Final Environmental Impact Statement

Land and Resource Management Plan

Mt. Baker-Snoqualmie National Forest

Dear Reader,

You have received the "Summary Packet" of information for the Mt. Baker-Snoqualmie National Forest, Land and Resource Management Plan (the Forest Plan). This packet includes the 72-page Summary of the Final Environmental Impact Statement, the Record of Decision, and a set of maps for eight alternatives and various forest resources.

The Summary (with glossary) provides a concise version of the 750-page Final Environmental Impact Statement. The Record of Decision, signed by Regional Forester John F. Butruille, explains the actual decision made for management of the Mt. Baker-Snoqualmie National Forest, plus the rationale for that decision. These two documents, plus the maps, will provide you with the basic information needed to understand the final decision.

These documents were sent either at your request, or because you commented on the Draft Environmental Impact Statement and Proposed Forest Plan.

If, after reviewing the "Summary Packet" and maps, you are interested in the detailed information contained in the complete set of documents, there are several options available to you.

The complete set of documents includes:

- the 750-page Final Environmental Impact Statement;
- two volumes of appendices, totaling 1,800 pages;
- and the 550-page Land and Resource Management Plan.

You may check out a complete set of documents from most Puget Sound area university, public, and community libraries. Two week "loaner" copies are also available from all Mt. Baker-Snoqualmie National Forest offices. You may also request a full set of documents from the Mt. Baker-Snoqualmie National Forest Supervisor's Office. The office is currently located in downtown Seattle, but will be relocating to Mountlake Terrace later this summer.

SUMMARY

Final Environmental Impact Statement
Land and Resource Management Plan
Mt. Baker-Snoqualmie National Forest

PART 1 - INTRODUCTION

This Final Environmental Impact Statement (FEIS) discusses the alternative strategies for future management of the land and resources of the Mt. Baker-Snoqualmie National Forest. The preferred alternative is developed into the accompanying Land and Resource Management Plan (the Forest Plan). The Record of Decision describes the decision to implement the Forest Plan and the rationale for that decision. While the Forest Plan will guide the management of the Forest for the next 10 to 15 years, the analysis covers a planning horizon of 150 years to evaluate and display the long-term effects of current actions.

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released for public review and comment in December, 1987. This FEIS and Forest Plan were developed in response to those comments and incorporates many suggestions made by the public and other agencies. Changes that were made between the DEIS and FEIS are described throughout the document and highlighted at the beginning of each chapter.

This is a general summary of the entire FEIS. It emphasizes the issues and concerns raised by the public, other agencies, and Forest Service personnel regarding management of the Mt. Baker-Snoqualmie National Forest. This summary is arranged in a slightly different order to facilitate understanding by the general reader. **Part 1** includes a brief discussion of the public responses to DEIS, the changes made between the DEIS and FEIS, the purpose and need for the proposed action, and a description of the affected environment. In **Part 2**, the major issues, concerns, and opportunities (ICO's) are presented.

Part 3 includes descriptions of eight alternatives; a goal statement is given for each and the "design criteria" that were used to develop each alternative are described. **Part 4** is a condensed version of Chapter IV of the FEIS: the environmental consequences of implementing the alternatives.

Public Response to the DEIS

On December 30, 1987 the DEIS and Proposed Forest Plan were released to the public. Copies were distributed to government agencies, libraries in the greater Puget Sound area, and interested members of the public. A "Public Summary" package, which included alternative and resource maps, was sent to several thousand individuals. Public open houses were held in 11 cities in the Puget Sound area; news releases inviting the public to attend were printed and circulated in area newspapers.

The Forest received nearly 12,000 responses to the DEIS during the 115 day review period. The most popular form used to comment was a response form (prepared by a public interest group) (67%), followed by personal letters and cards (30%), and other form letters (2%). Most replies came from the

five-county area of influence for the Forest; refer to the vicinity map, Figure S-1. Nearly half of the responses came from the Seattle-Tacoma-Everett metropolitan area.

The Interdisciplinary Planning Team read and considered every response. A detailed content analysis process was used for coding and analyzing the input received. This allowed the team to report what the public said, in their words. The results of this analysis were very useful in moving from a draft to final plan; most of the changes between the DEIS and FEIS are in response to public comment. A summary of the complete analysis of comments, plus the Forest Service responses to substantive comments can be found in Appendix J, FEIS.

Three alternatives generated the most comment: support for the Public Land Users Society (PLUS) Alternative (as outlined in their input); support for Alternative G, as presented in the DEIS but with the addition of Backcountry areas and more trails; and opposition to Alternative H, the Forest Service preferred alternative in the DEIS.

The comments on issues within the 12,000 responses were numerous and varied. Over 68,000 individual comments related to recreation and trails opportunities and uses. An additional 15,000 comments focused on timber; 14,000 on the northern spotted owl and other wildlife; and 4,000 related to old growth. Other issues generating considerable response included: roads, wild and scenic rivers, roadless areas, the cumulative effects of management activities, water quality and fisheries, jobs, log exports, and wide variety of technical planning process comments.

There were only two areas of general consensus: recreation (of all types) is a vitally important function of the Mt. Baker-Snoqualmie. Secondly, more trails are needed; opinion varied on who should use those trails. Strongly-voiced opinions on all sides of these issues were stated.

Changes Between Draft and Final

The tremendous public response to the DEIS provided the Forest with a wealth of suggestions for improvements about how to provide more benefits to the public. These ranged from broad conceptual approaches to specific technical changes.

Beginning with the DEIS Preferred Alternative (H), Alternative J was developed to respond to public comments and new information. This is the preferred alternative in the FEIS; it is described below, in Part 3.

A new alternative is included in the FEIS; Alternative I was developed to respond to the goals put forth in the PLUS response. Alternative G has been modified, to better reflect the comments received; it is Alternative G-Modified in the FEIS. Several alternatives included in the DEIS are not displayed in the FEIS, as they received little support in comments and are not needed to provide a full range of alternatives for analysis.

The issues, concerns, and opportunities were refocused, to reflect public comment. Wild and Scenic Rivers is now a major ICO, based on the comments.

New timber yield tables and technical corrections were made to the FORPLAN computer model in response to public comments.

The management requirements (MR's) were revisited. Spotted Owl Habitat Areas changed to meet the Record of Decision for the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide. MR's for mountain goats were enlarged, and deer and elk MR's were dropped to meet regional direction. An analysis of the condition of the Forest's watersheds was conducted; this formed the basis for a method to meet water quality and riparian area MR's. The procedure was developed in response to public comments.

The wild and scenic river eligibility process was redefined, also in response to public input. A committee was formed for this task, and it included representatives from several groups and Washington State agencies.

Proposed vegetative management in the Mt. Baker-Snoqualmie National Forest FEIS and Forest Plan is consistent with the FEIS for Managing Competing and Unwanted Vegetation, Pacific Northwest Region (released in December, 1988).

Finally, some data have been updated (such as the acres of timber harvested) since the DEIS was issued, new fisheries values were calculated, more discussion has been added to the diversity of plant and animal communities sections, and errors and omissions have been corrected.

Purpose and Need

The purpose of the Forest Plan is to direct all natural resource management activities on the Mt. Baker-Snoqualmie National Forest. The preferred alternative is the basis for the Forest Plan document. Preparation of the Land and Resource Management Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated Planning Regulations (36 CFR 219).

The preparation of an environmental impact statement disclosing a preferred alternative and a broad range of additional alternatives is required by the National Environmental Policy Act of 1969 (NEPA) and its implementing regulations (40 CFR 1500), and the implementing regulations of NFMA. For purpose of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents.

The Planning Period

The Forest Plan period is ten to fifteen years. Throughout this document, projections beyond that time are provided for informational purposes. The Forest Service is required to revise the plan within 15 years of its adoption.

Current Management Situation

The Mt. Baker-Snoqualmie National Forest is currently managed under several different plans. Examples of these include Timber Management Plans, District Multiple Use Plans, and the Glacier Peak Wilderness Management Plan. The Forest Plan supersedes or incorporates all previous land and resource management plans; the Alpine Lakes Land Area Management Plan and the Skagit Wild and Scenic River Management Plan will be incorporated into the Plan. Upon implementation, all Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities.

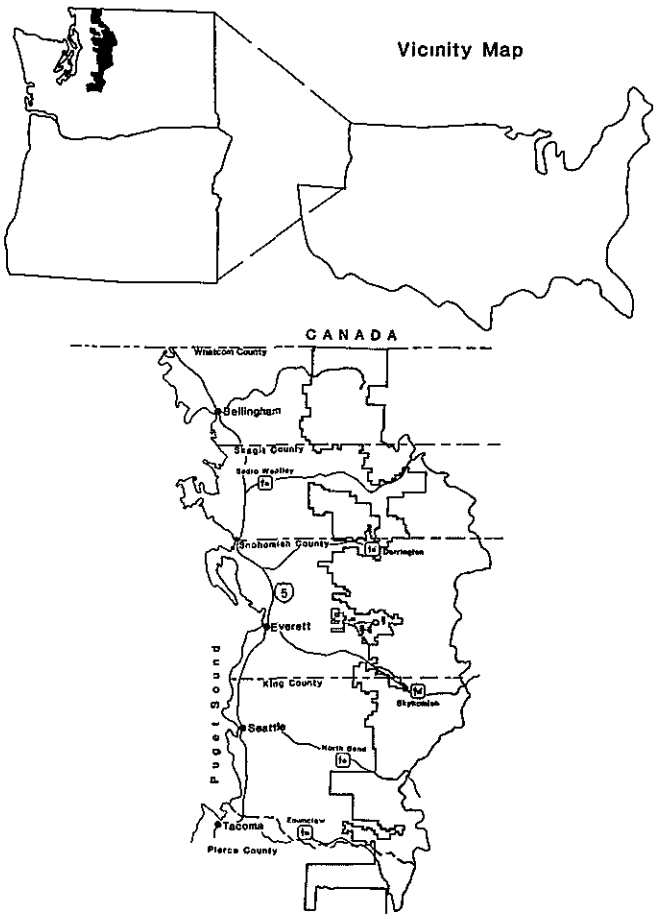
The Affected Environment

The 1.7 million acre Mt. Baker-Snoqualmie National Forest serves a large and diverse population. The Forest is located in some of the nation's most beautiful country - the Cascade Mountains - in northwest Washington state. The Forest contains lush, forested valleys; steep and rugged mountain peaks; glaciers; and numerous high-elevation lakes. The diversity of both the physical and social settings contributes to the complexity of issues facing Forest managers. The Forest includes land from the Canadian border south to the northern boundary of Mt. Rainier National Park, 130 miles, and is adjacent to North Cascades National Park, Wenatchee National Forest, and Mt. Rainier National Park.

The five-county area that includes the Forest has a population of more than 2.5 million persons, over 56 percent of the total State population. Most of these 2.5 million people live in the greater Seattle-Everett-Tacoma metropolitan area, only 40 to 70 miles west of the forest boundary. Just north of the Forest is the Vancouver, B.C., Canada metropolitan area, with a population of 3.0 million people. The Puget Sound economy is quite diverse, although the aerospace industry is still a major employer. The forest products industry has experienced major changes over the last decade; wood products manufacturing outputs have been up the last three years, but with 25 percent fewer employees.

The Mt. Baker-Snoqualmie National Forest contains a wide variety of landforms and natural resources that provide a wide range of goods, services, and opportunities for use. The upper reaches of seven major river systems are located on the Forest. Approximately 1,500 stream miles and over 12,000 lake acres provide both seasonal and year-round spawning and rearing habitat for anadromous and resident fish. The existing annual value of anadromous and resident fish produced on the Mt. Baker-Snoqualmie is estimated at $23 million. Nineteen of the 88 hydrological watersheds on the Forest are currently in an unacceptable condition, due to a combination of moderate to heavy amounts of timber harvesting and road construction plus the presence of unstable soils, steep slopes, and periodic major floods and debris torrents.

Figure S-1



There are 18 municipal watersheds on the Forest serving a population of over 1.4 million. Water from only one of those watersheds requires treatment other than disinfectant, attesting to the high quality of the surface water.

The great diversity of plant and tree communities of the Forest provides a variety of habitats for a wide variety of wildlife species. Four federally-listed threatened and endangered species may occur on the Forest: the bald eagle, American peregrine falcon, grizzly bear, and the gray wolf. Several hundred bald eagles winter on the Forest. A decision on federal Threatened and Endangered listing for the spotted owl, a bird that lives primarily in dense, mature and old growth forests, is expected in 1990.

Fifteen American Indian tribes in the Puget Sound area use the land and resources of the Mt. Baker-Snoqualmie for religious and cultural practices. A 1981 inventory identified important use sites and areas. The Forest possesses some of the few remaining areas with the necessary purity, privacy, and isolation.

The Forest is rich in recreation opportunities and receives over five million recreation visits annually. Dispersed day-use recreation is a major use and occurs throughout the forest. Developed uses occur at seven alpine ski areas, campgrounds, and picnic areas. There are 1,384 miles of system trails on the Forest; 40% are located in wilderness. Ninety-six miles of the Pacific Crest National Scenic Trail are located within the Forest boundary. The Forest has enough roaded recreation lands to meet existing and projected demand, but it cannot meet current or future demand for unroaded, nonwilderness recreation without crowding and loss of solitude.

Nearly 42 percent (722,000 acres) of the Forest is designated wilderness. Wilderness received 455,000 recreation visitor days in 1988. Additional Congressionally designated areas include: the Skagit Wild and Scenic River System (a total of 58.5 miles of recreational river and 100 miles of scenic river); the Mt. Baker National Recreation Area (8,700 acres); and the multiple use Alpine Lakes Management Unit (148,000 acres).

There are 402,930 acres of roadless areas on the Forest; about 40 percent of these acres are tentatively suitable for timber production.

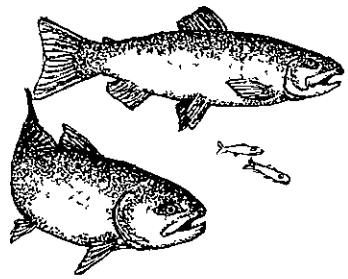
Forest-wide, approximately 160,000 acres of forest land are not suitable for timber production because of problems in replanting the land if the trees were cut. Many of these acres occur at higher elevations. Additional acres - over 95,000 - cannot be considered for potential timber cutting because of highly unstable soils. About 597,000 acres, or 35 percent, of the Forest have been identified as tentatively suitable for timber production. Nearly half of this acreage is currently forested with old growth trees. Almost 60% of the tentatively suitable old growth is in areas that are unroaded and undeveloped.

Between 1975 and 1988, an annual average of 250 million board feet of timber were sold from the dense forests of hemlock, cedar, and Douglas-fir. Changes in the land base as a result of wilderness designation, allocations for wildlife habitat protection, and other resource objectives have affected the amount of timber that can be sold from the Forest in the future.

Three existing Research Natural Areas (RNA) on the Forest are set aside as examples of typical or unique natural ecosystems. There are five potential RNA's, three located within wilderness.

About 9 percent of the Forest acres have moderate to high potential for copper, gold, molybdenum, silver, lead, zinc, chromium, nickel, and olivine. Currently, only olivine is commercially produced. The Forest has about 1,230,500 acres of land that are prospectively valuable for oil, gas, and geothermal resources.

There are 2,829 miles of system roads on the Forest; 52% are accessible only by high-clearance vehicles.



PART 2 - PUBLIC ISSUES AND MANAGEMENT CONCERNS

An extensive and continuing process has been used to identify the issues, concerns, and opportunities (ICO's). The Forest has involved the public throughout the planning process, including various State, county, and other Federal agencies, Indian Tribes, and three public liaison groups.

Several changes have been made to the ICO's since the DEIS was released, reflecting public comment and changing public interests and concerns. Several issues have been refocused (with slight changes in their title) to better reflect recent public response. The transportation issue and wood residue management opportunity have been incorporated as facets of other major ICO's. Wild and Scenic Rivers is now addressed as a major issue; it had been a facet of the recreation ICO.

The issues drive the planning process and play a key part in the development of alternatives. The issues are an expression of the wants and preferences of the various publics with respect to Mt. Baker-Snoqualmie National Forest resources. The issues are also an indication of areas of conflict and of the public's view of the need for a change in management direction.

The nine major issues, concerns, and opportunities are summarized below. The following list shows the indicators used in evaluating how responsive each alternative is to the issues; responsiveness is reported in Table S-4.

Issue, Concern, Opportunity Indicator of Response	Unit of Measure
Development versus Nondevelopment of the Forest	
Existing Roadless Areas Allocated to Nondevelopment	% Acres, M Acres
Roadless Areas Assigned to Roaded Mgt. Prescription But Not Developed in Next 15 Years	M Acres
Timber Supply	
Timber Harvest Level	MMCF/MMBF
Long-Term Sustained Yield Capacity	MMCF
Lands Suitable for Timber Production	M Acres
Employment: Jobs Supported by the Alternatives	M Jobs
Payments to Counties	MM Dollars
Old Growth Ecosystems and Fish/Wildlife/Plant Diversity	
Total Old Growth Remaining, End of Decades 1, 5	M Acres
Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Anadromous Fish Production	Pounds Per Year
Low-Elevation Old Growth Habitat for Wildlife	M Acres Under 3000'
Suitable Winter Range for Deer and Elk, Decade 1	M Acres
American Indian Religious and Cultural Use	
Inventoried Use Areas with High/Moderate Protection	% of Inventoried Ac.
Recreation Opportunities	
Demand Satisfied for Wilderness, Primitive, Semi-Primitive Nonmotorized Recreation, Decades 1 and 5	% of Capacity
Roads Open to Public Use, Passenger Car	Miles
Trail Construction, Reconstruction, Decade 1	Miles

Lands Managed for High Visual Quality Levels	M Acres Retention, Partial Retention
Wild and Scenic Rivers	
Rivers Recommended for Designation as Wild and Scenic	No. Rivers, Miles
Management of Municipal Watersheds	
Timber Harvest Level	MMCF (MMBF)
Effects of Timber Management and Related Activities	
Timber Harvest Level	MMCF (MMBF)
Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Annual Road Construction, Decade 1	Miles
Sediment Produced from All Sources, Annually, Decade 1	M Tons
Adjacent and Intermingled Lands	
Timber Harvest Level	MMCF (MMBF)

Development versus Nondevelopment of the Forest

How should the released, roadless areas be allocated and how will the resources be managed?

At what rate should the Forest Service enter those roadless areas that are allocated for development?

The allocation and management of 402,930 acres of unroaded area (23% of the net Forest acres) remains a highly controversial issue. This issue has been retitled, to better reflect public comments received on the DEIS.

These roadless lands were inventoried in RARE II; they were released from wilderness consideration by the 1984 Washington State Wilderness Act. Many comments on the DEIS focused less on the RARE II remnants and more on the general issue of whether the remaining unroaded and undeveloped lands on the Forest should be managed for commodity production/roaded recreation or remain undeveloped. This key issue encompasses facets of nearly all the other ICO's.

Some elected officials, environmental groups, many hikers, some Indian Tribes, and wildlife organizations want the unroaded areas to remain undeveloped and unroaded. Key concerns are protection of wildlife habitat, old growth, and other resource values. Maintain the option of future consideration for wilderness was also mentioned. A number of individuals and groups support a proposal for Backcountry Areas, roughly corresponding to five roadless areas.

Other individuals, plus timber and mining companies, trade organizations, and energy-related industries feel that the 1984 Wilderness Act "released" these lands for multiple uses. They are concerned that nondevelopment will limit the amount of timber and minerals available for use, affect the local and regional economy, and lead to future wilderness designation. Many people feel there is a need for more motorized access to the roadless areas, to encourage recreation. The commercial forest land within the roadless areas has been used to calculate the annual potential yield in the 1963 Timber Management Plans, as amended. However, this timber was not available for harvest from 1972 through 1984, resulting in a long-term concentration of timber harvesting on about one-half the land base. Approximately 155,700 acres, or 39 percent, of the unroaded areas are tentatively suitable for timber production.

Timber Supply

What is the capability and suitability of the Mt. Baker-Snoqualmie National Forest to produce timber?

What should the timber harvest level be considering all resources on the forest and their relationship to social, economic, and environmental factors including local, regional, and national demands?

A major public issue and management concern is the timber supply on the Mt. Baker-Snoqualmie National Forest. This issue has also been retitled since the DEIS, to better reflect public comments. The issue now includes facets of the wood residue opportunity.

Support for maintaining or increasing the timber supply comes from timber industry (management and employees), some community leaders, businesses dependent on the timber industry, and economic development agencies. Many individuals want the timber supply to be maintained, primarily to protect jobs. Environmentalists, some recreation users, wildlife and some hunting interests, fishing organizations, Indian tribes, some community leaders, and State wildlife agencies strongly support restricting or reducing the timber harvest, especially in low-elevation old growth. A number of people feel the loss of mill jobs is due to factors other than timber supply.

The timber industry is a small but still important part of the overall Puget Sound economy; 4% of the wage and salary jobs in two counties are based on lumber and wood manufacturing. The Forest currently supplies about 17% of the logs consumed in the Puget Sound area; a number of mills are dependent on National Forest logs.

The annual potential yield under the 1963 Plans (as amended) is 203.8 million board feet (MMBF). Over the period 1979 to 1988, the average timber volume sold was 235.8 MMBF and harvested was 229.6 MMBF, which is within the average annual potential yield for the decade: 229.7 MMBF. The timber supply potential on the Forest is considerably less than what past timber sale programs have indicated.

Approximately 597,000, or 35 percent, of the net Forest acres are considered to be tentatively suitable for timber production; about half of the tentatively suitable acres contain old-growth forest.

Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity

What management direction is needed and where should action be taken that will maintain and/or enhance old growth and diversity to meet multiple use objectives?

The title of this ICO has been adjusted, in response to public comment. Old growth is a major issue on the Mt. Baker-Snoqualmie National Forest. Its value in providing biological diversity, wildlife and fisheries habitat (including habitat for the northern spotted owl), recreation, aesthetics, water quality, as well as industrial raw material is widely recognized by the public and the scientific community.

Environmental groups, wildlife societies and organizations, many individuals, Indian Tribes, and State wildlife agencies want the remaining old-growth forests protected. Old growth is important to American Indians for religious and cultural purposes.

Timber company representatives, industry trade associations, some State and local agencies, and many individuals feel these resources are an important contribution to timber production and maintaining local economies. Some feel that converting these stands into second growth timber is important for increasing long-term forest productivity.

There are approximately 643,500 acres of old growth within the Forest; 232,500 acres (36%) are located in wilderness and are not available for harvest.

A related public issue and management concern is the maintenance and/or enhancement of plant, wildlife and fish diversity within the objectives of multiple use management. There is increasing recognition within the scientific community that ecosystem diversity is important; this issue also received considerable public comment. Many respondents to the DEIS felt national forest management should focus on wildlife. State Department of Wildlife officials, hunters, and recreationists are concerned about the population and habitat needs of big game animals, such as deer, elk, and mountain goats.

Indian tribes, sport and commercial fishing interests, and state and federal fishery agencies are increasingly concerned about the effects of water quality on the anadromous fish resource. The cumulative effects of management activities on fish/fish habitat was raised as a major concern by individuals, Indian Tribes, and State agencies.

American Indian Religious and Cultural Use

What policy and management direction is needed to comply with the Native American Religious Freedom Act and various treaties?

How can Inventoried religious and cultural use areas be protected within the objectives of multiple use management?

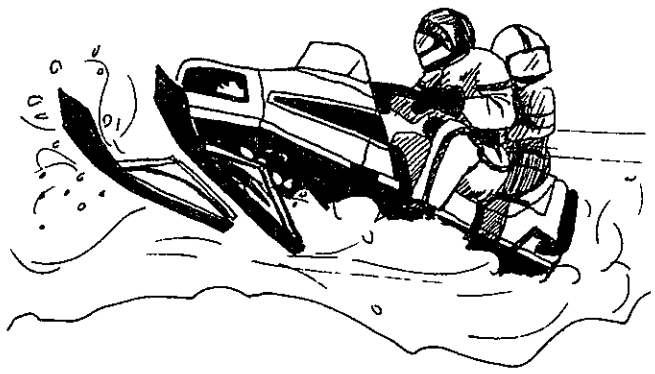
The 15 American Indian tribes who currently use the Mt. Baker-Snoqualmie for religious and cultural uses continue to challenge Forest management activities, primarily proposed road construction, timber harvest, and small hydroelectric power projects, that potentially threaten their religious use sites and areas.

The Tribes also have a significant interest and concern for protection and enhancement of the anadromous fisheries resource. Fishing has been, for many, a traditional and principle means of income. They are strongly opposed to any management activities that might adversely affect anadromous fish habitat.

In the 1981 inventory of religious use, practices, and localities, over 300 cultural use areas and sites were identified (totaling about 450,000 acres - 34% inside wilderness). Some sites cover less than one acre; larger areas average 3,000 to 15,000 acres. There are five broad categories of use areas: cedar sites, ceremonial flora, spirit sites, legendary sites, and cemeteries and archaeological sites. There is a wide variation in compatibility between types of management activities and categories of religious, ceremonial, and cultural use.

Since the completion of the 1981 inventory, the Forest has initiated a consultation process with the Tribes. When proposed projects fall within an inventoried use-areas, the proposed activity is reviewed in detail with representatives of the Tribe(s) which may be affected. As more management activities are proposed, there is the potential for increased conflict.

Individuals and Tribal representatives feel that the draft Forest Plan standards and guidelines and the inventory process were not adequate to protect Religious Freedom Act rights. Others, including some timber industry representatives, feel protection of religious and cultural use areas will constrain timber availability.



Recreation Opportunities

To what extent can the Mt. Baker-Snoqualmie National Forest provide recreation opportunities and how should they be managed?

How many miles of trails should be provided and in what locations?

Public comment on the DEIS reconfirmed that recreation use - of all types - is a major public issue on the Mt. Baker-Snoqualmie. Opinion is divided on what types of recreation opportunities should be provided.

Many groups and individuals - including hikers, horse users, some off-road vehicle users, naturalists, wildlife advocates, and environmentalists - want to preserve opportunities for unroaded dispersed recreation outside of wilderness. They prefer more remote, natural appearing recreation settings. National Forest lands are the major supplier of non-motorized dispersed

recreation in the Puget Sound area. Many other recreationists spoke to the need for better recreation access for young families and the elderly, more ORV areas, more snowmobile opportunities, and more campgrounds.

A large majority of people commenting on the DEIS favor more trails. There was support from environmentalists and many recreation/commodity groups for the "Trails 2000" proposal, developed by one environmental organization. ORV and horse users want more trails open for their use. Many hikers feel that trails should be closed to motorized use. Conflicts between recreation and other Forest resources were frequently mentioned. Some users dislike the expanding road system needed for timber harvest, while others feel roads are important for their activities and access.

Many recreation attractions and opportunities on the Mt. Baker-Snoqualmie are found within eight wildernesses. A concern is the level of management required to accommodate the high recreation demand within these areas, while protecting the wilderness resource. Some recreation and environmental groups, who strongly supported wilderness status for favorite areas, now find themselves debating the need for management actions in those areas, including limiting use. Facets of this issue include: the need for new or relocated trails to disperse recreation use in heavily-used areas; and whether roads that access popular wilderness attractions should be kept open to the public.

Wild and Scenic Rivers

How should the potential wild and scenic rivers of the Forest be managed and their values protected?

Wild and Scenic Rivers has been identified as a separate major issue, due to public response on the DEIS. There is one designated Wild and Scenic River on the Forest, the Skagit (designated in 1978). The Wild and Scenic Rivers Act established criteria for the addition of other rivers to the National System. The National Park Service (formally Heritage Conservation and Recreation Service) conducted an inventory of potential rivers; portions of the 16 rivers on that inventory are within the Forest boundary.

Portions of the Skykomish River system have been designated by the State of Washington as a Scenic River. This designation applies only to city, county, and State lands. A 1988 Washington State Scenic River Assessment identified 3 rivers on the Forest which possess values that would make them suitable additions to the Washington State Scenic River System (the Carbon, Nooksack, and Stillaguamish Rivers).

There was considerable public comment on the DEIS eligibility study, plus support for many more miles of wild and scenic rivers than recommended for study in the DEIS. There was also vocal opposition to more designation.

Between draft and final plans, eligibility criteria were re-evaluated and the list of eligible rivers adjusted. A total of 51 rivers were identified and studied for their eligibility and 47 of these were determined to be eligible. There was considerable public and agency involvement in this process. A suitability study for the 47 eligible rivers was also completed, again in response to public comment on the draft.

Wild and scenic river legislation has been considered but no action taken. Public concern on all sides is high. The portions of seven major river systems that lie within the Mt. Baker-Snoqualmie contain sections with unparalleled anadromous fisheries values. There are also high recreational and scenic values.

Management of Municipal Watersheds

What activities should be permitted within municipal watersheds?

What measures should be taken that will maintain or enhance water quality?

The title of this major ICO has been changed, to better reflect emerging issues. Maintenance of high water quality is a facet of the issue; it is also addressed on the Effects of Timber Management and Related Activities ICO. Changes in City of Seattle policies for the management of the Cedar River watershed may necessitate renegotiation of the existing, 1962 Cooperative Agreement. Under the 1989 Secondary Use Policies for the Cedar River, the City will set aside 50 percent of its lands in a reserve precluding timber harvest. The policies also call for acquiring 4-6,000 acres of old growth (currently national forest lands) to be maintained as old-growth habitat.

Maintaining high quality water remains as an objective of many individuals, sports and recreation organizations, municipalities, Indian Tribes, and State and federal agencies. These interests believe that timber harvest, road construction, mining, and some recreation activities are detrimental to water quality and support action to limit or prohibit development in the watersheds. Many also support maintenance of old growth habitat in the Cedar River watershed. Municipalities are concerned that increased access and recreation use will result in the need to install filtration facilities to assure potable water to the consumer.

Timber, energy, mining industries, plus a number of hunters feel that development can occur and any adverse impacts to water supply and quality can be mitigated. They believe that limiting or prohibiting activities unduly restricts the industry's ability to maintain or increase supplies of timber, electric power, and minerals. Hunters feel that big game populations could actually be enhanced with controlled hunts in the watersheds.

A significant portion of the watersheds supplying the cities of Seattle, Bellingham, Everett, and Tacoma is located on the Mt. Baker-Snoqualmie. Water is also provided for a number of smaller municipalities, ski areas, and other recreation sites. About 128,000 acres of national forest land supply municipal water to 1.4 million people. Water quality is high; only one municipality filters water, others use a disinfectant.

Currently, a wide range of activities occur within the municipal watersheds. Some watersheds have not been accessed by roads and remain primarily in a natural condition. Other watersheds have been developed, with extensive timber harvesting and road construction. Recreation is permitted or encouraged in some watersheds; in others, poor access and municipal opposition has limited recreation opportunities.

Effects of Timber Management and Related Activities

What management direction is needed for timber harvest and road construction activities to benefit or maintain the quality of other resources?

The effects of timber harvest and road construction, especially the cumulative effects of these activities, are of great concern to federal agencies, environmentalists, Indian Tribes, State Fish and Wildlife agencies and individuals. The effects of management activities on water quality, fish and fish habitat is of greatest concern, and this interest has increased since the DEIS was released. Other resources affected by timber harvest and road construction are wildlife, scenery, and dispersed unroaded recreation.

The timber industry, miners, and many individuals feel that the effects of these activities can be mitigated, and that not enough national forest land is open to full commodity production (and recreation use).

Management for the commercial production of timber includes a number of activities: road construction and/or reconstruction, preparation of the land for planting seedlings, possible thinning, et cetera. These activities have direct and indirect effects on other resources, including: fish and wildlife habitat, soil, water, and American Indian religious and cultural use. Recreation opportunities are changed, and the visual condition of the Forest changes. The visual impact of clear-cutting and loss of habitat for some wildlife species is a major concern. Changes in vegetation and the effects on diversity and sensitive plants have also been identified as concerns by some people commenting on the DEIS.

Adjacent and Intermingled Lands

How should National Forest lands adjacent to lands of non-federal owners be managed?

What management activities should be conducted on National Forest lands that are located near private developments?

The land ownership pattern within and adjacent to the National Forest boundary and the management of intermingled Federal and Private lands remains a major issue and concern.

A few environmental groups are actively proposing legislative land exchanges that would exchange high-elevation, low timber site class private lands for low elevation, high-site federal lands. Some major industrial timber land owners support these types of exchanges. Independent mill operators and loggers who depend on National Forest timber and some public interest groups strongly oppose such exchanges, as the exchanges would further reduce timber supplies available to them. Some people commenting on the DEIS urged the Forest Service to retain all mineral rights in any exchange.

Environmentalists, State Fish and Wildlife agencies, Indian Tribes and some sporting groups believe that management activities, such as timber harvest,

should be delayed or deferred on National Forest lands to mitigate the cumulative effects of large-scale timber harvest on private lands that are intermingled with Federal lands. Independent mill operators and loggers are opposed to any delays or deferrals that would reduce timber supplies available to them.

In many areas of checkerboard ownership, adjacent land owners have completely removed the old-growth timber (in approximately 640 acre blocks), leaving the timber present on National Forest land more vulnerable to wind-throw. Removing these blocks of old growth has also had the effect of reducing the amount of habitat available for wildlife species dependent on old-growth habitat. In areas of intermingled lands, management of National Forest land affects adjacent lands of non-Federal landowners, and activities on non-Federal lands affect management of National Forest land.

Urban growth is steadily moving east toward the Forest boundary. Forest lands, regardless of ownership, are affected by this growth. Resources such as wildlife, water, and air do not recognize ownership boundaries, but they are directly impacted as shopping centers, subdivisions, and residences - plus an increased network of roads - spread closer to the Forest boundary.

PART 3 - THE ALTERNATIVES, INCLUDING THE PROPOSED ACTION

Eight alternatives were developed in detail. The alternatives, including the proposed action (the Preferred Alternative) are based on the identified issues, concerns, and opportunities, the "drivers" of the planning process. Each alternative is designed to achieve specific goals and objectives. Each is a unique combination of land uses, forest management activities, and schedules designed to address, mitigate, or resolve the planning questions discussed above. A wide range of alternatives was developed to test for the combinations of goals and objectives that best maximize net public benefits while responding effectively to the ICO's. With one exception (the No Change Alternative), a computerized model (FORPLAN) was used to ascertain the potential outputs and effects of each alternative.

Each alternative, except Alternative NC (No Change), falls within the scope of the Mt. Baker-Snoqualmie Standards and Guidelines. These standards and guidelines were prepared to meet laws, regulations, and policy requirements; to direct management activities in meeting goals; to respond to the issues and concerns; and to mitigate potential adverse effects on a Forest-wide basis. Refer to the Forest Plan document and FEIS, Appendix D.

Each alternative, except Alternative NC, includes the management requirements (MR's) (36 CFR 219) pertaining to timber, fish and wildlife, soil and water, land productivity, and riparian areas. The management requirements are discussed in detail in FEIS, Appendix H.

Alternative J is the Preferred Alternative; it was selected by the Regional Forester as the alternative which best maximizes the net public benefits while responding effectively to all the issues.

The Alternatives - Items Treated the Same in All Alternatives

A number of resource management programs are treated the same in all the alternatives:

- Alpine Lakes Management Plan (1981) and the Skagit Wild and Scenic River Plan (1984) are incorporated in all alternatives except Alternative NC.
- The Mt. Baker National Recreation Area (1984) is the same in all;
- The three existing Research Natural Areas are retained in all alternatives;
- The foreground of Mather Memorial Parkway is managed to retain its scenic quality in all alternatives;
- The management requirements (MR's) necessary to integrate requirements of law and regulation are incorporated in all alternatives except Alternative NC;
- The rights established by the various Indian treaties are retained in all alternatives, as is the consultation process for any proposed projects within inventoried religious and cultural use areas;
- The acres of designated wilderness are the same. Acres assigned to classes of the Wilderness Recreation Opportunity Spectrum (WROS) vary by alternative; there are no WROS classes in Alternative NC;
- Even-aged management and regeneration harvest through clearcutting are assumed in estimating timber outputs in all alternatives. However, the use of other systems is not precluded (refer to Appendix F in the DEIS Appendices for more information);
- All alternatives would make full use of vegetation management techniques including herbicides and fire. In 1988, the Pacific Northwest Region, USDA Forest Service completed a final EIS on managing competing and unwanted vegetation (USDA 1988b). That final EIS, the Mediated Agreement, and accompanying implementation direction is incorporated by reference into this FEIS. It will guide vegetation management activities as the Forest Plan is implemented.
- All existing utility corridors, electronic sites, and administrative sites are retained in all alternatives.

ALTERNATIVE NC (NO CHANGE)

The No Change Alternative has been developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's.

The No Change Alternative is designed to continue the level of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1963 Timber Management Plans. This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA (it does not incorporate management requirements, including those designed to maintain viable plant and animal populations). The alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

Design Criteria for Alternative NC (No Change):

Timber: the 1963 Timber Management Plans are the basis for the alternative.

Roads: the Naches Pass road would not be constructed.

Roadless Areas: an estimated 60% of the roadless areas would remain undeveloped; this estimate is based on the acres of commercial forest land assumed to be in the roadless areas.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: no provision for study or protection of potential rivers is included in the TM Plans.

Research Natural Areas: no potential areas recommended.

Spotted Owls: no provisions made to protect old-growth habitat for wildlife.

Big Game Habitat: no provisions made for protection of big game habitat.

Cavity Excavators: no provisions made for protection of habitat.

Anadromous/Resident Fish: no provisions made for protection of fish habitat.

Municipal Watersheds: all are managed under current agreements, memoranda of understanding.

ALTERNATIVE A (NO ACTION)

Alternative A was developed to continue management direction as set out in plans formulated and approved prior to the passage of the National Forest Management Act. The alternative incorporates the requirements of the National Forest Management Act of 1976 (36 CFR 219.12 through 219.27). The goal of Alternative A is to provide maximum timber outputs while maintaining or exceeding existing recreation, wildlife, fisheries, and visual resource outputs. The plans approved prior to NFMA, plus current laws, regulations, and directions - including MR's - were used to assign management direction to different parts of the Forest. This is the No Action Alternative required by the Council on Environmental Quality Regulations for implementing the National Environmental Policy Act (NEPA).

