. Beaver activity is prevalent along the lower 2 miles of the river. The lower river also flows through a SOHA.

Salmon returning to the Baker River are trapped in lower Baker River below the dam. They are transported by truck to Baker Lake for release. An artificial spawning beach complex was built at the head of Baker Lake to handle beach-spawning sockeye salmon, whose natural lakeshore habitat was inundated. Coho and summer and fall chinook are released into the lake to seek their natural spawning grounds, which include Baker River. Summer-run steelhead are also transported. The Baker River provides salmon habitat upstream to Pass Creek.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: From the river's headwaters for 4 to 5 miles, the gradient is steep with numerous cascades and rapids. They are narrowly confined with few splits. The valley alternately broadens and narrows before opening onto a fairly wide, flat floodplain. Sheer rock outcroppings, large rocks and boulders with some rubble gravel are found. Below Eagle Creek, fast riffles and pool-riffles predominate with moderate gradient and increased braiding. From Sulphide Creek to Blum Creek, the river has a moderate gradient. The channel shifts and meanders with numerous channels. Fourteen tributaries drain into the Baker River above Blum Creek.

Water quality is excellent within the Wilderness. The entire river is colored by suspended glacial sediments during the snowmelt season.

GEOLOGY: The bedrock geology along the Baker River Valley is dominated by metasediments and metavolcanics with some lesser bodies of phyllite. Extensive glaciation during the last glacial period carved out the valley and left thick deposits of glacial till and lacustrine materials. The river is wide, braided, and carries a heavy bedload.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the proposed Baker River Wild and Scenic River corridor. Few project surveys have been conducted and historic research is limited. The lack of known sites is believed to reflect the lack of survey of the drainage. During the historic period, the area was within the territory of the Skagit Indians. No localities used for traditional religious practices are known within the corridor.

The Forest Service was present in the area in the 1930's. A shelter was built along the river, probably for use by fire suppression and detection crews. The shelter is still present, but has been determined ineligible for the National Register of Historic Places.

TIMBER: Along the lower half of the drainage, there are occasional views of logging activity on private land. No logging activity has occurred along the river corridor. Roads and logging activity have been a minor influence outside the Wilderness boundary.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
25.5	.096	.089

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Baker River is approximately 25 miles from Concrete (pop. 570) on SR 20. Concrete, once largely economically dependent on the cement plant (now closed) derives its major support from the timber industry and a shake mill. To an increasing degree, tourism and recreation contribute to the economy of the community. Baker Lake attracts many visitors for camping, boating and fishing. The Ross Lake recreation area is not far away and the Skagit River is renowned for its steelhead fishing.

CURRENT ADMINISTRATION: The first 10 miles of the river flow downstream through North Cascades National Park Service Complex Wilderness administered by the National Park Service. The remaining 3.3 miles flow through the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Baker River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$ 3,000
Costs of Implementation		3,000
Development of Management Plan		6,500
Development Costs	125,000	3,000
Operation and Maintenance Costs		1,000
TOTAL - First Five Years	**$126,000**	**$ 16,500**

General administration and operation and maintenance costs are estimated to continue at $1,000 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Semi-Primitive Non-Motorized Recreation	316
		Old Growth Habitat (spotted owl)	21
Segment 2	Scenic	Semi-Primitive Non-Motorized Recreation	337
		Scenic Corridor (Foreground)	21
		Scenic Corridor (Middleground)	63
		T&E Species (bald eagle)	105
		Goat Habitat	21

NOISY CREEK

Whatcom County — North Cascades National Park

Noisy Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Bacon Peak downstream to Baker Lake.

Segment 1 - Headwaters on Bacon Peak in SE 1/4 of Sec. 29, T.37 N., R.10 E. to Baker Lake (6.1 miles).

RIVER MILEAGE:

Study:	6.1 miles
Eligible:	6.1 miles
Forest Plan:	6.1 miles recommended for designation in preferred alternative

Note: This recommendation is pending evaluation by the National Park Service

OUTSTANDINGLY REMARKABLE VALUES: Noisy Creek was found to possess "Outstandingly Remarkable" values for the following: wildlife and ecological.

Species found in the drainage include deer, bear, mountain goats, bald eagles, osprey and cougar. A SOHA extends for most of the length of Noisy Creek through the Noisy-Diobsud Wilderness.

The drainage supports stands of low elevation old-growth.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	6.1	Wild	6.1

SUITABILITY DETERMINATION:

Noisy Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the lack of competing resource values. All but the lower one mile of the river is in forest service or national park service wilderness. There is public support for designation as well as outstandingly remarkable values for wildlife and ecology. It was felt that these values outweighed potential future use for hydropower.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
NPS, North Cascades National Park	2.7 miles	864 acres
Mt. Baker-Snoqualmie National Forest (Noisy-Diobsud Wilderness - 2.4 miles)	2.7 miles	864 acres
Private	0 7 mile	224 acres
Total	6.1 miles	1,952 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has no known occurrences of locatable mineral resources of significance. However, it is reported that placer gold does occur in the area. None of the area is encumbered by unpatented mining claims, mineral leases or mineral lease applications. BLM has classified the northern three miles as being prospectively valuable for geothermal resources. It is not considered to be prospectively valuable for any other leasable mineral commodities Based upon the available information, it appears that the area does have at least a low potential for the occurrence of gold deposits and geothermal resources. The potential for other locatable and leasable mineral resources appears to be relatively low and no serious interest in either the locatables or leasables is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along Noisy Creek. The creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council. A hydroelectric project license application was submitted to FERC. Proposed facilities within the river corridor consist of a transmission line, power house, diversion structure and penstock. The capacity of the project will be 10.7 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are no logging roads or bridges along the Noisy Creek drainage. A trail bridge once crossed Noisy Creek just as it entered Baker Lake, but has since been washed away. There are plans to replace the bridge when the East Bank Trail is completed

There are no developed campgrounds along the creek. The only camping occurs on Baker Lake, on a point north of the mouth of Noisy Creek.

A trail provides access to the upper reaches of the creek. The trail is located on the north side of Noisy Creek and crosses the creek at 1 mile. There is no bridge crossing.

There are no homesites or farms bordering the creek.

A cedar salvage sale is planned to be logged within 3 years.

RECREATION ACTIVITIES: Fishermen catch native trout along the lower 3 miles of the creek. There are no rafting or canoeing opportunities.
Dispersed recreation users hike a trail to the upper part of the creek.

Appendix E
Noisy Creek

Recreation Activities (in estimated Recreation Visitor Days (RVD's), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	250	360
Misc. (hike, picnic, berry picking, etc.)	150	210
TOTAL	400	570

WILDLIFE AND FISHERIES: The Noisy Creek area contains quality winter range for black-tailed deer. Other species found in the drainage include bear, mountain goats, bald eagles, osprey and cougar. A SOHA extends for most of the length of Noisy Creek through the Noisy-Diobsud Wilderness.

Native trout are found in Noisy Creek.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: *Water quality is excellent. Unnamed* glaciers are found above Noisy Creek on Bacon Peak and Mt. Watson. In the last miles, the creek falls rapidly through a series of short cascades.

GEOLOGY: The bedrock geology along Noisy Creek is comprised of phyllite schist, greenschist, and include some schistose metaconglomerate. Thick deposits of glacial till occur on this U-shaped glacial valley. Forested lower sideslopes merge into rock outcrops, brushy zones, and perennial snow patches on the higher slopes.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Noisy Creek and no prehistoric or historic sites are recorded. The lack of sites may represent the lack of surveys of the area.

Noisy Creek was within the territory of the Upper Skagit tribe during the historic period. Localities used in traditional religious practices exist within the proposed Wild and Scenic River corridor.

TIMBER: There is one old clearcut near the creek where it enters Baker Lake.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
3.8	0	0

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Accessible only by trail from the north end of Baker Lake, Noisy Creek has its headwaters in North Cascades National Park and tumbles into Baker Lake on its less developed east side. The community of Concrete (pop. 570) is approximately 25 miles from the trailhead.

Concrete, once largely economically dependent on the cement plant (now closed) derives its major support from the timber industry via logging and a shake mill. To an increasing degree, tourism and recreation contribute to the economy of the community. Baker Lake attracts many visitors for camping, boating, and fishing. The nearby Skagit River is renowned for its steelhead fishing, and the Ross Lake Recreation Area is nearby.

CURRENT ADMINISTRATION: The creek flows through the North Cascades National Park Service Complex Wilderness administered by the National Park Service from its headwaters downstream 2.7 miles. The next 2.5 miles flow through the Noisy-Diobsud Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Noisy Creek for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$1,000
Costs of Implementation		1,000
Development of Management Plan		2,300
Development Costs	60,000	
Operation and Maintenance Costs	0	
TOTAL - First Five Years	**$61,000**	**$4,300**

Development costs are for completion of East Bank trail.

General administration and operation and maintenance costs are estimated to continue at $400 annually.

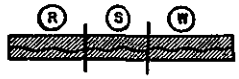
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Dedicated Trailless	823

Diobsud Creek

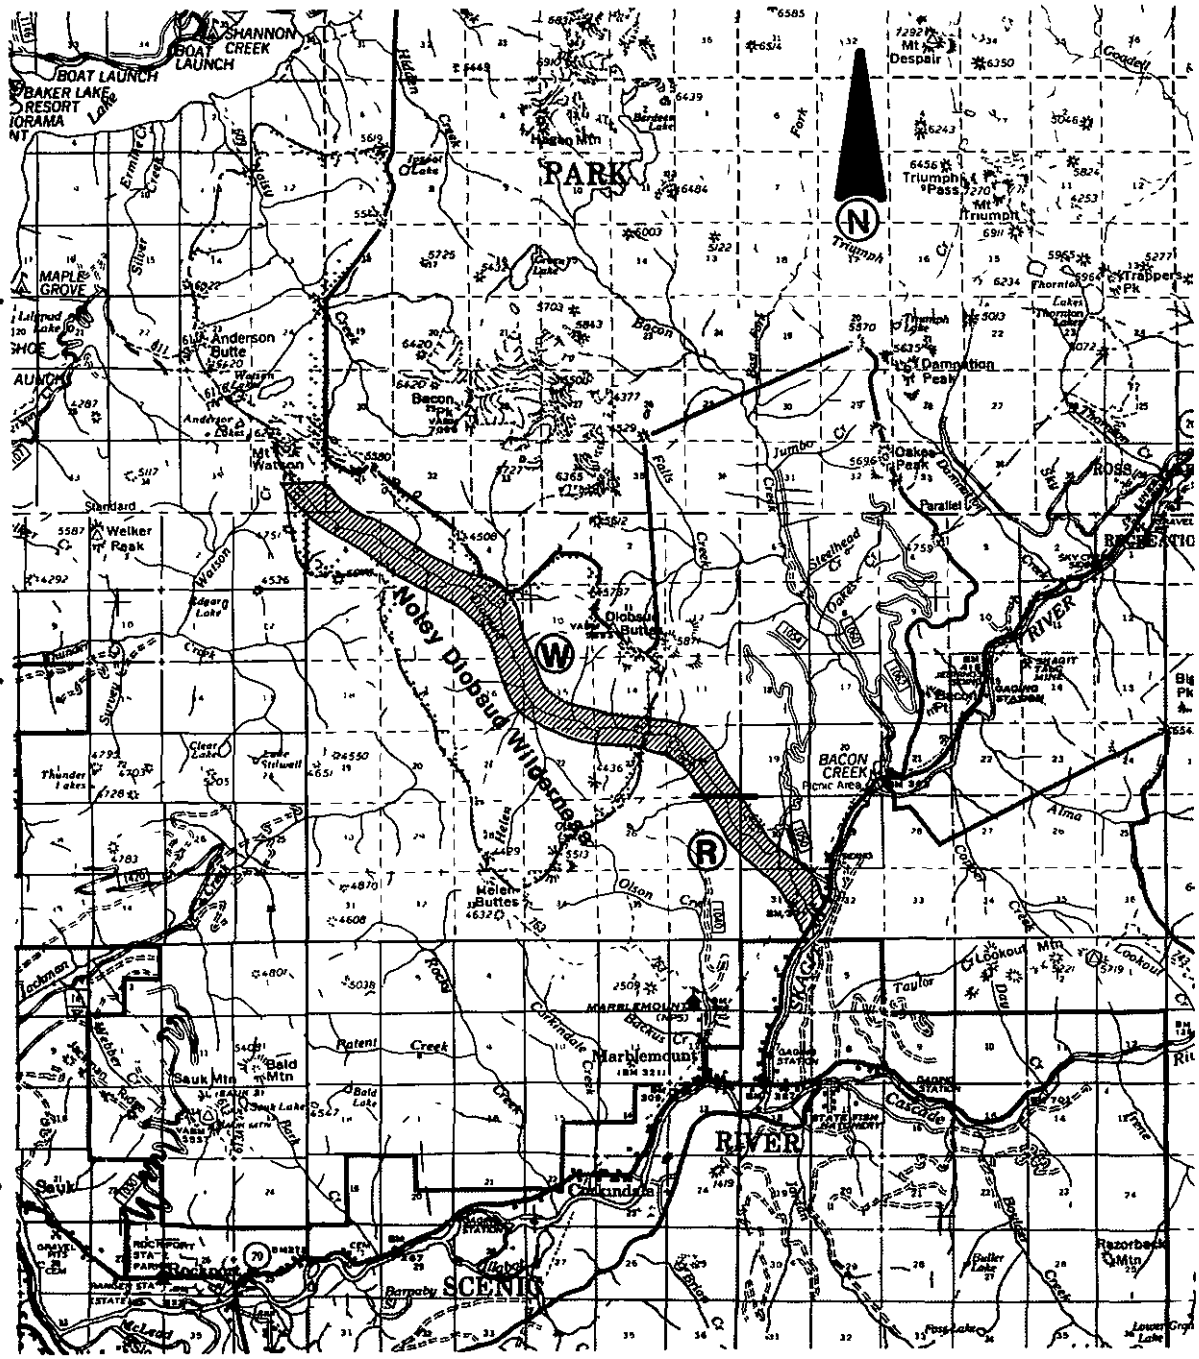
Potential River Classification



R - Recreational
S - Scenic
W - Wild

River Corridor
Wilderness Boundary
National Forest Boundary

0 1 2 3 miles



DIOBSUD CREEK

Whatcom and Skagit Counties

Diobsud Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Mt. Watson to its confluence with the Skagit River.

Segment 1 - The headwaters on Mt. Watson in the SE 1/4 of Section 36, T.37 N., R.9E. to the south section line of Section 24, T.36 N., R.10 E. (8.3 miles).

Segment 2 - The south section line of Section 24 to the confluence with the Skagit River (2.2 miles).

RIVER MILEAGE:

Study:	10.5 miles
Eligible:	10.5 miles
Forest Plan:	10.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Diobsud Creek was found to possess "Outstandingly Remarkable" values for the following: recreation and wildlife.

Fishing is the most popular recreation activity along the creek, especially on the lower 2 to 4 miles. Though the amount of use is presently low, the quality of the experience is high and there is potential for additional use.

Black-tailed deer, bears, and mountain goats inhabit the upper reaches of the creek below Mt. Watson. The creek corridor contains a moderate amount of deer winter range. A SOHA is located in the middle reaches of this creek.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	8.3	Wild	8.3
Segment 2	Recreation	2.2	Recreation	2.2

SUITABILITY DETERMINATION:

Diobsud Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the lack of resource conflicts, public support, and ease of management as most of the river is within wilderness. The Forest Plan allocation of this area to nonmotorized recreation is incompatible with potential hydro-electric values. The outstandingly remarkable values present on Diobsud Creek are recreation and wildlife.

Appendix E
Diobsud Creek

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Noisy-Diobsud Wilderness - 6.0 miles)	8.3 miles	2,656 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	1.1 miles	352 acres
Private	1.1 miles	312 acres
State	0.0 miles	40 acres
Total	10.5 miles	3,360 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified as an area of critical mineral potential. A review of available literature including the Bureau of Mines MILS data, indicates the area has no known occurrences of locatable mineral resources. None of the area is encumbered by unpatented mining claims, mineral leases or mineral lease applications, and only a small portion of the area (northern one mile) is classified by the BLM as being prospectively valuable for geothermal resources. Based upon the available information, it appears that the area has a relatively low potential for the occurrence of locatable and leasable mineral resources, and no serious interest in either type of mineral resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: This river was classified as "Protected" from hydropower development by the Northwest Power Planning Council. Prior to the classification, a hydroelectric project application was submitted to FERC. Proposed facilities within the river corridor consist of a transmission line, powerhouse, diversion structure and penstock. The capacity of the project will be 4 megawatts.

There are no water impoundments.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There is one bridge where Highway 20 crosses the creek near the confluence with the Skagit.

A road parallels the creek for approximately 1 mile upstream from the Skagit. There are several primitive roads in the vicinity.

Trail #631 follows the north side of the creek for 1.5 miles.

There are no developed campgrounds.

Three homesites and two farms are found along the lower mile of the creek.

There is some agricultural development in the lower reaches.

The creek has been channelized upstream from the Highway 20 bridge on private land (Section 31, T.36 N., R.11E.)

2,000 yards of rip-rap are located along the creek at the Highway 20 bridge crossing.

A powerline crosses the creek in Section 31, T.36 N., R 11E.

An old railroad track is located in Sections 31 and 32, T.36 N , R11E.

RECREATION ACTIVITIES: The greatest recreation opportunity on Diobsud Creek is fishing, especially on the lower 2 to 4 miles. There is no rafting, canoeing, kayaking or swimming.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	300	430
Camping	10	15
Viewing (scenery, wildlife, driving for pleasure)	10	15
Misc. (hike, picnic, berry picking, etc.)	20	39
TOTAL	340	499

WILDLIFE AND FISHERIES: Black-tailed deer, bears, and mountain goats inhabit the upper reaches of the creek below Mt. Watson. The creek corridor contains a moderate amount of deer winter range. A SOHA is located adjacent to the wilderness boundary in the middle reaches of this creek.

Salmon are able to migrate upstream for only 1.5 miles, where their passage is blocked by a series of cascades. The river is heavily utilized by pink salmon and steelhead trout and has good runs of coho, summer and fall chinook.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Diobsud Creek displays excellent water quality. The creek contains several waterfalls and glaciers on the south side of Bacon Peak. Sixteen tributaries drain into Diobsud Creek.

GEOLOGY: Phyllite schist and metasediments are the most prevalent rock types in the Diobsud area. Glacial till occurs along the last mile or so prior to the confluence with the Skagit. This stream is full of boulders and has very high energy. It is rapidly downcutting and has a deep V gorge throughout most of its length. The sideslopes along the majority of the stream are very steep, rugged, and rocky with numerous deeply dissected side channels.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Diobsud Creek, although some information is available from surveys made in conjunction with Federal projects, and from published historical sources. During the historic period, the creek was within the territory of the Upper Skagit tribe. Historical research indicates that the Diobsud Creek drainage was used by the Upper Skagit during seasonal food gathering activities and there was a camp at the mouth of the creek. Although no evidence of these sites has been found, this probably reflects the lack of survey, rather than lack of use. Both the Upper Skagit and the Samish Indian tribes have identified localities withing this drainage that are used in the practice of their traditional religion.

Appendix E
Diobsud Creek

TIMBER: Logging activity is limited along the creek to the last mile downstream.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
	Preferred	Preferred
Total	Alternative	Alt. with
Timber	w/o W&SR	Eligible W&SR
Volume	Designation	Designation
(MMBF)	(MMBF/yr.)1/	(MMBF/yr.)1/
17.0	.056	.052

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: Two small farms occur along the lower reaches of the creek.

SOCIO-ECONOMIC EFFECTS: Diobsud Creek enters the Skagit River about 3 miles east of Marblemount. Marblemount is located on the North Cascades Highway and is in close proximity to North Cascades National Park. Traditionally, the economy of the area has been closely tied to the timber industry. In recent years, tourism and recreation supplement the economic base of this small community. Ross Lake, a major recreation area, is only 25 miles to the east of Marblemount, offering visitors the opportunity to fish, boat and camp.

CURRENT ADMINISTRATION: The upper 6.0 miles of Diobsud Creek are within the Noisy-Diobsud Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river, if designated, would become an extension of the existing designated Skagit Wild and Scenic River System.

The Skagit County Comprehensive Plan has zoned the land along Diobsud Creek, outside of federal jurisdiction, for Forestry Use.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Diobsud Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 2,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		4,500
Development Costs	0	2,000
Operation and Maintenance Costs		1,000
TOTAL - First Five Years	**$ 2,000**	**$10,500**

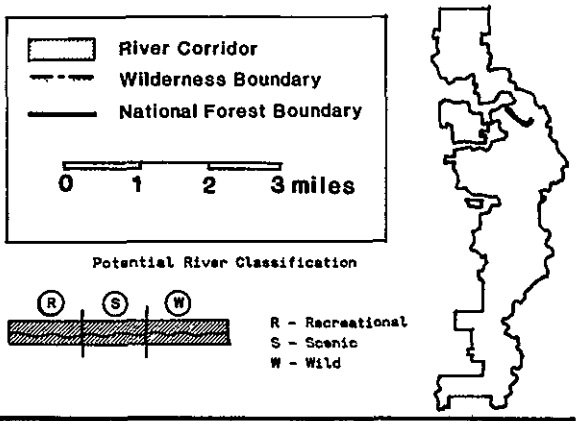
General administration and operation and maintenance costs are estimated to continue at $800 annually.

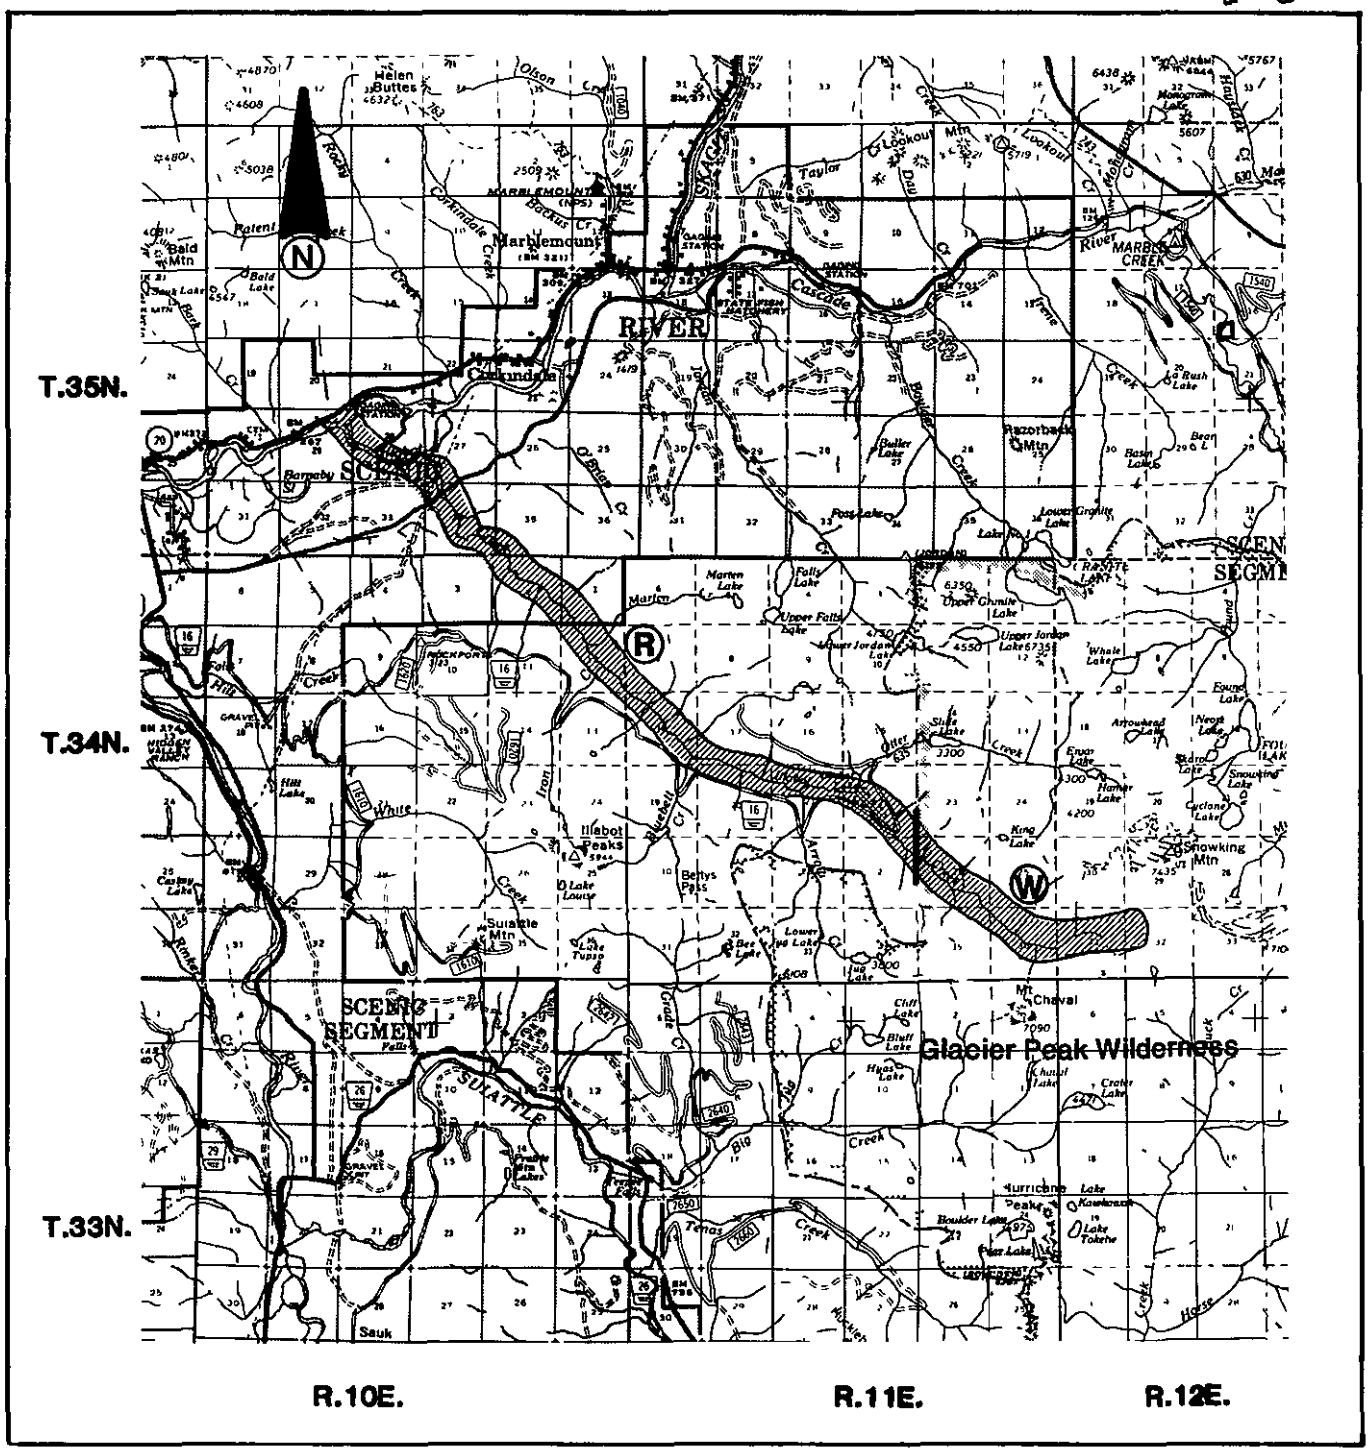
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service).

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Primitive Recreation	527
		Wilderness-Dedicated Trailless	2,217
		Semi-Primitive, Non-Motorized Recreation	126
Segment 2	Recreation	Semi-Primitive, Non-Motorized Recreation	253
		Scenic Corridor (Middleground)	42
		Old Growth Habitat (spotted owl)	84

Illabot Creek





ILLABOT CREEK

Skagit County

Illabot Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Mt. Chaval to its confluence with the Skagit River.

Segment 1 - Headwaters in NW 1/4 of Sec. 32, T.34 N., R.12 E. to Glacier Peak Wilderness boundary (4.3 miles).

Segment 2 - Glacier Peak Wilderness boundary to confluence with Skagit River (11.0 miles)

RIVER MILEAGE:

Study:	15.3 miles
Eligible:	15.3 miles
Forest Plan:	15.3 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Illabot Creek was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife

Illabot Creek is outstanding due to the overall production and species diversity of anadromous fish.

Illabot Creek provides very important habitat for bald eagles, bear, beaver, otter, black-tailed deer, Roosevelt elk, spotted owls and mountain goats There is a bald eagle communal night roost in the river corridor.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	4 3	Wild	4.3
Segment 2	Recreation	11 0	Recreation	11.0

SUITABILITY DETERMINATION:

Illabot Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the high degree of public support for designation, Washington State Department of Fisheries interest, and outstandingly remarkable values for fisheries and wildlife. Illabot Creek is outstanding due to overall production and species diversity of anadromous fish

Appendix E
Illabot Creek

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Glacier Peak Wilderness - 4.3 miles)	4.3 miles	1,376 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	6.2 miles	1,984 acres
Private	4.3 miles	1,096 acres
State	0.5 miles	440 acres
Total	15.3 miles	4,896 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has only one reported occurrence of possibly a locatable mineral resource (graphite in Section 2, T.34 N., R.10 E.). The mineral resources of a portion of the area have been studied by the U.S.G.S. and U.S.B.M. (Church and Others, 1984), and based upon the geology of the area and their sampling, they have concluded that a large portion of this river segment has at least a low potential for the occurrence of gold-bearing quartz-vein deposits in metamorphic host rocks. BLM mining claim recordation data does indicate numerous mining claims have been located in Sections 16 and 21, T. 34 N., R.11E. However, all of those claims have either been abandoned or declared to be null and void.

None of the area is classified by the BLM as being prospectively valuable for leasable mineral resources, and none of the area has been encumbered by leases or lease applications.

Based upon the available information, it appears that this river does have at least a low potential for the occurrence of lode gold deposits. It has little, if any, potential for the occurrence of other locatable and leasable mineral resources and no serious interest in either the locatables or leasables is currently being expressed.

WATER RESOURCE DEVELOPMENT: The lower two miles of Illabot Creek contain beaver ponds.

Illabot Creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The road from the town of Rockport to Illabot Lake is 1/4 to 1 mile from the creek. The road crosses the creek above the lake and then loops back down the other side of Illabot Creek for 4 miles.

The Rockport-Cascade Road crosses Illabot Creek about 2 miles from its confluence with the Skagit River. A Forest Service road crosses above Illabot Lake. A private bridge crosses about 1 mile above the mouth of the river.

The land below the Rockport-Cascade Road is used for agricultural purposes. There is one farm, but no other residences, within the drainage.

There are no developed campgrounds along the creek.

There is 200 yards of rip-rap at mile post 19.9 on Rd. #16, and 500 yards on the South Skagit Highway.

Powerlines cross the creek at 1.5 miles from the confluence of Illabot Creek and the Skagit.

There is an existing timber sale at the end of Forest Road 16, downstream from Illabot Lake in T.34 N., R.11E., Section 17.

RECREATION ACTIVITIES: There is fishing from the mouth of the creek upstream 2 1/2 miles and in lakes tributary to the Illabot: Marten Lake, Jug Lake, Slide Lake and Enjar Lake.

There is mountaineering on Snowking and Mt. Chaval. The upper reaches provide opportunities for hunting, berry picking and mushroom gathering.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	10	15
Fishing, Hunting	300	432
Camping	100	150
Viewing (scenery, wildlife, driving for pleasure)	50	76
Misc. (hike, picnic, berry picking, etc.)	50	98
TOTAL	510	771

WILDLIFE AND FISHERIES: Illabot Creek provides feeding and daytime perching habitat for bald eagles and is adjacent to a known bald eagle communal night roost. This is thought to be the largest concentration of eagles in the continental U.S. In addition, there are bear, beaver, and otters. Moderate quality black-tailed deer and Roosevelt elk forage and cover extend throughout the river corridor. Mountain goat winter range is located along the upper reaches of the creek. The creek flows through the middle of a SOHA for 3 miles, three-fourths of which is in the Glacier Peak Wilderness.

Coho salmon, summer steelhead and dolly varden have been reported to swim upstream as far as Illabot Lakes. However, the best spawning habitat for chinook, coho, chum and pink salmon and steelhead is found from the mouth of the Illabot upstream for 1 1/4 miles. Chum salmon spawn mostly in Illabot Slough, at the mouth of the creek.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Glaciers are found near the headwaters on Snowking and Mt. Chavel, which feed the creek, causing discoloration of the water. From Illabot Lake, the creek descends through a narrow canyon with numerous cascades and falls.

The gradient in the upper end of Illabot Creek drops at the rate of 200 feet per mile and contains large boulders and rubble. The last mile is a wide channel with good gravel. The channel then splits into two with a sand bottom and little gravel. Illabot Creek contains 31 tributaries and two side channels.

Appendix E
Illabot Creek

GEOLOGY: The bedrock geology consists of granitic and gneissic rocks associated with large bodies of phyllite schist. Previous glaciation has carved out this U-shaped valley and left deep deposits of glacial till and lacustrine materials. Most of the valley consists of long, relatively smooth forested sideslopes blending into ridgetops dominated by rock outcrops and perennial snow patches.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Illabot Creek, and no prehistoric or historic sites are recorded. The lack of known sites is believed to reflect the lack of survey rather than use. During the historic period, Illabot Creek was within the territory of the Upper Skagit Tribe, and an important fishery was located on the creek. Both the Upper Skagit and the Samish Indian Tribes have identified localities within this this drainage that are used in the practice of their traditional religion.

TIMBER: The land between the Rockport-Cascade Road and the wilderness boundary has been used extensively for logging. The deciduous forest bordering Illabot Creek and the steep slopes of its tributaries have been heavily logged and are currently in various stages of reforestation.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
71.2	1.729	1.624

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The Skagit County Comprehensive Plan (May, 1982) recommends that the Barnaby Slough area near the mouth of Illabot Creek be designated as prime agricultural land. This area is located within the creeks'floodplain. Industrial and residential development would be discouraged.

The remainder of the river's length is dominated by logging. The timber industry has been the economic mainstay of the communities in the area. However, outdoor recreation pursuits are diversifying the economies of the area. Increasing numbers of visitors are travelling to the North Cascades to take advantage of hiking, camping, boating, fishing and sightseeing opportunities.

CURRENT ADMINISTRATION: The upper five miles of the creek are within Glacier Peak Wilderness. The wilderness and other National Forest lands are administered by Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river, if designated, would become an extension of the existing designated Skagit Wild and Scenic River System.

Most of the land along Illabot Creek, outside of federal jurisdiction, has been zoned by Skagit Country for Forestry Use. At the confluence of Illabot Creek and the Skagit River, the land is zoned Rural Use, Public Use District and Agricultural Reserve District.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Illabot Creek for the next five years:

	Expenses Expected Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 3,000	$ 2,000
Costs of Implementation		2,000
Development of Management Plan		13,800
TOTAL - First Five Years	**$ 3,000**	**$17,800**

General administration and operation and maintenance costs are estimated to continue at $1,000 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	**Management Emphasis**	**Acres**
Segment 1	Wild	Wilderness-General Trailless	1,351
		Wilderness-Dedicated Trailless	84
Segment 2	Recreation	Semi-Primitive, Non-Motorized Recreation	126
		Deer and Elk Habitat Enhancement	1,436
		Old Growth Habitat (spotted owl)	105
		Goat Habitat	63
		Timber Management	274

BUCK CREEK

Skagit and Snohomish Counties

Buck Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: *From its headwaters on Mt. Chaval to the confluence with the* Suiattle River.

Segment 1 - Headwaters in NE 1/4 of Sec. 4, T.33 N., R.12 E. to Glacier Peak Wilderness boundary (10.1 miles).

Segment 2 - Glacier Peak Wilderness boundary to the confluence with the Suiattle River (1.0 mile).

RIVER MILEAGE:

Study:	11.1 miles
Eligible:	11.1 miles
Forest Plan:	11.1 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Buck Creek was found to possess "Outstandingly Remarkable" values for the following: Fisheries.

Spring chinook and coho salmon spawn in the lower reaches of the creek. There is also a population of dolly varden.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	10.1	Wild	10.1
Segment 2	Scenic	1.0	Scenic	1.0

SUITABILITY DETERMINATION:

Buck Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to lack of resource conflicts, outstanding fisheries resources, and ease of management. Ninety-one percent of this river is within wilderness.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Glacier Peak Wilderness - 10.1 miles)	10.1 miles	3,232 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	1.0 miles	320 acres
TOTAL	11.1 miles	3,552 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified by the BLM as an area of critical mineral potential or encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates the river has no reported locatable mineral resource occurrences. However, the area's mineral resources have been studied by the U.S.G.S. and U.S.B.M. (Church and Others, 1984). Based upon the geology of the area and their sampling, they have concluded the area does have at least a moderate potential for the occurrence of copper and molybdenum resources.

None of the area has been classified as being prospectively valuable for leasable mineral resources. However, Section 13, T.32 N., R.11 E. has been encumbered by two geothermal lease applications. Both applications have been withdrawn.

Based upon the available information, it appears that the area does have potential for the occurrence of copper and molybdenum resources. The potential for the occurrence of other locatable mineral resources and leasable mineral resources is relatively low and no serious interest in the mineral resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: The lower 1.5 miles of this river are classified as "Protected" from hydropower development by the NW Power Planning Council.

There are no water impoundments.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Campground access and dispersed recreation access roads are situated on both sides of the creek for the first 0.6 mile.

Buck Creek Campground (51 sites) is situated on both sides of the creek near the confluence with the Suiattle River.

A single lane concrete bridge spans the creek 0.3 miles upstream.

The bridge is protected by rip-rap. Also 50 feet of rip-rap protects unit #3 in the Buck Creek Campground (1988).

There are no communities or farms located on this creek.

Near the mouth, there are 4 log deflectors on the west bank (each is 2' x 55') and 32 log deflectors on the west bank side channel.

Bridge approach guard rails are planned for installation. Planned improvements in the campground include a new shelter and toilet facilities.

RECREATION ACTIVITIES: The river is not suitable for rafting, canoeing, or kayaking. It is also not suitable for swimming due to very cold water.

The lower reaches of the creek support low to moderate amounts of fishing for resident trout.

Dispersed camping is available between Road #26 and the Suiattle River.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	800	1,152
Camping	9,000	13,500
Viewing (scenery, wildlife, driving for pleasure)	50	76
Misc. (hike, picnic, berry picking, etc.)	200	392
TOTAL	10,200	15,120

WILDLIFE AND FISHERIES: Species typical of the westside of the Cascades, and associated with old-growth fauna, are found within the creek drainage.

Spring chinook and coho salmon spawn from the creeks mouth upstream for 1 1/2 miles. Steep cascades block further upstream access. The best spawning occurs in the lower 1/2 mile where excellent gravel riffles are found. Dolly varden is also found throughout the creek.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Buck Creek has excellent water quality. It contains steep gradients with extremely steep cascades, and the stream bottom is made up of boulders, rubble and scattered patch gravel. Glaciers are common at the headwaters of Buck Creek and its twenty-eight tributaries.

GEOLOGY: Deeply weathered, incompetent, phyllite schist and greenschist comprise the lower slopes whereas the upper slopes contain more competent schist. Past glaciation has carved out the valley and left deposits of glacial till and lacustrine materials The once predominant U-shaped valley characteristic is disappearing as the creek rapidly downcuts through the soft bedrock and forms a V-shaped valley. Landflows and other mass movements are common due to high instability. Areas adjacent to the creek are very brushy. Most of the valley consists of long, relatively smooth forested sideslopes blending into ridgetops dominated by rock outcrops and perennial snow patches.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Buck Creek. Few project surveys have been conducted and historic research is limited. The lack of known sites is believed to reflect the lack of survey of the drainage. During the historic period, the area was within the territory of the Sauk-Suiattle Indians. The mouth of Buck Creek has been reported as a historic fishing and long house site by the Sauk-Suiattle tribe. The area currently has values for traditional Indian religious practices.

TIMBER: Salvage logging occurs from the confluence for 1 mile upstream to the wilderness boundary.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest systems lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
5.4	.109	.108

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Buck Creek lies almost entirely within the Glacier Peak Wilderness. It enters the Suiattle River near a forest road system approximately 25 miles from Darrington. Darrington, approximately 50 miles from Everett, is a community traditionally and presently dependent on the logging and forest products industry. Located on the Mountain Loop Highway in an area noted for its scenery and recreation opportunities, Darrington also benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: The mouth of this creek is within the corridor of the Skagit Wild and Scenic River for the first 0.7 miles and thus would become an extension of the Skagit System if it were designated. The rest of the river is within the Glacier Peak Wilderness which is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Buck Creek for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$ 1,000
Costs of Implementation		1,000
Development of Management Plan		4,900
Development Costs		
Operation and Maintenance Costs	60,000	0
TOTAL - First Five Years	**$61,000**	**$ 6,900**

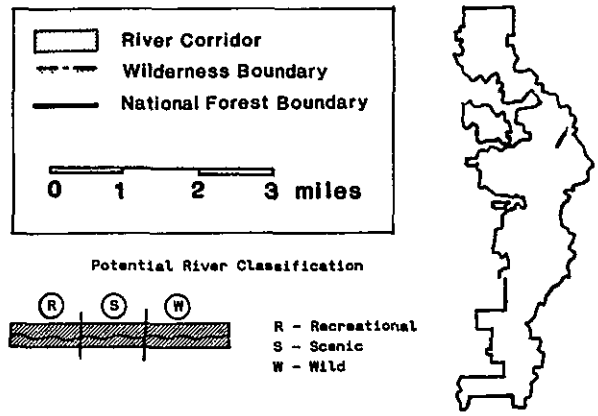
General administration and operation and maintenance costs are estimated to continue at $12,400 annually.

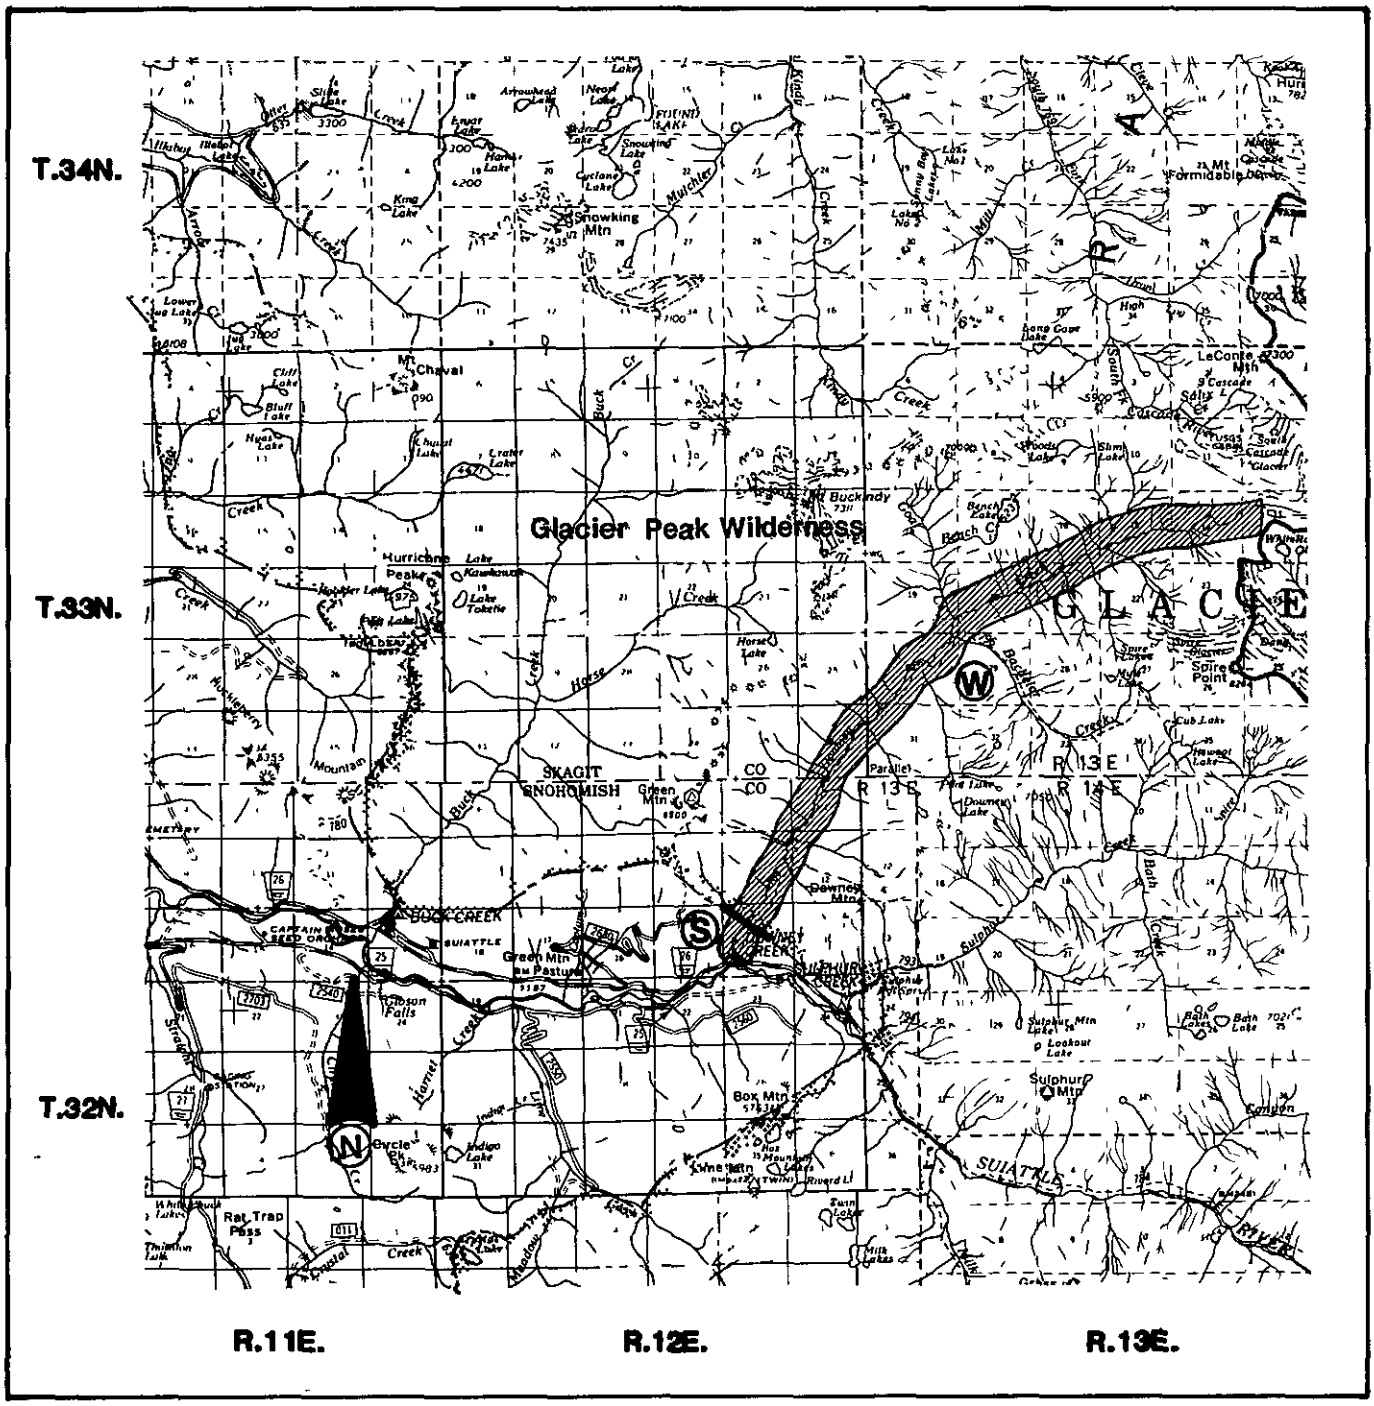
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	105
		Wilderness-Dedicated Trailless	3,231
Segment 2	Scenic	Semi-Primitive, Non-Motorized Recreation	21
		Skagit Wild and Scenic River	168
		Deer and Elk Habitat Enhancement	21

Downey Creek





DOWNEY CREEK

Skagit and Snohomish Counties

Downey Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Lizard Mountain to the confluence with the Suiattle River.

Segment 1 - Headwaters on Lizard Mtn. in NW 1/4 of Sec. 13, T.33 N., R.13 E. to Glacier Peak Wilderness boundary (10.0 miles)

Segment 2 - Glacier Peak Wilderness boundary to confluence with Suiattle River (0 8 mile)

RIVER MILEAGE:

Study:	10.8 miles
Eligible·	10.8 miles
Forest Plan:	10.8 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Downey Creek was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife

Downey Creek provides habitat for a diverse population of fish. The creek supports runs of spring chinook, coho salmon, summer steelhead and dolly varden.

A SOHA extends along the river inside the Glacier Peak Wilderness. Three pairs of spotted owls have been observed.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	10.0	Wild	10.0
Segment 2	Scenic	0.8	Scenic	0 8

SUITABILITY DETERMINATION:

Downey Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to lack of resource conflicts, outstanding fish and wildlife values and ease of management. Almost all of this river is within wilderness.

Appendix E
Downey Creek

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Glacier Peak Wilderness - 10.0 miles)	10.0 miles	3,200 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.8 miles	256 acres
TOTAL	10.8 miles	3,456 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified by the BLM as areas of critical mineral potential or encumbered by unpatented mining claims. A review of available literature including the Bureau of Mines MILS data indicates the river has no reported locatable mineral resource occurrences. However, the area's mineral resources have been studied by the U.S.G.S. and U.S.B.M. (Church and Others, 1984). Based upon the geology of the area and their sampling, they have concluded the area does have at least a low potential for the occurrence of nickel, cobalt, chromium and platinum-group metal resources in magmatic segregations of mafic layered complexes.

The BLM has classified the southern two miles as being prospectively valuable (PV) for geothermal resources. However, none of the area is considered "PV" for other leasable mineral resources and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears the area does have at least a low potential for the occurrence of nickel, cobalt, chromium and platinum-group metal resources. A small portion of the area has at least a low potential for the occurrence of geothermal resources. No serious interest in either type of mineral resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: This river is classified as "Protected" from hydropower development by the NW Power Planning Council.

There are no water impoundments.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The only bridge is located where Forest Road No. 29 crosses Downey Creek at the confluence with the Suiattle River.

There is approximately 100 feet of rip-rap under the bridge on both banks.

The Downey Creek Trailhead #768 is located at the junction of the Suiattle River Road #26 and the old Downey Creek Campground now used as a dispersed site. The trail parallels the creek for 6.6 miles to Bachelor Creek.

There are no homes, farms or agricultural developments along the creek.

Guard rails are planned for installation on the bridge approaches. Also, trailhead parking and toilet facilities are proposed.

RECREATION ACTIVITIES: Fishing dominates the recreation opportunities on Downey Creek, mostly for trout. The lower reaches have a low to moderate amount of fishing use.

This creek is not suitable for rafting, canoeing, kayaking, or swimming.

Several dispersed recreation opportunities are available including hiking, camping, and big game hunting, all of which are associated with the Downey Creek trail.

Recreation Activities (in estimated Recreation Visitor Days (RVD's), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	800	1,152
Camping	1,600	2,400
Misc. (hike, picnic, berry picking, etc.)	500	980
TOTAL	2,900	4,532

WILDLIFE AND FISHERIES: A SOHA with three sighted pairs extends along the river inside the Glacier Peak Wilderness.

Downey Creek provides habitat for a diverse population of fish, particularly in the lower 0.5 miles The creek contains good spawning and rearing habitat for spring chinook. There are also runs of coho salmon, summer steelhead and dolly varden.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The water quality of Downey Creek is excellent. Its eighteen tributaries are pristine at higher elevations. They have glaciers at their headwaters and contain numerous falls and cascades. Downey Creek has a steep gradient.

GEOLOGY: Deeply weathered, incompetent, phyllite schist and greenschist are common on lower slopes whereas the upper slopes contain more competent schist in association with granitic and gneissic rocks. Past glaciation has carved out the valley and left deposits of glacial till and lacustrine materials. The once predominant U-shaped valley characteristic is disappearing as the creek rapidly downcuts through the soft bedrock and forms a V-shaped valley. Landflows and other mass movements are common due to the high instability. Long, mostly forested sideslopes, contain numerous deep avalanche tracks. Upper slopes and ridgetops are dominated by rock outcrops, meadows, and perennial snow fields

CULTURAL RESOURCES: No systematic archaeological survey has been made of Downy Creek. Few project surveys have been done and historic research is limited. The lack of sites is believed to reflect lack of survey in the drainage. During historic times, the area was within the territory of the Sauk-Suiattle Indians. The mouth of Downy Creek was reportedly a historic fishing site for the Sauk-Suiattle tribe. The area currently has value to local Indians for gathering materials used in their traditional religious practices.

TIMBER: Salvage logging occurs in and adjacent to the Downey Creek Campground.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
9.2	.302	.286

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Downey Creek lies almost entirely within the Glacier Peak Wilderness. The creek enters the Suiattle River near a forest road system approximately 25 miles from Darrington. Darrington is a community traditionally and presently dependent on logging and the forest products industry. Located on the Mountain Loop Highway in an area noted for its scenery and recreation opportunities, Darrington also benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: The mouth of this creek flows into the Suiattle River which is a part of the Skagit Wild and Scenic River System. The remainder of the creek is within the Glacier Peak Wilderness. The whole creek is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Downey Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 1,000
Costs of Implementation		1,000
Development of Management Plan		4,600
Development Costs	51,000	
Operation and Maintenance Costs	15,000	0
Total - First Five Years	**$67,000**	**$ 6,600**

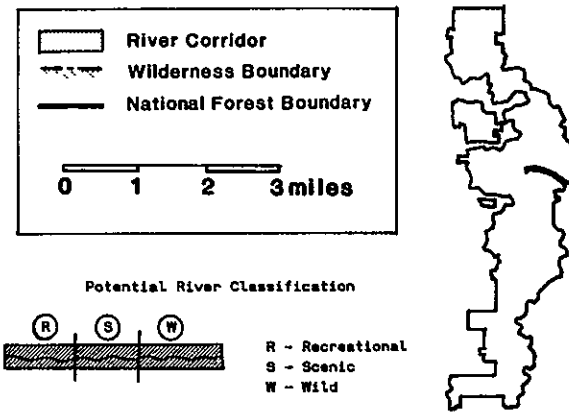
General administration and operation and maintenance costs are estimated to continue at $3,400 annually.

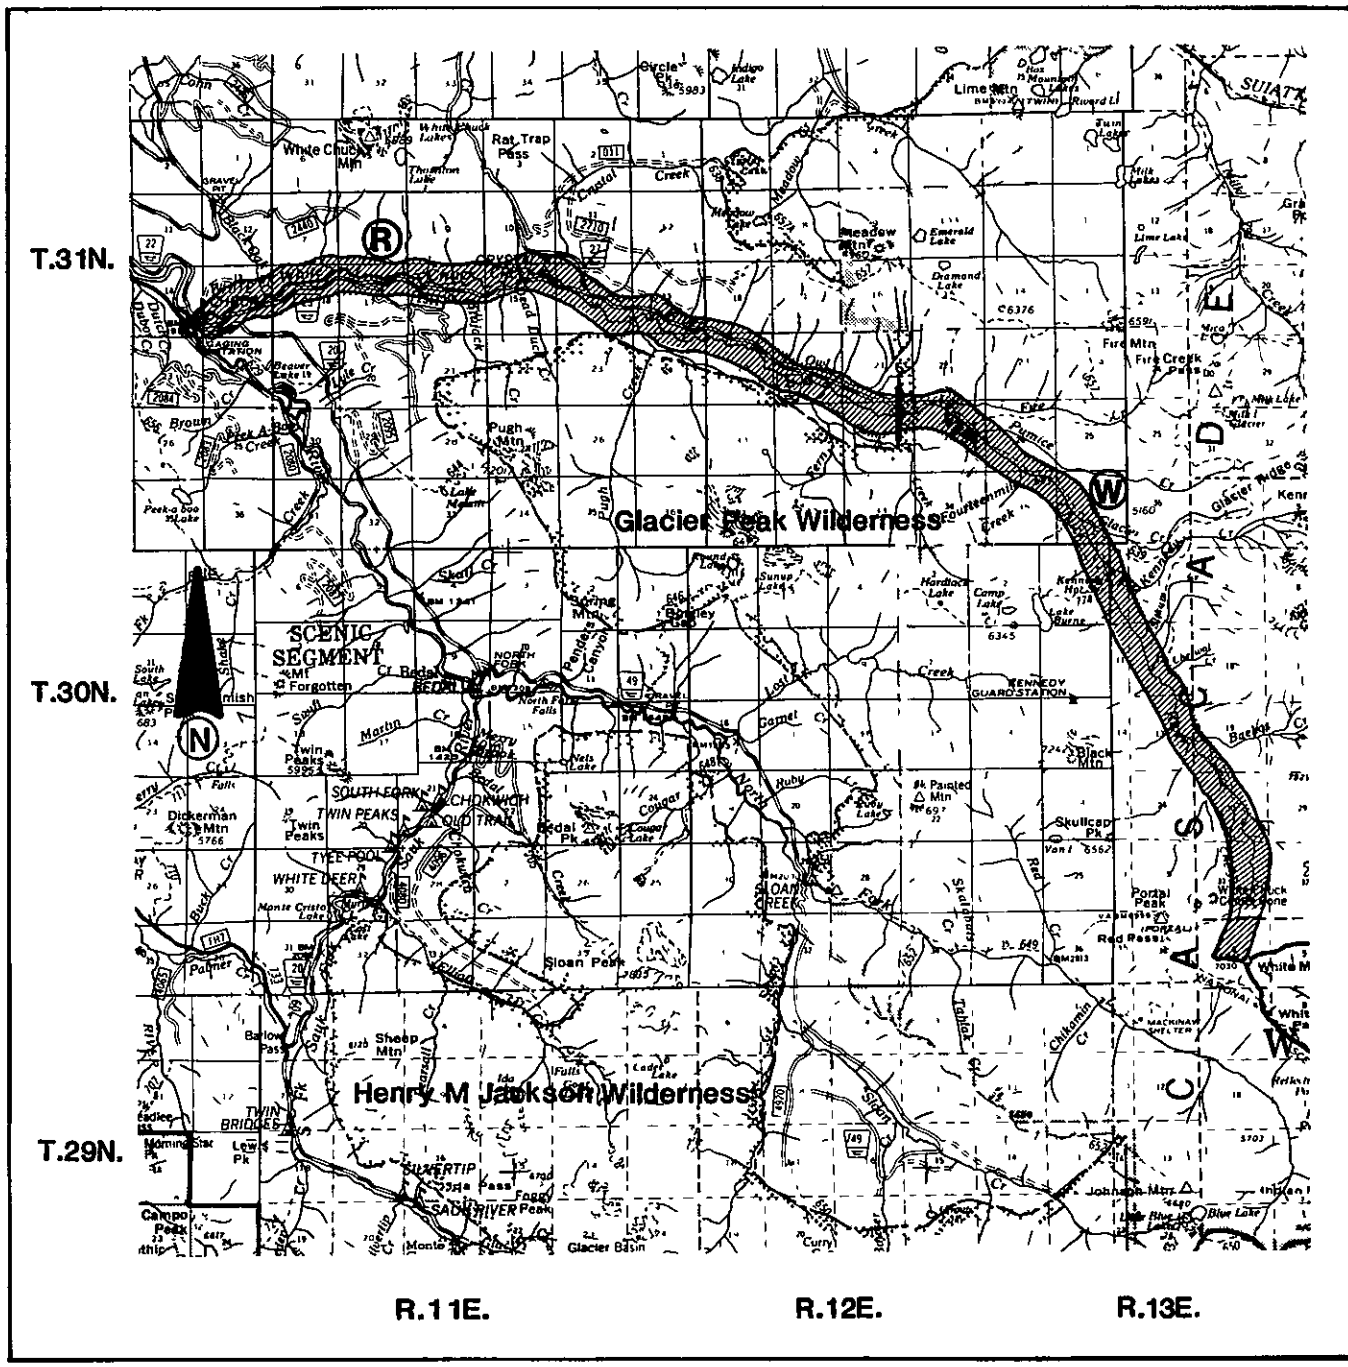
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Trailled	908
		Wilderness-General Trailless	2,238
		Wilderness-Dedicated Trailless	844
Segment 2	Scenic	Old Growth Habitat (spotted owl)	21
		Timber Management	42

White Chuck River





WHITE CHUCK RIVER

Snohomish County

The White Chuck River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters in rugged mountainous country between White Chuck Mountain and Meadow Mountain to its confluence with the Sauk River.

Segment 1 - Headwaters in NW 1/4 of Sec. 6., T.29 N., R.14 E. to Glacier Peak Wilderness boundary (10.5 miles).

Segment 2 - Glacier Peak Wilderness boundary to confluence with Sauk River (12.0 miles).

RIVER MILEAGE:

Study:	22.5 miles
Eligible:	22.5 miles
Forest Plan:	22.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The White Chuck River was found to possess "Outstandingly Remarkable" values for the following: Scenic, Recreation, Fisheries and Wildlife.

The White Chuck River and its tributaries flow through rugged mountainous terrain and contain numerous cascades and falls.

There are abundant camping and hiking opportunities throughout the river corridor. Trails parallel the river for its entire length. Kennedy Hot Springs is a very popular hiking destination. Canoeing and kayaking potential exists from 6 miles upstream to the mouth of the river for experienced boaters looking for challenging hydraulics.

A SOHA exists within the river corridor.

The river provides habitat for spring chinook and coho salmon, dolly varden and resident rainbow trout.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	10.5	Wild	10.5
Segment 2	Recreation	12.0	Recreation	12.0

SUITABILITY DETERMINATION:

The White Chuck River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to high public interest and high number of outstandingly remarkable features. The White Chuck possessed remarkable values for scenery, recreation, fisheries and wildlife. The travel corridor up this drainage is allocated for scenic protection in the preferred alternative, and contains an abundance of recreational opportunities.

LANDOWNERSHIP:

Segment 1	**River Miles**	**Corridor Acres**
Mt. Baker-Snoqualmie National Forest (Glacier Peak Wilderness - 10.5 miles)	10.5 miles	3,360 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	12.0 miles	3,840 acres
Total	22.5 miles	7,200 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither of the river segments are classified by the BLM as areas of critical mineral potential or are encumbered by unpatented mining claims. A review of available literature, including Bureau of Mines MILS data, indicates the river has no reported locatable mineral resource occurrences of significance. However, the area's mineral resources have been studied by the U.S.G.S. and U.S.B.M. (Church and Others, 1984). Based upon the geology of the area and their sampling, they have concluded that the area does have at least a low potential for the occurrence of hot springs precious metal deposits.

The BLM has classified the entire river as being prospectively valuable for geothermal resources. Kennedy Hot Springs is found in Section 1, T.30 N., R.12 E. However, none of the area appears to have potential for the occurrence of other leasable mineral resources and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the area does have at least a low potential for the occurrence of precious metal resources and geothermal resources. No serious interest in either type of mineral resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the river.

The White Chuck River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Forest Road 23 crosses the White Chuck River near the confluence with the Sauk River. A Forest Service road parallels the river for 11.5 miles upstream, crossing the river 6 miles upstream.

On the north side, forest trail No. 731 parallels the river from the junction of the Sauk River upstream for 6 miles.

In addition to the Forest Service road crossings, an abandoned structure spans the river at river mile 4.0.

There are no homes or farms located within the drainage.

White Chuck Campground is located at the confluence of the White Chuck and Sauk Rivers.

The White Chuck Trailhead #643 is located at the end of the White Chuck Road #23. The trail parallels the river to Kennedy Hot Springs, a popular hot springs. Hikers can gain access to the Pacific Crest Trail near Kennedy Creek. The Pacific Crest Trail follows the White Chuck River drainage upstream for approximately 5 miles, where it crosses the river's headwaters.

RECREATION ACTIVITIES: There is camping and hiking associated with the area trails. Trails parallel the river for its entire length. Kennedy Hot Springs is a popular hiking destination.

Fishing is generally poor due to suspended glacial sediment during the summer. Fall fishing season results in higher use.

Rafting is considered to be unsuitable on the river.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	400	660
Waterplay (swim, wade)	100	150
Fishing, Hunting	300	432
Camping	13,000	19,500
Viewing (scenery, wildlife, driving for pleasure)	100	152
Misc. (hike, picnic, berry picking, etc.) berry picking, etc.)	26,000	50,960
TOTAL	39,900	71,854

WILDLIFE AND FISHERIES: Mineral seeps near Kennedy Hot Springs attract big game animals to the surrounding vegetation. A SOHA with 3 sighted pair extends along the river corridor within the Wilderness boundary.

The White Chuck River contains spawning habitat for spring chinook and coho salmon. Dolly varden and resident rainbow trout are also found. There are major limiting factors to increased fish production The fast runoff of snow melt creates flooding conditions. The small gravel substrate is washed away, leaving behind only boulders and coarse material. Cold water conditions in the upper watershed tend to retard fish growth and reduce the abundance of food organisms.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Beginning 2 miles above the confluence with the Sauk River, the river valley is confined and becomes progressively narrower upstream. It creates steep gradients, dropping over 100 feet per mile. The bottom of the river is composed of rubble and boulders with only scattered fish spawning areas. There are extensive glacier systems on nearby Glacier Peak. The tributaries, which are precipitous and pristine in nature, contain many cascades and falls. Thirty-five tributaries flow into the White Chuck River.

Appendix E
White Chuck River

GEOLOGY: Originating within the pumice deposits and volcanic flows on the flanks of Glacier Peak, this river passes through bedrock dominated by gneiss and granite and then through metasediments and schist. Although the valley has had a strong glacial influence, the traditional glacial U-shape is only dominate in the lower part of the valley. This is because post glacial volcanic activity from Glacier Peak has filled in the upper part of the valley and subsequent river downcutting has formed a steep aided V drainage. Landslides are common on the unstable volcanic material on these inner gorge sidewalls.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the White Chuck River, however, information is available from some project surveys. There is scant evidence of prehistoric use; the lack of sites is believed to represent survey patterns rather than lack of use. Historically, the river was within the territory of the Sauk-Suiattle Tribe. Localities used by the Sauk-Suiattle in the practice of their traditional religion exist within the proposed corridor.

Historic sites represent logging and Forest Service administration. The Sauk River Logging Company operated in the area from the 1920's to the 1950's. Railroad tracks extended a couple of miles up the White Chuck. None of the sites known on the White Chuck is listed on the National Register of Historic Places. Kennedy Hot Springs cabin, a Forest Service administrative structure built in 1924, may be determined eligible for the historic register after an evaluation is completed.

TIMBER: Approximately 50 years ago, the lower 5 miles of the river were extensively logged using railroads. Logging is still common on both sides of the river to Dead Duck Creek and on the north side of the river to the Wilderness boundary.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
105.3	2.787	2.674

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The White Chuck River enters the Sauk River about 10 miles southeast of Darrington (pop. 1020). Darrington is a community traditionally and presently dependent on logging and the forest products industry for its support. Located on the Mountain Loop Highway and in an area noted for its scenery and recreation opportunities, Darrington also benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: From its headwaters downstream 10.5 miles, the White Chuck River flows through the Glacier Peak Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river if designated would become an extension of the existing designated Skagit Wild and Scenic River System.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the White Chuck River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 7,500	$ 1,000
Costs of Implementation		3,000
Development of Management Plan		17,200
Development Costs	40,000	
Operation and Maintenance Costs	34,000	1,000
Total - First Five Years	**$81,500**	**$22,200**

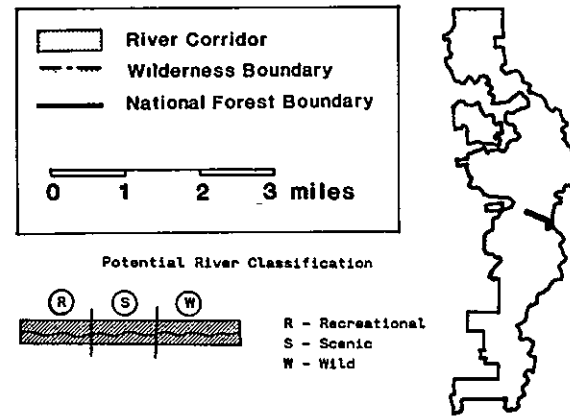
General administration and operation and maintenance costs are estimated to continue at $22,200 annually.

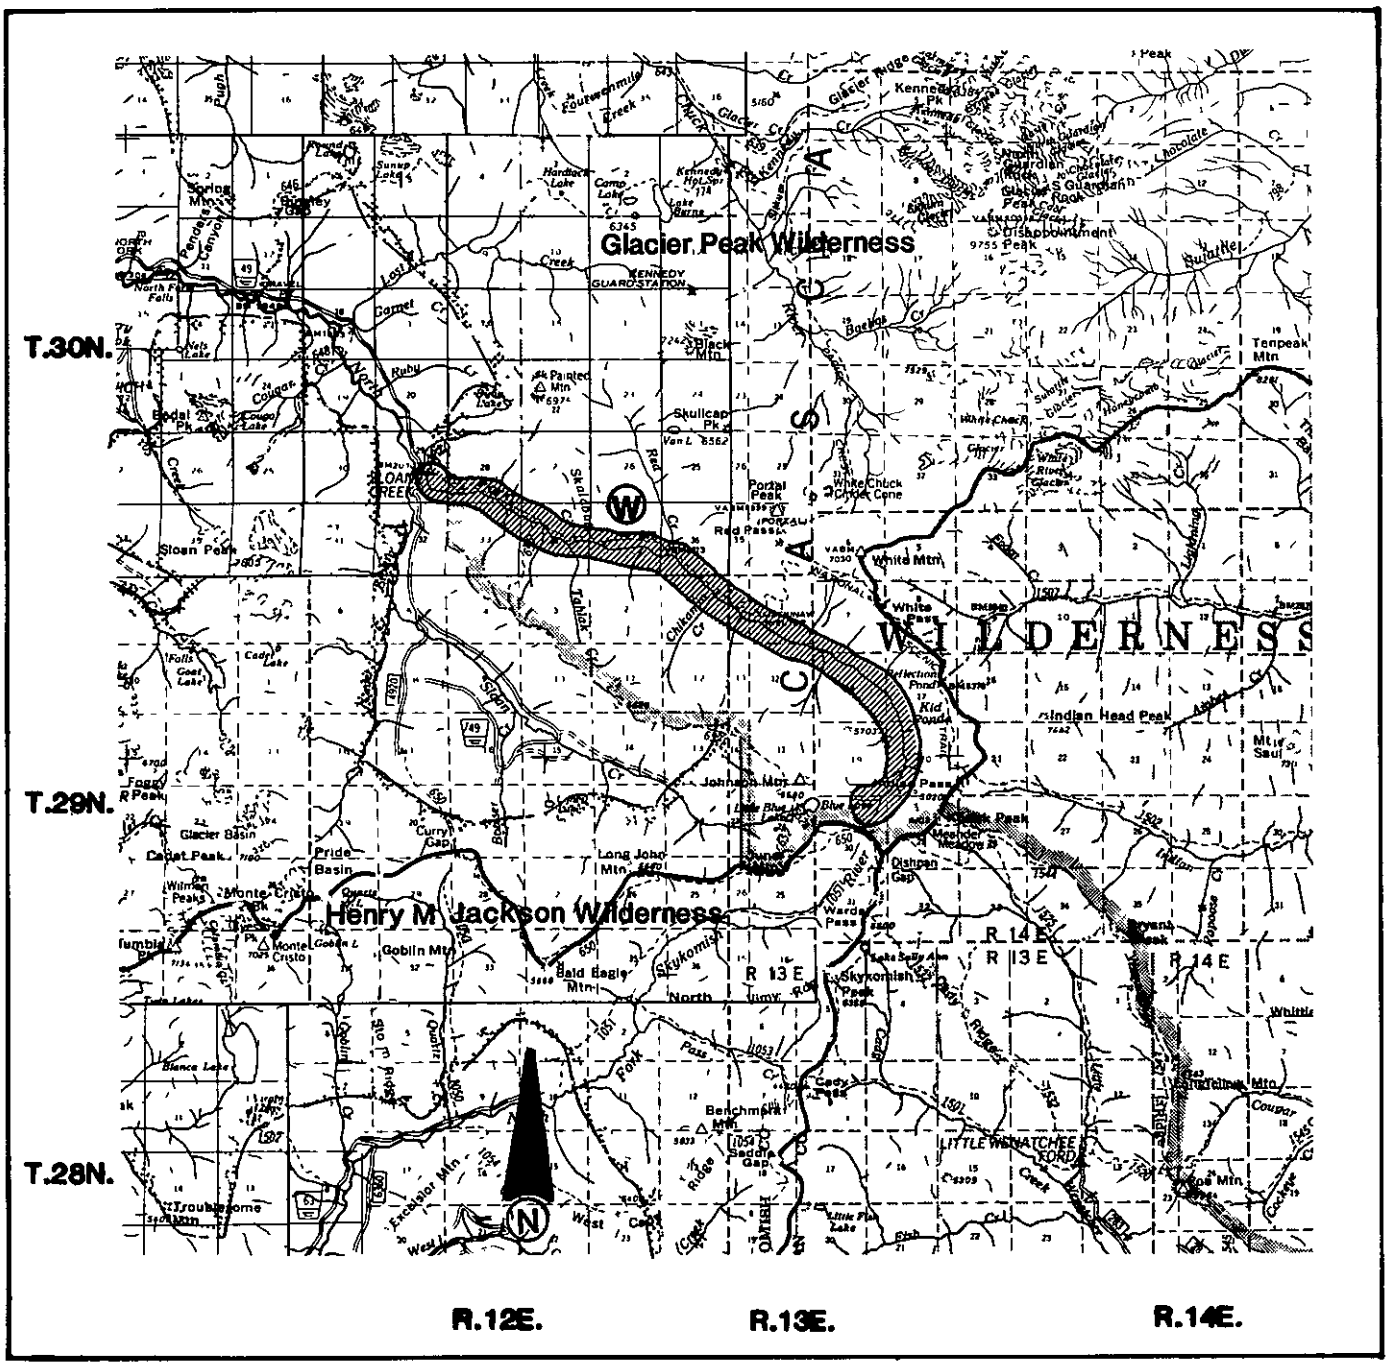
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	549
		Wilderness-Trailed	739
		Wilderness-General Trailless	591
		Wilderness-Dedicated Trailless	1,964
Segment 2	Recreation	Semi-Primitive, Non-Motorized Recreation	295
		Scenic Corridor (Foreground)	2,534
		Scenic Corridor (Middleground)	612
		Old Growth Habitat (spotted owl)	21
		Martin/pileated woodpecker habitat	21
		Goat Habitat	63
		Timber Management	147

North Fork Sauk River Extension





NORTH FORK SAUK RIVER

Snohomish County

The North Fork Sauk River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: The North Fork Sauk River Extension originates on Kodak Peak and flows westward ending at the Glacier Peak Wilderness boundary where it flows into the congressionally designated Wild and Scenic River.

Segment 1 - Headwaters in SW 1/4 of Sec. 19, T.29 N., R 14 E. to the boundary of the designated Wild and Scenic Skagit River in SE 1/4 of Sec 29, T.30 N., R.12 E. (Glacier Peak Wilderness boundary) (9.2 miles).

RIVER MILEAGE:

Study:	9.2 miles
Eligible:	9.2 miles
Forest Plan:	9.2 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The North Fork Sauk River was found to possess "Outstandingly Remarkable" values for the following: Wildlife.

The North Fork Sauk River area provides an extensive winter range for black-tailed deer and mountain goat. A SOHA exists within Glacier Peak Wilderness.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	9.2	Wild	9.2

SUITABILITY DETERMINATION:

The North Fork Sauk River extension was found to be suitable for inclusion in the preferred alternative of the Forest Plan. The river is located entirely within the Glacier Peak Wilderness and is a logical extension of the existing Wild and Scenic River.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Glacier Peak Wilderness - 9.2 miles)	9.2 miles	2,944 acres
TOTAL	9 2 miles	2,944 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified by the BLM as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the river has no reported locatable mineral resource occurrences of significance. However, Section 30, T.29 N., R.13 E. is encumbered by 4 unpatented mining claims. Based upon a U.S.G.S and U.S.B.M.'s mineral resource evaluation (Church and Others, 1984), it has been concluded that portions of the area does have a low potential for the occurrence of precious metal resources in hot spring type deposits, a low to moderate potential for the occurrence of base metal resources in several areas, and a moderate potential for disseminated porphyry base metal deposits.

The BLM has classified the entire river segment as being prospectively valuable for geothermal resources. However, it is not considered to have potential for the occurrence of other leasable mineral resources. None of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the area does have potential for the occurrence of base metal resources, precious metal resources and geothermal resources. Except for the four unpatented mining claims, no serious interest in either the locatable or leasable mineral resource potential of the area is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Forest Service Road No. 49 crosses the North Fork Sauk near the Sloan Creek confluence. A concrete bridge with approach guardrails is planned for this crossing.

The old Sloan Creek Campground road parallels the river for 0.25 miles.

The old site of Sloan Creek Campground now serves as a trailhead facility for horse and other Wilderness user's entry.

The North Fork Sauk Trail #649 begins at Sloan Creek. The trail parallels the North Fork for several miles before heading uphill to White Mountain and the junction with the Pacific Crest Trail.

The Sloan Peak Trailhead #648 is also located in the old Sloan Creek Campground. The trail crosses the North Fork Sauk. There is no footbridge; the river must be forded during periods of low water.

The Pilot Ridge Trail #652 is accessed 2 miles up the North Fork Sauk Trail. The Pilot Ridge Trail crosses the North Fork via a footlog before ascending Pilot Ridge.

Trail reconstruction, trailhead parking and a shelter reconstruction are proposed for development.

There are no homes, farms, or agricultural development.

RECREATION ACTIVITIES: There is little opportunity for rafting, canoeing, kayaking or swimming on the North Fork Sauk River Extension. There is high native trout fishing use on the lower reaches.

Dispersed recreation opportunities include hiking, horseback riding, hunting and camping.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	20	30
Camping	11,800	17,700
Viewing (scenery, wildlife driving for pleasure)	9,000	13,680
Misc. (hike, picnic, berry picking, etc.)	11,900	23,325
TOTAL	32,720	54,735

WILDLIFE AND FISHERIES: The North Fork Sauk River area provides an extensive winter range for black-tailed deer and mountain goat. A SOHA exists within Glacier Peak Wilderness.

There are no anadromous fish found on the North Fork Sauk Extension. The North Fork Falls, below the beginning of the river extension, acts as a total barrier to fish migration upstream. Native rainbow and cutthroat trout are found in the river's waters.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The water quality of the river is excellent. Small glaciers are found on the headwaters of the tributary streams. The river and its tributaries are filled with many cascades and falls.

The upper watershed contains steep gradients, dropping 100 feet per mile and lies in a valley which becomes narrower downstream. The bottom composition is rubble and boulders with only scattered fish spawning areas.

Fifteen tributaries drain into the North Fork Sauk River Extension.

GEOLOGY: Granite, granodiorite, hornblende gneiss, and associated rock types comprise the bedrock of the rugged topography in this area. Past glaciation has carved out the valley and left deposits of glacial till and lacustrine materials in this mostly U-shaped valley. Lower sideslopes, dominated by stringers of conifers and brushy avalanche tracks, merge into long steep and barren upper sideslopes where patches of snow often last through summer.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the North Fork Sauk River proposed Wild and Scenic River corridor. No prehistoric sites are known, however, the lack of sites is thought to reflect lack of survey of the drainage rather than lack of use. During the historic period, the North Fork Sauk was within the territory of the Sauk-Suiattle Tribe. An Indian trail that followed the North Fork to the upland meadows was documented in 1870. Localities used by the Sauk-Suiattle for traditional religious practices exist within the proposed corridor.

Known sites represent logging history and Forest Service administration. Logging railroads were built up the North Fork Sauk during the 1920's to 1950's. In the 1920's, Forest Service trail and telephone maintenance crews built two trail shelters along the river as part of the fire detection and suppression system. Both of these are still standing. Of the known historic sites, the Mackinaw trail shelter has been determined eligible for listing on the National Register of Historic Places.

TIMBER: The entire segment is within the Glacier Peak Wilderness, thus it is not available for logging.

LIVESTOCK GRAZING: There is occasional sheep grazing along the headwater divide, and recreation livestock grazing adjacent to the North Fork Sauk and Pacific Crest Trail.

SOCIO-ECONOMIC EFFECTS: The North Fork Sauk River enters the Sauk River about 10 miles SE of Darrington (pop. 1020). Timber has long been a vital component of Darrington's economy. The community is dependent on the periodic fluctuations of the timber industry. However, Darrington also serves as a primary gateway into the North Cascades. Located on the Mountain Loop Highway and in an area noted for its scenery and recreation opportunities, Darrington also benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: The river flows entirely within the Glacier Peak Wilderness. The wilderness is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This portion of the North Fork, if designated, would become an extension of the existing designated Skagit Wild and Scenic River System.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Fork Sauk River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 500	
Costs of Implementation		200
Development of Management Plan		3,400
Development Costs	80,000	
Operation and Maintenance Costs	1,000	
TOTAL - First Five Years	**$81,500**	**$3,600**

General administration and operation and maintenance costs are estimated to continue at $300 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	654
		Wilderness-Trailled	84
		Wilderness-General Trailless	42
		Wilderness-Dedicated Trailless	2,365

SOUTH FORK SAUK RIVER

Snohomish County

The South Fork Sauk River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Monte Cristo Peak to its confluence with Elliot Creek. Downstream from Elliot Creek, the river is already designated under the Skagit Wild and Scenic River System.

Segment 1 - Headwaters in SE 1/4 of Sec. 28, T.29 N., R.11 E. to Henry M. Jackson Wilderness boundary (1.0 mile).

Segment 2 - Henry M. Jackson Wilderness boundary to confluence with Elliot Creek (to existing W & SR designation) (7.4 miles).

RIVER MILEAGE:

Study	8.4	miles
Eligible:	8.4	miles
Forest Plan:	0.0	miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The South Fork Sauk River was found to possess "Outstandingly Remarkable" values for the following: Scenic and Wildlife.

The South Fork Sauk River lies between Bedal Peak and Sheep Mountain on the east shore and between Twin Peaks and Lewis Peak on the west shore. Views of these rugged mountain peaks are dramatic.

The area serves as a high quality winter range for black-tailed deer as well as a good riparian habitat area.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	1.0	None recommended	0
Segment 2	Scenic	7.4	None recommended	0

SUITABILITY DETERMINATION:

The South Fork of the Sauk extension was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to low public interest, high competing resource values in timber and mining, and the lack of anadromous fisheries.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Henry M. Jackson Wilderness - 1.0 mile)	0.9 miles	288 acres
Private	0.1 miles	32 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	7.2 miles	2,304 acres
Private	0.2 miles	64 acres
TOTAL	8.4 miles	2,688 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither of the river segments are classified by the BLM as areas of critical mineral potential. However, a review of available literature, including the Bureau of Mines MILS data, indicates numerous reported prospects for gold resources occur along the river and 168 unpatented mining claims have been located on or adjacent to the river. Of these claims, 41 have either been abandoned or declared to be null and void. The majority of the remaining 127 claims lie in Sections 20, 21, 22, 23, 26, and 27, T.29 N., R.11 E. The U.S.G.S. and U.S.B.M. (S.E. Church and Others, 1983) have evaluated the mineral resources of at least part of the area. Based upon the available information, the geology of the area and the results of their sampling they have concluded that:

> The upper end of the segment (Silver Creek and above) lies within an area that has "proven" reserves of base and precious metal resources, and it lies within a geologic terrain which has a high potential for additional precious and base metal mineral resources.

The BLM has classified the entire river as being prospectively valuable for geothermal resources, and one mile of the river is classified prospectively valuable for coal resources. However, the area is not considered to have potential for the occurrence of other leasable mineral resources, and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it does appear a large portion of the river has a moderate to high potential for the occurrence of both precious metal and base metal mineral resources. A serious interest in these resources is currently being expressed. The river also has at least a low potential for the occurrence of geothermal resources. However, no serious interest in these resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: The river is classified as "Protected" from hydropower development by the NW Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The Mountain Loop Highway follows the South Fork Sauk upstream from Elliott Creek and continues 3 miles to Barlow Pass. From the pass, a county road parallels the river to the Monte Cristo townsite. The road is closed to public vehicle traffic, but is well used by hikers. The road encroaches on the channel and immediate river banks at several points along the river.

There are plans to pave and widen the Mountain Loop Highway from Barlow Pass to the White Chuck River junction.

Appendix E
South Fork Sauk River

A concrete bridge spans the river at Mowich on the Mountain Loop Highway, a severely damaged wooden structure spans the river at Twin Bridges, and a substandard wooden structure spans the river near Monte Cristo on the county road.

There is 100 feet of rip-rap on both banks of the bridge in Section 6, T.29 N., R.11 E.

On private land, on and adjacent to the Monte Cristo townsite, there are several summer homes and restored mining structures.

The Poodledog Pass Trail #708 begins at the Monte Cristo townsite. The trail follows the river to the divide between the South Fork Sauk and Silver Creek drainages, before ending at Silver and Twin Lakes.

The Weden Creek Trailhead #724 is located along the Monte Cristo Road past Twin Bridges Camp. The trail crosses the South Fork Sauk before heading uphill to Foggy Lake.

The only developed campground is found at Monte Cristo, with a 40-person capacity.

Additional developed view points, trailhead parking and trails are planned.

RECREATION ACTIVITIES: Resident rainbow trout, steelhead and dolly varden are caught on the South Fork Sauk.

The Monte Cristo area is a popular destination hike as well as a gateway to the Henry M. Jackson Wilderness.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	100	144
Camping	8,300	12,450
Viewing (scenery, wildlife, driving for pleasure)	3,400	5,168
Misc. (hike, picnic, berry picking, etc.)	2,800	5,488
TOTAL	14,600	23,250

WILDLIFE AND FISHERIES: The area serves as a high quality winter range for black-tailed deer and mountain goat. The area around Monte Cristo Lake is an important wetland habitat.

Due to the river's extreme flows, cold water conditions and boulder-filled bottom, only scattered fish spawning areas are found. Spring chinook have been reported as far upstream as Barlow Pass. However, most spawning is in the lower 1/2 mile of the river. Pink salmon also spawn in the lower reaches. Resident trout, dolly varden and mountain whitefish are found along the length of the river.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The South Fork Sauk River contains steep gradients, dropping over 100 feet per mile. The bottom of the riverbed is composed of rubble and boulders. Thirteen tributaries flow into the South Fork Sauk River above Elliot Creek.

GEOLOGY: The bedrock geology consists of granitic and gneissic rocks associated with local extrusive igneous rocks of andesite and diabase flows. This high energy stream is relatively wide, braided and flows through a U-shaped glacial valley. Surrounding mountains rise thousands of feet above the valley floor. Sparsely forested lower slopes merge into massive barren rock capped by perennial snow and ice. Snow and debris tracks are numerous on these long steep sideslopes.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the South Fork Sauk River. However, some information is available from project surveys and historical research. No prehistoric sites have been documented, but literature research indicates that Indians used this area during the historic period. A known prehistoric site near the headwaters of the North Fork indicates use of the drainage as a travel corridor.

The drainage was within the territory of the Sauk-Suiattle tribe during the historic period. Today, localities important in the practice of their traditional religion exist within the proposed corridor.

Most of the documented history of the South Fork Sauk relates to the development of the Monte Cristo Mining District. Minerals, principally silver, were discovered at Monte Cristo in 1889, and within a couple of years, several claims had been made. A tote road was built, and in 1893, the Everett to Monte Cristo Railroad was completed. This was the only railroad in the state to be constructed solely for the purposes of mining. The railroad and the town of Monte Cristo were abandoned in 1898. Interest in the mines and railroad was intermittent through the next 30 years. At the onset of the Depression era, a flood closed the railroad for the last time, but small scale mining interests continue today. Historic sites and features associated with the mining history of the drainage may be determined eligible for the National Register of Historic Places after an evaluation is completed, however, no sites are currently listed on the register.

TIMBER: In the past, private lands have been logged. The Forest Service has performed patch cutting and salvage logging adjacent to the area roads.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only.

	----------ASQ----------	
	Preferred	Preferred
Total	Alternative	Alt. with
Timber	w/o W&SR	Eligible W&SR
Volume	Designation	Designation
(MMBF)	(MMBF/yr.)1/	(MMBF/yr.)1/
30.9	.762	.760

1/ Based on preferred alternative with management requirements.

Appendix E
South Fork Sauk River

SOCIO-ECONOMIC EFFECTS: The South Fork of the Sauk River enters the Sauk River about 15 miles southeast of Darrington (pop. 1020). Darrington is a community traditionally and presently dependent on logging and the forest products industry for its economic survival. Located on the Mountain Loop Highway and in an area noted for its scenery and recreation opportunities, Darrington also benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: With the exception of small parcels of private land, the South Fork Sauk is entirely administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. The river if designated would become an extension of the existing designated Skagit Wild and Scenic River System.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the South Fork Sauk River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 10,000	$ 2,000
Costs of Implementation		3,000
Development of Management Plan		8,600
Development Costs	56,000	10,000
Operation and Maintenance Costs	16,800	4,000
TOTAL - First Five Years	**$ 82,800**	**$ 27,600**

General administration and operation and maintenance costs are estimated to continue at $6,560 annually.

NORTH FORK STILLAGUAMISH RIVER

Skagit and Snohomish Counties

The North Fork Stillaguamish River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The North Fork Stillaguamish River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters on Rinker Ridge downstream to its confluence with the South Fork Stillaguamish River, near the town of Arlington.

Segment 1 - Headwaters in SE 1/4 of Sec. 17, T.34 N., R.9 E. to the confluence with the South Fork Stillaguamish

RIVER MILEAGE:

Study:	49.8 miles
Eligible:	49.8 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The North Fork Stillaguamish River was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife.

Nearly all gravel areas above Rollins Creek, located near community of Hazel, are suitable for the spawning and rearing of chinook, pink, chum and some coho salmon The lower six miles of the river contains excellent spawning, holding and rearing habitat for adult salmon.

The North Fork Stillaguamish River corridor has an excellent winter range for black-tailed deer. It also provides excellent riparian, furbearer, and elk habitat.

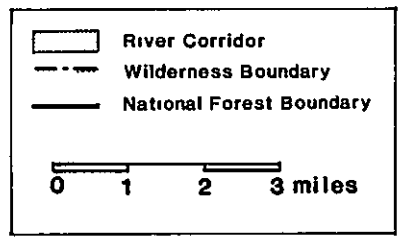
POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	49.8	None recommended	0

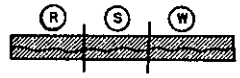
SUITABILITY DETERMINATION:

The North Fork of the Stillaguamish River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan because the majority of the outstandingly remarkable values are found off of the National Forest. A large portion of the river is in private ownership leading to potential management problems. There are high competing resource values on that portion of the river within the National Forest.

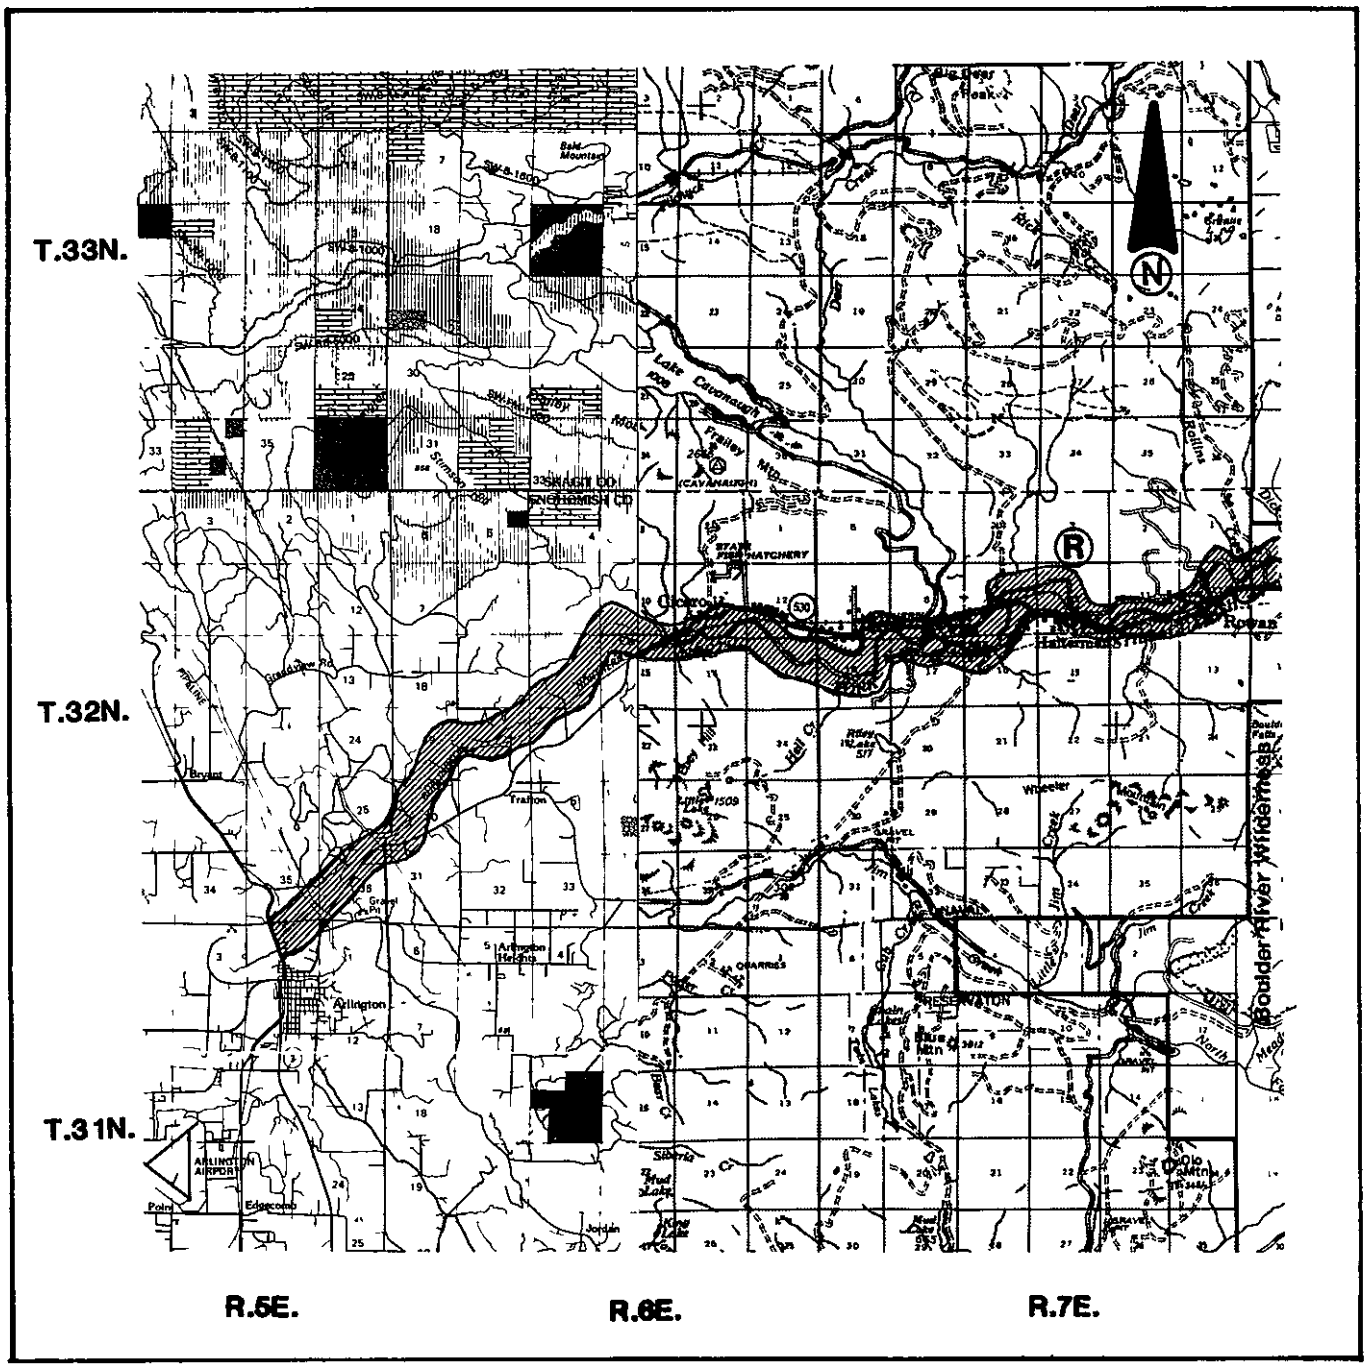
North Fork Stillaguamish River North Branch (1)



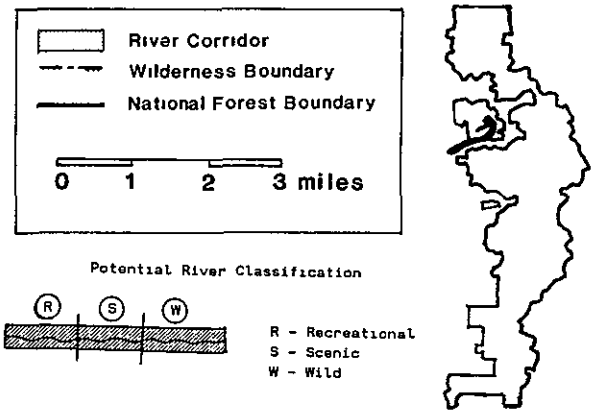
Potential River Classification

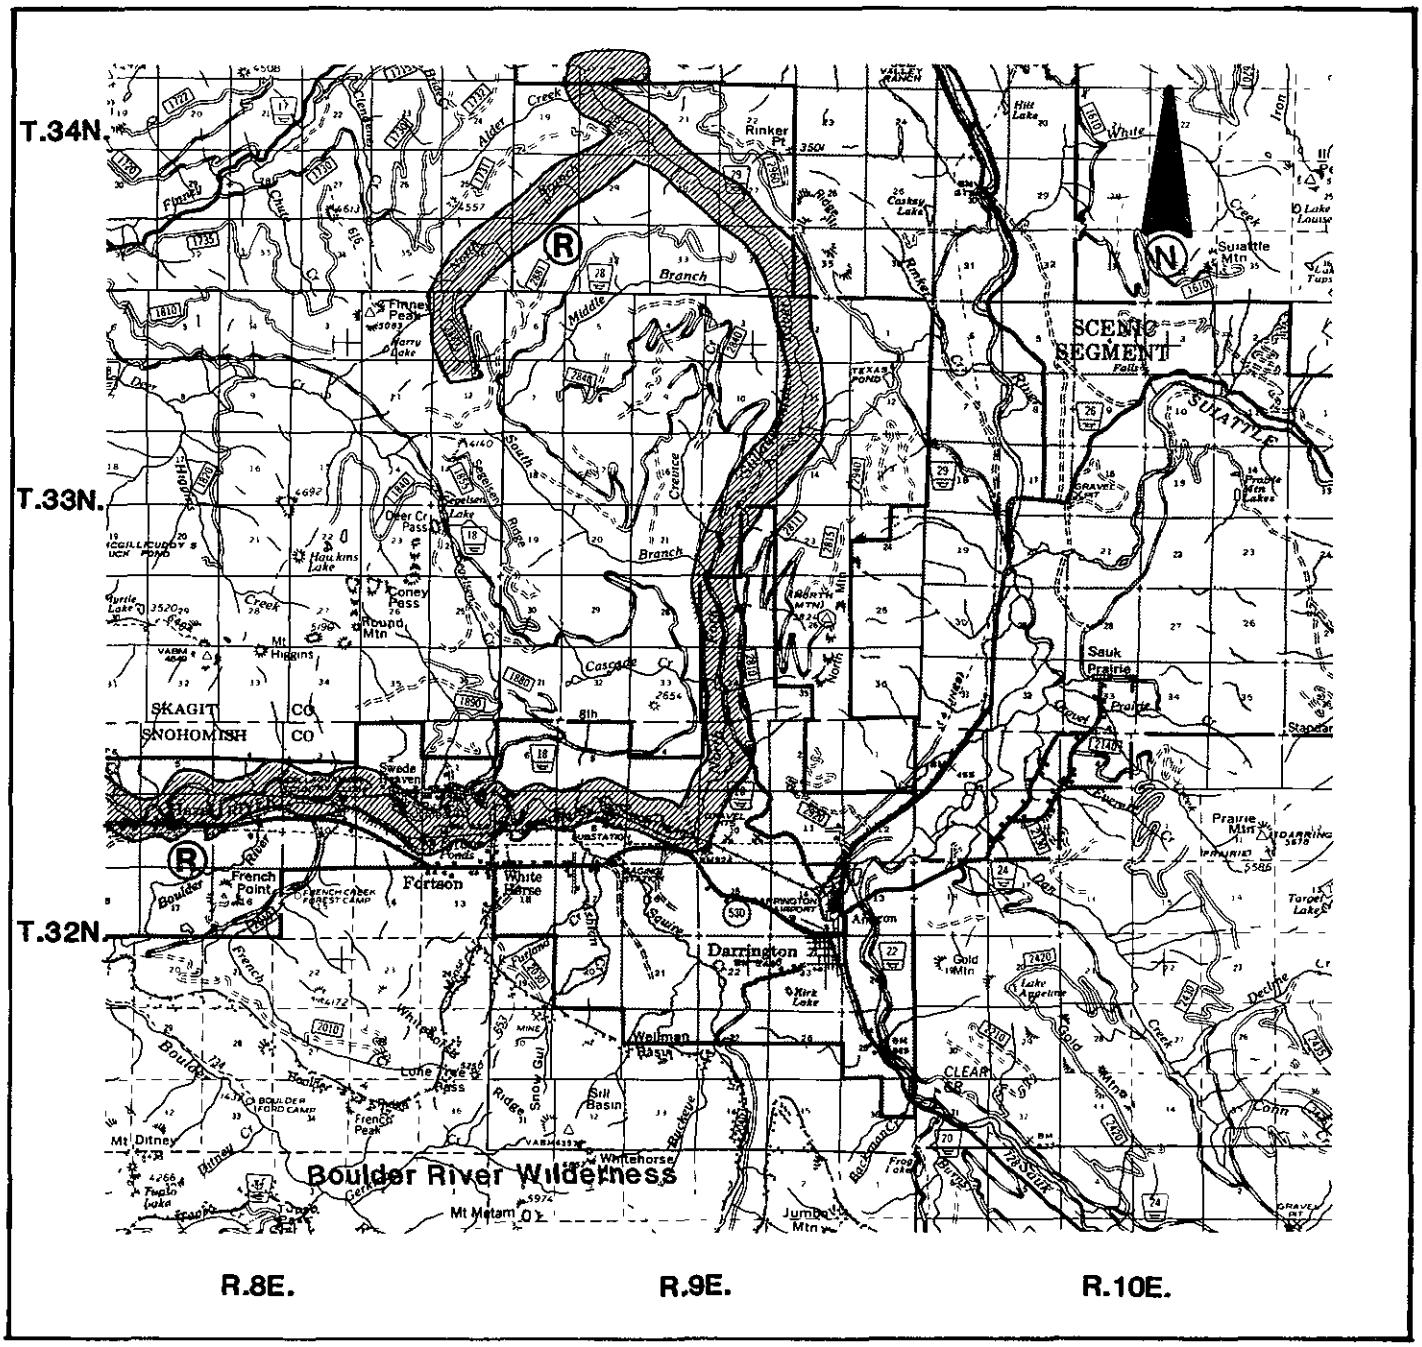


R - Recreational
S - Scenic
W - Wild



North Fork Stillaguamish River North Branch (2)





Appendix E
North Fork Stillaguamish River

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	10.8 miles	3,456 acres
Private	35.9 miles	11,040 acres
State	3.1 miles	1,440 acres
TOTAL	49.8 miles	15,936 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified by the BLM as an area of critical mineral potential. Neither is it encumbered by unpatented mining claims, and a review of available literature, including the Bureau of Mines MILS data, indicates the river has no reported locatable mineral resource occurrences of interest although one gold prospect was reported for T.32 N., R.8 E., Section 14. There are, however, numerous reported occurrences of both rock and sand and gravel resources which have been produced in the past.

The BLM has classified the west two miles as being prospectively valuable for oil and gas, and has classified the west 8 miles and a 9 mile section in the middle part of the river as "PV" for coal. However, none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears the area has a relatively low potential for the occurrence of locatable mineral resources. Portions of the river have at least a low potential for the occurrence of coal, oil and gas resources. No serious interest in either type of mineral resource is currently being expressed. The area does have mineral material resources which are being or have been produced in the past, and there appears to be a continuing interest in those resources.

WATER RESOURCE DEVELOPMENT: There are no water impoundments located on the river.

The Stillaguamish River is listed by the State Department of Ecology as a "River of Statewide Significance" based on water volume.

The North Fork Stillaguamish is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Highway 530 and other roads link the communities and residences in this area. Highway 530 parallels the river for its entire length in Snohomish County. Numerous logging roads also parallel the river and tributaries in the National Forest.

The river flows under a number of bridges. Highway 530 crosses the river east of Oso in Sec. 9, T.32 N, R.7 E. and again at NE 1/4 Sec. 15, T.32 N., R.6 E. Local roads cross the river at Sections 10 and 17, T.32 N., R.7 E.

The Northern Pacific Railroad parallels the river for all of its length in Snohomish county. It crosses the river east of Oso near Deer Creek, and again in NE 1/4 Sec. 15, T.32 N., R.6 E. and SW 1/4 Sec. 30, T.32 N., R.6 E.

Outside the forest boundary, the predominant land use is agricultural.

In the lower valley, there are farms and rural residences. The small communities of Whitehorse, Trafton and Arlington are all located in the valley Some summer and recreation developments are located along river-front lands.

At the confluence of the North Fork and the South Fork Stillaguamish Rivers Twin Rivers County Park is a 50-acre site with soccer fields, fishing, etc. The facilities are planned specifically to tolerate the regular flooding that takes place there.

A small picnic area is located at the Fortson Fish Hatchery.

Steelhead Haven Park with fishing access is approximately 5 miles west of Darrington near Swede Heaven Road in NE 1/4 Sec. 12, T.32 N., R.8 E.

River access is available off SR530 17.3 miles northeast of Arlington and 8.6 miles and 2.5 miles west of Darrington. A primitive boat launch is located 7.5 miles northeast of Arlington off SR530.

Seattle City Light Transmission Lines parallel much of the river. There are three powerlines in the river corridor. One is south of the river at RM 15-34, one crosses the river at 2.2 miles from the confluence of the North Fork and the Stillaguamish Rivers, and the other crosses the river .7 mile from the confluence of the North Fork and the Stillaguamish Rivers.

RECREATION ACTIVITIES: Big game hunting and camping occurs in association with the Forest Service road system. Heavy fishing use occurs from Oso to the confluence with the South Fork.

Canoeing and kayaking are above average from Oso to South Branch. The North Fork Stillaguamish is considered a good training river. There is no rafting use inside the forest boundary and low use outside. Swimming use is moderate.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	1,000	1,440
Camping	3,500	5,250
Viewing (scenery, wildlife, driving for pleasure)	400	608
Misc. (hike, picnic, berry picking, etc.)	100	196
TOTAL	5,000	7,494

WILDLIFE AND FISHERIES: The North Fork Stillaguamish River corridor provides excellent winter range for black-tailed deer. It also provides excellent riparian, furbearer, and elk habitat

The North Fork Stillaguamish is accessible to anadromous fish upstream to an impassable falls, located 3/4 mile below the mouth of the South Branch. However, the prime spawning and rearing habitat is located between Squire Creek and the community of Hazel. Large numbers of pink, chum and summer and fall

chinook use the North Fork and its accessible tributaries. Above Squire Creek, high summer water temperatures and low flows limit fish production. Below Hazel, near Rollins Creek, a major mud and clay slide on the river's right bank is depositing large amounts of silt into the river. The silt covers the gravel riffles, making them unsuitable for successful spawning and egg incubation. Deep pools located in the lower 6 miles of the river offer excellent holding and resting areas for adult salmon and provide exceptional rearing habitat. Sea-run cutthroat trout, mountain whitefish and resident rainbow and cutthroat trout also inhabit the river.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The area from the headwaters to the community of Fortson contains two different stream characteristics. The upper 14 miles has many boulders. The river is swift flowing over a steep gradient through a relatively deep-cut channel. The stream width varies from 2 to 5 yards. The banks are generally stable with sharp earth or rock cuts and only a few gently sloping rock beaches. The lower 6 miles are floodway in nature and present a moderate gradient and winding stream course There are numerous, relatively broad riffles separated by deeper pool and glide stretches. There are low banks with naturally stable, earth-cut or gently sloping gravel-rubble beaches.

From Fortson to Oso, the valley floor is relatively broad and gently sloping. Stream gradient is moderate with considerable meandering and numerous channel splits. Pool-riffle balance is good to excellent with a mix of broad riffles and lengthy gravel beaches with some patch gravel sections. Pools are large and deep.

From Oso to Arlington, the river meanders a great deal, offering moderate gradient with good to excellent pool-riffle conditions. Just north of Trafton, the gradient decreases considerably and the stream channel contains numerous long, deep pools and relatively shallow, slow-moving glides. The channel width ranges from 45 feet to 100 feet. Numerous riffles are composed of gravel and mixed rubble with layers of silt deposit in slower waters.

In the upper headwaters, the stream bottom is mainly boulders and rubble with only occasional patch gravel. Further downstream, the channel is well-defined with only a few channel splitting sections, and the bottom is stable with clean rubble and gravel.

The sixty-three tributaries are predominantly steep-gradient, mountain-type streams with numerous cascades and small falls. Water quality is medium.

GEOLOGY: This river passes through two distinctly different geologic and topographic areas. From the headwater area to the Forest boundary, the bedrock is dominated by relatively soft and incompetent phyllite and greenschist. The river is rapidly downcutting through this soft rock producing a steep, unstable, V-shaped canyon Upon leaving the Forest boundary the river enters a very wide, previously glaciated, U-shaped valley. Surrounding bedrock is primarily metasediments However, very deep glacial till is the controlling geologic feature on the valley bottom and toeslopes.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the North Fork Stillaguamish River. However, information is available from a number of surveys made in conjunction with Federal projects and from published historical research. That no prehistoric sites have been recorded to date is believed to reflect the lack of survey of the drainage. During the historic period, the area was within the territory of the Stillaguamish tribe. Historic

sources indicate that there were several Indian villages and campsites along the North Fork during the historic period. Localities, used by the Samish, Sauk-Suiattle and Tulalip tribes in the practice of their traditional religion, exist in the upper segments of the river.

Historic period sites represent logging and railroading. In 1901, the Seattle International Railroad was extended to Darrington, primarily to serve mining developments of the Whitehorse Mining District. With the trains, came equipment for the first sawmills; and railroad logging spurs were extended up several of the tributaries of the drainage. None of the sites known from the North Fork are listed on the National Register of Historic Places.

TIMBER: There is extensive patch logging in the upper watershed. Some patch logging and clearcutting now takes place on the valley floor and on the adjacent hillsides. However, most of the lower slopes were clearcut during the early days of railroad logging.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest System lands only

	----------ASQ----------	
	Preferred	Preferred
Total	Alternative	Alt with
Timber	w/o W&SR	Eligible W&SR
Volume	Designation	Designation
(MMBF)	(MMBF/yr.)1/	(MMBF/yr)1/
78.2	6.621	6.031

1/ Based on preferred alternative with management requirements

LIVESTOCK GRAZING: Extensive grazing of dairy and beef cattle occurs adjacent to Highway 530.

SOCIO-ECONOMIC EFFECTS: The North Fork of the Stillaguamish River meets SR 530 three miles west of Darrington (pop 1020). Its confluence with the Stillaguamish River lies near Arlington (pop 2990). Darrington is traditionally and presently a community which is supported by logging and the forest products industry Arlington and nearby communities depend more on agriculture for their economic livelihood. A number of Arlington residents are employed in Everett. There is pressure to convert farmland to residences and businesses. Located on the Mountain Loop Highway, communities along the North Fork also benefit from tourism and outdoor recreation enthusiasts.

CURRENT ADMINISTRATION: Of the headwaters, 10.8 miles are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the North Fork Stillaguamish has been classified by Skagit and Whatcom counties as Conservancy or Rural. There are flood hazard zones all along the river. These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes areas characterized by

agricultural uses, low density residential where most urban services are not available, and areas which provide buffer zones and open space between predominantly urban areas.

Almost all of the river corridor is classified as "Environmentally Sensitive" by Snohomish County. Lands along the river corridor, outside of federal jurisdiction, are zoned by Snohomish and Skagit Counties for Forestry or Rural Uses.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Fork Stillaguamish River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$ 50,000
Costs of Implementation		15,000
Development of Management Plan		98,100
Development Costs		150,000
Operation and Maintenance Costs		25,000
TOTAL - First Five Years	**$ 1,000**	**$338,100**

General administration and operation and maintenance costs are estimated to continue at $15,200 annually.

NORTH BRANCH OF THE NORTH FORK STILLAGUAMISH RIVER

Skagit County

The North Branch Stillaguamish River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Finney Peak downstream to its confluence with the North Fork Stillaguamish River.

Segment 1 - Headwaters in NE 1/4 of Sec. 12, T.33 N., R.8 E. to the confluence with the North Fork Stillaguamish River (5.1 miles).

RIVER MILEAGE:

Study:	5.1	miles
Eligible:	5.1	miles
Forest Plan:	0.0	miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The North Branch Stillaguamish River was found to possess "Outstandingly Remarkable" values for the following: Wildlife.

The North Branch area supplies winter range for black-tailed deer. It also supports excellent furbearer and riparian habitat.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	5.1	None recommended	0

SUITABILITY DETERMINATION:

The North Branch of the Stillaguamish was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to high competing resource values and low public interest. The North Branch is a logical addition only if the North Fork of the Stillaguamish is also suitable.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt Baker-Snoqualmie National Forest	5.1 miles	1,632 acres
TOTAL	5.1 miles	1,632 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified by the BLM as lying within an area of critical mineral potential. Neither is it encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates the river has no reported occurrences of locatable mineral resources. The BLM has not classified any part of this river as being prospectively valuable for leasable mineral resources, and no part of the river has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the river has a relatively low, if any, potential for the occurrence of both locatable and leasable mineral resources, and no serious interest in either type of mineral resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the river.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are no developments on the river at this time. Logging roads are proposed for the future.

RECREATION ACTIVITIES: Trout fishing and big game hunting are the major recreation activities in this area.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Misc. (hike, picnic, berry picking, etc.)	100	196

WILDLIFE AND FISHERIES: The North Branch area contains winter range for black-tailed deer. It also supports excellent furbearer and riparian habitat.

Anadromous fish cannot access the river due to an impassable falls located on the North Fork Stillaguamish River. The river is inhabited by cutthroat and rainbow trout.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The North Branch contains many boulders. The river is swift, flowing over steep gradient through a relatively deep-cut channel. Stream width varies from 2 to 5 yards and the banks are generally stable.

The North Branch has 10 tributaries.

GEOLOGY: The bedrock geology is dominated by relatively soft and incompetent phyllite and greenschist. The river is rapidly downcutting through this soft rock producing steep and unstable V-shaped canyons. Adjacent sideslopes and ridges are forested or cutover.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the North Branch, and no prehistoric or historic resources are known. No localities used for traditional religious practices are known to exist within the potential wild and scenic river corridor.

TIMBER: The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
48.7	2.999	2.729

1/ Based on preferred alternative with revised requirements.

SOCIO-ECONOMIC EFFECTS: The North Branch, like the North Fork Stillaguamish which it joins, is near forest roads. Its confluence with the North Fork Stillaguamish is approximately 14 miles from Darrington (pop. 1020) Darrington is a community traditionally and presently dependent on logging and the forest products for its economic survival. It is located on the Mountain Loop Highway in an area noted for its scenery and recreation opportunities and benefits economically from the many visitors to the area.

CURRENT ADMINISTRATION: The river corridor is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Branch of the North Fork Stillaguamish River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$500	$ 0
Costs of Implementation		1,000
Development of Management Plan		5,700
Development Costs		2,000
Operation and Maintenance Costs		500
TOTAL - First Five Years	**$500**	**$9,200**

General administration and operation and maintenance costs are estimated to continue at $200 annually.

DEER CREEK

Skagit and Snohomish Counties

Deer Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters near Coney Pass to its confluence with the North Fork Stillaguamish River at Oso.

Segment 1 - The headwaters near Coney Pass in the SW 1/4 of Section 23, T.33 N., R.8 E. to the confluence with the North Fork Stillaguamish River (23.5 miles).

RIVER MILEAGE:

Study:	23.5 miles
Eligible:	23.5 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Deer Creek was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife.

The Deer Creek drainage supports an excellent, extensive black-tailed deer winter range. Two SOHA's are located in the upper reaches of the creek.

Deer Creek is accessible to anadromous fish runs nearly to its headwaters. The creek is known for its famous summer steelhead run. Fall and spring chinook, coho, pink and chum salmon and resident trout also inhabit the creek.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	23.5	Not recommended	0.0

SUITABILITY DETERMINATION:

Deer Creek was found to be not suitable for inclusion in the preferred alternative of the Forest Plan since only a small portion of the river is within the National Forest.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	7.4 miles	2,368 acres
Private	9.1 miles	2,912 acres
State	7.0 miles	2,240 acres
TOTAL	23.5 miles	7,520 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segment is classified by the BLM as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has had only one reported prospect for a locatable mineral resource. That prospect was for nickel, and it was located in T.33 N., R.7 E., Section 31. The BLM mining claim recordation data does indicate that 48 unpatented mining claims were located in Sections 22, 23, 26 and 27, T.33 N., R.8 E. However, of those 48 claims, 36 have either been abandoned or declared to be null and void, and the remaining 12 may or may not lie within the river corridor.

BLM has classified a 14 mile segment in the middle part of the river as being prospectively valuable for coal resources. The river is not considered to be prospectively valuable for any other leasable mineral resources, and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the river has a relatively low potential for the occurrence of locatable mineral resources. A portion of it does have at least a low potential for the occurrence of coal resources. However, no serious interest in the coal resources has been expressed, and only a minor interest in locatable mineral resources has been expressed for the eastern-most two miles of the river.

WATER RESOURCE DEVELOPMENT: This river is classified as "Protected" from hydropower development by the NW Power Planning Council.

There are no water impoundments.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Logging roads provide the principal access throughout most of the area. A single lane gravel road parallels the creek.

Highway 530 crosses Deer Creek at the town of Oso. In addition, the creek flows under 2 other road bridges and the Burlington Northern Railroad bridge just north of Oso.

Rip-rap has been placed along the creek in the following locations: 3,000 yards under the Highway 530 and Burlington Northern bridges, 1,000 yards at the mouth of Rick Creek, 2,000 yards under the Forest Road 1820 bridge crossing, and 200 yards near mile post 1.5 of Forest Road 1840.

The mouth of tributary Deforest Creek has been channelized and stabilized.

Fish habitat improvement and stream stabilization projects are planned for several locations along the creek.

There are a few rural residences along the lower reaches of the creek and in the community of Oso.

There are no developed campgrounds.