Design Criteria for Alternative A (No Action):

Timber: an exception to "Items Treated the Same in All Alternatives", in FORPLAN, Alternative A was run with an objective of maximize timber volume for the first five decades, then was rerun to maximize PNV for 15 decades with the same timber outputs as in Decades 1-5. This resulted in some timber prescriptions having less than maximum economic efficiency. Approximately 70 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 26 miles of arterial and collector roads would be built. During that same period, about 330 miles of local roads would be constructed. The Naches Pass road would not be constructed.

Roadless Areas: would be managed under the direction contained in the Ranger District Multiple Use Plans; approximately 73 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: 15 of the 16 rivers included in the National Park Service Nation-wide Inventory are recommended for designation as part of the National Wild and Scenic River System. Jim Creek is excluded as not eligible. These 15 rivers include a total of 287 miles - 215 within the forest boundary.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat is provided for viable populations at the MR levels; additional habitat for some species in wilderness, RNA, and areas not suited for timber production.

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of their potential population levels.

Anadromous/Resident Fish: current populations are maintained through habitat maintenance or improvement at the MR level (low investment).

Municipal Watersheds: are managed under current agreements, memoranda of understanding.

ALTERNATIVE B (RPA)

The goal of Alternative B is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation, as specified in the 1980 RPA Program.

Design Criteria for Alternative B (RPA):

Timber: is produced at the highest level possible, while meeting the other goals of the alternative. Approximately 64 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 28 miles of arterial and collector roads would be built. During that same period, about 280 miles of local roads would be constructed. The option to construct Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 79 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic designation.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 79,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on land suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of their potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE C

The goal of Alternative C is to emphasize primitive and semi-primitive nonmotorized recreation (accomplished through retention of existing roadless areas and, over time, reversion of some roaded areas to unroaded condition); protect scenery, fish, and wildlife habitat; and protect sites and areas important to American Indians for religious and cultural use.

Design Criteria for Alternative C:

Timber: no production goals set; suitable acres and harvest level will be the lowest of all alternatives considered in detail. Approximately 43 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 300 miles of existing arterial and collector roads. In the first two decades, about 15 miles of arterial and collector roads would be built, and about 180 miles of local roads would be constructed. Construction of the the Naches Pass road is precluded by management of surrounding lands for unroaded dispersed recreation.

Roadless Areas: nearly all (96%) of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: high to moderately-high protection of the foreground and middleground of all inventoried primary and secondary viewsheds.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers included is 606, of which 446 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

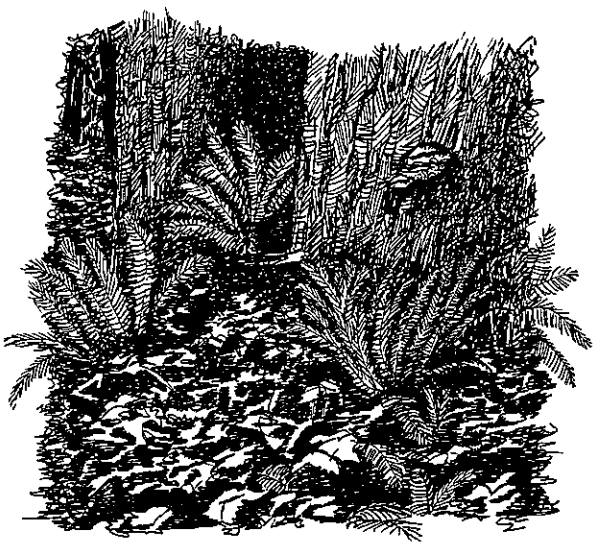
Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat provided to maintain cavity excavators at 60% of their potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, with stipulation that habitat be maintained as old growth when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - closed watershed, exchange NF lands; Others - no timber harvest, limited recreation use.



ALTERNATIVE G-MODIFIED

The goal of Alternative G-Modified is to emphasize maintenance of natural ecosystems and diversity of native plants and animals, emphasize providing uses not found on private lands, and produce timber in a way that is consistent with the other goals and is non-damaging to soils.

Design Criteria for Alternative G-Modified:

Timber: timber production will occur on currently accessed sites first. Maintenance or development of old growth, especially at lower elevations, is emphasized. Approximately 41 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 65 miles of existing arterial and collector roads. In the first two decades, approximately 13 miles of arterial and collector roads would be built, and about 145 miles of local roads would be constructed. Construction of the Naches Pass road is precluded by management of surrounding lands for undeveloped recreation.

Roadless Areas: approximately 93% of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: the foreground of selected corridors is protected, including the upper end of Mt. Baker Highway, portions of the Cascade River and North

Fork of the Cascade, portions of the Mt. Loop Highway, the upper Sauk, lower Sultan, and Mather Memorial Parkway. Integral vistas within and from Class I airsheds and other wildernesses (not yet designated Class I) are protected.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers include is 796, of which 446 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Twin Sisters, Monte Cristo, Baker Lake, Naches Pass, and along the Mather Memorial Parkway.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide **with additional habitat areas** being protected to meet the objectives of the alternative. Approximately 113,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat provided for viable populations at the MR levels; some additional habitat for some species in wilderness, RNA.

Cavity Excavators: on lands suitable for timber production, habitat is provided for cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - managed to retain old-growth habitat with stipulation that it be maintained when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE H

The goal of Alternative H is to provide an increased emphasis on unroaded recreation; protection of scenic values in the foreground and middleground of heavily traveled highway corridors; increasing big game populations; plus emphasis on timber production on tentatively suitable acres not assigned to other objectives.

Design Criteria for Alternative H:

Timber: about 60 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. About 20 miles of existing roads, located in areas assigned to unroaded dispersed recreation, will be closed. In the first two decades, approximately 11 miles of arterial and collector roads would be built. During that same period, about 250 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 82 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways.

Wild and Scenic Rivers: the five rivers determined in the DEIS to be eligible for Wild and Scenic River designation are recommended for designation - North Fork Nooksack, North Fork Skykomish, South Fork Skykomish, Tye, and Middle Fork Snoqualmie Rivers, a total of 154 miles, of which 71 miles are within the national forest boundary.

Research Natural Areas: five potential are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

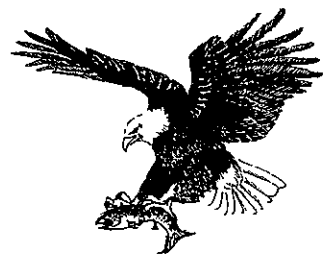
Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 61,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - current direction (exchange NF lands to City of Seattle, no old-growth habitat maintained); Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.



ALTERNATIVE I

The goal of Alternative I is to emphasize those resources with an established price in the market place: timber production, anadromous fish, developed recreation, and minerals. Emphasis is also placed on enhancement of big game wildlife and fish habitat, and developing/maintaining an extensive trail system to accommodate a wide variety of users on a year-round basis. Other resources are managed at levels that do not reduce the outputs from the market resources.

Design Criteria for Alternative I:

Timber: timber production is emphasized. Approximately 65 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed, to meet timber production goals. In the first two decades, approximately 34 miles of arterial and collector roads would be built. During that same period, about 290 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 78 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual: the foreground of heavily-traveled highways are managed for scenic quality (I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways).

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic River designation.

Research Natural Areas: no potential areas are recommended for designation.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. About 93,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous fish populations are increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan

River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE J (PREFERRED)

This is the Preferred Alternative. It is a new alternative and was not displayed in the DEIS. Beginning with the draft EIS Preferred Alternative (H), Alternative J was developed to respond to public comment and new information. Differences between the draft and this Preferred Alternative include: a considerable increase in trail mileage; an increase in the number of rivers recommended for addition to the National Wild and Scenic Rivers System; allocation of three Special Areas (Botanic, Scenic, and Recreation/Education); an increased emphasis on unroaded recreation; and greater protection of scenic values within travel corridors. Timber production is emphasized on suitable acres assigned to a timber harvest prescription. Other resources will be managed at levels commensurate with the objectives of the alternative.

Design Criteria for Alternative J (Preferred):

Timber: about 58 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. Roads to be closed include about 25 miles of existing roads, located in areas assigned to unroaded dispersed recreation. In the first two decades, approximately 15 miles of arterial and collector roads would be built, and about 240 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 86 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, Baker Lake Highways, Cascade River road, and Crystal Mountain Highway.

Wild and Scenic Rivers: 30 of the 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for inclusion in the National Wild and Scenic Rivers System. A total of 452 miles are recommended, with 276 of those miles located within the national forest boundary. This recommendation is a preliminary administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Mather Memorial Parkway, Heather Meadows, and Sulphur Creek.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 54,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - initiate negotiations on a new Cooperative Agreement to reestablish goals and management for the watershed; until then, do not enter into land exchanges affecting National Forest lands; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

The Management Areas

To complement the description of alternatives, Table S-1 presents the acres assigned to each management area, by alternative. Management areas (MA's) are areas of the Forest to which a set of management practices, standards, and guidelines apply. (Alternative NC is not shown; it is based on the 1963 Timber Management Plans and has no management areas.) Multiple use will continue to be the overall goal of the Mt. Baker-Snoqualmie; one or more uses may be emphasized in a management area, but many uses are compatible and will occur in every MA.

Management areas are identified by a number or number/letter, plus a short, descriptive title. The letters are various "intensities" of a broader management area. Some MA's have only one intensity. The MA's are described on the alternative maps accompanying this package of documents. The standards and guidelines that apply to each MA are discussed in detail in the Forest Plan (for Alternative J (Preferred)) and in FEIS, Appendix D. The maps show the on-the-ground location of the management areas for each alternative.

Table S-1 is a useful summary, but some items should be noted. The alternatives are presented in descending order of acres suitable for timber harvest, an indicator of the level of vegetative management. Many of the outputs and effects discussed later in this Summary are either directly or inversely correlated to the amount of vegetative management in the alternatives. This order of presentation facilitates quicker and easier comparisons among the alternatives.

Acres are assigned to management areas to meet the overall goals and objectives of each alternative, in response to the issues. Simply comparing the number of acres in each management area does not give the full picture of an alternative. Where compatible uses occur on the same area, the acres have been assigned and mapped to the set of management practices, standards, and guidelines that cover management for both uses. Example, an area assigned to nonmotorized dispersed recreation (MA 1A, 1B) may also be capable of providing old-growth wildlife habitat (MA 11). In this case, the MA mapped would be 1A or 1B, not 11 because old-growth habitat has been "overridden" by an MA that is more restrictive: roads cannot be built in 1A/1B; they may be constructed outside the core area in MA 11 (if habitat objectives can be met).

Note that the acres for the wildlife management requirements (MR's) vary among the alternatives. This is primarily due to "overrides." For example, Alternative C shows the fewest acres assigned to MA 11 Old Growth, yet C has a goal of emphasizing wildlife. Old-growth habitat is protected at a high level in Alternative C but many acres of old growth habitat are located within MA's 1A or 1B, which provide for both wildlife habitat and nonmotorized recreation. The designated old growth acres are still "there", but they are mapped as 1A or 1B, and are listed in Table S-1 as 1A or 1B.

Table S-1

Acreages in Management Areas by Alternative 1/

Management Area	A (No Action)	I	B (RPA)	H	J (Preferred)	C	C-Modified
Lands Suitable for Timber Production	412,508	386,512	380,448	358,754	346,411	256,206	247,091

1/ Total acres in each alt vary due to rounding MA 9 not used, MA 24 Min Mgt not assigned in any alternative

2/ Applies only to Alt A, includes mostly unroaded, but some roaded recreation, from exisitng Multiple Use Plans

3/ Parcels of the 1926 area that remain outside of wilderness and the Mt Baker NRA are included here

4/ Acres are protected, at varying levels, in the alternatives, but not shown to protect confidential nature

5/ Includes Cultural-Historic, Geologic, Biologic, Botanic, and Scenic Special Areas

6/ Many acres of riparian zone fall within other MA's and are protected through those management prescritptions

7/ Management Areas 16B Grizzly Bear, 16C American Peregrin Falcon and 16D Gray Wolf have no acres assigned at this time, because no specific habitat has been identified or evaluated

8/ Acres of existing or proposed RNA located within wilderness are included in MA 10, not here

9/ These acres overlap other MA's

10/ Includes acres within the congressionally designated Alpine Lakes Management Unit that are not otherwise assigned to other, compatible management areas (Compatible MA's include 5, 11, 12, 14, 15, and 16)

PART 4 - COMPARISON OF ALTERNATIVES

The following figures show how the alternatives compare to each other in just a few of the Forest activities or resource outputs. The graphs tie to the detailed output tables in the next section (where other outputs are displayed). Again, the alternatives are arranged in order of decreasing acres of land suitable for timber production. Alternative NC (No Change) was not modeled in FORPLAN, therefore not all outputs for this alternative can be reasonably estimated. Refer to the text and footnotes for each figure.

Figure S-2 shows average annual timber sale program quantity (TSPQ) for Decade 1 (in million board feet). TSPQ includes live (green) wood, plus salvage, fuelwood, and other non-industrial wood. Figure S-3 shows the acres of final timber harvest, each decade, for Decades 1, 2, and 5. Refer to Table S-2 for more comparisons.

Figure S-2

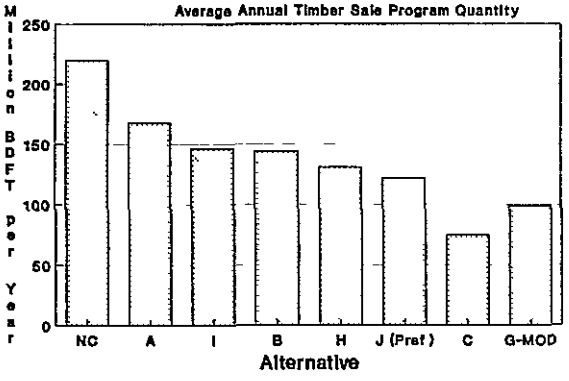

Figure S-3

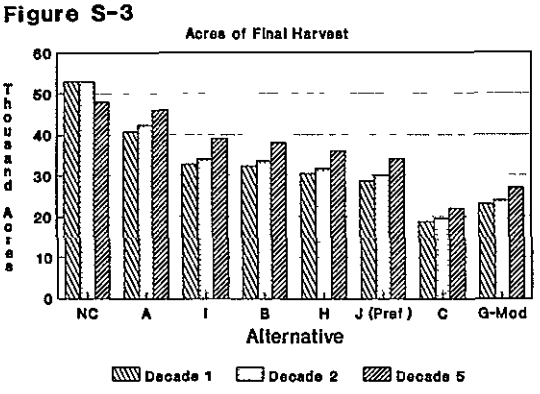

Figure S-4 shows the total amount of old-growth forest remaining, which includes old growth located in wilderness and other no-harvest areas. The starting point is the beginning of plan implementation. The figures then show acres remaining at the end of Decades 1, 2, and 5.

Figure S-4

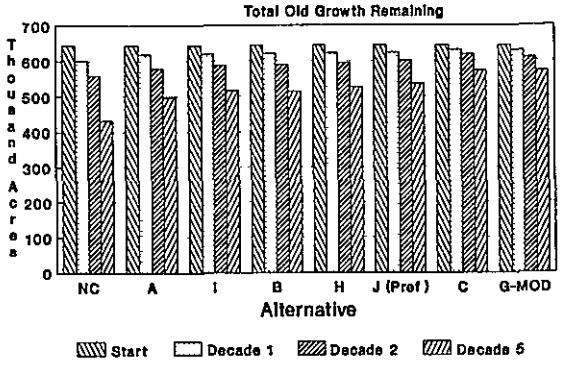

Figure S-5 shows total road construction, in miles per year. Most of the miles are local (timber purchaser) roads. Refer to Table S-2. In all alternatives, all arterial/collector road construction, but not all local road construction, will be completed by Decade 3. In Alternative C, about 300 miles of arterial and collector roads are closed starting in Decade 1; about 65 miles are closed

in Alternative G; 20 miles closed in Alternative H; and about 25 miles closed in Alternative J (Preferred).

Figure S-6 shows the disposition of the 402,930 acres of roadless areas: the percent remaining undeveloped at the end of Decades 1, 2, and 5. No data can reasonably be estimated for Alternative NC. In the first 10 to 15 years, from 1% to 7% would be developed, depending on the alternative. The acres shown for Alternative A are an estimate.

Figure S-5

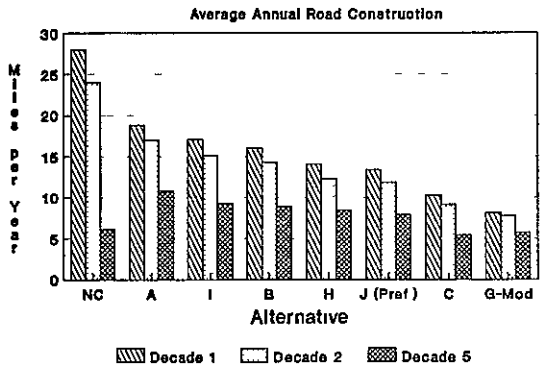

Figure S-6

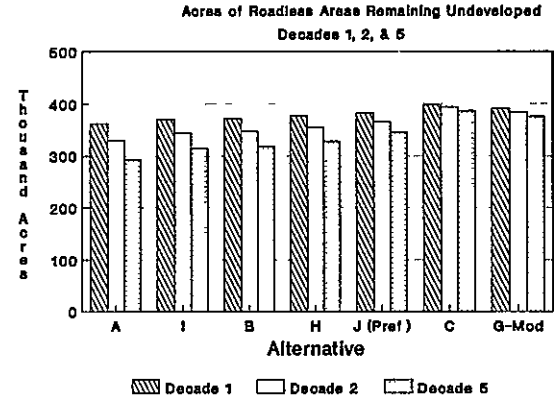

Does not apply to NC Alt

Figures S-7 and S-8 show the acres of dispersed recreation by ROS classes. Alternative NC is estimated to be similar to Alternative A. The term "reached by Decade 4" is used because, as an alternative is implemented, land allocated to MA's, and standards and guidelines applied, the recreation setting will slowly change toward the desired future condition. The figures show the expected ROS acres after four decades of implementing each alternative. While no alternative can meet future demand for unroaded dispersed recreation,

Figure S-7

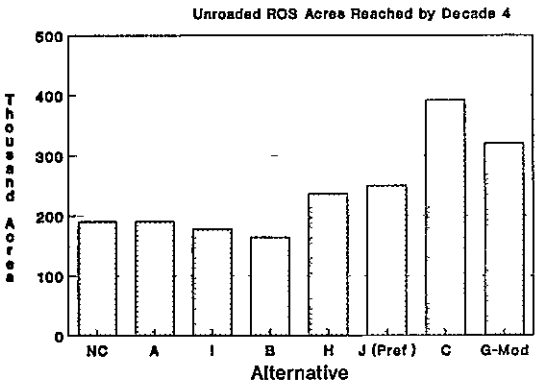

Figure S-8

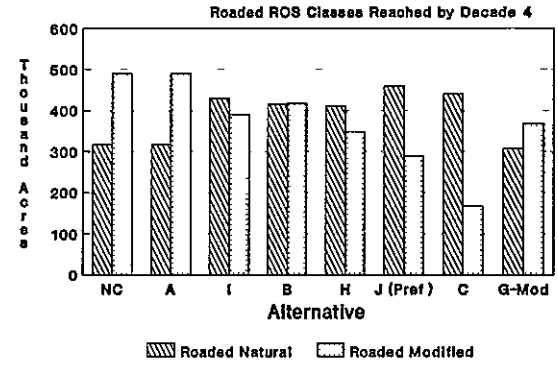
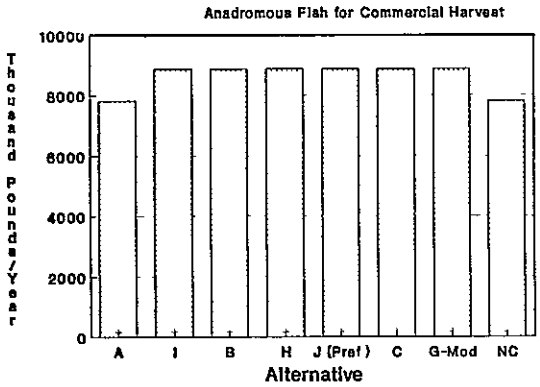


Alternatives C and G-Modified come the closest. Alternative B cannot meet the RPA target for dispersed recreation. Looking at Figure S-8, the alternatives with more timber harvest activities and associated road construction (NC, A, and I) provide the most roaded dispersed recreation; however, much of this recreation will occur in landscapes that have been heavily altered.

Figure S-9 shows the pounds of anadromous fish available for commercial harvest. The differences between alternatives are a function of investments in habitat improvements: a higher level of investment and more restoration/ enhancement results in more available fish. Alternative NC is similar to A. While not shown in this figure, resident fish habitat is also improved/enhanced in Alternatives C, G-Modified, and J (Preferred).

Figure S-9



Quantitative Outputs and Effects of the Alternatives

Tables S-2 and S-2a show some of the key outputs and effects of the eight alternatives. Again, the alternatives are displayed in descending order of acres suitable for timber harvest, an indicator of the level of vegetative management. Many outputs and effects are either directly or inversely correlated to this order.

Alternative NC (No Change) is based on the 1963 Timber Management Plans (as amended), which were not integrated resource plans and consequently did not address all resource uses and outputs. Data for Alternative NC is presented where it can be reasonably estimated, or where information was addressed in the 1963 Plans. Alternative NC was not modeled in FORPLAN, therefore, economic measures comparable with the other alternatives were not determined.

While the alternatives and the decision apply only for the life of this Forest Plan - 10 to 15 years - outputs and effects for Decades 2 and 5 are included to show some long-term trends of implementation.

Both allowable sale quantity and timber sale program quantity are shown; the footnotes explain the difference in these two terms. Allowable sale quantity (ASQ) is shown in board feet per year only for the first decade. ASQ and timber sale program quantity, by alternative, are shown in cubic feet per year for all time periods.

Generally, as suitable acres increase, the amount of harvest increases, as does road construction, and environmental effects, such as sediment index.
For the recreation and wilderness resource, the most useful way to compare the alternatives is to first look at current use and capacity, and then compare how well each alternative is able to provide for future demand, which is expressed as a range.

For this Forest, capacity means practical, or realistic, capacity not the theoretical maximum. 1/ It was assumed that projected recreation use will not exceed capacity for any particular activity. It is expected that use will be limited by a combination of direct management actions by the Forest Service (such as permits, area closures) and by the users themselves: when use of a site or area approaches capacity, people will substitute other activities (such as nordic skiing when alpine ski areas are full), or shift their activities to other lands, if they cannot satisfy their expected recreation experience on the Forest.

For non-wilderness unroaded dispersed recreation, current use already exceeds practical capacity. In total recreation use, current capacity far exceeds use (primarily due to the large reserve of developed capacity in ski areas, campgrounds, and in roaded dispersed recreation). However, by the fifth decade, all alternatives will fall short of meeting the range of total recreation demand.

Most of the miles of new trail construction, in all alternatives, are outside wilderness.

Note footnote number 8/ when comparing acres of old growth, by alternative. The "starting point" total acres of old growth, including acres within wilderness, is 643,538 acres. The acres within wilderness (232,500) remain constant in all alternatives over time. Proposed timber harvest will occur only on those old growth acres that are suitable for timber production and are assigned to a management prescription that includes timber harvest.

The pounds of anadromous fish available for commercial harvest are a direct function of the investment level for fish habitat improvement. MR's for water quality and riparian areas will also benefit this resource.

Population estimates for the spotted owl exceed the MR level in all alternatives, except Alternative NC, for all time periods. However, wildlife populations that primarily use mature and old-growth habitats (northern spotted owl, pine marten, pileated woodpecker) will decrease over time, in all alternatives, primarily due to harvest of mature and old-growth timber stands.

Winter range habitat capability for deer and elk increases from the current situation (which supports 9,140 deer and 470 elk) through the first decade, a result of increased forage from timber harvest activities. Habitat capability declines in Decade 2, as winter thermal cover becomes limiting. By Decade 5, habitat capability again increases, due to habitat improvements implemented in the first decade.

The text discussing Table S-2a, "Percentage of Inventoried American Indian Religious and Cultural Use Areas Assigned to MA's Providing High and Moderate Levels of Protection" follows all of the S-2 tables.

1/ Theoretical capacity is an estimate of the maximum use of the Forest, assuming all facilities are 100% full, all days of the maximum use season. Practical capacity recognizes physical and social limitations, such as low mid-week use and periods of unfavorable weather, when use declines.

1/ The TM Plans upon which the No Change Alternative is based were developed in 1963 The outputs and effects are generated from previous inventories All other alt. outputs and effects were calculated using updated inventories and yield tables and the latest method of calculating timber harvest levels. For Alt NC, tentatively suitable lands were not determined and standard plus special commercial forest land is shown as lands suitable for timber production

2/ ASQ Quantity of timber that may be sold, from suitable land. Includes only chargeable, live (green) not salvage, fuelwood or other non-industrial wood Potential yield from the TM Plan is shown for Alternative NC

3/ Includes ASQ, nonchargeable mortality volume, volume not meeting utilization standards, and volume used for other than board products from lands suitable for timber production, and volume from unsuitable lands. Includes PY and all other volume for NC

9/ Populations would be expected to decline at a rate faster than Alternative A because no specific provision is made in Alt. NC to maintain viable populations and more of the old growth is suitable for timber harvest and will be fragmented.

1/ The 1963 TM Plans, upon which Alternative NC is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated because, except for cemeteries, the percentages were developed by overlaying inventoried areas with MA's; no MA's were assigned in Alternative NC.

Table S-2a shows, by alternative, an estimated percentage of the inventoried American Indian religious and cultural use sites assigned to management areas that generally preclude or limit ground-disturbing activities.

The percents given should be viewed as only an approximation as some use sites and areas were not identified in the Inventory, but were included in a larger "buffer" area by tribal respondents. Therefore, the actual degree of protection in each alternative can only be estimated.

In the table, the difference between "high" and "moderate" is derived from the expected frequency of human encounters. There is no timber harvest or road construction under either high or moderate protection. All cemeteries have high protection. The actual protection of all sites will be determined using Forest-wide Standards and Guidelines (Forest Plan, Chapter 4) and consultation with appropriate tribes. To protect the confidential nature of the inventory, use sites and areas are not reported in Table S-1 nor are they mapped.

Economic Tradeoffs Among Alternatives

Present net value (PNV) is an estimate of the potential economic effectiveness of managing the Forest. PNV is defined as the discounted dollar value of all benefits of an alternative, less the discounted costs of management and investments needed to implement the alternative. Discounting is a way of combining current and future values to show them in today's terms. The values used in this plan are expressed in terms of 1982 dollars, with a discount rate of 4%. This concept is discussed in detail in Appendix B of the FEIS.

Table S-3 compares PNV and the benefits and costs among alternatives for major resource groups. An exact relationship between the dollar benefits associated with a particular priced output and the resource costs should not be assumed. For example, some recreation and wildlife benefits are joint outputs of timber management. The dollar values assigned are discussed in Appendix B.

Table S-3 indicates that almost all of the variation in PNV, discounted costs, and discounted benefits is due to the variation in timber outputs of the alternatives. With some minor exceptions, as timber outputs decline, so do discounted costs and benefits.

Discounted costs and benefits for recreation change very little from one alternative to another. This is partly due to the fact that current recreation use is very close to capacity on the Forest for most types of recreation, except roaded dispersed. There is little opportunity to significantly increase the recreation supply in wilderness, primitive, semi-primitive nonmotorized, or semi-primitive motorized outside of wilderness. Although there is some variation between alternatives in these dispersed recreation capacities, it is a very small percentage of the current capacity and affects discounted recreation benefits only about 6% between the alternatives. Discounted recreation benefits exceed discounted timber benefits in all alternatives, though actual cash flow or returns to the Treasury are much lower than for timber.

Alternative C has the lowest discounted recreation benefits of all the alternatives but the highest levels of primitive and semi-primitive nonmotorized recreation capacity. Although primitive and semi-primitive

nonmotorized recreation use has a higher value per Recreation Visitor Day (RVD) than motorized use, it has a lower RVD per acre coefficient (the number of people who do or can recreate on an acre). The result is that on a per-acre basis, motorized use is more valuable than nonmotorized use.

The alternatives in Table S-3 are displayed in order of highest to lowest PNV.

Major Tradeoffs Among Alternatives

Table S-4 presents tradeoffs among economic benefits of the alternatives and their response to the major issues and concerns, as measured by quantitative indicators (listed in the ICO section of the Summary). Across the top of the table are the quantitative measures selected to indicate responsiveness to an ICO. To provide a partial framework for assessing these tradeoffs, the long-term resource demands or needs of the Nation, region, and local economic area are briefly summarized.

National, Regional, and Local Overview

National (RPA) planning estimates that total national demands will rise for all outputs of the National Forest. At the same time, there is a strong demand to protect and enhance the quality of the environment. Many people view the production of goods and services from the National Forests as competing with protection and enhancement of a quality environment.

Demands and prices for commodity products are generally determined in regional and national markets. The nation benefits most when supplies are provided from the most efficient sources of production.

The Mt. Baker-Snoqualmie National Forest is an efficient supplier of timber products. The 1980 RPA program assigned approximately 2.5 percent of the total projected timber outputs for the National Forest System in 1990 to the Mt. Baker-Snoqualmie National Forest. The Forests' share of the projected Regional outputs in 1990 is approximately 6 percent. The Mt. Baker-Snoqualmie produces about 15 percent of the logs consumed in the Puget Sound area; forest industry and other private owners are the major producers of logs consumed in the area. Nearly all (97%) of the logs produced on the Forest are processed in the local economic area (Larsen and others 1983). The resulting products are consumed primarily in the Western U.S. market.

Demands on the Forest for outdoor recreation uses are more localized than the regional and national demands for timber. Most of the Forest recreation users reside in the major population centers along the Interstate 5 highway corridor.

Recreation use and the demand for recreation of many types is growing, and at a rate faster than the population growth of the Puget Sound area. Total recreation use increased approximately 40 percent on the Forest in the 10 year period from 1975-1984. In a similar time period, the population of the five county area of the Forest increased approximately 20 percent. The fastest growing segment of the recreation spectrum is wilderness use: + 145 percent, compared to an increase of 65 percent in developed recreation use. Wilderness use represents approximately 4.5 percent of the total recreation use on the Forest for the period 1975 to 1984.

The Mt. Baker-Snoqualmie National Forest is a major supplier of National Forest wilderness in the Pacific Northwest and the nation. The Forest contains 16 percent of the National Forest wilderness in the Pacific Northwest Region and 2.2 percent of the total National Forest wilderness system. Available data collected in the late 1970's and early 1980's indicates that 82-94 percent of wilderness use on the Forest originated from Washington State, and 49-65 percent of the users are from the Puget Sound area. Several of the Forest wildernesses are among the most heavily used in the nation.

Salmon, by a large margin, is the most valuable fish or wildlife species, as measured by the market value of the harvest. An estimated 50 percent of the harvest of naturally produced (as opposed to hatchery produced) salmon for the Puget Sound area are produced from Mt. Baker-Snoqualmie National Forest water systems.

The Forest has extremely low capability to produce economically efficient forage for commercial grazing of domestic livestock.

How the Alternatives Respond to Major Issues, National Concerns. With the discussion above to set the stage, Table S-4 and the text that follows show the major differences among the alternatives. In this table, the alternatives are displayed in order of highest PNV to lowest. The main reason that alternatives differ is that each alternative is designed to respond to major ICO's in a different way. Note: two issues - Management of Municipal Watersheds and Adjacent and Intermingled Lands - are not listed separately in the table, but their indicators are included in other ICO's. When an indicator is used to measure responsiveness for more than one ICO, such as timber harvest level, the indicator is displayed only once. See page S-6 for the full list of indicators.

NC 3/	N/A	N/A	N/A	NA	NA	NA	45.0	(220)	N/A	547	30.1	9 5

1/ Roadless Areas refer to the 402,930 acres of remaining RARE II parcels.

2/ This is an approximate figure. Alternative A is unique because an unspecified amount of development is permitted in the Upper Forest Resource Zone. See description of Management Area 1E

3/ The TM Plans upon which Alternative NC is based were developed in 1963; they are not integrated resource plans, and consequently did not address all resource uses and outputs Missing data in this table (NA) cannot be reasonably estimated, since the TM plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect standards in the NFMA regulations, or are otherwise inappropriate

Table S-4
Response, By Alternative, to Major Issues and National Concerns

7/ From all sources, including timber harvest, new road construction, old roads, and background (which includes sediment from previously disturbed ground and natural sedimentation).

Economic Benefit and Issue Response Tradeoffs Among Alternatives

The alternatives were designed to respond to specific major issues, or a combination of issues. In responding to one set of issues, some potential benefits or responses to other issues may be limited or "traded off." In Table S-4, the alternatives are displayed in order of highest PNV to lowest. Most of the indicators of response follow a specific pattern as PNV declines. The indicators of response are grouped into those patterns in the display below. A detailed discussion of why these changes occur in each alternative can be found in Chapter II of the FEIS.

Indicators That Decline As PNV Declines:

- Net Receipts
- Non-cash Benefits (slightly) in 5th Decade
- Timber Sale Program Quantity, Long-Term Sustained Yield, Suitable Lands
- Jobs (slightly), Payments to Counties
- Old Growth on Suitable Lands

Indicators That Remain More-or-Less Stable Among Alternatives As PNV Declines:

- Non-cash Benefits in 1st Decade

- Demand Satisfied for Wilderness, Primitive, Semi-Primitive Nonmotorized Recreation

Indicators That Rise As PNV Declines:

- Visual Quality, Retention Acres
- Habitat for Low-elevation Old-Growth Wildlife Species, 1st Decade
- Habitat for Low-elevation Old-Growth Wildlife Species, 5th Decade
- Old Growth Remaining on All Lands in 5th Decade
- Existing Roadless Areas Allocated to Nondevelopment
- Religious and Cultural Use Areas Afforded High/Moderate Protection

Indicators That Vary Irregularly As PNV Declines:

- Visual Quality, Partial Retention Acres
- Acres of Deer and Elk Winter Range in 1st Decade
- Anadromous Fish Production (in pounds)
- Old Growth Remaining on All Lands in 1st Decade

PART 5 - ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

In the following section, only the significant direct and indirect effects of implementing the alternatives are summarized. Brief narratives show how the acre assignments, outputs, and schedules of each alternative will affect the physical, biological, social, and economic environment. Refer to Chapter IV of the DEIS for more detail.

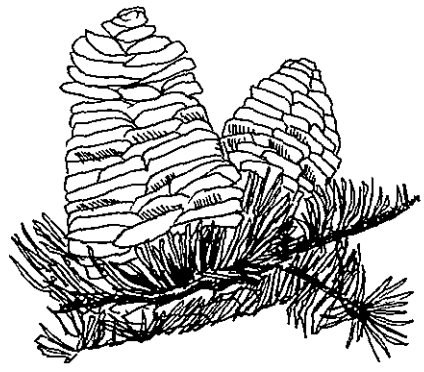
The Effects On Soils. In all alternatives, except Alternative NC (which has a high level), there will be moderate to moderately-high levels of "background" or existing erosion and sedimentation of streams. Some of this is natural, a result of unstable soils and steep terrain, and some results from old timber harvest areas and existing roads.

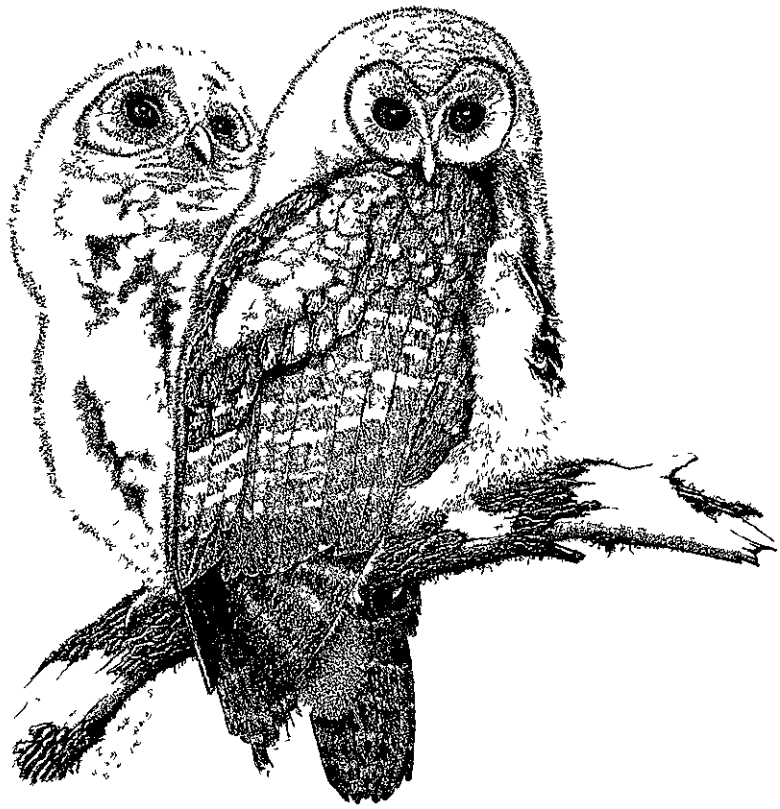
Implementing Alternative NC would result in the most erosion from timber harvest and roads during the 1st Decade; there would be moderately high erosion in Alternatives A, I, B, H, and J (Preferred). Alternatives C and G-Modified will result in considerably less erosion. Refer to the sediment index in Table S-2 for the effects on the Forest aquatic systems. There is limited broadcast burning in all alternatives; the least in Alternatives G-Modified and C.

The Effects On Water. In all alternatives, the Washington State Water Quality Regulations (designed to protect fish and water for domestic use) will be met, through the application of site-specific, Best Management Practices (see Appendix I, FEIS). Meeting water quality and riparian management requirements in all alternatives, except NC, will allow watersheds in an unacceptable condition to recover. Mitigation measures will result in a reduction in stream sediment, in all alternatives, from a current level of 125,000 tons per year in Alternative NC. Total sediment produced is the lowest in Alternatives C and G-Modified; Alternative J (Preferred) is second lowest.