RECREATION ACTIVITIES: The river is seldom used for rafting, due to poor access. The lower 11 miles offer a moderate amount of kayaking. The river gets only incidental use for swimming at Oso. There is minimal use of the creek corridor for dispersed recreation.

Deer Creek has been closed to fishing since 1941 in order to protect and rebuild stocks of summer steelhead.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	50	75
Camping	200	300
Viewing (scenery, wildlife, driving for pleasure)	150	230
Misc. (hike, picnic, berry picking, etc.)	50	100
TOTAL	450	705

WILDLIFE AND FISHERIES: The Deer Creek drainage supports an excellent, extensive black-tailed deer winter range. Two SOHA's are located in the upper reaches of the creek.

Deer Creek is accessible to anadromous fish runs nearly to its headwaters. Fall and spring chinook, coho, some pink and an occasional chum salmon and steelhead utilize the creek for spawning and rearing. Deer Creek is known for its famous summer steelhead run. Resident trout are found in the headwaters area. Additional fish production is limited by heavy silt loading and a tendency toward flash flooding. This condition has been aggravated by areas of extensive clearcut logging in the upper watershed.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The stream gradient is moderately steep. Very narrow, ravine- and canyon-like conditions are predominant in the lower five miles with very steep gradients. The creek bottom is boulder-strewn, interspersed with rubble and a few riffle and patch gravel sections. There are 23 tributaries flowing into Deer Creek. The tributaries exhibit steep gradients common to mountain streams. They contain numerous cascades and waterfalls. The main channel of Deer Creek contains several passable cascades. There is a heavy sediment load in the water below DeForest Creek due to land slides.

GEOLOGY: Within the confines of the Forest boundary and extending downstream several miles, the bedrock geology is dominated by nonmarine sedimentary rocks formed from sediments of silt and sand deposited on the floors of ancient fresh water lakes. These rocks consists of graywacke or arkose sandstone interbedded with mudstone, siltstone and shale Extensive glaciation occurred during the last glacial period depositing till and lacustrine materials hundreds of feet thick. Subsequent rapid downcutting through these often unstable materials has caused oversteepening of the sidewalls resulting in numerous old and recent landslides.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Deer Creek and no prehistoric or historic sites have been recorded. The lack of known sites is believed to reflect the lack of survey of the drainage. During the historic period the area was within the territory of the Stillaguamish tribe. The mouth of the river was known as a large campground for Indians during forays to the high country for berry picking and hunting. The Deer Creek drainage currently has some value for local Indians in the practice of their traditional religion.

The town of Oso developed as a logging town. The Oso Elementary School is recognized on the State Register of Historic Place.

TIMBER: There has been extensive clear-cut logging in the upper watershed. Views are of logged lands and second growth tree stands.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
54.9	3.284	3.005

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Deer Creek is in close proximity to forest roads. It flows into the North Fork Stillaguamish near the community of Oso. Oso (pop. 75) is located on the Mountain Loop Highway. The economy of the area in the vicinity of Deer Creek is traditionally dependent on the forest products industry and small farming. However, an increasing number of visitors are seeking out the recreation opportunities available along the Stillaguamish River system and surrounding mountains. Camping, fishing, hiking, hunting, cross-country skiing and sightseeing all attract visitors into the area.

CURRENT ADMINISTRATION: The river corridor inside the Forest boundary is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of Deer Creek has been classified by Snohomish County as Conservancy. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A conservancy designation denotes shoreline areas which are primarily free from intensive development. Flood hazard zones have also been designated in the shoreline area.

Within Snohomish County, much of the land along Deer Creek, that is outside of federal jurisdiction, is zoned for Agricultural Use with 10-acre tracts and Rural Use with 5-acre tracts. There are also some parcels of land zoned for Forestry Use. All of the Deer Creek corridor that lies within Skagit County is zoned for Forestry Use.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Deer Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		43,800
Development Costs	0	5,000
Operation and Maintenance Costs		1,000
TOTAL - First Five Years	**$ 1,000**	**$52,800**

General administration and operation and maintenance costs are estimated to continue at $600 annually.

BOULDER RIVER

Snohomish County

The Boulder River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Boulder River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters on Three Fingers Mountain to its confluence with the North Fork Stillaguamish River.

Segment 1 - Headwaters in SW 1/4 of Sec. 7, T.31 N., R.9 E. to Boulder River Wilderness boundary (9.0 miles)

Segment 2 - Boulder River Wilderness boundary to confluence with North Fork Stillaguamish River (4.0 miles).

RIVER MILEAGE:

Study	13.0 miles
Eligible:	13.0 miles
Forest Plan.	13.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Boulder River was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife.

The Boulder River provides habitat for a diverse number of fish species. The river provides spawning and rearing habitat for fall chinook, coho, pink and chum salmon and also supports a population of summer steelhead and dolly varden.

An extensive winter range for black-tailed deer and habitat for bald eagles are contained within the river corridor. There is mountain goat habitat at the headwaters and two SOHA's are located within the wilderness.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	9.0	Wild	9.0
Segment 2	Recreation	4.0	Recreation	4.0

Appendix E
Boulder River

SUITABILITY DETERMINATION:

Boulder River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to a lack of resource conflicts and the support of other public agencies. This river was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982. Ease of management would be facilitated by a majority of the river being located in wilderness.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Boulder River Wilderness - 9.0 miles)	9.0 miles	2,880 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.9 miles	288 acres
Private	1.0 miles	222 acres
State	2.1 miles	770 acres
TOTAL	13.0 miles	4,160 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither of the river segments are classified by the BLM as areas of critical mineral potential or are encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates the river has only one reported occurrence of a locatable mineral resource, which was a prospect for manganese located in Section 16, T.32 N., R.8 E. No part of the river has been classified by the BLM as being prospectively valuable for leasable mineral resources, and none of it has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the river has a relatively low potential for the occurrence of both locatable and leasable mineral resources, and no serious interest in the mineral resources of this river is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the river.

This river is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Highway 530, the Northern Pacific Railroad, and powerlines cross the Boulder River 0.5 mile from its confluence with the North Fork Stillaguamish.

There are a few homes located near the mouth of the river.

Some hay farming occurs near the mouth of the river.

The Boulder River Trailhead #734 is located at the end of Forest Road 2010. The trail follows the river past Boulder Falls to Boulder Ford Camp.

There are no developed campgrounds along the river.

RECREATION ACTIVITIES: Recreation use in the National Forest is low. Some camping occurs along the river in undeveloped sites. A trail parallels the river inside the Wilderness boundary.

The lower 3 miles of the Boulder River receives moderate use for steelhead fishing. The upper reaches have moderate use for rainbow and cutthroat trout fishing.

There is Class V whitewater kayaking below Boulder Falls to the confluence with the North Fork Stillaguamish River. The river is not suitable for rafting or swimming.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	400	576
Camping	3,000	4,500
Viewing (scenery, wildlife, driving for pleasure)	20	30
Misc. (hike, picnic, berry picking, etc.)	1,900	3,724
TOTAL	5,320	8,830

WILDLIFE AND FISHERIES: The Boulder River provides winter range habitat for the black-tailed deer. The corridor also provides a wintering area for the federally listed Threatened and Endangered species, the bald eagle. Habitat for mountain goats occurs near the headwaters and two SOHA's are located within the wilderness.

The Boulder River is accessible to anadromous fish runs for nearly 3 miles upstream from the mouth. This section provides spawning and rearing area for fall chinook, coho, pink, and some chum. The river also supports a population of summer steelhead and dolly varden.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The upper river drops sharply through a deep narrow cut. The Boulder River Canyon section, lying 3 to 5 miles downstream from the headwaters is very narrow and almost entirely composed of cascades. There are many falls with vertical drops of greater than 20 feet. At Boulder Falls, 8 miles downstream from the headwaters, the valley walls narrow and steepen into a deep ravine for 2 miles. At Boulder Falls the river drops 50 feet. Below the falls, the valley floor widens, the stream gradient is moderate and the stream width averages 24 feet. Ten tributaries drain into the Boulder River.

The water is discolored due to glacial runoff from Three Finger Mountain, but the water quality is good.

Appendix E
Boulder River

GEOLOGY: Beginning in granitics and gneissic rocks, the river flows mostly through weathered and incompetent phyllite schist and greenschist. Very deep deposits of unstable lacustrine materials and glacial till occur throughout much of the middle portion of the valley. Rapid downcutting since glaciation has removed side support and has caused frequent areas where the inner gorge sidewalls have collapsed. Some very deep V notches are present where the river has downcut through local inclusions of relatively competent bedrock that has resisted failing.

CULTURAL RESOURCES: No systematic cultural resource survey has been done on the Boulder River, and research is limited. During the historic period, the drainage was within the territory of the Stillaguamish tribe. Localities used by the Samish and Sauk-Suiattle tribes to practice their traditional religion have been identified within the proposed Wild and Scenic River corridor.

Some historic sites are recorded, primarily associated with logging and Forest Service administration; however, no sites are listed or known to be eligible for the National Register of Historic Places.

TIMBER: The lower 3 miles along the river have been clearcut in the past. Stands of second growth poles now occupy the site.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
5.4	.614	.558

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Boulder River has its headwaters in the Boulder River Wilderness. It joins the North Fork of the Stillaguamish River approximately 7 miles east of Oso. Oso is on the Mountain Loop Highway and in close proximity to the Everett metropolitan area. Economies traditionally dependent on forest products and small farming are supplemented by benefits from an increasing number of visitors seeking the recreation opportunities available in the area. Camping, hiking, hunting, fishing, cross-country skiing and sightseeing all attract people into the area.

CURRENT ADMINISTRATION: From its headwaters downstream 9 miles, the Boulder River flows within the Boulder River Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA, Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the Boulder River has been classified as Conservancy by Snohomish County. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

The Snohomish County Comprehensive Plan has zoned all land along the river corridor, outside of federal jurisdiction, for Forestry Use, except for a small rural diversification zone near the confluence with the North Fork Stillaguamish.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Boulder River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 2,000	$ 1,000
Costs of Implementation		3,000
Development of Management Plan		11,200
Development Costs		10,000
Operation and Maintenance Costs		2,000
TOTAL - First Five Years	**$ 2,000**	**$27,200**

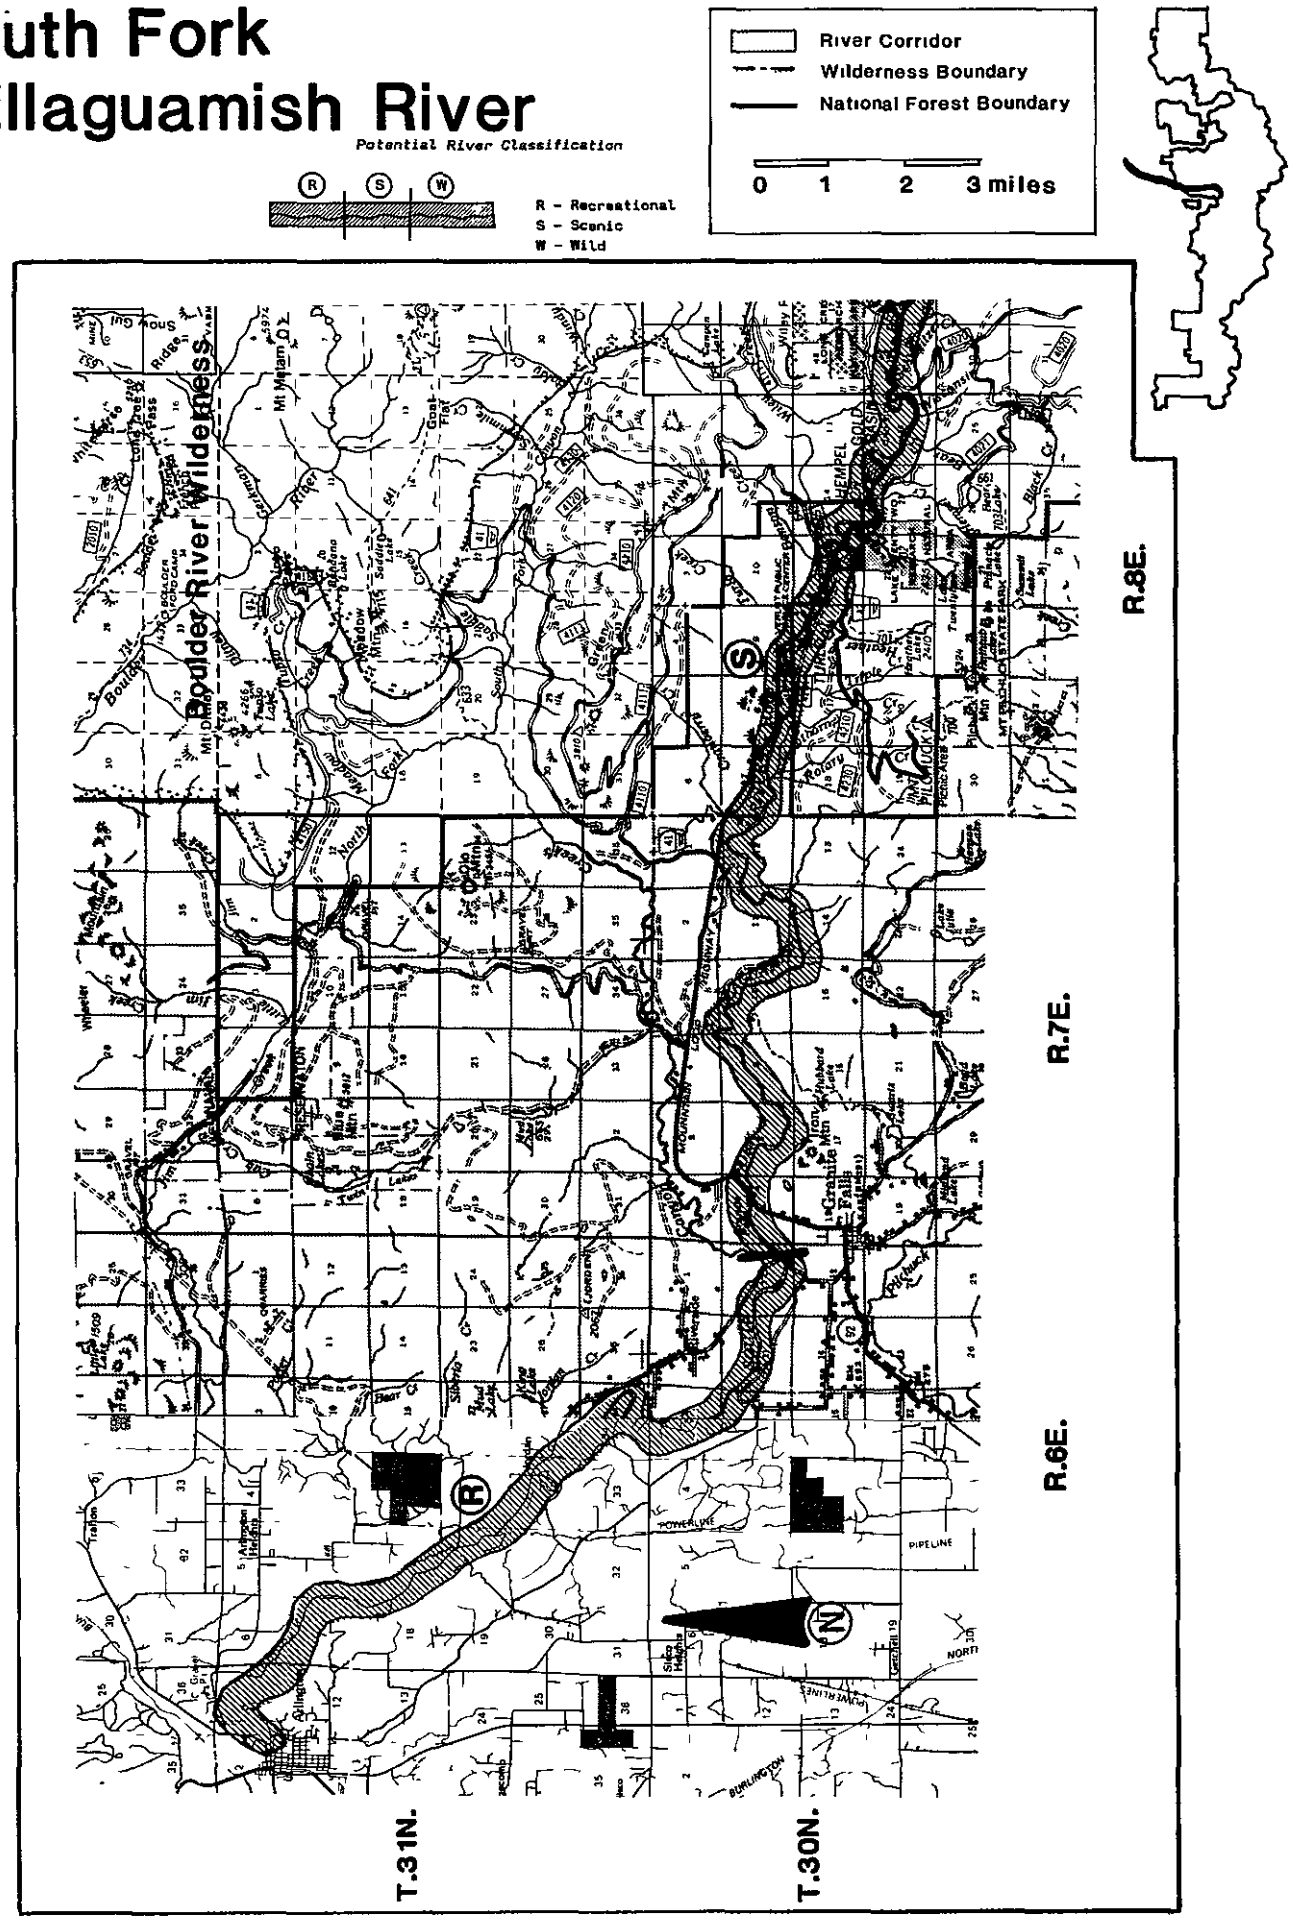
General administration and operation and maintenance costs are estimated to continue at $1,000 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

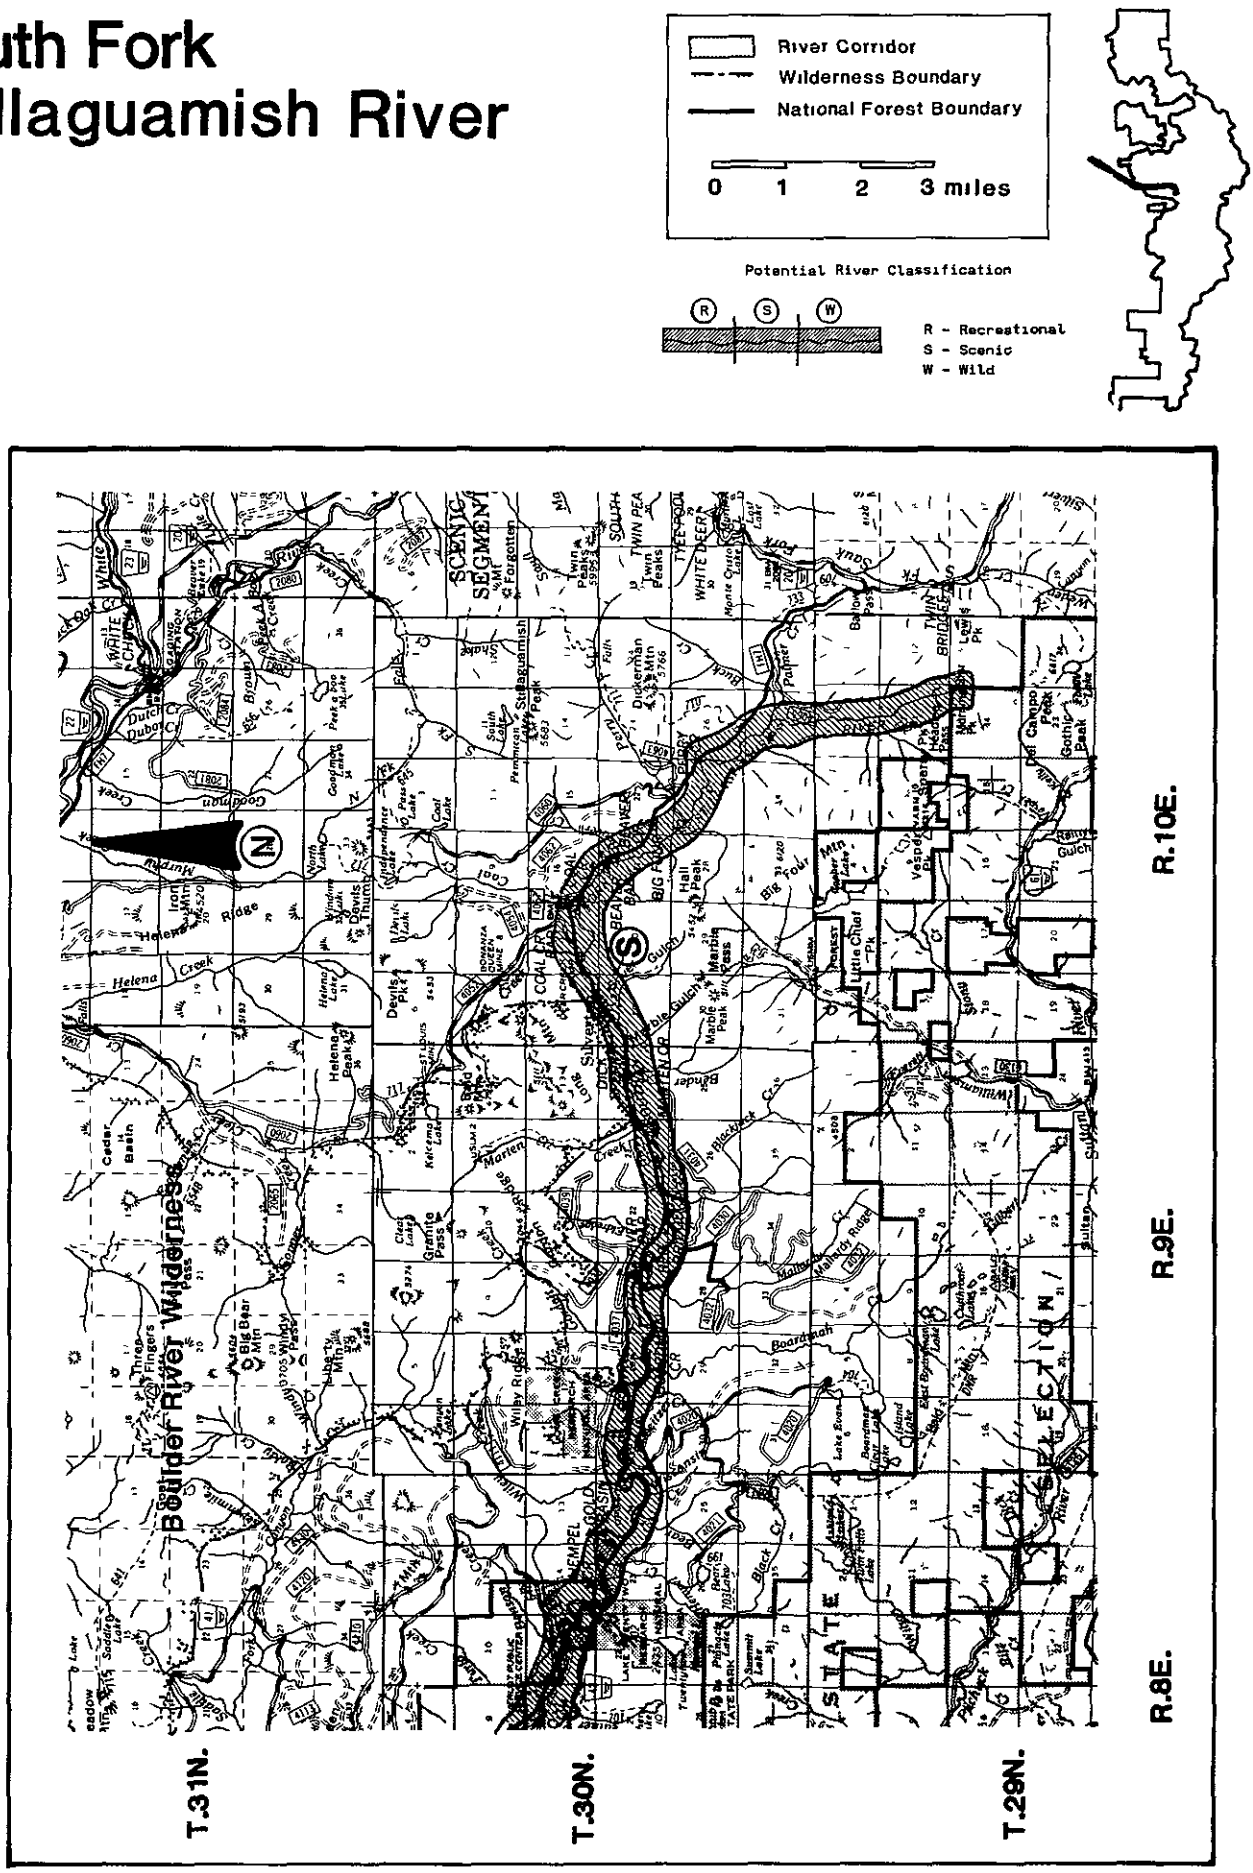
This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	422
		Wilderness-General Trailless	1,499
		Wilderness-Dedicated Trailless	1,055
Segment 2	Recreation	Wilderness-Transition	21
		Wilderness-General Trailless	21
		Timber Management	147

South Fork Stillaguamish River (1)



South Fork Stillaguamish River
(2)



SOUTH FORK STILLAGUAMISH RIVER

Snohomish County

The South Fork Stillaguamish River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The South Fork Stillaguamish River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From its headwaters on Morning Star Mountain downstream to its confluence with the North Fork Stillaguamish, near the town of Arlington.

Segment 1 - Headwaters between Morning Star and Lewis Peaks in NE 1/4 of Sec. 14, T.29 N., R.10 E. to Canyon Creek (36.6 miles).

Segment 2 - Canyon Creek to the confluence with the North Fork Stillaguamish River (15.9 miles).

RIVER MILEAGE:

Study:	52.5 miles
Eligible:	52.5 miles
Forest Plan:	52.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The South Fork Stillaguamish River was found to possess "Outstandingly Remarkable" values for the following: Scenic, Recreation, Fisheries, Wildlife, Historical/Cultural, and Ecological.

There is a wide range of landscapes from pastoral scenes in the lower valley to extraordinary mountain scenes of Big Four, Vesper Peak and Del Compo.

The South Fork Stillaguamish receives heavy use by kayakers, canoeists and campers. Many visitors to the area drive the Mountain Loop Highway.

The river corridor contains an extensive winter range for black-tailed deer and bald eagles. Several SOHA's are located in the Big Four area.

There is good spawning and rearing habitat for chinook, chum, coho, and some pink salmon. A fish ladder was constructed in 1954 at Granite Falls.

Historic sources indicate that the South Fork Stillaguamish was used extensively by the Stillaguamish tribe. The river served as a travelway, with portages to the Sauk and Pilchuck Rivers. Historic period sites represent mining, logging, homestead settlements, recreation development and Forest Service administration.

Dense stands of conifers are found from the headwaters to Verlot and dense stands of mixed deciduous trees and conifers grow further downstream to Arlington. Along the upper reaches, there is a well-developed riparian zone with isolated fresh water wetlands containing sphagnum bogs and cedar stands.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Scenic	36.6	Scenic	36.6
Segment 2	Recreation	15.9	Recreation	15.9

SUITABILITY DETERMINATION:

The South Fork of the Stillaguamish River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the high number of outstandingly remarkable values, public support, and other agency support. The South Fork of the Stillaguamish was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982. More recently, in 1988, the Washington State Scenic River Assessment included the South Fork as a river "possessing the natural, cultural, and recreational values that would make it a suitable addition to the Washington State Scenic Rivers System".

LANDOWNERSHIP:

	River Miles	Corridor Acres
Segment 1		
Mt. Baker-Snoqualmie National Forest	19.7 miles	6,304 acres
Private	15.1 miles	4,632 acres
County	0.8 mile	256 acres
State	1.0 mile	520 acres
Segment 2		
Private	15.9 miles	5,048 acres
State	0.0 miles	40 acres
TOTAL	52.5 miles	16,800 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Approximately six miles of this river have been identified by the BLM as an area of critical mineral potential (Sections 22,23 and 24, T. 30 N., R.9 E. and Sections 22,26 and 32, T.30 N., R.10 E.). A review of available literature, including the Bureau of Mines MILS data, indicates numerous reported locatable and salable mineral resource occurrences consisting of gold, silver, copper, lead, zinc, limestone, rock and sand and gravel. Most of these occurrences appear to have only experienced some prospecting activity, although, some have actually produced. Of most interest for the locatable mineral resources are the limestone deposits in Section 9 and 14, T. 30 N., R.7 E., and the precious and base metal occurrences reported along the river in T. 29 and 30 N., R.9 and 10 E. and in T.30 N., R.7 E., Sections 8,9 and 18. The limestone deposits, however, do appear to have been exhausted and abandoned. According the BLM mining claim recordation data, numerous unpatented mining claims (258) have been located along the river or adjacent to the corridor from Section 20, T. 30 N., R.9 E. eastward to the end of the river. Of these 258 or so claims, 117 have either been abandoned or declared to be null and void, and the majority of the remaining active claims are located in Sections 2,11 and 12, T.29 N., R.10 E.

The BLM has classified the eastern 5 miles of the river as being prospectively valuable ("PV") for geothermal resources, and the western 11 miles and a 3 mile section near Silverton have been classified "PV" for coal resources. However, none of the river corridor has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that from Section 20, T.30 N., R.9 E. eastward the area has a low to moderate potential for the occurrence of both precious and base metal mineral resources. This area is encumbered by numerous unpatented mining claims which indicate a continuing interest in the locatable mineral resources of that part of the river. The remaining part of the river appears to have a relatively low potential for the occurrence of locatable mineral resources. No serious interest in these resources has recently been expressed. As indicated above, portions of the river do have at least a low potential for the occurrence of both coal and geothermal resources, however, no serious interest in those resources has been recently expressed.

WATER RESOURCE DEVELOPMENT: The river is classified as "Protected" from hydropower development by the NW Power Planning Council.

The Stillaguamish River is listed by State Department of Ecology as a "River of Statewide Significance" based on water volume.

Two preliminary permits for hydroelectric projects have been issued by FERC for a project on the Marten Creek and Boardman Creek tributaries. Proposed facilities within the river corridor consist of a transmission line and a powerhouse on each tributary. The Marten Creek project capacity will be 1.5 megawatts; the Boardman Creek project 1.4 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: County highways, private land access and timber access roads parallel all but a few miles of the river. The Mountain Loop Highway parallels the river west to Granite Falls and, from Granite Falls to Arlington it is paralleled by the Jordan road.

The Mountain Loop Highway crosses the river near the fish ladder at Sec. 15, T.30 N., R.8 E. and at Red Bridge in Sec. 7, T.30 N., R.7 E. The Jordan Road crosses near Granite Falls at Sec. 12, T.30 N., R.6 E. At Arlington, Highway 530 also crosses the river at Sec. 2, T.31 N., R.5 E.

There is also a private bridge at Silverton and a suspension bridge over the river near Jordan Road in NE 1/4 Sec. 28, T.31 N., R.6 E.

There is limited agricultural development. The amount of cleared farmland increases toward Arlington.

Along the river, there are numerous rural residences and summer homes, the small communities of Silverton, Robe, and Verlot as well as the larger towns of Arlington and Granite Falls.

Following are developed campgrounds and day use areas located along the river.

Beaver Creek Campground (4 sites)
Coal Creek Bar Campground (5 sites)
Martin Creek Campground (5 sites)
Esswine Campground (5 sites)
Boardman Campground (5 sites)
Red Bridge Campground (16 sites)
Turlo Campground (19 sites)
Verlot Campground (26 sites)
Gold Basin Campground (93 sites)
Silverton School Organization Camp
Wiley Creek Youth Organization Camp
Tulalip Millsite Organization Camp
Big Four Picnic Area
Hemple Creek Picnic Area
Dick Sperry Picnic Area

The Big Four Ice Caves Trailhead #723 is located at the Big Four Picnic Area, 14.5 miles east of Verlot. This is the most popular trail on the Darrington Ranger District. A trail bridge crosses the South Fork.

The Sunrise Mountain Trail #707 begins at the end of Forest Road 4065. The trail crosses the South Fork via a footlog before ascending Sunrise Mountain.

At the confluence of the North Fork and South Fork Stillaguamish Rivers, Twin Rivers County Park has soccer fields, fishing, etc. Facilities are planned specifically to tolerate the regular flooding.

River Meadows Country Park east of Arlington has a river access area with parking lot, walk-in fishing, and boat launch. A proposed boat launch a short distance down river at Jordan Road would utilize a more protected site with a slower current.

There is fishing access at Riverscene, about 8 miles upriver from Arlington at the confluence of Canyon Creek and South Fork Stillaguamish.

There are sections of rip-rap on National Forest land along the Mountain Loop Highway and many such sites off-Forest.

A salmon rearing pond has been constructed at Heather Creek. There is a fish ladder north of Granite Falls just below the highway crossing in Sec. 7, T.30 N., R.7 E.

There are plans to construct salmon rearing ponds at Gold Basin Mill Pond and Beaver Creek.

A powerline runs to Gold Basin Campground.

RECREATION ACTIVITIES: The South Fork Stillaguamish receives heavy use by kayakers and canoeists. From Riverbar (Mallardy Creek confluence) to Verlot, the river requires experienced (Class III) boaters. From Granite Falls to Arlington the river is suitable for beginners. Likewise, the river receives high use for swimming and tubing. The river receives relatively low use from rafters.

Use for fishing is moderate to high inside the forest boundary and high outside the boundary to Arlington.

The river corridor is a gateway to the North Cascades. There is heavy camping use along the river. Many visitors to the area drive the Mountain Loop Highway. There is a wide range of landscapes from pastoral scenes in the lower valley to mountain scenes of Big Four, Vesper Peak and Del Compo.

Hiking takes place year around. Cross-country skiing is on the increase from Silverton to Barlow Pass.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	100	165
Waterplay (swim, wade)	300	450
Fishing, Hunting	1,000	1,440
Camping	110,400	165,600
Viewing (scenery, wildlife, for pleasure)	42,100	63,992
Misc. (hike, picnic, berry picking,etc.)	69,400	136,024
TOTAL	223,300	367,671

WILDLIFE AND FISHERIES: The river area contains extensive winter range for black-tailed deer and bald eagles. It also has Western pond turtle habitat and excellent riparian habitat for other animals.

Good coho salmons runs are found throughout the length of the river. A fish ladder was constructed at Granite Falls in 1954. Below the fishway, the spawning area has improved in recent years. However, it is greatly under-utilized by summer and fall chinook. Pink salmon use this section in moderate but increasing numbers. Above the falls, the river has a steeper gradient. Only coho use this section in large numbers. A few pink and chinook salmon spawn here. Chum are almost non-existent. A massive earth slide located near Verlot causes heavy silt loading on spawning beds during periods of heavy runoff. Many gravel riffles downstream have been rendered unsuitable for successful spawning or egg incubation. Resident rainbow and cutthroat trout inhabit the entire length of the river.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The South Fork Stillaguamish has medium water quality, due to heavy silt loading from the earth slides above Verlot. The river contains numerous rapids, cascades and falls. It is a stable, fast flowing, riffle-type river with numerous boulder strewn areas. In general, the bottom is boulder-rubble with some bed-rock. The gradient is fairly steep, and increases sharply below Boardman Creek. Fifty-one tributaries drain into the South Fork.

GEOLOGY: The bedrock geology consists primarily of metasedimentary and metavolcanic rocks. The most dominant geological process is very deep deposition of till and unstable lacustrine materials during the previous ice age. Most of the valley contains the characteristic glaciated U-shape. However, a deep gorge occurs within the lower 7 miles.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the South Fork Stillaguamish River. Existing information comes primarily from published historical research. No prehistoric sites have been recorded, however, it is believed that this reflects the lack of survey of the drainage. Historic sources indicate that the South Fork Stillaguamish was used extensively by the Stillaguamish Tribe, and that the river was used as a travelway, with portages to the Sauk and Pilchuck Rivers. No locations used for traditional religious practices are known within the potential Wild and Scenic River corridor.

Historic period sites represent mining, logging, homestead settlements, recreation development and Forest Service administration. During the 1890's, hundreds of mining claims were located in the Silverton Mining District. During the same period, a railroad was built up the South Fork Stillaguamish to provide access to the Monte Cristo Mining District. Mining interests peaked and declined before the turn of the century, but the railroad, under new ownership, continued to operate for some time. Many settlements, such as Granite Falls, Robe, Verlot and Silverton were established in the valley. In 1920, a recreation resort was built on the river. The only access to this was by way of the railroad, then operating under the name Hartford and Eastern. The resort did very well until the onset of the Depression. In the 1930's, the railroad tracks were removed and sold for scrap. The highway up the South Fork follows the railroad in part, and portions of the old grade are visible from the highway. The Hartford and Eastern Railroad is listed on the State Registry of Historic Places.

In the early 1900's, logging interests were developed in the South Fork Stillaguamish drainage. The major operation within the drainage was the Gold Basin Timber and Shingle Company. Remains of this operation have not been fully inventoried.

Forest Service administration is represented by the Verlot Public Service Center. This administrative site was built by the Civilian Conservation Corps as a ranger station and living quarters for the Monte Cristo Ranger District. The buildings that remain of the original 1930's compound are listed on the National Register of Historic Places.

TIMBER: Considerable timber harvesting has occurred with numerous and large-scale clear-cut areas.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
121.6	3.155	2.865

1/ Based on proposed preferred alternative with revised minimum management requirements.

SOCIO-ECONOMIC EFFECTS: The South Fork of the Stillaguamish river is accessible by forest roads and local roads over its entire length. The small communities of Silverton, Verlot and Robe are all within or near the Mt. Baker Forest boundaries. Granite Falls and Arlington are larger communities located on the South Fork. The historic gold mining community of Monte Cristo is accessible from Silverton. Campsites are dispersed all along the South Fork. The availability of recreation and scenic resources contributes to the economy of the more remote communities which still derive their major support from the forest products industry.

CURRENT ADMINISTRATION: The river corridor inside the forest boundary is administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the South Fork Stillaguamish has been classified by Snohomish County as Conservancy from the forest boundary to Granite Falls and Rural from Granite Falls to Arlington. These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes shoreline areas characterized by agricultural uses, low density residential where most urban services are not available, and areas which provide buffer zones and open space between predominantly urban areas.

The Snohomish County Comprehensive Plan has zoned land along the South Fork Stillaguamish, outside of federal jurisdiction, for Forest Use or Residential Use, with 5 or 10 acre lots. Many flood hazard zones are identified along the river.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the South Fork Stillaguamish River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 51,000	$ 50,000
Costs of Implementation		30,000
Development of Management Plan		94,200
Development Costs	124,800	100,000
Operation and Maintenance Costs	204,500	30,000
TOTAL - First Five Years	**$380,300**	**$304,200**

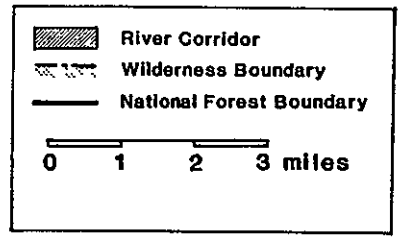
General administration and operation and maintenance costs are estimated to continue at $67,100 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

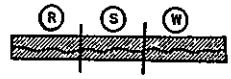
This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Scenic	Semi-Primitive, Non-Motorized Recreation	1,140
		Scenic Corridor (Foreground)	4,202
		Scenic Corridor (Middleground)	422
		Wilderness-General Trailless	126
		Old Growth Habitat (spotted owl)	168
		Pine martin/pileated woodpecker habitat	380
		Timber Management	84

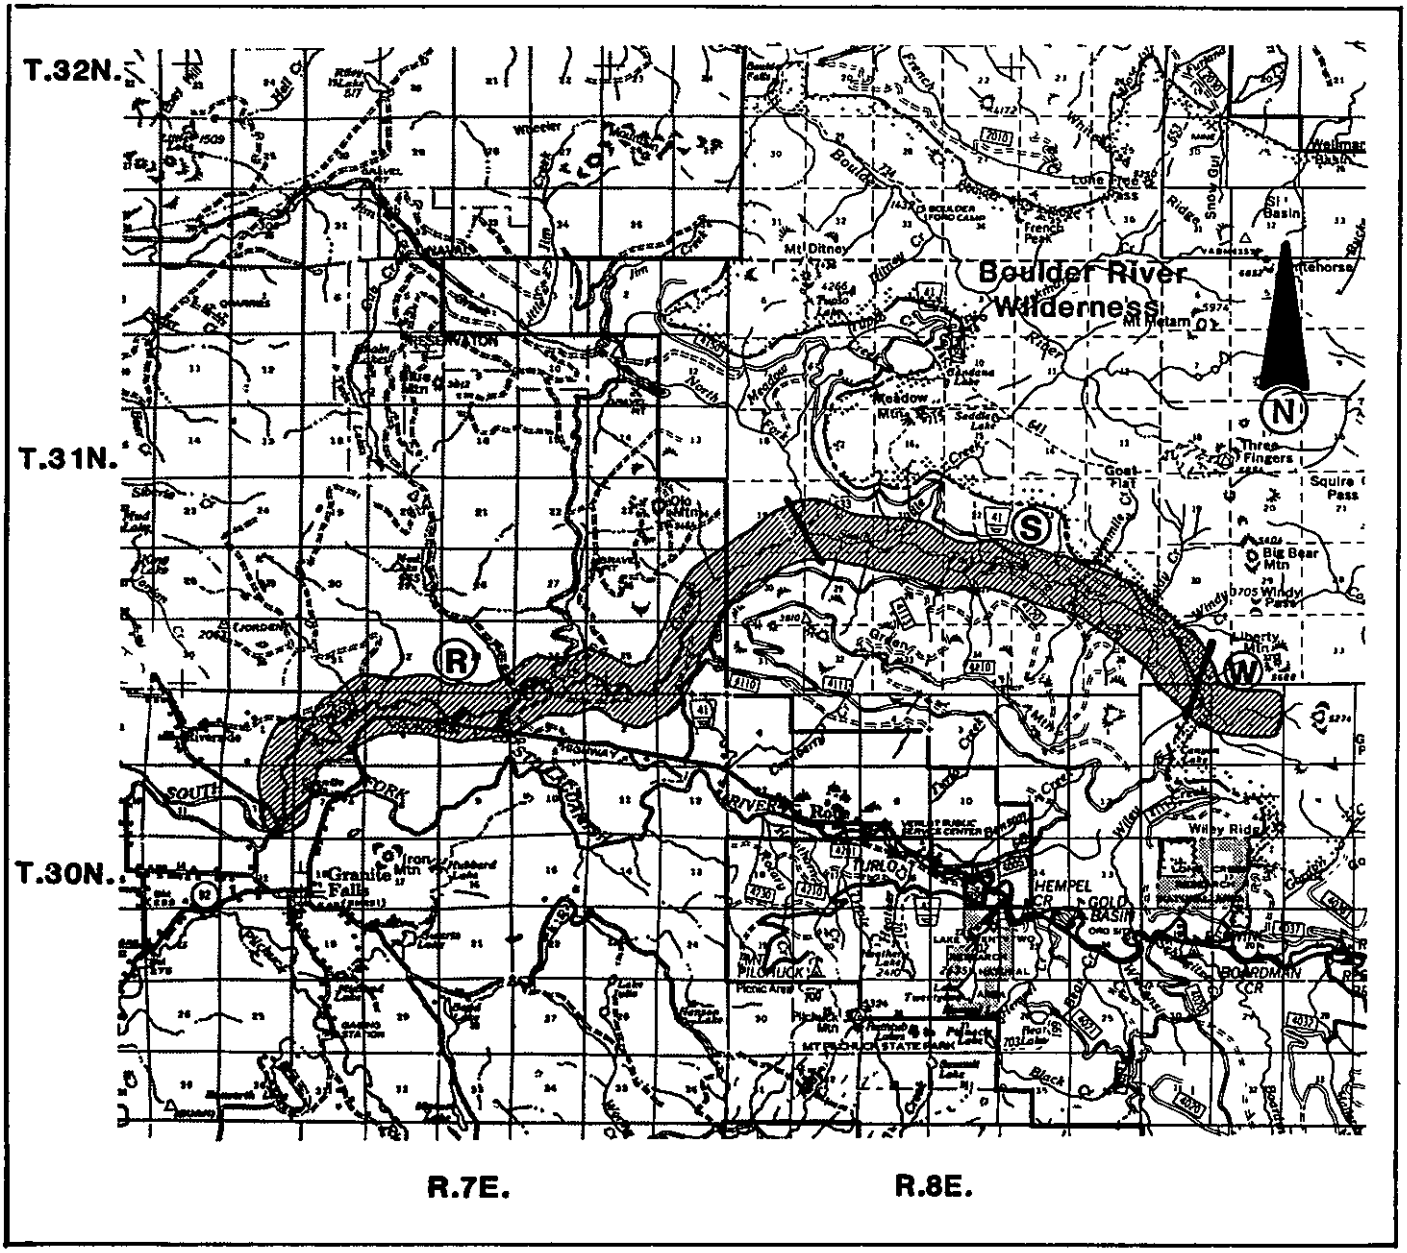
Canyon Creek and South Fork Canyon Creek



Potential River Classification



R - Recreational
S - Scenic
W - Wild



CANYON CREEK (TO FORK)
SOUTH FORK CANYON CREEK

Snohomish County

Canyon Creek and South Fork Canyon Creek were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Canyon and South Fork Canyon Creeks were identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From the headwaters of the South Fork of Canyon Creek to the confluence of Canyon Creek with the South Fork Stillaguamish River.

Segment 1 - Headwaters of S. Fork Canyon Creek in NE 1/4 of Sec. 5, T.30 N., R.9 E. to the Boulder River Wilderness boundary (1.3 miles).

Segment 2 - Boulder River Wilderness boundary to the confluence with the North Fork of Canyon Creek (7.1 miles).

Segment 3 - Confluence of North and South Forks of Canyon Creek to the confluence with the South Fork Stillaguamish River (11.9 miles).

RIVER MILEAGE:

Study:	20.3 miles
Eligible:	20.3 miles
Forest Plan:	0 0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Canyon Creek and South Fork Canyon Creek were found to possess "Outstandingly Remarkable" values for the following: Fisheries and Ecological. South Fork Canyon Creek also has values for Wildlife.

Chinook, coho, pink and chum salmon spawn and rear in Canyon Creek. Summer and winter steelhead are also present.

Areas within the Canyon Creek drainage contain dense conifer stands of large timber, including old-growth.

Both rivers have an extensive black-tailed deer winter range, as well as other excellent riparian habitat. There is wintering bald eagle habitat, raptor nesting of osprey, excellent furbearer habitat, and a SOHA.

Appendix E
Canyon Creek/
South Fork Canyon Creek

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	1.3	Not recommended	0
Segment 2	Scenic	7.1	Not recommended	0
Segment 3	Recreation	11.9	Not recommended	0

SUITABILITY DETERMINATION:

Canyon Creek and the South Fork of Canyon Creek were found to be not suitable for inclusion in the preferred alternative of the Forest Plan.

Canyon Creek to the fork is almost entirely in private ownership. Designation of the South Fork would conflict with other resource values, principally high timber values. Existing old-growth in this area is already protected by other land allocations.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	1.3 miles	416 acres
(Boulder River Wilderness - 1.3 miles)		
Segment 2		
Mt. Baker-Snoqualmie National Forest	6.6 miles	2,112 acres
Private	.5 miles	160 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest	1.5 miles	480 acres
Private	9.7 miles	2,908 acres
State	0.7 mile	420 acres
Total	20.3 miles	6,496 acres

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: No part of these rivers is classified by the BLM as areas of critical mineral potential, nor does the BLM Mining Claim Recordation Data indicate any part is encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates the rivers have only one reported mineral resource occurrence which may be of a locatable nature. That occurrence is reported as a limestone deposit which has produced in the past. Little information is available concerning the deposits specific location or characteristics.

The BLM has not classified any part of these river segments as being prospectively valuable for leasable mineral resources, and none of the subject lands have been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that, except for the limestone deposit upon which there is little information, these rivers have a relatively low potential for the occurrence of either locatable or leasable mineral resources. No serious interest in these resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on either creek, but some water is used for irrigation.

These creeks are classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Roads are visible from Canyon Creek and the South Fork of Canyon Creek from the mouth for 11 miles Roads cross the creeks at Sections 4 and 6, T.30 N., R.7 E., and on the line of Sec. 4 & 5, T.30 N., R.7 E

Along the lower reaches of Canyon Creek, there is some cattle ranching and corn and hay farming.

In the lower 4 miles of Canyon Creek, there are approximately 25 home sites situated along the creek.

The Forks of Canyon Creek Trail #633 begin on the Tupso Pass Road #41. The trail leads to the confluence of the North and South Forks of Canyon Creek. A dispersed camping site is located near the confluence.

There are no developed campgrounds nor potential opportunity for development along either creek.

There is fishing access at Riverscene, about 8 miles upriver from Arlington, at the confluence of Canyon Creek and South Fork Stillaguamish.

RECREATION ACTIVITIES: There is low recreation use along both creeks due to restricted access on private land and little access provided on public land. Near the mouth of Canyon Creek, there is a moderate amount of fishing. The lower 10 miles of Canyon Creek is classified at Class IV whitewater kayaking. The creeks are not suitable for rafting or swimming.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only.

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	100	144
Misc. (hike, picnic, berry picking, etc)	100	196
TOTAL	200	340

WILDLIFE AND FISHERIES: There is extensive black-tailed deer winter range along both rivers, as well as other excellent riparian habitat. There is wintering bald eagle habitat, raptor nesting of osprey and excellent furbearer habitat. A SOHA is located on the South Fork Canyon Creek.

Chinook and steelhead spawn and rear in the mainstem and the South Fork up to the barrier falls. Given adequate water conditions, coho and some chinook can ascend the falls and swim upstream as far as Tiger Creek.

Appendix E
Canyon Creek/
South Fork Canyon Creek

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Canyon Creek, below the North and South Forks, is characterized by moderately steep gradients with steep side valley slopes. At 1.5 miles above the mouth, the creek narrows into a canyon with a steep gradient, narrow channels and numerous rapids. The creek bottom is littered with boulders and gravel. Eighteen tributaries drain into Canyon Creek.

Sediment loading into the creek is significant due to 2 earth slides, heavy logging and road building in the upper watershed.

GEOLOGY: The bedrock geology consists primarily of metasedimentary and metavolcanic rocks. During the previous ice age, glaciers carved out a U-shaped valley and left very thick lacustrine and till deposits. Rapid downcutting is returning the valley to its pre-glacial V-shape. This is also causing destabilization of the lacustrine materials resulting in numerous mass failures.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Canyon Creek, and no prehistoric or historic sites are recorded. The lack of known sites is believed to reflect the lack of survey of the drainage. During the historic period the area was within the territory of the Stillaguamish tribe. Localities used for traditional religious practices by the Samish tribe have been identified within the South Fork drainage.

No sites associated with logging or Forest Service administration have been listed or identified as eligible for the National Register of Historic Places.

TIMBER: Private lands have been clearcut down to the river. National Forest lands have been patch clearcut.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system land only:

	ASQ	
Total Timber *Volume* (MMBF)	Preferred Alternative w/o W&SR *Designation* (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR *Designation* (MMBF/yr.)1/
54.1	7.931	7.805

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: Some cattle grazing occurs along the lower reaches of Canyon Creek on private land.

SOCIO-ECONOMIC EFFECTS: Canyon Creek joins the South Fork of the Stillaguamish about 1 mile north of Granite Falls, a community strongly dependent on forest resources for employment.

CURRENT ADMINISTRATION: From its headwaters downstream 1.3 miles, the South Fork of Canyon Creek flows through the Boulder River Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of Canyon Creek has been classified by Snohomish County as Conservancy. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

Land along the Canyon Creek corridor, outside of federal jurisdiction, is zoned by Snohomish County for:

Forestry Use from the forest boundary downstream for 5 miles.

Rural Use with 1 home per 5 acre lots from the Canyon Creek Lodge area to the confluence with the South Fork Stillaguamish. Flood hazard zones exist throughout this area, possibly affecting future development.

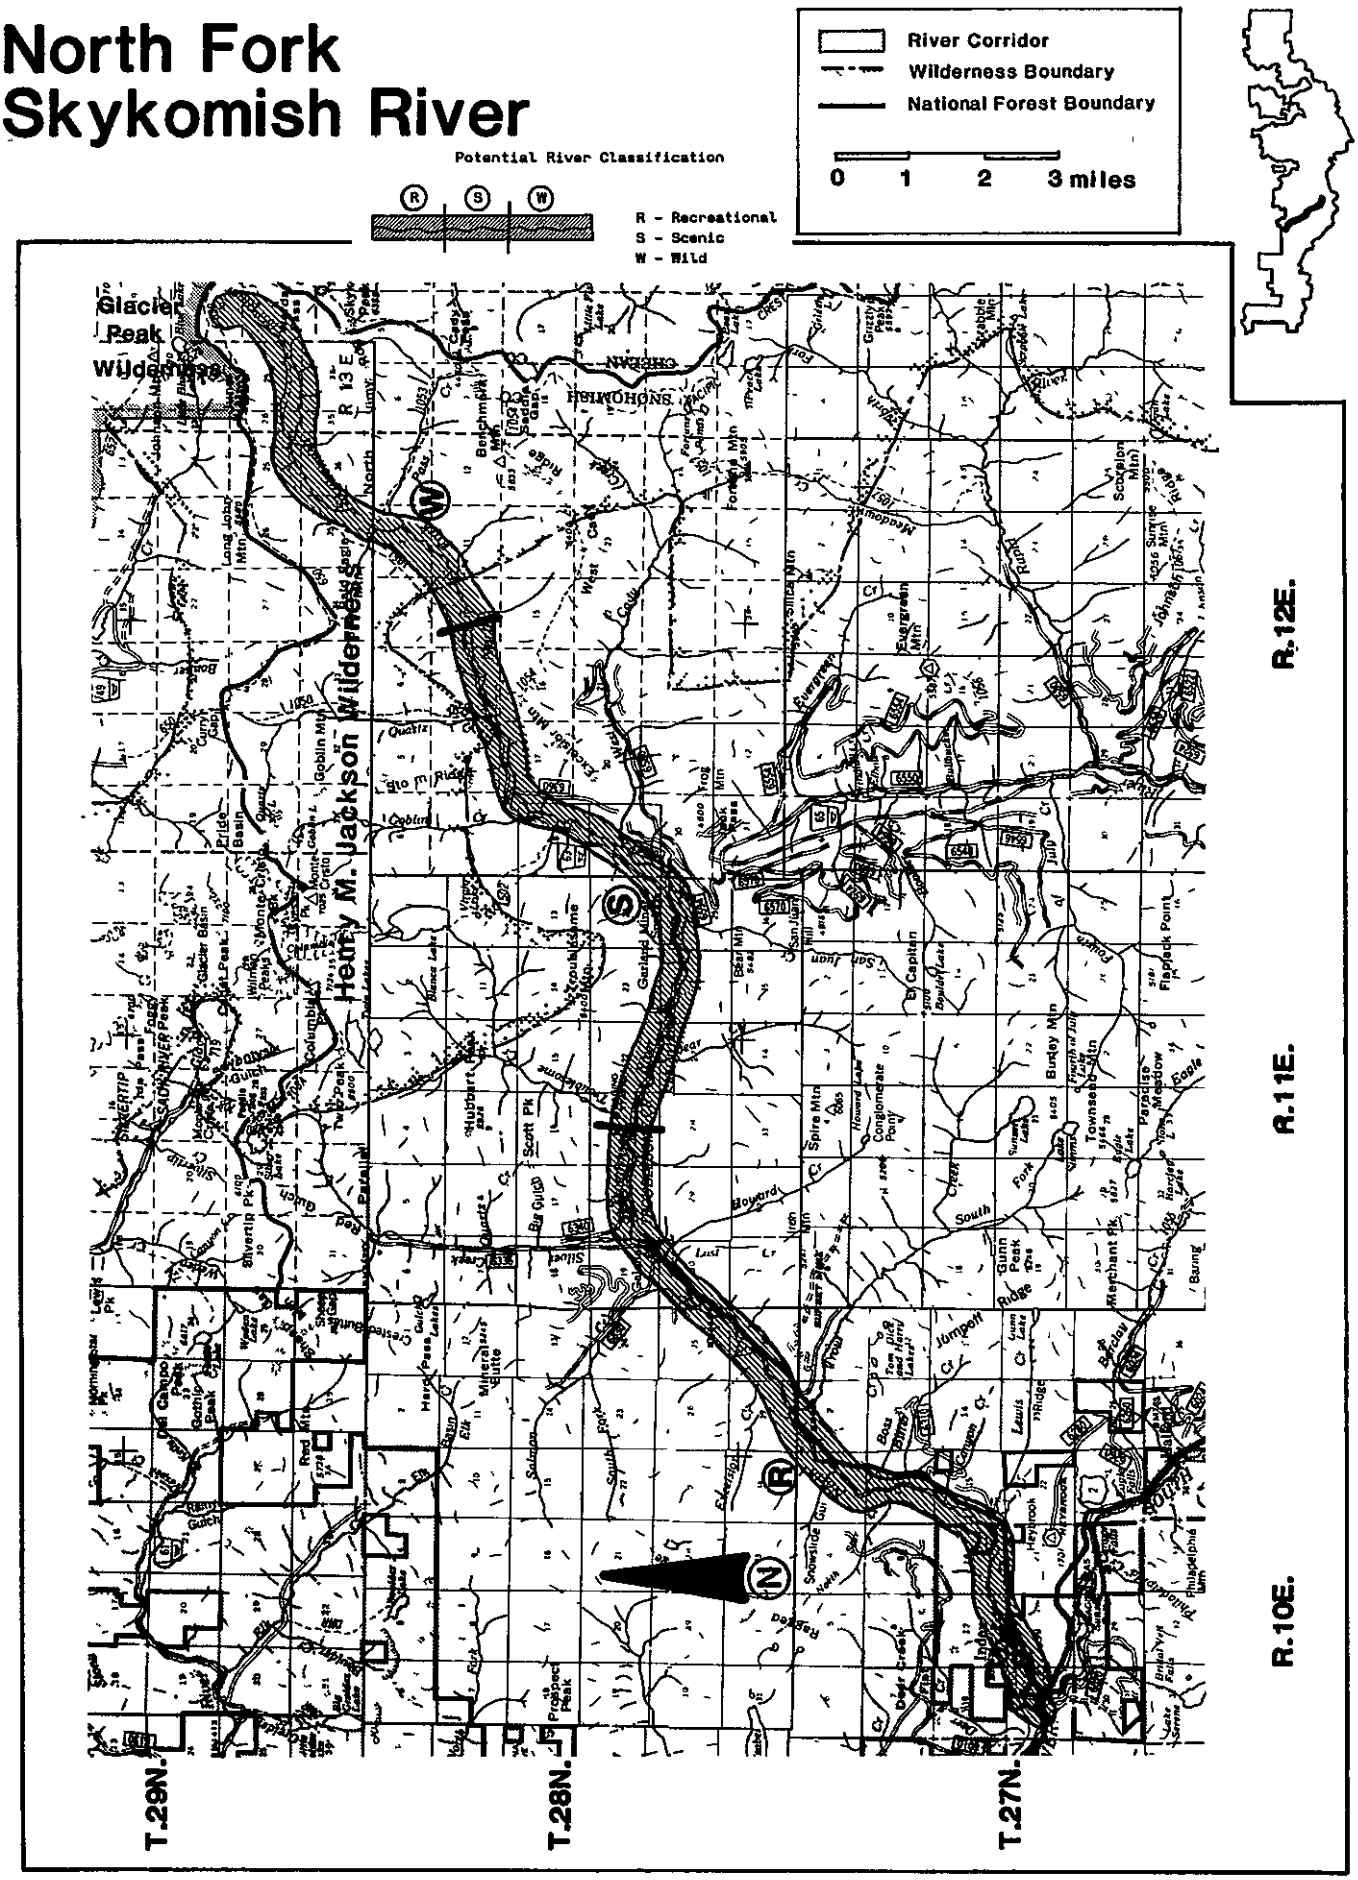
FUNDING NEEDS IF CLASSIFIED AS A WILD AND A SCENIC RIVER:

The following are expected funding requirements for the Canyon and South Fork Canyon Rivers for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		33,500
TOTAL - First Five Years	**$ 1,000**	**$ 36,500**

General administration and operation and maintenance costs are estimated to continue at $400 annually.

North Fork Skykomish River



NORTH FORK SKYKOMISH RIVER

Snohomish County

The North Fork Skykomish River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability

The North Fork Skykomish River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

The North Fork Skykomish River to the Bear Creek tributary is designated by the State of Washington as a Scenic River under the State's Scenic Rivers Act.

LOCATION: From its headwaters north of Skykomish Peak to the confluence with the South Fork Skykomish River

Segment 1 - Headwaters in NW 1/4 of Sec. 30, T.29 N., R.14 E. to end of F.S. Road #63 in NW 1/4 of Sec. 10, T.28 N., R.12 E (8.2 miles).

Segment 2 - Road end to Troublesome Creek (8.4 miles).

Segment 3 - Troublesome Creek to confluence with South Fork Skykomish River (12.0 miles).

RIVER MILEAGE:

Study:	28.6 miles
Eligible:	28.6 miles
Forest Plan:	28.6 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The North Fork Skykomish River was found to possess "Outstandingly Remarkable" values for the following: Scenic, Recreation, Fisheries and Wildlife.

Prominent features along the North Fork Skykomish River include Deer Falls, Bear Falls, Troublesome Mountain, Bear Mountain and Keyes Peak.

The North Fork is one of Washington State's most continuously challenging whitewater rafting runs. Eleven miles of the river is Class III or Class IV. The river is also a favorite of expert kayakers. Fishing is popular for steelhead, salmon and resident trout. Backpacking and horseback riding are popular along the upper reaches of the river Cross-country skiing and snow play along the river are popular during the winter.

The river corridor is significant for its population of bald and golden eagles and spotted owl habitat area. A key winter range for black-tailed deer lies on both sides of the lower section of the river. There is also has excellent furbearer and riparian habitats for black bear, cougar, coyote, bobcat, and marten.

The North Fork supports a population of chinook, coho and pink salmon as well as steelhead trout.

Appendix E
North Fork Skykomish River

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	8.2	Wild	8.2
Segment 2	Scenic	8.4	Scenic	8.4
Segment 3	Recreation	12.0	Recreation	12.0

SUITABILITY DETERMINATION:

The North Fork of the Skykomish River was found to be suitable for inclusion in the preferred alternative of the Forest Plan. The river has a high number of outstandingly remarkable values. It is one of Washington State's most continuously challenging whitewater rafting and kayaking runs, with 11 miles of class III or IV river. The corridor is significant for its population of bald and golden eagles, as well as spotted owls. There is public and other agency support for designation. The North Fork was identified as a potential wild and scenic river in the Nationwide Rivers Inventory published by the National Park Service in 1982.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Henry M. Jackson Wilderness - 6.8 miles)	8.2 miles	2,624 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	8.0 miles	2,638 acres
Private	0.4 mile	50 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest	6.0 miles	1,920 acres
Private	5.0 miles	1,320 acres
State	1.0 mile	600 acres
Total	28.6 miles	9,152 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: The BLM has classified about 10 miles of this river (T.28 N., R.11 E.) as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates numerous reported occurrences of both precious and base metals resources. Of most importance, appear to be those located in Section 35, T.28 N., R.10 E., Section 19, T.28 N., R.11 E. The BLM mining claim recordation data indicates that 140 unpatented mining claims have been located along or adjacent to the river from Section 36, T. 28 N., R.10 E. eastward. Of these 140 claims, however, 37 have either been abandoned or declared to be null and void. Of the remaining 103 claims most are located in Sections 19, 20, 21, 22, 28 and 29, T.28 N., R.11 E. The mineral resources of a part of the area have been evaluated by the U.S.G.S. and U.S.B.M. (Church and Others, 1983 and 1984), and based upon the geology of the area and the results of their sampling they have concluded the following:

The vicinity of Section 35, T 28 N., R.10 E. and Sections 2 and 3, T.27 N., R.10 E. has a moderate potential for the occurrence of copper and silver resources, and Sections 25,26,35 and 36, T.29 N., R.13 E., Section 31, T. 29 N., R14 E. and Sections 25 and 36, T.29 N., R12 E. have a low potential for the occurrence of precious metal resources in hot spring type deposits, a low potential for the occurrence of base and precious metal resources in hydrothermal veins and a moderate potential for the occurrence of base metal resources in disseminated porphyry deposits.

The BLM has classified the entire river as being prospectively valuable ("PV") for geothermal resources, and three miles of the river near Galena is classified "PV" for coal resources. However, none of the area has been encumbered by mineral leases or lease applications.

Based upon available information, it appears that a large portion of the area does have potential for the occurrence of both precious and base metal mineral resources and a potential for the occurrence of coal and geothermal resources. The mining claims located along the river indicate that there is at least some serious interest in the locatable mineral resources. However, no serious interest in the leasable mineral resources has recently been expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the North Fork Skykomish. This river is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

Nine preliminary permits for hydroelectric projects have been issued by FERC and two license applications have been submitted on tributary rivers to the North Fork. The following is a list of the tributaries, proposed facilities and the capacity of the project in megawatts:

Tributary	Proposed Facilities within Corridor	Megawatts
West Cady	Transmission line	4.0
Goblin Creek	Transmission line	1.0
San Juan Creek	Transmission line	2.2
Bear Creek	Transmission line	2 7
Troublesome Creek	Transmission line	3.7
Howard Creek	Transmission line	3.5
Trout Creek	Transmission line	4.9
Excelsior Creek	Transmission line	1.7
Salmon Creek	Transmission line	2.9
Silver Creek	Transmission line	3.4
Storm Ridge1/	Transmission line, powerhouse, diversion structure and penstock	15.0

1/ Storm Ridge project is on the main North Fork Skykomish, not a tributary.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENT: Segments 2 and 3 of the North Fork is paralleled by a road. U.S. 2 passes the river corridor near the confluence of the North and South Forks of the Skykomish River. From the junction with U.S. 2, the paved North Fork Road #6300 passes the community of Index and follows the North Fork River to a fork about a mile beyond the San Juan Campground. It continues, unpaved over Jack Pass and back to U.S. 2 via the Beckler River Road. This is a popular scenic loop and has long been under consideration for paving as a scenic drive. At the fork by San Juan Campground, F.S. Road 63 takes off and runs unpaved along the river. It ends

at the North Fork Skykomish Trailhead about 3/4 mile from the Henry M. Jackson Wilderness boundary.

F.S. Road 6360 crosses the North Fork above Goblin Creek. F.S. Road 65 crosses above San Juan Creek. County Road 63 crosses near Troublesome Creek. County Road 6335 crosses below Silver Creek. The Index road bridge and railroad bridge cross at Index. A powerline crosses just above the confluence with the South Fork.

The North Fork Skykomish/Dishpan Gap Trail #1051 begins at the end of F.S. Road 63. The trail follows the North Fork Skykomish valley to the northeast to the headwaters of the river.

The Quartz Creek/Curry Gap Trailhead #1050 is located 1 mile west of the end of F.S. Road 63. The trail heads uphill along Quartz Creek.

The West Cady Ridge Trailhead #1054 is also located 1 mile west of the end of F.S. Road 63. The trail heads up West Cady Ridge to Saddle Gap.

The Blanca Lake Trail #1052 begins on F.S. Road 63, 2 miles northeast of Garland Mineral Springs.

The communities of Index, Galena, and Garland are located on the west bank of the river. Downstream from Silver Creek, there are 4 private subdivisions which support recreation residences. There are also a few scattered summer cabins. Along the lower 2 to 3 miles of the river, rural and suburban residences are found along the river.

There is a cable tram crossing at Trout Creek and several old bridge crossings from early railroad logging. A log stringer bridge is located near Excelsior Mountain.

The Burlington Northern Railroad is in the river corridor near the confluence of the North and South Forks of the Skykomish River.

There are two campgrounds located along the river: Troublesome Creek Campground and San Juan Campground. Both are widely used for overnight camping.

Many fish habitat structures were put in the river in 1986-87 near Goblin Creek.

There are sections of dikes from Garland to Jack's Pass and also at the town of Index.

Rip-rap is found at Index, Garland, F.S. Road 65 and Troublesome Creek Campground.

RECREATION ACTIVITIES: The lower portion of the North Fork Skykomish receives high recreation use, much of which is oriented toward river activity. The North Fork is one of Washington States most continuously challenging whitewater rafting runs. Eleven miles of the river is Class III or Class IV. The river is also a favorite of expert kayakers. Use of the river is low by swimmers. Fishing is popular for steelhead and salmon up to Bear Falls. Resident trout fishing is also popular in the upper reach. Some planting takes place.

Hunting occurs in the surrounding areas. Backpacking and horseback riding are popular in the upper reaches of the river. Cross-country skiing and snow play along the river are popular during the winter.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	265	437
Waterplay (swim, wade)	15	22
Fishing, Hunting	1,470	2,117
Camping	69,670	104,505
Viewing (scenery, wildlife, driving for pleasure)	15,635	23,765
Misc. (hike, picnic, berry picking, etc.)	2,880	5,645
TOTAL	89,935	136,491

WILDLIFE AND FISHERIES: The entire area is within the big game management unit 448 and goat management units 11 and 37. The river corridor is significant for its population of bald and golden eagles and spotted owl habitat area. A key winter range for black-tailed deer lies on both sides of the lower section of the river. There is also excellent furbearer and riparian habitats for black bear, cougar, coyote, bob cat, and marten.

Birds include band-tailed pigeons, dipper, harlequin duck, spotted sand piper, warbling vireos, red-tailed hawk, bald eagle, white tailed ptarmigan, Audubon's warber, downy woodpecker, evening gosbeak, red crossbill, western tanager, spotted owl, and great grey owl.

The North Fork supports a population of chinook, coho and pink salmon as well as steelhead trout. Chinook salmon is the principal species and is common up to Bear Falls. The anadromous steelhead are numerous below Bear Falls and sparse above Bear Falls to Deer Falls. Resident trout inhabit the entire length of the river. Angler use is heavy for steelhead and light for all other species. Holding ponds and fish planting has been in operation for several years through mutual agreements with the Index Sportsman, Washington State Department of Wildlife and Department of Fisheries, and U.S. Forest Service.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Small falls and cascades are found in the upper 10 miles of the river, separated by short rapids or occasional pool-riffle stretches. Bear Falls and Deer Falls are two of the larger falls along the river.

There are 64 tributaries to the North Fork Skykomish. All exhibit steep mountain characteristics over their entire length. They contain narrow channels with numerous cascades, small falls and a few riffles or pools with bottoms generally consisting of boulder rubble material.

GEOLOGY: The upper 10 miles of the river covers steep mountainous terrain, with the river flowing though a narrow, occasionally canyon-like valley. The valley broadens slightly between Goblin and San Juan Creeks. Downstream below San Juan Creek, the valley again narrows with rugged side slopes. Down river from Silver Creek, the river courses through a relatively narrow, very steep sloped valley. The valley broadens slightly over the lower two to three

miles. Most of the river flows through glacial material deposited from glaciers along the canyon bottom.

There are 2 distinctive geologic features along the river: the Index Town Wall (cliffs) and Troublesome Mountain formations which provide a striking addition to the forested slopes.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the North Fork Skykomish. Information is available primarily from published historic sources.

No prehistoric sites have been recorded to date. The absence of sites probably reflects the lack of survey of the area. Historically, the drainage was within the territory of the Skykomish Indians. The Skykomish and Wenatchee Indians used a trail that followed the North Fork as a main travel and track route across the Cascades. No localities used for traditional religious practices are known within the proposed Wild and Scenic River corridor.

Historic period sites represent mining, logging and Forest Service administration. The Silver Creek Mining District was established in 1871, but mining began in earnest in 1882, when several discoveries were made in rapid succession. As a result, the townsites of Mineral City and Galena were established on the North Fork. Between 1890 and 1894, a trail was built between Mineral City and Galena.

A small lumber mill was established in 1904 at the town of Index. From this, the Index-Galena Logging Company was formed in 1907. By 1922, the company operated approximately 14 miles of logging railroad along both sides of the North Fork. It operated until 1928.

There are two sites within the proposed Wild and Scenic River corridor that are listed on the National Register of Historic Places. Both are buildings located within the town of Index and associated with the development of the town.

TIMBER: *Extensive logging occurs from Deer Falls downstream*

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
188.2	3.441	3.378

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The North Fork of the Skykomish River has its headwaters at Dishpan Gap near the Cascade Crest in the Henry M. Jackson Wilderness. A traditional horse use area, the river is bordered by pack trail, then by forest road. This area offers developed campgrounds, ample dispersed camping, and several trailheads. Many visitors are drawn to the area by its scenic and recreation attractions.

The community of Index (pop. 147) lies on the river one mile north of its confluence with the Skykomish River. Traditionally a mining and logging community, Index has also become a magnet for retirees and vacation home-owners. The "Index Town Wall" (cliffs) attract many skilled rock climbers who have established numerous routes on the "wall".

CURRENT ADMINISTRATION: From its headwaters downstream 6.8 miles, the North Fork Snoqualmie flows through the Henry M. Jackson Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, most of the shoreline of the North Fork Skykomish River has been classified as Conservancy by Snohomish County. Several areas that have been subdivided near the town of Index have been classified Rural. These classifications are applicable only to lands not under federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes shoreline areas characterized by agricultural uses, low density residential where most urban services are not available, and areas which provide buffer zones and open space between predominantly urban areas.

The land along the North Fork Skykomish River corridor, outside of federal jurisdiction, is zoned by Snohomish County for Forestry Use. Subdivisions near the town of Index, are in a flood hazard zone, which may inhibit further development.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Fork Skykomish River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 570,000	$ 50,000
Costs of Implementation		10,000
Development of Management Plan		82,000
Development Costs	883,000	60,000
Operation and Maintenance Costs	61,500	15,000
Total - First Five Years	**$1,514,500**	**$217,200**

General administration and operation and maintenance costs are estimated to continue at $139,300 annually.

Appendix E
North Fork Skykomish River

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Semi-Primitive, Non-Motorized Recreation	211
		Wilderness-Trailed	1,055
		Wilderness-General Trailless	922
Segment 2	Scenic	Semi-Primitive, Non-Motorized Recreation	2,977
		Old Growth Habitat (spotted owl)	21
		Timber Management	168
Segment 3	Recreation	Semi-Primitive, Non-Motorized Recreation	549
		Deer and Elk Habitat Enhancement	1,098
		Timber Management	549

TROUBLESOME CREEK

Snohomish County

Troublesome Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters in the Henry M Jackson Wilderness at Blanca Lake to the confluence with the North Fork Skykomish River.

Segment 1 - Headwaters at Blanca Lake to Forest Road 63 (4.4 miles).

Segment 2 - Forest Road 63 to the confluence with the North Fork Skykomish River (0.1 mile).

RIVER MILEAGE:

Study:	4.5 miles
Eligible:	4.5 miles
Forest Plan:	4.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Troublesome Creek was found to possess "Outstandingly Remarkable" values for the following: Wildlife.

Mountain goats and spotted owls are predominant wildlife in the drainage.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	4.4	Wild	4.4
Segment 2	Scenic	0.1	Scenic	0.1

SUITABILITY DETERMINATION:

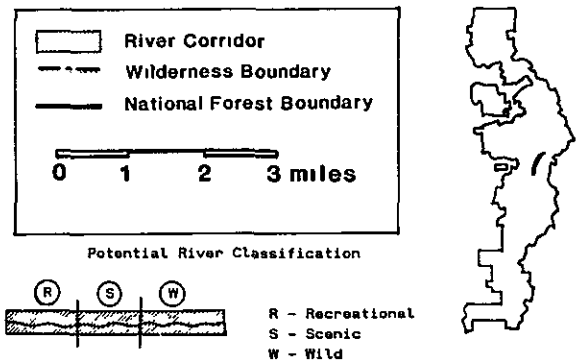
Troublesome Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the lack of competing resource values. Designation would have no impact on timber resources and the potential hydro-electric value is incompatible with Forest Plan land allocations.

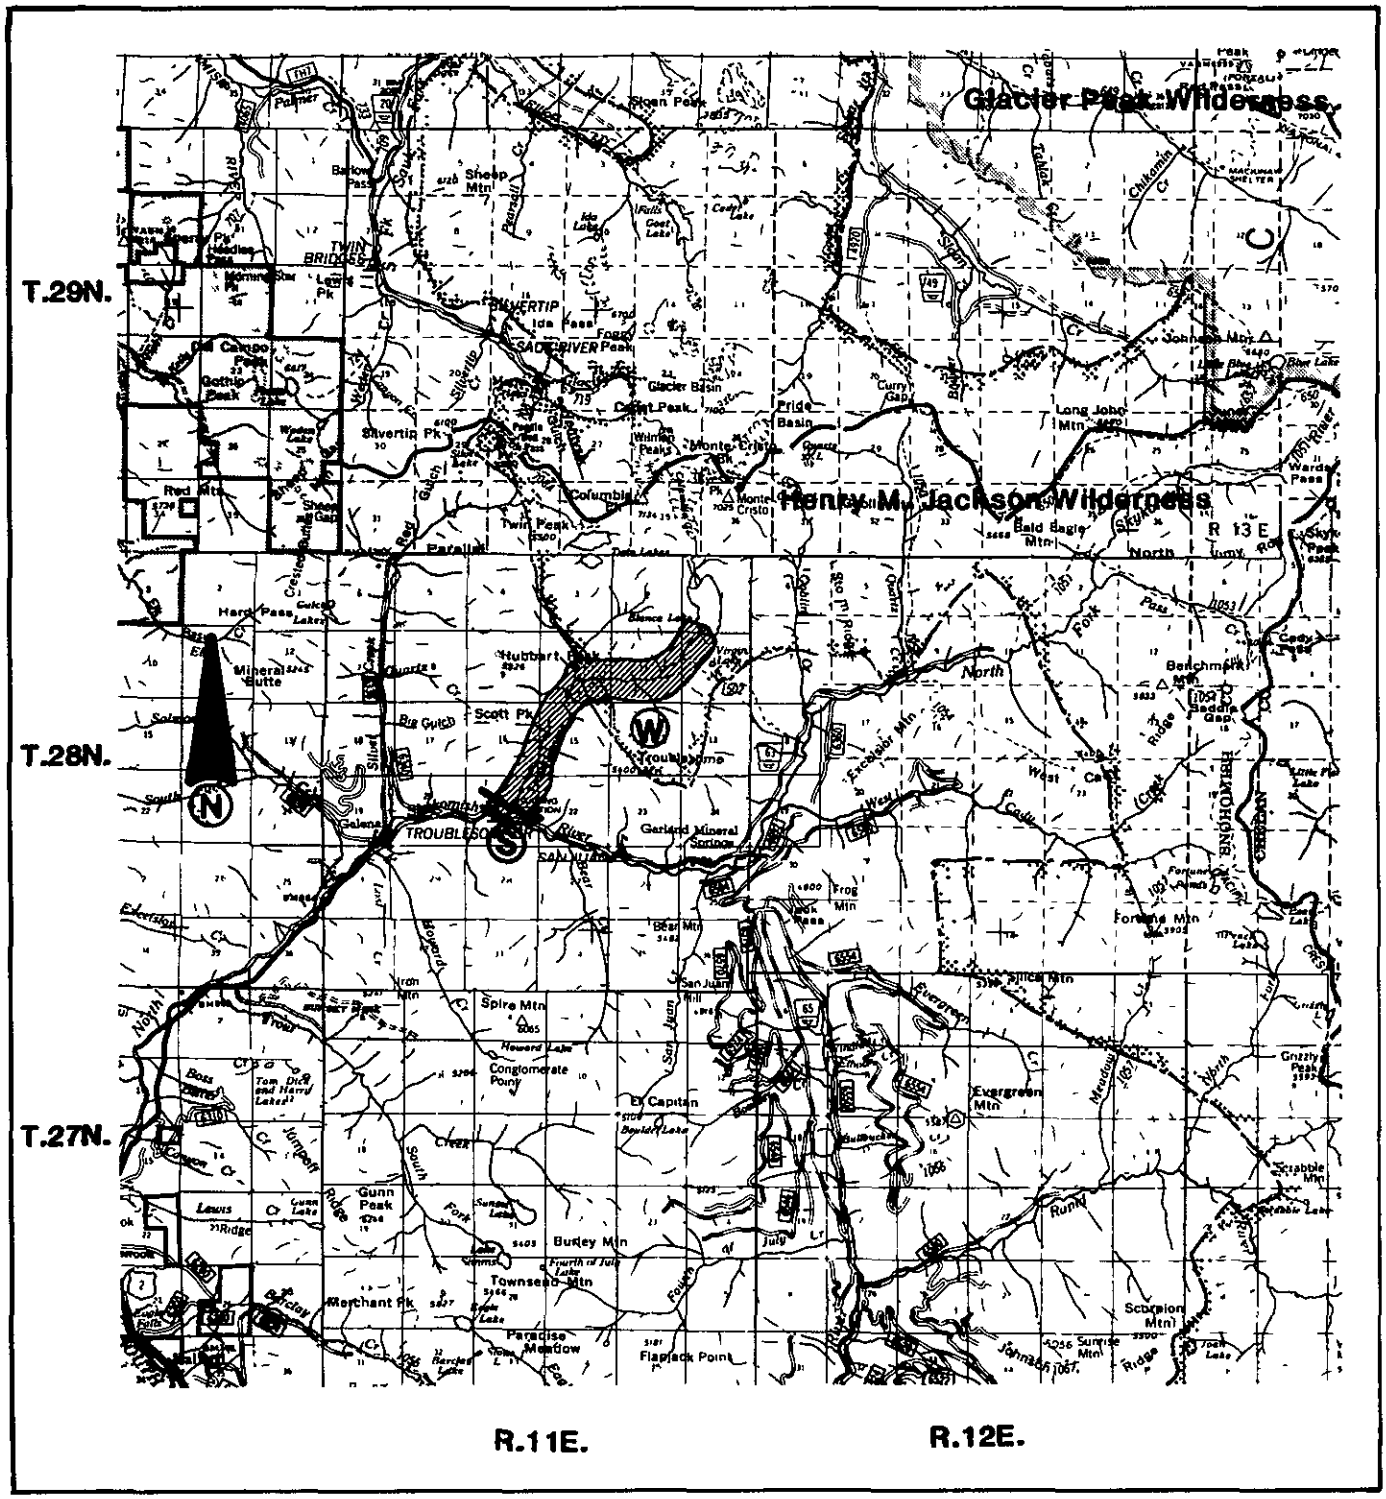
LANDOWNERSHIP:

	River Miles	Corridor Acres
Segment 1		
Mt. Baker-Snoqualmie National Forest (Henry M. Jackson Wilderness - 2.3 miles)	4.4 miles	1,408 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.1 miles	32 acres
Total	4.5 miles	1,440 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

Troublesome Creek





MINERAL AND ENERGY RESOURCE ACTIVITIES: The entire creek lies within an area classified by the BLM as having critical mineral potential. Even though the area has no reported mineral resource production history, a review of available literature, including the Bureau of Mines MILS data, does indicate the area has precious and base metal resource occurrences. These occurrences appear to be concentrated in Sections 10, 15 and 21, T.28 N., R.11 E. The BLM mining claim recordation data also indicates that 144 mining claims have been located along or adjacent to the river corridor in Sections 9, 10, 15, 16, 21 and 22, T.28 N., R.11 E. Of these 144 claims, only 8 have been abandoned or declared to be null and void

The BLM has classified the entire river as being prospectively valuable ("PV") for geothermal resources. None of the area is considered to be "PV" for other leasable mineral resources and none of the area has been encumbered by mineral leases or lease applications

Based upon the available information it appears that the area does have at least a low and possibly a moderate potential for the occurrence of precious and base metal resources. The number of unpatented mining claims being maintained in the area indicates a serious and continuing interest in these resources. Even though the area does have potential for the occurrence of geothermal resources, no serious interest in that resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along the creek. Troublesome Creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A preliminary permit for a hydroelectric project has been issued by FERC. Proposed facilities within the river corridor consist of a transmission line, a powerhouse, and a diversion structure and penstock. The project capacity will be 3.7 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: County Road 63 crosses above the mouth of the river.

Troublesome Creek Campground (35 sites) is located near the mouth of the river. There is some rip-rap at the campground.

Troublesome Creek Nature Trail (#1079) is adjacent to the campground. It is a 1/2-mile loop trail. Two trail bridges cross Troublesome Creek at its confluence with the North Fork Skykomish.

There are no homes or farms bordering the creek.

Several fish habitat structures were put in during 1985-86: 25 log deflectors, 1 digger log, 1 area of bank seeding/planting, and 2 rock deflectors

RECREATION ACTIVITIES: The predominant activities are camping, hiking and fishing Camping receives the heaviest use Some swimming use is associated with the campground, but cold water acts to limit this activity.

Appendix E
Troublesome Creek

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	10	15
Waterplay (swim, wade)	25	35
Fishing, Hunting	245	353
Camping	45,000	67,500
Viewing (hiking, wildlife, driving for pleasure)	2,525	3,840
Misc. (hike, picnic, berry picking, etc.)	390	765
TOTAL	48,195	72,508

WILDLIFE AND FISHERIES: Mountain goats and spotted owls are predominant wildlife in the drainage. Coho and some chinook and pink salmon spawn near the mouth of Troublesome Creek. Further access upstream is blocked by a series of cascades-falls. The creek does support a population of resident rainbow trout.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The Columbia Glacier feeds into Blanca Lake, which in turn drains into Troublesome Creek. The creek exhibits the steep mountain character typical of this area over its entire length. There are numerous cascades, falls and rapids. Eleven tributaries drain into Troublesome Creek. The creek bottom is mainly boulder and rubble.

Water quality is excellent.

GEOLOGY: This creek originates and passes through rugged granitic mountains. Previous glaciation has carved out the valley and oversteepened the sideslopes. Lower sideslopes dominated by stringers of conifers interspersed with deeply dissected and extremely steep side drainages and avalanche tracks merge into upper slopes of barren rock and perennial snow. The numerous side tributaries abound with waterfalls during spring runoff.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Troublesome Creek, and no prehistoric sites are recorded within the proposed Wild and Scenic River corridor. The lack of sites may be a result of the lack of a survey. Historically, the Troublesome Creek drainage was within the territory of the Skykomish Indian tribe. No localities used for traditional religious purposes are known.

The discovery of silver on Lost Creek in 1871 resulted in the filing of additional mining claims up Troublesome Creek. No historic sites are listed on the National Register of Historic Places.

TIMBER: There is some logging in the drainage in conjunction with mining claims. The logging occurs below the Wilderness boundary.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

Total Timber Volume (MMBF)	ASQ: Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	ASQ: Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
23.5	0	0

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: Troublesome Creek has its confluence with the North Fork of the Skykomish River at Troublesome Creek Campground. Rapids near the mouth of the river have been made accessible by construction of the high standard Troublesome Creek Nature Trail. Many visitors are attracted to the North Fork area by its scenic and recreation attractions, and the community of Index (pop. 147). Index is located on the North Fork Skykomish, and benefits economically from the visitors Traditionally a mining and logging community, Index has also become a magnet for retirees and vacation home owners. The "Index Town Wall" (cliffs) attract many skilled rock climbers who have established numerous routes on the "wall".

CURRENT ADMINISTRATION: The upper 2.3 miles of the creek are inside the Henry M. Jackson Wilderness. The wilderness and other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Troublesome Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	
Costs of Implementation		500
Development of Management Plan		1,800
Development Costs	15,000	
Operation and Maintenance Costs	1,000	
TOTAL - First Five Years	**$17,000**	**$2,300**

General administration and operation and maintenance costs are estimated to continue at $400 annually

Appendix E
Troublesome Creek

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Semi-Primitive, Non-Motorized Recreation	654
		Wilderness-Transition	42
		Wilderness-General Trailless	696
Segment 2	Scenic	Semi-Primitive, Non-Motorized Recreation	63

WEST CADY CREEK

Snohomish County

West Cady Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters in the Henry M. Jackson Wilderness to the confluence with the North Fork Skykomish River.

Segment 1 - Headwaters in NE 1/4 of Sec. 13, T.28 N., R.12 E. to bridge in Sec. 21, T.28 N., R.12 E. (4.8 miles).

Segment 2 - Bridge to confluence with North Fork Skykomish River (2.7 miles).

RIVER MILEAGE:

Study:	7.5 miles
Eligible:	7.5 miles
Forest Plan:	7.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: West Cady Creek was found to possess "Outstandingly Remarkable" values for the following: Wildlife.

There is a golden eagle nest site in the drainage.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	4.8	Wild	4.8
Segment 2	Recreation	2.7	Recreation	2.7

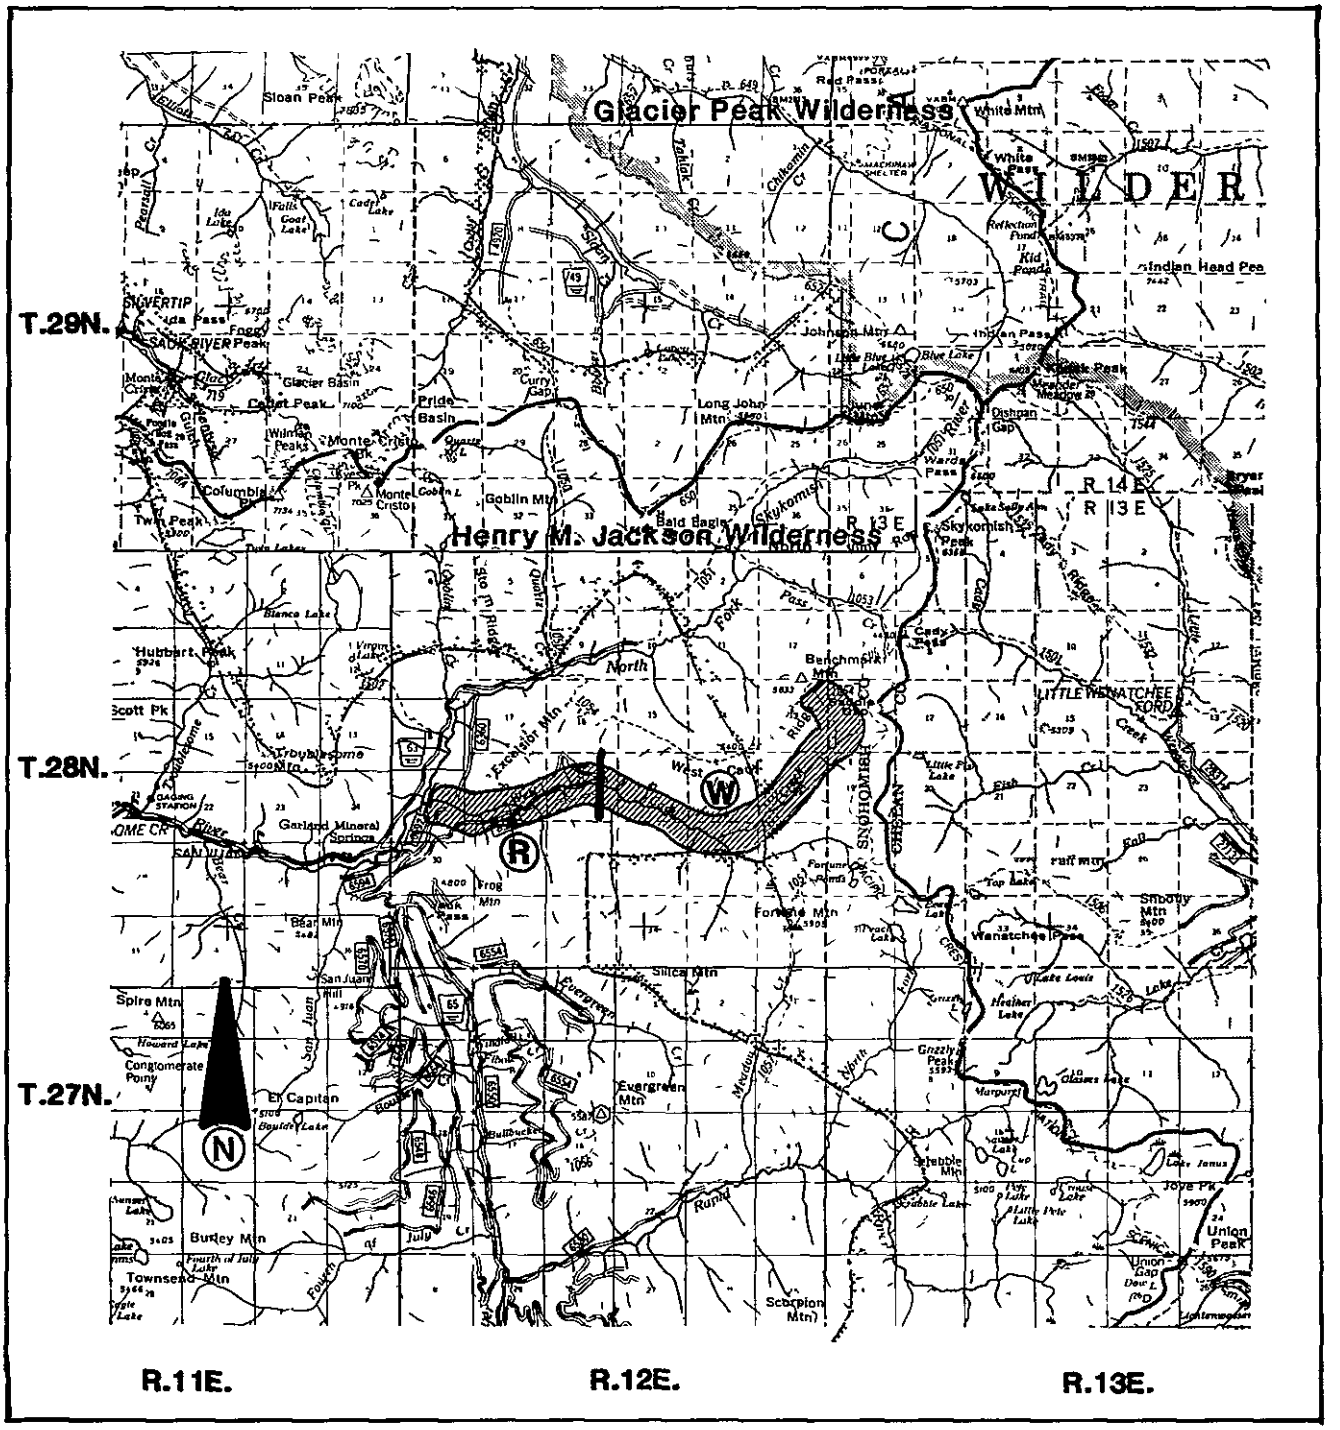
SUITABILITY DETERMINATION:

West Cady Creek was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to little to no resource conflict, and compatibility with the existing Forest Plan land allocation. West Cady Creek has outstandingly remarkable values for wildlife.

West Cady Creek

River Corridor
Wilderness Boundary
National Forest Boundary
0 1 2 3 miles

Potential River Classification
R - Recreational
S - Scenic
W - Wild



LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Henry M. Jackson Wilderness - 2.5 miles)	4.8 miles	1,536 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	2.5 miles	800 acres
Private	0.2 miles	64 acres
TOTAL	7.5 miles	2,400 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither of the river segments are classified by the BLM as areas of critical mineral potential or are encumbered by unpatented mining claims. A review of available literature including the Bureau of Mines MILS data, indicates the river has no reported locatable mineral resource occurrences.

The BLM has classified the entire river as being prospectively valuable for geothermal resources. None of the area is considered to have potential for other leasable mineral resources and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears the area has a relatively low potential for the occurrence of locatable mineral resources. No serious interest in the locatable minerals is currently being expressed. The area does have at least a low potential for the occurrence of geothermal resources. However, as with the locatables, no serious interest in the geothermal potential is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along West Cady Creek. This creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A license application has been completed for a small hydroelectric project on West Cady Creek. Proposed facilities within the river corridor consist of a transmission line, powerhouse, and a diversion structure and penstock. The project capacity would be 4 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: F.S. Road 6580 parallels the river for 2 miles along its lower reaches. Two miles upstream from the mouth, the road crosses to the north side of the creek. The bridge was developed to provide logging access to the area.

There are no homes, farms or developed campgrounds bordering the creek.

RECREATION ACTIVITIES: The West Cady Creek drainage has low recreation use. Limited amounts of camping, hunting and fishing for resident species occurs along its banks. Rafting and kayaking are not suitable and the water is too cold for swimming.

Appendix E
West Cady Creek

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	25	40
Camping	865	1,300
Viewing (scenery, wildlife, driving for pleasure)	4,100	6,230
Misc. (hike, picnic, berry picking, etc.)	160	315
TOTAL	5,150	7,885

WILDLIFE AND FISHERIES: There is a golden eagle nest site in the drainage.

Chinook and coho salmon spawn and rear in the lower mile of the creek. An impassable series of cascades-falls prohibits further migration upstream. *Rainbow and cutthroat trout inhabit the entire creek.*

STREAMFLOW, GRADIENT AND VALLEY PROFILE: West Cady Creek exhibits the steep mountain character typical of this region over its entire length. There are numerous cascades, falls and rapids. Sixteen tributaries drain into the creek. The bottom of the creek is mainly boulders and rubble.

GEOLOGY: West Cady Creek flows through a steep V-shaped valley dominated by granitic and gneissic bedrock. Lower slope conifers blend into old burn meadow areas on the adjacent ridgetops.

CULTURAL RESOURCES: No systematic archaeological survey has been made of West Cady Creek, and no prehistoric or historic sites are recorded. The lack of sites may be a result of the lack of survey of the drainage. Historically, West Cady Creek was within the territory of the Skykomish Indian tribe. No localities used for traditional religious purposes are recorded.

There are no sites within the proposed Wild and Scenic River corridor listed on *the National Register of Historic Places.*

TIMBER: The lower three miles of the creek have been extensively clearcut logged.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
51.8	2.810	2.572

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The North Fork Skykomish drainage, providing access to West Cady Creek, has developed campgrounds, dispersed camping opportunities, and several trailheads. Many visitors are drawn to the area by its scenic and recreation attractions.

Index, traditionally a mining and logging community, also has become a magnet for retirees and vacation home owners The "Index Town Wall" (cliffs) attract many skilled rock climbers who have established numerous routes on the "wall".

CURRENT ADMINISTRATION: The upper 2.2 miles of the creek flow within the Henry M. Jackson Wilderness. The Wilderness and other National Forest lands, are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for West Cady Creek for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 2,000	$ 3,000
Costs of Implementation		3,000
Development of Management Plan		5,000
Development Costs	15,000	80,000
Operation and Maintenance Costs		20,000
Total - First Five Years	**$17,000**	**$111,000**

General administration and operation and maintenance costs are estimated to continue at $5,000 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

SKYKOMISH RIVER
SOUTH FORK SKYKOMISH RIVER
TYE RIVER

Snohomish and King Counties

The Skykomish, South Fork Skykomish, and Tye Rivers were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Skykomish, South Fork Skykomish, and the Tye Rivers were identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

The Skykomish upstream from Sultan, South Fork Skykomish, and the Tye Rivers are designated by the State of Washington as a Scenic River under the State's Scenic Rivers Act.

LOCATION: The Tye River is under evaluation from its headwaters near Stevens Pass on U.S. Highway 2 downstream to the confluence with the South Fork Skykomish and Foss Rivers. The South Fork becomes the main Skykomish River at the confluence with the North Fork Skykomish River.

Segment 1 - Headwaters of the Tye River in SE 1/4 of Sec. 14 , T.26 N., R 13 E. to the confluence with the South Fork Skykomish and Foss Rivers (14 5 miles).

Segment 2 - Confluence of Tye and Foss Rivers to the confluence with the Snohomish River (48.6 miles)

OUTSTANDINGLY REMARKABLE VALUES: The Skykomish, South Fork Skykomish, and Tye Rivers were found to possess "Outstandingly Remarkable" values for the following. Scenic, Recreation, Fisheries, and Wildlife. The Tye River also has values for Historical/Cultural

The river system has many falls that have become popular viewing sites. One of the most dramatic is Eagle Falls, located 12 miles west of the Ranger Station off of Highway 2. The water cascades to a large emerald green pool. Other falls include Sunset, Bridal Veil, Alpine and Deception Falls. Bridal Veil Falls is located on Bridal Veil Creek, a tributary of the Skykomish. The falls cascade down steep rock cliffs forming 2 "veils" in summer and a solid sheet of blue ice in winter. The falls can be viewed from Highway 2 near Index.

All river segments provide boating opportunities. The Tye provides above average opportunity for kayaking. The main Skykomish River is considered to be one of the most outstanding boating rivers in the state due to its rafting and kayaking runs. Overnight camping opportunities are scattered throughout the area with low to moderate use. Hikers can access the Pacific Crest Trail from Stevens Pass. Many people drive for pleasure along U.S. Highway 2 which gains more than 3000 feet elevation from Skykomish to Stevens Pass, winding its way around steep mountainsides.

Winter range is provided for black-tailed deer and mountain goats. Below Alpine Falls, bald eagles, a federally listed Threatened and Endangered species, forage in winter.

Good spawning and rearing habitat exist for chinook, coho and pink salmon. Winter steelhead, resident rainbow and cutthroat trout also inhabit the waters.

The most significant historic resource in the Skykomish system is the Stevens Pass Historic District. Listed on the National Register of Historic Places, the district is nationally significant. It represents 35 years of effort by the Great Northern Railroad to construct and improve a transcontinental line.

RIVER MILEAGE:

Study:	63.1 miles
Eligible:	63.1 miles
Forest Plan:	42.8 miles recommended for designation in preferred alternative

Note: Recommendation includes the Tye and portion of Skykomish system to Gold Bar.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	14.5	Recreation	14.5
Segment 2	Recreation	48.6	Recreation	28.3

SUITABILITY DETERMINATION:

The Skykomish, South Fork of the Skykomish, and Tye Rivers were found to be suitable for inclusion in the preferred alternative of the Forest Plan due to a very high number of outstandingly remarkable values. The main Skykomish is considered to be one of the most outstanding boating rivers in the state due to its rafting and kayaking runs. A scenic corridor parallels much of the river and provides habitat for bald eagle wintering and foraging. The Skykomish system flows through the Stevens Pass Historic District, a National Register of Historic Places site. The Skykomish is currently the only designated Washington State Scenic River. The Skykomish System was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982.

Designation is recommended downstream on the main branch of the Skykomish only as far as the town of Gold Bar due to private ownership concerns.

The Tye River is recommended as a logical extension of the main Skykomish.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	10.5 miles	3,360 acres
Private	2.0 miles	120 acres
State	2.0 miles	1,160 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	2.3 miles	736 acres
State	2.2 miles	784 acres
Private	44.1 miles	14,032 acres
TOTAL	48.6 miles	15,552 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified by the BLM as lying within an area of critical mineral potential. However, a review of available literature including the Bureau of Mines MILS data does indicate numerous sand and gravel resource occurrences and a few base and precious metal resource occurrences along the river. Of most importance, appears to be limestone deposits in Section 12 and 13, T.26 N., R.10 E. and Sections 15 and 16, T.27 N., R.9 E., gold occurrences in Section 31, T. 28 N., R.8 E., Section 5 and 6, T.27 N., R.8 E and in Section 7, T.27 N., R.9 E. The BLM mining claim recordation data indicates a few unpatented mining claims (43) have been located in Sections 17, 18, 19, 20 and 21, T.26 N., R.11 E. Of these 43 claims, however, 21 have been abandoned or declared to be null and void, and it is not known what part of the remaining 22 claims lie within the river corridor.

The BLM has classified the western 10 miles as being prospectively valuable ("PV") for oil and gas, the eastern 17 miles as being "PV" for geothermal resources, and the western 16 miles as "PV" for coal resources. However, none of the area has been encumbered by mineral leases or lease applications

Based upon the available information, it appears that only a small part of the river has at least a low potential for the occurrence of precious metal resources, and only in Sections 17,18,19, and 20, T.26 N., R.11 E. has any serious interest in locatable minerals been recently expressed. Even though a large part of the area is considered to have at least a low potential for the occurrence of leasable minerals (coal, oil and gas, and geothermal), no serious interest in those resources has been recently expressed.

WATER RESOURCE DEVELOPMENT: The Skykomish River and the lower 8.3 miles of the Tye River are classified as "Protected" from hydropower development by the NW Power Planning Council.

Preliminary permits for hydroelectric projects have been issued by FERC on seven tributary streams to the South Fork of the Skykomish River. Also one license application has been submitted. Following is a list of the tributaries, proposed facilities and the capacity of each project in megawatts:

Tributary	Proposed Facilities within Corridor	Megawatts
Proctor Creek	Transmission line	2.3
Anderson Creek	Transmission line	1.4
Inder Creek	Transmission line	3.4
Lowe Creek	Transmission line	1.7
Money Creek	Transmission line	3.0
Duffy Creek	Transmission line	13.4
Lake Isabel	Transmission line	5.0
Barclay Creek	Transmission line	6.3

No major water diversions are known, but perhaps there are pump stations for agricultural irrigation.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Tye River: Highway 2 parallels the river for the entire segment, crossing the river 3 times. The Stevens Pass Ski Area and associated development occurs within the Tye River near the headwaters. The upper portion includes Highway 2, and F.S. Roads 6099 (Old Cascade Hwy), 050, and 910. The middle section is paralleled by Highway 2 and F.S. Road 6099. The Old Cascade Highway crosses twice via earth covered culverts. The lower section continues to be closely paralleled by Highway 2 and F.S. Road 6810.

The Burlington Northern Railroad parallels the river for the entire segment. The railroad crosses the Tye and enters an underground tunnel (Cascade Tunnel) which goes under the Tye. The Cascade Tunnel is the longest railroad tunnel in the western hemisphere. An abandoned railroad grade parallels the right bank of the upper Tye.

The Pacific Crest Trail passes near the headwaters of the Tye.

Bonneville transmission lines parallel the entire length of the Tye from Stevens Pass to Sultan. They cross the river repeatedly between the confluence with the Foss River and Deception Falls. A buried pipeline crosses the river at Sec. 19, T.27 N., R.10 E. It is no longer in use.

There are a few scattered residences and the small communities of Timberland Village and Scenic. Historically significant townsites on the Tye River are Martin City, Alpine, Corea, and Alpine Camps 1 & 2.

Deception Falls Picnic Area is located off Highway 2 at Deception Creek. A 1/2-mile nature trail leads from the falls to the Tye.

There is rip-rap and a couple of private homes at Profitts Ponds.

South Fork and main Skykomish River: The entire length of the mainstem Skykomish River has developments along its banks. U.S. Highway 2 parallels most of Skykomish, as does the Burlington Northern Railroad. Highway 2 crosses at confluence of the North and South Forks and east of Gold Bar. Highway 522 crosses just below the confluence of Skykomish and Snoqualmie Rivers.

U.S. Highway 2 crosses the South Fork Skykomish 3 times. County roads 12 and 6030 and F.S. Roads 210 and 6020 each cross the river. The railroad crosses 3 times.

There are many powerline crossings over the Skykomish River. The following is a list of the locations

1. approximately 3 miles west of Sultan in Sec. 11.
2. at confluence of South Fork Skykomish River, North Fork Skykomish and Skykomish
3 0.1 mile upstream from the confluence of South Fork and Skykomish
4. 1 mile below Baring
5. 0.5 mile below the confluence with the Tye River
6. just above the confluence of the North Fork and Skykomish Rivers

The powerline also runs along the corridor between Baring and Grotto.

There are scattered rural residences and summer vacation residences along the lower stretch of the river. Major communities along the Skykomish include: Gold Bar, Startup, Sultan, and Monroe Most of the South Fork is bordered by communities (Skykomish, Grotto, Baring), roads (especially U.S. Highway 2), and other developments. There are old bridge crossings at Grotto and Baring.

There is agricultural development on the lower 2/3 of the river.

Money Creek Campground (24 sites) and Picnic Area (4 sites) is the only developed National Forest campground. There is a privately owned and operated campground along the river approximately seven miles southeast of Goldbar.

The High Bridge Site just east of Reiter Road under the Highway 2 bridge is an existing recreation site with proposed improvements. At present it receives high use from illegal ORV users. Plans are to accommodate ORV users elsewhere and improve High Bridge for fishing use

A high use dispersed camping area is under the bridge in Sultan. This recreation site and High Bridge are susceptible to flooding.

At the confluence of the Skykomish and Snohomish Rivers is the planned Lord Hill Regional Park site. A coalition of government agencies is planning the development of the park for area recreation.

There is a fish hatchery on Wallace River 4 miles above its confluence with Skykomish River.

Rip-rap is found on the South Fork at Money Creek Campground and at Eagle Falls. Eagle Falls has been modified by blasting in 1926. Additional stabilizing materials undoubtedly occur on private land.

There is diking at the town of Skykomish. Remains of old wood diking exist at Milltown (old town site).

RECREATION ACTIVITIES: **Tye River:** There is canoeing and above average kayaking use from Carrol Creek to confluence with Foss River. Fishing for anadromous fish species occurs below Alpine Falls; resident species only above Alpine Falls. There is low use of the river for swimming, due to cold water and lack of opportunities.

Dispersed camping opportunities are scattered throughout the area with low to moderate use. Hikers can access the Pacific Crest Trail from Stevens Pass. A short 1/2 mile loop nature trail starts at Deception Falls Picnic Area and winds along the Tye River and Deception Creek. A wheelchair view point along the trail has been proposed.

Many people drive for pleasure along U.S. Highway 2 which gains more than 3000 feet elevation from Skykomish to Stevens Pass, winding its way around steep mountainsides.

South Fork and main Skykomish Rivers: The river reach between Sunset Falls and Goldbar is heavily used by a number of commercial river rafting companies. From Skykomish to Monroe the river offers a range of canoeing and kayaking from beginner (Class I) to experienced (Class V) with a number of put-in and take-out locations. The river is considered to be one of the most outstanding boating rivers in the state. Use is heavy and increasing yearly. The Ben Howard Public Fishing Area is located between Sultan and Monroe.

Eagle Falls, located 12 miles west of the Ranger Station off of Highway 2, is a favorite spot for swimmers and skindivers. It falls to a large emerald green pool below and is enjoyed by many.

The highest dispersed recreation use is driving for pleasure along U.S. Highway 2, which parallels most of the river. Sunset Falls may be viewed from Highway 2, east of Index. Also known for its beauty is Bridal Veil Falls, located 1/4 mile east of Index on Highway 2. The falls are on Bridal Veil Creek, a tributary of the Skykomish. The falls cascade down steep rock cliffs forming 2 "veils" in summer and a solid sheet of blue ice in winter.

The only developed campground on the river is Money Creek Campground, located 4.2 miles from the Skykomish Ranger District on Highway 2.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	125	210
Waterplay (swim, wade)	675	1,015
Fishing, Hunting	1,545	2,225
Camping	52,120	78,180
Viewing (scenery, wildlife, driving for pleasure)	203,160	308,800
Misc. (hike, picnic, berry picking, etc.)	261,120	511,795
TOTAL	518,745	902,225

Note: The miscellaneous category includes the Stevens Pass Ski Area use.

WILDLIFE AND FISHERIES: Tye River: There is bald eagle wintering and foraging habitat below Alpine Falls, as well as an anadromous fish run of chinook and coho salmon. Some winter steelhead and resident rainbow and cutthroat trout also inhabit the waters.

The river area offers an extensive black-tailed deer winter range, and excellent riparian and furbearer habitats

South Fork and main Skykomish Rivers: Notable species or habitats include bald eagle (a federally listed Threatened and Endangered species), spotted owl, and winter range for mountain goat and deer.

There is good spawning and rearing habitat for chinook, coho, and some pink salmon. The main stem of the Skykomish is heavily utilized. In the upper area, Cass Pond was created in the lower 1/4 mile of Anthracite Creek for trout rearing and production of juvenile fish. Adult salmon are captured at Sunset Falls fishing trap, hauled four miles and released above Eagle Creek by the State. There is also a state salmon hatchery between Startup and Goldbar. In the lower area, the bottom has ideal spawning gravel with superb salmon production in the main channels. There is a large rearing pond on Wagleys Creek for rearing coho and a state salmon hatchery on Wallace River. In this area there are large deep pools and long glides used as resting areas and holding waters for the maturation of adult salmon.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Tye River: For the first three miles, the Tye River falls through a narrow, steep-sloped, densely forested valley. Then for seven miles, the valley alternately widens and narrows The river exhibits a steep gradient in a confined channel. About 3 1/2 miles from its confluence with the Foss, the river gradient becomes moderate and the channel winds across a relatively flat valley floor. There are numerous channel splits with good to excellent pool-riffle conditions. The banks are low earth cuts, and there are many logs and related debris in the streambed. In the lower mile, the gradient again becomes moderately steep with a number of cascades and rapids, a few fast riffles, and large deep pools. The nineteen tributaries exhibit steep mountain features throughout, and many fall directly off steep side slopes into the river. Alpine Falls, 5.1 miles east of the Ranger Station, has a 50 foot drop

South Fork and main Skykomish River: The river is situated in a confined valley with high mountain ranges of moderate to moderately steep slopes. A large channel split near Grotto forms a rock island about .5 mile in length covered with deciduous growth. On the south side of the rock island, a large island of sand and gravel is formed in the main river at the mouth of Money Creek. The river gradients descend gradually at the rate of under twenty feet a mile. Five and a half miles beyond Grotto, just below Barclay Creek, the river falls rapidly for three miles. Eagle Falls (28 feet), Canyon Falls (48 feet), and Sunset Falls (88 feet) form a series of cascades and falls. Below Sunset Falls, the river returns to a moderate gradient with mostly pool riffles. At the confluence of the North Fork and the South Fork, the main stem enlarges and slows down as it enters a more gradual gradient in the lower valley. The valley goes from 1/4 mile to 3 miles wide. In the Sultan area, the valley floor is flat, cleared land with side valley terrain that rises gradually and is densely forested with mixed coniferous and deciduous trees. There are extensive channel splits winding through large islands of gravel.

Excellent pool-riffle and long glide areas prevail with moderate gradient throughout. The river retains this character to its confluence with the Snohomish River at Monroe. Forty tributaries drain into the Skykomish River. Stream flows reach a maximum in late May and early June with over 7000 cubic feet per second (cfs) at the Goldbar stream gauge. The low flows occur in late August at about 1000 cfs.

GEOLOGY: The bedrock geology is dominated by granitic and metasedimentary rocks. Upper river basins are predominantly V-shaped but become U-shaped downslope where previous glaciation has been a dominant influence. Glacial till and lacustrine materials are common surficial deposits. The Skykomish River basin becomes very wide in the downstream reaches.

CULTURAL RESOURCES: No systematic archeological survey has been made of the Skykomish. However, information is available from a number of surveys made in conjunction with Federal projects, and from published historical sources.

Few prehistoric sites have been recorded to date. Known sites are believed to represent the period shortly before white exploration and settlement, but contain relatively little distinctive material. During the historic period, the area was occupied by the Skykomish and Snohomish Indians. Localities used in traditional religious practices exist along the Skykomish.

Historic period sites represent logging, mining and railroading. Logging of the Skykomish began in 1860 and produced numerous mills and some miles of logging railroad. By the 1930's, much of the private timber had been removed. Limited production of gold and copper ores occurred in the Index, Silver Creek and Miller River districts. The Silver Creek district was one of the earliest established in the Cascades (1871). Production was at a peak between 1880 and 1900, but was never very great. Sporadic activity continued until World War II.

The most significant historic resource in the Skykomish system is the Stevens Pass Historic District. Listed on the National Register of Historic Places, the district is Nationally significant. It represents 35 years of effort by the Great Northern Railroad to construct and improve a transcontinental line. The line contributed substantially to the economic development of Washington State. The district includes a segment of railroad's Cascade crossing, with numerous engineering features such as switchbacks, snowsheds and tunnels that were unusual or unique engineering achievements in their day. The historic district runs from Martin Creek drainage easterly up over Stevens Pass to Berne Camp on the eastside.

TIMBER: Extensive logging has taken place on both rivers, on private, state and federal lands, especially below the town of Scenic.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

Total Timber Volume (MMBF)	ASQ: Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	ASQ: Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
143.2	3.411	3.311

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: The Tye River has no livestock grazing. There is some localized grazing below Sultan on private property along the Skykomish River.

SOCIO-ECONOMIC EFFECTS: The Skykomish River, the South Fork of the Skykomish and the Tye River are paralleled by U.S. Highway 2, a major link between western and eastern Washington, crossing the North Cascades at Stevens Pass. Communities along the rivers and highway are Monroe, Sultan, Startup, Gold Bar, Index, Grotto, Baring and Skykomish

These communities derive their support increasingly from tourism and recreation. The ski area at Stevens Pass draws many visitors, in addition to those who utilize the area for hiking, camping, climbing, fishing, hunting, river rafting, cross-country skiing and ORV use. The scenic qualities of the rivers, mountains and forest also attract many sightseers.

Local businesses serve these visitors with restaurants, hotels, rafting and guide outfits, ski rental and camping supply stores, and grocery/gas stations.

Timber harvesting and the wood products industry have traditionally and continue to be important to the economic health of the area. Some mining activity can still be found.

Monroe, with its close proximity to Seattle and Everett, serves increasingly as a bedroom community to both, and houses a state prison facility and Valley General Hospital.

CURRENT ADMINISTRATION: National Forest lands along the Skykomish River System are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. The area from east of Grotto to the headwaters of the Tye are within the Alpine Lakes Management Unit. Management direction is found in the Alpine Lakes Management Plan.

Under the guidelines of the Washington State Shoreline Management Act of 1971, most of the shorelines of the Skykomish, South Fork and Tye Rivers are classified by King and Snohomish Counties as Conservancy. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A small suburban development lies inside the loop of the river near Sunset Falls and Canyon Falls. This area is classified as a Flood Hazard Zone and may not be developed. For approximately 2 1/2 miles between the forks of the rivers, the area has been classified as Natural. A Natural designation denotes areas

characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relatively intolerant of intensive human use.

The King and Snohomish County Comprehensive Plans have zoned the land along the Skykomish River System, outside of federal jurisdiction, as:

Rural Use or Forestry Use along the Tye and South Fork Skykomish. There are a few residential developments and the town of Skykomish, where a greater dwelling density is permitted.

Forestry Use from the King/Snohomish County line to Gold Bar, with Flood Hazard Zones designated near the communities situated along the river.

Rural Use, with 1 dwelling per 10 acres, from Gold Bar to Sultan.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Skykomish, South Fork Skykomish and Tye Rivers for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 15,000	$100,000
Costs of Implementation		80,000
Development of Management Plan		125,000
Development Costs	291,000	75,000
Operation and Maintenance Costs	115,000	25,000
TOTAL - First Five Years	**$421,500**	**$405,000**

General administration and operation and maintenance costs are estimated to continue at $51,100 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Recreation	Scenic Corridor (Foreground)	42
		Winter Developed Recreation	295
		Timber Management	84
		Alpine Lakes Dispersed Recreation	21
		Alpine Lakes Scenic	2,576
Segment 2	Recreation	Scenic Corridor (Foreground)	147
		Scenic Corridor (Middleground)	337
		Timber Management	147
		Alpine Lakes Scenic	1,245

FOSS RIVER (TO FORK)
EAST FORK FOSS RIVER
WEST FORK FOSS RIVER

King County

The Foss, East Fork Foss, and the West Fork Foss Rivers were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Foss River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: The East Fork Foss River flows from its headwaters on Mt. Daniels' Lynch Glacier to its confluence with the Foss River. The West Fork Foss River flows from its headwaters in Delta Lake to its confluence with the Foss River. The Foss River flows from the confluence of the East and West Forks of the Foss River to its confluence with the Tye River.