The Effects On Vegetation and Plant Diversity. Diversity is primarily affected by timber harvest and road construction. In Decade 1, timber harvest in all alternatives will occur almost exclusively in old-growth forest. As old growth is removed, significant changes occur in the ecosystems. Over time, there is a decrease in acres of old-growth age classes and an increase in younger trees. However, this will also result in an increase in timber growth rate in the regenerated stands.

Alternatives G-Modified and C have fewer suitable acres and assign more acres of old growth to non-development. Alternative A (NC would be similar) has the highest suitable acres and harvests old growth at the fastest rate, followed by Alternatives I and then B. Both of these alternatives retain some old growth for deer and elk winter thermal cover. Alternatives H and J (Preferred) have moderately high acres of suitable land, and harvest at a moderate rate. Refer to Table S-2 for changes in acres of old growth, by alternative.





The Effects On Wildlife. Changes in wildlife habitats lead to a shift in the distribution and levels of wildlife habitats and populations. The most significant effects on wildlife are those resulting from timber harvest activities, road construction, and road use. However, MR's for viable populations of all species are met in all alternatives except Alternative NC; in that alternative no specific provisions are included to maintain viable wildlife populations. Federal Threatened and Endangered species are protected in all alternatives.

All alternatives reduce old-growth wildlife habitat. Population estimates for the spotted owl exceed the MR level in all alternatives, except Alternative NC, for all time periods. However, wildlife populations that primarily use mature and old-growth habitats (northern spotted owl, pine marten, pileated woodpecker) will decrease over time, in all alternatives, primarily due to harvest of mature and old-growth timber stands. They decrease the fastest in Alternatives NC, A, I, and B.

Winter range habitat capability for deer and elk increases from the current situation through Decade 1, especially in Alternatives NC and A, a result of increased forage from timber harvest activities. Habitat capability declines in Decade 2, as winter thermal cover becomes limiting. By Decade 5, habitat capability again increases in Alternatives NC, A, I, B, I and slightly in J (Preferred), due to habitat improvements implemented in the first decade.

The Effects On Fish. The major effect of all alternatives on fish is a change in habitat condition. Viable populations of fish are maintained on the Forest in all alternatives (viable defined as the current or existing levels of fish production). The amount of fish habitat capability to support and maintain

fish populations above the viability level varies by alternative, primarily in response to effects of forest management on key, in-channel and upslope conditions within stream systems, plus the emphasis on fish habitat restoration and improvement capital investment activities. Alternative A provides MR levels for anadromous fish. Alternatives I, B, and H provide high levels of capital investments for restoration/enhancement for anadromous fish habitat. Alternatives J (Preferred), G-Modified, and C provide high levels for both anadromous and resident fish.

The Effects On The Human Community. None of the alternatives will affect population in the five-county area. Only minimal effects to lifestyle would be noticed, and then, primarily among groups or individuals who work in forest products, who live near the Forest boundary, or who use the Forest for recreation, cutting firewood, or gathering forest products such as mushrooms or berries.

Implementation of any alternative will, at the most, decrease the total area employment/income by four-tenths to six-tenths of one percent. With or without implementation of the Forest Plan, traditional lifestyles in the smaller, rural communities will be challenged by new, more urban values and lifestyles. However, towns such as Darrington that are further from the urban areas, will experience change more slowly.

The Effects On American Indian Religious and Cultural Uses. In all alternatives, the consultation process will be continued for any proposed ground-disturbing project located in an inventoried site or area. Also, all cemetery sites will have high protection.

Refer to Table S-2a for the amount of protection afforded religious and cultural use areas. Alternative NC would have the greatest impact on religious and cultural use areas, because of high levels of timber harvest, road construction, and other development activities. Alternative G-Modified and C would have the least impact, with Alternatives A, B, H, I, and J (Preferred) resulting in intermediate levels of impacts.

The Effects On Archaeological and Historic Properties. Any ground disturbing activity, such as timber harvest or road building, has the potential to affect archaeological and historic properties. In all alternatives, ground-disturbing activities will include a professionally supervised inventory, evaluation, and mitigation, in compliance with the National Historic Preservation Act.

Implementation of Alternatives NC or A will result in the greatest loss of historic and cultural resources, due to the high level of timber production and road construction, plus high mitigation costs. Alternatives I, B, H, and J (Preferred) have moderate levels of impact. Alternatives C and G-Modified will result in the least amount of ground disturbance and the fewest losses.

The Effects On Scenery. Generally, alternatives that emphasize commodity production will, in the long term, result in a lower visual quality level and a more visually altered landscape than alternatives with a non-market emphasis. The foreground of Mather Memorial Parkway will be protected in all alternatives. In Alternatives J (Preferred) and G-Modified, the Mather Parkway is allocated to MA 8, Special Area; no scheduled timber harvest is allowed and scenery is emphasized.

Alternatives NC, A, and B will have the greatest effect on scenery. Visual quality will deteriorate over time for almost all the lands accessible by roads in these alternatives. Alternative I protects the foreground of selected, heavily traveled highways. In Alternative G-Modified, scenic quality would be reduced moderately in several significant viewsheds (as no middleground MA 2B is allocated), but would remain high in unroaded areas.

Alternatives C, H, and J (Preferred) protect both the foreground and middleground of selected major highway corridors; J (Preferred) manages for a high level of visual quality in additional viewsheds. Within these viewsheds, scenic quality will be retained at it's current level or improve gradually. Outside of the designated viewsheds and unroaded areas, scenic quality will decrease moderately.

The Effects On Recreation. Opportunities for various types of recreation vary among the alternatives. The supply of campgrounds is adequate to meet present demand; future demand can be met with a slight expansion of facilities. Expansion is planned, in varying degrees, in all alternatives except Alternatives B and G-Modified, which provide no further developed site construction.

The Forest will continue to be a supplier of dispersed motorized and a primary supplier of dispersed nonmotorized recreation for the Puget Sound area. All alternatives easily meet projected future demand for roaded motorized dispersed use; Alternatives NC, A, B, I and H provide the most. The major effect of alternatives with high, new road construction will be modification of the overall recreation setting. A shift will take place from the Semi-Primitive ROS classes, to Roaded Natural and Roaded Modified settings.

In all alternatives, under Regional and Forest standards of resource degradation, the Forest will not meet current or projected demand for non-wilderness, unroaded dispersed recreation. The deficit will be largest in those alternatives assigning the most unroaded acres to development. Alternatives A, B, and I develop 30%, 34%, and 36% of the roadless areas, respectively. Alternatives C and G-Modified develop the least acres of unroaded land and include large amounts of trail construction. I and J (Preferred) also include large increases in new trail construction.

While the demand already exceeds supply for Semi-Primitive Motorized, unroaded ORV opportunities, there is currently very little land suitable for this experience. This situation will not improve in any alternative, as most trails on the Forest are not suitable for ORV use due to terrain, unstable soils, and heavy precipitation.

The Effects On Wilderness. The total acres of wilderness are the same in all alternatives, but assignment of acres to different intensities of Wilderness Recreation Opportunity Spectrum (WROS) will vary the social and physical settings within the wilderness. Alternatives B, I, and J (Preferred) assign more acres to the Transition WROS class (over the current situation) and will generally provide for increased wilderness use. The average number of visitors per acre will be higher, resulting in degradation of naturalness and loss of solitude. All other alternatives reduce the amount of Transition, and offer a more natural setting with less social interaction. Alternative NC has no provision for management under the WROS system, therefore acres could not be reasonably estimated.

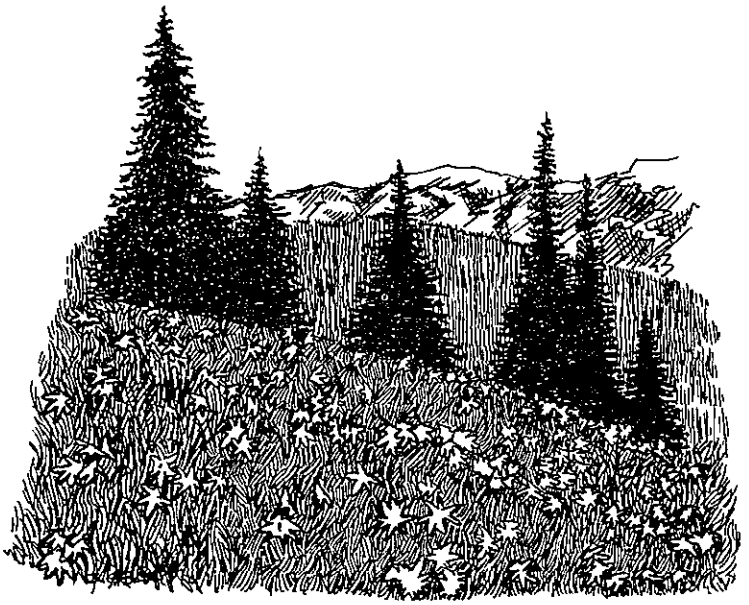
Easier road access in Alternatives NC, A, B, I, and H will likely result in more visitors, based on past experience, and will result in greater impact on the social and environmental features of wilderness. Alternatives C and G-Modified provide the fewest miles of new road construction, and close miles of existing roads, resulting in fewer impacts.

If more acres are available for primitive and semi-primitive dispersed recreation outside of wilderness, there is more opportunity to mitigate impacts on wilderness by offering alternative recreation sites. Alternatives NC, A, B, I and H will have the greatest potential effect on the wilderness, through elimination of alternate sites for primitive and semi-primitive nonmotorized recreation. Alternatives C and G-Modified will retain the most undeveloped area. Only Alternative C will increase acreage in primitive and semi-primitive ROS classes over the current situation.

The Effects On The Roadless Areas. A maximum of 36% of the total roadless area acres could be developed in any alternative, due to the lack of resource capability, the presence of wildlife habitat needed to meet the MR level for the Forest (except in Alternative NC), and because of the steep, high-elevation terrain of most of the areas. Only 39% of the roadless acres are tentatively suitable for timber production.

During the first decade, from 1 to 9 percent of the roadless areas will be developed in any alternative. The amount of proposed development cannot be estimated for Alternative NC; however, it is unlikely - based on the existing vegetation - that more than 50% of the total roadless areas would be developed in the foreseeable future.

Although additional wilderness is not being considered in this plan, areas left roadless now would maintain that option for the future. All alternatives foreclose that option to varying degrees. Alternatives NC, A, B, and I develop the most acres; Alternatives C, and G-Modified would assign the most acres to non-development, maintaining future wilderness consideration.



The Effects On Recommended Wild and Scenic Rivers. There were 795.9 miles of rivers and streams in 47 segments studied for possible inclusion in the National Wild and Scenic River System. The direct effect of implementing any of the alternatives will be a decision to recommend (or not recommend) designation of a river for inclusion in the National System. If a river is recommended, then management will be oriented toward protecting the features of the river system which would be important under the National Wild and Scenic River Act. No activities would be allowed which could preclude future designation. Management will protect all eligible rivers until Congress acts on the Forest's recommendation.

The number of rivers recommended for Wild and Scenic River designation range from none in Alternatives NC, B, and I, to all 47 rivers in Alternatives C and G-Modified. Alternative A recommends 15 rivers and J (Preferred) has 30 rivers recommended for inclusion.

The Effects On Air Quality. Implementation of any of the alternatives should not significantly impact air quality in the Forest area. Residue burning in all alternatives should drop to 20 percent of the acres harvested by 1990. Also, the amount of residue will decrease over time, as more logging is done in second growth timber, which contains less cull or unusable material than does old growth. Visibility in the Class I areas (two wildernesses) should continue to be good, with only brief periods of haze, often from urban pollutants or from activities off the Forest.

The Effects On Minerals. Mining operations may significantly impact soil, water, vegetative cover, plant diversity, wildlife, fish and recreation activities. On the Mt. Baker-Snoqualmie National Forest, such operations have occurred on a small scale and are very localized. However, mineral extraction could increase if market conditions become more favorable.

Implementation of some alternatives could make mineral access very difficult, due to acre assignments to management areas that restrict or prohibit various types of mineral activity. Access is a major consideration in determining whether commercial extraction is feasible. Alternatives NC and A are the least restrictive, with high miles of new road construction and only 13 percent (Alternative A - NC would be similar) of the Forest "withdrawn" or highly restricted for mineral activity. Alternatives B, I, H, and J (Preferred) withdraw or restrict a moderate amount of acres. Alternatives G C and G-Modified are most restrictive, two due to management of most of the roadless areas for non-development.

Relationship Between Short-Term Uses of The Environment and Maintenance and Enhancement of Long-Term Productivity

The relationship between short-term uses of the environment and the maintenance and/or enhancement of long-term productivity is complex. Short-term uses refer to those that would occur within the life of this plan, generally 10 years or less, but a maximum of 15 years. Long-term productivity refers to the capability of the land and water to produce a continuous supply of resources and values for future generations. Soil and water are the primary factors of productivity and represent the measurement of the relationship between short-term use and long-term productivity.

Some short-term uses can be detrimental to long-term productivity, particularly if effective mitigation measures are not implemented. Surface mining can leave an area with greatly diminished productivity for growing vegetation if the top soil is removed and not replaced. This adverse effect can be mitigated effectively by requiring stock piling and spreading of topsoil. Introduction of sediments into a stream on a continuous basis could adversely effect the future long-term productivity of that stream for production of fish. This potential adverse effect can be effectively mitigated by elimination of sediment sources or trapping sediment before it reaches the stream by maintaining vegetation along stream banks.

Some short-term uses also have the potential to increase long-term productivity. Harvest of old-growth timber stands and establishment of young faster growing stands increases the long-term productivity of the land to produce wood fiber. The current productivity of the Mt. Baker-Snoqualmie National Forest in terms of net timber growth is approximately 34 cubic feet per acre per year (1976 Timber Inventory). Harvest of these old growth stands can increases average annual growth on the Forest up to 90 cubic feet per acre per year.

The Multiple-Use Sustained-Yield (MUSY) Act of 1960, one of the principal laws relating to the Forest Service activities, requires the management of the various resources in such a manner that the productivity of the land will not be impaired. This law along with Forest Service Policy that was in effect prior to the MUSY Act have provided the basic frame work for development of management activities that are centered around maintaining the long-term productivity of the National Forests.

Many of the mitigation measures described in detail in Chapter II, Mitigation Incorporated in Alternatives, are designed specifically to maintain or enhance long-term productivity as short-term uses (projects) are designed and implemented. In all resource ares, long-term productivity of soil and water will be maintained or enhanced as a result of implementing the alternatives.

Implementation of the Forest Plan, which accompanies this FEIS, includes a monitoring plan. This monitoring plan will provide the data necessary to determine if the prescribed mitigation measures are effective in maintaining long-term productivity.

Irreversible or Irretrievable Commitment of Resources

An "irreversible commitment of resources" results from decisions to use or modify resources or environmental components of the Forest that cannot be renewed, or are renewable only over long periods of time. Examples are: old growth, soil productivity, minerals, cultural resources, scenery, and roadless areas. Once these resources are used or modified, they are irreversibly lost.

Soil productivity can be irreversibly lost or reduced by dedicated uses of the land. Examples of these uses would be arterial and collector roads, administrative sites, and developed recreation sites. Soil erosion, as a result of management activities, is an irretrievable loss because once the soil particles are removed from the site and deposited into a stream or river, they are no longer available. Accelerated erosion rates can reduce soil productivity and also reduce the water-holding capacity of the soil.

Removal of mineral or energy resources is an irreversible commitment of resources. The removal and utilization of rock resources for road construction would be an example of a common use on the Forest.

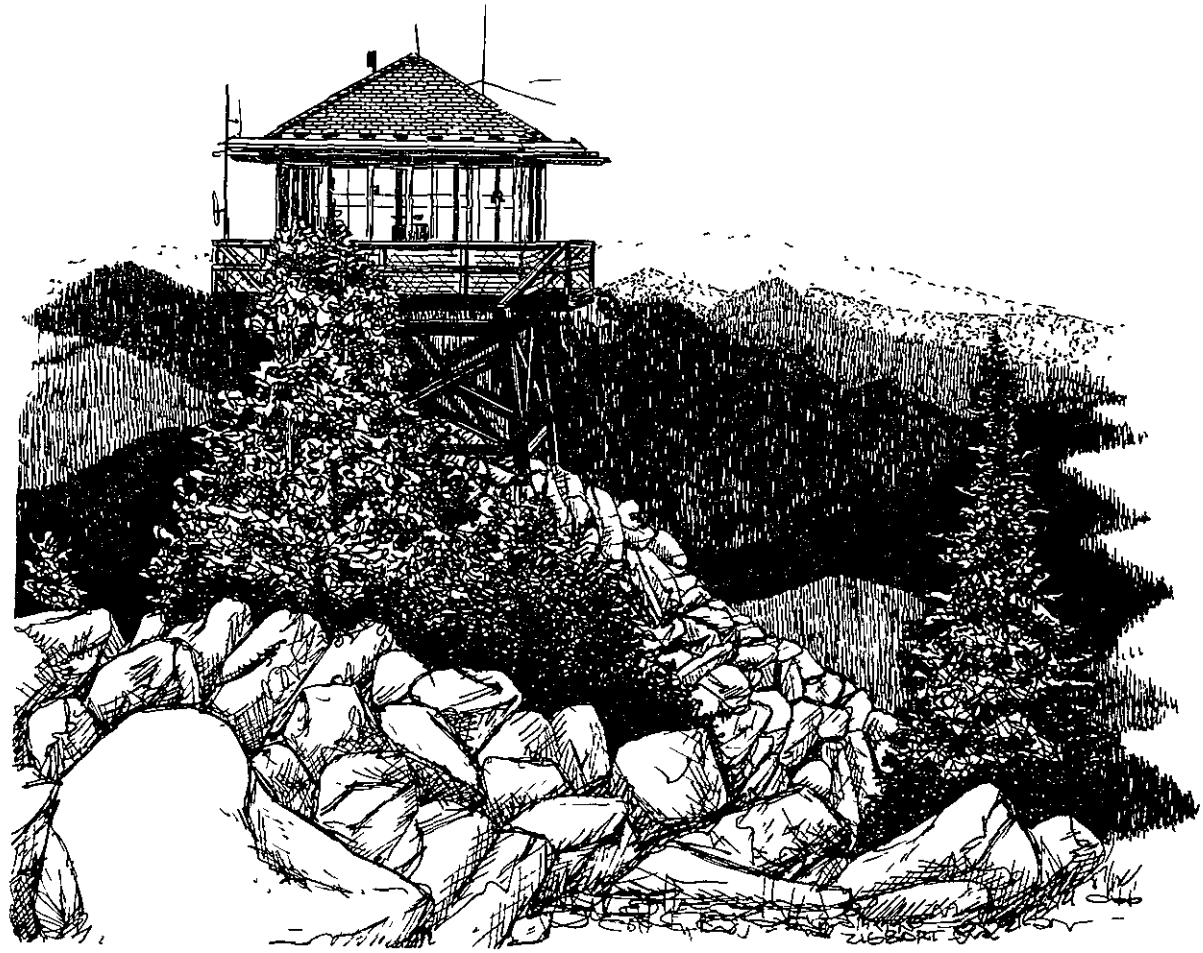
Reductions in habitat capability for old-growth-dependent species due to timber harvesting involve an irreversible and irretrievable commitment of resources.

The development of roadless areas would mean an irreversible loss of the characteristics which qualify these areas for Wildernesses or Roadless Areas. Development could also mean an irreversible loss of natural scenery and, in some cases, old-growth habitat.

Archaeological resources may be damaged by ground-disturbing activities; Irreversible information loss can result. Even when mitigation occurs prior to the activity, future study with more advanced techniques is precluded.

For American Indian religious use, land development removes the spiritual influence on the environment; this irreversibly removes the opportunity to conduct religious activities.

An "irretrievable commitment of resources" refers to a resource that is lost because of land use decisions or designations and/or scheduling decisions. These are opportunities foregone for the period of time that the resource cannot be used. Timber stands in management areas where timber harvest is not permitted represent an irretrievable loss of growth increases that could be made if the stands were being actively managed for timber production. Although the lost growth is irretrievable, the decision is not irreversible, since the stands could be managed at a later date in the future.



Probable Adverse Environmental Effects That Cannot Be Avoided

Implementation of Alternative J (Preferred) will result in some adverse environmental effects that cannot be avoided. The identification of an "adverse effect" is somewhat subjective, depending upon an individual's point of view. There are some effects considered to be adverse, by general agreement. The following effects are associated with implementation of Alternative J (Preferred). Although many of these effects can be reduced through the use of mitigation measures, they cannot be completely eliminated.

Timber harvest and associated road construction will result in adverse effects on scenery, water quality, soils, American Indian religious and cultural use areas, and dispersed recreation use in a non-motorized environmental setting.

Harvest of old-growth timber stands will reduce the amount of habitat available for old-growth dependent species and reduce their populations.

Ground-disturbing management activities and facilities management will probably result in inadvertent destruction or displacement of archeological and historical resources. Even when mitigation occurs, future study and interpretation are precluded.

Any mineral extraction activities that occur will result in destruction of vegetation, production of sediments, and effects on scenery.

Development and use of recreation facilities will result in compaction of soil, loss of vegetation, water pollution, dislocation of wildlife and disturbance of their habitat, noise and dust production in small areas, and localized air pollution from campfire smoke and vehicle exhaust.

Air quality will be degraded on a localized and short-term basis from prescribed fire and activities that generate dust from unpaved roads.

Any of the proposed small hydroelectric projects that reach the construction stage will result in adverse impacts on soil, water, and vegetation to some degree. These would generally be on a localized area. Construction techniques and mitigation measures can minimize most impacts and limit them to the construction effects on the visual resource. Some projects will also have long-term impacts on wildlife, American Indian religious and cultural use (effects on purity of streams), and recreation.

Development, especially timber harvest and hydroelectric projects, will create features and habitats out-of-keeping with traditional Indian religious use, and will reduce the availability of some plant materials, such as cedar.

Environmental Conditions Unchanged by Alternatives

Some environmental conditions and resource uses are essentially unchanged by any of the alternatives. These are resources which are often protected by law and are managed consistently in all alternatives. They include:

The wilderness acres are unchanged in any of the alternatives (refer to Chapter II, Alternatives Considered but Eliminated for Detailed Study). The acres

assigned to each wilderness ROS class vary between alternatives, but total wilderness acreage does not.

Management of the Skagit Wild and Scenic River is unchanged across all alternatives. The existing management plan for this river system (which is incorporated into this Forest Plan) will provide the same set of environmental conditions in each alternative (refer to Chapter II, Alternatives Considered but Eliminated from Detailed Study).

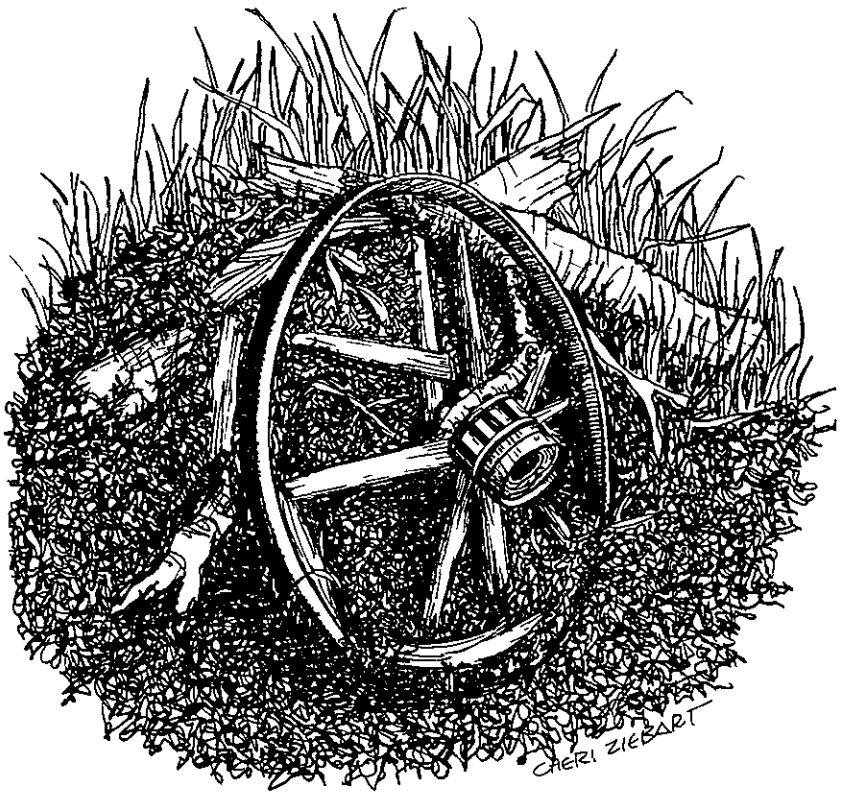
The basic land allocations established through implementation of the Alpine Lakes Area Land Management Plan (1981) are the same in all alternatives (refer to Chapter II, Alternatives Considered But Eliminated from Detailed Study).

The Mt. Baker National Recreation Area, size and management, is unchanged in any of the alternatives.

Management of the North Fork Nooksack, Lake Twenty-two, and Long Creek Research Natural Areas will remain the same in all alternatives. Although the alternatives recommend different numbers of new research natural areas for designation, the existing ones remain unchanged.

None of the alternatives result in any environmental consequences on prime farmlands, prime rangelands, or prime forestlands. None of these prime lands would be converted to other uses as a result of the implementation of any of the alternatives.

None of the alternatives results in any change in Indian Treaty Rights.



Abbreviations and Glossary for the Summary

ASQ - Annual Allowable Sale Quantity

BMP - Best Management Practices

CF - Cubic Foot

CFR - Code of Federal Regulations

DBH - Diameter at Breast Height

DEIS - Draft Environmental Impact Statement

FEIS - Final Environmental Impact Statement

FS - Forest Service

FSH - Forest Service Handbook

FSM - Forest Service Manual

FWS - Fish and Wildlife Service, U S. Department of the Interior

LAC - Limits of Acceptable Change

LTSYC - Long-Term Sustained Yield Capacity

MBS - Mt. Baker-Snoqualmie National Forest

MBF - Thousand Board Feet

MMBF - Million Board Feet

MCF - Thousand Cubic Feet

MMCF - Million Cubic Feet

MR - Management Requirement

NEPA - National Environmental Policy Act

NFMA - National Forest Management Act

PAOT - Persons-At-One-Time

ORV - Off-Road Vehicle

PNV - Present Net Value

RARE II - Roadless Area Review and Evaluation

RNA - Research Natural Area

ROS - Recreation Opportunity Spectrum

RPA - Forest and Rangeland Renewable Resources Planning Act
RVD - Recreation Visitor Day

SFEIS - Final Supplemental to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide - Spotted Owl Guidelines, 1986

SOHA - Spotted Owl Habitat Area

TSPQ - Timber Sale Program Quantity

USDA - United States Department of Agriculture

USDI - United States Department of Interior

USFWS - United States Fish and Wildlife Service

WFUD - Wildlife Fish User Day

WROS - Wilderness Recreation Opportunity Spectrum

Glossary

Activity - Actions, measures, or treatments that are undertaken that directly or indirectly produce, enhance, or maintain forest and rangeland outputs or achieve administrative or environmental quality objectives. An activity can generate multiple outputs. Forest Service activity definitions, codes, and units of measure are contained in the Management Information Handbook (FSM 1309.11).

Allowable Sale Quantity (ASQ) - The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the plan. This quantity is usually expressed on an annual basis as the "Average Annual Allowable Sale Quantity." For timber resource planning purposes, the allowable sale quantity applies to each decade over the planning horizon and includes only chargeable volume. Consistent with the definition of timber production, fuelwood and other non-industrial wood shall not be included in the allowable sale quantity.

Alternative - One of several policies, plans, or projects proposed for decision making.

Amenity - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. Amenity value is typically used in land use planning to describe those resource properties for which market values (or proxy values) are not or cannot be established (such as clean air and water, scenic quality, etc.).

Anadromous Fish - Those species of fish that mature in the sea and migrate into streams to spawn. Salmon, steelhead, and shad are examples.

Arterial Roads - See "Road, Arterial."

Best Management Practices (BMP's) - A practice or combination of practices that is determined by a State (or designated area-wide planning agency) after

problem assessment, examination of alternative practices, and appropriate public participation, to be the most effective, practicable (including technological, economic, and institutional considerations) means of preventing or reducing the amount of pollution generated by nonpoint sources to a level compatible with water quality goals (Federal Register, Volume 40, No. 230 dated 11/28/75).

Big Game - Those species of large mammals normally managed for sport hunting. Big Game Summer Range - A range, usually at higher elevation, used by deer and elk during the summer. Summer ranges are usually much more extensive than winter ranges.

Big Game Winter Range - A range, usually at lower elevation, used by migratory deer and elk during the winter months; usually more clearly defined and smaller than summer ranges.

Board Foot - The amount of timber equivalent to a piece of wood one foot square and one inch thick, being the unit in board foot measure

Broadcast Burn - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard or as a silvicultural treatment, or both.

Capability - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at given levels of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils, and geology, as well as on the application of management practices, such as silviculture or protection from fire, insects, and disease.

Carrying Capacity - 1) The number of organisms of a given species and quality that can survive in, without causing deterioration of, a given ecosystem through the least favorable environmental conditions that occur within a stated interval of time 2) In recreation management, the level of recreational use that a site can provide without deterioration of the quality of the recreation experience of the resource.

Cavity Excavators - The hollow excavated in trees by birds or other natural phenomena; used for roosting and reproduction by many birds and mammals.

Cedar - Areas that have been sources of various cedar products, or are at least identified as significant stands of cedar. Cedar is used in everything from smokehouse construction to spirit dancer costumes to basketry and other utilitarian items. Of all forest products it may be the most significant to the Indians of today, although it cannot survive without a total appropriate environment, most of which was used by the Indians in the past.

Cemeteries & Archaeological Sites - Villages, camps, and burial areas (not in most instances known to be cemeteries). Other sites are ethnographically and/or historically known cemeteries. Some are maintained and still used, others are not.

Ceremonial Flora - Locations known to contain certain plants that have ritual or healing properties. Some areas so designated are large and may contain several such plant species, others are small and may possess only a few. Often

areas containing specific flora are considered as ceremonially, ritually, and/or religiously powerful.

Chargeable Volume - All volume that is included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on Regional utilization standards.

Code of Federal Regulations (CFR) - A codification of the general and permanent rules published in the Federal Register by the Executive departments and agencies of the Federal Government.

Collector Roads - See "Road, Collector."

Commodity - A transportable resource product with commercial value; all resource products that are articles of commerce.

Concern - A point, matter, or question raised by management and/or the public that must be addressed in the planning process.

Congressionally Classified and Designated Areas - Areas that require congressional enactment for their establishment, such as National Wilderness Areas, National Wild and Scenic Rivers, and National Recreation Areas.

Constraint - A confinement or restriction on the range of permissible choices.

Cubic Foot - A unit of quantity for lumber or timber equal to a cube 1x1x1 foot.

Cumulative Effects or Impacts - The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7 - these regulations use effects and impacts synonymously.)

DBH (d.b.h.) - Diameter at breast height, measured at 4 feet 6 inches from the ground.

Demand - The amount of an output that users are willing to take at a specified price, time period, and condition of sale.

Developed Recreation - Recreation that requires facilities that, in turn, result in concentrated use of an area. Examples of recreation areas are campgrounds and ski areas; facilities might include roads, parking lots, picnic tables, toilets, drinking water, ski lifts, and buildings.

Dispersed Recreation - A general term referring to recreation use outside a developed recreation site, such as scenic driving, hiking, fishing, cross-country skiing, horseback riding, snow mobiling, hunting, backpacking, and recreation in primitive environments.

Diversity - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. See also "Edge," "Horizontal Diversity," and "Vertical Diversity."

Douglas-fir Type - An association of tree species in which Douglas-fir is recognized as one of the principal seral species.

Draft Environmental Impact Statement (DEIS) - The draft statement of environmental effects which is required for major federal actions under Section 102 of the National Environmental Policy Act, and released to the public and other agencies for comment and review.

Ecosystem - An interacting system of organisms considered together with their environment; for example, marsh, watershed, and lake ecosystems.

Effects - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and occur later in time and/or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air, water, and/or other natural systems, including ecosystems.

> Effects and impacts as used in this statement/plan are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial (40 CFR 1508.8).

Endangered Species - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified by the Secretary of the Interior as endangered in accordance with the Endangered Species Act of 1973, as amended.

Environmental Analysis - A process associated with the preparation of an environmental assessment or environmental impact statement. An analysis of alternative actions and their predictable short- and long-term environmental effects, including physical, biological, social, and economic.

Erosion - 1) The wearing away of the land surface by running water, wind, ice, or other geologic agents, including such processes as gravitation creep; or 2) detachment and movement of soil or rock fragments by water, wind, ice, or gravity.

Even-Aged Management - The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together. Managed even-aged forests are characterized by a distribution of stands of varying ages (tree sizes) throughout the forest area. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands. (36 CFR 219.3)

Final Environmental Impact Statement (FEIS) - The final version of the statement of environmental effects required for major federal actions under section 102 of the National Environmental Policy Act. A revision of the draft

environmental impact statement to include public and agency responses to the draft.

Fisheries Habitats - Streams, lakes, and reservoirs that support fish populations.

Foreground - A term used in visual management to describe the portions of a view between the observer and up to 1/4 to 1/2 mile distant. The stand of trees immediately adjacent to a high-value scenic area, recreation facility, or forest highway. See "Background," "Middleground."

Forest or Forest Land - 1) Forest is used in the text as a proper noun to substitute for Mt. Baker-Snoqualmie National Forest. 2) See "Timber Resource Land Suitability Classification."

Forest Service Handbook (FSH) - For Forest Service use, directives that provide detailed instructions on how to proceed with a specialized phase of a program or activity.

Forest Service Manual (FSM) - A system of manuals which provides direction for Forest Service activities.

FORPLAN - Acronym for Forest Planning Model. A linear programming system used for developing and analyzing forest planning activities. Can be used to simulate management practices while at the same time optimizing for any given desired objective. As a manageable representation of reality, it can be used to manipulate information and look at alternative approaches to management, calculating tradeoffs and opportunity costs. See Appendix B for more detail.

Goal - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms with no specific completion date. Goal statements form the principal basis from which objectives are developed

Guideline - An indication or outline of policy or conduct that is not a mandatory requirement (as opposed to a standard, which is mandatory).

Habitat Capability - The estimated ability of an area, given existing or predicted habitat conditions, to support a wildlife, fish or plant population. Measured in terms of potential population numbers

Hydrology - The scientific study of the properties, distribution, and effects of water in the atmosphere, on the earth's surface, and in soil and rocks.

Indicator Species - Species identified in a planning process that are used to monitor the effects of planned management activities on viable populations of wildlife and fish including those that are socially or economically important. See Management Indicator Species.

Interdisciplinary Team (ID Team) - A group of individuals with different training assembled to solve a problem or perform a task. The team is assembled out of recognition that no one scientific discipline is sufficiently broad to adequately assess the situation.

Intermingled Ownerships - Lands within the National Forest boundaries or surrounded by National Forest lands owned by private interests or other

government agencies. Because of early land grants, these lands frequently are in a checkerboard ownership pattern.

Irretrievable - Applies to losses of production, harvest, or use of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

Irreversible - Applies primarily to the use of non-renewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods. Irreversible also includes loss of future options.

Issue - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process.

Legendary - Locations that may have, or may have had, spiritual significance. They appear also to be areas which are significant to the cosmology of the Indian groups in the project area. They are significant in mythology having to do with the origin and development of the area and of the people of that area.

Long-Term Sustained-Yield Capacity (LTSYC) - The highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives.

Management Area - An area or non-contiguous areas of the Forest assigned to a specific management strategy (the management strategy then becomes the management prescription for the area(s)).

Management Direction - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them.

Management Indicator Species (MIS) - A species selected because its welfare is presumed to be an indicator of the welfare of other species using the same habitat. A species whose condition can be used to assess the impacts of management actions on a particular area. See "Indicator Species."

Management Intensity - A management practice or combination of management practices and associated costs designed to obtain different levels of goods and services.

Management Requirement (MR) - Minimum standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, soil and water diversity, to be met in accomplishing National Forest System goals and objectives.

Market Resources - Products derived from renewable and nonrenewable resources that have a well-established market value for example, forage, timber, water, and minerals.

MBF - One thousand board feet. Lumber or timber measurement term.

MCF - One thousand cubic feet. Lumber or timber measurement term.

Middleground - The visible terrain beyond the foreground where individual trees are still visible, but do not stand out distinctly from the stand. See "Foreground" and "Background."

Minerals - Common - mineral deposits which do not possess distinct, special economic value, such as common varieties of sand, stone, gravel, pumice, pumicite and cinders. They may have value for use in trade, manufacturing, science, or in the mechanical or ornamental arts.

> **Leasable** - federally owned minerals which are disposed of under the Mineral Leasing Act of 1920, as amended. These include coal, oil, gas, phosphate, sodium, potassium, oil shale, and in some states sulphur and geothermal steam.
>
> **Locatable** - federally owned minerals which can be located and patented under the 1892 Mining Law, as amended. In general, the locatable minerals are those hardrock minerals which are mined and processed for the recovery of metals. They also may include certain nonmetallic minerals and uncommon varieties of mineral materials, such as valuable and distinctive deposits of limestone or silica.

Mitigation - Avoiding or minimizing impacts by limiting the degree or magnitude of the action and its implementation, rectifying the impact by repairing, rehabilitating, or restoring the effected environment; reducing or eliminating the impact by preservation and maintenance operations during the life of the action.

MMBF - Million board feet. Lumber or timber measurement term.

MMCF - Million cubic feet. Lumber or timber measurement term.

Monitoring - A process to collect significant data from defined sources to identify departures or deviations from expected plan outputs.

Multiple Use - The management of all the various renewable surface resources of the National Forest System so that they are utilized in the combination that will best meet the needs of the American people; making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions; that some lands will be used for less than all of the resources; and harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land, with consideration being given to the relative values of the various resources, and not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output.

Municipal Supply Watershed - A watershed that provides water for human consumption, where Forest Service management could have a significant effect upon the quality of water at the intake point, and that provides water used by a community, or any other public water system that regularly serves at least 25 individuals at least 60 days out of the year or that provides at least 15 service connections. In addition to cities, this includes campgrounds, residential developments, and restaurants.