Segment 1 - Headwaters of the East Fork Foss River at Lynch Glacier in SW 1/4 of Sec. 11, T.24 N., R.13 E. to the Alpine Lakes Wilderness boundary (6.7 miles).

Segment 2 - Alpine Lakes Wilderness boundary to the confluence with the West Fork Foss River (1.2 miles).

Segment 3 - Headwaters of the West Fork Foss River at Delta Lake to the Alpine Lakes Wilderness boundary (3.1 miles).

Segment 4 - Alpine Lakes Wilderness boundary to the confluence with the East Fork Foss River (1.5 miles).

Segment 5 - Confluence of East and West forks of the Foss River to confluence with Tye River (4.4 miles).

RIVER MILEAGE:

Study:	16.9 miles
Eligible:	16.9 miles
Forest Plan:	16.9 miles recommended for designation in preferred alternative

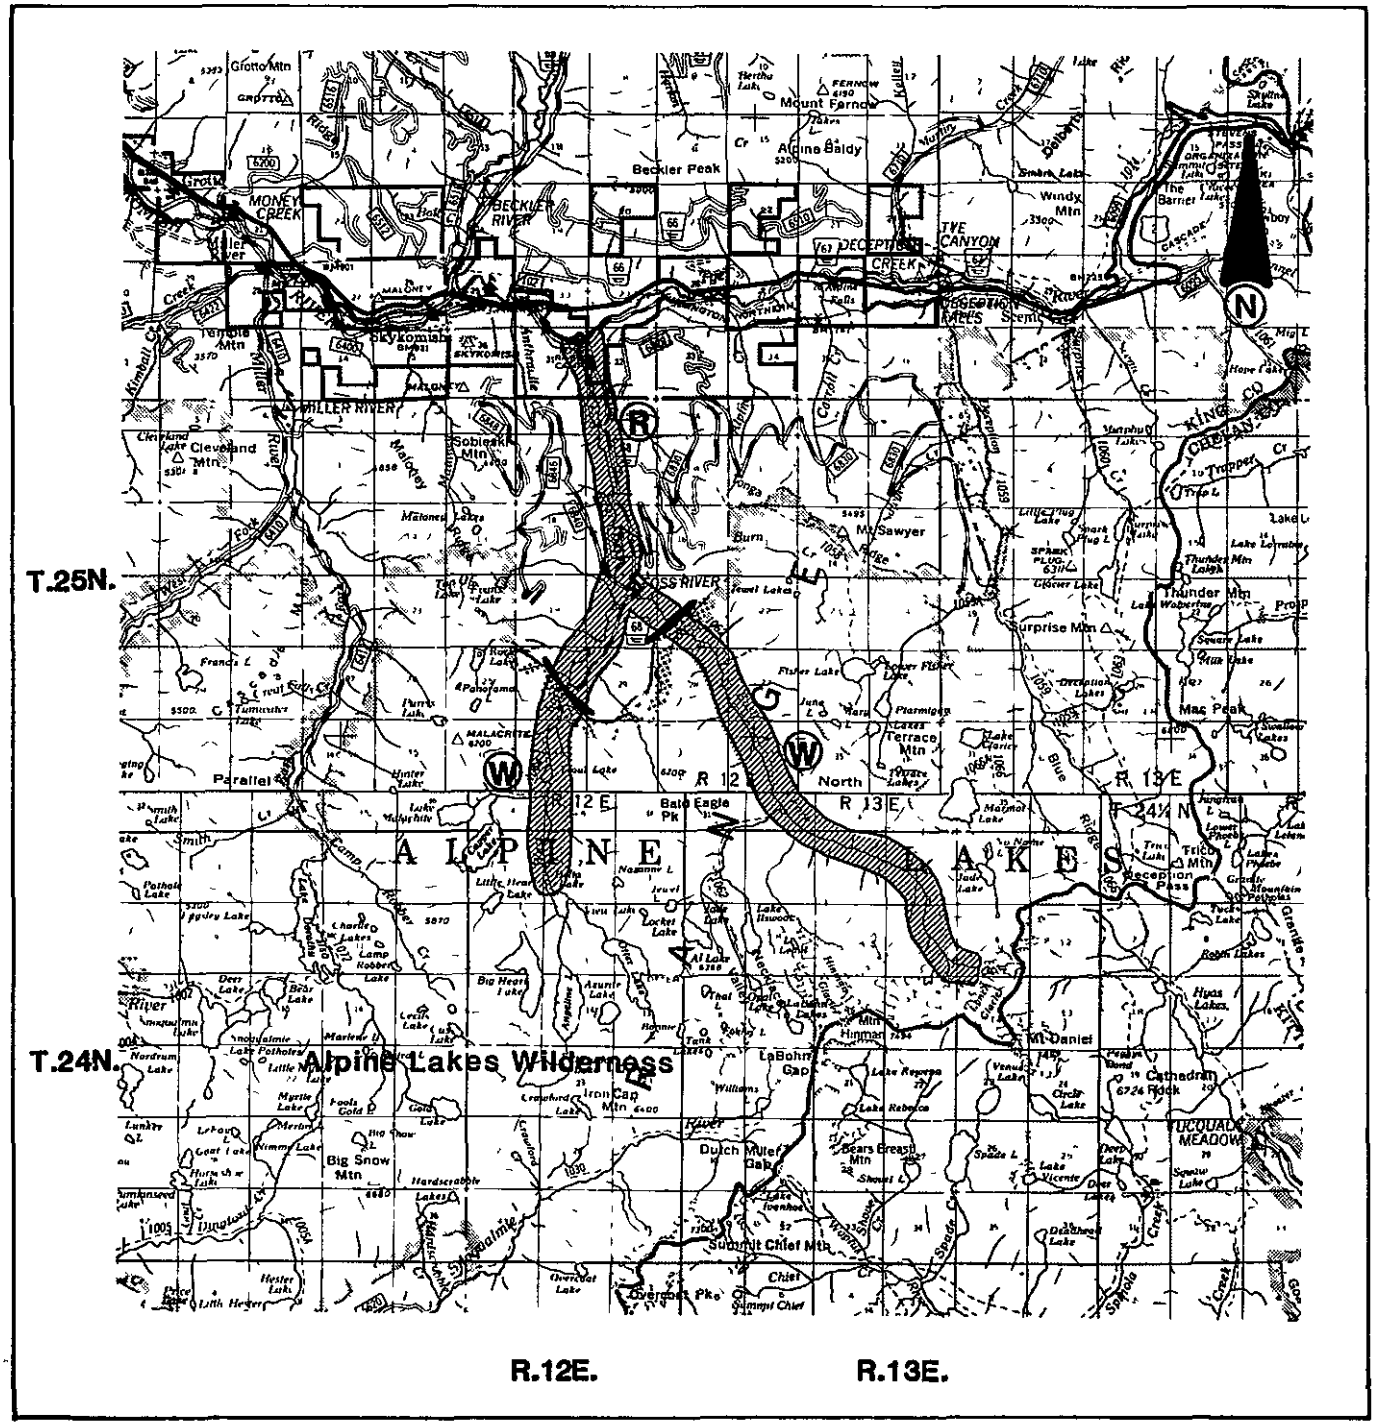
OUTSTANDINGLY REMARKABLE VALUES: The Foss, East Fork and West Fork Rivers were found to possess "Outstandingly Remarkable" values for the following: Recreation, Fisheries and Wildlife.

Many forest visitors drive the forest road for pleasure or to gain access for hunting, fishing and hiking opportunities. Two very popular hiking trails lead into the Alpine Lakes Wilderness. The Foss River system provides excellent whitewater kayaking opportunities.

Foss River
East Fork Foss River
West Fork Foss River

River Corridor
Wilderness Boundary
National Forest Boundary
0 1 2 3 miles

Potential River Classification
R S W
R - Recreational
S - Scenic
W - Wild



Bald eagles forage near the mouth of the Foss River and black-tailed deer winter range occurs throughout the drainage. The river also provides excellent furbearer and riparian habitat.

Chinook and coho salmon, rainbow and cutthroat trout inhabit the river system.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	6.7	Wild	6.7
Segment 2	Recreation	1.2	Recreation	1.2
Segment 3	Wild	3.1	Wild	3.1
Segment 4	Recreation	1.5	Recreation	1.5
Segment 5	Recreation	4.4	Recreation	4.4

SUITABILITY DETERMINATION:

The Foss, West Fork Foss, and East Fork Foss Rivers were found to be suitable for inclusion in the preferred alternative of the Forest Plan due to a lack of competing resource values or uses, high public support, and other public agency support. The potential hydro-electric projects on tributaries of the Foss system would not be ruled out due to designation. The Foss system was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982.

LANDOWNERSHIP:

	River Miles	Corridor Acres
Segment 1		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 6.7 miles)	6.7 miles	2,144 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.7 mile	224 acres
Private	0.5 mile	160 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 3.1 miles)	2.5 miles	800 acres
Private	.6 mile	192 acres
Segment 4		
Mt. Baker-Snoqualmie National Forest	1.3 miles	416 acres
Private	.2 mile	64 acres
Segment 5		
Mt. Baker-Snoqualmie National Forest	3.3 miles	1,056 acres
Private	1.1 miles	312 acres
State	0.0 miles	40 acres
TOTAL	16.9 miles	5,408 acres

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified as lying within areas of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, does indicate the area has a few precious and base metal resource prospects, none of which have a history of production. According to the BLM mining claim recordation data, only one mining claim has been located along the corridor. However, it has been abandoned.

The BLM has classified the entire river as being prospectively valuable for geothermal resources and for coal resources. None of the area is encumbered by mineral leases or lease applications.

Based upon the available information, it appears the area does have at least a low potential for the occurrence of locatable mineral resources. No serious interest in such resources is currently being expressed. The area also has at least a low potential for the occurrence of both coal and geothermal resources. However, as with the locatables, no serious interest in those resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on any of the rivers.

The entire river system, with the exception of the East Fork Foss above Necklace Valley, is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A preliminary permit for a hydroelectric project has been issued by FERC for Burn Creek, a tributary of the Foss River. Proposed facilities within the river corridor consist of a transmission line. The project capacity will be 3.4 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: A county road parallels the Foss River upstream from its mouth, crossing the river at "Foss River Camp", just above the confluence with the Tye River. The county road becomes FS Road #68, and continues along the east bank of the Foss River and the West Fork Foss to the Alpine Lakes Wilderness boundary. The road crosses the East Fork Foss near the confluence of the two forks.

FS Collector Road 6840 crosses the Foss River below the confluence of the two forks and parallels the right bank downstream for 1.5 miles.

There are no roads paralleling the East Fork Foss. However, an old mining railroad grade parallels the river for 1-2 miles.

The Burlington Northern Railroad parallels the Foss on the west for 1.4 miles, crosses the river and heads back north to the SR 2 Highway corridor. This curious detour originated around the turn of the century when many coal claims existed on the Foss.

Three vehicle and one railroad bridge cross the river.

Many private summer homes are found along the lower 2 miles of the Foss River. Some homes are within 100 feet of the river.

The East Fork Foss Trailhead #1062 is located on Forest Road #68 near the confluence of the East and West Forks. The trail parallels the East Fork Foss River for 4 miles to the junction of the Necklace Valley Trail #1063. The West Fork Foss Lakes Trailhead #1064 begins at the end of Forest Road #68 and follows the West Fork Foss River for 1.5 miles to Trout Lake, before heading uphill to Big Heart Lake.

There are no developed campgrounds along the river system, and limited opportunities exist for their construction. The old Foss River Campground is located near the confluence of the East and West Forks. It is now used as a primitive campsite.

RECREATION ACTIVITIES: Many forest visitors drive the forest road for pleasure or to gain access for hunting, fishing and hiking opportunities. Two very popular hiking trails lead into the Alpine Lakes Wilderness. Both trails are heavily traveled; summer weekends are usually crowded.

Above the railroad bridge, there are 2 miles of Class IV and V water. This is the last kayak run of this type left in western Washington. There are technical Class III and IV rapids below the railroad bridge. There are no opportunities on the rivers for rafting. There is only occasional use by swimmers due to the cold water temperatures. Fishing for resident fish is a popular pastime.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	160	240
Fishing, Hunting	2,130	3,070
Camping	34,590	51,885
Viewing (scenery, wildlife, driving for pleasure)	7,000	10,640
Misc. (hike, picnic, berry picking, etc.)	16,560	32,460
TOTAL	60,440	98,295

WILDLIFE AND FISHERIES: Bald eagles forage near the mouth of the Foss River and black-tailed deer winter range occurs throughout the drainage. The river also provides excellent furbearer and riparian habitat.

Chinook and coho salmon spawn in the mainstem of the Foss River and the lower reaches of the two forks. Rainbow and cutthroat trout are also found. Loss of streamside cover due to logging may limit further production.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The gradient is moderately steep with fast riffle character, some rapids and a few cascades River width ranges from 21 to 60 feet wide. Twenty-six tributaries drain into the Foss River system.

GEOLOGY: Originating in massive mountains of granitic bedrock, this river system passes through volcanic and metasedimentary rocks on its way to the Skykomish. Deep V-shaped upper valleys become U-shaped down valley where glaciation has had a dominant influence.

Appendix E
Foss River
East and West Forks

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Foss River drainage. Limited information is available from project surveys and published historical sources. No prehistoric sites have been recorded. The lack of sites may reflect the lack of a survey of the drainage. During the historic period, the area was within the territory of the Skykomish Indians. No locations used for traditional religious practices are known within the potential Wild and Scenic River corridor.

Known historic period sites represent mining and logging. The main use of this drainage around the turn of the century was for access to mines in the Snoqualmie drainage. The Dutch Miller Mine was reached from Seattle via the Great Northern Railway line to the Foss Creek Station, then by horse and foot trail up the Foss River to a pass between the Foss and Snoqualmie drainages. The mining company developed an interest in logging along the river and constructed a railroad to connect with the Great Northern line. No sites associated with these uses have been listed or identified as eligible for the National Register of Historic Places.

TIMBER: Clearcuts dominate downstream from the confluence of the East and West Forks.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
55.6	1.114	.144

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The Foss River, paralleled by forest roads, meets the South Fork Skykomish and Tye Rivers 3 miles east of Skykomish (pop. 280).

The West Fork of the Foss River, with its headwaters in the lakes above Delta Lake in the Alpine Lakes Wilderness, is paralleled by one of the most heavily used trails on the district. The thousands of visitors to this area significantly impact the environment as well as the economic climate of the Skykomish Area.

The East Fork of the Foss River, with its headwaters in the Alpine Lakes Wilderness in the well-known Necklace Valley, is bordered by a popular hiking trail, which also draws many of the visitors to this area. The community of Skykomish is about 8 miles from the confluence of the East Fork of the Foss and the Foss Rivers.

Skykomish is traditionally a logging, mining, and railroad community. The town also benefits economically from the many visitors attracted by the scenic and recreation characteristics of the area's rivers, mountains, and forests. Sixty miles from Everett and 75 miles from Seattle, Skykomish is within easy travel distance for thousands of visitors every year. Local businesses cater to campers, hikers, fishers, and hunters, as well as providing hotel facilities for Stevens Pass skiers.

CURRENT ADMINISTRATION: Downstream from their headwaters, the East Fork Foss flows through 6.7 miles of the Alpine Lakes Wilderness and the West Fork flows through 3.1 miles. Public lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river is in the Alpine Lakes area under management direction found in the Alpine Lakes Management Plan.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the Foss River has been classified as Conservancy by King County. This classification is applicable only to lands within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

The land along the east bank of the Foss River, outside of federal jurisdiction, has been zoned by King County for Forestry Use. The land along the west bank has been zoned Rural Use.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Foss, East Foss, and West Foss Rivers for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 2,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		12,800
Development Costs	75,000	10,000
Operation and Maintenance Costs	0	2,500
TOTAL - First Five Years	**$77,000**	**$28,300**

General administration and operation and maintenance costs are estimated to continue at $1,100 annually.

Appendix E
Foss River
East and West Forks

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	295
		Wilderness-Trailled	21
		Wilderness-General Trailless	2,090
Segment 2	Recreation	T&E Species (bald eagle)	21
		Alpine Lakes Scenic	168
Segment 3	Wild	Wilderness-Transition	168
		Wilderness-General Trailless	929
Segment 4	Recreation	T&E Species (bald eagle)	190
		Alpine Lakes Scenic	126
Segment 5	Recreation	T&E Species (bald eagle)	168
		Timber Management	147
		Alpine Lakes Scenic	718

MILLER RIVER (TO FORK)
EAST FORK MILLER RIVER
WEST FORK MILLER RIVER

King County

The Miller, East Fork Miller, and West Fork Miller Rivers were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Miller River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

LOCATION: From their sources in the Alpine Lakes Wilderness to the confluence with the South Fork Skykomish River.

Segment 1 - East Fork Miller River from Lake Dorothy to the Alpine Lakes Wilderness boundary (0.8 miles).

Segment 2 - East Fork Miller River from the Alpine Lakes Wilderness boundary to the confluence with the West Fork Miller River (6.0 miles).

Segment 3 - West Fork Miller River from the headwaters in the SE 1/4 of Section 31, T 24 1/2 N., R.11 E. to the Alpine Lakes Wilderness boundary (2.1 miles).

Segment 4 - W. Fork Miller River from the Alpine Lakes Wilderness boundary to the confluence with the E. Fork Miller River (4.2 miles).

Segment 5 - Miller River from the confluence of the East and West Forks of the Miller River to the confluence with the South Fork Skykomish River (3.7 miles).

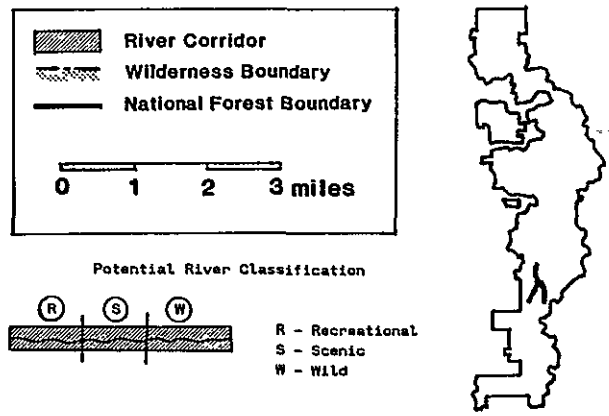
OUTSTANDINGLY REMARKABLE VALUES: The Miller River and its East and West Forks were found to possess "Outstandingly Remarkable" values for the following: Recreation, Fisheries and Wildlife

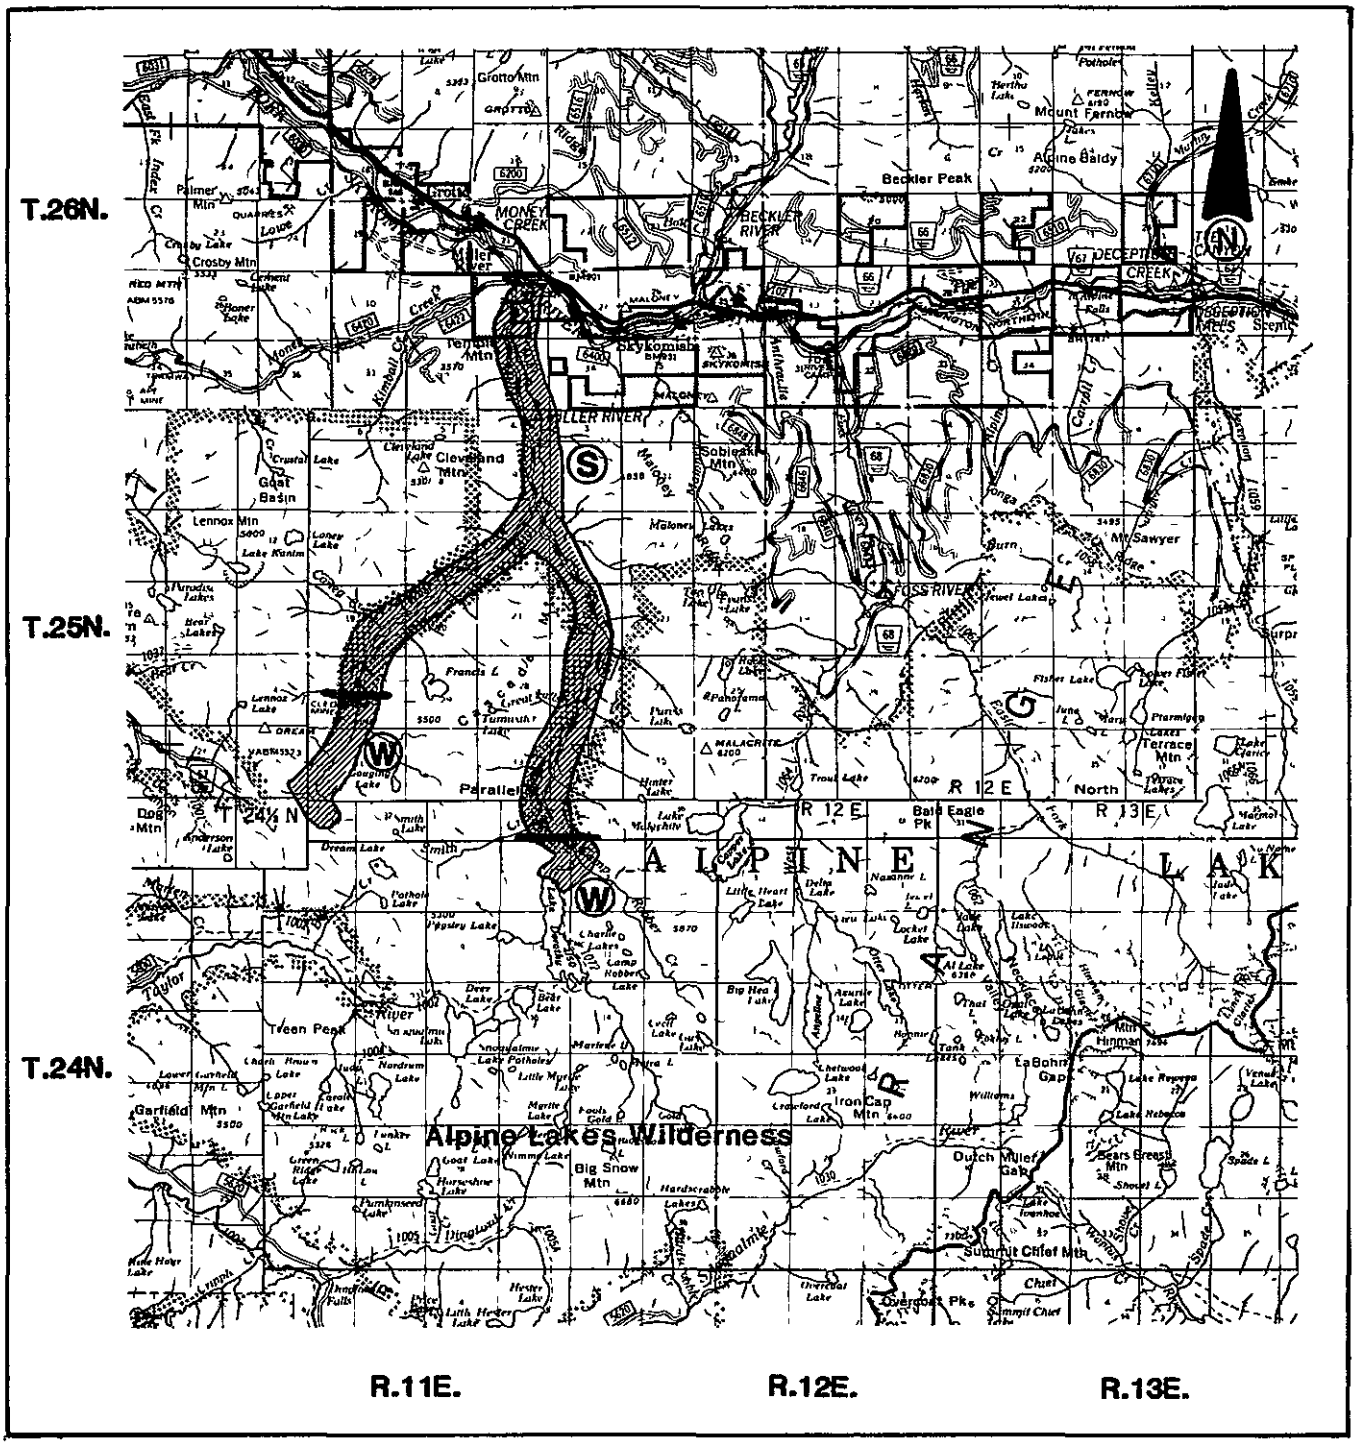
The very popular Lake Dorothy trailhead is located at the end of the East Fork Miller River Road. Area roads are used for pleasure driving. Fishing and kayaking are also popular activities.

The river corridor contains winter range for mountain goats and bald eagles. A SOHA has been identified on the West Fork.

Chinook and coho salmon spawn and rear in the drainage. Resident rainbow trout also inhabit the waters.

Miller River
East Fork
West Fork





RIVER MILEAGE:

Study:	16.8 miles
Eligible	16.8 miles
Forest Plan:	16.8 miles recommended for designation in preferred alternative

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	0.8	Wild	0.8
Segment 2	Scenic	6.0	Scenic	6.0
Segment 3	Wild	2 1	Wild	2.1
Segment 4	Scenic	4.2	Scenic	4.2
Segment 5	Scenic	3.7	Scenic	3.7

SUITABILITY DETERMINATION:

The Miller, East Fork Miller and West Fork Miller Rivers were found to be suitable for inclusion in the preferred alternative of the Forest Plan due to the lack of competing resource values and other public agency support. The potential hydro-electric value is incompatible with the Forest Plan land allocation. The Miller system was identified as a potential Wild and Scenic river in the Nationwide Rivers Inventory published by the National Park Service in 1982.

LANDOWNERSHIP:

	River Miles	Corridor Acres
Segment 1		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 0.8 miles)	0.8 miles	256 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	6.0 miles	1,920 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 2.1 miles)	2 1 miles	672 acres
Segment 4		
Mt. Baker-Snoqualmie National Forest	4.0 miles	1,280 acres
Private	0 2 miles	64 acres
Segment 5		
Mt. Baker-Snoqualmie National Forest	2.9 miles	928 acres
Private	0.8 miles	256 acres
TOTAL	16.8 miles	5,376 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified by the BLM as areas of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, however, does indicate the river corridor and adjacent areas have numerous reported occurrences of gold, silver, copper, zinc and antimony Of most significance are those occurrences reported to lie in Sections 10, 17, 24, 27 and 30, T. 25N., R.11 E. The BLM mining claim recordation data also indicates that 68 unpatented mining claims have been located in or adjacent to the river corridor. Of these 68 claims, however, 39 have been abandoned or declared to be null and void. The remaining claims lie within Sections 17, 19, 20, 30, T.25N., R.11 E. and in Sections 1 and 2, T. 24 N., R11 E.

The BLM has classified the entire river segment as being prospectively valuable ("PV") for geothermal resources and has classified 4 miles near the north end as "PV" for coal resources. However, none of the area has been encumbered by mineral leases or lease applications

Based upon the available information, it does appear that the area as a whole does have at least a low potential and the West Fork has a moderate potential for the occurrence of both precious and base metal mineral resources. The mining claims located along the West Fork indicate a continuing interest in that area's locatable mineral resources. The area also has a potential for the occurrence of both coal and geothermal resources, however, no serious interest in those resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the rivers. The river system is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A preliminary permit for a hydroelectric project has been issued by FERC. Proposed facilities within the river corridor consist of a transmission line, a powerhouse, and a diversion structure and penstock. The project capacity will be 5.9 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: County Road 6410 parallels the Miller River from its mouth to the confluence of the East and West Forks. The road continues up the East Fork, becoming FS Road 6412, ending at the Wilderness boundary.

FS Road 210 crosses 3/4 mile below the confluence of the West and East Forks. Local FS Roads 110, 120, and 130 are within 1/4 mile of the west bank in the upper half of the Miller County Road 64 crosses 1/4 mile above the confluence with the South Fork Skykomish.

Three vehicle bridges and one railroad bridge cross the rivers.

Seven summer homes line the Miller River in T 25N., R 11 E., Section 9.

The Miller River Campground is located 1 1/2 miles downstream from the East Fork and West Fork junction.

The Lake Dorothy Trail #1072 begins at the end of FS Road 6412. The trail parallels the river for 2 miles to its headwaters at Lake Dorothy. This is a popular and crowded trail on weekends

There have been some fish habitat projects on the Miller River. One mile upstream, several structures were put in the side channels in 1986-87: 23 digger logs, 10 boulder pools, 2 rock deflectors/groins, 6 boulder clusters, and 20 log deflectors.

Diking has been constructed at the confluence with the Skykomish River. The first mile above the confluence was diked in the early 1900's.

RECREATION ACTIVITIES: The very popular Lake Dorothy trailhead is located at the end of the East Fork Road. The roads are also popular for pleasure driving.

Fishing is a popular activity along the banks of the river. Swimmers occasionally use the rivers, but cold water limits use. The Miller River is a Class III to IV kayak run from the confluence of the East and West Forks to the South Fork Skykomish River.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	65	100
Fishing, Hunting	500	720
Camping	18,480	27,720
Viewing (scenery, wildlife, driving for pleasure)	2,300	3,500
Misc. (hike, picnic, berry picking, etc.)	6,700	13,100
TOTAL	28,045	45,140

WILDLIFE AND FISHERIES: The river drainage supports winter range for mountain goats and bald eagles. A SOHA has been identified on the West Fork.

Chinook spawn primarily in the mainstem of the Miller River. Coho use the two forks and shallow side channels. The juveniles rear throughout these waters, with coho having year round habitation. Resident rainbow trout are found throughout the drainage. Fish production is limited by a series of falls on the West Fork and loss of streamside cover, due to logging and increased development along the shorelines of the rivers.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The gradient is moderately steep. River width averages approximately 30 feet. The upper East Fork has numerous falls and cascades. At 6 miles, there is a 20-foot waterfall. Thirty tributaries drain into the Miller River system.

GEOLOGY: Originating in massive mountains of granitic bedrock, these river systems pass through volcanics and metasediments. Deep V-shaped upper valleys give way to broader U-shaped glacial valleys downstream where previous glaciation has had a dominant influence. These are high energy systems as evidenced by braiding and high bedloads.

Appendix E
Miller River
East and West Forks

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Miller River drainage, and no prehistoric sites are recorded. The absence of sites is probably a result of lack of a survey. During the historic period, the drainage was within the territory of the Skykomish Indians. No locations used for traditional religious practices are known within the proposed Wild and Scenic River corridor.

Several mining claims were made in the vicinity of the West Fork during the late nineteenth and early twentieth centuries. Logging, recreation and Forest Service administration sites are also represented within the drainage. None of these are listed or identified as eligible for the National Register of Historic Places.

TIMBER: Land along the lower 2 miles of the Miller River is cut-over to the river. Public lands from the East and West Fork confluence to the South Fork Skykomish is primarily alder with scattered patches of old growth coniferous species. Above the confluence of the two forks, primarily old growth can be seen with scattered clearcuts present.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
72.7	1.751	2.643

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The East Fork of the Miller River begins at well-known Dorothy Lake in the Alpine Lakes Wilderness. The thousands of visitors to this area impact the environment as well as the economic climate of the Skykomish area.

The community of Skykomish is 5 miles from the confluence of the West Fork and the East Fork of the Miller River. Traditionally a logging, mining, and railroad centered community, Skykomish also benefits economically from the many visitors drawn by the scenic and recreation characteristics of the area's rivers, mountains and forests. Sixty miles from Everett and 75 miles from Seattle, Skykomish is within easy travel distance for thousands of visitors every year. Local businesses cater to campers, hikers, fishers, and hunters, as well as providing hotel facilities for Stevens Pass skiers.

CURRENT ADMINISTRATION: The first 0.8 miles of the East Fork and 2.1 miles of the West Fork are located inside the Alpine Lakes Wilderness. The wilderness and other National Forest lands are administered by Mt. Baker-Snoqualmie National Forest, USDA Forest Service. These rivers are in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the Miller River has been classified as Conservancy by King County. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

The land near the confluence of the Miller River and South Fork Skykomish, outside of federal jurisdiction, has been zoned by King County for Rural Use, with 1 home per 5 acres. The remainder of the river corridor is zoned for Forestry Use

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Miller, East Fork Miller and West Fork Miller Rivers for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 2,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		10,900
Development Costs	56,000	10,000
Operation and Maintenance Costs	40,500	2,500
TOTAL - First Five Years	**$98,500**	**$26,400**

General administration and operation and maintenance costs are estimated to continue at $9,200 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies lands administered by the National Forest Service.)

Appendix E
Miller River
East and West Forks

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	84
		Wilderness-General Trailless	211
Segment 2	Scenic	Old Growth Habitat (spotted owl)	253
		Goat Habitat	42
		Timber Management	42
		Alpine Lakes Dispersed Recreation	211
		Alpine Lakes Scenic	739
Segment 3	Wild	Wilderness-General Trailless	823
Segment 4	Scenic	Alpine Lakes Dispersed Recreation	696
		Alpine Lakes Scenic	105
Segment 5	Scenic	Goat Habitat	21
		T&E Species (bald eagle)	21
		Timber Management	232
		Alpine Lakes Scenic	380

BECKLER RIVER
RAPID RIVER

Snohomish and King Counties

The Beckler and Rapid Rivers were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Beckler River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory (NRI) published by the National Park Service in 1982.

The Beckler River, upstream to the Rapid River, is designated by the State of Washington as a Scenic River under the State's Scenic Rivers Act.

LOCATION: The Beckler River flows from its headwaters near Jack Pass to its confluence with the Tye and South Fork Skykomish Rivers.

The Rapid River flows from its headwaters on Scrabble Mountain to its confluence with the Beckler River.

Segment 1 - The headwaters of the Beckler at Jack Pass in the NW 1/4 of Section 31, T 28 N., R.12 E. to the confluence with the South Fork Skykomish River (13.5 miles).

Segment 2 - The headwaters of Rapid River upstream from Janus Lake in the SE 1/4 of Section 13, T.27 N., R.13 E. to the Henry M. Jackson Wilderness boundary (7.0 miles).

Segment 3 - The Henry M. Jackson Wilderness boundary to the confluence with the Beckler River (6.0 miles).

RIVER MILEAGE:

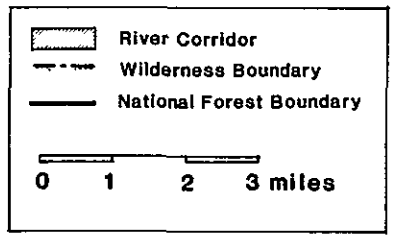
Study:	26.5 miles
Eligible:	26.5 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Beckler and Rapid Rivers were found to possess "Outstandingly Remarkable" values for the following: Recreation, Fisheries, and Wildlife.

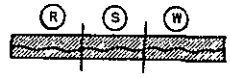
There are numerous camping opportunities along the Beckler and Rapid Rivers. All receive high use. Sightseers can complete a scenic loop trip by driving up the North Fork Skykomish Road out of Index, climb over Jack Pass and drop down into the Beckler Valley to Skykomish. Fishing for resident rainbow trout is a moderate to high use activity. Class III kayaking with some portages is found from the confluence of the Rapid and Beckler Rivers downstream to the mouth of the Beckler.

An extensive winter habitat for bald eagles and black-tailed deer is found along the corridors of both rivers. Spotted owls and mountain goats inhabit the Rapid River drainage.

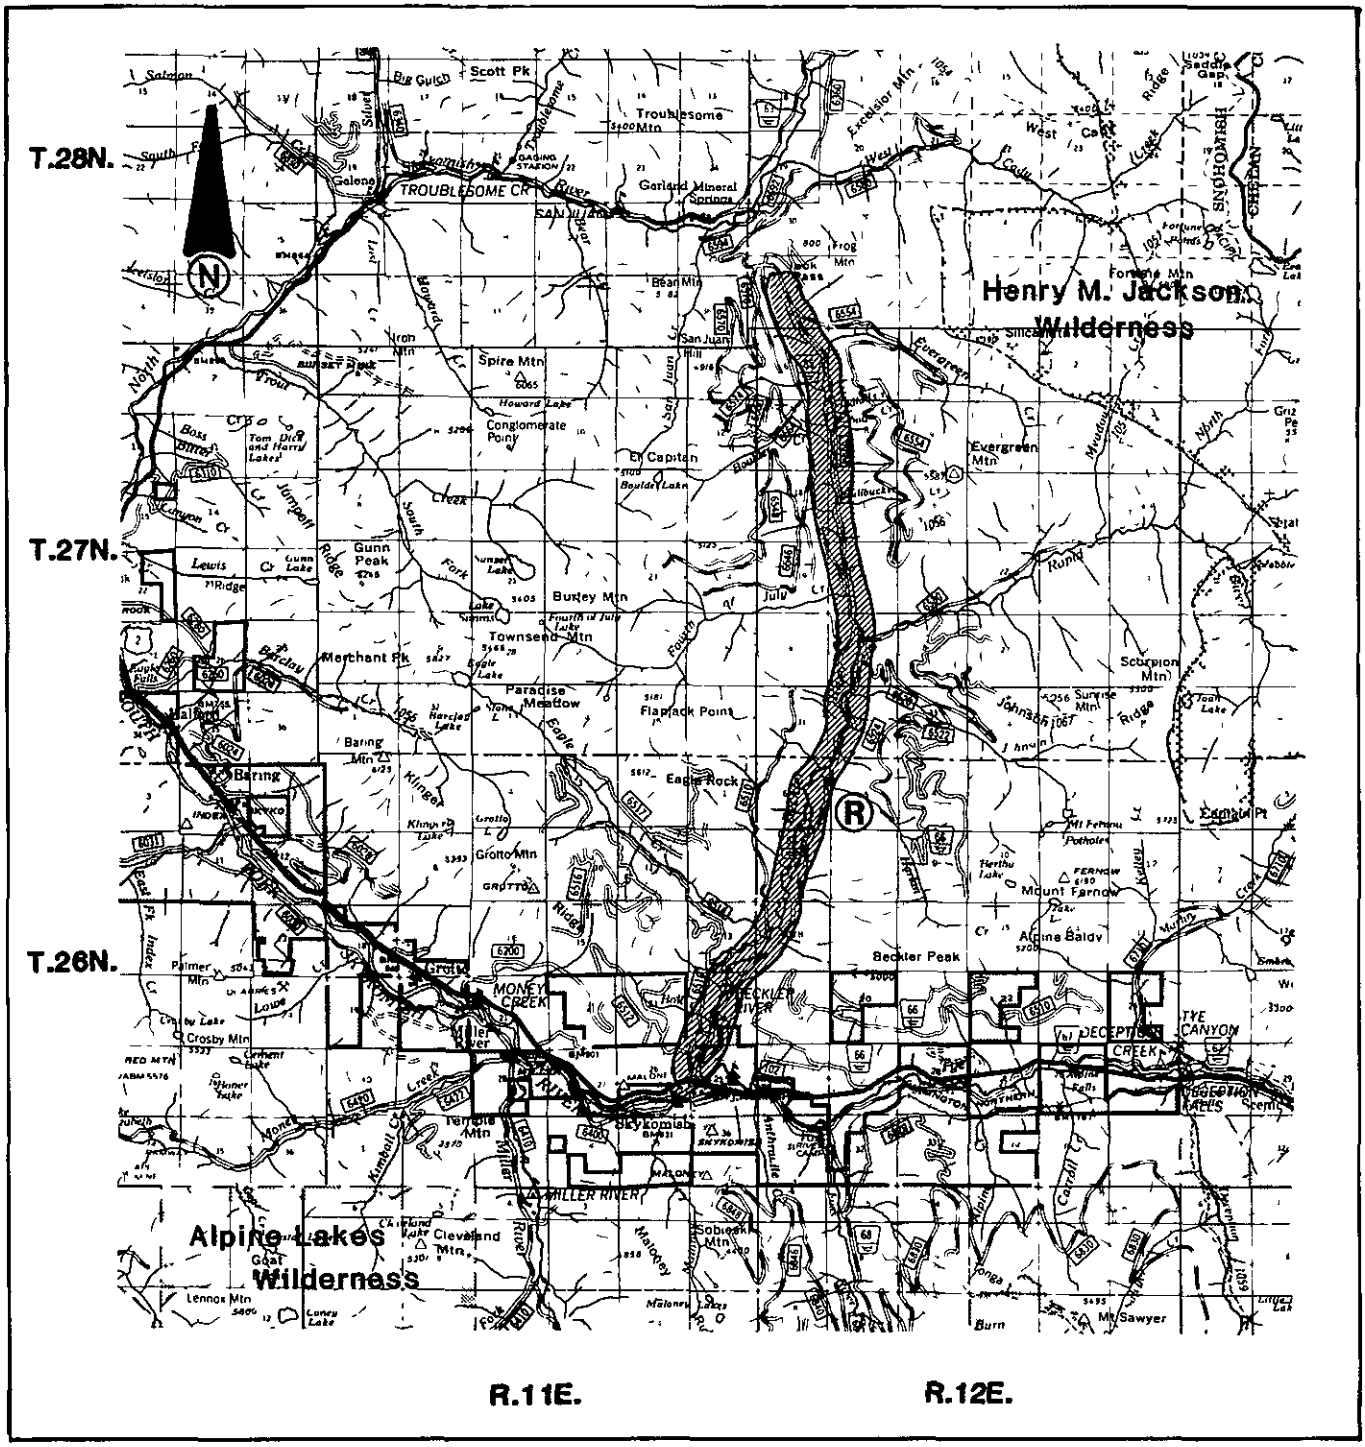
Beckler River



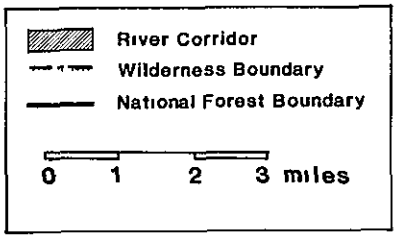
Potential River Classification



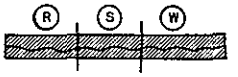
R - Recreational
S - Scenic
W - Wild



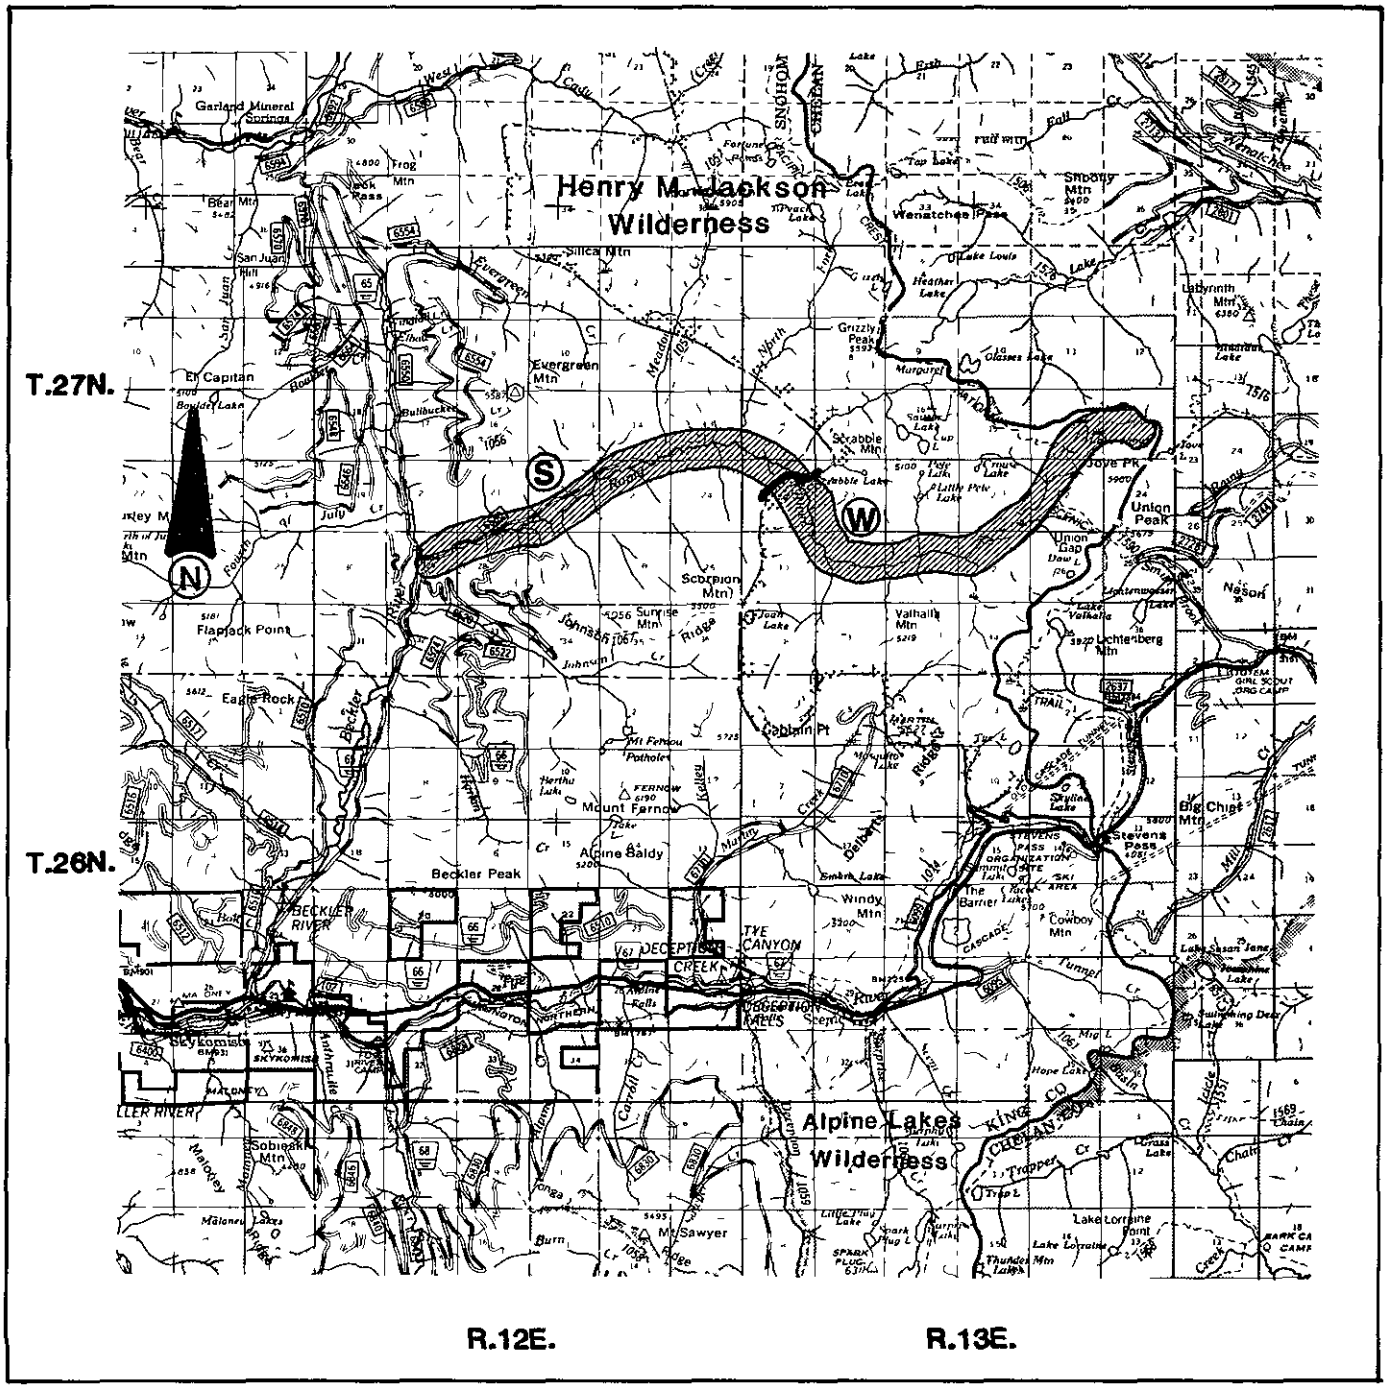
Rapid River



Potential River Classification



R - Recreational
S - Scenic
W - Wild



Both rivers support runs of steelhead trout, chinook, and coho salmon. The Beckler also receives use from chum and sockeye salmon.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	13.5	Not recommended	0.0
Segment 2	Wild	7.0	Not recommended	0.0
Segment 3	Scenic	6.0	Not recommended	0.0

SUITABILITY DETERMINATION:

The Beckler and Rapid Rivers were found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to high competing resource values and the presence of extensive clearcut logging in both drainages. Preliminary permits for 8 hydro-electric projects have been issued by the FERC.

The Rapid River is not a logical addition to the system, unless the Beckler River was also found to be suitable.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	9.3 miles	2,976 acres
Private	3.2 miles	984 acres
State	1.0 miles	360 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest (Henry M. Jackson Wilderness - 7.0 miles)	7.0 miles	2,240 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest	4.3 miles	1,376 acres
Private	1.7 miles	544 acres
TOTAL	26.5 miles	8,840 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified as areas of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has no known locatable mineral resources. The BLM mining claim recordation data does indicate that four mining claims were located along the Rapid River. However, all four have either been abandoned or declared to be null and void. On the Beckler River, 28 unpatented mining claims have been located in Sections 7, 18, 19 and 32, T.27 N., R.11 E. However, of those 28 claims, 20 have either been abandoned or declared to be null and void.

The BLM has classified both rivers as being prospectively valuable for geothermal resources. However, the areas are not considered to have potential for the occurrence of other leasable mineral commodities. None of the areas have been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the Rapid River area has a relatively low potential for the occurrence of locatable mineral resources. No serious interest in the locatables is currently being expressed. The claims located in the Beckler River area in Sections 18 and 19, T 27 N., R.12 E. do indicate some continuing interest in the areas potential. Both areas have at least a low potential for the occurrence of geothermal resources. However, as with the locatables, no serious interest in the geothermal potential is currently being expressed.

WATER RESOURCE DEVELOPMENT: Both the Beckler River and Rapid River have been classified as "Protected" from hydropower development by the Northwest Power Planning Council.

There is a high potential for small hydro use on the Beckler River. Over 20 applications have been filed. Preliminary permits for hydroelectric projects have been issued by FERC for 7 tributaries of the Beckler and 1 for Rapid River. The following table shows the location of the projects, the proposed facilities and the project capacity in megawatts:

Tributary	Proposed Facilities within Corridor	Megawatts
Beckler:		
Evergreen Creek	Transmission line	1.7
Rapid River	Transmission line	see below
Johnson Creek	Transmission line	2.5
Harlan Creek	Transmission line	2 3
Eagle Creek	Transmission line	1.9
4th of July Creek	Transmission line	1.7
Boulder	Transmission line	1.3
Rapid River:		
	Transmission line	17.3
	Powerhouse	
	Diversion structure & penstock	

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Several Forest Roads converge at Jack Pass near the headwaters of the Beckler: 6550, 6570, 6500, 616, 110 and 65. FS Road 6550 parallels the east bank downstream from Jack Pass until rejoining Forest Road 65 at 4th of July Creek. Road 65 continues to follow the Beckler to its mouth. Forest Road 6510 follows the west bank of the Beckler from Eagle Creek to the road intersection with Road 65, 1.5 miles upstream from the mouth of the river. The Beckler is traversed by 3 bridges. All major tributaries are crossed with either bridges or earth-covered culverts.

FS Road 6530 parallels the Rapid River from the wilderness boundary downstream to the confluence with Beckler River. The road crosses the river 3 times. This road also crosses the North Fork Rapid River just above the confluence. FS Road 65 crosses the mouth of Rapid River.

The Beckler River Campground (24 sites) and Picnic Area (2 sites) are on the east bank of the Beckler River 2.5 miles from the Skykomish Ranger District. Numerous dispersed recreation sites are found along the Beckler River.

There are two logging camps near Rapid River and numerous old railroad trestles in the lower six miles. One old railroad bridge lies 2 miles up from the confluence. A powerline crosses the Beckler near its mouth.

The Pacific Crest Trail crosses the headwaters area of Rapid River within the Henry M. Jackson Wilderness.

The Meadow Creek/Fortune Ponds Trailhead (#1057) is located at the end of FS Road 6530. The trail parallels the river for 1-1/2 miles before heading up Meadow Creek.

There are no homes or farms along either river.

There are no fish habitat projects on the mainstem Beckler, but some do exist on its tributaries. There has been bank seeding/planting, fish passage improvement, and 2 gabion deflectors placed on Boulder Creek. Bullbucker Creek has 3 weirs, 9 root wads, 4 log deflectors, 3 fish passage improvements, 2 boulder pools, 7 digger logs, and bank seeding/planting. Fish passage has been improved on Johnson Creek. Beagle Creek has 2 gabion deflectors, 1 weir, 29 log deflectors, 6 root wads, 3 boulder clusters, 3 boulder pools, and 26 digger logs.

RECREATION ACTIVITIES: There are camping opportunities along Beckler and Rapid River. All receive high use. Hikers use the Meadow Creek and Pacific Crest Trails. The Pacific Crest Trail crosses the Rapid River below Lake Janus. However, there is no developed access to the trail from the Beckler River Basin.

Sightseers can complete a scenic loop trip by driving up the North Fork Skykomish Road out of Index, climb over Jack Pass and drop down into the Beckler Valley to Skykomish. From the 2,500-foot summit of Jack Pass, there are impressive views of the Monte Cristo Peaks, and the North Fork Skykomish and Beckler River valleys.

Fishing for resident rainbow trout is a moderate to high use activity. Class III kayaking with some portages is available from the confluence of the Rapid and Beckler Rivers downstream to the mouth of the Beckler. There is no significant rafting use on the Beckler and low to moderate use by swimmers.

Recreation Activities (in estimated Recreation Visitor Days (RVD's)), for National Forest system lands only:

	1988 RVD'S	Projected 2000 RVD'S
Boating (power and non-power)	10	15
Waterplay (swim, wade)	240	360
Fishing, Hunting	2,900	4,175
Camping	18,000	27,000
Viewing (scenery, wildlife, driving for pleasure)	8,575	13,000
Misc. (hike, picnic, berry picking, etc.)	2,530	4,960
TOTAL	32,255	49,510

WILDLIFE AND FISHERIES: Along the rivers, there is extensive wintering bald eagle forage habitat. Both rivers have excellent black-tailed deer winter range, as well as furbearer habitat. Excellent riparian habitat exists for the black bear. Spotted owls and mountain goats can be found along the Rapid River.

The Beckler River has runs of chinook, coho, steelhead, chum and sockeye, while the Rapid River runs are limited to chinook, coho and steelhead. Resident rainbow trout inhabit both rivers. Increased fish production may be limited by loss of streamside cover from logging activities.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The upper Beckler River watershed is mountainous and quite steep with a narrow valley floor. The river drops sharply through a deep narrow cut. At Boulder Falls, 8 miles downstream from the headwaters, the valley walls narrow and steepen into a deep ravine for 2 miles. Below this, the valley floor widens, stream gradient becomes moderate and stream width averages 24 feet. The bottom of the river is predominantly boulder and rubble with some patch gravel. There are numerous cascades and rapids along the course of the river. Twenty-eight tributaries drain into the Beckler River. Water quality is excellent.

Rapid River is a steep mountain stream down to the last 3 miles. The gradient then becomes moderately steep as it cuts through a narrow channel. The bottom of the river is predominantly boulder and rubble with some patch gravel. There are numerous cascades and rapids. Thirty-one tributaries flow into the Rapid River. The water is clear and quality is excellent.

GEOLOGY: The bedrock in the Beckler River Valley is dominated by metasediments and schist with volcanic and granitic rocks occurring locally. The river flows through a typical glacial-shaped valley. Steep long sideslopes are mostly cutover. The V-shaped Rapid River is surrounded primarily by granitic and schist rocks.

CULTURAL RESOURCES: No systematic survey has been made of Beckler River. However, information is available from surveys made in conjunction with Federal projects, and published historical sources. No prehistoric sites have been recorded to date. The lack of sites may reflect the lack of survey of the drainage. During the historic period, the area was within the territory of the Skykomish Indians. No areas have been identified as important for traditional Indian religious practices.

Historic sites primarily represent logging activities of the Bloedel-Donovan Lumber Co. Logging began up the river in 1917, and a large camp was established just south of Fourth of July Creek. A railroad was constructed up the river with a branch leading off to the east, along the Rapid River. Camp 9 was situated at the mouth of the Rapid River Bloedel-Donovan sold the land at the end of World War II, and shortly after large company logging gave way to independent enterprises in the valley. None of the known historic sites are listed on the National Register of Historic Places.

TIMBER: Extensive clearcut logging, past and present has taken place along the Beckler River. Currently, the entire drainage has a "patch work" appearance.

Over half of the Rapid River watershed has been burned and salvage logged, and is in varying stages of reforestation.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

Total Timber Volume (MMBF)	ASQ: Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	ASQ: Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
195.1	9.823	9.052

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The Beckler River is paralleled by forest roads for its entire length. It enters the South Fork of the Skykomish River about a mile east of Skykomish (pop. 280).

Rapid River flows through undisturbed forest before being paralleled by a forest road to its confluence with the Beckler River. Eight miles southeast is the community of Skykomish (pop. 280).

Skykomish is traditionally a logging, mining, and railroad community. The town also benefits economically from the many visitors drawn by the scenic and Recreation characteristics of the area's rivers, mountains, and forests. Sixty miles from Everett and 75 miles from Seattle, Skykomish is within easy travel distance for thousands of visitors every year. Local businesses cater to campers, hikers, fishers, and hunters, as well as providing hotel facilities for Stevens Pass skiers.