National Environmental Policy Act (NEPA) of 1969 - An act to declare a National policy which will encourage productive and enjoyable harmony between humankind

and the environment, to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of humanity, to enrich the understanding of the ecological systems and natural resources important to the Nation, and to establish a Council on Environmental Quality. (The Principal Laws Relating to Forest Service Activities, Agriculture Handbook No. 453, USDA, Forest Service, 359 pp.)

National Forest Management Act (NFMA) of 1976 - A law passed as an amendment to the Forest and Rangeland Renewable Resources Planning Act, requiring the preparation of Regional Guides and Forest Plans and the preparation of regulations to guide that development.

Net Public Benefits - An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs), whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of units of the National Forest System is consistent with the principles of multiple use and sustained yield.

Noncash Benefits - These are benefits or values that people derive from the good or service being provided, but where there is no market in which to exchange that good or service for cash, i.e. the person benefitting does not pay any of the actual value received.

Nonchargeable Volume - All volume that is not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity. (FSH 2409.13)

Non-declining Flow - Where the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than the long-term sustained yield capacity.

Non-market - Products derived from National Forest resources that do not have a well-established market value for example, recreation, wilderness, wildlife.

Objective - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals.

Off-Road Vehicle (ORV) - Any motorized vehicle designed for or capable of cross-country travel on or immediately over land, water, sand, snow, ice, marsh, swampland, or other natural terrain. The term excludes any registered motorboat, any military, fire, emergency, or law enforcement vehicle when used for emergency purposes, and any vehicle whose use is expressly authorized by the respective agency head under a permit, lease, license, or contract. (Executive Order 11644)

Old-Growth Stand - Any stand of trees 10 acres or greater generally containing the following characteristics: 1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage; 2) stands will usually contain a multi-layered canopy and trees of several age classes; 3) standing dead trees and down material are present; and 4) evidence of human

activity may be present, but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand.

Output - The goods, end products, or services that are purchased, consumed, or used directly by people. Goods, services, products, and concerns produced by activities that are measurable and capable of being used to determine the effectiveness of programs and activities in meeting objectives. A broad term for describing any result, product, or service that a process or activity actually produces.

Persons-At-One-Time (PAOT) - The number of people in an area or using a facility at the same time. May be used as "maximum PAOT" to indicate the capacity of an area or facility to support peak usage within established user density standards and without degradation to biophysical resources.

Potential Yield - Sustainable output of wood fiber available after the yield foregone for the management opportunities of other resources has been deducted from the biological potential.

Present Net Value (PNV) - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area. (36 CFR 219.3)

Primary Cavity Excavators - Wildlife species that excavate cavities in wood, for food and shelter. Example: woodpeckers.

Public Issue - A subject or question of widespread public interest relating to management of National Forest System. (36 CFR 219.3)

Record of Decision - A document separate from but associated with an Environmental Impact Statement which states the decision, identifies all alternatives, specifying which were environmentally preferable, and states whether all practicable means to avoid environmental harm from the alternative have been adopted, and if not, why not.

Recreation Capacity - The number of people that can take advantage of the supply of a recreation opportunity during an established use period without substantially diminishing the quality of the recreation experience or the biophysical resources.

Recreation Opportunity Spectrum (ROS) - A conceptual framework for defining types of recreation opportunities, physical settings, and experiences a visitor can expect. It is an inventory system and a management tool. There are six ROS classes. Each class is defined in terms of the degree to which it satisfies certain recreation experience needs, based on the extent to which the natural environment has been modified, the type of facilities provided, the degree of outdoor skills needed to enjoy the area, and the relative density of recreation use. Five of the 6 classes are (urban not included here):

1. Primitive--Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and controls. Motorized use within the area is not permitted.

2. Semi-primitive nonmotorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but would be subtle. Motorized recreation use is not permitted.

3. Semi-primitive Motorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but would be subtle. Motorized recreation use of local primitive or collector roads with predominantly natural surface and trails suitable for motor bikes is permitted.

4. Roaded Natural--Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment. Interaction between users may be moderate to high, with evidence of other users prevalent. Resource modification and utilization practices are evident, but harmonize with the natural environment. Conventional motorized use is allowed and incorporated into construction standards and design of facilities.

5. Rural--Area is characterized by a natural environment that has been substantially modified by development of structures, vegetative manipulation, or pastoral agricultural development. Resource modification and utilization practices may be used to enhance specific recreation activities and to maintain vegetative cover and soil. Sights and sounds of humans are readily evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people. Facilities are often provided for special activities. Moderate user densities are present away from developed sites. Facilities for intensified motorized use and parking are available.

Recreation Visitor Day (RVD) - A measure of recreation use. Twelve visitor hours, which may be aggregated continuously, intermittently, or simultaneously by one or more persons.

Regeneration - The actual seedling and saplings existing in a stand; or the act of establishing young trees naturally or artificially.

Regeneration Cutting (Harvest) - Any removal of trees intended to assist regeneration already present or to make regeneration possible.

Region - An area covered by a Regional Guide. See FSM 1221.3 for organizational definitions.

Regional Forester - The Forest Service official responsible for administering a single Region.

Regional Guide - The guide developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended. It guides all

natural resource management activities, and establishes management standards and guidelines for the National Forest System lands within a given Region. It also disaggregates the assigned Regional RPA objectives to the Forests within that Region.

Research Natural Area (RNA) - In USDA Forest Service usage, RNAs are areas designated to ensure representative samples of as many of the major naturally-occurring plant communities as possible. An area established specifically to preserve a representative sample of an ecological community, primarily for scientific and educational purposes.

Riparian Area - A geographically delineated area with distinctive resource values and characteristics that is comprised of aquatic and riparian ecosystems. This includes floodplains, wetlands, and all areas within a horizontal distance of approximately 100 feet from the normal line of high water of a perennial stream channel or from the shoreline of other bodies of water.

Road: Arterial - A road that serves a large land area and usually connects with a public highway or other arterial road to form an integrated network of primary travel routes. The location and standard are often determined by a demand for maximum mobility and travel efficiency rather than specific resource-management service. They are usually developed and operated for long-term land and resource management purposes and constant service.

Collector - A road that serves a smaller land area than an arterial road and is usually connected to an arterial road or public highway. They collect traffic from local roads or terminal facilities. The location and standard are influenced by both long-term multi-resource service needs, as well as travel efficiency. Collector roads may be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility (FSM 7700).

Local - A road that connects terminal facilities with a collector road, arterial road, or public highway. The location and standard are usually determined by that required to serve a specific resource activity, rather than travel efficiency. Local roads may be developed and operated for either long- or short-term service.

Roaded Natural (RN) - See "Recreation Opportunity Spectrum."
Roaded Modified (RM) - " " " "

Roadless Area Review and Evaluation (RARE II) - A comprehensive process directed by the Secretary of Agriculture to identify roadless and undeveloped land areas in the National Forest system and to determine their uses for either wilderness or other resource management and development and to determine areas that would require further planning to make such a decision.

Roadless Areas - These lands, inventoried in the Roadless Areas Review and Evaluation (RARE II), were not designated wilderness by the Washington State Wilderness Act of 1984. See "Released Roadless," and Unroaded."

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974. Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of the act. The most recent recommended program was completed in 1985.

Second Growth - Forest growth that has come up naturally after some drastic interference (for example, wholesale cutting, serious fire, or insect attack) with the previous forest growth.

Sediment - Solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface.

Semi-primitive Motorized ROS Class - See "Recreation Opportunity Spectrum."
Semi-primitive Nonmotorized ROS Class - See "Recreation Opportunity Spectrum."

Sensitive Species - Plant or animal species which are susceptible or vulnerable to activity impacts or habitat alterations. Those species that have appeared in the Federal Register as proposed for classification and are under consideration for official listing as endangered or threatened species, that are on an official State list, or that are recognized by the Regional Forester as needing special management to prevent their being placed on Federal or State lists.

SOHA (Spotted Owl Habitat Area) - A habitat area designated to support one pair of owls. See the Final SEIS for the Pacific Northwest Regional Guide.

Standard - A statement which describes a condition when a job is done properly. Standards show how well something should be done, rather than what should be done.

Suitable Forest Land - Land to be managed for timber production on a regulated basis. See Timber Resource Land Suitability Classification.

Thermal Cover - Cover used by animals to lessen the effects of weather; for elk, a stand of coniferous trees 40 feet or more tall with an average crown closure of 70 percent or more.

Threatened Species - Those plant or animal species likely to become endangered species throughout all or a significant portion of their range within the foreseeable future.

Timber Resource Land Suitability Classification - National Forest System lands are classified according to the following definitions:

1. **Non-forest** - Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2. **Forest** - Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for non-forest use.

3. **Unsuitable Forest Land (Not Suited)** - Forest land that is not managed for timber production because (a) the land has been withdrawn by Congress, the Secretary, or the Chief; (b) the land is not producing or capable of producing crops of industrial wood; (c) technology is not available to prevent irreversible damage to soils, productivity, or watershed conditions; (d) there is no reasonable assurance that lands can be adequately restocked within 5 years after final harvest,

based on existing technology and knowledge, as reflected in current research and experience, (e) there is at present, a lack of adequate information to responses to timber management activities; or (f) timber management is inconsistent with or not cost efficient (not appropriate) in meeting the management requirements and multiple-use objectives specified in a Forest Plan land management alternative.

4. **Tentatively Suitable Forest Land** - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils, productivity, or watershed conditions; (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvest; and (d) adequate information is available to project responses to timber management activities.

5. **Suitable** - Tentatively suitable forest land identified as appropriate for timber production in a Forest Plan land management alternative.

6. **Commercial Forest (CFL)** - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; and (c) where existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

Timber Production - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use other than for fuelwood.

Timber Sale Program Quantity (TSPQ) - The volume of timber planned for sale during the first decade of the planning horizon. It includes the allowable sale quantity (chargeable volume) and any additional material (nonchargeable volume) planned for sale. The timber sale program quantity is usually expressed as an annual average for the first decade.

Unroaded - 1) RARE II roadless areas released by the Washington State Wilderness Act of 1984 from being considered for designation as wilderness during development of the initial Forest Plan; 2) In the Forest's FORPLAN Model, an analysis area identifier which includes roadless areas defined in "1" above in addition to other unroaded areas in the Forest containing tentatively suitable forest land; 3) A term used to equal the sum of recreation use or carrying capacity from the primitive, semi-primitive nonmotorized, and semi-primitive motorized recreation opportunity spectrum areas outside wilderness.

Viable Population - The number of individuals of a species required to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their region.

Viewshed - (Sometimes termed "Viewshed Corridor" or "Visual Corridor") Viewsheds are the "seen" landscape visible to most Forest visitors from roads, trails, rivers, and recreation areas. Most are corridors, one-quarter to two miles wide. Viewsheds viewed from primary travel routes and use areas are "Sensitivity Level 1." Viewsheds viewed from secondary travel routes and use areas are "Sensitivity Level 2."

Visual Quality Levels (VQL) - An inventoried measure of acceptable levels of modification of the visual resource. VQL's are used in Forest planning as an indicator of social (visual) acceptability and as an input for management decisions. VQL's become Visual Quality Objectives in the approved Forest Land Management Plan.

1. **Preservation**--Allows ecological changes only
2. **Retention**--*Human activities are not evident to the casual Forest visitor.*
3. **Partial Retention**--Human activity may be evident, but must remain subordinate to the characteristic landscape.
4. **Modification**--Human activity may dominate the characteristic landscape, but must, at the same time, follow naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.
5. **Maximum Modification**--Human activity may dominate the characteristic landscape, but should appear as a natural occurrence when viewed as background.

Wilderness - Areas designated by congressional action under the 1964 Wilderness Act Wilderness is defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation. Wilderness areas are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature, with the imprint of human activity substantially *unnoticeable, have outstanding opportunities for solitude or for a primitive* and confined type of recreation; include at least 5,000 acres or are of sufficient size to make practical their preservation, enjoyment, and use in an unimpaired condition, and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest.

Wild and Scenic Rivers - Those rivers or sections of rivers designated as such by congressional action under the 1968 Wild and Scenic Rivers Act, as supplemented and amended, or those sections of rivers designated as wild, scenic, or recreational by an act of the Legislature of the State or States through which they flow. Wild and Scenic Rivers may be classified and administered under one or more of the following categories:

1. Wild River Areas--Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.

2. Scenic River Areas--Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

3. Recreational River Areas--Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development

along their shorelines, and that may have undergone some impoundment or diversion in the past.

Wilderness Recreation Opportunity Spectrum - See "Recreation Opportunity Spectrum." Wilderness ROS and their standards apply to all designated wilderness on the Forest. For specific direction regarding Alpine Lakes, consult the Alpine Lakes Area Land Management Plan. Within each WROS Class there are Limits of Acceptable Change (LAC). LAC is a maximum limit of change allowed. Managers try to achieve the best conditions possible rather than allowing conditions to deteriorate until the threshold is reached. See "Limits of Acceptable Change."

1. Transition - This trailed class includes system trails that have a travelway worn to mineral soil over long distances, and is characterized by having a large proportion of day-users, often mixed in with overnight and long distance travelers. This area is usually adjacent to trailheads and extends into the wilderness a distance that is typically traveled in one day by a hiker. This class includes areas accessed by trail, around lakes, or other attractions used by people or pack stock, within the day-use influence area. The class extends at least 500 feet on either side of a trail; it may be wider around lakes or heavily used areas. The length of this trail class will be established for each trail depending on ease of travel, distance from trailhead outside wilderness, and destination attractions inside wilderness. Length will generally be 3 to 5 miles inside the wilderness boundary If the day-use activity occurs entirely outside wilderness, the trail will have no Transition Class.

2. Trailed - This class includes all managed system trails. It extends beyond the Transition Class. This class extends at least 500 feet on either side of the trail but may be wider around lakes or heavily used areas.

3. General Trailless - This class includes areas not falling into the other classes. It attracts very low use because of a relative lack of trails or destination spots. The area is unmodified; user-made trails are not encouraged, but they may exist. If obvious user-made trails become well established, or are causing resource damage, consideration will be given to their reconstruction in order to protect the wilderness resource from further damage. Reclassification from general trailess to railed requires a supplement of the Forest Plan, which shall include full public involvement. This class is available for new trail construction or relocation of existing trails to protect resources or meet objectives by dispersing use. If this should occur, the trail will only be constructed to no higher than "more difficult or "most difficult" standards.

4. Dedicated Trailless - This class is managed forever trailless; user-made trails are not permitted. It may include popular attractions accessed only by cross-country travel. Human impact and influence is, by design, minimal; therefore user restrictions may be necessary to insure that trailless experiences remain. Dedicated Trailless areas should be of a size that will allow for a meaningful experience and can be reasonably protected for the experiences and remoteness identified. Generally the class is at least 1,000 acres in

size and contain whole drainages or basins out of sight and sound of trails or areas outside the wilderness.

5. Special Areas - The intent of this class is to provide for significant changes in standards or other management guidelines for unique areas. Areas that qualify for Special Area designation include congressionally acknowledged areas, areas of significant cultural or historic value, areas with special considerations, and areas with limited management options to deal with unique situations. Areas do not qualify for this class for administrative convenience in dealing with overuse. The class is rare and will not exist in many wildernesses.

Wildlife Fish User Day (WFUD) - One WFUD consists of 12 hours of recreation that is the result of fish or wildlife, such as hunting, fishing, birdwatching, etc.

Wood Residue - The residual wood remaining as a result of timber cutting, other vegetation disturbing activity, storms, fire, or other natural event. It includes any unutilized woody material. See "Slash" and "Residue Utilization."

Yield Tables - Tables that estimate the level of outputs that would result from implementing a particular activity. Usually referred to in conjunction with FORPLAN input or output. Yield tables can be developed for timber volumes, range production, soil and water outputs, and other resources.

Abstract: This final Environmental Impact Statement describes and analyzes eight alternatives for managing 1,724,229 aces of land administered by the Mt. Baker-Snoqualmie National Forest. Public comment on the Draft Environmental Impact Statement resulted in modification of Alternative G and formation of two new alternatives: I and J. Draft EIS Alternatives D, E, E-Departure, F, and H-Departure were dropped because of lack of public support in response to the DEIS; they were not needed to provide a full range of alternatives. Each of the alternatives responds differently to the major issues and concerns identified. **Alternative NC (No Change)** continues management of the Forest under existing plans, including the 1963 Timber Management Plans (as amended) without compliance with all the provisions of the National Forest Management Act of 1976 (NFMA) implementing regulations. **Alternative A (No Action)** continues the management of the Forest under current plans, policies, and direction, updated to comply with new legislation, including NFMA. **Alternative B (RPA)** responds to the 1980 Resource Planning Act Program. **Alternative C** emphasizes primitive/semi-primitive dispersed recreation, scenery, fish and wildlife. **Alternative G-Modified**, developed to be responsive to the goals and objectives of the Conservation Liaison Group, emphasizes natural ecosystems, diversity of native plants and animals, providing uses not found on private land, an extensive trails system, and timber production consistent with other goals. **Alternative H** emphasizes unroaded recreation, scenic values, wildlife, and timber production. **Alternative I**, developed to be responsive to the goals and objectives of the Public Land Users' Society, emphasizes marketable resources (timber, developed recreation, minerals), enhancement of big game habitat, and an extensive trails system. **Alternative J** is the Forest Service preferred alternative, and was developed in response to public comments received on the draft EIS. The goal is similar to Alternative H, but the

Preferred Alternative provides a considerable increase in trail mileage, an increase in the number of rivers recommended for addition to the National Wild and Scenic River System, three Special Areas, increased emphasis on unroaded recreation, greater protection of scenic values on travel corridors, and timber production on suitable acres assigned to a harvest prescription. Other resources are managed at levels commensurate with the objectives of the alternative.

This document presents the results of an environmental analysis of alternative ways of managing the Mt. Baker-Snoqualmie National Forest for the next 10 to 15 years. Long-term estimates of Forest resources and environmental conditions are considered; however, the alternative adopted as the basis for the Forest Plan would apply for 15 years or less.

The Forest Land and Resource Management Plan outlines the treatment of issues and concerns, analyzes the current management situation, and sets forth the proposed standards and guidelines for managing the Mt. Baker-Snoqualmie National Forest under Alternative J.

SUMMARY

Final Environmental Impact Statement
Land and Resource Management Plan
Mt. Baker-Snoqualmie National Forest

PART 1 - INTRODUCTION

This Final Environmental Impact Statement (FEIS) discusses the alternative strategies for future management of the land and resources of the Mt. Baker-Snoqualmie National Forest. The preferred alternative is developed into the accompanying Land and Resource Management Plan (the Forest Plan). The Record of Decision describes the decision to implement the Forest Plan and the rationale for that decision. While the Forest Plan will guide the management of the Forest for the next 10 to 15 years, the analysis covers a planning horizon of 150 years to evaluate and display the long-term effects of current actions.

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released for public review and comment in December, 1987. This FEIS and Forest Plan were developed in response to those comments and incorporates many suggestions made by the public and other agencies. Changes that were made between the DEIS and FEIS are described throughout the document and highlighted at the beginning of each chapter.

This is a general summary of the entire FEIS. It emphasizes the issues and concerns raised by the public, other agencies, and Forest Service personnel regarding management of the Mt. Baker-Snoqualmie National Forest. This summary is arranged in a slightly different order to facilitate understanding by the general reader. **Part 1** includes a brief discussion of the public responses to DEIS, the changes made between the DEIS and FEIS, the purpose and need for the proposed action, and a description of the affected environment. In **Part 2**, the major issues, concerns, and opportunities (ICO's) are presented.

Part 3 includes descriptions of eight alternatives; a goal statement is given for each and the "design criteria" that were used to develop each alternative are described. **Part 4** is a condensed version of Chapter IV of the FEIS: the environmental consequences of implementing the alternatives.

Public Response to the DEIS

On December 30, 1987 the DEIS and Proposed Forest Plan were released to the public. Copies were distributed to government agencies, libraries in the greater Puget Sound area, and interested members of the public. A "Public Summary" package, which included alternative and resource maps, was sent to several thousand individuals. Public open houses were held in 11 cities in the Puget Sound area; news releases inviting the public to attend were printed and circulated in area newspapers.

The Forest received nearly 12,000 responses to the DEIS during the 115 day review period. The most popular form used to comment was a response form (prepared by a public interest group) (67%), followed by personal letters and cards (30%), and other form letters (2%). Most replies came from the five-county area of influence for the Forest; refer to the vicinity map, Figure S-1. Nearly half of the responses came from the Seattle-Tacoma-Everett metropolitan area.

The Interdisciplinary Planning Team read and considered every response. A detailed content analysis process was used for coding and analyzing the input received. This allowed the team to report what the public said, in their words. The results of this analysis were very useful in moving from a draft to final plan; most of the changes between the DEIS and FEIS are in response to public comment. A summary of the complete analysis of comments, plus the Forest Service responses to substantive comments can be found in Appendix J, FEIS.

Three alternatives generated the most comment: support for the Public Land Users Society (PLUS) Alternative (as outlined in their input); support for Alternative G, as presented in the DEIS but with the addition of Backcountry areas and more trails; and opposition to Alternative H, the Forest Service preferred alternative in the DEIS.

The comments on issues within the 12,000 responses were numerous and varied. Over 68,000 individual comments related to recreation and trails opportunities and uses. An additional 15,000 comments focused on timber; 14,000 on the northern spotted owl and other wildlife; and 4,000 related to old growth. Other issues generating considerable response included: roads, wild and scenic rivers, roadless areas, the cumulative effects of management activities, water quality and fisheries, jobs, log exports, and wide variety of technical planning process comments.

There were only two areas of general consensus: recreation (of all types) is a vitally important function of the Mt. Baker-Snoqualmie. Secondly, more trails are needed; opinion varied on who should use those trails. Strongly-voiced opinions on all sides of these issues were stated.

Changes Between Draft and Final

The tremendous public response to the DEIS provided the Forest with a wealth of suggestions for improvements about how to provide more benefits to the public. These ranged from broad conceptual approaches to specific technical changes.

Beginning with the DEIS Preferred Alternative (H), Alternative J was developed to respond to public comments and new information. This is the preferred alternative in the FEIS; it is described below, in Part 3.

A new alternative is included in the FEIS; Alternative I was developed to respond to the goals put forth in the PLUS response. Alternative G has been modified, to better reflect the comments received; it is Alternative G-Modified in the FEIS. Several alternatives included in the DEIS are not displayed in the FEIS, as they received little support in comments and are not needed to provide a full range of alternatives for analysis.

The issues, concerns, and opportunities were refocused, to reflect public comment. Wild and Scenic Rivers is now a major ICO, based on the comments.

New timber yield tables and technical corrections were made to the FORPLAN computer model in response to public comments.

The management requirements (MR's) were revisited. Spotted Owl Habitat Areas changed to meet the Record of Decision for the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide. MR's for mountain goats were enlarged, and deer and elk MR's were dropped to meet regional direction. An analysis of the condition of the Forest's watersheds was conducted; this

formed the basis for a method to meet water quality and riparian area MR's. The procedure was developed in response to public comments.

The wild and scenic river eligibility process was redefined, also in response to public input. A committee was formed for this task, and it included representatives from several groups and Washington State agencies.

Proposed vegetative management in the Mt. Baker-Snoqualmie National Forest FEIS and Forest Plan is consistent with the FEIS for Managing Competing and Unwanted Vegetation, Pacific Northwest Region (released in December, 1988).

Finally, some data have been updated (such as the acres of timber harvested) since the DEIS was issued, new fisheries values were calculated, more discussion has been added to the diversity of plant and animal communities sections, and errors and omissions have been corrected.

Purpose and Need

The purpose of the Forest Plan is to direct all natural resource management activities on the Mt. Baker-Snoqualmie National Forest. The preferred alternative is the basis for the Forest Plan document. Preparation of the Land and Resource Management Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated Planning Regulations (36 CFR 219).

The preparation of an environmental impact statement disclosing a preferred alternative and a broad range of additional alternatives is required by the National Environmental Policy Act of 1969 (NEPA) and its implementing regulations (40 CFR 1500), and the implementing regulations of NFMA. For purpose of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents.

The Planning Period

The Forest Plan period is ten to fifteen years. Throughout this document, projections beyond that time are provided for informational purposes. The Forest Service is required to revise the plan within 15 years of its adoption.

Current Management Situation

The Mt. Baker-Snoqualmie National Forest is currently managed under several different plans. Examples of these include Timber Management Plans, District Multiple Use Plans, and the Glacier Peak Wilderness Management Plan. The Forest Plan supersedes or incorporates all previous land and resource management plans; the Alpine Lakes Area Management Plan and the Skagit Wild and Scenic River Management Plan will be incorporated into the Plan. Upon implementation, all Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities.

The Affected Environment

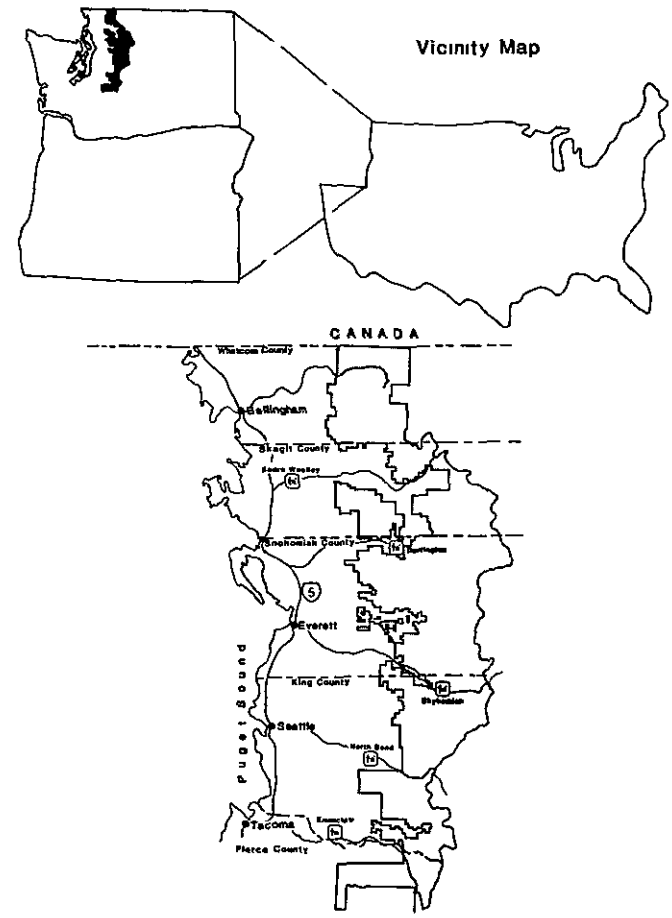
The 1.7 million acre Mt. Baker-Snoqualmie National Forest serves a large and diverse population. The Forest is located in some of the nation's most beautiful country - the Cascade Mountains - in northwest Washington state. The Forest contains lush, forested valleys; steep and rugged mountain peaks; glaciers; and numerous high-elevation lakes. The diversity of both the

physical and social settings contributes to the complexity of issues facing Forest managers. The Forest includes land from the Canadian border south to the northern boundary of Mt. Rainier National Park, 130 miles, and is adjacent to North Cascades National Park, Wenatchee National Forest, and Mt. Rainier National Park.

The five-county area that includes the Forest has a population of more than 2.5 million persons, over 56 percent of the total State population. Most of these 2.5 million people live in the greater Seattle-Everett-Tacoma metropolitan area, only 40 to 70 miles west of the forest boundary. Just north of the Forest is the Vancouver, B.C., Canada metropolitan area, with a population of 3.0 million people. The Puget Sound economy is quite diverse, although the aerospace industry is still a major employer. The forest products industry has experienced major changes over the last decade; wood products manufacturing outputs have been up the last three years, but with 25 percent fewer employees.

The Mt. Baker-Snoqualmie National Forest contains a wide variety of land forms and natural resources that provide a wide range of goods, services, and opportunities for use. The upper reaches of seven major river systems are located on the Forest. Approximately 1,500 stream miles and over 12,000 lake acres provide both seasonal and year-round spawning and rearing habitat for

Figure S-1



anadromous and resident fish. The existing annual value of anadromous and resident fish produced on the Mt. Baker-Snoqualmie is estimated at $23 million. Nineteen of the 88 hydrological watersheds on the Forest are currently in an unacceptable condition, due to a combination of moderate to heavy amounts of timber harvesting and road construction plus the presence of unstable soils, steep slopes, and periodic major floods and debris torrents.

There are 18 municipal watersheds on the Forest serving a population of over 1.4 million. Water from only one of those watersheds requires treatment other than disinfectant, attesting to the high quality of the surface water.

The great diversity of plant and tree communities of the Forest provides a variety of habitats for a wide variety of wildlife species. Four federally-listed threatened and endangered species may occur on the Forest: the bald eagle, American peregrine falcon, grizzly bear, and the gray wolf. Several hundred bald eagles winter on the Forest. A decision on federal Threatened and Endangered listing for the spotted owl, a bird that lives primarily in dense, mature and old growth forests, is expected in 1990.

Fifteen American Indian tribes in the Puget Sound area use the land and resources of the Mt. Baker-Snoqualmie for religious and cultural practices. A 1981 inventory identified important use sites and areas. The Forest possesses some of the few remaining areas with the necessary purity, privacy, and isolation.

The Forest is rich in recreation opportunities and receives over five million recreation visits annually. Dispersed day-use recreation is a major use and occurs throughout the forest. Developed uses occur at seven alpine ski areas, campgrounds, and picnic areas. There are 1,384 miles of system trails on the Forest; 40% are located in wilderness. Ninety-six miles of the Pacific Crest National Scenic Trail are located within the Forest boundary. The Forest has enough roaded recreation lands to meet existing and projected demand, but it cannot meet current or future demand for unroaded, nonwilderness recreation without crowding and loss of solitude.

Nearly 42 percent (722,000 acres) of the Forest is designated wilderness. Wilderness received 455,000 recreation visitor days in 1988. Additional Congressionally designated areas include: the Skagit Wild and Scenic River System (a total of 58.5 miles of recreational river and 100 miles of scenic river); the Mt. Baker National Recreation Area (8,700 acres); and the multiple use Alpine Lakes management unit (148,000 acres).

There are 402,930 acres of roadless areas on the Forest; about 40 percent of these acres are tentatively suitable for timber production.

Forest-wide, approximately 160,000 acres of forest land are not suitable for timber production because of problems in replanting the land if the trees were cut. Many of these acres occur at higher elevations. Additional acres - over 95,000 - cannot be considered for potential timber cutting because of highly unstable soils. About 597,000 acres, or 35 percent, of the Forest have been identified as tentatively suitable for timber production. Nearly half of this acreage is currently forested with old growth trees. Almost 60% of the tentatively suitable old growth is in areas that are unroaded and undeveloped.

Between 1979 and 1988, an annual average of 250 million board feet of timber were sold from the dense forests of hemlock, cedar, and Douglas-fir. Changes in the land base as a result of wilderness designation, allocations for

wildlife habitat protection, and other resource objectives have affected the amount of timber that can be sold from the Forest in the future.

Three existing Research Natural Areas (RNA) on the Forest are set aside as examples of typical or unique natural ecosystems. There are five potential RNA's, three located within wilderness.

About 9 percent of the Forest acres have moderate to high potential for copper, gold, molybdenum, silver, lead, zinc, chromium, nickel, and olivine. Currently, only olivine is commercially produced. The Forest has about 1,230,500 acres of land that are prospectively valuable for oil, gas, and geothermal resources.

There are 2,829 miles of system roads on the Forest; 52% are accessible only by high-clearance vehicles.

PART 2 - PUBLIC ISSUES AND MANAGEMENT CONCERNS

An extensive and continuing process has been used to identify the issues, concerns, and opportunities (ICO's). The Forest has involved the public throughout the planning process, including various State, county, and other Federal agencies, Indian Tribes, and three public liaison groups.

Several changes have been made to the ICO's since the DEIS was released, reflecting public comment and changing public interests and concerns. Several issues have been refocused (with slight changes in their title) to better reflect recent public response. The transportation issue and wood residue management opportunity have been incorporated as facets of other major ICO's. Wild and Scenic Rivers is now addressed as a major issue; it had been a facet of the recreation ICO.

The issues drive the planning process and play a key part in the development of alternatives. The issues are an expression of the wants and preferences of the various publics with respect to Mt. Baker-Snoqualmie National Forest resources. The issues are also an indication of areas of conflict and of the public's view of the need for a change in management direction.

The nine major issues, concerns, and opportunities are summarized below. The following list shows the indicators used in evaluating how responsive each alternative is to the issues; responsiveness is reported in Table S-4.

Issue, Concern, Opportunity Indicator of Response	Unit of Measure
Development versus Nondevelopment of the Forest	
Existing Roadless Areas Allocated to Nondevelopment	% Acres, M Acres
Roadless Areas Assigned to Roaded Mgt. Prescription But Not Developed in Next 15 Years	M Acres
Timber Supply	
Timber Harvest Level	MMCF/MMBF
Long-Term Sustained Yield Capacity	MMCF
Lands Suitable for Timber Production	M Acres
Employment: Jobs Supported by the Alternatives	M Jobs
Payments to Counties	MM Dollars
Old Growth Ecosystems and Fish/Wildlife/Plant Diversity	
Total Old Growth Remaining, End of Decades 1, 5	M Acres

Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Anadromous Fish Production	Pounds Per Year
Low-Elevation Old Growth Habitat for Wildlife	M Acres Under 3000'
Suitable Winter Range for Deer and Elk, Decade 1	M Acres
American Indian Religious and Cultural Use	
Inventoried Use Areas with High/Moderate Protection	% of Inventoried Ac.
Recreation Opportunities	
Demand Satisfied for Wilderness, Primitive, Semi-Primitive Nonmotorized Recreation, Decades 1 and 5	% of Capacity
Roads Open to Public Use, Passenger Car	Miles
Trail Construction, Reconstruction, Decade 1	Miles
Lands Managed for High Visual Quality Levels	*M Acres Retention, Partial Retention*
Wild and Scenic Rivers	
Rivers Recommended for Designation as Wild and Scenic	No. Rivers, Miles
Management of Municipal Watersheds	
Timber Harvest Level	MMCF (MMBF)
Effects of Timber Management and Related Activities	
Timber Harvest Level	MMCF (MMBF)
Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Annual Road Construction, Decade 1	Miles
Sediment Produced from All Sources, Annually, Decade 1	M Tons
Adjacent and Intermingled Lands	
Timber Harvest Level	MMCF (MMBF)

Development versus Nondevelopment of the Forest

How should the released, roadless areas be allocated and how will the resources be managed?

At what rate should the Forest Service enter those roadless areas that are allocated for development?

The allocation and management of 402,930 acres of unroaded area (23% of the net Forest acres) remains a highly controversial issue. This issue has been retitled, to better reflect public comments received on the DEIS.

These roadless lands were inventoried in RARE II; they were released from wilderness consideration by the 1984 Washington State Wilderness Act. Many comments on the DEIS focused less on the RARE II remnants and more on the general issue of whether the remaining unroaded and undeveloped lands on the Forest should be managed for commodity production/roaded recreation or remain undeveloped. This key issue encompasses facets of nearly all the other ICO's.

Some elected officials, environmental groups, many hikers, some Indian Tribes, and wildlife organizations want the unroaded areas to remain undeveloped and unroaded. Key concerns are protection of wildlife habitat, old growth, and other resource values. Maintain the option of future consideration for wilderness was also mentioned. A number of individuals and groups support a proposal for Backcountry Areas, roughly corresponding to five roadless areas.

Other individuals, plus timber and mining companies, trade organizations, and energy-related industries feel that the 1984 Wilderness Act "released" these lands for multiple uses. They are concerned that nondevelopment will limit the amount of timber and minerals available for use, affect the local and regional economy, and lead to future wilderness designation. Many people feel there is

a need for more motorized access to the roadless areas, to encourage recreation. The commercial forest land within the roadless areas has been used to calculate the annual potential yield in the 1963 Timber Management Plans, as amended. However, this timber was not available for harvest from 1972 through 1984, resulting in a long-term concentration of timber harvesting on about one-half the land base. Approximately 164,500 acres, or 40 percent, of the unroaded areas are tentatively suitable for timber production.

Timber Supply

What is the capability and suitability of the Mt. Baker-Snoqualmie National Forest to produce timber?

What should the timber harvest level be considering all resources on the forest and their relationship to social, economic, and environmental factors including local, regional, and national demands?

A major public issue and management concern is the timber supply on the Mt. Baker-Snoqualmie National Forest. This issue has also been retitled since the DEIS, to better reflect public comments. The issue now includes facets of the wood residue opportunity.

Support for maintaining or increasing the timber supply comes from timber industry (management and employees), some community leaders, businesses dependent on the timber industry, and economic development agencies. Many individuals want the timber supply to be maintained, primarily to protect jobs. Environmentalists, some recreation users, wildlife and some hunting interests, fishing organizations, Indian tribes, some community leaders, and State Wildlife agencies strongly support restricting or reducing the timber harvest, especially in low-elevation old growth. A number of people feel the loss of mill jobs is due to factors other than timber supply.

The timber industry is a small but still important part of the overall Puget Sound economy; 4% of the wage and salary jobs in two counties are based on lumber and wood manufacturing. The Forest currently supplies about 17% of the logs consumed in the Puget Sound area; a number of mills are dependent on National Forest logs.

The annual potential yield under the 1963 Plans (as amended) is 203.8 million board feet (MMBF). Over the period 1979 to 1988, the average timber volume sold was 235.8 MMBF and harvested was 229.6 MMBF, which is within the average annual potential yield for the decade: 229.7 MMBF. The timber supply potential on the Forest is considerably less than what past timber sale programs have indicated.

Approximately 597,000, or 35 percent, of the net Forest acres are considered to be tentatively suitable for timber production; about half of the tentatively suitable acres contain old-growth forest.

Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity

What management direction is needed and where should action be taken that will maintain and/or enhance old growth and diversity to meet multiple use objectives?

The title of this ICO has been adjusted, in response to public comment. Old growth is a major issue on the Mt. Baker-Snoqualmie National Forest. Its value in providing biological diversity, wildlife and fisheries habitat (including habitat for the northern spotted owl), recreation, aesthetics, water quality, as well as industrial raw material is widely recognized by the public and the scientific community.