CURRENT ADMINISTRATION: Seven miles of the Rapid River, starting at its headwaters, flow through the Henry M. Jackson Wilderness. Public lands along these rivers are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. The lower two miles of the Beckler is in the Alpine lakes Area under management direction found in the Alpine Lakes Management Plan.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the Beckler River has been classified as Conservancy by King County. This classification is applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

The King County Comprehensive Plan has zoned land along the Beckler River corridor, outside of federal jurisdiction, for Rural Use.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

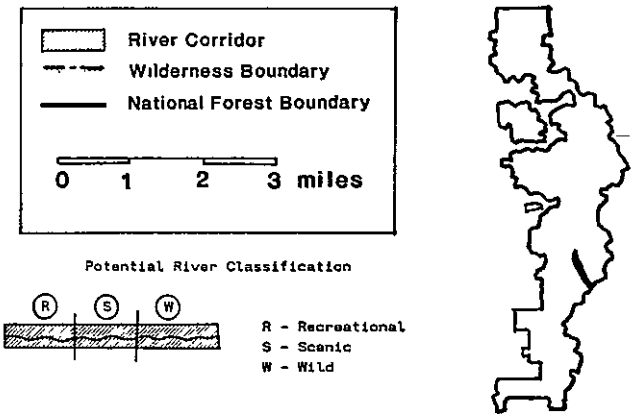
The following are expected funding requirements for the Beckler and Rapid Rivers for the next five years:

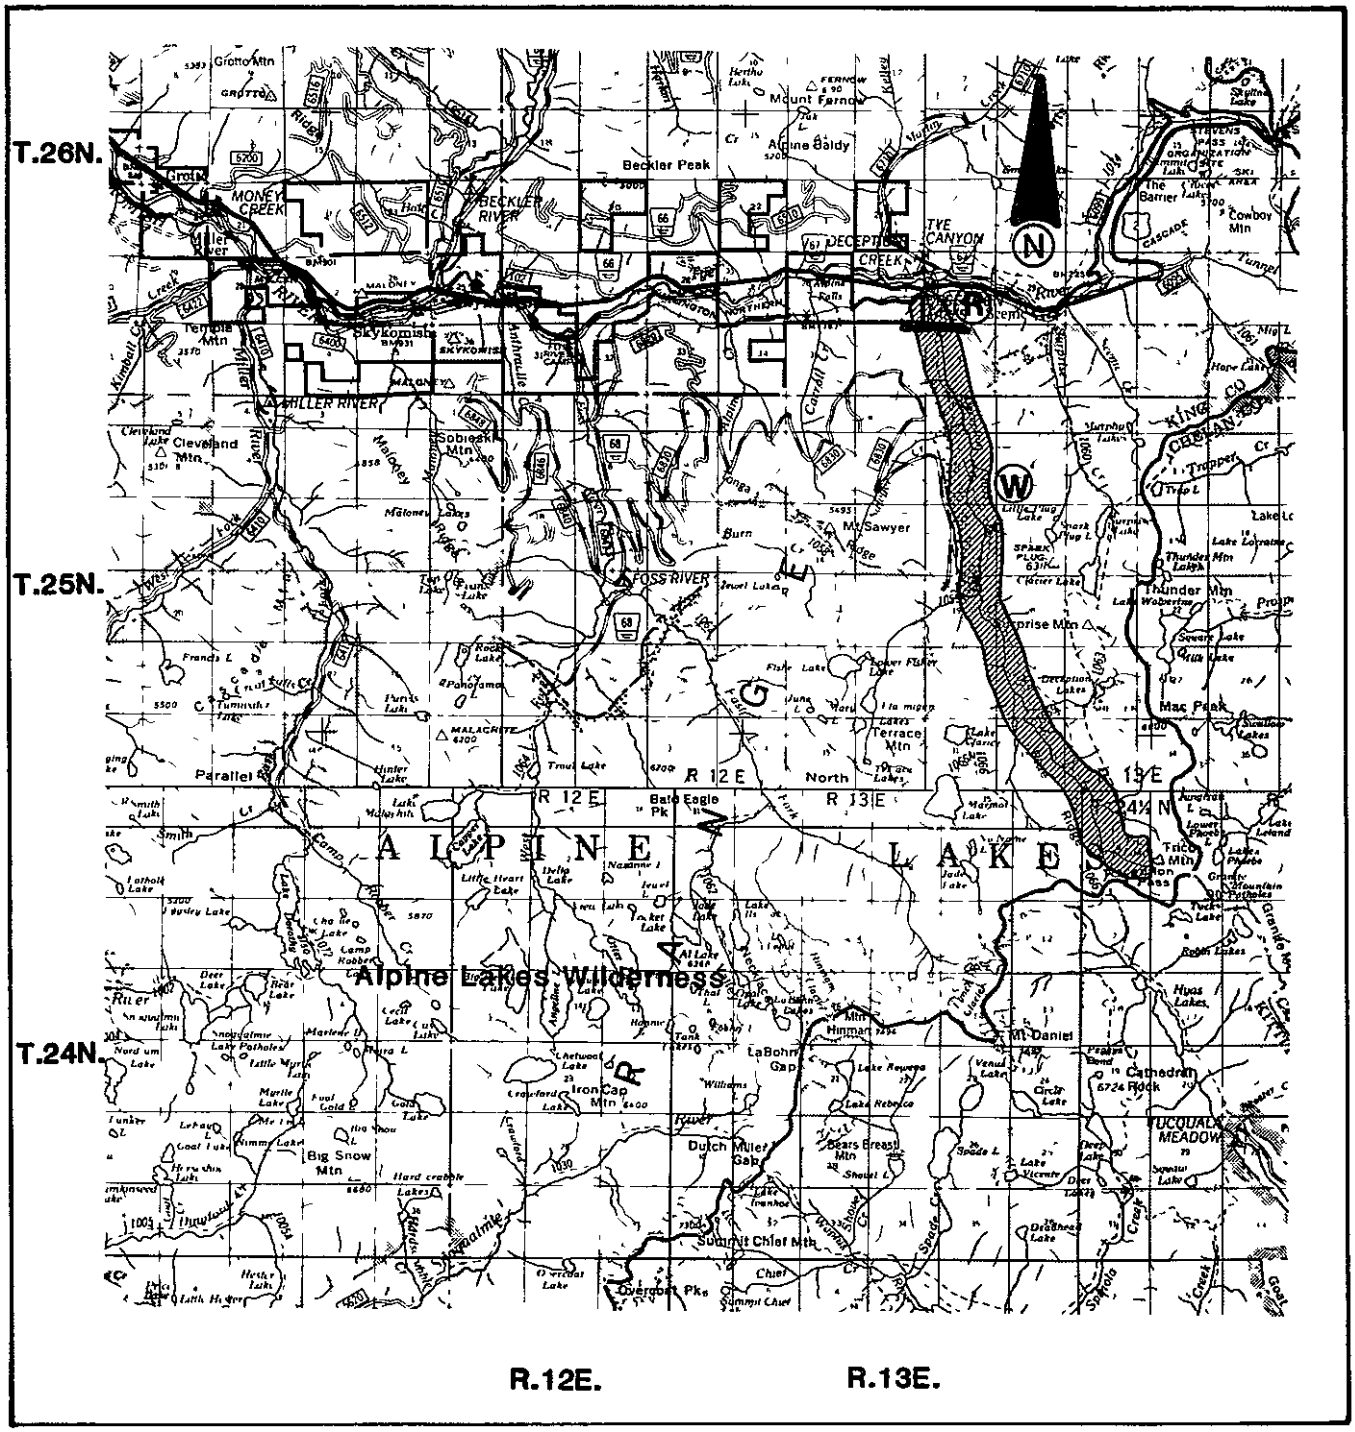
	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 3,000	$ 1,500
Costs of Implementation		3,000
Development of Management Plan		28,800
Development Costs	4,035,000	
Operation and Maintenance Costs	64,500	
TOTAL - First Five Years	**$4,102,500**	**$33,300**

The developed costs include a highway paving rest area and a trailhead.

General administration and operation and maintenance costs are estimated to continue at $13,800 annually.

Deception Creek





DECEPTION CREEK

King County

Deception Creek was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters at Deception Pass in the Alpine Lakes Wilderness downstream to the confluence with the Tye River.

Segment 1 - The headwaters at Trico Lake in the SW 1/4 of Section 5, T.24 N., R.14 E. to the Alpine Lakes Wilderness boundary (9.8 mi).

Segment 2 - The Alpine Lakes Wilderness boundary to the confluence with the Tye River (0.5 mi).

RIVER MILEAGE:

Study:	10.3 miles
Eligible:	10.3 miles
Forest Plan:	10.3 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Deception Creek was found to possess "Outstandingly Remarkable" values for the following. Wildlife and Historical/Cultural.

The drainage supports an extensive black-tailed deer winter range. There is also excellent riparian habitat for black bears and furbearer habitat. Spotted owls have been found in the drainage.

The mouth of Deception Creek is within the Stevens Pass Historic District, listed on the National Register of Historic Places. Established in 1976, the Historic District recognizes the engineering achievements of the Great Northern Railroad in constructing a route across the Cascades.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	9.8	Wild	9 8
Segment 2	Recreation	0.5	Recreation	0 5

SUITABILITY DETERMINATION:

Deception Creek was found to be eligible for inclusion in the preferred alternative of the Forest Plan due to a lack of competing resource values and ease of management. All but .5 mile of Deception Creek is in the Alpine Lakes Wilderness.

Appendix E
Deception Creek

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 9.8 mi)	9.8 miles	3,136 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.5 miles	160 acres
TOTAL	10.3 miles	3,296 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither river segment is classified as an area of critical mineral potential nor is encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates the area has no known locatable mineral resources.

The BLM has classified the entire river as being prospectively valuable ("PV") for geothermal resources. The southern 7 miles is classified as "PV" for coal resources. One lease application was received for Section 31, T.26 N., R.13 E., however, that application has been withdrawn.

Based upon the available information, it appears that the area has a relatively low potential for the occurrence of locatable mineral resources, and no serious interest in the locatables is currently being expressed. The area does have at least a low potential for the occurrence of geothermal and coal resources. However, as with the locatables, no serious interest in these resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on Deception Creek.

Deception Creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The Deception Creek Trail #1059 follows the creek for most of its length. The trail intersects the Pacific Crest Trail near Deception Pass. The Pacific Crest Trail crosses Deception Creek near its headwaters. A short road goes from U.S. Highway 2 to the trailhead and accesses the powerlines The powerlines, railroad and Highway 2 cross Deception Creek in the lower 1/4 mile.

Deception Falls Picnic Area and Nature Trail, located at the mouth of the river, is planned to be improved. The current trail is a 1/2-mile loop from Deception Falls to the Tye River.

A footbridge is planned for construction between the U.S. Highway 2 bridge and the confluence with the Tye River. The Highway 2 bridge is planned to be widened.

There are no homes, farms or developed campgrounds in the drainage.

Two sets of powerlines cross the river at .2 miles from the confluence with the South Fork Skykomish River.

RECREATION ACTIVITIES: Hiking is a popular activity along Deception Creek The Deception Creek Trail provides access to the Alpine Lakes Wilderness and receives heavy use. The Deception Creek Picnic Area, Nature Trail and Viewpoint is heavily used by sightseers.

There are very limited opportunities for rafting, canoeing and kayaking. Both fishing and swimming are low use activities in the creek.

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	10	15
Fishing, Hunting	10	15
Camping	1,600	2,300
Viewing (scenery, wildlife, driving for pleasure)	46,575	70,800
Misc. (hike, picnic, berry picking, etc.)	28,820	56,500
TOTAL	77,015	129,630

WILDLIFE AND FISHERIES: The drainage supports an extensive black-tailed deer winter range. There is also excellent riparian habitat for black bears and furbearer habitat. Spotted owls have been found in the drainage.

There are no anadromous fish runs due to the impassable falls located near the mouth of Deception Creek The creek does contain a population of resident trout.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Deception Creek is a steep mountain stream typical of the Skykomish River drainage. There are numerous cascades and rapids. Eleven tributaries drain into Deception Creek.

Water quality is excellent.

GEOLOGY: The bedrock geology is dominated by granitics and metasediments This mostly V-shaped valley heads in massive long, forested slopes which blend into rock outcrop and perennial snow on the upper ridges. Numerous tributary streams and occasional avalanche tracks are present on the sideslopes.

CULTURAL RESOURCES: No systematic archaeological survey has been made of Deception Creek and no prehistoric sites are known. The lack of known sites is believed to reflect the lack of a survey in the drainage. During the historic period, the area was within the territory of the Skykomish Indians. No locations used for traditional religious practices are known within the drainage.

The mouth of Deception Creek is within the Stevens Pass Historic District, listed on the National Register of Historic Places Established in 1976, the Historic District recognizes the engineering achievements of the Great Northern Railroad in constructing a route across the Cascades. No railroad features have been identified within the potential Wild and Scenic River corridor.

TIMBER: Limited logging has occurred along the lower 1/2 mile of the creek. No clearcuts are visible from the creek.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system land only:

Total Timber Volume (MMBF)	ASQ: Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	ASQ: Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
7.7	.010	.010

1/ Based on proposed preferred alternative with revised minimum management requirements.

SOCIO-ECONOMIC EFFECTS: Deception Creek flows into the Tye River close to Deception Falls, 8 miles east of Skykomish. Skykomish has traditionally been a logging, mining and railroad community. The town now also benefits economically from the many visitors drawn by the scenic and recreation characteristics of the area's rivers, mountains and forest. Sixty miles from Everett and 75 miles from Seattle, Skykomish is within easy travel distance for thousands of visitors every year. Local businesses cater to campers, hikers, fishers and hunters, as well as providing hotel facilities for Stevens Pass skiers.

CURRENT ADMINISTRATION: All but the lower 1/2 mile of the creek is located within the Alpine Lakes Wilderness. The Wilderness, and other National Forest lands, are administered by the Mount Baker-Snoqualmie National Forest, USDA Forest Service. This river is in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for Deception Creek for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$10,000	
Development of Management Plan		4,200
Development Costs	70,000	
Total - First Five Years	**$80,000**	**$4,200**

General administration and operation and maintenance costs are estimated to continue at $2,000 annually.

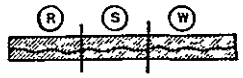
LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

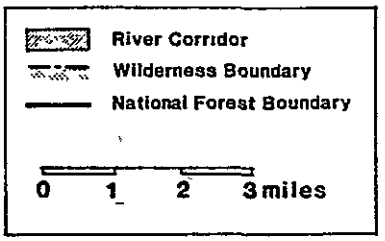
	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Trailled	929
		Wilderness-General Trailless	2,027
		Alpine Lakes Dispersed Recreation	63
		Alpine Lakes Scenic	21
Segment 2	Recreation	Old Growth Habitat (spotted owl)	84
		Alpine Lakes Dispersed Recreation	42

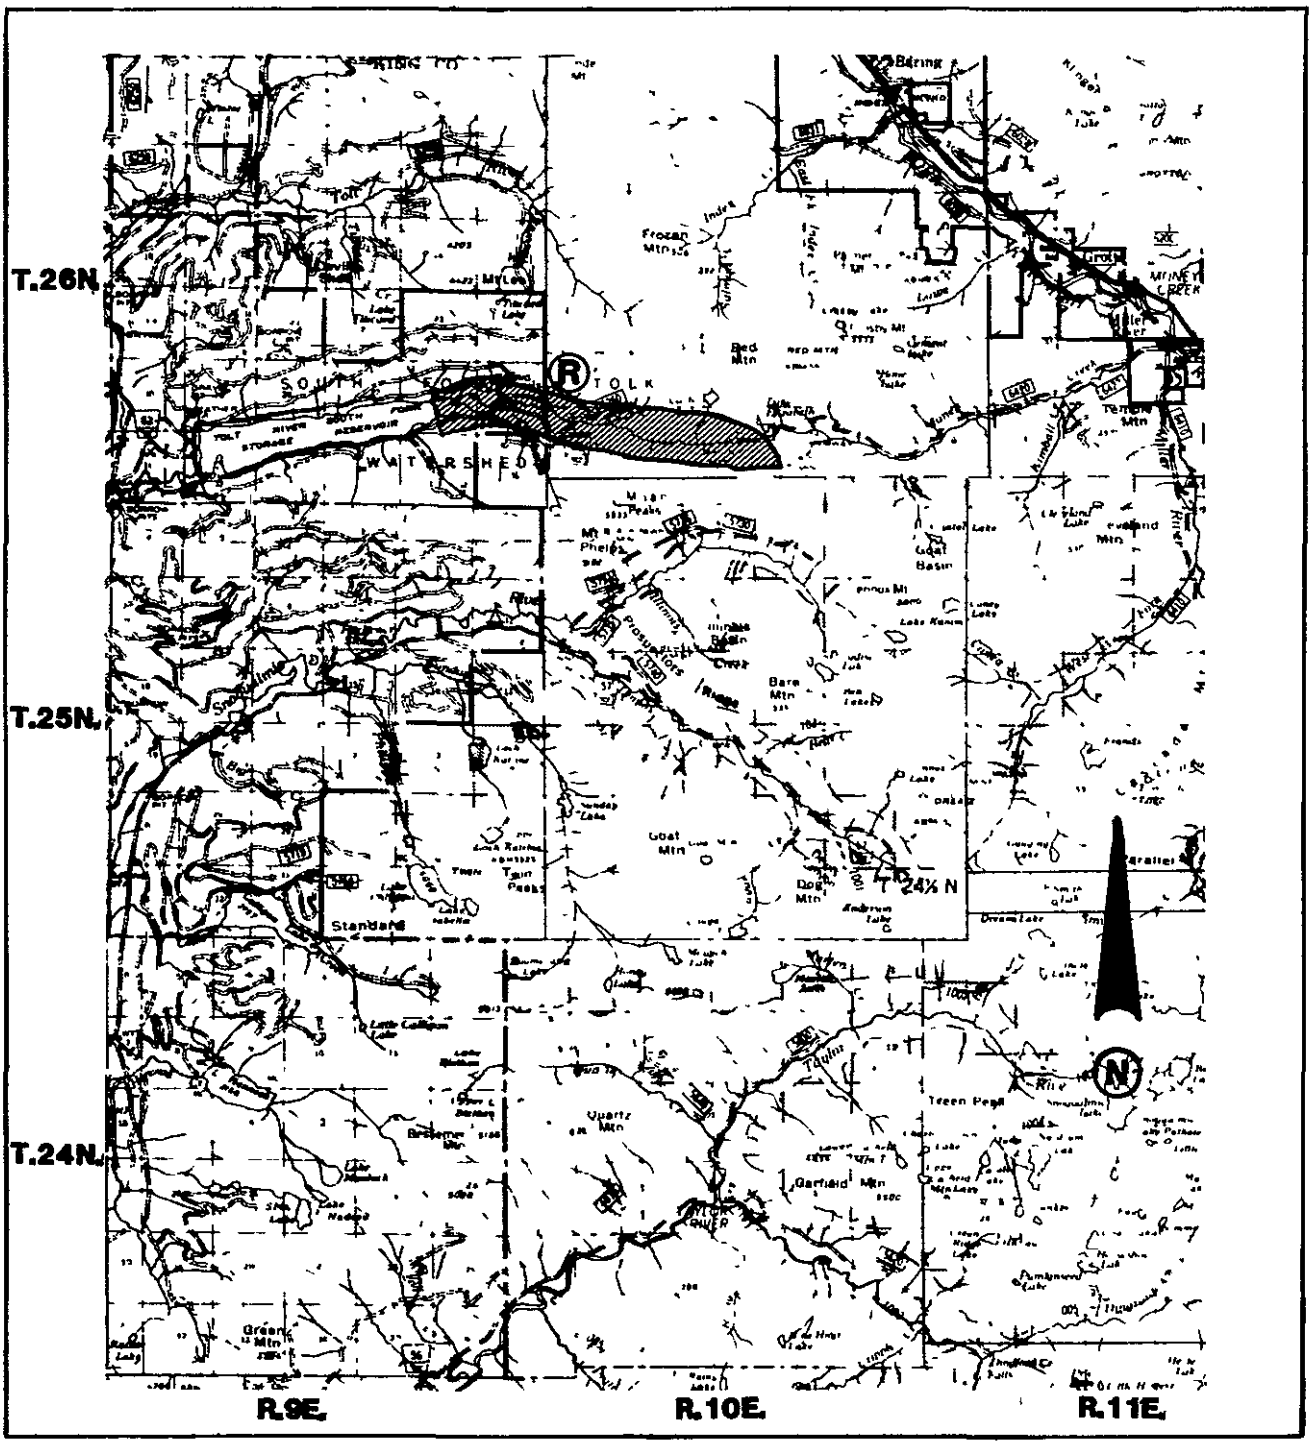
South Fork Tolt River

Potential River Classification



R - Recreational
S - Scenic
W - Wild





SOUTH FORK TOLT RIVER

King County

The South Fork Tolt River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters, near Lake Elizabeth downstream to the eastern end of the Tolt River Reservoir, owned by the City of Seattle.

Segment 1 - Headwaters in SE 1/4 of Sec 33, T.26 N., R.10 E. to the Tolt Reservoir (5.4 mi).

RIVER MILEAGE:

Study:	5.4 miles
Eligible:	5.4 miles
Forest Plan:	0 0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The South Fork Tolt River was found to possess "Outstandingly Remarkable" values for the following: Fisheries.

The South Fork is an important wild resident trout river. Special fishing restrictions provide quality fishing.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	5.4	Not recommended	0.0

SUITABILITY DETERMINATION:

The South Fork of the Tolt River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan. There is extensive logging in the drainage and timber harvest is the highest value. Difficult access for the public, due to private ownership to the west, creates a management problem.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	3 4 miles	1,089 acres
Private	2.0 miles	639 acres
TOTAL	5.4 miles	1,728 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segment has been classified by the BLM as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates the area has no known locatable mineral resource occurrences. However, BLM mining claim recordation data does indicate that Section 33, T.26 N., R.10 E. has been encumbered by forty unpatented mining claims, of which ten have been abandoned or declared to be null and void.

The BLM has classified the eastern 3 miles of the river as being prospectively valuable for geothermal resources. However, the area is not considered to have potential for the occurrence of other leasable mineral commodities and none of the area is encumbered by mineral leases or pending lease applications.

Based upon the available information, it appears that the area has a relatively low potential for the occurrence of locatable mineral resources. However, interest in Section 33, T.26 N., R.10 E. is being expressed by the thirty *remaining unpatented mining claims located there. The area does have at least* a low potential for the occurrence of geothermal resources. No serious interest in that resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along the river.

The South Fork Tolt is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The reservoir and virtually the entire river, except for the uppermost two miles, have existing roads within the 1/4 mile corridor. Forest roads for log haul parallel both sides of the river along the lower 2.9 miles, ending in NW 1/4 Sec. 31, T.26 N., R.10 E.

The private portion of the river is closed to public access because it is a domestic water supply for the City of Seattle.

Two bridges cross the river on log hauling roads in Sec. 25, T.26 N., R.9 E. and NE 1/4 Sec. 31, T.26 N., R.10 E.

There are no homes, farms, or developed campgrounds along the South Fork Tolt.

RECREATION ACTIVITIES: *There are low levels of recreation use along the South* Fork Tolt drainage due to the restriction on public access. Limited amounts of hunting and fishing occur.

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	100	145
Viewing (scenery, wildlife, driving for pleasure)	100	150
Misc. (hike, picnic, berry picking, etc.)	100	200
TOTAL	300	495

WILDLIFE AND FISHERIES: The upper basin contains a population of mountain goats.

No anadromous fish can navigate upstream past the South Fork Falls and the Tolt Reservoir dam. However, the South Fork Tolt is an important wild resident trout river. Special fishing restrictions and limited access provide quality fishing.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The upper three miles of the South Fork Tolt has a steep gradient. The next three miles is moderately steep, with mostly fast riffles, a few cascades and a few short pool-riffle stretches. The river bottom is composed mostly of rubble, scattered boulders and some gravel areas.

Water quality is excellent.

GEOLOGY: The bedrock geology consists of granitic and metasedimentary rocks. This short river originates in steep, massive, mountains of rock outcrop and perennial snow on ridgetops and peaks. The valley becomes relatively wide within a few miles of origin due to the pronounced effects of continental glaciation.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Tolt River and few projects have been done to provide information.

The lack of sites is believed to reflect the lack of survey rather than use. Historically, the Tolt River was within the territory of the Skykomish tribe. Locations used by the Duwamish tribe for traditional religious practice exist within the corridor.

The Tolt River watershed does not appear to have played a significant role in regional development and is virtually unmentioned in historic documents.

Reviewing mining documents from the turn of the century reveals that many mining claims existed in the area. Ore was taken out through Lake Elizabeth and Money Creek, where there were a number of mill sites. Red Mountain is also mentioned often in old documents.

TIMBER: Except for the highest slopes, the South Fork Tolt receives heavy logging use.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
16.2	1.305	1.192

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The headwaters of the South Fork of the Tolt River lie near Lake Elizabeth and the once-profitable Damon Mine. The South Fork Tolt flows into the Tolt Reservoir, a municipal watershed for Seattle.

Although roads do exist into the area from Carnation, 15 miles from the north end of the Reservoir, public access is restricted by the City of Seattle. Any access would be into the headwaters area, on foot from the Money Creek drainage off the Skykomish River drainage.

CURRENT ADMINISTRATION: The public lands along this river are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river is in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

The shoreline environment from the National Forest boundary in Sec. 31, T.26 N., R.10 E. downstream to the Tolt Reservoir is designated by King County as Conservancy. The Conservancy Environment consists of shoreline areas which are primarily free from intensive development. It is the most suitable designation for shoreline areas of high scenic or historical values, for areas unsuitable for development due to biophysical limitations and for commercial forest lands.

The zoning ordinance on private land along the South Fork Tolt River is Forestry.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the South Fork Tolt River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$1,000	
Development of Management Plan		6,000
Total - First Five Years	**$1,000**	**$6,000**

General administration and operation and maintenance costs are estimated to continue at $200 annually.

NORTH FORK SNOQUALMIE RIVER
LENNOX CREEK

King County

The North Fork Snoqualmie River and Lennox Creek were studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: Lennox Creek flows from its headwaters inside the Alpine Lakes Wilderness downstream to its confluence with the North Fork Snoqualmie River. The North Fork of the Snoqualmie River flows from its headwaters at Lake Kanim in the Alpine Lakes Wilderness downstream 26 miles to its confluence with the Middle Fork Snoqualmie.

Segment 1 - Headwaters of Lennox Creek in NW 1/4 of Sec. 36, T.25N., R.10 E. to the Alpine Lakes Wilderness boundary (0.3 mi)

Segment 2 - Alpine Lakes Wilderness boundary to the confluence with the North Fork Snoqualmie River (6.9 mi).

Segment 3 - Headwaters of North Fork Snoqualmie at Lake Kanim in SE 1/4 of Sec. 11, T.25N., R.10 E. to the Alpine Lakes Wilderness boundary (1.0 mi).

Segment 4 - Alpine Lakes Wilderness boundary to Lennox Creek (5.1 mi).

Segment 5 - Lennox Creek to Wagner Bridge in NE 1/4 of Sec. 20, T.25N., R.9 E. (8.0 mi).

Segment 6 - Wagner Bridge to confluence with Middle Fork Snoqualmie River (12.1 mi).

RIVER MILEAGE:

Study:	33.4 miles
Eligible:	33.4 miles
Forest Plan:	12.1 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: Lennox Creek was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife.

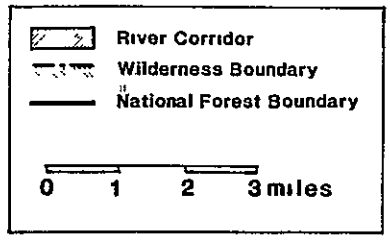
The North Fork Snoqualmie River was found to possess "Outstandingly Remarkable" values for the following: Recreation and Fisheries.

Both the North Fork Snoqualmie and Lennox Creek are important resources for resident cutthroat trout. Special fishing restrictions provide quality fisheries.

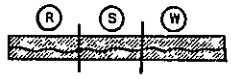
The Lennox River corridor provides extensive winter range for black-tailed deer and mountain goats, as well as good riparian habitat.

North Fork Snoqualmie River

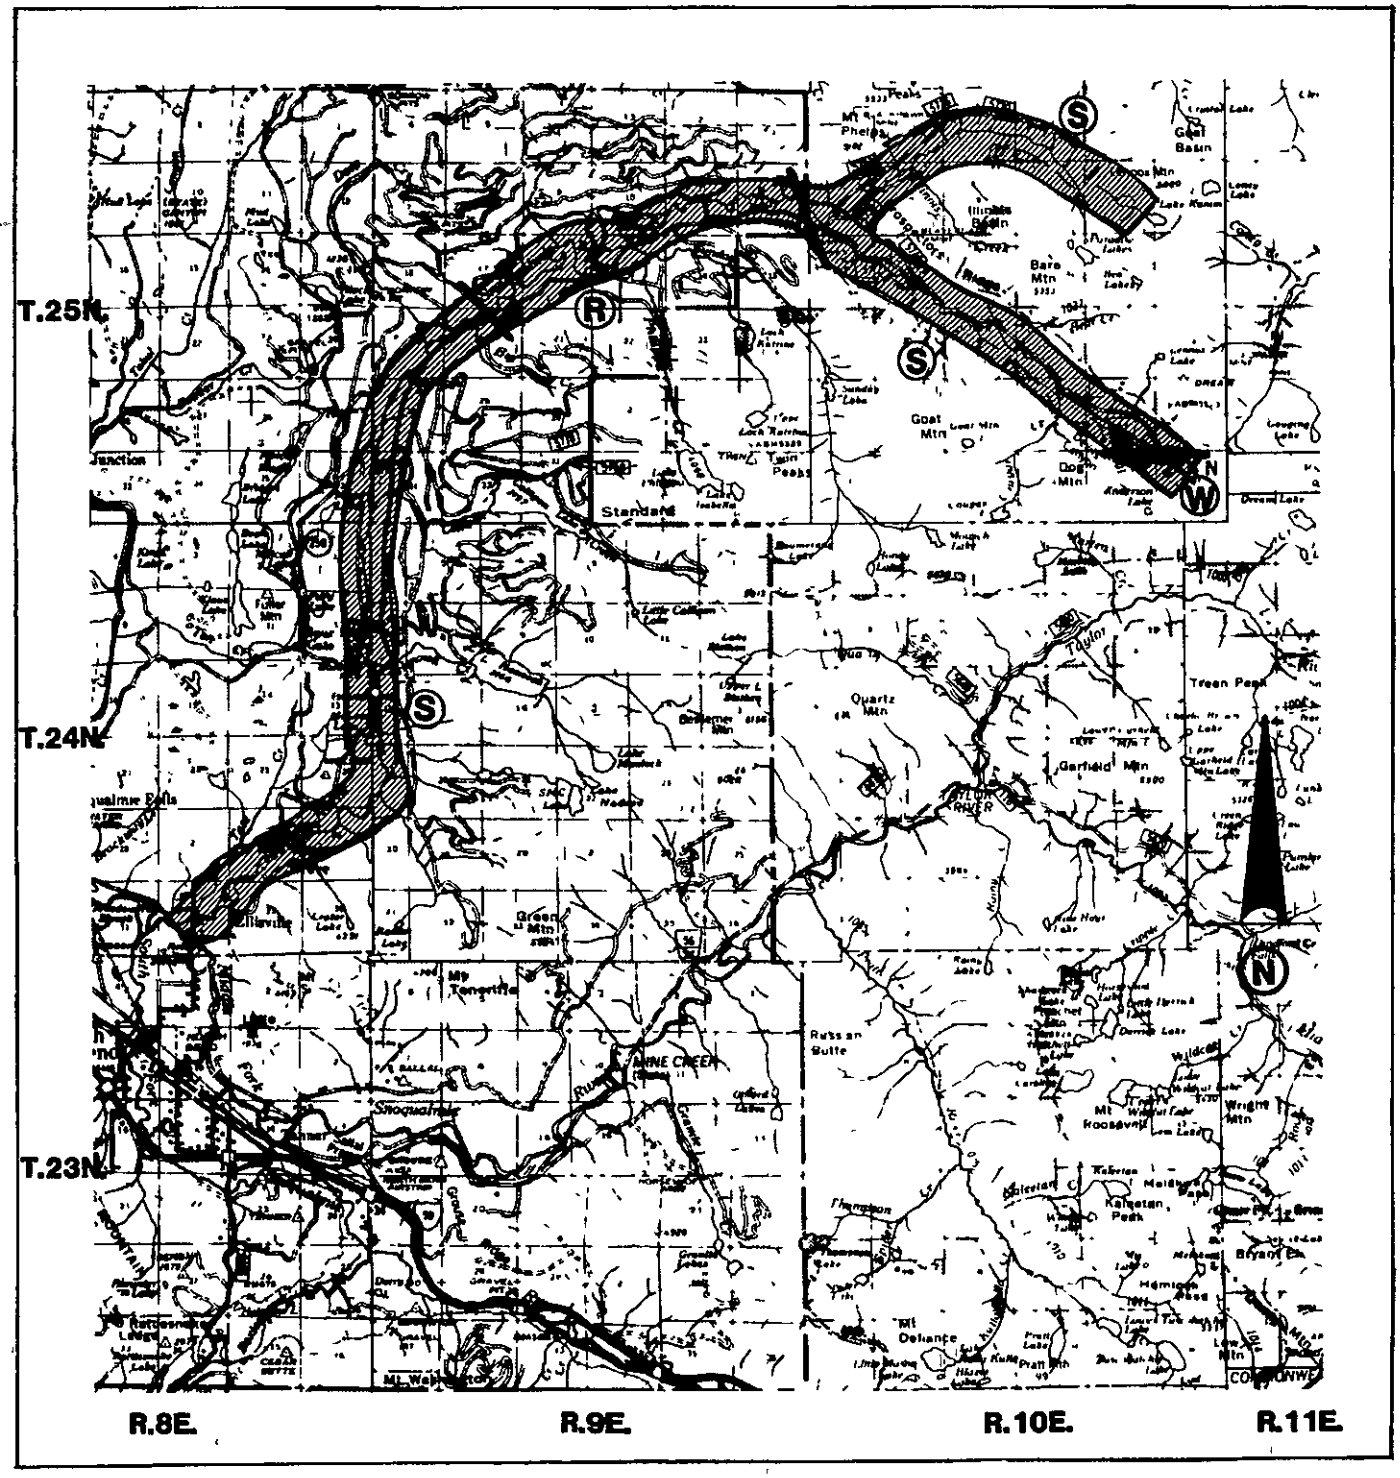
Lennox Creek



Potential River Classification



R - Recreational
S - Scenic
W - Wild



The lower 6 miles of the North Fork Snoqualmie offers a great diversity of challenges for advanced kayaking and canoeing. Fishing for trout is also a high use activity.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	.3	None recommended	0.0
Segment 2	Scenic	6.9	None recommended	0.0
Segment 3	Wild	1.0	None recommended	0.0
Segment 4	Scenic	5.1	None recommended	0.0
Segment 5	Recreation	8.0	None recommended	0.0
Segment 6	Scenic	12.1	Scenic	12.1

SUITABILITY DETERMINATION:

Portions of the North Fork of the Snoqualmie River were found to be suitable for inclusion in the preferred alternative of the Forest Plan. The lower seven miles below the Wagner Bridge - all state or private ownership - are recommended for designation. While there was little public support for designation and timber harvest is the highest value on the National Forest lands in this area, it was felt that the lower river had very high recreation potential and deserved designation.

Lennox Creek was found to be not suitable for inclusion in the preferred alternative. It is tributary to the North Fork of the Snoqualmie, and is an illogical addition without the upper reaches of the North Fork.

LANDOWNERSHIP:

	River Miles	Corridor Acres
Segment 1		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 0.3 mi)	0.3 mile	96 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	6.9 miles	2,208 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 1.0 mi)	1.0 mile	320 acres
Segment 4		
Mt. Baker-Snoqualmie National Forest	5.1 miles	1,632 acres
Segment 5		
Private	6.0 miles	2,200 acres
State	2.0 miles	360 acres
Segment 6		
Private	12.1 miles	3,872 acres
TOTAL	33.4 miles	10,688 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments have been classified as areas of critical mineral potential. However, the area near the eastern 7 miles of the river has been encumbered by 99 unpatented mining claims, of which 43 have either been abandoned or declared to be null and void. A review of available literature, including the Bureau of Mines MILS data, indicates that the portion of the river lying in T.25N., R.10 E. does contain reported occurrences of both precious and base metal mineral resources. In addition, Sections 24 and 25, T.24 N., R.8 E. contain reported occurrences of both copper and gold resources.

The BLM has classified the eastern 6 miles of the river as being prospectively valuable for geothermal resources. The area is not considered to have potential for the occurrence of other leasable mineral commodities, and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the eastern 6 miles of the river has a low to moderate potential for the occurrence of both precious and base metal resources. Interest in those resources is currently being expressed in the form of numerous unpatented mining claims. It also appears that a small part of the area has at least a low potential for the occurrence of geothermal resources. However, no interest in that resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: For many years, the North Fork Snoqualmie Valley has been considered to be a good location for a dam. The dam would control flooding downstream and/or create a water supply reservoir for domestic use.

The upper 15.4 miles of the North Fork Snoqualmie and all of Lennox Creek are classified as "Protected" from hydropower development by the Northwest Power Planning Council.

Preliminary permits for hydroelectric projects have been issued by FERC for four tributaries of the North Fork Snoqualmie: Lennox Creek, Big Creek, Hancock Creek and Tate Creek.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Logging roads are extensive along both sides of the North Fork Snoqualmie except for that portion in the wilderness. The North Fork County Road parallels the North Fork Snoqualmie sporadically, along with Weyerhaeuser logging roads, from its mouth to the Forest boundary, where it becomes F.S. Road #57. The road continues upstream, paralleling Lennox Creek from its mouth to the Wilderness boundary. F.S. Road #5730 parallels the North Fork from the confluence with Lennox Creek to the Wilderness boundary.

Six bridges traverse the North Fork Snoqualmie River. One bridge is found on the North Fork Road near the mouth of the river, one on the Weyco Road to Lake Hancock and one on the Weyco Road at Sunday Creek. The Wagner Bridge lies near the confluence with Big Creek, and the other two bridges are on F.S. Road #5730 over the North Fork. There are also 3 bridges that span Lennox Creek.

No developed campgrounds exist along either river.

The Bare Mtn. (#1037) and Lennox Cr. (#1001) Trailheads are located on F.S. Road #57 in the Lennox Creek drainage.

Residences line the North Fork Snoqualmie along the lower 3 miles

Pastures are also found in the lower 3 miles.

The proposed 905-acre Three Forks Park site is located at the confluence of the North, South and Middle Forks of the Snoqualmie River. In 1978, Washington State Parks prepared a draft conceptual plan to meet the Snohomish Mediated Agreements requirement of developing a major recreation area at the Three Forks location. The plan called for most of the site to be managed as a natural area for wildlife habitat. It was also suggested for teaching beginning recreation skills in canoeing, kayaking, hiking and camping. Limited development is envisioned.

RECREATION ACTIVITIES: From Deep Creek to the swinging bridge, the lower 6 miles of the North Fork Snoqualmie offers a great diversity of challenges for advanced kayaking and canoeing. Heaviest use is from late April through June. There is no kayaking on Lennox Creek.

Fishing for resident trout is a high use on the North Fork Snoqualmie. Lennox Creek receives moderate use. The wild resident trout population is of high quality.

Hunting occurs on the uplands. Other dispersed recreation use in the drainages is low to moderate.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power and nonpower)	50	80
Waterplay (swim, wade)	750	1,125
Fishing, Hunting	750	1,080
Camping	8,000	12,000
Viewing (scenery, wildlife, driving for pleasure)	500	760
Misc. (hike, picnic, berry picking, etc.)	1,000	1,960
TOTAL	11,050	17,005

WILDLIFE AND FISHERIES: The river corridors provide extensive winter range for black-tailed deer and mountain goats, as well as good riparian habitat.

There are no natural salmon runs above Snoqualmie Falls. Hatchery propagated chinook and coho have been planted in the upper drainages. Both the North Fork Snoqualmie and Lennox Creek are important resources for resident cutthroat trout. Special fishing restrictions provide quality fisheries.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The entire length of Lennox Creek and the upper 6 miles of the North Fork Snoqualmie cut through a narrow, steep-sloped valley. Below Lennox Creek for 7 miles, the valley is broad and flat. Downstream, the valley narrows and then broadens.

Appendix E
North Fork Snoqualmie River
Lennox Creek

Numerous small falls are found on the lower reaches of Lennox Creek. Below Hancock Creek, the North Fork Snoqualmie River falls over a series of cascades, with some drops exceeding 4 feet.

Water quality is excellent of both river.

GEOLOGY: Originating in massive, granite dominated mountains, the river flows through a wide, U-shaped glacially carved valley. Headwater mountains are highly dissected with rock outcrop and patches of perennial snow at higher elevations. The downstream topography is more subdued and is surrounded by forested (or cutover) ridge systems.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the North Fork Snoqualmie/Lennox Creek drainage. Existing information comes primarily from published historical sources. During the historic period, the area was within the territory of the Snoqualmie Indians. There is some evidence that the mouth of the North Fork was used during the historic period by the Indian groups and currently holds some value for traditional religious practices.

Mining began in the upper valley in 1896 and numerous claims were filed within a year. The Lennox Mining and Development Company was located on Lennox Creek and prospectors built a small town at the mouth of the creek. A railroad was extended up the North Fork for logging in the early part of the century. None of the sites known from the North Fork Snoqualmie - Lennox Creek drainage are listed on the National Register of Historic Places.

TIMBER: Logged areas are found intermittently for most of the length of Lennox Creek. Extensive logging is found throughout most of the North Fork Snoqualmie drainage, especially on private land outside the forest boundary.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest systems lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
89.0	4.628	4.268

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The North Fork Snoqualmie River flows into the Snoqualmie River approximately 1/2 mile from the community of North Bend and about 5 miles from the community of Snoqualmie. Lennox Creek has its origin in the Alpine Lakes Wilderness but for most of its length is paralleled by a forest road.

The local communities, only about 30 miles from Seattle, are increasingly populated by people who work in the city. They are also strongly impacted by visitors seeking the scenic and recreation amenities of the area. These include hiking, camping, hunting and fishing. Traditional occupations within the timber industry still provide the livelihood of a number of residents.

CURRENT ADMINISTRATION: The upper 0.3 miles of Lennox Creek and 1.0 miles of the North Fork flow within the Alpine Lakes Wilderness. Public lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. These lands are in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

The Shoreline Environment has been designated by King County as Conservancy for both river banks outside Federal jurisdiction. The Conservancy Environment consists of shoreline areas which are primarily free from intensive development. It is the most suitable designation for shoreline areas of high scenic or historical values, for areas unsuitable for development due to biophysical limitations and for commercial forest lands.

Zoning for the banks of both rivers is classified as Forestry except for the section from Crater Lake to the mouth of the North Fork. This section is zoned as Rural Area with one home per 2.5 - 10 acres.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the North Fork Snoqualmie River and Lennox Creek for the next five years.

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$5,000	$ 5,000
Costs of Implementation		1,000
Development of Management Plan		58,200
Development Costs		60,000
Operation and Maintenance Costs		12,000
Total - First Five Years	**$5,000**	**$136,000**

General administration and operation and maintenance costs are estimated to continue at $4,400 annually.

MIDDLE FORK SNOQUALMIE RIVER

King County

The Middle Fork Snoqualmie River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

The Middle Fork Snoqualmie River was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982.

LOCATION: From its headwaters near La Bohn Gap in the Alpine Lakes Wilderness downstream to its confluence with the South Fork Snoqualmie River.

Segment 1 - The headwaters near La Bohn Gap in the NW 1/4 of Section 20, T.24 N., R.13 E. to the Alpine Lakes Wilderness Boundary (6.4 mi).

Segment 2 - The Alpine Lakes Wilderness boundary to the confluence with the Taylor River (13.2 mi)

Segment 3 - The Taylor River confluence to a location near the community of Tanner in the NW 1/4 of Section 13, T.23N., R.8 E., (15.9 mi).

Segment 4 - Near the community of Tanner to the confluence with the North Fork Snoqualmie River (4.2 mi)

RIVER MILEAGE:

Study:	39 7 miles
Eligible:	39.7 miles
Forest Plan:	39 7 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Middle Fork Snoqualmie River was found to possess "Outstandingly Remarkable" values for the following: Recreation, Wildlife and Fisheries.

Though use is only moderate at the present time, the potential is high for rafting, canoeing, kayaking and fishing. Use is high for hunting and for driving for pleasure along the river corridor. Planned trail reconstruction along the river and the numerous existing trailheads provide excellent hiking and dispersed recreation opportunities.

A SOHA with three sighted pair is located adjacent to the river in the Dingford Creek area. There is a large variety of wildlife species including elk, black-tailed deer, mountain goat, black bear and beaver. The river corridor contains extensive deer winter range, and excellent riparian and furbearer habitat.

There are excellent resident cutthroat populations throughout the entire drainage.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	6.4	Wild	6.4
Segment 2	Scenic	13.2	Scenic	13.2
Segment 3	Scenic	15.9	Recreation	15 9
Segment 4	Recreation	4.2	Recreation	4.2

SUITABILITY DETERMINATION:

The Middle Fork of the Snoqualmie River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to its many outstandingly remarkable features, very high public support, and the support of other agencies for designation. The Middle Fork has a very high potential for recreation, and was identified as a potential Wild and Scenic River in the Nationwide Rivers Inventory published by the National Park Service in 1982.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 6.4 mi)	6.4 miles	2,048 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	12.0 miles	3,864 acres
Private	1 2 miles	360 acres
Segment 3		
Mt. Baker-Snoqualmie National Forest	4.9 miles	1,568 acres
Private	9.6 miles	2,960 acres
State	1.4 miles	560 acres
Segment 4		
Private	4.2 miles	1,344 acres
State	0.0 miles	160 acres
TOTAL	39.7 miles	12,704 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified by the BLM as areas of critical mineral potential. However, a review of available literature, including the Bureau of Mines MILS data does indicate the area has some occurrences of both precious and base metal resources. The BLM mining claim recordation data indicates that 259 unpatented mining claims have been located along the river from Section 16, T.23N., R.11 E., eastward. Of these 259 claims, only 2 have been abandoned. Of the reported occurrences, those of most interest are quartz deposits located near the river, and the gold, silver and copper occurrences reported for Sections 1, 14 and 18, T. 23N., R.11 E. and for Section 36, T.24 N., R11 E. According to V.E. Livingston (1971), the Middle Fork mineralized zone extends northeast from Goldmeyer Hot Springs to Crawford Creek, a distance of about 6 miles

This mineralization contains widespread low-grade copper and possible molybdenum concentrations which have been extensively explored in the past. At least 5 to 10 million tons of ore containing copper concentrations of 0.5 to 0.7 percent have been identified.

The BLM has classified the eastern 24 miles of the river as being prospectively valuable for geothermal resources. None of the area is considered to have a potential for the occurrence of other leasable mineral commodities Sections 10, 11, 15 and 23, T.23N., R.11/E. have been leased in the past. However, these leases have terminated.

Based upon the available information, it appears that the eastern 12 to 13 miles have a moderate potential for the occurrence of base and precious metal resources. The numerous unpatented mining claims in that area indicate a continuing interest in its locatable mineral resources. The area does have a potential for the occurrence of geothermal resources. However, no serious interest in the resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: The Middle Fork Snoqualmie River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

Preliminary permits for hydroelectric projects have been issued by FERC on the following tributaries to the Middle Fork Snoqualmie: Burntboot Creek, Dingford Creek, Taylor River, Granite Creek and Pratt River Proposed facilities within the river corridor consist of a transmission power line.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Forest roads parallel the river from its confluence with the South Fork Snoqualmie River to within 1 mile of the Alpine Lakes Wilderness boundary.

Three road bridges cross the river· 1 near the confluence with the North Fork, 1 at North Bend and 1 at the confluence with Granite Creek. Two trail bridges cross the river. One is in the Alpine Lakes Wilderness in Section 26, T. 24 N., R. 12 E. The other is near Dingford Creek confluence in Section 6, T.26 N., R.11 E

Many private dwellings and new housing developments are found along the lower seven miles of the river. An occupied cabin on private property is located near the confluence with the Taylor River.

The Dingford Creek Trailhead #1005 is located on Forest Road 5620 At the end of the road, the Dutch Miller Gap Trail #1030 begins. The trail heads eastward, paralleling the river for the length of the trail. The Pratt River Trailhead #1035 and the Rock Creek #1013.1 are accessed by fording across the Middle Fork.

The Middle Fork Trail #1003 is planned for reconstruction and expansion. The trail will parallel the south bank of the river from the Pratt River area to connect with the Dutch Miller Gap Trail #1030. Bridge crossings are planned one mile upstream from the confluence of Taylor River, Burntboot Creek and another upstream of Burntboot Creek.

The Taylor River Campground has been closed, however, the Alpine Lakes Plan identifies need for construction of a new campsite near the Taylor River confluence with the Middle Fork Snoqualmie River. The Department of Natural Resources has a campground at Mine Creek (17 sites), about 5 miles upstream from Tanner.

A minor amount of rip-rap is in place at the confluence with Rock Creek. There are also extensive sections of rip-rap along the river from the town of North Bend to the mouth of the river.

King County has proposed acquiring land along the north bank of the river near the mouth to create the Mt. Si Conservation Area. The area will be used for general recreation and hiking.

King County has received 55 acres of land for a proposed regional park at the confluence of the three forks of the Snoqualmie River. Most of the site will be managed as a natural area for wildlife habitat. The U.S. Army Corps of Engineers has proposed a 1.25 mile levee along the Middle Fork for flood control. The levee top would be used as a pedestrian/bicycle trail and would have a small rest area with benches. Future extension of the trail to connect with the proposed multi-agency sponsored Sound to Mountain Trail is possible.

There is substantial housing developments being constructed along the Mt. Si Road upstream to Section 13, T.23N., R.8 E.

The proposed Puget Sound to Mountain Trail would link the Snoqualmie Valley Trail from the town of Snoqualmie to the Granite Lakes. The trail would follow the Middle Fork from Tanner to Granite Creek.

RECREATION ACTIVITIES: The Middle Fork Snoqualmie drainage incurs heavy use by hunters, sightseers, hikers and campers. The drainage is within an easy driving distance from Seattle and attracts many visitors. There is moderate fishing use along most of the river downstream of Goldmeyer Hot Springs. Moderate kayaking and canoeing use exists downstream of the Taylor River confluence. Outside of the Forest boundary, the use increases. Rafting use is moderate outside the Forest boundary and swimming use is low.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power and nonpower)	65	100
Waterplay (swim, wade)	5,100	7,650
Fishing	5,100	7,345
Camping, Hunting	40,600	60,900
Viewing (scenery, wildlife, driving for pleasure)	4,000	6,080
Misc. (hike, picnic, berry picking, etc.)	1,500	2,940
TOTAL	56,365	85,015

WILDLIFE AND FISHERIES: A SOHA with three sighted pair is located adjacent to the river in the Dingford Creek area. There is a large variety of wildlife species including elk, black-tailed deer, mountain goat, black bear and beaver. The river corridor contains extensive deer winter range, and excellent riparian and furbearer habitat.

No natural salmon utilization exists above Snoqualmie Falls on the Snoqualmie River. Juvenile chinook and coho salmon are occasionally planted to make use of natural rearing potential. There are excellent resident cutthroat and rainbow trout populations throughout the entire drainage.

Appendix E
Middle Fork Snoqualmie River

STREAMFLOW, GRADIENT AND VALLEY PROFILE: From its headwaters to Burntboot Creek, the Middle Fork Snoqualmie exhibits typical mountain stream character, flowing swiftly within a confined channel over steep gradient. There are numerous cascades and fast riffle stretches. Below Burntboot Creek, the gradient is mostly moderate for 19 miles to below Granite Creek. Here the river is contained within a broad, stable channel with a fast riffle character. A few rapids, short cascades and a number of large deep pools separate fast water stretches. Sixty tributaries drain into the Middle Fork Snoqualmie River.

Stream flows reach a maximum in June and again in December when the river reaches almost 2,000 cubic feet per second (cfs) at the Middle Fork stream gauge. The low flow occurs in late August to mid-September at 500 cfs.

The Snoqualmie River system is listed by the State Department of Ecology as a "River of Statewide Significance" based on water volume.

Water quality is excellent above Taylor River. Below this junction, clay deposits cause muddying of the water during periods of high runoff.

GEOLOGY: Granite, grandodiorite, honrblende gneiss, and associated rock types comprise the bedrock geology in this rugged area. Past glaciation has carved out the valley and left deposits of glacial till and unstable lacustrine materials in this mostly U-shaped valley. Valley sideslopes, consisting of deeply dissected forested slopes associated with nearly vertical massive rock bluffs, merge into rocky upper slopes where patches of snow often last through summer.

CULTURAL RESOURCES: No systematic archeological survey has been made of the Middle Fork. Few project surveys have been conducted, and historical research is limited. No prehistoric sites have been recorded. The lack of sites is believed to reflect the lack of a survey of the drainage During the historic period, the area was within the territory of the Snoqualmie Indians. No locations used for traditional religious practices are known within the potential Wild and Scenic River corridor.

Historic period sites represent mining, logging, recreation and Forest Service administration. Prospecting began on the Middle Fork in 1869, but no substantial placers or lodes were discovered. The main use of the drainage was for accessing other mining districts Timber harvest commenced in the 1920's and included the construction of logging railroads. Camp Brown was used by the North Bend Lumber Company during this period. It later housed a CCC crew, and then became a Fire Guard Station. The building was washed away in a 1959 flood. None of the sites known from the Middle Fork are listed on the National Register of Historic Places.

TIMBER: Most of the drainage is in second growth forest as a result of old railroad logging. Logging is a low influence along the river.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
138.6	1.880	1.880

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The river flows through the town of North Bend (population 1,701) and about 8 miles from the town of Snoqualmie (population 1,370). Both communities have been traditionally supported by logging and the forest products industry. More recently, many of the residents are employed in the Seattle metropolitan area, 24 miles distant. North Bend is also a retail and service area for residents in the Upper Snoqualmie Valley and is promoting its industrial development potential. The economy of the area is increasingly changed by the thousands of visitors yearly who are attracted to the scenic and recreation qualities of the area. The recreation opportunities include skiing, camping, hiking, hunting and fishing.

CURRENT ADMINISTRATION: The upper 5.5 miles of the river flow through the Alpine Lakes Wilderness. These, and other National Forest lands, are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. These lands are in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shorelines of the Middle Fork Snoqualmie has been classified as Natural from the forest boundary to the west section line of Sec. 17, T.23N., R.9 E. and as Conservancy from the west section line to the river mouth. These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Natural designation denotes shoreline areas characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relatively intolerant of intensive human use. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

From the forest boundary to the Mt. Si Road in North Bend, the land along the Middle Fork Snoqualmie, outside of federal jurisdiction, has been zoned for Forestry Use. From Mt. Si Road to the confluence with the North Fork, the land is zoned for Rural Use, with 1 dwelling per 2.5 to 10 acres.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Middle Fork Snoqualmie River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 10,000	$ 50,000
Costs of Implementation		15,000
Development of Management Plan		52,700
Development Costs	1,000,000	50,000
Operation and Maintenance Costs	360,000	5,000
Total - First Five Years	**$1,370,000**	**$172,700**

General administration and operation and maintenance costs are estimated to continue at $85,000 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	42
		Wilderness-Trailled	633
		Wilderness-General Trailless	1,182
Segment 2	Scenic	Alpine Lakes Dispersed Recreation	506
		Alpine Lakes Scenic	3,019
		Old Growth Habitat (spotted owl)	232
Segments 3 and 4	Recreation	Old Growth Habitat (spotted owl)	63
		Pine martin/Pileated woodpecker Habitat	63
		Alpine Lakes Scenic	781

TAYLOR RIVER

King County

The Taylor River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Snoqualmie Lake within the Alpine Lakes Wilderness to its confluence with the Middle Fork Snoqualmie River.

Segment 1 - Snoqualmie Lake to the Alpine Lakes Wilderness boundary (1.2 mi).

Segment 2 - Alpine Lakes Wilderness boundary to Quartz Creek Road (5.4 mi).

Segment 3 - Quartz Creek Road to confluence with Middle Fork Snoqualmie River (1.6 mi).

RIVER MILEAGE:

Study:	8.2	miles
Eligible:	8.2	miles
Forest Plan:	8.2	miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Taylor River was found to possess "Outstandingly Remarkable" values for the following: Recreation and Fisheries.

A large number of hunters use the area surrounding the Taylor River. Dispersed camping occurs along the river corridor. Large numbers of dayhikers and backpackers use trails that head into lakes within the Alpine Lakes Wilderness.

There are excellent resident cutthroat trout populations throughout the entire drainage.

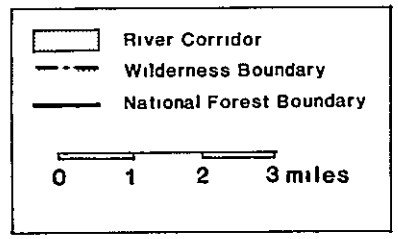
POTENTIAL AND RECOMMENDED CLASSIFICATION:

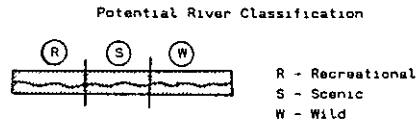
Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	1.2	Wild	1.2
Segment 2	Wild	5.4	Scenic	5.4
Segment 3	Recreation	1.6	Recreation	1.6

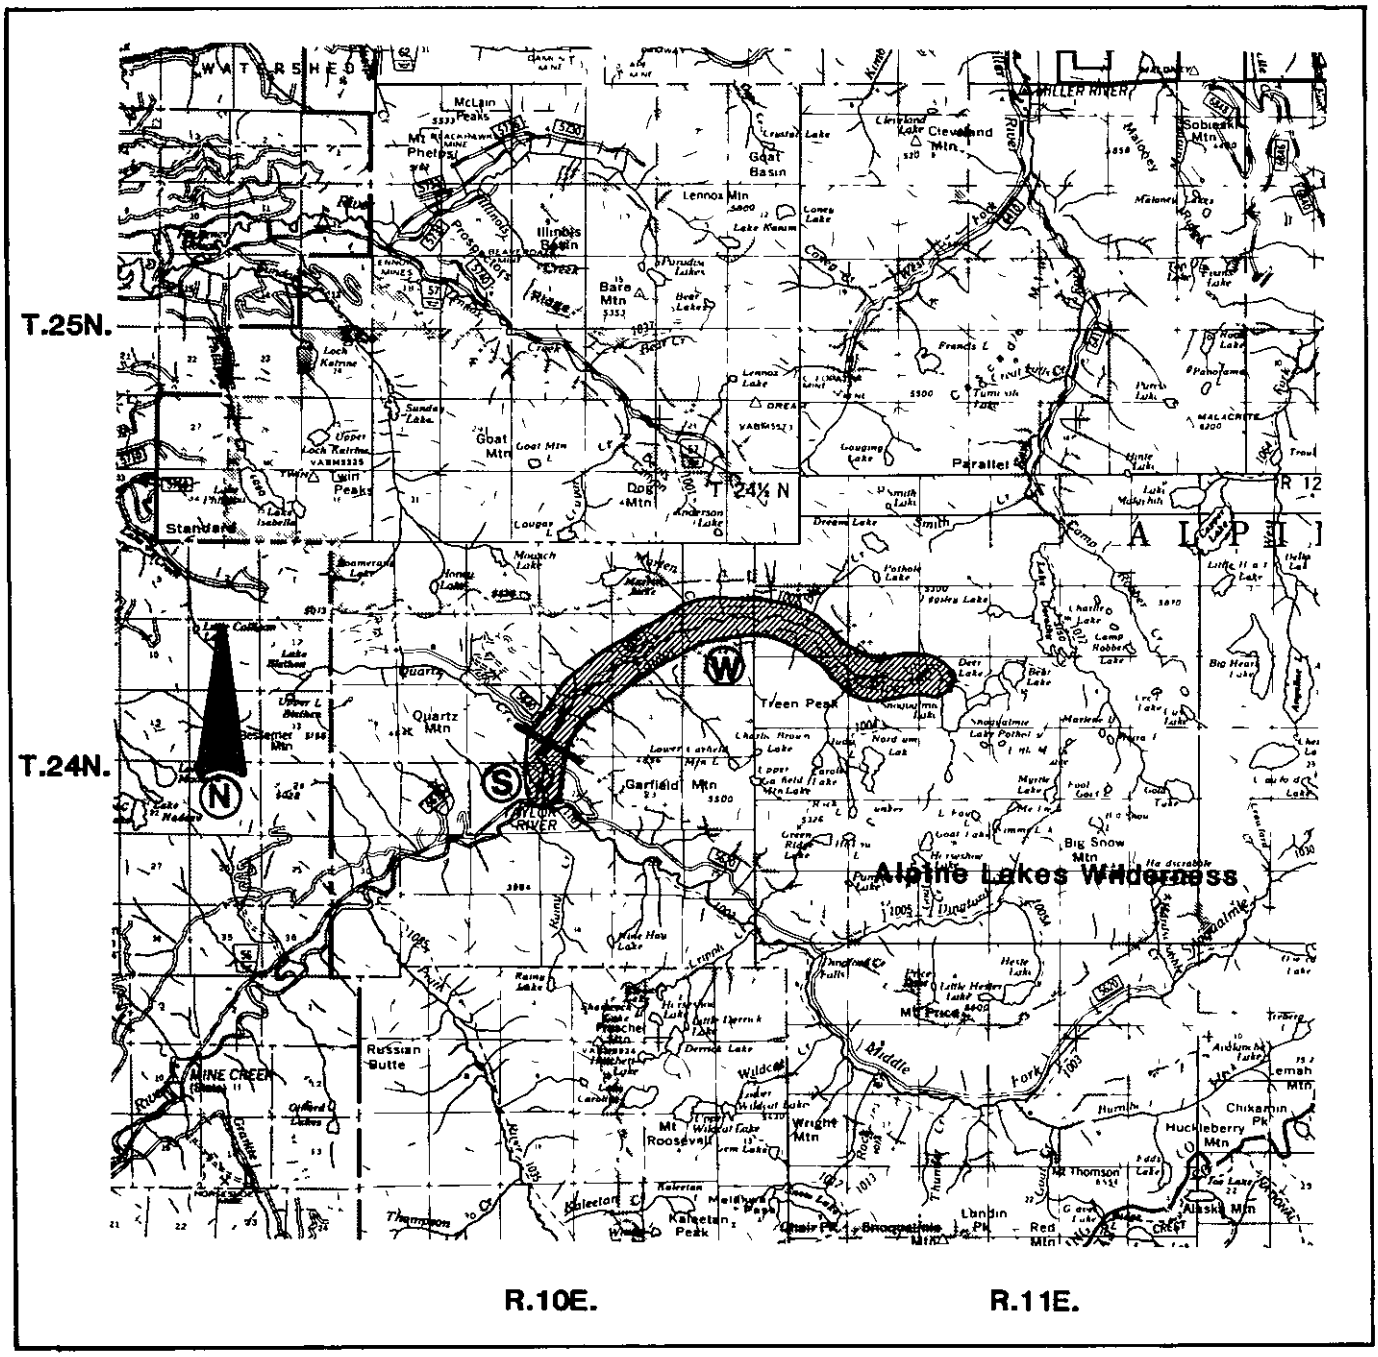
SUITABILITY DETERMINATION:

The Taylor River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due to little or no competing resource value, high public interest, high potential recreation value. Designation is compatible with the Alpine Lakes Management Plan.