Environmental groups, wildlife societies and organizations, many individuals, Indian Tribes, and State wildlife agencies want the remaining old-growth forests protected. Old growth is important to American Indians for religious and cultural purposes.

Timber company representatives, industry trade associations, some State and local agencies, and many individuals feel these resources are an important contribution to timber production and maintaining local economies. Some feel that converting these stands into second growth timber is important for increasing long-term forest productivity.

There are approximately 643,500 acres of old growth within the Forest; 232,500 acres (36%) are located in wilderness and are not available for harvest.

A related public issue and management concern is the maintenance and/or enhancement of plant, wildlife and fish diversity within the objectives of multiple use management. There is increasing recognition within the scientific community that ecosystem diversity is important; this issue also received considerable public comment. Many respondents to the DEIS felt national forest management should focus on wildlife. State Department of Wildlife officials, hunters, and recreationists are concerned about the population and habitat needs of big game animals, such as deer, elk, and mountain goats.

Indian tribes, sport and commercial fishing interests, and state and federal fishery agencies are increasingly concerned about the effects of water quality on the anadromous fish resource. The cumulative effects of management activities on fish/fish habitat was raised as a major concern by individuals, Indian Tribes, and State agencies.

American Indian Religious and Cultural Use

What policy and management direction is needed to comply with the Native American Religious Freedom Act and various treaties?

How can Inventoried religious and cultural use areas be protected within the objectives of multiple use management?

The 15 American Indian tribes who currently use the Mt. Baker-Snoqualmie for religious and cultural uses continue to challenge Forest management activities, primarily proposed road construction, timber harvest, and small hydroelectric power projects, that potentially threaten their religious use sites and areas. The Tribes also have a significant interest and concern for protection and enhancement of the anadromous fisheries resource. Fishing has been, for many, a traditional and principle means of income. They are strongly opposed to any management activities that might adversely affect anadromous fish habitat.

In the 1981 inventory of religious use, practices, and localities, over 300 cultural use areas and sites were identified (totaling about 450,000 acres - 34% inside wilderness). Some sites cover less than one acre; larger areas

average 3,000 to 15,000 acres. There are five broad categories of use areas: cedar sites, ceremonial flora, spirit sites, legendary sites, and cemeteries and archaeological sites. There is a wide variation in compatibility between types of management activities and categories of religious, ceremonial, and cultural use.

Since the completion of the 1981 inventory, the Forest has initiated a consultation process with the Tribes. When proposed projects fall within an inventoried use-areas, the proposed activity is reviewed in detail with representatives of the Tribe(s) which may be affected. As more management activities are proposed, there is the potential for increased conflict.

Individuals and Tribal representatives feel that the draft Forest Plan standards and guidelines and the inventory process were not adequate to protect Religious Freedom Act rights. Others, including some timber industry representatives, feel protection of religious and cultural use areas will constrain timber availability.

Recreation Opportunities

To what extent can the Mt. Baker-Snoqualmie National Forest provide recreation opportunities and how should they be managed?

How many miles of trails should be provided and in what locations?

Public comment on the DEIS reconfirmed that recreation use - of all types - is a major public issue on the Mt. Baker-Snoqualmie. Opinion is divided on what types of recreation opportunities should be provided.

Many groups and individuals - including hikers, horse users, some off-road vehicle users, naturalists, wildlife advocates, and environmentalists - want to preserve opportunities for unroaded dispersed recreation outside of wilderness. They prefer more remote, natural appearing recreation settings. National Forest lands are the major supplier of non-motorized dispersed recreation in the Puget Sound area. Many other recreationists spoke to the need for better recreation access for young families and the elderly, more ORV areas, more snowmobile opportunities, and more campgrounds.

A large majority of people commenting on the DEIS favor more trails. There was support from environmentalists and many recreation/commodity groups for the "Trails 2000" proposal, developed by one environmental organization. ORV and horse users want more trails open for their use. Many hikers feel that trails should be closed to motorized use. Conflicts between recreation and other Forest resources were frequently mentioned. Some users dislike the expanding road system needed for timber harvest, while others feel roads are important for their activities and access.

Many recreation attractions and opportunities on the Mt. Baker-Snoqualmie are found within eight wildernesses. A concern is the level of management required to accommodate the high recreation demand within these areas, while protecting the wilderness resource. Some recreation and environmental groups, who strongly supported wilderness status for favorite areas, now find themselves debating the need for management actions in those areas, including limiting use. Facets of this issue include: the need for new or relocated trails to disperse recreation use in heavily-used areas; and whether roads that access popular wilderness attractions should be kept open to the public.

Wild and Scenic Rivers

How should the potential wild and scenic rivers of the Forest be managed and their values protected?

Wild and Scenic Rivers has been identified as a separate major issue, due to public response on the DEIS. There is one designated Wild and Scenic River on the Forest, the Skagit (designated in 1978). The Wild and Scenic Rivers Act established criteria for the addition of other rivers to the National System. The National Park Service (formally Heritage Conservation and Recreation Service) conducted an inventory of potential rivers; portions of the 16 rivers on that inventory are within the Forest boundary.

Portions of the Skykomish River system have been designated by the State of Washington as a Scenic River. This designation applies only to city, county, and State lands. A 1988 Washington State Scenic River Assessment identified 3 rivers on the Forest which possess values that would make them suitable additions to the Washington State Scenic River System (the Carbon, Nooksack, and Stillaguamish Rivers).

There was considerable public comment on the DEIS eligibility study, plus support for many more miles of wild and scenic rivers than recommended for study in the DEIS. There was also vocal opposition to more designation.

Between draft and final plans, eligibility criteria were re-evaluated and the list of eligible rivers adjusted. A total of 51 rivers were identified and studied for their eligibility and 47 of these were determined to be eligible. There was considerable public and agency involvement in this process. A suitability study for the 47 eligible rivers was also completed, again in response to public comment on the draft.

Wild and scenic river legislation has been considered but no action taken. Public concern on all sides is high. The portions of seven major river systems that lie within the Mt. Baker-Snoqualmie contain sections with unparalleled anadromous fisheries values. There are also high recreational and scenic values.

Management of Municipal Watersheds

What activities should be permitted within municipal watersheds?

What measures should be taken that will maintain or enhance water quality?

The title of this major ICO has been changed, to better reflect emerging issues. Maintenance of high water quality is a facet of the issue; it is also addressed on the Effects of Timber Management and Related Activities ICO. Changes in City of Seattle policies for the management of the Cedar River watershed may necessitate renegotiation of the existing, 1962 Cooperative Agreement. Under the 1989 Secondary Use Policies for the Cedar River, the City will set aside 50 percent of its lands in a reserve precluding timber harvest. The policies also call for acquiring 4-6,000 acres of old growth (currently national forest lands) to be maintained as old-growth habitat.

Maintaining high quality water remains as an objective of many individuals, sports and recreation organizations, municipalities, Indian Tribes, and State and federal agencies. These interests believe that timber harvest, road

construction, mining, and some recreation activities are detrimental to water quality and support action to limit or prohibit development in the watersheds. Many also support maintenance of old growth habitat in the Cedar River watershed. Municipalities are concerned that increased access and recreation use will result in the need to install filtration facilities to assure potable water to the consumer.

Timber, energy, mining industries, plus a number of hunters feel that development can occur and any adverse impacts to water supply and quality can be mitigated. They believe that limiting or prohibiting activities unduly restricts the industry's ability to maintain or increase supplies of timber, electric power, and minerals. Hunters feel that big game populations could actually be enhanced with controlled hunts in the watersheds.

A significant portion of the watersheds supplying the cities of Seattle, Bellingham, Everett, and Tacoma is located on the Mt. Baker-Snoqualmie. Water is also provided for a number of smaller municipalities, ski areas, and other recreation sites. About 128,000 acres of national forest land supply municipal water to 1.4 million people. Water quality is high; only one municipality filters water, others use a disinfectant.

Currently, a wide range of activities occur within the municipal watersheds. Some watersheds have not been accessed by roads and remain primarily in a natural condition. Other watersheds have been developed, with extensive timber harvesting and road construction. Recreation is permitted or encouraged in some watersheds; in others, poor access and municipal opposition has limited recreation opportunities.

Effects of Timber Management and Related Activities

What management direction is needed for timber harvest and road construction activities to benefit or maintain the quality of other resources?

The effects of timber harvest and road construction, especially the cumulative effects of these activities, are of great concern to federal agencies, environmentalists, Indian Tribes, State Fish and Wildlife agencies and individuals. The effects of management activities on water quality, fish and fish habitat of of greatest concern, and this interest has increased since the DEIS was released. Other resources affected by timber harvest and road construction are wildlife, scenery, and dispersed unroaded recreation.

The timber industry, miners, and many individuals feel that the effects of these activities can be mitigated, and that not enough national forest land is open to full commodity production (and recreation use).

Management for the commercial production of timber includes a number of activities: road construction and/or reconstruction, preparation of the land for planting seedlings, possible thinning, et cetera. These activities have direct and indirect effects on other resources, including· fish and wildlife habitat, soil, water, and American Indian religious and cultural use. Recreation opportunities are changed, and the visual condition of the Forest changes. The visual impact of clear-cutting and loss of habitat for some wildlife species is a major concern. Changes in vegetation and the effects on diversity and sensitive plants have also been identified as concerns by some people commenting on the DEIS.

Adjacent and Intermingled Lands

How should National Forest lands adjacent to lands of non-federal owners be managed?

What management activities should be conducted on National Forest lands that are located near private developments?

The land ownership pattern within and adjacent to the National Forest boundary and the management of intermingled Federal and Private lands remains a major issue and concern.

A few environmental groups are actively proposing legislative land exchanges that would exchange high-elevation, low timber site class private lands for low elevation, high-site federal lands. Some major industrial timber land owners support these types of exchanges. Independent mill operators and loggers who depend on National Forest timber and some public interest groups strongly oppose such exchanges, as the exchanges would further reduce timber supplies available to them. Some people commenting on the DEIS urged the Forest Service to retain all mineral rights in any exchange.

Environmentalists, State Fish and Wildlife agencies, Indian Tribes and some sporting groups believe that management activities, such as timber harvest, should be delayed or deferred on National Forest lands to mitigate the cumulative effects of large-scale timber harvest on private lands that are intermingled with Federal lands. Independent mill operators and loggers are opposed to any delays or deferrals that would reduce timber supplies available to them.

In many areas of checkerboard ownership, adjacent land owners have completely removed the old-growth timber (in approximately 640 acre blocks), leaving the timber present on National Forest land more vulnerable to wind-throw. Removing these blocks of old growth has also had the effect of reducing the amount of habitat available for wildlife species dependent on old-growth habitat. In areas of intermingled lands, management of National Forest land affects adjacent lands of non-Federal landowners, and activities on non-Federal lands affect management of National Forest land.

Urban growth is steadily moving east toward the Forest boundary. Forest lands, regardless of ownership, are affected by this growth. Resources such as wildlife, water, and air do not recognize ownership boundaries, but they are directly impacted as shopping centers, subdivisions, and residences - plus an increased network of roads - spread closer to the Forest boundary.

PART 3 - THE ALTERNATIVES, INCLUDING THE PROPOSED ACTION

Eight alternatives were developed in detail. The alternatives, including the proposed action (the Preferred Alternative) are based on the identified issues, concerns, and opportunities, the "drivers" of the planning process. Each alternative is designed to achieve specific goals and objectives. Each is a unique combination of land uses, forest management activities, and schedules designed to address, mitigate, or resolve the planning questions discussed above. A wide range of alternatives was developed to test for the combinations of goals and objectives that best maximize net public benefits while responding effectively to the ICO's. With one exception (the No Change Alternative), a

computerized model (FORPLAN) was used to ascertain the potential outputs and effects of each alternative.

Each alternative, except Alternative NC (No Change), falls within the scope of the Mt. Baker-Snoqualmie Standards and Guidelines. These standards and guidelines were prepared to meet laws, regulations, and policy requirements; to direct management activities in meeting goals; to respond to the issues and concerns; and to mitigate potential adverse effects on a Forest-wide basis. Refer to the Forest Plan document and FEIS, Appendix D.

Each alternative, except Alternative NC, includes the management requirements (MR's) (36 CFR 219) pertaining to timber, fish and wildlife, soil and water, land productivity, and riparian areas. The management requirements are discussed in detail in FEIS, Appendix H.

Alternative J is the Preferred Alternative; it was selected by the Regional Forester as the alternative which best maximizes the net public benefits while responding effectively to all the issues.

The Alternatives – Items Treated the Same in All Alternatives

A number of resource management programs are treated the same in all the alternatives:

- Alpine Lakes Management Plan (1981) and the Skagit Wild and Scenic River Plan (1984) are incorporated in all alternatives except Alternative NC.
- The Mt. Baker National Recreation Area (1984) is the same in all;
- The three existing Research Natural Areas are retained in all alternatives;
- The foreground of Mather Memorial Parkway is managed to retain its scenic quality in all alternatives;
- The management requirements (MR's) necessary to integrate requirements of law and regulation are incorporated in all alternatives except Alternative NC;
- The rights established by the various Indian treaties are retained in all alternatives, as is the consultation process for any proposed projects within inventoried religious and cultural use areas;
- The acres of designated wilderness are the same. Acres assigned to classes of the Wilderness Recreation Opportunity Spectrum (WROS) vary by alternative; there are no WROS classes in Alternative NC;
- Even-aged management and regeneration harvest through clearcutting are assumed in estimating timber outputs in all alternatives. However, the use of other systems is not precluded (refer to Appendix F in the DEIS Appendices for more information);
- All alternatives would make full use of vegetation management techniques including herbicides and fire. In 1988, the Pacific Northwest Region, USDA Forest Service completed a final EIS on managing competing and unwanted vegetation (USDA 1988b). That final EIS, the Mediated Agreement, and accompanying implementation direction is incorporated by reference into

this FEIS. It will guide vegetation management activities as the Forest Plan is implemented.

- All existing utility corridors, electronic sites, and administrative sites are retained in all alternatives.

ALTERNATIVE NC (NO CHANGE)

The No Change Alternative has been developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's.

The No Change Alternative is designed to continue the level of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1963 Timber Management Plans. This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA (it does not incorporate management requirements, including those designed to maintain viable plant and animal populations). The alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

Design Criteria for Alternative NC (No Change):

Timber: the 1963 Timber Management Plans are the basis for the alternative.

Roads: the Naches Pass road would not be constructed.

Roadless Areas: an estimated 60% of the roadless areas would remain undeveloped; this estimate is based on the acres of commercial forest land assumed to be in the roadless areas.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: no provision for study or protection of potential rivers is included in the TM Plans.

Research Natural Areas: no potential areas recommended.

Spotted Owls: no provisions made to protect old-growth habitat for wildlife.

Big Game Habitat: no provisions made for protection of big game habitat.

Cavity Excavators: no provisions made for protection of habitat.

Anadromous/Resident Fish: no provisions made for protection of fish habitat.

Municipal Watersheds: all are managed under current agreements, memoranda of understanding.

ALTERNATIVE A (NO ACTION)

Alternative A was developed to continue management direction as set out in plans formulated and approved prior to the passage of the National Forest Management Act. The alternative incorporates the requirements of the National Forest Management Act of 1976 (36 CFR 219.12 through 219.27). The goal of Alternative A is to provide maximum timber outputs while maintaining or exceeding existing recreation, wildlife, fisheries, and visual resource outputs. The plans approved prior to NFMA, plus current laws, regulations, and directions - including MR's - were used to assign management direction to different parts of the Forest. This is the No Action Alternative required by the Council on Environmental Quality Regulations for implementing the National Environmental Policy Act (NEPA).

Design Criteria for Alternative A (No Action):

Timber: an exception to "Items Treated the Same in All Alternatives", in FORPLAN, Alternative A was run with an objective of maximize timber volume for the first five decades, then was rerun to maximize PNV for 15 decades with the same timber outputs as in Decades 1-5. This resulted in some timber prescriptions having less than maximum economic efficiency. Approximately 70 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 26 miles of arterial and collector roads would be built. During that same period, about 330 miles of local roads would be constructed. The Naches Pass road would not be constructed.

Roadless Areas: would be managed under the direction contained in the Ranger District Multiple Use Plans; approximately 82 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: the 15 rivers included in the National Park Service Nation-wide Inventory are recommended for designation as part of the National Wild and Scenic River System. These fifteen rivers include a total of 375 miles, of which 142 miles are within the national forest boundary.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat is provided for viable populations at the MR levels; additional habitat for some species in wilderness, RNA, and areas not suited for timber production.

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of their potential population levels.

Anadromous/Resident Fish: current populations are maintained through habitat maintenance or improvement at the MR level (low investment).

Municipal Watersheds: are managed under current agreements, memoranda of understanding.

ALTERNATIVE B (RPA)

The goal of Alternative B is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation, as specified in the 1980 RPA Program.

Design Criteria for Alternative B (RPA):

Timber: is produced at the highest level possible, while meeting the other goals of the alternative. Approximately 64 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 28 miles of arterial and collector roads would be built. During that same period, about 280 miles of local roads would be constructed. The option to construct Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 87 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Items Treated the Same in All Alternatives."

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic designation.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 79,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on land suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of their potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan

River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE C

The goal of Alternative C is to emphasize primitive and semi-primitive nonmotorized recreation (accomplished through retention of existing roadless areas and, over time, reversion of some roaded areas to unroaded condition); protect scenery, fish, and wildlife habitat; and protect sites and areas important to American Indians for religious and cultural use.

Design Criteria for Alternative C:

Timber: no production goals set; suitable acres and harvest level will be the lowest of all alternatives considered in detail. Approximately 43 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 300 miles of existing arterial and collector roads. In the first two decades, about 15 miles of arterial and collector roads would be built, and about 180 miles of local roads would be constructed. *Construction of the the Naches Pass road is precluded by* management of surrounding lands for unroaded dispersed recreation.

Roadless Areas: nearly all (97%) of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: high to moderately-high protection of the foreground and *middleground of all inventoried primary and secondary viewsheds.*

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers included is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: *five potential RNA's are recommended for designation* - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat provided to maintain cavity excavators at 60% of their potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, with stipulation that habitat be maintained as old growth when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - closed watershed, exchange NF lands; Others - no timber harvest, limited recreation use.

ALTERNATIVE G-MODIFIED

The goal of Alternative G-Modified is to emphasize maintenance of natural ecosystems and diversity of native plants and animals, emphasize providing uses not found on private lands, and produce timber in a way that is consistent with the other goals and is non-damaging to soils.

Design Criteria for Alternative G-Modified:

Timber: timber production will occur on currently accessed sites first. Maintenance or development of old growth, especially at lower elevations, is emphasized. Approximately 41 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 65 miles of existing arterial and collector roads. In the first two decades, approximately 13 miles of arterial and collector roads would be built, and about 145 miles of local roads would be constructed. Construction of the Naches Pass road is precluded by management of surrounding lands for undeveloped recreation.

Roadless Areas: approximately 96% of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: the foreground of selected corridors is protected, including the upper end of Mt. Baker Highway, portions of the Cascade River and North Fork of the Cascade, portions of the Mt. Loop Highway, the upper Sauk, lower Sultan, and Mather Memorial Parkway. Integral vistas within and from Class I airsheds and other wildernesses (not yet designated Class I) are protected.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers include is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Twin Sisters, Monte Cristo, Baker Lake, Naches Pass, and along the Mather Memorial Parkway.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide with additional habitat areas being protected to meet the objectives of the alternative. Approximately 113,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat provided for viable populations at the MR levels; some additional habitat for some species in wilderness, RNA.

Cavity Excavators: on lands suitable for timber production, habitat is provided for cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: *Cedar River - managed to retain old-growth habitat with* stipulation that it be maintained when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE H

The goal of Alternative H is to provide an increased emphasis on unroaded recreation; protection of scenic values in the foreground and middleground of heavily traveled highway corridors; increasing big game populations; plus emphasis on timber production on tentatively suitable acres not assigned to other objectives.

Design Criteria for Alternative H:

Timber: about 60 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. About 20 miles of existing roads, located in areas assigned to unroaded dispersed recreation, will be closed. In the first two decades, approximately 11 miles of arterial and collector roads would be built. During that same period, about 250 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: *areas with a high percentage of tentatively suitable lands are* available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 88 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways.

Wild and Scenic Rivers: the five rivers determined in the DEIS to be eligible for Wild and Scenic River designation are recommended for designation - North Fork Nooksack, North Fork Skykomish, South Fork Skykomish, Tye, and Middle Fork Snoqualmie Rivers, a total of 154 miles, of which 71 miles are within the national forest boundary.

Research Natural Areas: five potential are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 61,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - current direction (exchange NF lands to City of Seattle, no old-growth habitat maintained); Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

ALTERNATIVE I

The goal of Alternative I is to emphasize those resources with an established price in the market place: timber production, anadromous fish, developed recreation, and minerals. Emphasis is also placed on enhancement of big game wildlife and fish habitat, and developing/maintaining an extensive trail system to accommodate a wide variety of users on a year-round basis. Other resources are managed at levels that do not reduce the outputs from the market resources.

Design Criteria for Alternative I:

Timber: timber production is emphasized. Approximately 65 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed, to meet timber production goals. In the first two decades, approximately 34 miles of arterial and collector roads would be built. During that same period, about 290 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 86 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual: the foreground of heavily-traveled highways are managed for scenic quality (I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways).

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic River designation.

Research Natural Areas: *no potential areas are recommended for designation.*

Spotted Owls: spotted owl habitat is inventoried, identified, and protected *following the direction in the SFEIS amending the Regional Guide. About 93,000* acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous fish populations are increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

ALTERNATIVE J (PREFERRED)

This is the Preferred Alternative. It is a new alternative and was not displayed in the DEIS. Beginning with the draft EIS Preferred Alternative (H), Alternative J was developed to respond to public comment and new information. Differences between the draft and this Preferred Alternative include: a *considerable increase in trail mileage; an increase in the number of rivers* recommended for addition to the National Wild and Scenic Rivers System; allocation of three Special Areas (Botanic, Scenic, and Recreation/Education); an increased emphasis on unroaded recreation; and greater protection of scenic values within travel corridors. Timber production is emphasized on suitable acres assigned to a timber harvest prescription. Other resources will be managed at levels commensurate with the objectives of the alternative.

Design Criteria for Alternative J (Preferred):

Timber: about 58 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. Roads to be closed include about 25 miles of existing roads, located in areas assigned to unroaded dispersed recreation. In the first two decades, approximately 15 miles of arterial and collector roads would be built, and about 240 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter

range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 91 percent of the roadless area acres remain in an undeveloped condition at the end of the ~~fifth~~ 1st decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, Baker Lake Highways, Cascade River road, and Crystal Mountain Highway.

Wild and Scenic Rivers: 30 of the 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for inclusion in the National Wild and Scenic Rivers System. A total of 452 miles are recommended, with 276 of those miles located within the national forest boundary. This recommendation is a preliminary administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Mather Memorial Parkway, Heather Meadows, and Sulfur Creek.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 54,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level.

Municipal Watersheds: Cedar River - initiate negotiations on a new Cooperative Agreement to reestablish goals and management for the watershed; until then, do not enter into land exchanges affecting National Forest lands; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

The Management Areas

To complement the description of alternatives, Table S-1 presents the acres assigned to each management area, by alternative. Management areas (MA's) are areas of the Forest to which a set of management practices, standards, and guidelines apply. (Alternative NC is not shown; it is based on the 1963 Timber Management Plans and has no management areas.) Multiple use will continue to be the overall goal of the Mt. Baker-Snoqualmie; one or more uses may be emphasized in a management area, but many uses are compatible and will occur in every MA.

Management areas are identified by a number or number/letter, plus a short, descriptive title. The letters are various "intensities" of a broader management area. Some MA's have only one intensity. The MA's are described on the alternative maps accompanying this package of documents. The standards and guidelines that apply to each MA are discussed in detail in the Forest Plan (for Alternative J (Preferred) and in FEIS, Appendix D. The maps show the on-the-ground location of the management areas for each alternative.

Table S-1 is a useful summary, but some items should be noted. The alternatives are presented in descending order of acres suitable for timber harvest, an indicator of the level of vegetative management. Many of the outputs and effects discussed later in this Summary are either directly or inversely correlated to the amount of vegetative management in the alternatives. This order of presentation facilitates quicker and easier comparisons among the alternatives.

Acres are assigned to management areas to meet the overall goals and objectives of each alternative, in response to the issues. Simply comparing the number of acres in each management area does not give the full picture of an alternative. Where compatible uses occur on the same area, the acres have been assigned and mapped to the set of management practices, standards, and guidelines that cover management for both uses. Example, an area assigned to nonmotorized dispersed recreation (MA 1A, 1B) may also be capable of providing old-growth wildlife habitat (MA 11). In this case, the MA mapped would be 1A or 1B, not 11 because old-growth habitat has been "overridden" by an MA that is more restrictive: roads cannot be built in 1A/1B; they may be constructed outside the core area in MA 11 (if habitat objectives can be met).

Note that the acres for the wildlife minimum management requirements (MR's) vary among the alternatives. This is primarily due to "overrides." For example, Alternative C shows the fewest acres assigned to MA 11 Old Growth, yet C has a goal of emphasizing wildlife. Old-growth habitat is protected at a high level in Alternative C but many acres of old growth habitat are located within MA's 1A or 1B, which provide for both wildlife habitat and nonmotorized recreation. The designated old growth acres are still "there", but they are mapped as 1A or 1B, and are listed in Table S-1 as 1A or 1B.

1/ Total acres in each alt vary due to rounding MA 9 not used, MA 24 Min Mgt not assigned in any alternative.

2/ Applies only to Alt A, includes mostly unroaded, but some roaded recreation, from exisitng Multiple Use Plans

3/ Parcels of the 1926 area that remain outside of wilderness and the Mt. Baker NRA are included here.

4/ Acres are protected at varying levels in the alternatives, but not shown to protect confidential nature

5/ Includes Cultural-Historic, Geologic, Biologic, Botanic, and Scenic Special Areas

6/ Many acres of riparian zone fall within other MA's and are protected through those management prescritptions

7/ Management Areas 16B Grizzly Bear, 16C American Peregrin Falcon and 16D Gray Wolf have no acres assigned at this time, because no specific habitat has been identified or evaluated

8/ Acres of existing or proposed RNA located within wilderness are included in MA 10, not here

9/ These acres overlap other MA's

10/ Includes acres within the congressionally designated Alpine Lakes Management Unit that are not otherwise assigned to other, compatible management areas (Compatible MA's include 5, 11, 12, 14, 15, and 16)

PART 4 - COMPARISON OF ALTERNATIVES

The following figures show how the alternatives compare to each other in just a few of the Forest activities or resource outputs. The graphs tie to the detailed output tables in the next section (where other outputs are displayed). Again, the alternatives are arranged in order of decreasing acres of land suitable for timber production. Alternative NC (No Change) was not modeled in FORPLAN, therefore not all outputs for this alternative can be reasonably estimated. Refer to the text and footnotes for each figure.

Figure S-2 shows average annual timber sale program quantity (TSPQ) for Decade 1 (in million board feet). TSPQ includes live (green) wood, plus salvage, fuelwood, and other non-industrial wood. Figure S-3 shows the acres of final timber harvest, each decade, for Decades 1, 2, and 5. Refer to Table S-2 for more comparisons.

Figure S-2

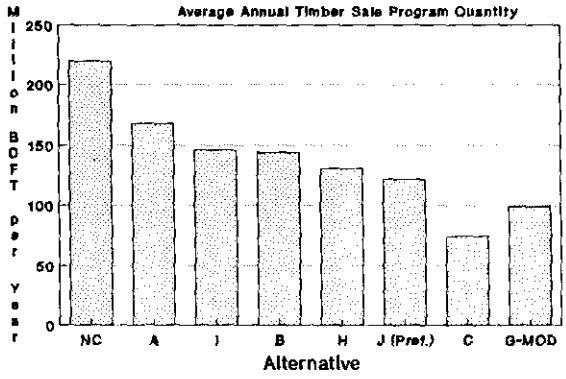

Figure S-3

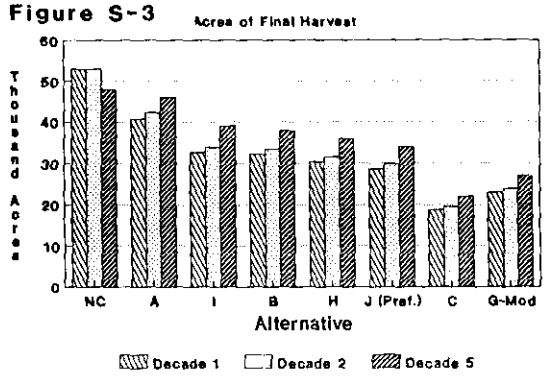

Figure S-4 shows the <u>total</u> amount of old-growth forest remaining, which includes old growth located in wilderness and other no-harvest areas. The starting point is the beginning of plan implementation. The figures then show acres remaining at the end of Decades 1, 2, and 5.

Figure S-4

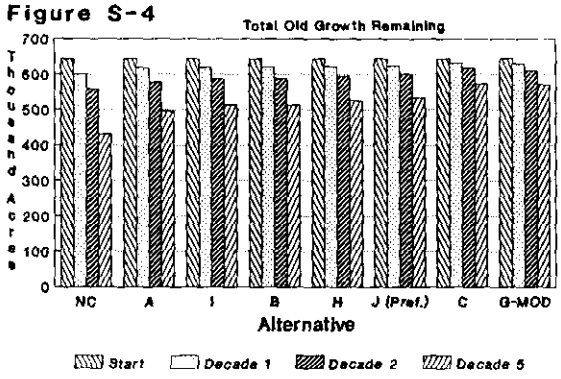

Figure S-5 shows total road construction, in miles per year. Most of the miles are local (timber purchaser) roads. Refer to Table S-2. In all alternatives, all arterial/collector road construction, but not all local road construction, will be completed by Decade 3. In Alternative C, about 300 miles of arterial and collector roads are closed starting in Decade 1; about 65 miles are closed in Alternative G; 20 miles closed in Alternative H; and about 25 miles closed in Alternative J (Preferred).

Figure S-6 shows the disposition of the 402,930 acres of roadless areas: the percent remaining undeveloped at the end of Decades 1, 2, and 5. No data can reasonably be estimated for Alternative NC. In the first 10 to 15 years, from 1% to 7% would be developed, depending on the alternative. The acres shown for Alternative A are an estimate.

Figure S-5 Average Annual Road Construction

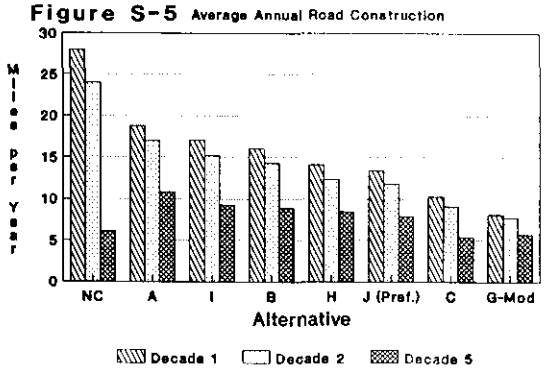

Figure S-6 Acres of Roadless Areas Remaining Undeveloped Decades 1, 2, & 5

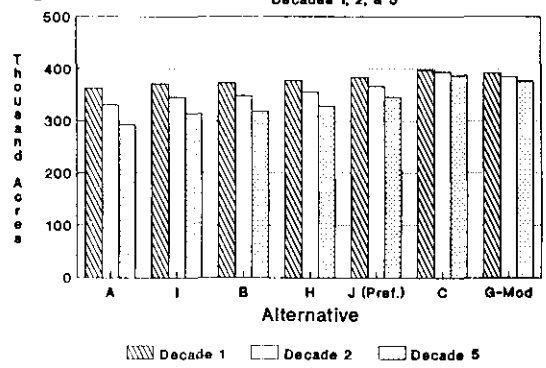

Does not apply to NC Alt

Figures S-7 and S-8 show the acres of dispersed recreation by ROS classes. Alternative NC is estimated to be similar to Alternative A. The term "reached by Decade 4" is used because, as an alternative is implemented, land allocated to MA's, and standards and guidelines applied, the recreation setting will slowly change toward the desired future condition. The figures show the expected ROS acres after four decades of implementing each alternative. While no alternative can meet future demand for unroaded dispersed recreation,

Figure S-7 Unroaded ROS Acres Reached by Decade 4

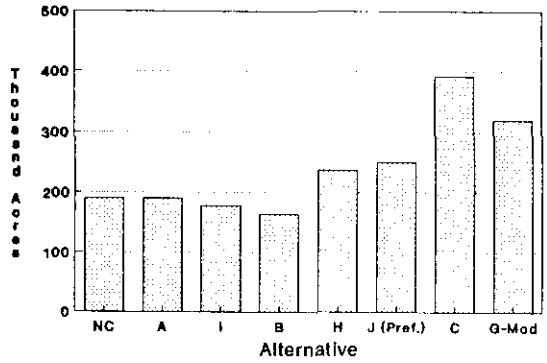

Figure S-8 Roaded ROS Classes Reached by Decade 4

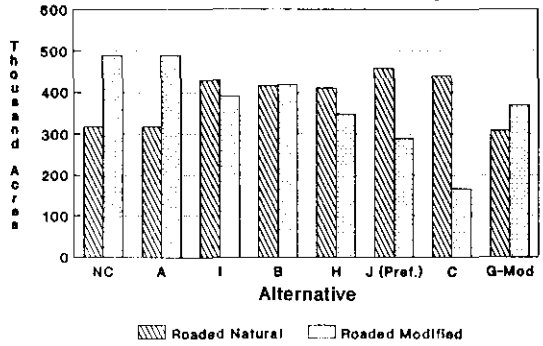
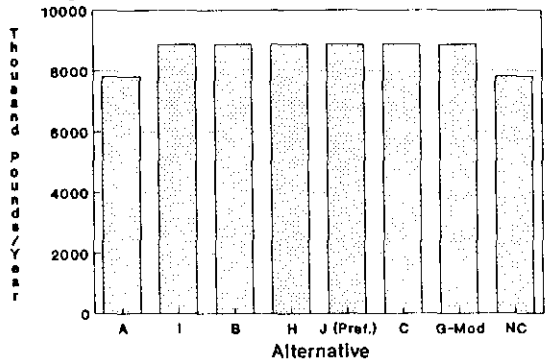


NC Alternative combines RN & RM

Alternatives C and G-Modified come the closest. Alternative B cannot meet the RPA target for dispersed recreation. Looking at Figure S-8, the alternatives with more timber harvest activities and associated road construction (NC, A, and I) provide the most roaded dispersed recreation; however, much of this recreation will occur in landscapes that have been heavily altered.

Figure S-9 shows the pounds of anadromous fish available for commercial harvest. The differences between alternatives are a function of investments in habitat improvements: a higher level of investment and more restoration/ enhancement results in more available fish. Alternative NC is similar to A. While not shown in this figure, resident fish habitat is also improved/enhanced in Alternatives C, G-Modified, and J (Preferred).

Figure S-9 Anadromous Fish for Commercial Harvest



Quantitative Outputs and Effects of the Alternatives

Tables S-2 and S-2a show some of the key outputs and effects of the eight alternatives. Again, the alternatives are displayed in descending order of acres suitable for timber harvest, an indicator of the level of vegetative management. Many outputs and effects are either directly or inversely correlated to this order.

Alternative NC (No Change) is based on the 1963 Timber Management Plans (as amended), which were not integrated resource plans and consequently did not address all resource uses and outputs. Data for Alternative NC is presented where it can be reasonably estimated, or where information was addressed in the 1963 Plans. Alternative NC was not modeled in FORPLAN, therefore, economic measures comparable with the other alternatives were not determined.

While the alternatives and the decision apply only for the life of this Forest Plan - 10 to 15 years - outputs and effects for Decades 2 and 5 are included to show some long-term trends of implementation.

Both allowable sale quantity and timber sale program quantity are shown; the footnotes explain the difference in these two terms. Allowable sale quantity (ASQ) is shown in board feet per year only for the first decade. ASQ and timber sale program quantity, by alternative, are shown in cubic feet per year for all time periods.

Generally, as suitable acres increase, the amount of harvest increases, as does road construction, and environmental effects, such as sediment index.

Summary

For the recreation and wilderness resource, the most useful way to compare the alternatives is to first look at current use and capacity, and then compare how well each alternative is able to provide for future demand, which is expressed as a range.

For this Forest, capacity means practical, or realistic, capacity not the theoretical maximum. 1/ It was assumed that projected recreation use will not exceed capacity for any particular activity. It is expected that use will be limited by a combination of direct management actions by the Forest Service (such as permits, area closures) and by the users themselves: when use of a site or area approaches capacity, people will substitute other activities (such as nordic skiing when alpine ski areas are full), or shift their activities to other lands, if they cannot satisfy their expected recreation experience on the Forest.

For non-wilderness unroaded dispersed recreation, current use already exceeds practical capacity. In total recreation use, current capacity far exceeds use (primarily due to the large reserve of developed capacity in ski areas, campgrounds, and in roaded dispersed recreation). However, by the fifth decade, all alternatives will fall short of meeting the range of total recreation demand.

Most of the miles of new trail construction, in all alternatives, are outside wilderness.

Note footnote number 8/ when comparing acres of old growth, by alternative. The "starting point" total acres of old growth, including acres within wilderness, is 643,538 acres. The acres within wilderness (232,500) remain constant in all alternatives over time. Proposed timber harvest will occur only on those old growth acres that are suitable for timber production and are assigned to a management prescription that includes timber harvest.

The pounds of anadromous fish available for commercial harvest are a direct function of the investment level for fish habitat improvement. MR's for water quality and riparian areas will also benefit this resource.

Population estimates for the spotted owl exceed the MR level in all alternatives, except Alternative NC, for all time periods. However, wildlife populations that primarily use mature and old-growth habitats (northern spotted owl, pine marten, pileated woodpecker) will decrease over time, in all alternatives, primarily due to harvest of mature and old-growth timber stands.

Winter range habitat capability for deer and elk increases from the current situation (which supports 9,140 deer and 470 elk) through the first decade, a result of increased forage from timber harvest activities. Habitat capability declines in Decade 2, as winter thermal cover becomes limiting. By Decade 5, habitat capability again increases, due to habitat improvements implemented in the first decade.

The text discussing Table S-2a, "Percentage of Inventoried American Indian Religious and Cultural Use Areas Assigned to MA's Providing High and Moderate Levels of Protection" follows all of the S-2 tables.

1/ Theoretical capacity is an estimate of the maximum use of the Forest, assuming all facilities are 100% full, all days of the maximum use season. Practical capacity recognizes physical and social limitations, such as low mid-week use and periods of unfavorable weather, when use declines.

1/ The TM Plans upon which the No Change Alternative is based were developed in 1963. The outputs and effects are generated from previous inventories. All other alt. outputs and effects were calculated using updated inventories and yield tables and the latest method of calculating timber harvest levels. For Alt. NC, tentatively suitable lands were not determined and standard plus special commercial forest land is shown as lands suitable for timber production.

2/ ASQ: Quantity of timber that may be sold, from suitable land. Includes only chargeable, live (green) not salvage, fuelwood or other non-industrial wood. Potential yield from the TM Plan is shown for Alternative NC.

3/ Includes ASQ, nonchargeable mortality volume, volume not meeting utilization standards, and volume used for other than board products from lands suitable for timber production, and volume from unsuitable lands. Includes PY and all other volume for NC.

1/ The 1963 TM Plans, upon which Alternative NC is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated because, except for cemeteries, the percentages were developed by overlaying inventoried areas with MA's; no MA's were assigned in Alternative NC.

Summary

Table S-2a shows, by alternative, an estimated percentage of the inventoried American Indian religious and cultural use sites assigned to management areas that generally preclude or limit ground-disturbing activities.

The percents given should be viewed as only an approximation as some use sites and areas were not identified in the Inventory, but were included in a larger "buffer" area by tribal respondents. Therefore, the actual degree of protection in each alternative can only be estimated.

In the table, the difference between "high" and "moderate" is derived from the expected frequency of human encounters. There is no timber harvest or road construction under either high or moderate protection. All cemeteries have high protection. The actual protection of all sites will be determined using Forest-wide Standards and Guidelines (Forest Plan, Chapter 4) and consultation with appropriate tribes. To protect the confidential nature of the inventory, use sites and areas are not reported in Table S-1 nor are they mapped.

Economic Tradeoffs Among Alternatives

Present net value (PNV) is an estimate of the potential economic effectiveness of managing the Forest. PNV is defined as the discounted dollar value of all benefits of an alternative, less the discounted costs of management and investments needed to implement the alternative. Discounting is a way of combining current and future values to show them in today's terms. The values used in this plan are expressed in terms of 1982 dollars, with a discount rate of 4%. This concept is discussed in detail in Appendix B of the FEIS.

Table S-3 compares PNV and the benefits and costs among alternatives for major resource groups. An exact relationship between the dollar benefits associated with a particular priced output and the resource costs should not be assumed. For example, some recreation and wildlife benefits are joint outputs of timber management. The dollar values assigned are discussed in Appendix B.

Table S-3 indicates that almost all of the variation in PNV, discounted costs, and discounted benefits is due to the variation in timber outputs of the alternatives. With some minor exceptions, as timber outputs decline, so do discounted costs and benefits

Discounted costs and benefits for recreation change very little from one alternative to another This is partly due to the fact that current recreation use is very close to capacity on the Forest for most types of recreation, except roaded dispersed. There is little opportunity to significantly increase the recreation supply in wilderness, primitive, semi-primitive nonmotorized, or semi-primitive motorized outside of wilderness. Although there is some variation between alternatives in these dispersed recreation capacities, it is a very small percentage of the current capacity and affects discounted recreation benefits only about 6% between the alternatives. Discounted recreation benefits exceed discounted timber benefits in all alternatives, though actual cash flow or returns to the Treasury are much lower than for timber.

Alternative C has the lowest discounted recreation benefits of all the alternatives but the highest levels of primitive and semi-primitive nonmotorized recreation capacity. Although primitive and semi-primitive nonmotorized recreation use has a higher value per Recreation Visitor Day (RVD) than motorized use, it has a lower RVD per acre coefficient (the number of

people who do or can recreate on an acre). The result is that on a per-acre basis, motorized use is more valuable than nonmotorized use.

The alternatives in Table S-3 are displayed in order of highest to lowest PNV.

Major Tradeoffs Among Alternatives

Table S-4 presents tradeoffs among economic benefits of the alternatives and their response to the major issues and concerns, as measured by quantitative indicators (listed in the ICO section of the Summary). Across the top of the table are the quantitative measures selected to indicate responsiveness to an ICO.

To provide a partial framework for assessing these tradeoffs, the long-term resource demands or needs of the Nation, region, and local economic area are briefly summarized.

National, Regional, and Local Overview

National (RPA) planning estimates that total national demands will rise for all outputs of the National Forest. At the same time, there is a strong demand to protect and enhance the quality of the environment. Many people view the production of goods and services from the National Forests as competing with protection and enhancement of a quality environment.

Demands and prices for commodity products are generally determined in regional and national markets. The nation benefits most when supplies are provided from the most efficient sources of production.

Summary

The Mt. Baker-Snoqualmie National Forest is an efficient supplier of timber products. The 1980 RPA program assigned approximately 2.5 percent of the total projected timber outputs for the National Forest System in 1990 to the Mt. Baker-Snoqualmie National Forest. The Forests' share of the projected Regional outputs in 1990 is approximately 6 percent. The Mt. Baker-Snoqualmie produces about 15 percent of the logs consumed in the Puget Sound area; forest industry and other private owners are the major producers of logs consumed in the area. Nearly all (97%) of the logs produced on the Forest are processed in the local economic area (Larsen and others 1983). The resulting products are consumed primarily in the Western U.S. market.

Demands on the Forest for outdoor recreation uses are more localized than the regional and national demands for timber. Most of the Forest recreation users reside in the major population centers along the Interstate 5 highway corridor.

Recreation use and the demand for recreation of many types is growing, and at a rate faster than the population growth of the Puget Sound area. Total recreation use increased approximately 40 percent on the Forest in the 10 year period from 1975-1984. In a similar time period, the population of the five county area of the Forest increased approximately 20 percent. The fastest growing segment of the recreation spectrum is wilderness use: + 145 percent, compared to an increase of 65 percent in developed recreation use. Wilderness use represents approximately 4.5 percent of the total recreation use on the Forest for the period 1975 to 1984.

The Mt. Baker-Snoqualmie National Forest is a major supplier of National Forest wilderness in the Pacific Northwest and the nation. The Forest contains 16 percent of the National Forest wilderness in the Pacific Northwest Region and 2.2 percent of the total National Forest wilderness system. Available data collected in the late 1970's and early 1980's indicates that 82-94 percent of wilderness use on the Forest originated from Washington State, and 49-65 percent of the users are from the Puget Sound area. Several of the Forest wildernesses are among the most heavily used in the nation.

Salmon, by a large margin, is the most valuable fish or wildlife species, as measured by the market value of the harvest. An estimated 50 percent of the harvest of naturally produced (as opposed to hatchery produced) salmon for the Puget Sound area are produced from Mt. Baker-Snoqualmie National Forest water systems.

The Forest has extremely low capability to produce economically efficient forage for commercial grazing of domestic livestock.

How the Alternatives Respond to Major Issues, National Concerns. With the discussion above to set the stage, Table S-4 and the text that follows show the major differences among the alternatives. In this table, the alternatives are displayed in order of highest PNV to lowest. The main reason that alternatives differ is that each alternative is designed to respond to major ICO's in a different way. Note: two issues - Management of Municipal Watersheds and Adjacent and Intermingled Lands - are not listed separately in the table, but their indicators are included in other ICO's. When an indicator is used to measure responsiveness for more than one ICO, such as timber harvest level, the indicator is displayed only once. See page S-6 for the full list of indicators.

NC 3/	N/A	N/A	N/A	NA	NA	NA	45.0	(220)	N/A	547	30.1	9.5

1/ Roadless Areas refer to the 402,930 acres of remaining RARE II parcels

2/ This is an approximate figure. Alternative A is unique because an unspecified amount of development is permitted in the Upper Forest Resource Zone. See description of Management Area 1E

3/ The TM Plans upon which Alternative NC is based were developed in 1963; they are not integrated resource plans, and consequently did not address all resource uses and outputs. Missing data in this table (NA) cannot be reasonably estimated, since the TM plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect standards in the NFMA regulations, or are otherwise inappropriate.

7/ From all sources, including timber harvest, new road construction, old roads, and background (which includes sediment from previously disturbed ground and natural sedimentation).

Economic Benefit and Issue Response Tradeoffs Among Alternatives

The alternatives were designed to respond to specific major issues, or a combination of issues. In responding to one set of issues, some potential benefits or responses to other issues may be limited or "traded off." In Table S-4, the alternatives are displayed in order of highest PNV to lowest. Most of the indicators of response follow a specific pattern as PNV declines. The indicators of response are grouped into those patterns in the display below. A detailed discussion of why these changes occur in each alternative can be found in Chapter II of the FEIS.

Indicators That Decline As PNV Declines:

- Net Receipts
- Non-cash Benefits (slightly) in 5th Decade
- Timber Sale Program Quantity, Long-Term Sustained Yield, Suitable Lands
- Jobs (slightly), Payments to Counties
- Old Growth on Suitable Lands

Indicators That Remain More-or-Less Stable Among Alternatives As PNV Declines:

- Non-cash Benefits in 1st Decade
- Demand Satisfied for Wilderness, Primitive, Semi-Primitive Nonmotorized Recreation

Indicators That Rise As PNV Declines:

- Visual Quality, Retention Acres
- Habitat for Low-elevation Old-Growth Wildlife Species, 1st Decade
- Habitat for Low-elevation Old-Growth Wildlife Species, 5th Decade
- Old Growth Remaining on All Lands in 5th Decade
- Existing Roadless Areas Allocated to Nondevelopment
- Religious and Cultural Use Areas Afforded High/Moderate Protection

Indicators That Vary Irregularly As PNV Declines:

- Visual Quality, Partial Retention Acres
- Acres of Deer and Elk Winter Range in 1st Decade
- Anadromous Fish Production (in pounds)
- Old Growth Remaining on All Lands in 1st Decade

PART 5 - ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

In the following section, only the significant direct and indirect effects of implementing the alternatives are summarized. Brief narratives show how the acre assignments, outputs, and schedules of each alternative will affect the physical, biological, social, and economic environment. Refer to Chapter IV of the DEIS for more detail.

The Effects On Soils. In all alternatives, except Alternative NC (which has a high level), there will be moderate to moderately-high levels of "background" or existing erosion and sedimentation of streams. Some of this is natural, a result of unstable soils and steep terrain, and some results from old timber harvest areas and existing roads.

Implementing Alternative NC would result in the most erosion from timber harvest and roads during the 1st Decade; there would be moderately high erosion in Alternatives A, I, B, H, and J (Preferred). Alternatives C and G-Modified will result in considerably less erosion. Refer to the sediment index in Table

S-2 for the effects on the Forest aquatic systems. There is limited broadcast burning in all alternatives; the least in Alternatives G-Modified and C.

The Effects On Water. In all alternatives, the Washington State Water Quality Regulations (designed to protect fish and water for domestic use) will be met, through the application of site-specific, Best Management Practices (see Appendix I, FEIS). Meeting water quality and riparian management requirements in all alternatives, except NC, will allow watersheds in an unacceptable condition to recover. Mitigation measures will result in a reduction in stream sediment, in all alternatives, from a current level of 125,000 tons per year in Alternative NC. Total sediment produced is the lowest in Alternatives C and G-Modified; Alternative J (Preferred) is second lowest.

The Effects On Vegetation and Plant Diversity. Diversity is primarily affected by timber harvest and road construction. In Decade 1, timber harvest in all alternatives will occur almost exclusively in old-growth forest. As old growth is removed, significant changes occur in the ecosystems. Over time, there is a decrease in acres of old-growth age classes and an increase in younger trees. However, this will also result in an increase in timber growth rate in the regenerated stands.

Alternatives G-Modified and C have fewer suitable acres and assign more acres of old growth to non-development. Alternative A (NC would be similar) has the highest suitable acres and harvests old growth at the fastest rate, followed by Alternatives I and then B. Both of these alternatives retain some old growth for deer and elk winter thermal cover. Alternatives H and J (Preferred) have moderately high acres of suitable land, and harvest at a moderate rate.

Refer to Table S-2 for changes in acres of old growth, by alternative.

The Effects On Wildlife. Changes in wildlife habitats lead to a shift in the distribution and levels of wildlife habitats and populations. The most significant effects on wildlife are those resulting from timber harvest activities, road construction, and road use. However, MR's for viable populations of all species are met in all alternatives except Alternative NC; in that alternative no specific provisions are included to maintain viable wildlife populations. Federal Threatened and Endangered species are protected in all alternatives.

All alternatives reduce old-growth wildlife habitat. Population estimates for the spotted owl exceed the MR level in all alternatives, except Alternative NC, for all time periods. However, wildlife populations that primarily use mature and old-growth habitats (northern spotted owl, pine marten, pileated woodpecker) will decrease over time, in all alternatives, primarily due to harvest of mature and old-growth timber stands. They decrease the fastest in Alternatives NC, A, I, and B.

Winter range habitat capability for deer and elk increases from the current situation through Decade 1, especially in Alternatives NC and A, a result of increased forage from timber harvest activities. Habitat capability declines in Decade 2, as winter thermal cover becomes limiting. By Decade 5, habitat capability again increases in Alternatives NC, A, I, B, I and slightly in J (Preferred), due to habitat improvements implemented in the first decade.

The Effects On Fish. The major effect of all alternatives on fish is a change in habitat condition. Viable populations of fish are maintained on the Forest in all alternatives (viable defined as the current or existing levels of fish

production). The amount of fish habitat capability to support and maintain fish populations above the viability level varies by alternative, primarily in response to effects of forest management on key, in-channel and upslope conditions within stream systems, plus the emphasis on fish habitat restoration and improvement capital investment activities. Alternative A provides MR levels for anadromous fish. Alternatives I, B, and H provide high levels of capital investments for restoration/enhancement for anadromous fish habitat. Alternatives J (Preferred), G-Modified, and C provide high levels for both anadromous and resident fish.

The Effects On The Human Community. None of the alternatives will affect population in the five-county area. Only minimal effects to lifestyle would be noticed, and then, primarily among groups or individuals who work in forest products, who live near the Forest boundary, or who use the Forest for recreation, cutting firewood, or gathering forest products such as mushrooms or berries.

Implementation of any alternative will, at the most, decrease the total area employment/income by four-tenths to six-tenths of one percent. With or without implementation of the Forest Plan, traditional lifestyles in the smaller, rural communities will be challenged by new, more urban values and lifestyles. However, towns such as Darrington that are further from the urban areas, will experience change more slowly.

The Effects On American Indian Religious and Cultural Uses. In all alternatives, the consultation process will be continued for any proposed ground-disturbing project located in an inventoried site or area. Also, all cemetery sites will have high protection.

Refer to Table S-2a for the amount of protection afforded religious and cultural use areas. Alternative NC would have the greatest impact on religious and cultural use areas, because of high levels of timber harvest, road construction, and other development activities. Alternative G-Modified and C would have the least impact, with Alternatives A, B, H, I, and J (Preferred) resulting in intermediate levels of impacts.

The Effects On Archaeological and Historic Properties. Any ground disturbing activity, such as timber harvest or road building, has the potential to affect archaeological and historic properties. In all alternatives, ground-disturbing activities will include a professionally supervised inventory, evaluation, and mitigation, in compliance with the National Historic Preservation Act.

Implementation of Alternatives NC or A will result in the greatest loss of historic and cultural resources, due to the high level of timber production and road construction, plus high mitigation costs. Alternatives I, B, H, and J (Preferred) have moderate levels of impact. Alternatives C and G-Modified will result in the least amount of ground disturbance and the fewest losses.

The Effects On Scenery. Generally, alternatives that emphasize commodity production will, in the long term, result in a lower visual quality level and a more visually altered landscape than alternatives with a non-market emphasis. The foreground of Mather Memorial Parkway will be protected in all alternatives. In Alternatives J (Preferred) and G-Modified, the Mather Parkway is allocated to MA 8, Special Area; no scheduled timber harvest is allowed and scenery is emphasized.

Alternatives NC, A, and B will have the greatest effect on scenery. Visual quality will deteriorate over time for almost all the lands accessible by roads in these alternatives. Alternative I protects the foreground of selected, heavily traveled highways. In Alternative G-Modified, scenic quality would be reduced moderately in several significant viewsheds (as no middleground MA 2B is allocated), but would remain high in unroaded areas.

Alternatives C, H, and J (Preferred) protect both the foreground and middleground of selected major highway corridors; J (Preferred) manages for a high level of visual quality in additional viewsheds. Within these viewsheds, scenic quality will be retained at it's current level or improve gradually. Outside of the designated viewsheds and unroaded areas, scenic quality will decrease moderately.

The Effects On Recreation. Opportunities for various types of recreation vary among the alternatives. The supply of campgrounds is adequate to meet present demand; future demand can be met with a slight expansion of facilities. Expansion is planned, in varying degrees, in all alternatives except Alternatives B and G-Modified, which provide no further developed site construction.

The Forest will continue to be a supplier of dispersed motorized and a primary supplier of dispersed nonmotorized recreation for the Puget Sound area. All alternatives easily meet projected future demand for roaded motorized dispersed use; Alternatives NC, A, B, I and H provide the most. The major effect of alternatives with high, new road construction will be modification of the overall recreation setting. A shift will take place from the Semi-Primitive ROS classes, to Roaded Natural and Roaded Modified settings.

In all alternatives, under Regional and Forest standards of resource degradation, the Forest will not meet current or projected demand for non-wilderness, unroaded dispersed recreation. The deficit will be largest in those alternatives assigning the most unroaded acres to development. Alternatives A, B, and I develop 30%, 34%, and 36% of the roadless areas, respectively. Alternatives C and G-Modified develop the least acres of unroaded land and include large amounts of trail construction. I and J (Preferred) also include large increases in new trail construction.

While the demand already exceeds supply for Semi-Primitive Motorized, unroaded ORV opportunities, there is currently very little land suitable for this experience. This situation will not improve in any alternative, as most trails on the Forest are not suitable for ORV use due to terrain, unstable soils, and heavy precipitation.

The Effects On Wilderness. The total acres of wilderness are the same in all alternatives, but assignment of acres to different intensities of Wilderness Recreation Opportunity Spectrum (WROS) will vary the social and physical settings within the wilderness. Alternatives B, I, and J (Preferred) assign more acres to the Transition WROS class (over the current situation) and will generally provide for increased wilderness use. The average number of visitors per acre will be higher, resulting in degradation of naturalness and loss of solitude. All other alternatives reduce the amount of Transition, and offer a more natural setting with less social interaction. Alternative NC has no provision for management under the WROS system, therefore acres could not be reasonably estimated.

Easier road access in Alternatives NC, A, B, I, and H will likely result in more visitors, based on past experience, and will result in greater impact on the social and environmental features of wilderness. Alternatives C and G-Modified provide the fewest miles of new road construction, and close miles of existing roads, resulting in fewer impacts.

If more acres are available for primitive and semi-primitive dispersed recreation outside of wilderness, there is more opportunity to mitigate impacts on wilderness by offering alternative recreation sites. Alternatives NC, A, B, I and H will have the greatest potential effect on the wilderness, through elimination of alternate sites for primitive and semi-primitive nonmotorized recreation. Alternatives C and G-Modified will retain the most undeveloped area. Only Alternative C will increase acreage in primitive and semi-primitive ROS classes over the current situation.

The Effects On The Roadless Areas. A maximum of 36% of the total roadless area acres could be developed in any alternative, due to the lack of resource capability, the presence of wildlife habitat needed to meet the MR level for the Forest (except in Alternative NC), and because of the steep, high-elevation terrain of most of the areas. Only 40% of the roadless acres are tentatively suitable for timber production.

During the first decade, from 1 to 9 percent of the roadless areas will be developed in any alternative. The amount of proposed development cannot be estimated for Alternative NC; however, it is unlikely - based on the existing vegetation - that more than 50% of the total roadless areas would be developed in the foreseeable future.

Although additional wilderness is not being considered in this plan, areas left roadless now would maintain that option for the future. All alternatives foreclose that option to varying degrees. Alternatives NC, A, B, and I develop the most acres; Alternatives C, and G-Modified would assign the most acres to non-development, maintaining future wilderness consideration.

The Effects On Recommended Wild and Scenic Rivers. There were were 795.9 miles of rivers and streams in 47 segments studied for possible inclusion in the National Wild and Scenic River System. The direct effect of implementing any of the alternatives will be a decision to recommend (or not recommend) designation of a river for inclusion in the National System. If a river is recommended, then management will be oriented toward protecting the features of the river system which would be important under the National Wild and Scenic River Act. No activities would be allowed which could preclude future designation. Management will protect all eligible rivers until Congress acts on the Forest's recommendation.

The number of rivers recommended for Wild and Scenic River designation range from none in Alternatives NC, B, and I, to all 47 rivers in Alternatives C and G-Modified. Alternative A recommends 15 rivers and J (Preferred) has 30 rivers recommended for inclusion.

The Effects On Air Quality. Implementation of any of the alternatives should not significantly impact air quality in the Forest area. Residue burning in all alternatives should drop to 20 percent of the acres harvested by 1990. Also, the amount of residue will decrease over time, as more logging is done in second growth timber, which contains less cull or unusable material than does old growth. Visibility in the Class I areas (two wildernesses) should continue

to be good, with only brief periods of haze, often from urban pollutants or from activities off the Forest.

The Effects On Minerals. Mining operations may significantly impact soil, water, vegetative cover, plant diversity, wildlife, fish and recreation activities. On the Mt. Baker-Snoqualmie National Forest, such operations have occurred on a small scale and are very localized. However, mineral extraction could increase if market conditions become more favorable.

Implementation of some alternatives could make mineral access very difficult, due to acre assignments to management areas that restrict or prohibit various types of mineral activity. Access is a major consideration in determining whether commercial extraction is feasible. Alternatives NC and A are the least restrictive, with high miles of new road construction and only 13 percent (Alternative A - NC would be similar) of the Forest "withdrawn" or highly restricted for mineral activity. Alternatives B, I, H, and J (Preferred) withdraw or restrict a moderate amount of acres. Alternatives G C and G-Modified are most restrictive, two due to management of most of the roadless areas for non-development.

Relationship Between Short-Term Uses of The Environment and Maintenance and Enhancement of Long-Term Productivity

The relationship between short-term uses of the environment and the maintenance and/or enhancement of long-term productivity is complex. Short-term uses refer to those that would occur within the life of this plan, generally 10 years or less, but a maximum of 15 years. Long-term productivity refers to the capability of the land and water to produce a continuous supply of resources and values for future generations. Soil and water are the primary factors of productivity and represent the measurement of the relationship between short-term use and long-term productivity.

Some short-term uses can be detrimental to long-term productivity, particularly if effective mitigation measures are not implemented. Surface mining can leave an area with greatly diminished productivity for growing vegetation if the top soil is removed and not replaced. This adverse effect can be mitigated effectively by requiring stock piling and spreading of topsoil. Introduction of sediments into a stream on a continuous basis could adversely effect the future long-term productivity of that stream for production of fish. This potential adverse effect can be effectively mitigated by elimination of sediment sources or trapping sediment before it reaches the stream by maintaining vegetation along stream banks.

Some short-term uses also have the potential to increase long-term productivity. Harvest of old-growth timber stands and establishment of young faster growing stands increases the long-term productivity of the land to produce wood fiber. The current productivity of the Mt. Baker-Snoqualmie National Forest in terms of net timber growth is approximately 34 cubic feet per acre per year (1976 Timber Inventory). Harvest of these old growth stands can increases average annual growth on the Forest up to 90 cubic feet per acre per year.

The Multiple-Use Sustained-Yield (MUSY) Act of 1960, one of the principal laws relating to the Forest Service activities, requires the management of the various resources in such a manner that the productivity of the land will not be impaired. This law along with Forest Service Policy that was in effect

prior to the MUSY Act have provided the basic frame work for development of management activities that are centered around maintaining the long-term productivity of the National Forests.

Many of the mitigation measures described in detail in Chapter II, Mitigation Incorporated in Alternatives, are designed specifically to maintain or enhance long-term productivity as short-term uses (projects) are designed and implemented. In all resource ares, long-term productivity of soil and water will be maintained or enhanced as a result of implementing the alternatives.

Implementation of the Forest Plan, which accompanies this FEIS, includes a monitoring plan. This monitoring plan will provide the data necessary to determine if the prescribed mitigation measures are effective in maintaining long-term productivity.

Irreversible or Irretrievable Commitment of Resources

An "irreversible commitment of resources" results from decisions to use or modify resources or environmental components of the Forest that cannot be renewed, or are renewable only over long periods of time. Examples are: old growth, soil productivity, minerals, cultural resources, scenery, and roadless areas. Once these resources are used or modified, they are irreversibly lost.

Soil productivity can be irreversibly lost or reduced by dedicated uses of the land. Examples of these uses would be arterial and collector roads, administrative sites, and developed recreation sites. Soil erosion, as a result of management activities, is an irretrievable loss because once the soil particles are removed from the site and deposited into a stream or river, they are no longer available. Accelerated erosion rates can reduce soil productivity and also reduce the water-holding capacity of the soil.

Removal of mineral or energy resources is an irreversible commitment of resources. The removal and utilization of rock resources for road construction would be an example of a common use on the Forest.

Reductions in habitat capability for old-growth-dependent species due to timber harvesting involve an irreversible and irretrievable commitment of resources.

The development of roadless areas would mean an irreversible loss of the characteristics which qualify these areas for Wildernesses or Roadless Areas. Development could also mean an irreversible loss of natural scenery and, in some cases, old-growth habitat.

Archaeological resources may be damaged by ground-disturbing activities; Irreversible information loss can result. Even when mitigation occurs prior to the activity, future study with more advanced techniques is precluded.

For American Indian religious use, land development removes the spiritual influence on the environment; this irreversibly removes the opportunity to conduct religious activities.

An "irretrievable commitment of resources" refers to a resource that is lost because of land use decisions or designations and/or scheduling decisions. These are opportunities foregone for the period of time that the resource cannot be used. Timber stands in management areas where timber harvest is not permitted represent an irretrievable loss of growth increases that could be

made if the stands were being actively managed for timber production. Although the lost growth is irretrievable, the decision is not irreversible, since the stands could be managed at a later date in the future.

Probable Adverse Environmental Effects That Cannot Be Avoided

Implementation of Alternative J (Preferred) will result in some adverse environmental effects that cannot be avoided. The identification of an "adverse effect" is somewhat subjective, depending upon an individual's point of view. There are some effects considered to be adverse, by general agreement. The following effects are associated with implementation of Alternative J (Preferred). Although many of these effects can be reduced through the use of mitigation measures, they cannot be completely eliminated.

Timber harvest and associated road construction will result in adverse effects on scenery, water quality, soils, American Indian religious and cultural use areas, and dispersed recreation use in a non-motorized environmental setting.

Harvest of old-growth timber stands will reduce the amount of habitat available for old-growth dependent species and reduce their populations.

Ground-disturbing management activities and facilities management will probably result in inadvertent destruction or displacement of archeological and historical rsesources. Even when mitigation occurs, future study and interpretation are precluded.

Any mineral extraction activities that occur will result in destruction of vegetation, production of sediments, and effects on scenery.

Development and use of recreation facilities will result in compaction of soil, loss of vegetation, water pollution, dislocation of wildlife and disturbance of their habitat, noise and dust production in small areas, and localized air pollution from campfire smoke and vehicle exhaust.

Air quality will be degraded on a localized and short-term basis from prescribed fire and activities that generate dust from unpaved roads.

Any of the proposed small hydroelectric projects that reach the construction stage will result in adverse impacts on soil, water, and vegetation to some degree. These would generally be on a localized area. Construction techniques and mitigation measures can minimize most impacts and limit them to the construction effects on the visual resource. Some projects will also have long-term impacts on wildlife, American Indian religious and cultural use (effects on purity of streams), and recreation.

Development, especially timber harvest and hydroelectric projects, will create features and habitats out-of-keeping with traditional Indian religious use, and will reduce the availability of some plant materials, such as cedar.

Environmental Conditions Unchanged by Alternatives

Some environmental conditions and resource uses are essentially unchanged by any of the alternatives. These are resources which are often protected by law and are managed consistently in all alternatives. They include:

Summary

The wilderness acres are unchanged in any of the alternatives (refer to Chapter II, Alternatives Considered but Eliminated for Detailed Study). The acres assigned to each wilderness ROS class vary between alternatives, but total wilderness acreage does not.

Management of the Skagit Wild and Scenic River is unchanged across all alternatives. The existing management plan for this river system (which is incorporated into this Forest Plan) will provide the same set of environmental conditions in each alternative (refer to Chapter II, Alternatives Considered but Eliminated from Detailed Study).

The basic land allocations established through implementation of the Alpine Lakes Area Land Management Plan (1981) are the same in all alternatives (refer to Chapter II, Alternatives Considered But Eliminated from Detailed Study).

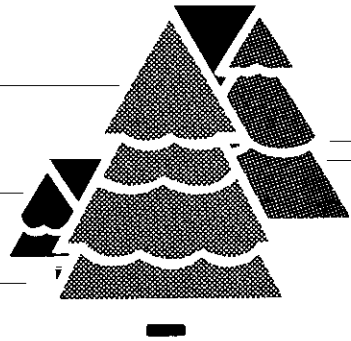
The Mt. Baker National Recreation Area, size and management, is unchanged in any of the alternatives.

Management of the North Fork Nooksack, Lake Twenty-two, and Long Creek Research Natural Areas will remain the same in all alternatives. Although the alternatives recommend different numbers of new research natural areas for designation, the existing ones remain unchanged.

None of the alternatives result in any environmental consequences on prime farmlands, prime rangelands, or prime forestlands. None of these prime lands would be converted to other uses as a result of the implementation of any of the alternatives.

None of the alternatives results in any change in Indian Treaty Rights.

Chapter



CHANGES BETWEEN DRAFT AND FINAL - CHAPTER I

The Final Environmental Impact Statement (FEIS) includes:
Summary and FEIS, Land and Resource Management Plan
Appendices A-I
Appendix J, Response to Public Comments
Packet of Maps

The content of this FEIS has been modified from the Draft Environmental Impact State (DEIS), in response to public comment. In Chapter I, changes include revisiting and modifying the issues, concerns, and opportunities (ICO's) in response to the 11,718 letters received, commenting on the DEIS.

- Wild and Scenic Rivers are identified as a separate major ICO, rather than as a facet of the recreation issue. This better reflects public concern.

- Based on public comment, two issues were dropped as major ICO's: Transportation Systems and Wood Residue. They are still considered, but as facets of other issues.

- Several other issues have been re-titled, or additional facets considered, to better respond to public comment on the DEIS. Increased recognition is given to diversity, old growth ecosystems, cumulative effects of management activities, watershed management, fisheries resources, and trails.

The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA 1988a) that addressed spotted owl guidelines has been completed since the Mt. Baker-Snoqualmie DEIS was released. The FEIS for Managing Competing and Unwanted Vegetation (USDA 1988b) was also released since the DEIS. The relationship of these documents to this final EIS is discussed below.

CHAPTER I - PURPOSE AND NEED

A. INTRODUCTION

This Final Environmental Impact Statement (FEIS) culminates over ten years of public involvement and environmental analysis spent in preparing the Mt. Baker-Snoqualmie National Forest Land and Resource Management Plan (Forest Plan).

This FEIS describes eight alternative ways of managing the land and resources of the Mt. Baker-Snoqualmie National Forest (the Forest), the environment that will be affected when the plan is implemented, and it discloses the environment consequences, including significant impacts, of implementing each alternative. The FEIS identifies a Preferred Alternative.

Each of the eight alternatives address, in a different way, local, regional, and national public issues and management concerns. Each alternative provides a different mix of goods and service from the Forest. All eight alternatives provide for the use and protection of resources and (except Alternative NC) fulfill legislative requirements.

The guiding principle for each alternative is multiple-use and sustained-yield management. Each alternative is evaluated to determine its potential to provide a sustained yield of goods and services in a way that maximizes net public benefits, in an environmentally sound manner. Net public benefits are the overall long-term net value of all Mt. Baker-Snoqualmie National Forest outputs and activities, whether assigned a dollar value or not. Net Public Benefits are discussed in more detail in Chapter II, page II-2 and in Appendix B of the FEIS. The Preferred Alternative is the alternative which, in the considered opinion of the Forest Service, provides for a level of multiple uses, goods, and services that best maximize long-term, net public benefits while responding effectively to all the public issues.

The Forest Plan

The Preferred Alternative is the basis for the accompanying Land and Resource Management Plan (Forest Plan). The purpose of the Forest Plan is to direct and guide all natural resource management activities on the Mt. Baker-Snoqualmie National Forest. Forest Plan preparation is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated National Forest System Land and Resource Planning Regulations, Title 36, part 219, Code of Federal Regulations (36 CFR 219).

Legal Requirements

The preparation of an environmental impact statement (EIS) is required by NFMA and the National Environmental Policy Act (NEPA) of 1969, the Council on Environmental Quality (CEQ) Regulations for implementing NEPA (40 CFR 1500-1508). For purposes of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents. In accordance with NEPA, an EIS is required because the implementation of a Forest Plan is a "major federal action significantly affecting the quality of the human

environment." Its purpose is to disclose to the decision maker and the public alternative ways to manage the land and resources of the Mt. Baker-Snoqualmie National Forest, and to aid the decision maker in selecting a course of action.

This FEIS provides decision-makers with an environmental disclosure sufficiently detailed to permit a reasoned choice among the alternatives, to aid in the selection of management direction for the Mt. Baker-Snoqualmie National Forest. Equally important, the FEIS is a public document. Descriptions of the alternatives and the environmental consequences of implementing each alternative are available for public review. The public is encouraged to participate in the development and refinement of this information.

A Record of Decision (ROD) documenting the Pacific Northwest Regional Forester's decision for managing the Mt. Baker-Snoqualmie accompanies this FEIS. The ROD displays the decisions made, the rational for the decisions, and identifies what options were considered before making the decision.

The Plan Period

The alternatives presented in this document contain management direction for the plan period: the next 10 to 15 years. NFMA regulations define the plan period as one decade, while the law permits a 15-year maximum. Conditions on the Forest will be re-analyzed every 5 years; under certain circumstances, the plan may be revised.

Management actions, outputs, and environmental effects for several decades beyond the plan period are also discussed for each alternative. These discussions are included to: 1) provide an estimate of the long-term outputs for each alternative; 2) present a long-term analysis (for decision-makers and the public) of the management necessary to achieve and maintain the resource outputs of each alternative, in perpetuity, and without impairment to the productivity of the land; and 3) provide the required information for the Forest and Rangeland Renewable Resources Planning Act (RPA).

Program development for RPA requires information for four decades beyond the plan period (16 USC 1602). To link the analysis of alternatives for the RPA program to the actual conditions and local issues of the Mt. Baker-Snoqualmie, estimates of outputs, costs, and effects for the RPA time horizon are important. The total time period discussed throughout this FEIS is generally five decades.

The Forest Service is required to revise the plan within 15 years of its adoption. This revision may establish different long-term goals with different projected effects and outputs.

B. PLANNING PROCESS

National, Regional, and Forest Planning

As required by the RPA, NFMA, and the related implementing regulations cited above, the Forest Service has a multi-level, integrated planning process. At the national level, the RPA Program establishes long-range resources objectives. These are based on the present and anticipated supply of, and demand for, various resources, including: wildlife and fish, developed and dispersed recreation, timber, range, water, minerals, soils, and others. A portion of each national resource objective is distributed to each of the nine Forest Service Regions in the nation.

At the Regional level, a Regional Guide presents the tentative distribution of its portion of the national resource objectives to each National Forest. This Guide also establishes Regional management standards and guidelines. The Pacific Northwest Regional Guide (USDA 1984b) provides this direction for the Mt. Baker-Snoqualmie. Standards and guidelines for management of spotted owl habitat are established in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA 1988a). The EIS for Managing Competing and Unwanted Vegetation (USDA 1988b) provides direction for vegetation management.

At the Forest level, a Forest Plan is prepared, with an accompanying EIS. Both are tiered to the Regional Guide and include direction provided by RPA and NFMA (implementing regulations). Alternatives are developed, each with a different mix or range of resource objectives. One or more of these alternatives attempts to meet or exceed the resource objectives from the RPA Program, as distributed to the Forest in the Regional Guide.

This planning process is a continuous one. Data from the planning efforts at the Forest level, including project planning, flows up to the national level. The analysis of the outputs of Forest Plan alternatives and their effects provide valuable information regarding each Forest's capabilities and resource programs. This information is then incorporated into the National RPA Program.

The RPA Program is submitted to Congress as an aid to determine appropriation and authorization of the agency's annual budget. Since allocations in the annual budget have a major effect on forest management activities, many of the Forest's actual outputs and environmental effects are ultimately determined in large part by the annual budget. But, through the overall planning process, the annual budget can be responsive to demands on and capacities of the Forests.

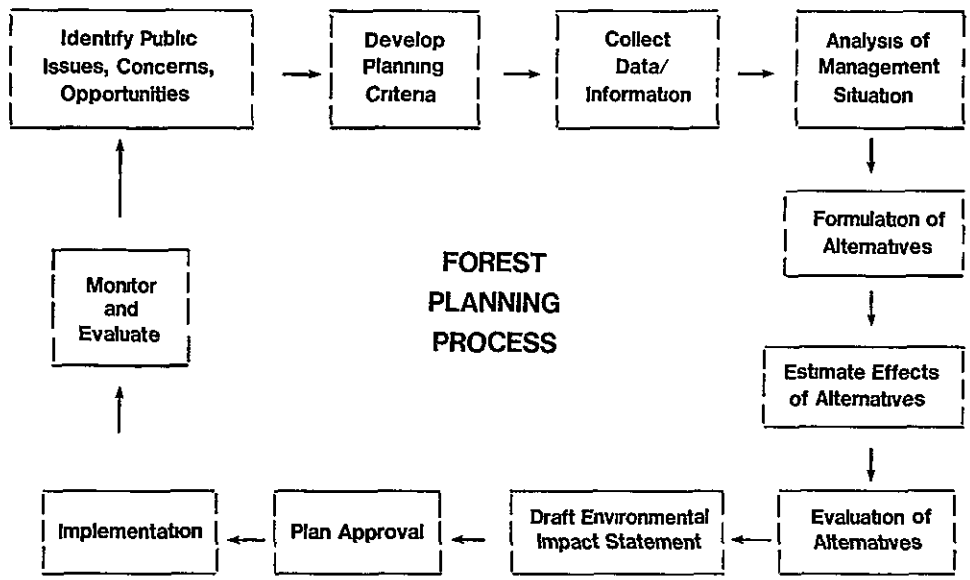
The RPA Program is updated every five years. The Forest Plan is reviewed every five years; ordinarily, it is revised every ten years, or at least every 15 years. When changes in the RPA Program significantly affect Forest programs, or whenever conditions or demands in the planning area change significantly, the Forest Plan will be amended.