Taylor River







LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 1.2 mi)	1.2 miles	384 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	5.4 miles	1,728 acres
Segment 3		
Mt. Baker-Snoquamie National Forest	1.4 miles	448 acres
Private	0.2 miles	64 acres
TOTAL	8 2 miles	2,624 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segments are classified by the BLM as areas of critical mineral potential, and none are encumbered by unpatented mining claims. Although a review of available literature indicates Section 16, T.24 N , R.10 E. contains an interesting mineral occurrence, the river corridor itself has no reported locatable mineral resource occurrences

The BLM has classified the entire river as being prospectively valuable for geothermal resources, however, the area is not considered to have potential for the occurrence of other leasable mineral commodities, and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the river has at least a low potential for the occurrence of locatable mineral resources. However, there is no current serious interest in the locatable minerals. Even though the area has potential for the occurrence of geothermal resources, no serious interest in that resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are no water impoundments along the river. The Taylor River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

A preliminary permit for a hydroelectric project has been issued by FERC The project will be 44 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Forest Road 5630 follows the river upstream for 6 1/2 miles to the wilderness boundary. Only the lower mile is presently open. At 1 mile, a concrete bridge is being constructed across the river to replace one that was burned several years ago. The bridge will provide access up the Quartz Creek Road (5640). Forest Road 5630 will remain closed to motorized traffic beyond the Quartz Creek Road junction.

Forest Road 5630 crosses the river twice, both times near the confluence with Quartz Creek.

Forest Road 5630 is now used as a trail and provides access to the Martin Lake Trailhead (#1006). The Snoqualmie Lake Trail (#1002) begins at the east end of the road and parallels the Middle Fork to its headwaters at Snoqualmie Lake. The Nordrum Lake Trail (#1004) also begins at the end of the road and crosses the river (no bridge) on its route up to the lake.

There are no homes, farms or developed campgrounds along the Taylor River.

Rip-rap has been placed along the piers of the new concrete bridge.

RECREATION ACTIVITIES: A large number of hunters use the area surrounding the Taylor River. Dispersed camping occurs from the confluence with the Middle Fork to about 1/2 miles upstream. The Forest Service Road is currently closed to motorized traffic beyond the first bridge crossing. The road is used by day hikers and by backpackers heading to lakes within the Alpine Lakes Wilderness.

Fishing is a moderate use along the entire length of the river. Little river use occurs by rafters, kayakers or swimmers.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	30	50
Waterplay (swim, wade)	2,000	3,000
Camping	10,000	15,000
Viewing (scenery, wildlife, driving for pleasure)	500	760
Misc. (hike, picnic, berry picking, etc.)	800	1,570
TOTAL	14,080	20,380

WILDLIFE AND FISHERIES: A number of species use the Taylor River drainage, including deer, marten, mountain goats, bear and beaver. It is an excellent winter range for black-tailed deer and also provides excellent riparian and furbearer habitat.

Salmon cannot migrate past Snoqualmie Falls on the Snoqualmie River. There are excellent resident cutthroat trout populations throughout the entire river drainage.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The Taylor River contains lengthy reaches with mostly moderate gradients and good pool-riffle conditions. The river bottom is primarily gravel-rubble. Twenty-two tributaries drain into the river.

Water quality is excellent.

GEOLOGY: The bedrock geology is comprised of granite, granodiorite, hornblend gneiss, and associated rock types in this rugged area. Past glaciation has carved out and left deposits of glacial till in this mostly U-shaped valley. Valley side slopes, consisting of dissected, very steep, forested sideslopes associated with nearly vertical cliffs, merge into massive rock ridgetops and peaks where patches of snow last through summer.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Taylor River. However, one prehistoric site is known and others may exist. Localities used by members of the Indian community to practice their traditional religion exist within the river corridor.

There was some logging activity up the Taylor River in the early 1900's However, no historic sites associated with this logging are documented at this time. The lack of sites is probably reflective of survey patterns rather than lack of use. The Forest Service presence was established as early as 1910, by which time a ranger station had been constructed near the mouth of the river. This site is believed to be eligible for the National Register of Historic Places.

TIMBER: The area is primarily second growth forest. The valley bottom was logged extensively.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National System lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
52.6	.438	438

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The communities in the area were traditionally supported by the logging and forest products industries. The economy of the area is increasingly changed by the thousands of visitors yearly attracted to the scenic and recreation qualities of the area. These include camping, hiking, hunting, and fishing.

CURRENT ADMINISTRATION: The upper 1 1/2 miles of the river is within the Alpine Lakes Wilderness. These, plus other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. These lands are in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Taylor River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 1,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		3,800
Development Costs	87,000	20,000
Operation and Maintenance Costs		4,000
Total - First Five Years	**$88,000**	**$30,800**

General administration and operation and maintenance costs are estimated to continue at $1,200 annually.

Appendix E
Taylor River

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Transition	211
		Wilderness-General Trailless	190
		Alpine Lakes Dispersed Recreation	42
Segment 2	Scenic	Wilderness-General Trailless	274
		Alpine lakes Dispersed Recreation	865
		Alpine Lakes Scenic	675
Segment 3	Recreation	Alpine Lakes Scenic	211

PRATT RIVER

King County

The Pratt River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters near Melakwa Lake in the Alpine Lakes Wilderness to its confluence with the Middle Fork Snoqualmie River

Segment 1 - Headwaters at Melakwa Lake in the NE 1/4 of Sec 25, T.23N., R.10 E. to the Alpine Lakes Wilderness boundary (1.6 mi).

Segment 2 - Alpine Lakes Wilderness boundary to the confluence with the Middle Fork Snoqualmie River (7.9 mi).

RIVER MILEAGE:

Study:	9.5 miles
Eligible:	9.5 miles
Forest Plan	9.5 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Pratt River was found to possess "Outstandingly Remarkable" values for the following: Recreation, Geological, Fisheries, Wildlife and Ecological.

There is moderate to heavy hiking use near Tuscohatchie Lake and moderate hunting use near the mouth. An old trail system that originally ran the whole length of the Pratt River is scheduled to be reconstructed at a future date. There is also light fishing use.

Clay formations called concretions are found in the river and along its banks in the lower stretches

The Pratt River area has extensive winter range for black-tailed deer and mountain goats. There are also excellent riparian and furbearer habitats for black bear, beaver and other furbearers.

The Pratt River hosts a population of resident cutthroat trout.

The Pratt drainage supports stands of low elevation old-growth. The old-growth is predominant in the wilderness and near the river's mouth.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	1.6	Wild	1.6
Segment 2	Wild	7.9	Recreation	7.9

SUITABILITY DETERMINATION:

The Pratt River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due its many outstandingly remarkable values. It is one of the few relatively undisturbed drainages in the North Cascades. The Pratt received the greatest number of site-specific comments during the DEIS public response period; nearly all of these comments supported Wild and Scenic River designation and/or protection from timber harvesting.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Alpine Lakes Wilderness - 1.6 mi)	1.6 miles	512 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	6.7 miles	2,168 acres
Private	1.2 miles	360 acres
Total	9.5 miles	3,040 acres1/

1/Acres based on a 1/4-mile corridor on each side of the river

MINERAL AND ENERGY RESOURCE ACTIVITIES: None of the river segment is classified by the BLM as an area of critical mineral potential or is encumbered by unpatented mining claims. A review of available literature indicates that the area has only one reported locatable mineral prospect, which is a tungsten prospect located in Section 27, T.23N., R.10 E.

The BLM has classified the entire river as being prospectively valuable for geothermal resources. The area is not considered to have potential for the occurrence of other leasable mineral commodities and none of the area has been encumbered by mineral leases or lease applications.

Based upon the available information, it appears that the river has a relatively low potential for the occurrence of locatable mineral resources. There is no serious interest in the locatable minerals. The area does have a potential for the occurrence of geothermal resources, but no serious interest in that resource is currently being expressed.

WATER RESOURCE DEVELOPMENT: No water impoundments exist on the Pratt River. The Pratt River is classified as "Protected" from hydropower development by the Northwest Power Planning Council

A preliminary permit for a hydroelectric project has been issued by FERC. The proposed project facilities consist of a transmission line, diversion structure, power house and pen stock. The project capacity will be 44 megawatts.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are no roads, trail bridges, home sites or campgrounds along the river.

The Pratt River Trail (#1035) follows an old railroad grade up the river, beginning near the confluence with the Middle Fork Snoqualmie. In places, the trail is within 1/4 mile of the river. Currently, there is no direct access to the trail. The trailhead is reached by fording across the Middle Fork Snoqualmie River.

About half the length of the river flows through a clearcut area created in the 1940's.

RECREATION ACTIVITIES: There is moderate to heavy hiking use near Tuscohatchie Lake and moderate hunting use near the mouth. An old trail system that originally ran the whole length of the Pratt River is scheduled to be reconstructed at a future date. The lower portion of the drainage receives low recreation use due to the lack of access. There is light fishing use and no use by rafters, kayakers or swimmers.

	1988 RVD'S	Projected 2000 RVD'S
Waterplay (swim, wade)	50	75
Fishing, Hunting	200	300
Camping	50	75
Viewing (scenery, wildlife, driving for pleasure)	500	760
Misc. (hike, picnic, berry picking, etc)	1,000	1,960
TOTAL	1,800	3,170

WILDLIFE AND FISHERIES: The Pratt River area has extensive winter range for black-tailed deer and mountain goats. There are also excellent riparian and furbearer habitats for black bear, beaver and other furbearers.

The Pratt River hosts a population of resident cutthroat trout. There are no anadromous fish due to the impassable falls on the Snoqualmie River.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The river contains lengthy reaches with moderate gradients and good pool-riffle conditions. Short stretches of rapids are common. Fourteen tributaries drain into the river.

The water quality is excellent. The lower one mile has clay banks which contribute to sedimentation. The bottom of the river consists of gravel-rubble.

GEOLOGY: Granite, granodiorite, hornblend gneiss, and associated rock types comprise the bedrock geology in this area. Past glaciation has carved out the valley and left deposits of glacial till and unstable lacustrine materials in this mostly U-shaped valley. Clay banks along the lower river contain interestingly shaped hard clay concretions. Long forested valley sideslopes merge into rock outcrops and perennial snow patches on ridgetops and peaks.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Pratt River. Few project surveys have been done and historical research is limited. There are no known localities used for traditional Indian religious practices within the potential Wild and Scenic River corridor.

Around the turn of the century, there were mining interests near the headwaters of the river. None of these early claims is within the river corridor However, there was a trail known in the 1890's as Tuscohatchie Creek and provided access to the iron ore deposits.

The North Bend Logging Company extended a logging railroad up the Pratt in the early 1900's. Evidence of this railroad can still be seen. There are no sites within the river corridor listed on the National Register of Historic Places.

TIMBER: The Pratt River drainage is primarily in second growth forest. Most of the valley bottom was railroad logged in the 1940's.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest systems land only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
54.2	3.230	2.957

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The mouth of the Pratt is located approximately 10 miles from North Bend (pop. 1,825). The community was traditionally supported by the logging and forest products industries. Currently, it is attracting many residents whose employment is in Seattle. The economy of the area is increasingly changed by the thousands of visitors yearly attracted to the scenic and recreation qualities of the area which include camping, hiking, hunting, and fishing.

CURRENT ADMINISTRATION: The upper 1.6 miles of the river are in the Alpine Lakes Wilderness. These, plus other National Forest lands in the drainage, are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. This river is in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Pratt River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 2,000	$2,000
Costs of Implementation		2,000
Development of Management Plan		3,500
Development Costs	35,000	
Total - First Five Years	**$37,000**	**$7,700**

General administration and operation and maintenance costs are estimated to continue at $800 annually.

Appendix E
Pratt River

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the *preferred alternative. (Note: This applies to lands administered by the* National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Wild	Wilderness-Trailled	253
		Wilderness-General Trailless	316
Segment 2	Recreation	Old Growth Habitat (spotted owl)	570
		Deer and Elk Habitat Enhancement	337
		Goat Habitat	42
		Timber Management	718
		Alpine Lakes Dispersed Recreation	105
		Alpine Lakes Scenic	190

SOUTH FORK SNOQUALMIE RIVER

King County

The South Fork Snoquamie River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters at Source Lake three miles north of Snoqualmie Pass, downstream to its confluence with the Snoqualmie River.

Segment 1 - Headwaters at Source Lake in NE 1/4 of Sec. 30, T.23N., R.11 E. to the confluence with the Snoqualmie River (30.6 mi)

RIVER MILEAGE:

Study:	30.6 miles
Eligible:	30.6 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The South Fork Snoqualmie River was found to possess "Outstandingly Remarkable" values for the following: Wildlife, and Historical/Cultural.

The river corridor contains excellent habitat for black-tailed deer, elk, black bear and furbearers.

The South Fork was the natural travel route between Snoqualmie Pass and the mainstream Snoqualmie. This cross-cascade route was known in the middle 1800's as the Indian Foot Trail. Other historic period sites represent mining, railroad and logging activities

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Recreation	30.6	None recommended	0

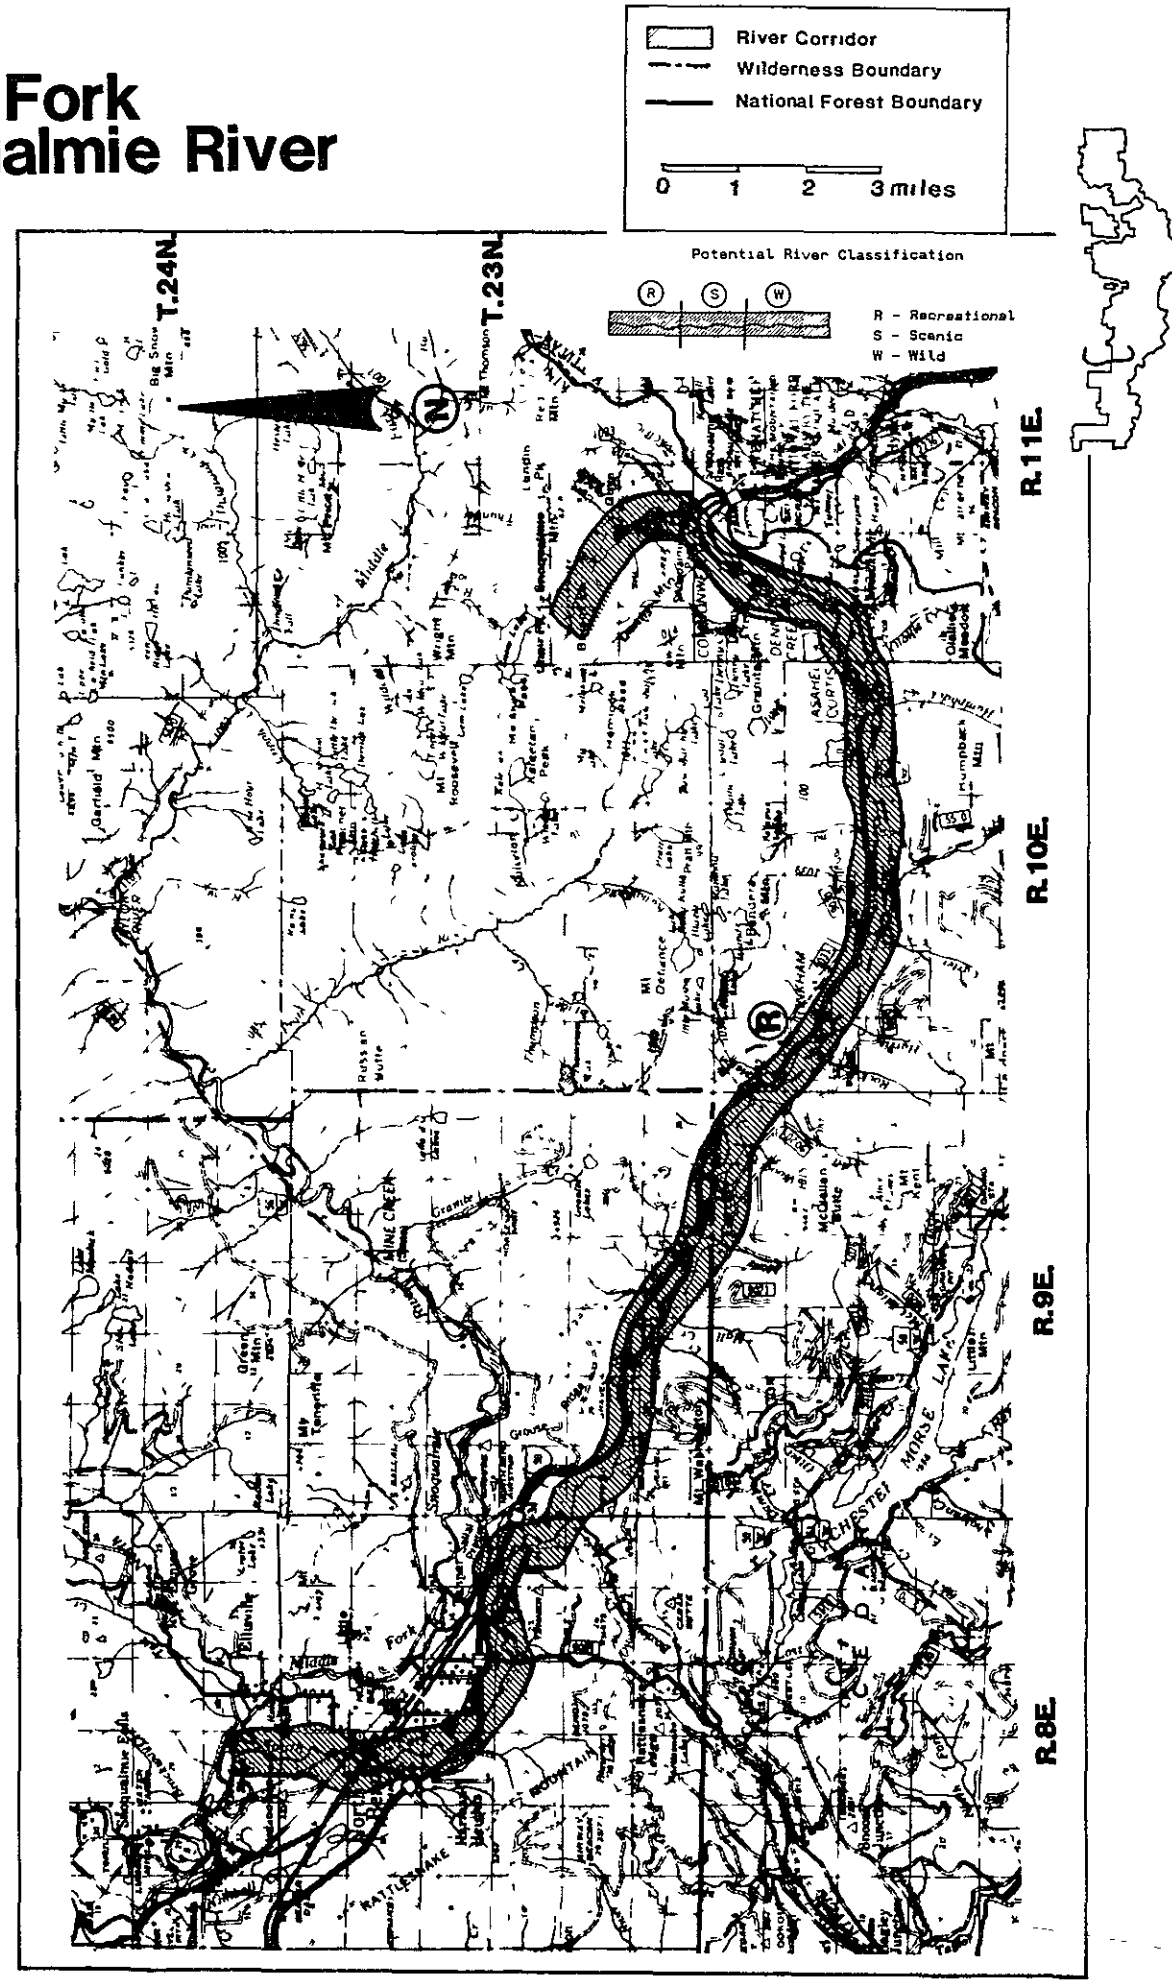
SUITABILITY DETERMINATION.

The South Fork of the Snoqualmie River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to low public support, and because most of the river is in state or private ownership.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest	9.0 miles	2,880 acres
State Park	0 9 miles	288 acres
Private	19.5 miles	6,224 acres
State	1.2 miles	400 acres
Total	30.6 miles	9,792 acres

South Fork Snoqualmie River



MINERAL AND ENERGY RESOURCE ACTIVITIES: None of this river segment is classified by the BLM as an area of critical mineral potential. BLM mining claim recordation data indicates that only thirteen mining claims have been located along the river. Of those thirteen, ten have been abandoned or have been declared to be null and void. A review of available literature does indicate that a few precious and base metal prospects do occur along the river. However, none are known to have experienced any significant exploration or development activity. The Denny Mountain limestone deposit is reported to occur in Sections 5 and 6, T.22 N., R.11 E. None of the deposit appears to lie within the river corridor.

The BLM has classified the eastern 6 miles of the river as being prospectively valuable ("PV") for coal resources and the eastern 12 to 14 miles as "PV" for geothermal resources. None of the area has been encumbered by mineral leases or lease applications.

Based upon the available information it appears that the area does have at least a low potential for the occurrence of both base and precious metal resources. Little interest in such resources is currently being expressed. Portions of the area also have a potential for both coal and geothermal resources. However, no interest in these resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: There are a number of falls which prevent fish migration along the upper 6 to 7 miles.

Two FERC projects are located on the South Fork Snoqualmie. One has been constructed on Weeks Falls with impacts in the proposed corridor consisting of a transmission line, a diversion structure and penstock, and a powerhouse. The project generates 3.5 megawatts of power and is located on State Park lands.

The other FERC Project is at Twin Falls. Facilities within the river corridor consist of a transmission line, a diversion structure and penstock and a powerhouse. The project capacity is 19 megawatts of power. This project is also located on State Park lands.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: Interstate 90 parallels the river for most of its length. Numerous other forest roads also parallel and cross the river.

There are at least 14 bridge crossings. Several are major interstate highway bridges.

There are farms along the lower 10 miles of the river.

Numerous home sites, commercial businesses, and the town of North Bend are found at the lower end of the river.

There are several cabins above Twin Falls and twelve summer homes in the Denny Creek area.

The upper 3 1/2 miles of the river is in the permit area of downhill ski areas.

Forest Service campgrounds are found at Denny Creek (39 sites plus 1 group site), Tinkham Road (47 sites) and Commonwealth (6 tent sites). Asahel Curtis Picnic Area (28 sites) is just downstream from Olallie Creek. Twin Falls State Park is also found on the river, though it is currently undeveloped with difficult access.
Trails that begin near the South Fork include the Asahel Curtis Nature Trail (#1023), the Wagon Road (#1021), the Denny Creek Trail (#1014), the McClellan Butte Trail (#1015), and Annette Lake Trail (#1019). The Franklin Falls Trail (#1036), and Snow Lake Trail (#1013) parallel stretches of the river.

The proposed Sound to Mountain Trail would parallel the South Fork from Cedar Falls to Cabin Creek, using the old Burlington-Northern Railroad grade.

Fifty-five acres of land have been acquired by King County to create Three Forks Park at the confluence of the North, Middle and South Forks of the Snoqualmie River. The final size of the park is proposed to be 905 acres. The plan calls for the park to be managed as a natural area for wildlife habitat.

Camp Waskowitz is located 2 miles east of North Bend. The camp is owned by the Shoreline School District.

The old Milwaukee Railroad Covered Bridge crosses the river north of Highway 202.

Powerlines cross the river in the SE 1/4, Sec. 4 north of North Bend and at the confluence with Boxley Creek (below Twin Falls State Park).

Dikes have been placed along the river banks near the town of North Bend to protect residents and businesses from floods up to the 500-year flood plain.

Extensive sections of rip-rap are found from Snoqualmie Pass to the mouth of the river.

The only known section of channelization is near Twin Falls State Park, where the Washington D.O.T. re-channeled the river to put in a bridge for Interstate 90.

There is a small emergency airfield open to the public in Section 16, T.22 N., R.10 E.

RECREATION ACTIVITIES: The ski areas at Snoqualmie Pass are very popular destination stops during the winter. Denny Creek Road, as well as other area roads, receive moderate cross-country skiing use.

The campgrounds along Interstate 90 are heavily used throughout the summer months. A popular nature trail loops around the Asahel Curtis Picnic Area. Numerous trailheads are located within the river drainage. Many receive heavy use during summer weekends.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	65	110
Waterplay (swim, wade)	4,000	6,000
Fishing, Hunting	5,000	7,200
Camping	54,000	81,000
Viewing (scenery, wildlife, driving for pleasure)	5,000	7,600
Misc. (hike, picnic, berry picking, etc.)	26,640	52,215
TOTAL	94,705	154,125

WILDLIFE AND FISHERIES: The river corridor area has excellent riparian habitat for black-tailed deer, black bear and furbearers. Elk also inhabit the area.

There is no natural utilization by salmon above Snoqualmie Falls. The Falls are located over three miles downstream from the South Fork. Hatchery propagated chinook and coho juveniles are occasionally planted in the South Fork Snoqualmie, making use of its available rearing potential. A large portion of the river provides high quality production habitat, suitable for use by adult and juvenile salmon. The South Fork Snoqualmie has an important population of wild resident trout. Special fishing restrictions promote a quality fishery.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Numerous falls, cascades and rapids occur in the upper 7 miles of the river. Below Change Creek, is a narrow channel with numerous cascades and rapids with 2 large falls. Approximately 30 small tributaries feed into the South Fork Snoqualmie. Each one is a short, very steep mountainous stream.

Water quality is excellent.

GEOLOGY: Granite, granidorite, and associated rock types comprise the bedrock geology. Past glacial activity has carved out this mostly U-shaped valley. A ravine-like valley persists.

CULTURAL RESOURCES: No systematic archaeological survey has been done of the South Fork Snoqualmie River and no prehistoric resources are known. The lack of sites is believed to reflect survey patterns rather than lack of use. There are documented prehistoric sites on the mainstream Snoqualmie and the South Fork is the natural travel route between Snoqualmie Pass and the mainstream Snoqualmie. This cross-cascade route was known in the middle 1800's as the Indian Foot Trail.

Locations used by the Indian community for practice of their traditional religion exist within the corridor.

During the Indian conflict of 1855 - 56, Fort Smalley was built in the vicinity of North Bend. It was abandoned shortly thereafter and is presently marked by a plaque and listed on the county historic site inventory.

Attention was focused on a transportation system after the decline of military activity. The first train of six wagons crossed Snoqualmie Pass and followed the route along the South Fork in 1865. In 1905, the first motorized traffic passed along the route. Segments of this original route are preserved.

The Chicago, Milwaukie and St. Paul Railroad was built across Snoqualmie Pass and along the South Fork in 1908.

Other historic period sites represent mining and logging activities. Iron-ore was mined in the vicinity of the headwaters during the 1880's - 90's. In the early 1900's, the South Fork Timber Company operated an immense mill three miles upriver from North Bend. The railroad was being constructed up the South Fork at this time. None of the sites known from these activities is listed on the National Register of Historic Places.

TIMBER: Harvest units are common on Forest Service lands along the upper slopes, but these rarely reach down into the river corridor. Logging on private lands is extensive in this drainage.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
79.7	1.060	1.052

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The lower portion of the South Fork Snoqualmie River flows through the community of North Bend, population 1,825. North Bend has traditionally been dependent upon the timber industry. The community is now a retail and service area for residents in the upper Snoqualmie Valley and is promoting its industrial development potential. Additionally, the recreation and scenic attractions of the area and the nearness to Seattle attract thousands of visitors each year. Alpine skiing, cross-country skiing, camping, hiking, hunting and fishing are available and contribute to the economy of the area.

CURRENT ADMINISTRATION: Public lands along the river are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service. These lands are in the Alpine Lakes Area under management direction found in the Alpine Lakes Management Plan.

Under the guidelines of the the Washington State Shoreline Management Act of 1971, the shoreline of the South Fork Snoqualmie has been classified by King County as:

Northern Bank: Conservancy from the National Forest boundary in Sec. 33, T.23N., R.11 E downstream to approximately the N/S centerline of the NW 1/4 of the NW 1/4 of Sec. 24, T.23N., R.8 E.

Rural from approximately the N/S centerline of the NW 1/4 of NW 1/4 of Sec. 24, T.23N., R.8 E downstream to bridge on Cedar Falls Road in Sec. 22, T.23N., R.8 E.

Conservancy from the bridge on the Cedar Falls Road in Sec. 22, T.23N., R.8 E downstream to the confluence with the Main Fork of Snoqualmie River in Sec. 33, T.24 N., R.8 E.

Southern Bank: Conservancy from the Snoqualmie National Forest boundary in Sec. 33, T.23N., R.11 E downstream to east section line of Sec. 23, T.23N., R.8 E.

Rural from the east section line of Sec. 23, T.23N., R.8 E. downstream to the bridge on the Cedar Falls Road in Sec. 22, T.23N., R.8 E.

Conservancy from the bridge on the Cedar Falls Road in Sec. 22, T.23N., R.8 E. downstream to the confluence with the Main Fork of Snoqualmie River in Sec. 33, T.24 N., R.8 E.

These classifications are applicable only to lands outside of federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes areas characterized by agricultural uses, low density residential where most urban services are not available, and areas which provide buffer zones and open space between predominantly urban areas.

The King County Comprehensive Plan has zoned the land along the South Fork Snoqualmie for Forestry Use for the area above Twin Falls. Below Twin Falls the area is zoned for Rural Use, permitting 1 home per 2.5 to 10 acres.

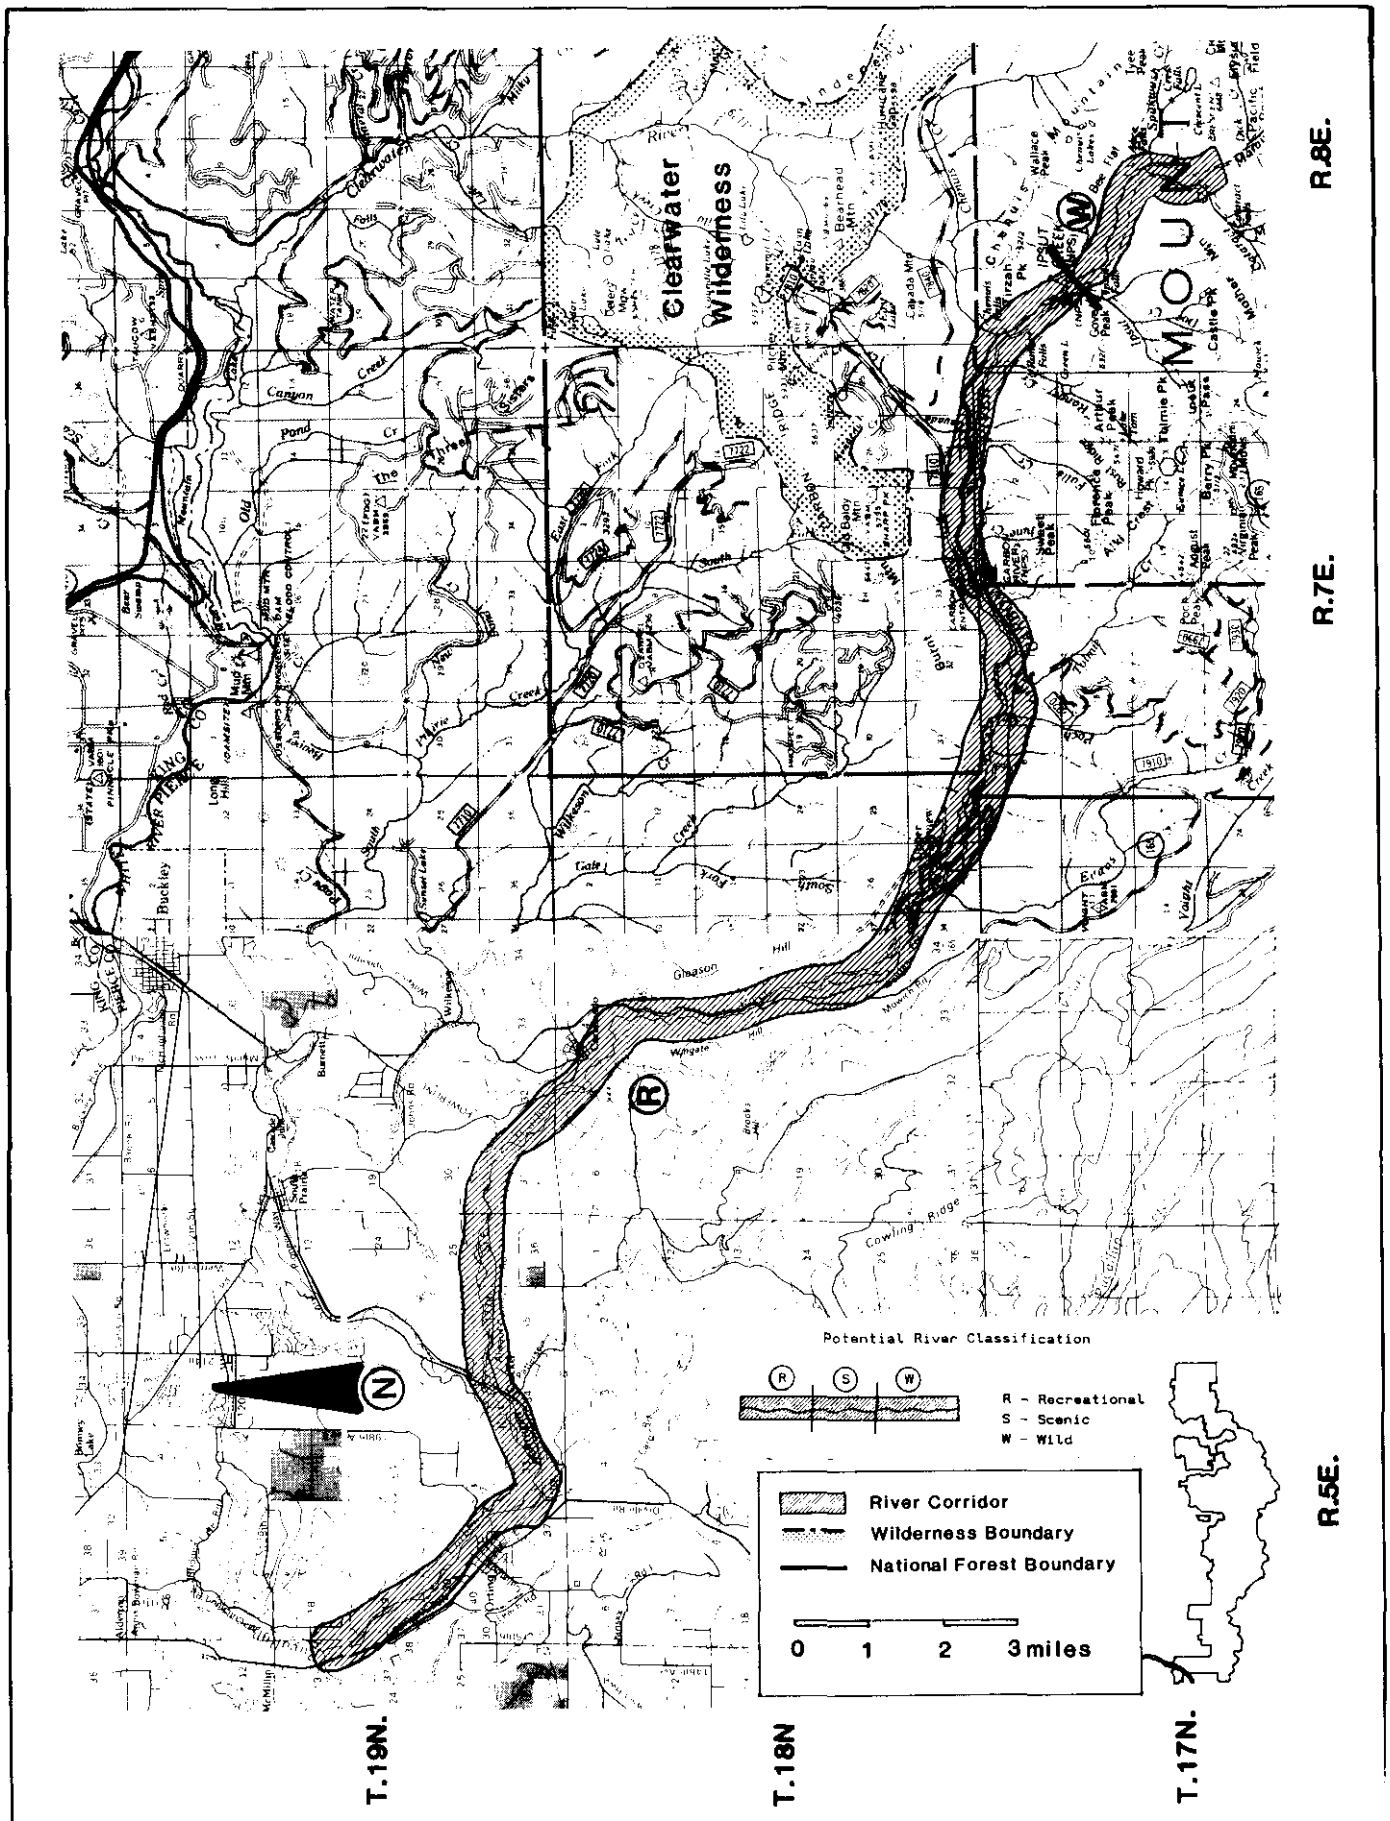
FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the South Fork Snoqualmie River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$ 2,000	$ 2,000
Costs of Implementation		12,000
Development of Management Plan		56,000
Development Costs	221,000	75,000
Operation and Maintenance Costs	177,000	15,000
Total - First Five Years	**$400,800**	**$160,700**

General administration and operation and maintenance costs are estimated to continue at $39,200 annually.

Carbon River



CARBON RIVER

Pierce County — Mt. Rainier National Park

The Carbon River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

A bill is currently in the State Legislature to designate the Carbon River, from its headwaters in Mt. Rainier National Park to its confluence with the Puyallup River, a State Scenic River.

LOCATION: From its headwaters in Mt. Rainier National Park to its confluence with the Puyallup River.

Segment 1 - Headwaters on Carbon Glacier on the northwest slopes of Mt. Rainier to Ipsut Creek (4.0 mi).

Segment 2 - Ipsut Creek to the confluence with the Puyallup River (28.4 mi).

RIVER MILEAGE:

Study:	32.4 miles
Eligible:	32.4 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

Note: This recommendation is pending evaluation by the National Park Service.

OUTSTANDINGLY REMARKABLE VALUES: The Carbon River was found to possess "Outstandingly Remarkable" values for the following: Scenic and Fisheries.

From the river, there are occasional, dramatic views of Mt. Rainier. Near the headwaters the steep gradient produces numerous cascades and waterfalls. The water course continues to flow through rapids and steep cascades and, in several places, through canyons.

Chinook, pink, chum and coho salmon spawn and rear in the river. There are also populations of dolly varden and sea-run and resident cutthroat trout.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	4.0	Not recommended	0.0
Segment 2	Recreation	28.4	Not recommended	0.0

SUITABILITY DETERMINATION:

The Carbon River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to the low amount of the total length within the National Forest. This river received little support in the response to the Draft EIS, but was listed as a suitable addition to the State Scenic River System in the 1988 Washington State Scenic River Assessment.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Rainier National Park	4.0 miles	1,280 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	1.2 miles	240 acres
Mt. Rainier National Park	5.0 miles	1,600 acres
Private	21.7 miles	7,088 acres
State	0.5 miles	160 acres
TOTAL	32.4 miles	10,368 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Even though approximately three miles of this river have been identified by the BLM as lying within an area of critical mineral potential, a review of available literature, including the Bureau of Mines MILS data, indicates that the area has no reported occurrences of locatable mineral resources. The area does have numerous reported occurrences of coal, and sand and gravel resources, some of which have produced in the past.

The BLM has classified the western 25 miles of the river as being prospectively valuable ("PV") for oil and gas resources and the eastern 5 miles as "PV" for geothermal resources. Most of the area is classified "PV" for coal, with a large portion of the classification being valuable for coal resources. Numerous occurrences of coal are reported for Sections 4, 5, 9 and 27, T.18 N., R.6 E., some of which have produced in the past. Of most interest, is the part of the river that crosses a deposit near Carbonado. This deposit is reported to contain resources of bituminous coal in numerous beds 28 inches to greater than 42 inches thick. The reserve is significant. In addition to the coal, interest in oil and gas has been expressed, and Sections 4 and 6, T.17 N., R.7 E. and Section 3, T.18 N., R.8 E. are presently encumbered and/or have been encumbered by oil and gas leases.

Based upon the available information it appears that the area has a relatively low potential for the occurrence of locatable mineral resources. No serious interest in the locatable mineral is currently being expressed. However, the area does have known coal resources and also has potential for the occurrence of oil, gas and geothermal resources. Interest in the oil and gas is currently being expressed in the maintenance of existing leases.

WATER RESOURCE DEVELOPMENT: There are no water impoundments in the river drainage. A preliminary permit for a FERC project has been granted for a location downstream from Prairie Creek on private land. The Carbon River below Tolmie Creek is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are a number of roads within the drainage, including: Fairfax Carbon Glacier Road, State Highway 165, Patterson Road, Orting Kapowsin Road and State Highway 162.

State Highway 162 parallels the river from McMillan to Crocker, where a highway bridge crosses the river at its confluence with South Prairie Creek. Highway 165 parallels the Carbon River from Carbonado to 1/2 mile south of the Fairfax Bridge. The highway crosses the river on the Fairfax Bridge. The Carbon River Road/Forest Highway 11 parallels the river from 1/2 mile south of the Fairfax Bridge to the end of the road inside Mt. Rainier National Park.

An abandoned railroad crossing traverses the river in Sec. 27, T.18 N., R. 6 E. at Fairfax.

Forest Road 7810/Copley Lake Road crosses the Carbon River near the National Park Boundary. The gabion construction of the bridge requires additional stabilization on the north side of the river. This crossing has washed out twice in the last 5 years.

Powerlines cross the river in Sec. 4, T.19 N , R.6 E. (at Carbonado)

The river has a history of flooding and is heavily channelized.

There is scattered land development around the mining towns of Fairfax and Carbonado. Farms are found in the vicinity of the town of Orting.

The Voight Salmon hatchery is located just east of Orting.

A National Park Service Campground is located at Ipsut Creek, at the end of the Carbon River Road. There are 29 sites.

The Chenius Falls Trailhead, inside Mt. Rainier National Park, is located 2 miles east of the Carbon River Entrance. The trail crosses the river.

The Moraine Park Trail, also inside Mt. Rainier National Park, begins at the Ipsut Creek Campground. The trail follows the Carbon River to its headwaters on the Carbon Glacier and then continues to Moraine Park and Mystic Lake. Portions of the this trail intersect the Wonderland Trail, which circles the base of Mt. Rainier. There is one river crossing.

The "Valley to Foothills Trail", a new "Rails to Trails" project, has been proposed. The route of the Northern Pacific Railway would become a foot trail, beginning at the confluence of the Carbon and Puyallup Rivers and ending at the town of Carbonado. This trail would parallel the Carbon River to Crocker, head north away from the river corridor along Highway 162 through South Prairie and Wilkeson, and meet the river again at Carbonado. The trail would cross the Carbon River at Crocker.

RECREATION ACTIVITIES: Except for fishing, river-based Recreation use of the Carbon River is low. Steelhead trout and coho salmon are heavily fished with sea-run cutthroat trout, dolly varden and resident trout also fished. There are above average conditions for canoeing and kayaking, except for a 4-mile stretch in the vicinity of Carbonado. Due to glacial discoloration and very cold temperatures, swimming is not practical.

The Carbon River Entrance provides campers, hikers and sightseers access to the northwest corner of Mt. Rainier National Park.

	1988 RVD'S	Projected 2000 RVD'S
Fishing, Hunting	2,000	2,880
Camping	500	750
Viewing (scenery, wildlife, driving for pleasure)	5,000	7,600
Misc. (hike, picnic, berry picking, etc.)	500	980
TOTAL	8,000	12,210

WILDLIFE AND FISHERIES: Elk, deer, bald eagles, mountain goats and various species of waterfowl are found within the Carbon River drainage.

Chinook, pink, chum and coho salmon spawn and rear as far upstream as Fairfax. Cold glacial waters and cascades limit further migration. Deep pools located in the lower river offer excellent holding and resting areas for adult salmon and provide exceptional rearing habitat. Dolly varden, and sea-run and resident cutthroat trout are also found in the river. The Washington Department of Fisheries established the Voight Creek Salmon Hatchery in 1917.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The Carbon River is fed by the Carbon Glacier on Mt. Rainier. Near the river's headwaters, the gradient is precipitous and there are numerous cascades and a few waterfalls. The narrow valley floor then broadens and the river gradient becomes moderately steep. The river channel is less confined and partially unstable with much channel splitting and some braiding. Below the town of Fairfax, side walls form a canyon with a steep gradient. There are numerous rapids and steep cascades separated by short, lesser gradient pool-riffle stretches. There is a cascade area at Carbonado followed by a 3.5 mile deep and narrow ravine. The river channel then widens and narrows intermittently with channel splitting and deep pools. The last 6 miles are a continuous series of long channel split sections down to the confluence with the Puyallup River. Twenty-two tributaries drain into the Carbon River. Water quality is discolored due to glacial runoff.

GEOLOGY: Volcanic pyroclastic and andesitic rocks compose the bedrock geology of the youthful valley. This river begins abruptly at the terminus of the Carbon Glacier at low elevation. This river is unique in that for approximately the first 15 miles the river channel is very wide and braided. It is sediment choked from the massive amount delivered by the Carbon Glacier allowing it to swing wildly throughout its channel. The valley does narrow to a deep ravine near the crossing of State Highway 165.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Carbon River and no resources are known. Localities used by Indians to practice their traditional religion exist within the river corridor.

Coal was discovered in the Carbon River area in 1862. Mining activities increased when the suitability of coal for manufacturing coke was realized. For the next 50 years, small towns (such as Carbonado, Melmont and Fairfax) located within the corridor, developed to provide housing, supplies, and services for the workers and their families. Regular rail shipments were made to the Puget Sound and San Francisco Bay markets. The market declined in 1920.

It is expected that a cultural resource inventory of historic sites within the corridor would result in the documentation of sites associated with these settlements and the mining activities.

Timber interests were growing as mining declined during the early 1900's. Several small companies used the railroad along the Carbon River to transport logs for sale to the mill in Fairfax. By 1930, much of the private timber had been removed, and by 1933, many of the companies went out of business.

TIMBER: Logging is the principal land use outside the National Park.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest lands only.

	----------ASQ----------	
	Preferred	Preferred
Total	Alternative	Alt. with
Timber	w/o W&SR	Eligible W&SR
Volume	Designation	Designation
(MMBF)	(MMBF/yr.)1/	(MMBF/yr.)1/
24.0	240	.240

1/ Based on preferred alternative with management requirements.

LIVESTOCK GRAZING: There is some grazing on private land in the lower valley and flatland areas.

SOCIO-ECONOMIC EFFECTS: The Carbon River is paralleled by trail and then by road, passing through the small communities of Carbonado, Wilkeson, Burnett, South Prairie and Orting. Increasingly inhabited by people who work in the Tacoma area, these communities were traditionally supported by farming and the forest product industries. Thousands of visitors every year seek the scenic and recreation opportunities of the area and make their contribution to the local economies.

CURRENT ADMINISTRATION: The upper 9 miles of the river are in Mount Rainier National Park which is administered by the National Park Service (NPS). The headwaters downstream to Ipsut Creek Campground are in the Mt. Rainier National Park Wilderness. Downstream from the campground to the NPS entrance headquarters, portions of the river corridor are in wilderness except for 100 feet on either side of the gravel road that parallels the river. National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

Under the guidelines of the Washington State Shoreline Management Act of 1971, approximately 50 percent of the shoreline along the Carbon River has been classified by Pierce County as Natural. The remaining shorelines are classified Conservancy or Rural. These classifications are applicable only to lands outside of federal jurisdiction within 200 feet of the ordinary high water mark. A Natural designation denotes areas characterized by the presence of some unique natural features considered valuable in their undisturbed or original condition and which are relative intolerant of intensive human use. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes shoreline areas that are characterized by agricultural uses, low density residential or areas providing open space between predominantly urban uses.

Sections 25, 26 and 27, all near the community of Crocker, are zoned for General Use by Pierce County.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the Carbon River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 10,000	
Costs of Implementation		5,000
Development of Management Plan		58,700
Operation and Maintenance Costs	250,000	
Total - First Five Years	**$260,000**	**$63,700**

General administration and operation and maintenance costs are estimated to continue at $52,000 annually.

WHITE RIVER

King and Pierce Counties — Mt. Rainier National Park

The White River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters in Mt. Rainier National Park downstream to the confluence with the Clearwater River.

Segment 1 - Headwaters at Emmons Glacier on the northeast slopes of Mt. Rainier to Huckleberry Creek (20.0 mi).

Segment 2 - Huckleberry Creek to the confluence with the Clearwater River (17.7 mi).

RIVER MILEAGE:

Study:	37.7 miles
Eligible.	37.7 miles
Forest Plan:	37.7 miles recommended for designation in preferred alternative

Note: This recommendation is pending evaluation by the National Park Service.

OUTSTANDINGLY REMARKABLE VALUES: The White River was found to possess "Outstandingly Remarkable" values for the following: Recreation, Fisheries, Wildlife and Historical/Cultural.

Trout fishing is a popular activity on the river. Good rafting exists from the West Fork Road bridge to the bridge at Bridge Camp. Campers, hikers and sightseers visit the area for access to the National Forest and Mt. Rainier National Park. There are magnificent views of Mt. Rainier from the river corridor.

Fish found in the White River include spring chinook and coho salmon, steelhead, dolly varden, rainbow and resident cutthroat trout.

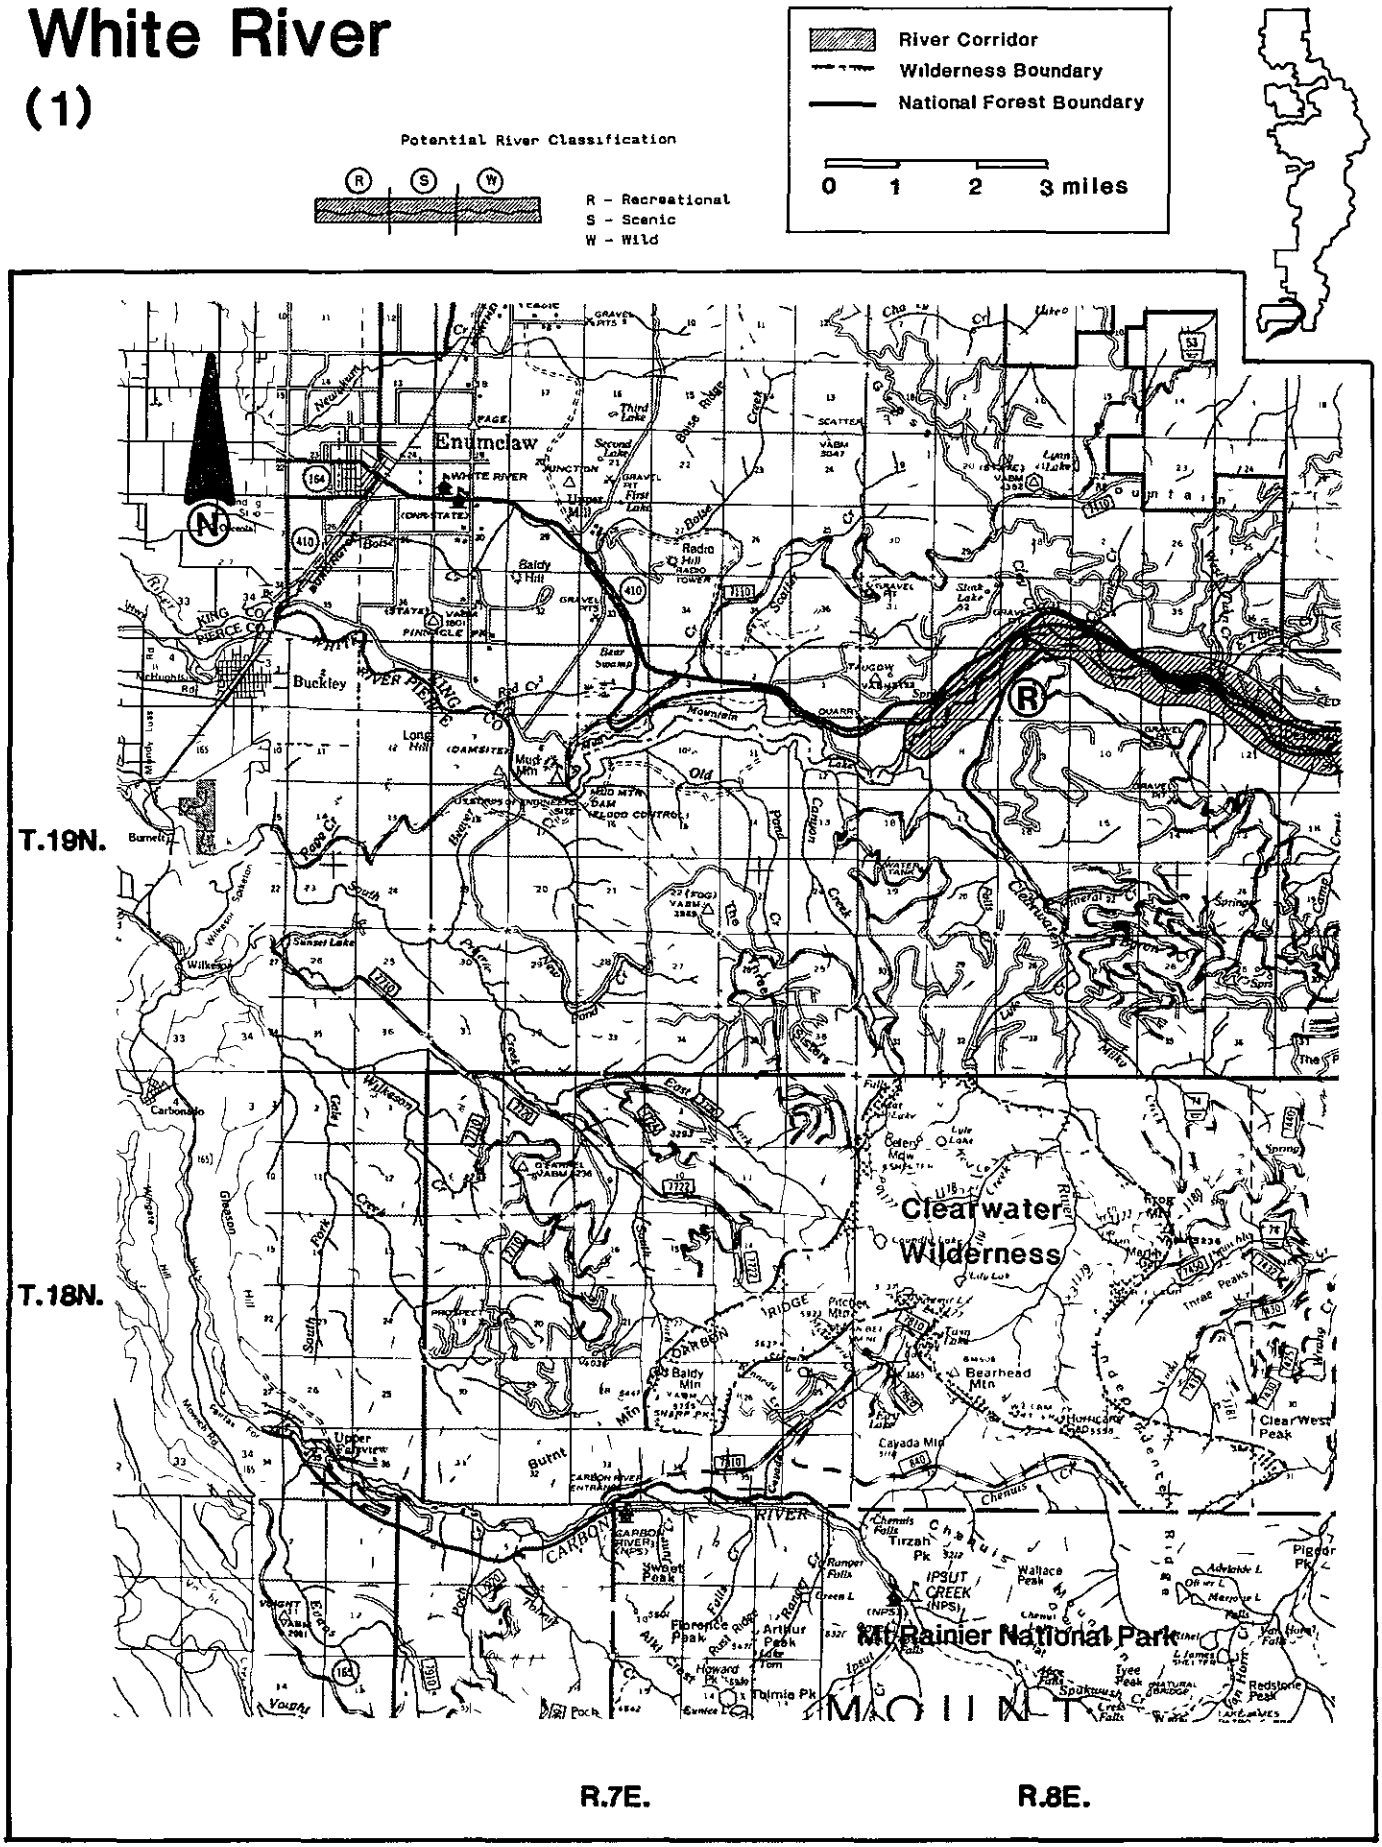
The area has excellent deer and elk winter range. Bald eagles and mountain goats are also a primary species of interest. A SOHA is centered on the river just north of Mt. Rainier National Park.