The Steps in the Planning Process

The steps in the planning process are displayed in the figure and short table below. They are discussed in more detail in the CEQ regulations for implementing NEPA, and in the NFMA implementing regulations.

1. **Identify Purpose and Need and Major Issues and Concerns**
2. **Develop Planning Criteria**
3. **Collect Inventory Data and Other Information**
4. **Analyze the Management Situation**
5. **Formulate Alternatives**
6. **Estimate Effects of the Alternatives**
7. **Evaluate the Alternatives**
8. **Selection of a Preferred Alternative**
9. **Plan Implementation**
10. **Monitor and Evaluate**

Figure I-1



Government agencies and the public were asked to review and comment on the DEIS and Proposed Forest Plan. All comments received were considered and used to evaluate the results of the first seven planning steps and to develop a Preferred Alternative and Forest Plan. Appendix J describes the public involvement process between the DEIS and FEIS; is also displays the comments received and the Forest's response to those comments.

This FEIS will be used by the Regional Forester as the information base for a Record of Decision. The ROD will be made available to the public. Issuance of the Record of Decision will complete planning step 8 and initiate the last two planning steps.

Upon implementation, the FEIS will be used for "tiering" in accordance with CEQ regulations. Tiering means that environmental analysis conducted for projects arising from the Forest Plan will refer to the FEIS and associated documents rather than repeat information presented in the FEIS. This will help narrow discussions and concentrate on issues pertinent to the project. Project scoping, public involvement and other agency involvement, and the ensuing environmental analyses will then be able to focus on issues unique to those projects and site conditions.

Relationship to Previous Plans

The Forest Plan supersedes or incorporates all previous land and resource management plans for the Mt. Baker-Snoqualmie National Forest. Upon implementation, Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest system lands and resource uses must be in conformance with the Forest Plan as soon as possible (36 CFR 219.10(e)).

The following plans are incorporated into this Forest Plan: (36 CFR 219.2)

The Alpine Lakes Area Management Plan
The Skagit Wild and Scenic River Management Plan

The following plans are superseded by this Forest Plan: (36 CFR 219.10(e))

Multiple Use Plan, Glacier Ranger District
Multiple Use Plan, Baker River Ranger District
Multiple Use Plan, Darrington Ranger District
Multiple Use Plan, Monte Cristo Ranger District
Multiple Use Plan, Skykomish Ranger District
Multiple Use Plan, North Bend Ranger District
Multiple Use Plan, White River Ranger District
Timber Management Plan, Mt. Baker National Forest
Timber Management Plan, Snoqualmie National Forest
Wilderness Management Plan, Glacier Peak Wilderness
Land Adjustment Plan, Snoqualmie National Forest
Land Adjustment Plan, Mt. Baker National Forest

Planning Records - Using The Documents

All of the documents and files that chronicle the planning process on the Mt. Baker-Snoqualmie National Forest are available for review at the Forest Supervisor's Office, in Seattle. These documents and files are referred to as the "Planning Records" and contain the detailed information and decisions used to develop this FEIS and the Forest Plan. This information is available upon request.

A glossary defining terms, units, and abbreviations is located at the back of this document. An index of topics and a list of references cited in the FEIS is provided. The reader will find it useful to consult the maps for each alternative - in a packet with this FEIS - when reviewing the documents.

C. FOREST OVERVIEW

The Mt. Baker-Snoqualmie National Forest has over 1.7 million acres and serves a large and diverse population. The Forest is located in some of the nation's most beautiful country - the Cascade Mountains - in the northwest corner of the State of Washington. The Forest contains lush, forested valleys, steep and rugged mountain peaks, glaciers, and numerous high-elevation lakes. It is drained by seven major river systems. The diversity of both the physical and social settings adds to the complexity of issues facing Forest managers.

Administrative History

The Mt. Baker National Forest was proclaimed a National Forest in 1898. Its original name was the Washington Forest Reserve; the name was changed to Mt. Baker in 1924. The Snoqualmie National Forest was established from the proclaimed Pacific Forest Reserve in 1893. Several land withdrawals, additions, and name changes occurred between 1893 and 1908. In 1908, the name Snoqualmie was established. Portions of both of these proclaimed National Forests were combined, for administrative purposes, in 1974. They are collectively referred to as the Mt. Baker-Snoqualmie National Forest. It is this area that is considered in this FEIS and the accompanying Forest Plan. The portions of the Mt. Baker and the Snoqualmie that were administratively assigned to other Forests - the Okanogan, Wenatchee, and Gifford Pinchot National Forests - will be addressed in the Forest Plans for each of those Forests.

The Land Base and Human Community

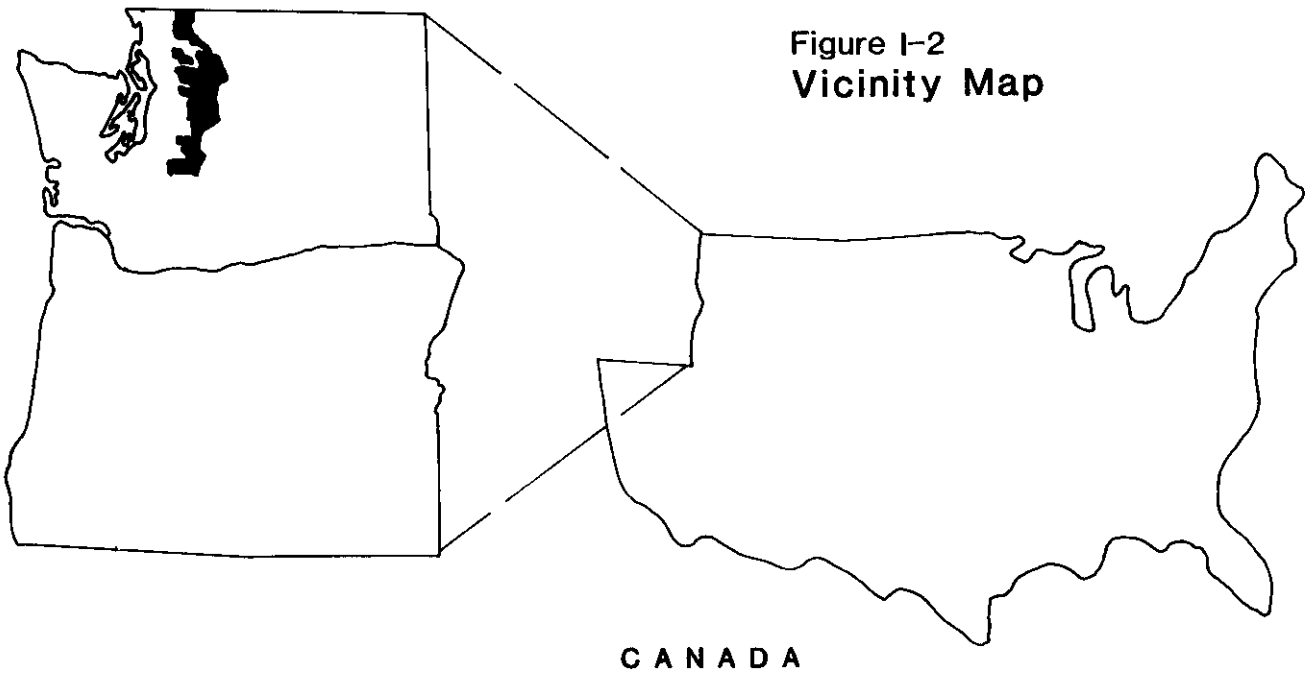
The Forest includes land from the Canadian border south, 130 miles, to the northern boundary of Mt. Rainier National Park, and is adjacent to: the North Cascades National Park, the Wenatchee National Forest, and Mt. Rainier National Park. The Mt. Baker-Snoqualmie occupies portions of Whatcom, Skagit, Snohomish, King, and Pierce Counties. See Figure I-2.

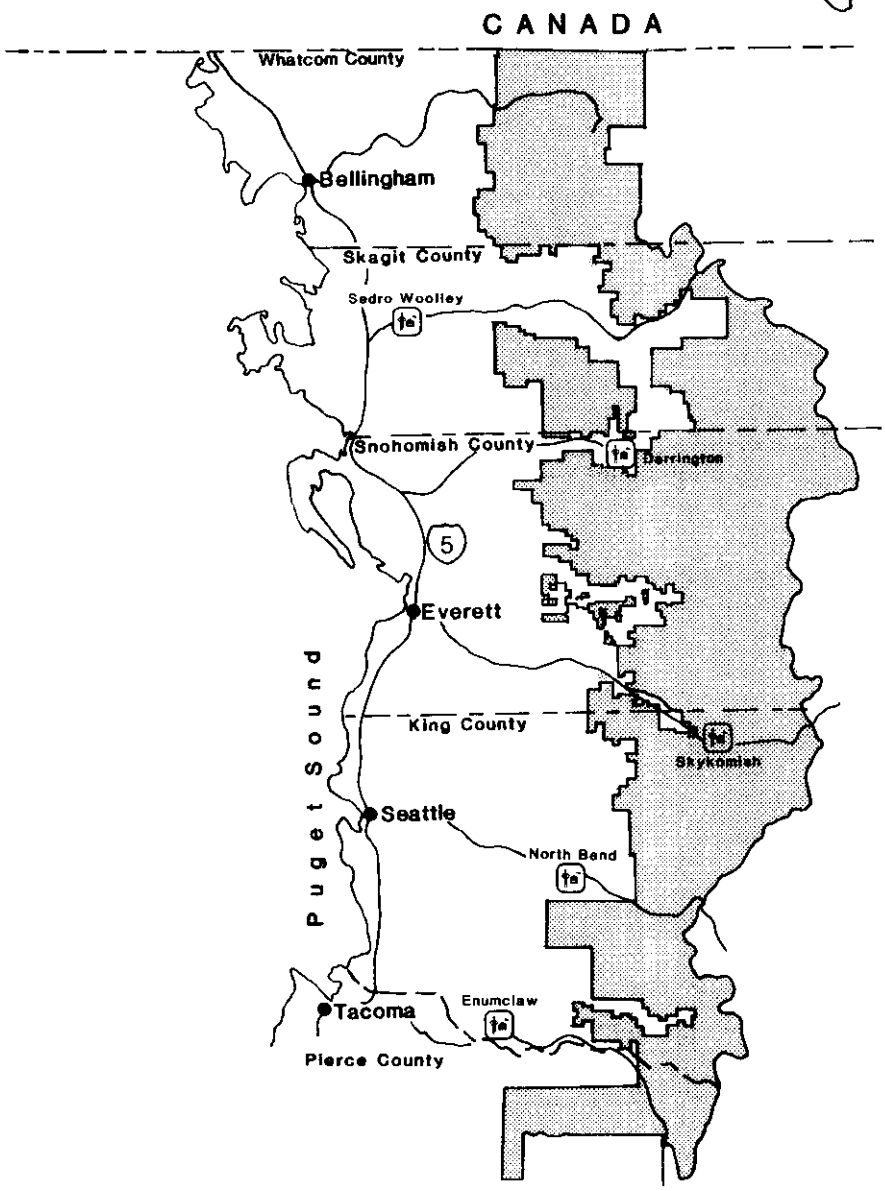
The five-county area has a population of more than 2.5 million persons, over 56 percent of the total State population. Most of these 2.5 million people live in the greater Seattle-Everett-Tacoma metropolitan area, only 40 to 70 miles west of the forest boundary. Just north of the Forest is the Vancouver, B.C., Canada metropolitan area, with a population of 3.0 million people. The Puget Sound economy is quite diverse today, although the aerospace industry is still a major employer (Pascall and others 1989). The metropolitan area is a major center for finance, trade - especially to Pacific Rim nations - administration, and government. Growth has not been even in the five-counties; the trade and service sectors and the high-technology industries continue to lead the economic growth. The forest products industry has experienced major changes over the last decade; wood products manufacturing outputs have been up the last three years, but with 25 percent fewer employees.

Forest Resources

The Mt. Baker-Snoqualmie National Forest contains a wide variety of land forms. The northern half of the Forest includes much of the North Cascade Mountains. These rugged peaks have been extensively glaciated and are dominated by the major Forest peaks: Mt. Baker - 10,778 feet; Glacier Peak - 10,568 feet; and other peaks 7,000 feet and higher.

Figure I-2
Vicinity Map





Volcanic rock types and less pronounced glaciation are prevalent on the southern half of the Forest. Winters are wet and mild, and summers are cool and relatively dry. The annual precipitation on the Forest ranges from 35 to 50 inches over the lowlands, 75 inches in the foothills, and from 100 to 200 inches near the Cascade Crest. Above 2,500 feet, most winter precipitation falls as snow.

The upper reaches of seven major river systems are located on the Forest and provide both seasonal and year-round spawning and rearing habitat for anadromous and resident fish. A rough estimate of anadromous fish (smolt) produced in Forest waters is 16 million fish. There are 18 municipal watersheds on the Forest serving a population of over 1.4 million. Only one of those watersheds provides treatment other than disinfectant, attesting to the high quality of the surface water.

The vegetation of the Forest consists of dense stands of western hemlock, Douglas-fir, and western redcedar at lower elevations, blending into Pacific silver fir, mountain hemlock, and true firs at the higher elevations. Underneath these stands of trees are numerous species of shrubs, forbs, and grasses. Above 6,000 feet, the vegetation is composed almost entirely of these low growing species with only an occasional tree, such as dwarf juniper or alpine larch.

This great diversity of plant and tree communities provides a variety of habitats for a wide variety of wildlife species. Four Federally listed threatened and endangered species may occur on the Forest: the bald eagle, American peregrine falcon, grizzly bear, and the gray wolf.

The Forest is rich in recreation opportunities and receives over 5 million recreation visits annually. Dispersed day-use recreation is emphasized; use occurs in unroaded nonwilderness areas, in roaded areas, and wilderness. Over 1,380 miles of trail provide recreation opportunities for hikers, horse riders, and motorized equipment users; over 100 miles of these trails are National Scenic or National Recreation Trails. The most popular developed use is alpine skiing, at seven areas on the Forest, followed by campground and picnic area use.

Nearly 42 percent of the Forest is designated wilderness. Additional Congressionally designated areas include the 158 mile long Skagit Wild and Scenic River System, the Mt. Baker National Recreation Area (8,700 acres), and the multiple use Alpine Lakes management unit (148,000 acres).

From 1975 to 1988, the dense forests of hemlock, cedar, and Douglas-fir have provided about 250 million board feet of timber sold annually. Changes in the land base over the last two decades (including designation of wilderness) have affected the amount of timber sold from Mt. Baker-Snoqualmie National Forest. The most recent revision to the 1963 Timber Management Plan (November 1984 Revision) included a timber sale potential of 203.8 million board feet. This reflects the addition of six new wildernesses to the Forest.

In 1986, 47 out of 87 lumber mills in the Puget Sound area (which does not include the 35 export mills) were one-third to 100 percent dependent on National Forest logs for their operations. Nearly all the timber cut from the Mt. Baker-Snoqualmie is consumed in the local area.

Approximately 159,700 acres of forest land are not suitable for timber production because of problems in replanting the land if the trees were cut. Many of these acres occur at higher elevations. Additional acres - over 95,500 - cannot be considered for potential timber cutting because of highly unstable soils. Approximately 597,000 acres, or 35 percent, of the Forest has been classified as tentatively suitable for timber production. Nearly half of this acreage is currently forested with old growth trees. (See Chapter III, Diversity for a definition and more discussion on old growth.) Almost 60% of the tentatively suitable old growth is in areas that are unroaded and undeveloped.

A more complete description of the Forest is located in Chapter III, FEIS, *Affected Environment*.

D. ISSUES, CONCERNS, AND OPPORTUNITIES

The complex natural systems of the Mt. Baker-Snoqualmie National Forest can be managed for many different mixes of land use, environmental conditions, and resource outputs. The elements of the physical, biological, social, and economic environment are interrelated; therefore, emphasizing one resource may necessitate changes, or less emphasis, in other resources.

There are certain limits to what can be provided in any alternative on the Mt. Baker-Snoqualmie. Some limits are biological, some physical, and some are legal. Other considerations in developing an alternative are the preferences of individuals and groups: the benefits people want in the form of goods, services and uses, and environmental conditions.

An important first step in the planning process is the identification of major public issues, management concerns, and resource use and development opportunities (ICO's). A public issue is a subject or question of widespread public interest relating to management of the National Forest System. A management concern is an issue, problem, or a condition which constrains the range of management practices.

Opportunities - to preserve, use, or develop the resources of the Forest - are the focus of many Forest Service programs. Resource use and development opportunities are the basis of many of the issues and concerns. Public issues and management concerns are generally part of every opportunity. Most opportunities are incorporated within the discussion of issues and concerns; they are also the principal focus of the alternatives developed in this FEIS.

The Tie to Alternatives and the Planning Process

These issues, concerns, and opportunities guide the planning process. They also play a key part in developing alternatives. By managing the land and resources in different ways, varied objectives can be achieved which respond to different issues, and provide different combinations of public benefits. Indicators of responsiveness measure how well the alternatives respond to the ICO's. The indicators are discussed in more detail below, and displayed in Table I-1.

Developing and Confirming the ICO's

Identifying the ICO's was a critical step in the planning process. An extensive process began in 1979. Involved were interested members of the public, adjacent private landowners, State and local agencies, Forest Service employees, Native American tribal leaders, and three liaison groups: the Conservation Liaison Group, the Timber Industry Liaison Group, and the Recreation Liaison Group.

An initial list of 70 potential ICO's was developed by the Planning Team and the Forest Management Team, using input from earlier planning efforts, letters to the Forest, newspaper articles, and from day to day contacts with Forest users and the interested public. This preliminary list was mailed to 3,300 individuals, groups, organizations, and agencies. Four public workshops were held within the five-county area of influence; written comments were also welcomed. More than 180 people commented on the preliminary list, either through participation in one of the workshops or through letters to the Forest.

The initial list of issues and concerns, along with the public response, was analyzed and the major issues and concerns were developed. See Appendix A for more detailed information on this process.

Confirming the ICO's

The ICO's have changed somewhat over time, to keep current with new events, changes in policy and procedure, and shifts in public values and concerns. Appendix A documents the changes occurring between draft and final. In addition - based on the public comments received on the DEIS - the ICO's have been confirmed or revised for this final EIS. Nearly 12,000 letters and cards were received in response to the draft EIS and proposed plan during the 110 day review period (the normal 90-day review period was extended).

Appendix J describes the public involvement process between the DEIS and FEIS; it also displays a summary of the analysis completed on all 11,718 letters and the substantive comments received plus the Forest's response to those comments.

The ICO's described below are the most current. It is around these issues that the alternatives contained in the FEIS are designed and analyzed, and on this foundation that the Preferred Alternative is selected. Several ICO's were re-titled, or refocused; Wild and Scenic Rivers is identified as a separate major ICO; and two issues were dropped. These changes were made in response to the considerable public comment. Refer to Appendix A for more information.

Indicators of Response

The measure of the Forest's ability to respond to the issues, concerns, and opportunities are referred to as "Indicators of Response." Indicators include the outputs, uses, or conditions that can be measured or described to gauge the response of each alternative to the ICO's. The indicators of response for each major ICO are shown in Table I-1. Refer to Chapter II, Table II-14 and accompanying narrative for an analysis of how each alternative responds to the issues, concerns, and opportunities.

Table I-1
Indicators of Response of Alternatives to the ICO's 1/

Issue, Concern, Opportunity *Indicator of Response*	Unit of Measure
Development versus Nondevelopment of the Forest	
Existing Roadless Areas Allocated to Nondevelopment	% Acres, M Acres
Roadless Areas Assigned to Roaded Mgt. Prescription But Not Developed in Next 15 Years	M Acres
Timber Supply	
Timber Harvest Level	MMCF/MMBF
Long-Term Sustained Yield Capacity	MMCF
Lands Suitable for Timber Production	M Acres
Employment: Jobs Supported by the Alternatives	M Jobs
Payments to Counties	MM Dollars
Old Growth Ecosystems and Fish/Wildlife/Plant Diversity	
Total Old Growth Remaining, End of Decades 1, 5	M Acres
Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Anadromous Fish Production	Pounds Per Year
Low-Elevation Old Growth Habitat for Wildlife	M Acres Under 3000'
Suitable Winter Range for Deer and Elk, Decade 1	M Acres
American Indian Religious and Cultural Use	
Inventoried Use Areas with High/Moderate Protection	% of Inventoried Ac.
Recreation Opportunities	
Demand Satisfied for Wilderness, Primitive, Semi-Primitive Nonmotorized Recreation, Decades 1 and 5	% of Capacity
Roads Open to Public Use, Passenger Car	Miles
Trail Construction, Reconstruction, Decade 1	Miles
Lands Managed for High Visual Quality Levels	M Acres Retention, Partial Retention
Wild and Scenic Rivers	
Rivers Recommended for Designation as Wild and Scenic	No. Rivers, Miles
Management of Municipal Watersheds	
Timber Harvest Level	MMCF (MMBF)
Effects of Timber Management and Related Activities	
Timber Harvest Level	MMCF (MMBF)
Old Growth Remaining on Suitable Acres, Decades 1, 5	M Acres
Annual Road Construction, Decade 1	Miles
Sediment Produced from All Sources, Annually, Decade 1	M Tons
Adjacent and Intermingled Lands	
Timber Harvest Level	MMCF (MMBF)

1/ Refer to the Glossary for an explanation of abbreviations used.

E. MAJOR ISSUES, CONCERNS, OPPORTUNITIES

Development versus Nondevelopment of the Forest

How should the released, roadless areas be allocated and how will the resources be managed?

At what rate should the Forest Service enter those roadless areas that are allocated for development?

The allocation and management of 402,930 acres of unroaded area remains a highly controversial issue. These acres equal approximately 55 percent of the roadless areas inventoried in RARE II, and 23 percent of the net acres on the Mt. Baker-Snoqualmie. These roadless lands were released from wilderness consideration by the 1984 Act. However, the legislation did not settle the issue.

This issue has been retitled, to better reflect public comments received on the DEIS. Some organizations and individuals referred to the "released" roadless areas, but many more focused less on the RARE II remnants and more on the general issue of whether the remaining unroaded and undeveloped lands on the Forest should be managed for commodity production/roaded recreation or remain undeveloped. This key issue encompasses facets of nearly all the other ICO's.

Some elected officials, environmental groups, many hikers, some Indian Tribes, and wildlife organizations want the unroaded areas to remain undeveloped and unroaded. Their concerns include: protection of wildlife habitat and old growth (especially low-elevation old growth), providing non-motorized recreation opportunities, and protection of water, soil, cultural, and scenic values. They also want to maintain the option of future consideration for wilderness. A number of individuals and groups support a proposal for Backcountry Areas, roughly corresponding to five roadless areas.

Timber and mining companies, trade organizations, energy-related industries, and some individuals feel that the 1984 Washington State Wilderness Act "released" these lands for multiple uses. They are concerned that nondevelopment will limit the amount of timber and minerals available for use, affect the local and regional economy, and lead to future wilderness designation. Many people feel there is a need for more motorized access to the roadless areas, to encourage recreation. Individuals, primarily living outside the Seattle metropolitan area, are concerned about saving timber jobs.

The commercial forest land within the roadless areas has been used to calculate the annual potential yield in the 1963 Timber Management Plan, as amended. However, this timber was not available for harvest from 1972 through 1984, resulting in a long-term concentration of timber harvesting on about one-half the land base. Approximately 164,500 acres, or 40 percent, of the unroaded areas are tentatively suitable for timber production.

Timber Supply

What is the capability and suitability of the Mt. Baker-Snoqualmie National Forest to produce timber?

What should the timber harvest level be considering all resources on the forest and their relationship to social, economic, and environmental factors including local, regional, and national demands?

A major public issue and management concern is the timber supply on the Mt. Baker-Snoqualmie National Forest. This issue has also been retitled since the DEIS, to better reflect public comments. The issue now includes facets of the wood residue opportunity, which was displayed in the DEIS, but dropped as a major ICO in this FEIS based on public comment. (See Appendix A, page A-18.)

Support for maintaining or increasing the timber supply comes from timber industry (management & employees), some community leaders, businesses dependent on the timber industry, and economic development agencies. Many individuals want the timber supply to be maintained, primarily to protect jobs. Environmentalists, some recreation users, wildlife and some hunting interests, fishing organizations, Indian tribes, some community leaders, and State Wildlife agencies strongly support restricting or reducing the timber harvest, especially in low-elevation old growth. A number of people feel the loss of mill jobs is due to factors other than timber supply.

Related issues and concerns are: how the National Forest timber supply affects jobs and the local and regional economy; the rate of harvest of old growth; the rate of entry into the unroaded areas; social and environmental effects; and wood residue utilization.

While the timber industry is a small part of the overall Puget Sound economy, it is still an important part. Four percent of the wage and salary jobs in two counties are based on lumber and wood manufacturing. The Forest currently supplies about 17 percent of the logs consumed in the Puget Sound area; a number of mills are dependent on National Forest logs.

The 1984 amendment to the 1963 Timber Management Plan reduced the annual potential yield to 203.8 million board feet (MMBF), to reflect the Washington State Wilderness Act. Over the 10-year period (1979-1988), the average timber volume sold was 235.8 MMBF and harvested was 229.6 MMBF, which is within the average annual potential yield for the decade: 229.7 MMBF. Refer to Chapter III, Table III-11. The timber supply potential on the Forest is considerably less than what past timber sale programs have indicated.

Approximately 597,000, or 35 percent, of the net Forest acres are considered to be tentatively suitable for timber production; about half of the tentatively suitable acres contain old-growth forest. The unroaded areas contain 164,500 acres of tentatively suitable (or 27% of the tentatively-suitable timber).

Old Growth Ecosystems and Fish, Wildlife, and Plant Diversity

What management direction is needed and where should action be taken that will maintain and/or enhance old growth and diversity to meet multiple use objectives?

The title of this ICO has been adjusted, in response to public comment. Old growth is a major issue on the Mt. Baker-Snoqualmie National Forest. Its value in providing biological diversity, wildlife and fisheries habitat, recreation, aesthetics, water quality, as well as industrial raw material is widely recognized by the public and the scientific community.

Environmental groups, wildlife societies and organizations, many individuals, Indian Tribes, and State wildlife agencies want the remaining old-growth forests protected. Old growth is important to American Indians for religious and cultural purposes.

Timber company representatives, industry trade associations, some State and local agencies, and many individuals feel these resources are an important contribution to timber production and maintaining local economies. Some feel that converting these stands into second growth timber is important for increasing long-term forest productivity.

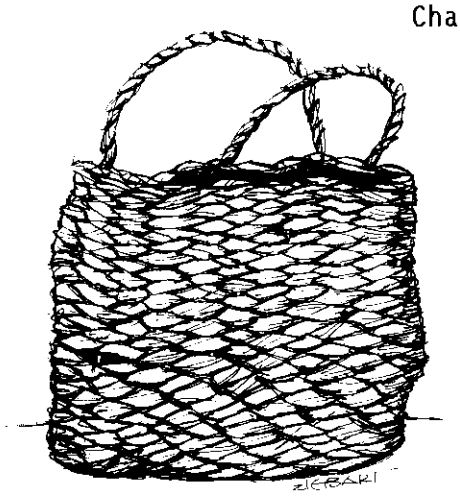
Old growth provides unique habitats for certain plant and wildlife species including the northern spotted owl. Habitat management for this indicator species has become increasingly controversial and is addressed in the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide (1988).

There are approximately 643,500 acres of old growth within the Forest; 232,500 acres (36%) are located in wilderness and are not available for harvest.

A related public issue and management concern is the maintenance and/or enhancement of plant, wildlife and fish diversity within the objectives of multiple use management. There is increasing recognition within the scientific community that ecosystem diversity is important; this issue also received considerable public comment. Many respondents to the DEIS felt national forest management should focus on wildlife.

The Forest provides habitat for a variety of wildlife species, including four Federally listed threatened and endangered species. The variety of elevation, aspect, soil depth, climate, and vegetation create a naturally diverse mosaic of habitats within the Forest boundary. An important facet of this issue is the distribution and protection of suitable habitat to ensure species viability through genetic exchange. State Department of Wildlife officials, hunters, and recreationists are concerned about the population and habitat needs of big game animals, such as deer, elk, and mountain goats.

There are approximately 1,500 stream miles and over 12,000 lake acres on the Forest that serve as both seasonal and year-round spawning and rearing habitat for anadromous and resident species. Indian tribes, sport and commercial fishing interests, and state and federal fishery agencies are increasingly concerned about the effects of water quality on the anadromous fish resource. The cumulative effects of management activities on fish/fish habitat was raised as a major concern by individuals, Indian Tribes, and State agencies.



American Indian Religious and Cultural Use

What policy and management direction is needed to comply with the Native American Religious Freedom Act and various treaties?

How can Inventoried religious and cultural use areas be protected within the objectives of multiple use management?

The 15 American Indian tribes who currently use the Mt. Baker-Snoqualmie for religious and cultural uses continue to challenge Forest management activities, primarily proposed road construction, timber harvest, and small hydroelectric power projects, that potentially threaten their religious use sites and areas. In 1981, an inventory of religious use, practices, and localities on the Mt. Baker-Snoqualmie National Forest was completed. Over 300 cultural use areas and sites were identified, totaling nearly 450,000 acres or 26 percent of the net Forest acres. About 34 percent of these areas are in designated wilderness. Some sites cover less than one acre; other larger areas average between 3,000 and 15,000 acres. Use-areas and sites are located throughout the Forest but are concentrated in the northern half.

The inventoried use areas can be placed in five broad categories: cedar sites, ceremonial flora, spirit sites, legendary sites, and cemeteries and archaeological sites. There is a wide variation in compatibility between types of management activities and categories of religious, ceremonial, and cultural use.

Since the completion of the 1981 inventory, the Forest has initiated a consultation process with the Tribes. When proposed projects fall within an inventoried use-areas, the proposed activity is reviewed in detail with representatives of the Tribe(s) which may be affected. As more management activities are proposed, there is the potential for increased conflict.

Individuals and Tribal representatives feel that the draft Forest Plan standards and guidelines and the inventory process were not adequate to protect Religious Freedom Act rights. Others, including some timber industry representatives, feel protection of religious and cultural use areas will constrain timber availability.

Puget Sound Indian Tribes also have a significant interest and concern for protection and enhancement of the anadromous fisheries resource. For many, this has been their traditional and principle means of income. They are strongly opposed to any management activities that might adversely affect anadromous fish habitat.

Recreation Opportunities

To what extent can the Mt. Baker-Snoqualmie National Forest provide recreation opportunities and how should they be managed?

How many miles of trails should be provided and in what locations?

Public comment on the DEIS reconfirmed that recreation use - of all types - is a major public issue on the Mt. Baker-Snoqualmie. One of the few areas of consensus, respondents agreed that recreation is a vitally important function of the Forest. Opinion is divided on what types of recreation opportunities should be provided.

Many groups and individuals - including hikers, horse users, some off-road vehicle users, naturalists, wildlife advocates, and environmentalists - want to preserve opportunities for unroaded dispersed recreation outside of wilderness. They prefer more remote, natural appearing recreation settings. National Forest lands are the major supplier of non-motorized dispersed recreation in the Puget Sound area. Many other recreationists spoke to the need for better recreation access for young families and the elderly, more ORV areas, more snowmobile opportunities, and more campgrounds.

A large majority of people commenting on the DEIS favor more trails. There was support from environmentalists and many recreation/commodity groups for the "Trails 2000" proposal, developed by one environmental organization. The proposal includes both new trail construction and reconstruction of existing trails. ORV and horse users want more trails open for their use. Many hikers feel that trails should be closed to motorized use.

Conflicts between recreation and other Forest resources are frequently mentioned. For example, the visual effects of clearcutting are generally not compatible with the values of many recreation users. Some users dislike the expanding road system needed for timber harvest, while others feel roads are important for their activities and access.

Many recreation attractions and opportunities on the Mt. Baker-Snoqualmie are found within eight wildernesses, which totals nearly 42% of the net Forest acres. A concern is the level of management required to accommodate the high recreation demand within these areas, while protecting the wilderness resource. Some recreation and environmental groups, who strongly supported wilderness status for favorite areas, now find themselves debating the need for management actions within the wilderness, including limiting use. Facets of this issue include: the need for new or relocated trails to disperse recreation use in heavily-used areas; and whether roads that access popular wilderness attractions should be kept open to the public.

The Mt. Baker-Snoqualmie contains some of the most scenic areas in the State. Its proximity to the major metropolitan areas along Puget Sound and the variety of opportunities available is reflected in the continual growth of recreation use. Use is now approximately 5 million RVD's (1989). It is expected that the demand for recreation on the Forest will grow through the end of the century. Some recreation uses are incompatible with each other; others cause resource damage because of the level or type of use. There is little public consensus regarding the quantity and type of recreation experiences the Forest should provide.

Wild and Scenic Rivers

How should the potential wild and scenic rivers of the Forest be managed and their values protected?

Wild and Scenic Rivers has been identified as a separate major issue, due to public response on the DEIS.

There is one designated Wild and Scenic River on the Forest (the Skagit, designated in 1978). The Wild and Scenic Rivers Act established criteria for the addition of other rivers to the National System. The National Park Service (formally Heritage Conservation and Recreation Service) conducted an inventory of potential rivers; portions of the sixteen rivers on that inventory are within the Forest boundary.

Portions of the Skykomish River system have been designated by the State of Washington as a Scenic River under the provisions of the State Scenic River System Act (RCW 79.72). This designation applies only to city, county, and State lands. This river features substantial runs of anadromous fish, bald eagle feeding and perching areas, and communal roost sites. Portions of the river, especially outside the Forest boundary, support a variety of boating opportunities including white-water rafting.

In 1988, the State of Washington released the Washington State Scenic River Assessment. This report documents the evaluation of several outstanding rivers in the state, and identifies 18 rivers which possess the natural, cultural, and recreational values that would make them suitable additions to the Washington State Scenic River System. The Carbon, Nooksack, and Stillaguamish Rivers are the rivers on the Mt. Baker-Snoqualmie that are included on this list.

There was considerable public comment on the DEIS eligibility study, plus support for many more miles of wild and scenic rivers than recommended for study in the DEIS. There was also vocal opposition to more designation.

Between draft and final plans, eligibility criteria were re-evaluated and the list of eligible rivers adjusted. A total of 51 rivers were identified and studied for their eligibility and 47 of these were determined to be eligible. There was considerable public and agency involvement in this process. A suitability study for the 47 eligible rivers was also completed, again in response to public comment on the draft.

Wild and scenic river legislation has been considered but no action taken. Public concern on all sides is high. The portions of seven major river systems that lie within the Mt. Baker-Snoqualmie contain sections with unparalleled anadromous fisheries values. There are also high recreational and scenic values. Resource compatibility with wild and scenic river designation includes riparian area, and fish and wildlife habitat protection, increased recreation opportunities (especially river-oriented), and visual quality.

Management of Municipal Watersheds

What activities should be permitted within municipal watersheds?

What measures should be taken that will maintain or enhance water quality?

The title of this major ICO has been changed, to better reflect an emerging key issue: the management of municipal watersheds. Maintenance of high water quality is still a facet of the issue, but it is also addressed on the Effects of Timber Management and Related Activities ICO. Changes in City of Seattle policies for the management of the Cedar River watershed may necessitate renegotiation of the existing, 1962 Cooperative Agreement. Under the 1989 Secondary Use Policies for the Cedar River, the City will set aside 50 percent of its lands in a reserve precluding timber harvest. The policies also call for acquiring 4-6,000 acres of old growth (currently national forest lands) to be maintained as old-growth habitat.

Maintaining high quality water remains as an objective of many individulas, sports and recreation organizations, municipalities, Indian Tribes, and State and federal agencies. These interests believe that timber harvest, road construction, mining, and some recreation activities are detrimental to water quality, primarily due to sedimentation and pollution. Most of the above interests support actions to limit, restrict, or prohibit developmental activities in the watersheds. Many also support maintenance of old growth habitat in the Cedar River watershed. Municipalities are concerned that increased access and recreation use will result in the need to install filtration facilities to assure potable water to the consumer.

Timber, energy, mining industries, plus a number of hunters feel that development can occur and any adverse impacts to water supply and quality can be mitigated. They believe that limiting or prohibiting activities unduly restricts the industry's ability to maintain or increase supplies of timber, electric power, and minerals. Hunters feel that big game populations could actually be enhanced with controlled hunts in the watersheds.

A significant portion of the watersheds supplying the cities of Seattle, Bellingham, Everett, and Tacoma is located on the Mt. Baker-Snoqualmie. Water is also provided for a number of smaller municipalities, ski areas, and other recreation sites. About 128,000 acres of national forest land supply municipal water to 1.4 million people. Water quality is high; only one municipality filters water, others use a disinfectant.

Currently, a wide range of activities occur within the municipal watersheds. Some watersheds have not been accessed by roads and remain primarily in a natural condition. Other watersheds have been developed, with extensive timber harvesting and road construction. Recreation is permitted or encouraged in some watersheds; in others, poor access and municipal opposition has limited recreation opportunities.

Effects of Timber Management and Related Activities

What management direction is needed for timber harvest and road construction activities to benefit or maintain the quality of other resources?