Historic period sites represent logging, recreation and Forest Service administration. During the 1930's there was a CCC camp located along the river and the construction of the Silver Creek Ranger Station was a result of that program.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Scenic	20.0	Scenic	20.0
Segment 2	Recreation	17.7	Recreation	17.7

White River
(1)



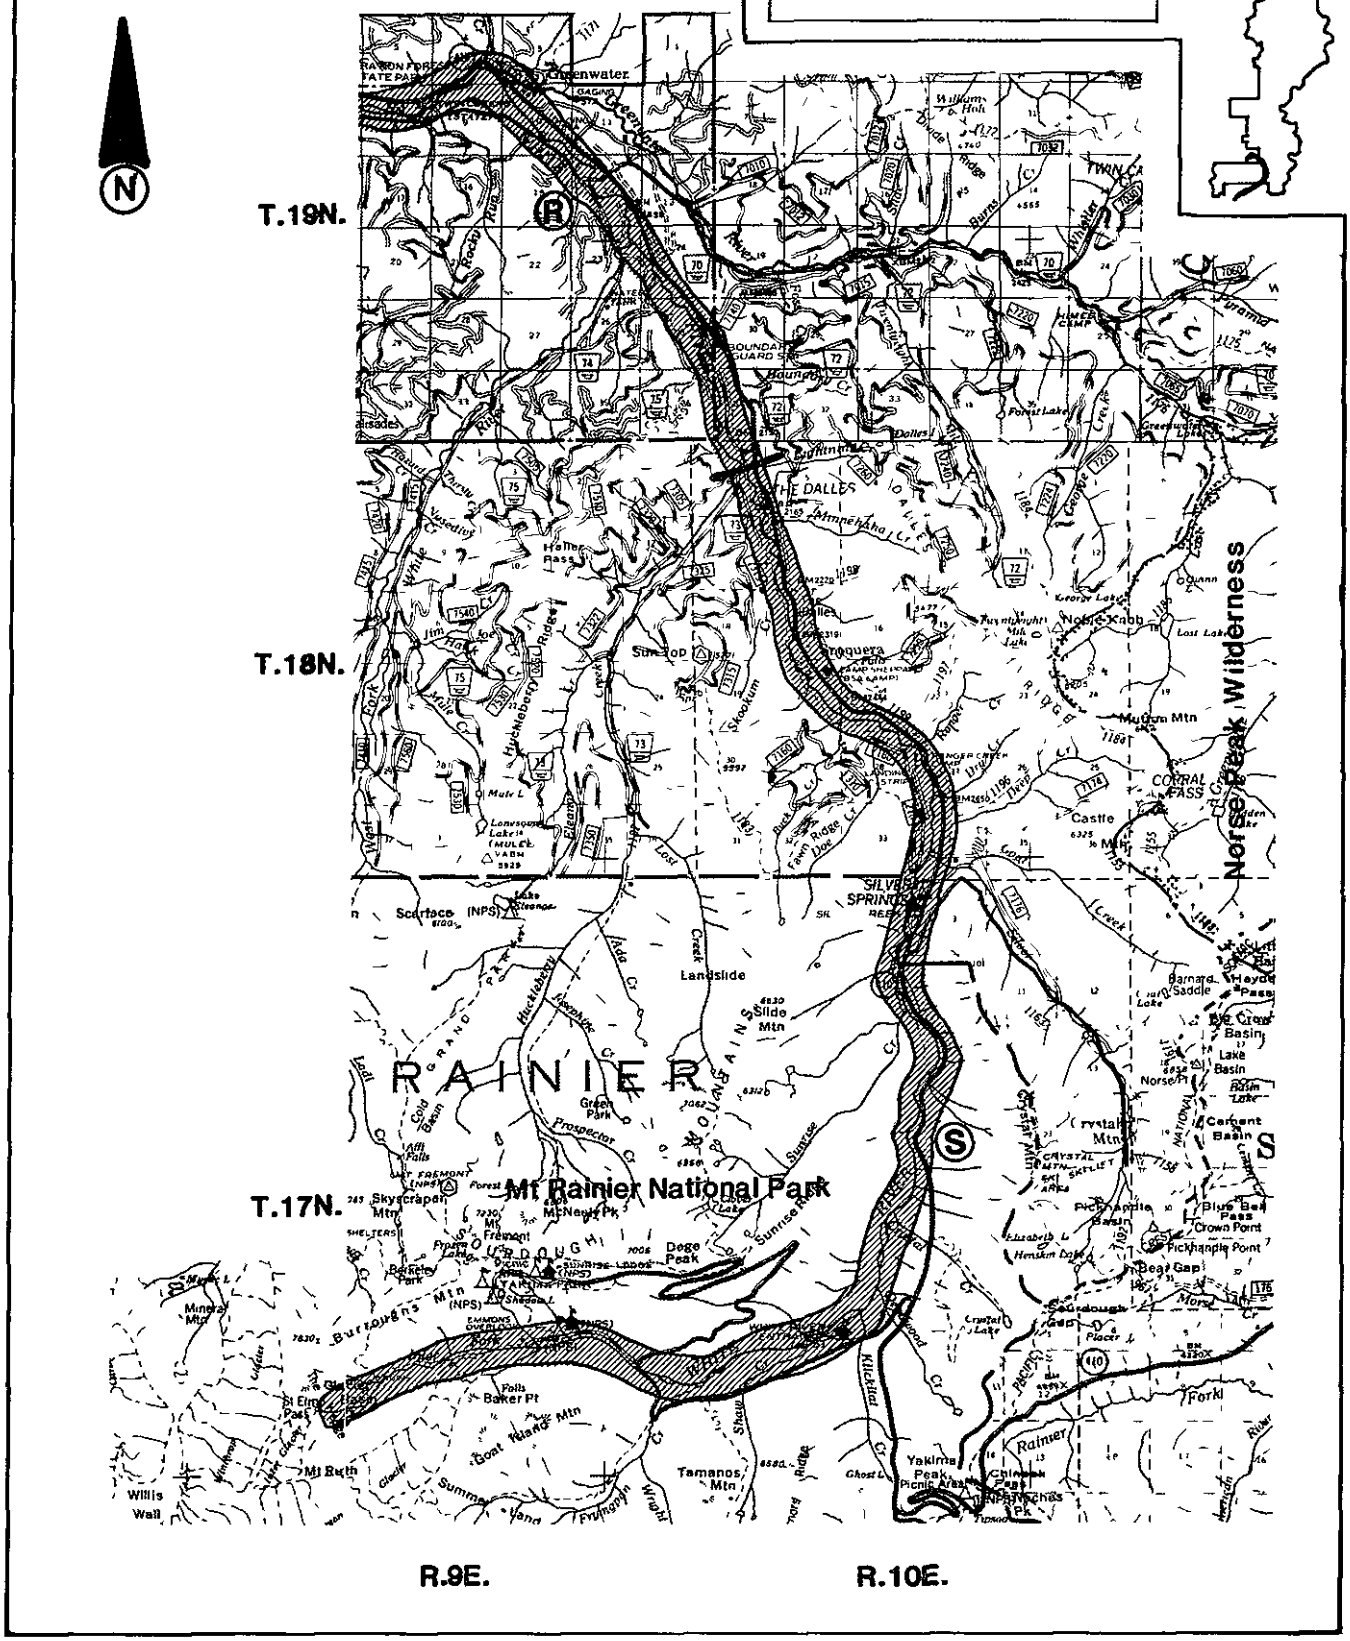
White River
(2)

Potential River Classification

R - Recreational
S - Scenic
W - Wild

River Corridor
Wilderness Boundary
National Forest Boundary

0 1 2 3 miles



SUITABILITY DETERMINATION:

The White River was found to be suitable for inclusion in the preferred alternative of the Forest Plan due its many outstandingly remarkable values, few competing resource uses, and high public support for designation. Joint Forest Service and Park Service management is recommended.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
NPS, Mt. Rainier National Park	13.3 miles	4,256 acres
Mt. Baker-Snoqualmie National Forest	6.7 miles	2,144 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.4 mile	128 acres
Private	15.9 miles	5,088 acres
State, Federation Forest State Park	1.4 miles	448 acres
TOTAL	37.7 miles	12,064 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither river segment is classified by the BLM as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates that there are clay deposits and sulfur and perlite prospects located in T.19 N., R.8 E., Sections 4, 7 and 11, and in T.19 N., R.8 E. Sections 32 and 33. The clay (alunite) deposit was first discovered in 1928 and at least 3,600 feet of diamond drilling and 4,400 feet of exploratory drilling has occurred. This deposit not only has significant potential for industrial uses, but it also represents a prime target for future precious metal exploration.

As indicated, the area has an alunite deposit. As a consequence, the western three miles has been classified as being prospectively valuable ("PV") for potassium resources. In addition, both river segments are classified as being "PV" for geothermal resources. The area is not considered to have potential for the occurrence of coal, nor is it classified "PV" for oil and gas. However, the following lands have been encumbered by oil and gas leases: T.18 N., R.10 E., Sections 5,6,7,8,17,20,21 and 34, T.19 N., R.10 E., Section 30 and T.17 N., R.10 E. Section 3.

Based upon the available information, it appears that most of the area has a relatively low potential for the occurrence of locatable mineral resources. No serious interest in the form of mining claims is currently being expressed. However, it does appear that the western five or six miles does contain known deposits of clay and possibly perlite, which may indicate a potential for the occurrence of a hydrothermal deposit of precious metals. That potential has not been appropriately evaluated. It also appears that the area has potential for the occurrence of geothermal resources. However, no interest in that resource is currently being expressed. The area is not "PV" for oil and gas but some interest has been expressed in the past with the issuance of noncompetitive leases. Whether such interest will continue is not known.

WATER RESOURCE DEVELOPMENT: Mud Mountain Reservoir extends from the confluence of the White and Clearwater Rivers downstream 5.5 miles to the Mud Mountain Dam. The reservoir is below the White River segments being considered for designation. The dam is earth core and rock-filled, and is 425 feet high and 700 feet long.
The White River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: There are numerous private roads, logging roads and Forest Service roads within the White River drainage. State Highway 410 parallels the river to the Mt. Rainier Park entrance. Park roads parallel the river to the White River Campground, 1 1/2 miles from Emmons Glacier.

Mather Memorial Parkway (State Hwy 410) has congressional designation and has been managed for recreation and viewing for pleasure.

Bridges cross the river at 6 locations.

The communities of Greenwater and Crystal Village are the only populated areas in the upper river above Mud Mountain Dam. There are approximately 180 recreation residences on private lands within the corridor.

Federation Forest State Park, 17 miles east of Enumclaw, contains 612 acres of virgin old growth forest. The park has an interpretive center depicting Washington flora and fauna, river access and a day-use area.

There are 2 National Forest campgrounds along the river. The Dalles Campground, near Minnehaha Creek, has 45 camp sites and 10 picnic sites. Silver Springs Campground has 56 camp sites and 10 picnic sites. Rip-rap is used to protect the campgrounds.

The Buck Creek Trail #1169 begins on State Highway 410, 28 miles from Enumclaw. The trail crosses the White River over a cable suspension bridge.

The Skookum Flats Trail, #1194, follows the west side of the White River for 8.2 miles. The trail begins on the Huckleberry Creek Road #73 and ends at the Mt. Rainier National Park Boundary

The Dalles Nature Trail, #1204, and the Dalles River Trail, #1204-A, begin at Dalles Campground. The Nature Trail is within the campground and is a barrier-free trail open to wheelchairs. The River Trail follows the White River from the campground to the Huckleberry Creek Road #73.

The White River Trail, #1199, parallels Highway 410 for 6 miles, beginning at Corral Pass Road, #7174, and heading downhill. The trail is on the opposite side of the road from the river.

Rearing channels have been constructed to protect fish habitat.

RECREATION ACTIVITIES: Trout fishing is a popular activity on the river. Good rafting exists from the West Fork Road bridge to the bridge at Bridge Camp. However, the remainder of the river is too shallow in summer for use. There is incidental canoeing and kayaking use from the West Fork confluence to the Old Pond Creek just above Mud Mountain Dam.

There is moderate use along the river by campers and picnickers. Some ORV use occurs on the gravel bars. Many hikers and sightseers visit to the area to use the extensive trail system and for views of wildflowers, glaciers and Mt. Rainier.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power, nonpower)	500	825
Fishing, Hunting	500	720
Camping	100,000	150,000
Viewing (scenery, wildlife, driving for pleasure)	500,000	760,000
Misc. (hike, picnic, berry picking, etc.)	50,000	98,000
TOTAL	651,000	1,009,545

WILDLIFE AND FISHERIES: The area has extensive winter range for black-tailed deer and Roosevelt elk. Bald eagles and mountain goats are also primary species of interest. A SOHA is centered on the river just north of Mt. Rainier National Park.

Salmon are transported and released 10 miles above the dam near Greenwater. Spring chinook and coho salmon spawn in the shallow, slower moving riffle areas. Steelhead, dolly varden, rainbow and resident cutthroat trout also inhabit the waters. Major limiting factors to increased salmon production include flooding, heavy silt loads, low summer flows, limited food supply in glacial watersheds and extremely cold water temperatures.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The White River is a fast-flowing glacial stream, fed by the Emmons and Fryingpan Glaciers on Mt. Rainier. The river displays its mountainous origins with heavy boulders, deep-cut banks and a meandering channel with many splits. The river flows from the snowfields to a narrow valley floor with a steep, precipitous gradient. Near the community of Greenwater, the gradient moderates and the valley floor broadens slightly.

The river channel is unstable with numerous splits and braiding. The river contains falls, rapids, cascades and riffles. The gradient is approximately fifty feet per mile. There are 33 tributaries to the White River.

GEOLOGY: Andesitic, basaltic, and associated pyroclastic rocks comprise the bedrock geology of the valley.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the White River and no prehistoric resources are recorded. The lack of sites may reflect survey patterns rather than lack of use. Some prehistoric sites may be expected to be associated with the use of Naches Pass as a travel and trade route. When documented during the historic period, this route followed the White River for a portion of its length. Prehistoric sites have been found along the river below the Wild and Scenic River corridor.

In the late 1800's, the upper reaches of the White River were actively explored for gold and quartz. Access to these claims were by way of a horse trail that followed the river.

Historic period sites represent logging, recreation and Forest Service administration. During the 1930's there was a CCC camp located along the river. The construction of the Silver Creek Ranger Station was one result of the program. This historic ranger station is still visible from the highway and will be evaluated for inclusion on the National Register of Historic Places.

TIMBER: Outside of Mt. Rainier National Park, timber harvesting is a major land use activity. Extensive clearcut areas cover the area.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
97.5	.056	.052

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The White River with its headwaters in Mt. Rainier National Park at Emmons Glacier, is paralleled by State Highway 410 for much of its length The highway passes through Greenwater, Buckley and Enumclaw. Logging and tourism help support the local economies. Many residents also find employment in the Tacoma and Seattle metropolitan areas.

Visitors come to this area to enjoy sightseeing in Mt. Rainier Park and the National Forest. Other recreation opportunities include climbing, hiking, skiing at Crystal Mountain Ski Area, cross-country skiing, ORV and horse use, fishing, hunting and camping.

CURRENT ADMINISTRATION: From its headwaters downstream 13.3 miles, the White River flows through Mount Rainier National Park, administered by the National Park Service Some of the river corridor is classified Mt. Rainier National Park Wilderness where the corridor is beyond 200 feet of the road that goes to Sunrise Lodge. From there, the river flows through Mt. Baker-Snoqualmie National Forest, USDA Forest Service

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the White River has been classified as:

> Conservancy from the National Forest Boundary to the community of Greenwater
>
> Intermingled areas of Conservancy and Rural from the community of Greenwater to the confluence with the Clearwater River.

These classifications are applicable only to lands not under federal jurisdiction and within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development. A Rural designation denotes shoreline areas characterized by agricultural uses, low density residential where most urban services are not available and areas which provide buffer zones and open space between predominantly urban areas.

The north bank of the river lies in King County and the south bank in Pierce County. The King County Comprehensive Plan has zoned the land along the north shore of the White River corridor, outside of federal jurisdiction, for Forestry Use. Pierce County has zoned land along the south shore for General Use.

FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

The following are expected funding requirements for the White River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$ 2,000
Costs of Implementation		10,000
Development of Management Plan		60,800
Development Costs	119,000	
Operation and Maintenance Costs	419,500	
Total - First Five Years	**$539,500**	**$72,800**

General administration and operation and maintenance costs are estimated to continue at $84,500 annually.

LAND ALLOCATION WITHIN RECOMMENDED WILD AND SCENIC RIVER:

This river is recommended for designation under the Wild and Scenic Rivers Act. The following lists the Forest Plan management emphasis allocations for the preferred alternative. (Note: This applies to lands administered by the National Forest Service.)

	Recommended River Classification	Management Emphasis	Acres
Segment 1	Scenic	Special Area - Mather Memorial Parkway	2,724
		Pine martin/pileated woodpecker habitat	42
Segment 2	Recreation	Scenic Corridor (Middleground)	42
		Special Area - Mather Memorial Parkway	211

CLEARWATER RIVER

Pierce County

The Clearwater River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987 Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From its headwaters on Bearhead Mountain in the Clearwater Wilderness to its confluence with the White River.

Segment 1 - The headwaters in the Clearwater Wilderness on Bearhead Mountain in the NW 1/4 of Section 28, T 18 N., R.8 E. to the Clearwater Wilderness boundary (3.6 mi).

Segment 2 - The Clearwater Wilderness boundary to the confluence with the White River (6.2 mi).

RIVER MILEAGE:

Study·	9.8	miles
Eligible:	9.8	miles
Forest Plan:	0 0	miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Clearwater River was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Wildlife

The river corridor supports an extensive black-tailed deer and Roosevelt elk winter range. Spotted owls are found in the upper river drainage within the wilderness boundary.

Chinook and coho spawn and rear in the Clearwater Resident cutthroat and rainbow trout populations are also found.

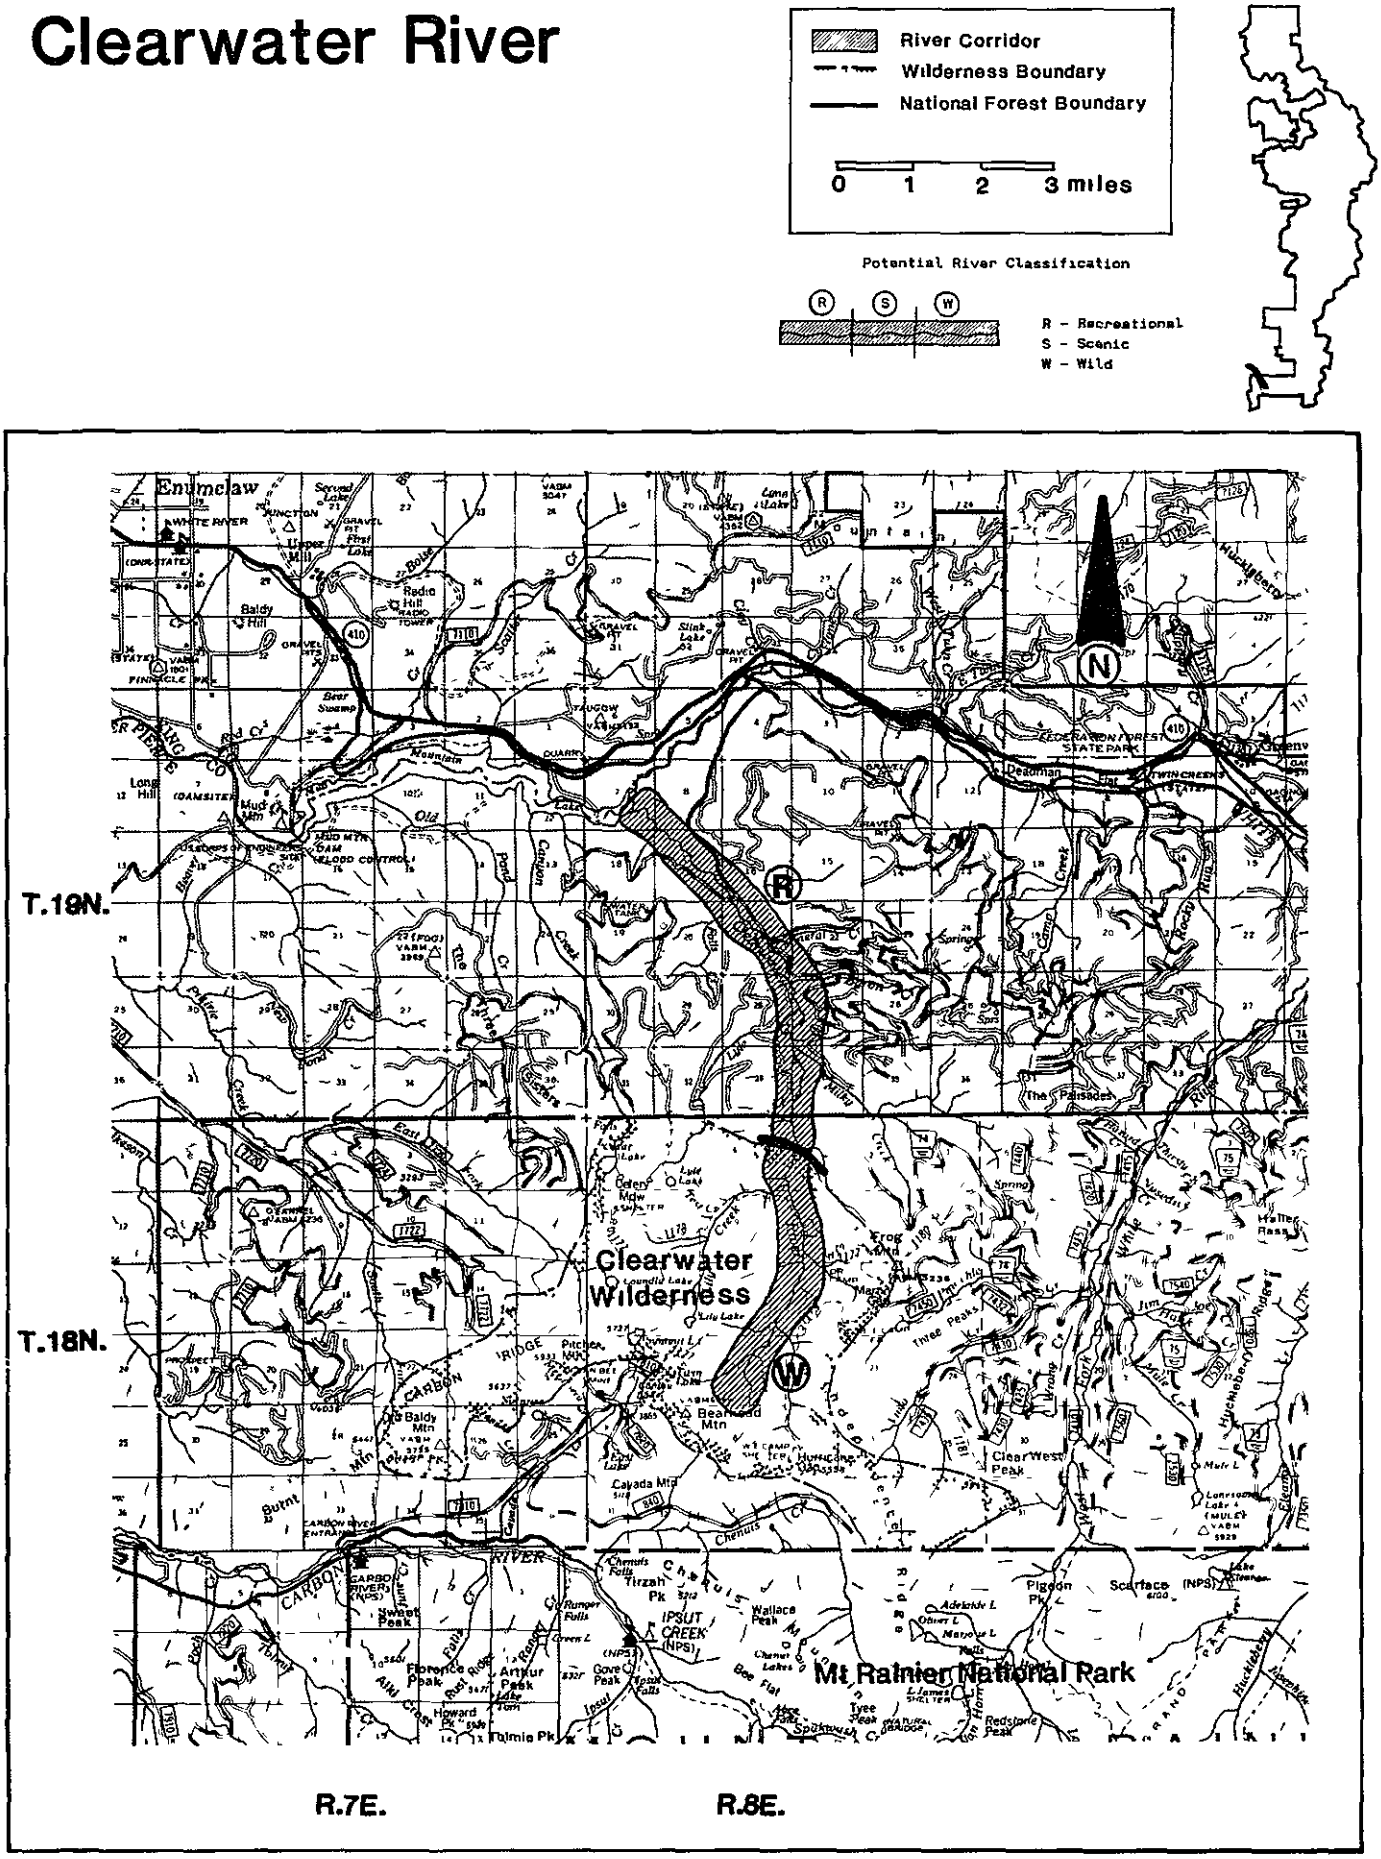
POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	3.6	Not recommended	0.0
Segment 2	Recreation	6.2	Not recommended	0.0

SUITABILITY DETERMINATION:

The Clearwater River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to the large amount of private ownership in the river corridor and low public interest. Wilderness designation protects the river inside of the National Forest.

Clearwater River



LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Clearwater Wilderness - 3.6 mi)	3.6 miles	1,152 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	0.4 mile	100 acres
Private	5.8 miles	1,884 acres
TOTAL	9.8 miles	3,136 acres1/

1/Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: The southern five miles, most of which lies in the Clearwater Wilderness area, have been classified by the BLM as an area of critical mineral potential. A review of available literature, including the Bureau of Mines MILS data, indicates that the area has no reported locatable mineral resources. BLM mining claim recordation data indicates that none of the area is currently encumbered by unpatented mining claims.

The north 1 mile of the river is classified by the BLM as prospectively valuable ("PV") for alunite (potassium-bearing clay) and the entire river is classified "PV" for geothermal resources. This may indicate a potential for the occurrence of precious metal resources. None of the area is currently encumbered by mineral leases or lease applications and no interest in those resources is currently being expressed.

WATER RESOURCE DEVELOPMENT: No water impoundments occur along the river. The Clearwater River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: A private forest road parallels the river. There are jeep trails and additional roads in the area. The private road crosses the Clearwater River approximately 2 1/4 miles south of its confluence with the White River.

There are no homes, farms or developed campgrounds along the river.

The Clearwater Trail #1178 crosses the Clearwater above Lily Creek.

RECREATION ACTIVITIES: There is a moderate amount of dispersed recreation use along the river. Steelhead, dolly varden, rainbow and cutthroat trout are frequently fished. There is limited kayaking from the private road bridge to the confluence with the White River.

	1988 RVD'S	Projected 2000 RVD'S
Misc. (hike, picnic, berry picking, etc.)	200	400

WILDLIFE AND FISHERIES: The river corridor supports an extensive black-tailed deer and Roosevelt elk winter range outside the wilderness. Spotted owls are found in the upper river drainage within the wilderness boundary.

Salmon are transported and released into the White River 10 miles above the dam near Greenwater. Adult chinook and coho salmon move downstream and into the Clearwater River. They have been observed as far as 5 miles up the Clearwater. Resident cutthroat and rainbow trout inhabit the entire drainage.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: The Clearwater River originates from springs and natural runoff on Bearhead Mountain and descends through a narrow, steep, heavily forested valley. In the lower 4 miles, the valley gradually broadens and the gradient moderates. Heavy rubble predominates with considerable angular rock and gravel in the lower portions of the river. There are several cascades in the river and a number of falls and cascades in the tributaries. Fourteen tributaries drain into the Clearwater River

The Clearwater River is listed by the State Department of Ecology as a "River of Statewide Significance" based on water volume. The water quality is excellent.

GEOLOGY: The area is dominated by andesitic and associated pyroclastic rocks, with some granitic intrusions occurring in the headwaters area. Most of the valley is V-shaped, but does broaden somewhat as it leaves the Forest.

CULTURAL RESOURCES: No systematic cultural resource surveys have been made of the Clearwater River and there are no known resources. No known locations used for traditional religious practices are within the potential Wild and Scenic River corridor.

TIMBER: Logging is the principal activity outside of the wilderness. On private lands, there are some areas with extensive clearcuts.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	----------ASQ----------	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt with Eligible W&SR Designation (MMBF/yr.)1/
6.9	025	.025

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The Clearwater River flows into the White River approximately 8 1/2 miles east of the town of Enumclaw, near State Highway 410. Easy access to Mt. Rainier National Park, scenic drives, camping opportunities and numerous hiking trails attract visitors who help to boost the economies of communities such as Enumclaw (population 5,427) and Buckley (population 3,143). These communities rely upon the forest product industry, farming and tourism. Many residents of the area are employed in the Tacoma or Seattle metropolitan areas and commute daily.

CURRENT ADMINISTRATION: The Clearwater River originates and flows through 3 1/2 miles of the Clearwater Wilderness. The wilderness plus other National Forest lands are administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.

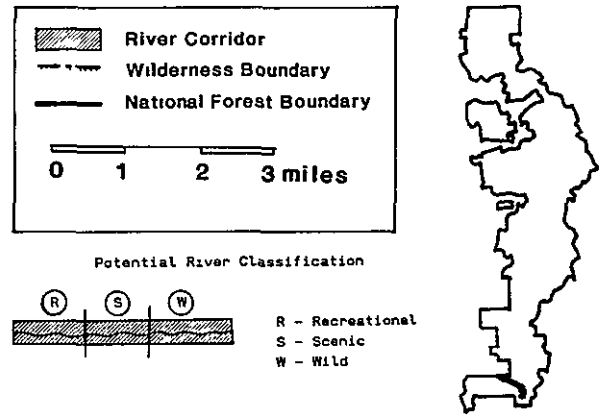
FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

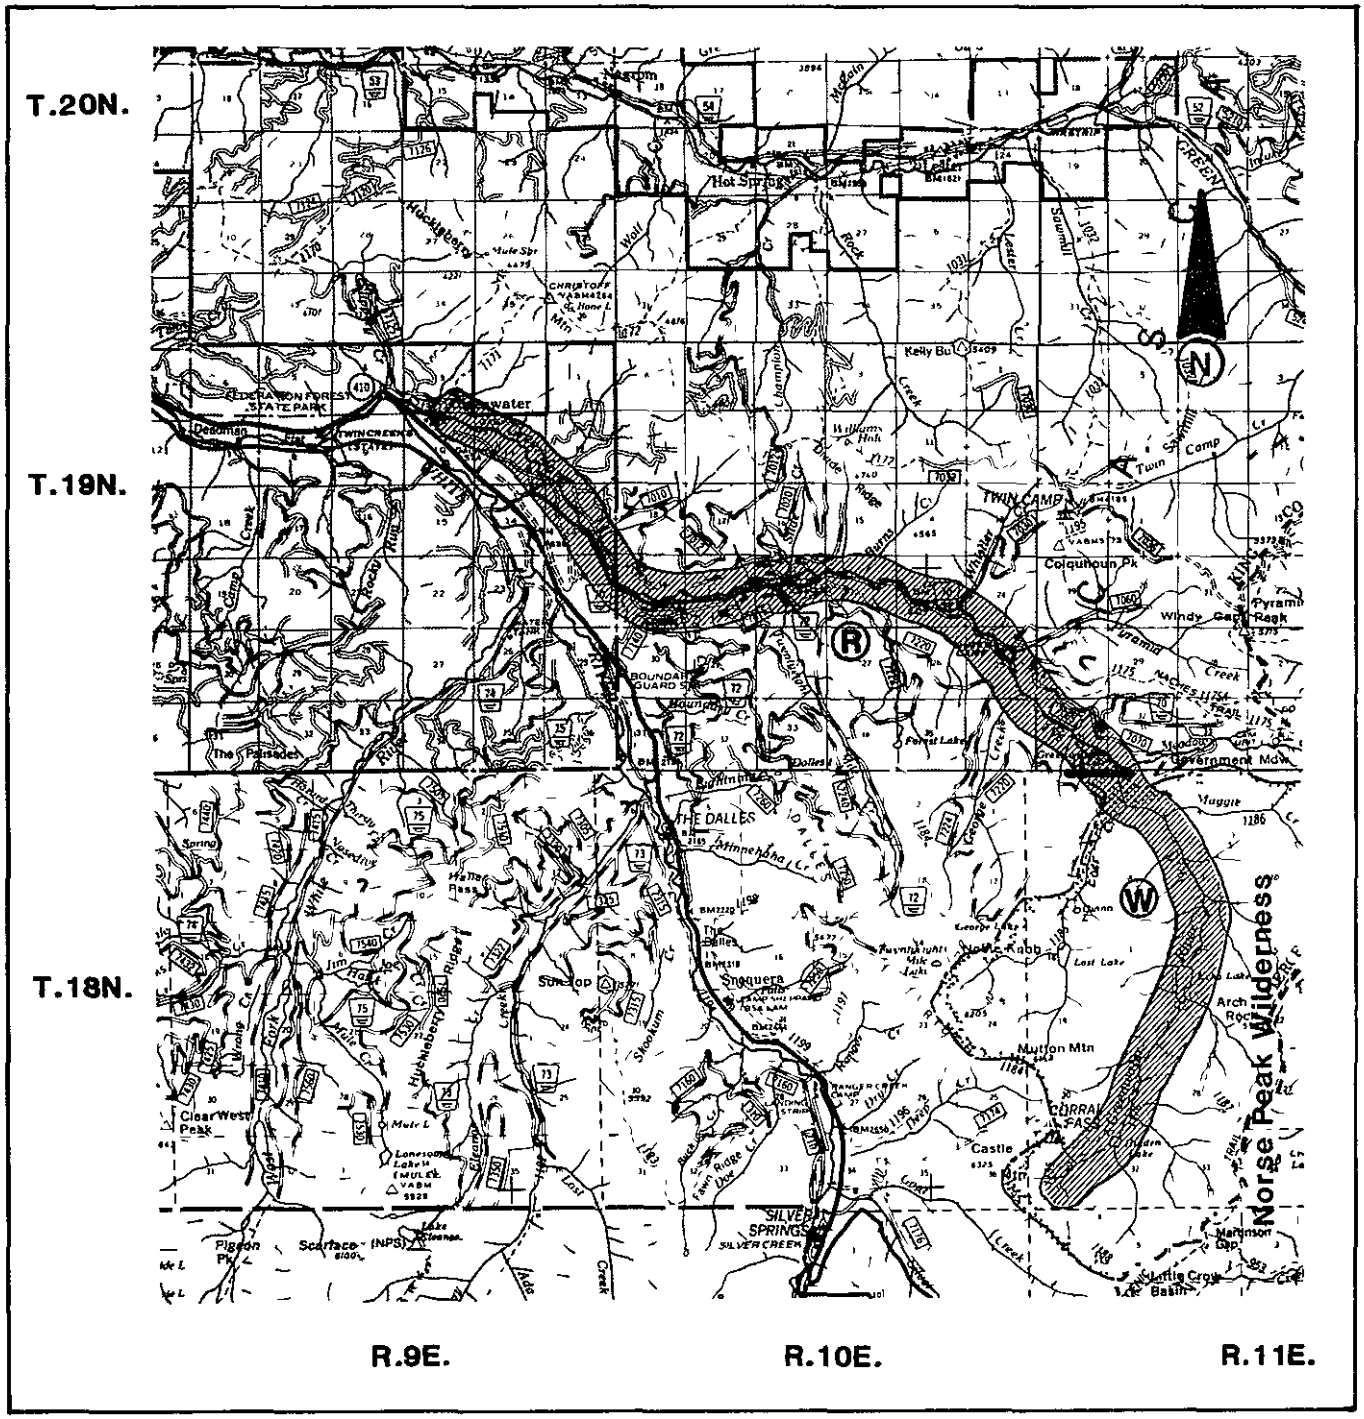
The following are expected funding requirements for the Clearwater River for the next five years:

	Expected Expenses Independent of Designation	Addit. Expenses with Designation
General Administration	$ 1,000	$ 1,000
Costs of Implementation		2,000
Development of Management Plan		15,100
Development Costs	70,000	
Operation and Maintenance Costs		
Total - First Five Years	**$71,000**	**$18,100**

General administration and operation and maintenance costs are estimated to continue at $400 annually.

Greenwater River





GREENWATER RIVER

Pierce County

The Greenwater River was studied for potential Wild and Scenic River designation by the MBS in conjunction with the Forest Planning process. The study included an eligibility and suitability assessment. The DEIS and Draft Plan were issued December, 1987. Public and other agency comment to the DEIS led to reevaluating eligibility and suitability.

LOCATION: From the headwaters on Castle Mountain to the confluence with the White River, near the community of Greenwater.

Segment 1 - Headwaters on Castle Mountain in the SW 1/4 of Sec. 5, T.17 N., R.11 E. to the Norse Peak Wilderness boundary (8.4 mi).

Segment 2 - Norse Peak Wilderness boundary to the confluence with the White River (13.0 mi).

RIVER MILEAGE:

Study:	21.4 miles
Eligible:	21.4 miles
Forest Plan:	0.0 miles recommended for designation in preferred alternative

OUTSTANDINGLY REMARKABLE VALUES: The Greenwater River was found to possess "Outstandingly Remarkable" values for the following: Fisheries and Historical/Cultural.

The Greenwater River is one of the principal spawning areas for spring chinook. Also found are coho salmon, eastern brook trout and resident cutthroat and rainbow trout.

A historic cross-country travel route through Naches Pass follows A PORTION OF the Greenwater. Other historic sites represent early homestead claims.

POTENTIAL AND RECOMMENDED CLASSIFICATION:

Segment	Potential Classification	Miles	Recommended Classification in Preferred Alt.	Miles
Segment 1	Wild	8.4	Not recommended	0
Segment 2	Recreation	13.0	Not recommended	0

SUITABILITY DETERMINATION:

The Greenwater River was found to be not suitable for inclusion in the preferred alternative of the Forest Plan due to high competing resource values.

LANDOWNERSHIP:

Segment 1	River Miles	Corridor Acres
Mt. Baker-Snoqualmie National Forest (Norse Peak Wilderness - 8.4 mi)	8.4 miles	2,688 acres
Segment 2		
Mt. Baker-Snoqualmie National Forest	8.5 miles	2,720 acres
Private	4.5 miles	1,440 acres
TOTAL	21.4 miles	6,848 acres1/

1/ Acres based on a 1/4 mile corridor on each side of the river.

MINERAL AND ENERGY RESOURCE ACTIVITIES: Neither river segment is classified by the BLM as an area of critical mineral potential nor encumbered by unpatented mining claims. A review of available literature, including the Bureau of Mines MILS data, indicates that none of the area has reported occurrences of locatable mineral resources.

The BLM has classified the entire river as being prospectively valuable ("PV") for geothermal resources. None of the area is considered to have potential for the occurrences of other leasable mineral commodities. Even though it is not classified "PV" for oil and gas, the following lands have been encumbered by noncompetitive oil and gas leases, all of which have terminated: T.18 N., R.11 E. Sections 5,9,29 and 32, and T.19 N., R.10 E., Sections 20,22 and 24.

Based upon available information, it appears that the area has a relatively low potential for the occurrence of locatable mineral resources. No interest in such resources is currently being expressed. The area does have potential for the occurrence of geothermal resources and some of the area has been encumbered by oil and gas leases in the past. However, no interest is currently being expressed in those resources.

WATER RESOURCE DEVELOPMENT: There are no water impoundments on the river. The Greenwater River is classified as "Protected" from hydropower development by the Northwest Power Planning Council.

TRANSPORTATION, FACILITIES AND OTHER DEVELOPMENTS: The area is served by Forest Road 70 and several private logging roads. They cross and recross the river through "checkerboard" ownership to Meadow Creek. There are plan to pave Forest Road 70 in 1989.

Highway 410 crosses above the confluence with the White River at the community of Greenwater. In addition, the Greenwater is crossed three times by other roads.

The community of Greenwater is the only populated area. Except for a few summer homes along the river banks, there is little development.

There are many dispersed sites, but no developed campgrounds along the river.

The Naches Wagon Road Trail #1175 begins near the intersection of Forest Roads 70 and 7060. The trails heads over Naches Pass into the Wenatchee National Forest.

The Echo Lake Trailhead #1176 is also located at the intersection of Forest Roads 70 and 7060. The trail parallels the river past Greenwater Lakes to Echo Lake. The trail then continues up the Greenwater River to Hidden Lake, before heading uphill to Corral Pass. There are numerous dispersed campsites along the trail.

Portions of the river are channelized to stabilize a meandering river for the purpose of improving salmon rearing and spawning.

RECREATION ACTIVITIES: There is heavy dispersed camping and ORV use along the river. Many of the sites are accessed by hiking along the river.

Canoeing and kayaking use occurs sporadically along the lower 6 miles. There is swimming and wading during late summer. Steelhead, resident rainbow and cutthroat trout fishing is extremely popular.

	1988 RVD'S	Projected 2000 RVD'S
Boating (power and nonpower)	500	825
Waterplay (swim, wade)	4,000	6,000
Fishing, Hunting	2,000	2,880
Camping	45,000	67,500
Viewing (scenery, wildlife, driving for pleasure)	2,000	3,040
Misc. (hike, picnic, berry picking, etc.)	10,000	19,600
TOTAL	63,500	99,845

WILDLIFE AND FISHERIES: Elk, deer, eagles, great egrets, and various waterfowl present. There is extensive winter range for black-tailed deer and Roosevelt elk.

Small to moderate numbers of coho populate the Greenwater. The river is one of the principal spawning areas for spring chinook in the White River drainage system. Adult salmon swim upstream as far as Burns Creek, where steep gradients and cascades block further access. Eastern brook trout and resident cutthroat and rainbow trout inhabit the entire river system. Logging activity in the drainage has reduced streamside cover and increased the rate of siltation.

STREAMFLOW, GRADIENT AND VALLEY PROFILE: Along the upper 12 miles, the river drops steeply and rapidly. There are numerous cascades, small lakes and falls above George Creek. Below Burns Creek the gradient moderates and the channel takes a more winding course toward the community of Greenwater. A few stretches have numerous channel splits. Over the lower four miles, the river flows through a relatively broad, flat valley with good pool-riffle balance.

The river bottom is composed primarily of bedrock and boulders. Thirty tributaries flow into the Greenwater River.

GEOLOGY: Andesitic, basaltic, and associated pyroclastic rocks comprise the bedrock geology of this area. Most of the valley is V-shaped but broadens somewhat during the last 5 miles or so.

CULTURAL RESOURCES: No systematic archaeological survey has been made of the Greenwater River. However, information is available from a number of project surveys. Evidence of use during the prehistoric period is present, but not abundant within the Wild and Scenic River corridor. The lack of sites is believed to represent survey patterns rather than lack of use. Prehistoric artifacts are thought to be associated with a cross-Cascade travel route through Naches Pass. This route was used during the historic period and followed a portion of the Greenwater.

The first non-Indian use of the Naches Pass Trail was probably by members of the Hudson's Bay Company in the 1830's. Efforts to establish a wagon road began in 1850 and continued for several years. In 1853, the historic immigrant wagon party made its way across Naches Pass, dropping into the Greenwater Valley and crossing the river 16 times. Portions of the trail are still visible and it is under consideration for inclusion on the National Register of Historic Places. It is currently listed on the State Historical Register.

Other historic sites represent early homestead claims, some of which were made for the financial gain of timber investors. Many were abandoned by 1910 with remains of some of the sites still found within the river corridor.

TIMBER: Logging is a principal activity with some areas having been extensively clearcut outside the Wilderness.

The following table describes total timber volume and annual sale quantity (ASQ) in millions of board feet for National Forest system lands only:

	ASQ	
Total Timber Volume (MMBF)	Preferred Alternative w/o W&SR Designation (MMBF/yr.)1/	Preferred Alt. with Eligible W&SR Designation (MMBF/yr.)1/
46.4	2.748	2.532

1/ Based on preferred alternative with management requirements.

SOCIO-ECONOMIC EFFECTS: The Greenwater River passes through a series of lakes, which are popular hiking and fishing destinations. Outside the wilderness area, the river is paralleled by roads to its confluence with the White River at Greenwater (pop. 100). Greenwater gains its economic support from the timber industry and by providing services to the many visitors who come to enjoy the many recreation opportunities in the National Forest and Mt. Rainier National Park.

CURRENT ADMINISTRATION: The upper 8 miles of the river is within the Norse Peak Wilderness. The wilderness and other National Forest lands are *administered by the Mt. Baker-Snoqualmie National Forest, USDA Forest Service.*

Under the guidelines of the Washington State Shoreline Management Act of 1971, the shoreline of the Greenwater River has been classified as Conservancy by King and Pierce Counties. This classification is applicable only to non-federal lands within 200 feet of the ordinary high water mark. A Conservancy designation denotes shoreline areas which are primarily free from intensive development.

The land along the north shore of the Greenwater River, outside of federal jurisdiction, is zoned by King County for Forestry Use. The land along the south shore is zoned by Pierce County for General Use.

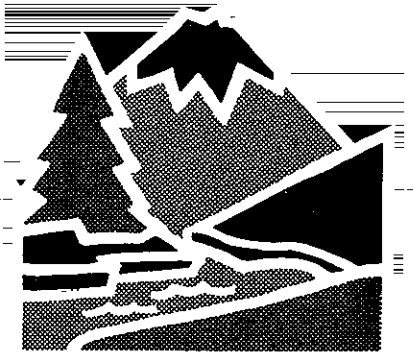
FUNDING NEEDS IF CLASSIFIED AS A WILD AND SCENIC RIVER:

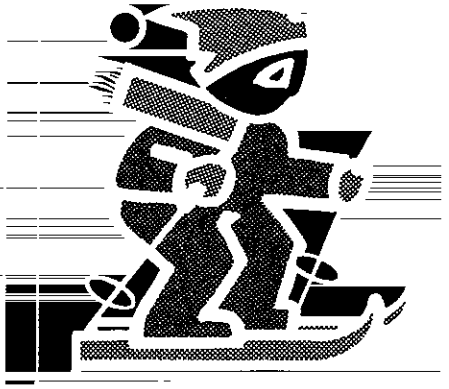
The following are expected funding requirements for the Greenwater River for the next five years:

	Expected Expenses Independent of Designation	**Addit. Expenses with Designation**
General Administration	$150,000	
Costs of Implementation		50,000
Development of Management Plan		22,500
Development Costs		120,000
Operation and Maintenance Costs	30,000	30,000
Total - First Five Years	**$180,000**	**$177,500**

General administration, operation and maintenance costs are estimated to continue at $42,000 annually.

Appendix





APPENDIX F

SELECTION OF HARVEST CUTTING METHOD

Harvest cutting methods include both even-aged and uneven-aged silvicultural systems. Even-aged harvest cutting methods (silvicultural treatment methods) generally include clearcutting, shelterwood cutting, and seedtree cutting. Uneven-aged harvest cutting methods (silvicultural treatment methods) generally include individual tree selection and group selection cutting. The intent of this appendix is to document the rationale for selection of the broad harvest cutting methods (even-aged or uneven-aged) to be applied on the Mt. Baker-Snoqualmie National Forest. The specific harvest treatment methods (such as clearcutting, seedtree cutting, or group selection) will be selected on a site specific basis as identified in project-level environmental analyses or in silvicultural prescriptions written or approved by certified silviculturists.

EVEN-AGED VERSUS UNEVEN-AGED SELECTION CRITERIA

The criteria used for selection of harvest cutting methods were developed using selection criteria identified in the Regional Guide for the Pacific Northwest Region (1984), as well as direction provided in 36 CFR 219.27 (b) for management prescriptions that involve manipulation of tree cover. A brief description of the criteria follows. These descriptions are intended as a guide; refer to the regulations and Regional Guide for more precise interpretations.

Selection Criteria From the Regional Guide

1. The selected method must permit the production of a volume of marketable trees sufficient to utilize all trees that meet utilization standards and are designated for harvest.

2. The selected method must permit use of a logging method which can remove designated trees without excessive damage to the residual stand and while meeting other established land management objectives. Table 3-1 in the Regional Guide displays the compatibility of logging systems with common harvest cutting methods. Generally, ground based logging methods, helicopters, and cable methods using slack pulling carriages are appropriate for all harvest methods while cable methods without slack pulling carriages and balloons are appropriate only for clearcuts.

3. The selected harvest method must be capable of providing special conditions that are required to meet resource management objectives. Table 3-2 in the Regional Guide displays commonly used harvest methods which achieve desired forest character. Generally, both even-aged and uneven-aged methods can meet desired forest character with the exception of a mosaic of forest and opening and maximum wildlife species diversity. Here, uneven-aged methods are not applicable.

4. The selected method must permit control of vegetation to establish desired numbers and rates of growth of trees as well as other vegetation needed to achieve special management objectives. Tables 3-3 and 3-4 in the Regional Guide outline these harvest cutting methods. Generally, both even-aged and uneven-aged methods can be used in vegetation zones occurring on the MBS; however, uneven-aged methods are not applicable for wildlife forage production or optimum tree seedling and sapling growth.

5. The selected method must promote a stand structure and species composition which minimizes serious risk from insects, disease, animal damage, and wildfire and will allow treatment of existing insect, disease and fuel conditions. Table 3-5 in the Regional Guide displays harvest cutting methods favorable to the reduction and treatment of these agents. Generally, uneven-aged methods are not applicable where dwarf mistletoe and root disease present serious risks.

6. The selected method must meet multiple-use management objectives identified in the Regional Guide and Forest Plan.

Selection Criteria From 36 CFR 219.27(b)

The seven criteria identified in 36 CFR 219.27(b) which direct management prescriptions for the manipulation of tree cover can be summarized as follows:

1. Be best suited to multiple use goals, considering biological, environmental, engineering, economics, and other impacts.

2. Assure that lands can be adequately restocked.

3. Not be chosen primarily because of the greatest dollar return or timber output, although these factors should be considered.

4. Consider the potential impacts on residual trees and adjacent stands.

5. Avoid permanent reduction of site productivity and ensure conservation of water and soil.

6. Provide the desired effects to meet special management objectives.

7. Be practical in terms of transportation and harvesting requirements and total costs of timber sale preparation, logging and administration.

Combined Criteria For Selection of Harvest Cutting Method

The criteria identified in the Regional Guide and in 36 CFR 217.27(b) were subsequently combined to eliminate duplication of intent and simplify the rationale for selecting the harvest cutting methods used to implement the Final Forest Plan. A summary of the seven combined criteria follows:

1. The selected method must permit the production of a volume of marketable trees sufficient to utilize all trees that meet utilization standards and are designated for harvest. (Regional Guide: Criterion 1)

2. The selected method must use available and acceptable logging methods. (Regional Guide: Criterion 2, 36 CFR: Criterion 4)

3. The selected method must be capable of meeting special management and multiple-use objectives. (Regional Guide: Criteria 3 and 6 , 36 CFR: Criteria 1 and 6)

4. The selected method must permit control of vegetation to establish desired species composition, density, and rates of growth (Regional Guide: Criterion 4, 36 CFR: Criteria 4 and 6)

5. The selected method must promote a stand structure and species composition which minimizes risks from insects, disease, and wildfire. (Regional Guide: Criterion 5)

6. The selected method must assure that lands can be adequately restocked. (36 CFR: Criterion 2)

7. The selected method must be practical and economical in terms of transportation, harvesting, preparation and administration of timber sales. (36 CFR: Criterion 7)

In addition, no harvest cutting method was selected primarily because it resulted in the greatest dollar return or provided the highest output of timber, or which permanently reduced site productivity, or could not assure conservation of the water and soil resources. (36 CFR: Criteria 3 and 5)

WORKING GROUPS AND MANAGEMENT AREAS

Both even-aged and uneven-aged harvest cutting methods were available and evaluated for selection within the Forest's species zones and management area combinations. The three species zones and their applicable management emphasis area combinations are summarized below:

Species Zones 1/	Management Emphasis
1. Western hemlock Tsuga heterophylla	a. Scenic Views and Recreation b. Riparian and Fish Habitat c. Big Game Habitat d. Threatened and Endangered Species e. Timber Production f. Municipal Watersheds
2. Pacific silver fir Abies amabilis	a. Scenic Views and Recreation b. Riparian and Fish Habitat c. Big Game Habitat d. Threatened and Endangered Species e. Timber Production f. Municipal Watersheds
3. Mountain hemlock & subalpine fir Tsuga mertensiana and Abies lasiocarpa	a. Scenic Views and Recreation b. Riparian and Fish Habitat c. Big Game Habitat d. Threatened and Endangered Species e. Timber Production f. Municipal Watersheds g. Mountain Hemlock Study

1/ Refer to Henderson for detailed zone descriptions and definitions; a brief description may be found in Chapter III of the FEIS. These species zones are based on climax species types. The species presently occupying these areas may be Douglas fir, red alder, or combinations of species.

RATIONALE FOR SELECTION OF HARVEST CUTTING METHOD

The following analysis documents the rationale for selection of harvest cutting method within each species zone/management emphasis area based on those combined criteria which have a significant effect on the selection:

General

The following are the most significant factors considered in selecting harvest cutting methods for most of the species/management emphasis zones on the Mt. Baker-Snoqualmie National Forest:

Blowdown: Mature and old growth stands on this National Forest are generally overstocked and have relatively small root systems resulting from decades of growing in an overstocked condition. When these stands are disturbed by the selective removal of some of the trees in the stand, the result is usually accelerated deterioration of the remaining stand manifested by extensive blowdown and sunscald. When clear cutting, area boundaries are designed to take advantage of windfirm boundaries as much as possible. Even so, some blowdown may occur along the boundary between the new clearcut and old growth stand.

Root Rot: Root rots are commonly found throughout the Mt. Baker-Snoqualmie. The diseases are spread by root-to-root contact between susceptible species. Control often requires killing trees in an area around the infected trees and replanting with resistant or immune species so infected roots can rot away and no longer serve as infection centers. Uneven-aged management, particularly the single-tree selection system, perpetuates these root disease centers and will increase the problem over time.

Bole Rots: Most bole rots are caused by wounding of the stems, especially when it occurs near ground level. Uneven-aged management causes much wounding of the leave trees during the logging operations, especially on the steep ground typical of most of this forest which must be logged by cable methods. The thin barked species such as western hemlock and true firs are more easily damaged than the relatively thicker barked Douglas-fir. Long term reductions in yields of about 10 to 15 percent would occur in our forest from bole rots if uneven-aged management were used (Wright 1956).

Dwarf Mistletoe (Arceuthobium spp.): Dwarf mistletoes are parasitic plants which are found primarily on western hemlock and the true firs on the MBS. Douglas-fir is not affected here. Dwarf mistletoes vigor improves when provided with more light in partial cuts which occur during uneven-aged methods. This parasite is spread primarily by a unique, explosive seed dispersal mechanism which ejects the seeds up to about 50 feet from the seed source; the seeds stick to the host where infection takes place. Uneven-aged methods intensify and perpetuate the spread of dwarf mistletoes. Growth of the host is reduced and mortality may occur. Old bole infections may provide entrance points for decay fungi and weakened trees are more susceptible to attack by insects. Dwarf mistletoe is the major forest disease problem in the west causing an estimated loss of 3.2 billion board feet of timber annually (Scharpt 1978). Figures are not available for the MBS, but yields are estimated to be reduced by up to 50 percent on some heavily infested stands.

Genetics: Even-aged methods permit the use of genetically improved seedlings. These seedlings come from a population with a broad genetic base due to tree selection throughout the breeding zone. Also, selection for superior form and growth is expected to increase the yield in stands planted with improved stock.

Stand Composition: Uneven-aged methods would lead to the development of stands composed primarily of shade tolerant species such as hemlock and silver fir. These species are generally of lower commercial value than Douglas-fir and noble fir, the two main commercial species which are shade intolerant and best suited to even-aged management methods. It is estimated that the intolerant species favored by even-aged methods have a commercial value of $70.00 per thousand board feet more than the shade tolerant species which would be fostered by uneven-aged management. With an average volume of 40 MBF per acre, this represents a difference in value of $2,800 per acre.

Stand Density: On the MBS, overstocking has a significant adverse effect on board foot yields. Uneven-aged management will result in overstocking and it will be difficult to control stand densities throughout the rotation. Even-aged management permits precommercial and commercial thinnings to be done at intervals during the life of the stand so that densities can be maintained at optimum levels.

Under uneven-aged management, young trees are forced to compete against older, more well-established trees; they do not grow as well as if they were free to grow. To maintain suitable growth rates, tree densities would have to be reduced significantly, which could adversely affect timber yields for uneven-aged methods.

Economics: As described under stand composition above, the difference in species value is significant. In addition, uneven-aged methods require about five times the equipment move-in and -out costs, and about the same increase for set up, skid road line changes, and take-down costs for cable logging topography. Felling costs would be more in uneven-aged methods because the same ground would be covered about five times, and it is more costly to fell trees in a partial-cut due to hang ups from leave trees. These increased logging costs are expected to result in about $200 per acre more for uneven-aged methods bringing the total difference in cost to about $3000 per acre.

Big Game Habitat: In order to provide optimum habitat for deer, elk, and mountain goats, vegetation is managed to provide diverse combinations of forage, hiding cover, and thermal cover. Even-aged methods provide the mosaic of forest and openings which best meet these needs. The frequent entries needed for uneven-aged methods present an undesirable probability of big game harassment. Prescribed burning for forage enhancement is only practical for even-aged methods.

Clear cutting is the most commonly appropriate even-aged method for the above factors.

Visual Management: Uneven-aged methods provide the most natural appearing stands but this type of appearance is usually only required in foreground areas. Visual objectives in middle and background areas can often be met by using techniques of shape, size, and timing of even-aged cuttings. Individual tree selection, group selection cutting, clear cutting, and shelterwood cutting are all commonly used to meet visual management objectives. Many different site specific factors enter into the decision of which method is most appropriate.

WESTERN HEMLOCK SPECIES ZONE

1a. Western Hemlock - Scenic Views and Recreation

Timber stands managed in this area will provide a variety of species, snags, and size classes. Large, old-growth trees will provide an important stand component. Both even-aged and uneven-aged harvest cutting methods are biologically applicable and can provide for the visual variety and maintenance of the large tree component. Here, the special conditions required to meet visual management objectives may be the primary consideration (combined criterion 3). Uneven-aged methods may produce a more uniform canopy which