The effects of timber harvest and road construction, especially the cumulative effects of these activities, are of great concern to federal agencies, environmentalists, Indian Tribes, State Fish and Wildlife agencies and individuals. The effects of management activities on water quality, fish and fish habitat of of greatest concern, and this interest has increased since the DEIS was released. Other resources affected by timber harvest and road construction are wildlife, scenery, and dispersed unroaded recreation.

The timber industry, miners, and many individuals feel that the effects of these activities can be mitigated, and that not enough national forest land is open to full commodity production (and recreation use).

Management for the commercial production of timber includes a number of activities: road construction and/or reconstruction, preparation of the land for planting seedlings, possible thinning, et cetera. These activities have direct and indirect effects on other resources, including: fish and wildlife habitat, soil, water, and American Indian religious and cultural use. Recreation opportunities are changed, and the visual condition of the Forest changes. The visual impact of clear-cutting and loss of habitat for some wildlife species is a major concern. Changes in vegetation and the effects on diversity and sensitive plants have also been identified as concerns by some people commenting on the DEIS.

Adjacent and Intermingled Lands

How should National Forest lands adjacent to lands of non-federal owners be managed?

What management activities should be conducted on National Forest lands that are located near private developments?

The land ownership pattern within and adjacent to the National Forest boundary and the management of intermingled Federal and Private lands remains a major issue and concern.

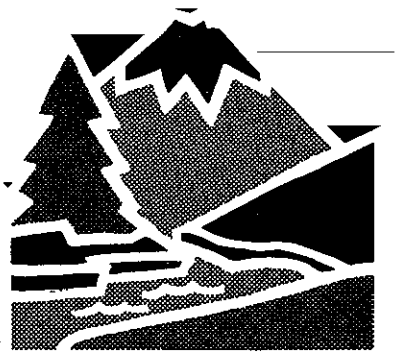
A few environmental groups are actively proposing legislative land exchanges that would exchange high-elevation, low timber site class private lands for low elevation, high-site federal lands. Some major industrial timber land owners support these types of exchanges. Independent mill operators and loggers who depend on National Forest timber and some public interest groups strongly oppose such exchanges, as the exchanges would further reduce timber supplies available to them. Some people commenting on the DEIS urged the Forest Service to retain all mineral rights in any exchange.

Environmentalists, State Fish and Wildlife agencies, Indian Tribes and some sporting groups believe that management activities, such as timber harvest, should be delayed or deferred on National Forest lands to mitigate the cumulative effects of large-scale timber harvest on private lands that are intermingled with Federal lands. Independent mill operators and loggers are opposed to any delays or deferrals that would reduce timber supplies available to them.

In many areas of checkerboard ownership, adjacent land owners have completely removed the old-growth timber (in approximately 640 acre blocks), leaving the timber present on National Forest land more vulnerable to wind-throw. Removing these blocks of old growth has also had the effect of reducing the amount of habitat available for wildlife species dependent on old-growth habitat. In areas of intermingled lands, the objectives and subsequent land practices of all owners affect the management of adjacent lands. Management of National Forest land affects adjacent lands of non-Federal landowners, and activities on non-Federal lands affect management of National Forest land.

Urban growth is steadily moving east toward the Forest boundary. Forest lands, regardless of ownership, are affected by this growth. Resources such as wildlife, water, and air do not recognize ownership boundaries, but they are directly impacted as shopping centers, subdivisions, and residences - plus an increased network of roads - spread closer to the Forest boundary. A question to be addressed: should National Forest land management practices be altered to compensate for these encroachments? Timber industry, adjacent land owners, County planners, and environmentalists are all involved in this concern.

Chapter 1



Changes Between Draft and Final - Chapter II

- o New yield tables were developed and technical corrections were made to the FORPLAN model in response to public input. Refer to Part B. Analysis Prior ot Formulation of Alternatives, this chapter, FEIS; also see Appendix B for more detailed discussion.

- o Alternatives D, E, E-Departure, F, and H-Departure received very little support in public comments on the DEIS. They are not needed to provide a full range of alternatives for analysis and were not carried forward to this FEIS. Alternative H, disclosed as the Forest Service Preferred Alternative in the DEIS, is not the preferred in this FEIS. Alternative G was modified to respond to public comment and to better meet its' objectives as stated in the draft; it is displayed in this FEIS as Alternative G-Modified.

- o Two new alternatives are disclosed in the FEIS. Alternative I was added in response to strong public support in comments on the DEIS. Alternative J is the new Forest Service Preferred Alternative. It was developed to respond to comments received on the draft preferred alternative and to public issues and concerns.

Table II-1 Alternatives Displayed in the Draft EIS and Final EIS

	NC	A	B	C	D	E	E-Dep	F	G	G-Mod	H	H-Dep	I	J
DEIS	x	x	x	x	x	x	x	x	x		x	x		
FEIS	x	x	x	x						x	x		x	x

- o The management requirements (MR's) were revisited with changes and additions made. Spotted Owl Habitat Areas changed to meet the Record of Decision for the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide. Management requirements for mountain goats were enlarged, and deer and elk MR's were dropped to meet regional direction, as discussed in DEIS Appendix I. Changes are documented in new Appendix H, FEIS.

  In response to public comment, a hydrologic cumulative effects analysis was completed to develop a procedure for meeting water quality and riparian management requirements. The procedure to meet these MR's was developed with public and scientific review; refer to new Appendix H for detailed documentation of the process, with additional information in Appendix B.

- o The 1978 version of IMPLAN was used to predict changes in jobs and income in the DEIS. For the FEIS, the updated 1982 version of IMPLAN was used.

- o Mitigation measures, discussed in Chapter IV in the DEIS, have been moved to this chapter in the FEIS, and incorporated into the alternatives. New Appendix I, FEIS, describes in greater detail the Best Management Practices (BMP's) to protect soil and water. They are selected on the basis of site-specific conditions.

CHAPTER II - ALTERNATIVES, INCLUDING THE PROPOSED ACTION

A. INTRODUCTION

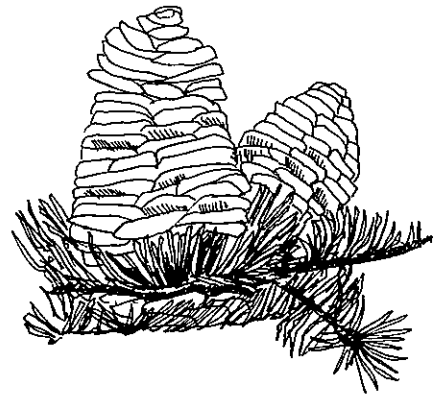
Chapter II is the heart of the FEIS. Alternative ways of managing the Mt. Baker-Snoqualmie National Forest and responding to the public issues are presented; alternative resource outputs, environmental effects, and economic costs and benefits displayed. This chapter also discusses how these alternatives were developed and how they compare to each other, including current Forest management. Chapter II of the FEIS summarizes information found in more detail in other chapters and in Appendix B. Chapter III describes the affected environment, and Chapter IV presents the environmental consequences that would result from implementation of any of the alternatives. There are seven parts of Chapter II:

A. Introduction
B. Analysis Prior to Formulation of Alternatives
C. Formulation of Alternatives
D. Alternatives Considered But Eliminated From Detailed Study
E. Alternatives Considered in Detail
F. Comparison of Alternatives:
G. Major Tradeoffs Among Alternatives

The alternatives displayed in this FEIS are designed to explore a variety of ways to respond to the public issues, management concerns, and resource use and development opportunities identified throughout the planning process. From this broad range of alternatives, the decision maker - the Regional Forester - has a basis for identifying the alternative (the preferred alternative) that best maximizes net public benefits while responding effectively to the issues and concerns.

Maximizing **net public benefits** is a goal of the forest planning process and a consideration in the development of alternatives. **Present net value** (PNV) is a component of net public benefit. PNV equals the discounted value (benefits) of all outputs to which a monetary value or established market price is assigned, minus the discounted costs of managing the area. Net public benefits are the overall, long-term value to the nation of all outputs and positive effects (benefits), less all associated inputs and negative effects (costs), whether or not they can be quantitatively measured. Net public benefits are estimated quantitatively by PNV and include some non-quantified components not reflected in PNV, such as threatened and endangered species protection benefits or the value of Forest visual quality.

A major objective of the forest planning process is to provide information that helps determine which alternative best responds to the issues and concerns while maximizing the net public benefits.



Process for Formulating Alternatives

The National Forest Management Act (NFMA) planning regulations [36 CFR 219.12(e) and (f)] prescribe a general process for formulating alternatives. Major points from these sections specify that alternatives must:

- be distributed to provide a broad range of outputs between the minimum resource potential and the maximum resource potential;
- be formulated to facilitate analysis of opportunity costs, resource use, and environmental trade-offs;
- be formulated to facilitate evaluation of the effects on PNV, benefits, and costs of achieving various outputs and benefits that are not assigned monetary values, but are provided at specified levels;
- provide different ways to address and respond to the major ICO's;
- be formulated to consider changes in existing laws or policy if necessary to address major ICO's;
- respond to and incorporate the RPA Program (in at least one alternative);
- reflect (in one alternative) the most likely amount of goods and services expected to be provided in the future if current management direction continues;
- represent the most cost-efficient combination of management prescriptions that can meet the objectives of each of the alternatives;
- state the conditions and uses that will result from long-term application of the alternative; the goals and services to be produced; the timing and flow of these resource outputs together with associated costs and benefits; resource management standards and guidelines; and the purpose of the management direction proposed.

In addition to the direction in the planning regulations, the Pacific Northwest Region of the Forest Service has provided guidance for the formulation of alternatives. This guidance requires inclusion of alternatives that:

- emphasize production of commodity outputs;
- emphasize production of amenity outputs;
- examine economic efficiency;
- evaluate roadless areas.

A broad range of alternatives has been developed using all of the above guidelines.

B. ANALYSIS PRIOR TO FORMULATION OF ALTERNATIVES

Forest Planning is a very complex process. A great deal of data must be considered in order to identify and analyze the many inputs, outputs, costs, benefits, and environmental effects of different ways of managing the Forest. Each acre of the Forest has biological limitations, as well as differing

opportunities to produce goods and services. The production of multiple goods and services on one part of the forest may have different costs and/or environmental effects associated with it than the production of those same goods and services on another portion of the forest.

In order to consider the almost infinite number of combinations of capabilities, opportunities, costs, and effects of producing desired outputs, a large, computerized linear programming model of the Forest called FORPLAN was used. The details of the FORPLAN model - and the entire analysis process - are discussed in Appendix B. It is summarized below.

Outline of the Analysis Process for Developing Alternatives

The alternatives are formed following the planning steps and direction identified in NFMA; the process includes a number of the 10 planning steps identified in Chapter I, page I-3.

- Identify public issues and concerns, and opportunities and consolidate into a series of planning problems. Refer to Chapter I and Appendix A. (Planning Step 1, in Chapter I.)

- Collect data from resource inventories and create a data base; the issues and concerns and the planning problems help determine what data should be collected (Planning Step 3).

- Develop analysis areas by grouping elements of the resource data - for selected resources - producing tracts of land assumed to be homogeneous in their capability to produce outputs and effects in response to alternative management options.

- Develop management direction, in the form of Forest-wide Standards and Guidelines and management strategies, that responds to the ICO's.

- Develop a range of potential alternatives by assigning unique combinations of management strategies, which group analysis areas, across the Forest. Each potential alternative will achieve a specific objective or set of objectives in responding to the issues.

- Analyze initial combinations of management strategies and prescriptions in the Forest computer model, "FORPLAN." The results of this analysis - called benchmarks - defined the maximum range of response to the issues for a given resource, consistent, in most cases, with meeting the management requirements (MR's). Arraying these resource production possibilities helped define different potential alternatives, and the range of alternatives to respond to the Forest issues. Opportunity costs of the MR's were also calculated. The results of this planning step were documented in the May 1985 Analysis of the Management Situation (Planning Step 4).

- Build alternative themes to respond to the issues and address concerns. Using these "themes," construct possible alternatives by applying management strategies to specific on-the-ground areas of the Forest. Once a management strategy is applied, the specific area becomes a management area (MA). Management area assignments are fixed for each alternative, but

vary among the alternatives. MA assignments determine which prescriptions are available for each analysis area. This tie to the land allowed outputs, costs, and effects of different management activities to be estimated for different land characteristics (Planning Step 5).

- Analyze the potential alternatives in FORPLAN for outputs, costs and effects (Planning Step 6).

Using this process, a broad range of alternative ways for managing the Forest, responsive to the public management's input on issues, concerns, and opportunities, was developed. Alternative NC (No Change) was not developed utilizing this process; it is based on the 1963 Timber Management Plans (USDA 1963).

Information Collection and Data Base Development

Information was collected prior to, during, and following the identification of issues, concerns, and opportunities. The interdisciplinary planning team assembled data on: resource capabilities, conditions, trends, existing supplies and demand, and expected outputs, benefits, and costs. Existing data were used and, in some cases, supplemented with new information to help address and resolve the issues. These numerous inventories helped to define the character, resource potentials, and limitations of the Forest. Between the DEIS and FEIS, the acres by condition class (poles, small sawtimber, etc.) were updated to reflect the harvesting that occurred between 1985 and 1988.

Table II-2, on the following page, summarizes the supply and demand information along with outputs under the existing situation (Alternative A, No Action), and Alternative J (Preferred). Refer to page II-13 for a discussion of benchmarks.

The planning team constructed a Forest-wide data base, aggregating most of the resource data. The data base, R2MAP, has the ability to track 46 attributes, such as acres of old growth. Information from the data base was used in FORPLAN to generate yield data for many resources.

Analysis Areas

Resource information on soils, slope, vegetation etc. was combined into a single map overlay, and like characteristics were aggregated into groups called analysis areas. Analysis areas are tracts of the Forest assumed to be homogeneous in terms of potential outputs and effects and responsiveness to forest management options.

Analysis areas serve as the basic units of land or building blocks in the planning model. They were based on the following delineation criteria:

- timber site class
- availability and suitability for timber production
- vegetative cover
- topographic class and soil stability
- timber size class and species composition
- road accessibility

Table II-2
Summary of Projected Supply and Anticipated Demand

	Decade 1 1986-1990	Decade 2 1991-2000	Decade 5 2021-2030
Recreation			
Developed Recreation Use (MRVD/Year)			
Projected Supply (Capacity)			
Alternative A (No Action)	5,382	5,792	6,842
Alternative J (Preferred)	5,598	6,098	7,238
Anticipated Demand 1/	2,834-3,464	3,848-4,702	6,718-8,210
Dispersed Recreation Use (Non-wilderness) Including Wildlife and Fish Use (MRVD/Year)			
Projected Supply (Capacity)			
Alternative A (No Action)	4,092	4,482	5,142
Maximum Recreation Benchmark 2/	7,458	7,468	7,481
Alternative J (Preferred)	4,030	4,487	4,751
Anticipated Demand	2,539-3,121	3,774-4,708	6,589-8,072
Roaded Recreation Use (MRVD/Year)			
Projected Supply (Capacity)			
Alternative A (No Action)	3,343	4,097	4,902
Maximum Recreation Benchmark	7,219	7,231	7,248
Alternative J (Preferred)	3,277	3,730	3,991
Anticipated Demand	1,854-2,266	2,837-3,467	4,817-5,887
Unroaded Recreation Use (MRVD/Year)			
Projected Supply (Capacity)			
Alternative A (No Action)	201	164	115
Maximum Recreation Benchmark	239	237	233
Alternative J (Preferred)	208	182	149
Anticipated Demand	225-293	382-492	713-890
Timber			
Allowable Timber Sale Quantity (MMCF/Year)			
Projected Supply			
Alternative A (No Action)	31.0	36 7	39.0
Maximum Timber Benchmark	68 4	68.4	68.4
Alternative J (Preferred)	22.4	25.7	29.7
Anticipated Demand 3/	≥ 22.4	≥ 25.7	≥ 29.7

1/ Anticipated recreation demand is based on historical use figures projected into the future and Puget Sound population projections.

2/ FORPLAN alternative runs (1989) have undergone changes in recreation modeling since the Benchmarks were run (3/85) to better reflect the spatial characteristics of the recreation opportunity spectrum (ROS) from a per acre to a per area basis.

3/ Projections indicate that demand for timber from the MBS will remain sufficiently high to allow the Forest to sell all the timber it can produce from lands allowing harvest, with no downward effect on prices

The criteria used to identify analysis areas were intended to capture the variations in outputs when different management prescriptions are applied. A total of 134 analysis areas were used, ranging in size from 212 acres to 494,871 acres. The analysis areas are fixed for all alternatives; the total acres of all 134 analysis areas equal the total Forest acres. Refer to Appendix B for a more detailed discussion.

Allocation Zones

The Forest land base was stratified into allocation zones, based on the boundaries of watersheds, roadless areas, wilderness, the Alpine Lakes Management Area, and the Skagit Wild and Scenic River. Allocation zones included all analysis areas contiguous to one another, within a specific geographic area, such as a watershed. Portions of an analysis area can be found across numerous allocation zones.

The allocation zones were used to control accessibility (for harvest dispersion requirements), to track the potential transportation system needs and costs, to analyze hydrologic cumulative effects (see Appendix H for more information), and to account for changes in the Recreation Opportunity Spectrum (ROS). Forest wide, a total of 86 allocation zones were identified and fixed for all alternatives. They range in size from 2,321 acres (a small watershed) to 282,161 acres (Glacier Peak Wilderness).

Management Strategies

Once the issues, concerns, and opportunities (ICO's) were identified, the interdisciplinary team generated 26 management strategies that responded to the range of public issues and demands on Forest resources. Some management strategies have several intensities of use or management. For example, the Dispersed Recreation management strategy includes six different management and use intensities, such as Primitive, Semi-Primitive Nonmotorized, etc.. These strategies/intensities were specifically developed to help address and resolve the ICO's, build and model alternatives, and identify implementation direction.

Management strategies/intensities define the overall direction and several means of achieving Forest goals, standards, and objectives. Strategies generally emphasize one or two resources, and contain guidelines and constraints for other resources. Each strategy also contains standards and guidelines for prescriptions to direct "on-the-ground" management. Standards and guidelines were written and/or incorporated from law, regulations, the Regional Guide, or other direction. For each strategy modeled in FORPLAN, one or more prescriptions (see below) were developed and available as choices in the model.

Each management strategy/intensity can be applied to a specific group of analysis areas whose resource characteristics and conditions are compatible with and capable of responding effectively to the strategy. For example, a big game winter range strategy could be applied to any analysis area or group of analysis areas located within existing winter range; this strategy would not be compatible with analysis areas located on summer range. Most analysis areas were able to respond to more than one strategy; thus, the sum of the areas suitable for each management strategy is greater than the total Forest acres due to overlapping capabilities.

The rationale for selection of harvest cutting methods for use in timber management strategies is documented in Appendix F. The rationale used in making this decision includes consideration of: blowdown; root rot; bole rot; dwarf mistletoe; genetics; stand composition; stand density; economics; big game habitat; and visual resource management.

Management Areas

When a management strategy/intensity is applied to a specific, on-the-ground area of the Forest, the specific area becomes a management area (MA). A management area is a group of analysis areas which have been allocated to the same management strategy/intensity. Management areas are the building blocks of the alternatives. The exception is Alternative NC (No Change), which is based on the 1963 Timber Management Plans; no management areas are assigned.

Management areas represent the site-specific response of management strategies/intensities to the issues. The number of acres in the management areas varies by alternative, as the alternatives are different ways of responding to the ICO's. Note that the sum of MA acres for each alternative equals the total Forest acres. Descriptions of the management areas are included later in this chapter; Tables II-8 and II-8a show MA acres by alternative.

Several factors influenced the choice of management strategies (and their acres) for assignment as management areas in an alternative. These factors were:

- Compatibility of the management strategy/intensity with the capability of an area. Some strategies, such as wilderness, are site specific and can only be applied to the given site.
- Response to the issues addressed by an alternative. The management strategy/intensity and number of acres of that strategy/intensity assigned to an alternative was a direct function of the goals and objectives of the alternative.
- Potential impacts on resource productivity. For example, maintenance of highly productive timber land for timber outputs was a factor in the management area assignment in many alternatives.
- Manageable on-the-ground boundaries.
- Planning requirements for a broad range of alternatives.

Management Prescriptions

A prescription is a set of management practices and intensities, and their application or sequence over time on a particular acre for a particular management strategy.

Management strategies determine the available prescriptions for a given analysis area. Each strategy can contain one or more prescriptions. Prescriptions are represented as decision choices in the Forest planning model.

(Table II-3, below, shows a summary of timber production prescription choices.) Selection of a particular prescription is based on: the objectives of the particular alternative; the production potential and benefits of the analysis areas within each management area in which prescriptions are available; and the cost of implementing the prescription within an analysis area.

The process of developing prescriptions used in the model included the development of timber yield tables, other resource yield coefficients, and the economic costs and benefits associated with each prescription. Timber yield tables were developed for managed stands (a timber stand where harvesting has occurred) and natural stands to meet timber, riparian, wildlife, and visual objectives. Other yield tables were developed for sediment, anadromous fish, wildlife, and big game; capacity levels were developed for recreation. A mathematical estimate of the economic costs and resource yields associated with each prescription was generated to identify the most efficient prescriptions and to schedule outputs. This is known as a Stage II suitability analysis; refer to Chapter III, section E in Appendix B, FEIS for more details.

FORPLAN

The primary analytical tool used in Forest planning to analyze alternatives is called FORPLAN (an acronym for FORest PLANning Model). FORPLAN is a large and complex computerized linear programming model. The FORPLAN model was specifically designed to help the interdisciplinary planning team analyze the economic and production tradeoffs associated with the recreation, timber, visual, and wildlife resources. The FORPLAN results for all alternatives provide output and economic information for comparing alternatives. That information was used to compare the alternatives (for efficiency and response to the ICO's) and to help identify an alternative that best maximizes net public benefits, while responding effectively to all the issues.

The FORPLAN model uses a series of mathematical equations to determine the optimal solution to a problem specified by an objective function (example, maximize present net value) and bounded by resource management opportunities and output objectives, priorities, or constraints. (These terms are defined later in this chapter and discussed in detail in Appendix B.) These boundaries and output levels incorporate goals, objectives, and physical targets; the goals, etc. are represented by technical constraints in the model. Within the limits of the FORPLAN computer software, the user is allowed a great deal of latitude in formulating the mathematical representation of the forest planning problem to be analyzed.

FORPLAN is used to optimize the design of each alternative (except Alternative NC) and quantify most of the results, inputs and, effects of each alternative. Each alternative has a different mix of goals and objectives, to respond to the issues, concerns, and opportunities.

The model formulation used in applying FORPLAN in the alternative development and analysis process included: analysis areas, allocation zones, prescriptions, time periods, resource constraints, estimates of resource outputs that result from applying prescriptions to analysis areas, and estimated benefits for the outputs produced.

Based on this information and the objectives of an alternative, FORPLAN determined which prescriptions to apply within each analysis area (and allocation zones), and when to schedule them for application. However, the management area assignments, which are fixed for each alternative, determine which prescriptions are available for each analysis area. For each alternative, the mix of management area assignments are different. See the discussion below.

In the Mt. Baker-Snoqualmie FORPLAN model, the outputs modeled were chosen because of their relationship to the issues, concern, and opportunities. Other outputs and effects were estimated outside of the FORPLAN model, or by interpreting the results of the FORPLAN solution. Because of model and computer limitations, and lack of knowledge about resource interrelationships, it was not practical to include all resource interactions in the FORPLAN model. Many of the elements of the alternatives were handled outside of FORPLAN, or used to develop constraints to apply to a particular alternative formulation. See Appendix B for more discussion on the FORPLAN model.

Use of FORPLAN in Alternative Analysis

A major step in formulating an alternative in FORPLAN is the assignment of management strategies to lands across the Forest. The decision is critical because each resultant management area determines the range of prescriptions or management choices available for that area.

The management areas are not assigned by FORPLAN, but are built into each alternative FORPLAN formulation to achieve the particular objectives of the alternative. When an analysis area, or part of an analysis area, is assigned to a management area that involves scheduled timber harvest, the FORPLAN model is given the choice of assigning that land to a no harvest prescription, or to one of the timber harvest prescriptions shown in Table II-3, on the next page. All of the timber harvest prescriptions shown across the top of Table II-3 were available for selection by FORPLAN on tentatively suitable lands in a management area where timber harvest was appropriate.

To assure that the alternatives developed could actually be implemented on the ground, the Forest Management Team reviewed the management areas assigned to respond to the ICO's addressed in each alternative. The Forest Management Team has on-the-ground knowledge of some physical, spatial and biological attributes of the Forest that are more detailed and site specific than the eight factors used to define the analysis areas.

In some portions of the Forest, there are small blocks or stringers of tentatively suitable timber that are not accessible by existing or potential road systems. These blocks can be characterized as less than 80 acres in size; low site productivity; low-valued species; would require helicopter logging; and are surrounded by lands not suitable for timber production. These blocks had been considered by the Forest Management Team for timber harvest during previous sale area planning activities, but eliminated through site-specific economic analysis, and consideration for other resource values. In all alternatives except those that emphasize timber production, the decision was made to include these blocks in the surrounding management area assignment which was not appropriate for timber production. In the alternatives that emphasized timber production, all such parcels were available for assignment to a prescription that included timber harvest.

1/ NR = Natural Regeneration PL = Planting using genetically improved stock PCT = Precommercial Thinning
CT = Commercial Thin FH = Final Harvest

2/ Extended rotation, option for three commercial thinnings

3/ Does not use genetically improved stock Hardwood site

4/ Management Area applicable only to Alternative A (No Action)

5/ No Scheduled Harvest in wild segments

6/ Consultation with affected tribes will determine appropriate prescription

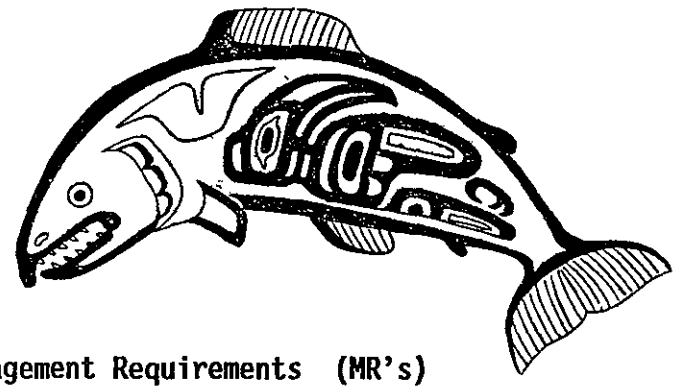
7/ Some limited harvest for experimental purposes is programmed

8/ All prescriptions are available in scenic forest and general forest management areas No timber harvest is appropriate in the special, dispersed recreation and developed recreation management areas

Some additional fixed prescriptions were used to meet non-timber resource objectives, including: the amount and schedule of developed recreation construction and reconstruction; the miles and schedule of trail construction and reconstruction; and the percent of the potential population of cavity nesters to be maintained in tentatively suitable lands.

The FORPLAN model was free to optimize the choice of timber prescriptions, subject to the resource management constraints and the objective of maximizing PNV. The resource management constraints were designed into the model to guarantee the spatial and temporal feasibility of management area assignments and harvest scheduling choices. While the management area assignments and other various resource design elements are fixed for each alternative, they vary across the range of alternatives. Once the model arrived at a feasible solution - by satisfying all of the constraints - the model searched for the set of prescriptions and timing choices which permitted an optimal solution according to the specified objective of maximum PNV.

Each FORPLAN solution was reviewed by the interdisciplinary team to determine operational feasibility. Several FORPLAN solutions were altered and reanalyzed before the team concurred on a final, feasible design for each alternative.



Development of Management Requirements (MR's)

While the analysis process was in the early stages, National direction was developed to assure compliance with the requirements of applicable laws and regulations. Subsequently, the Pacific Northwest Region developed specific direction for Region 6 to ensure that the requirements were applied consistently across the Region (USDA 1983).

The Regional Direction provided guidelines for MR's pertaining to the management of the following resources: timber; fish and wildlife; soil and water resources, and land productivity; water quality; riparian areas; and range. The MR's were not meant to establish a final or appropriate level of management. Instead, the MR's set the "floor" for alternative levels of management. They indicate the level below which management will not normally be considered.

The Regional direction recognized that some of the requirements were procedural in nature, could not be incorporated in the analysis, or were not likely to have an impact on analysis. These requirements have been incorporated into the Forest-wide Standards and Guidelines or into those standards and guidelines unique to a specific management area prescription.

Other requirements in the Regional direction that impose substantive standards and specific management direction were developed and incorporated in the Forest model. These include requirements for:

- maintenance of habitat for viable populations of fish and wildlife (anadromous fish, Northern spotted owl, pileated woodpecker, marten, mountain goat, black-tailed deer, Roosevelt elk, primary cavity excavators, bald eagle, peregrine falcon, and grizzly bear)
- dispersion of timber harvest units
- riparian area management
- compliance with the Clean Water Act, including consideration of hydrologic cumulative effects of management activities (see documentation in new Appendix H). The method used to meet MR's was developed in response to public review and comment.

The Regional Management Requirement direction has been reevaluated several times. The last evaluation resulted in two documents issued in July, 1986: "A Report on Minimum Management Requirements For Forest Planning on the National Forests of The Pacific Northwest Region" (USDA 1986), and "A Background Document on the Development and Review of Minimum Management Requirements For Forest Planning on the National Forests of the Pacific Northwest Region." The appendices of the latter document incorporate previous letters and documents containing pertinent direction.

Appendix B, Chapter IV discusses this direction in detail, including the constraints used in FORPLAN to model the MR's. Once the MR's were developed, they played a key role in the benchmark analysis (see below) and in formulating alternatives. The opportunity costs of MR's affecting timber supply are evaluated in Table II-5, following the Benchmark section.

The wildlife, riparian, dispersion, and water quality MR's, as discussed above, are included in all the alternatives considered in detail in this FEIS (except Alternative NC - No Change). Appendix H provides more detail on these MR's. In addition, the Best Management Practices (BMP's) for water quality (one of the MR's) are discussed in Appendix I.

The MR's with potentially significant interactions with other resources are: harvest dispersion, cavity excavators, riparian areas, northern spotted owls, and water quality. The development of the individual prescriptions and constraints to satisfy these minimum resource needs is documented in Appendices B and H. The requirements are based on the guidelines in the direction documents referenced above, and in the Regional Guide for the Pacific Northwest Region (USDA 1984). Specific requirements for the Mt. Baker-Snoqualmie National Forest were developed by the interdisciplinary team and are designed to accomplish each objective with the minimum adverse impacts on the resources.

A sensitivity analysis of MR's was conducted during development of the DEIS and FEIS. The effects of increasing and decreasing the individual MR's on selected outputs and effects for several alternatives are discussed in Appendix H. Because the emphasis of each alternative is different, the effects of varying the MR's are different in each alternative. The effects of increasing or

decreasing all of the selected MR's in combination is also analyzed and displayed in Appendix H.

MR's are based on the available research, supplemented by experience and professional judgement. MR's are designed to provide those minimum levels of resource protection required, while minimizing the adverse impacts to other values. As knowledge of these resources grows and additional research findings are revealed, the Forest Service is prepared to modify management direction, including the MR's, to stay current with the state-of-the-art in forest resource management.

Benchmarks

Prior to developing alternatives, an analysis of the current management situation, required by NFMA, was completed. Part of this required process is the "benchmark" analysis. The benchmarks have several purposes:

- They help define the maximum economic and biological resource production opportunities on the Mt. Baker-Snoqualmie;
- They assist in evaluating compatibilities and conflicts between market and nonmarket objectives;
- They define the range (decision space) within which integrated alternatives will be developed - refer back to Table II-2;
- and, among other purposes, they serve to analyze the implications and opportunity costs of legal and policy constraints.

Relationship of Benchmarks and Alternatives

Benchmarks are similar to alternatives in that they are a combination of land capability, management practices, and schedules to achieve certain objectives. Benchmark runs, like alternative runs, are done primarily in FORPLAN; resource outputs or results are analyzed and reported.

Unlike alternatives, benchmarks are not designed to respond to all the ICO's. Also, all the alternatives (except NC) must meet the management requirements of 36 CFR 219.27 (such as protecting the productivity of the land, meeting minimum air and water quality standards, and maintaining viable populations of fish and wildlife species.) Some of the benchmarks were also formulated to meet these MR's others were not. By comparing benchmarks with and without MR's, the opportunity costs of the MR's can be quantified. The opportunity costs are discussed later in this chapter.

Some benchmarks are economically based; others indicate the maximum biological productivity of the land for various resources, with a given set of constraints or requirements. In all cases, the benchmarks establish the decision space for developing a range of alternatives and the initial design dimensions of selected alternatives.

Required Benchmarks

There are several Benchmarks that are required by the regulations [36 CFR 219.12(e)] and National direction. They include:

Minimum Level. This benchmark specifies the minimum level of management which would be needed to maintain the Mt. Baker-Snoqualmie National Forest as part of the National Forest System.

Maximum Present Net Value Based on Established Market Price. This benchmark specifies the management of the Forest at a level which will maximize the present net value of those outputs that have an established market price.

Maximum Present Net Value Including Assigned Values. This benchmark specifies the management which will maximize the present net value of those outputs that have either an established market price or assigned monetary value (such as dispersed recreation.)

Current Level. This benchmark specifies the management of the Mt. Baker-Snoqualmie most likely to be implemented in the future if current direction is followed. This benchmark forms the basis for the "no action" alternative.

Maximum Resource Levels. Each of these benchmarks estimates the maximum capabilities of the Forest to provide a single resource emphasis level. On the Mt. Baker-Snoqualmie, the maximum resource benchmarks included timber and Primitive and Semi-primitive Nonmotorized Recreation. Because of the lack of demand for grazing (and except for transitory range, limited suitable grazing land), a maximum range benchmark run was not made.

A maximum wilderness benchmark was not developed due to the enactment of the Washington Wilderness Act of 1984. It added nearly 350,000 acres of wilderness. However, the maximum primitive and semi-primitive nonmotorized recreation benchmark allocated all released RARE II lands that were capable of producing these kinds of recreation to a non-development management strategy.

Results of Selected Benchmarks

Table II-4 displays several outputs and effects from selected benchmarks. Shown are several runs of required benchmarks, including three different current levels, three maximum resource level benchmarks, and two runs of maximum PNV benchmarks. The results shown in the table are only a small sample of the numerous benchmark runs that were made early in the analysis process. These eight, however, represent the resource outputs and economic decision space for formulation of the alternatives.

The additional benchmarks were used to analyze some of the required and discretionary constraints, such as rotation age and non-declining flow. The sensitivity of timber price trends, timber costs, and the discount rate were also analyzed through the benchmark analysis. Appendix B, Chapter VI includes a complete display of the benchmark analysis results.

Table II-4
Benchmark Analysis Results - Annual Figures

Benchmark	PNV (MM $)	LTSY (MMCF)	ASQ (MMCF) Decade 1	Suitable Land (M Ac)
Biological Timber Potential (Run #1) 1/	2599.7	72.6	68.4	606.9
Maximum PNV, No MR's (Run #3)	2630 9	66 2	63.9	606.9
Maximum PNV, with MR's (Run #7)	2254.0	37.5	37.5	463.8
Maximum Timber Resource (Run MXT) 1/	2302 3	62.9	57.2	529 7
Maximum P and SPNM Recreation (Run Max Rec)	2050.5	27.8	26.7	300.9
Current Direction (Run CD)	2319 8	56 9	44.8	473.7
Current Direct, Implementable With Timber Targets Specified in Current TM Plan	2192 7	51 9	41.7	434.3
Current Direction, Implementable With No Specified Timber Targets	2158 5	52 3	20.9	434.3

1/ Run #1 mazimizes timber outputs without consideration of resource integrating requirements; Run *MXT maximizes timber outputs with MR's as a constraint*

Opportunity Cost Analysis

As mentioned earlier, the benchmarks were also used to analyze the implications and opportunity costs of some legal and policy constraints that the alternatives must meet. The opportunity costs of four major constraint sets were analyzed: wildlife MR's, riparian area or streamside MR's, water quality management requirements, and dispersion of timber harvest units and accessibility requirements. 1/ The "cost" is measured in the amount of change from a Maximum PNV, without MR's benchmark in several areas: allowable sale quantity, acres of land suitable for timber production, PNV, and others.

The maximum opportunity cost of each of the four constraint sets was analyzed individually, then calculated with all four constraints applied simultaneously. Table II-5 shows the opportunity costs of the MR's. The effect of the MR constraint sets is largely additive, although there is some degree of interdependence, as the effects of all three constraint sets together is less then the sum of the effects of the three individual constraint sets.

1/ The latter include NFMA requirements for maximum size of timber harvest units and delaying cutting adjacent stands until the stands in cutover units are 4-1/2 feet in height.

Table II-5
Opportunity Costs of MR's

	LTSYC	ASQ 1st Decade	Suitable Lands	Final Harvest (5 Decade Total)	Planting (5 Decade Total)	Pre-Commercial Thin (5 Decade total)	PNV
Unit of Measure	MMCF	MMCF	M Acres	M Acres	M Acres	M Acres	$MM
Run #3 1/	66.2	63 9	606 9	39.0	29.5	21 4	2631
Dispersion MR	59 6	59.1	606.9	36.6	22 8	16.8	2484
Actual Change	-6 6	-4 8	0	-2.4	-6.7	-4.6	-147
Percent Change	-10%	-8%	0	-6%	-23%	-21%	-6%
Wildlife MR	51 3	50.1	529.5	31.4	18.7	14.2	2410
Actual Change	-14 9	-13.8	-77.4	-7.6	-10.8	-7.2	-221
Percent Change	-22%	-22%	-13%	-20%	-37%	-34%	-8%
Streamside MR	62.3	59.6	583.4	36.4	26.9	19.3	2580
Actual Change	-3.9	-4.3	-23.5	-2.6	-2.6	-2.1	+11
Percent Change	-6%	-7%	-4%	-7%	-9%	-10%	+0.4%
Water Quality & Riparian MR	41.3	41.0	482.0	26.4	11 3	9 2	2297
Actual Change	-24 9	-22.9	-124.9	-12.7	-18.2	-12.2	-334
Percent Change	-38%	-36%	-21%	-32%	-62%	-57%	-13%
Run #7 1/	37.5	37 5	463 8	24.4	8.4	7 3	2254
Actual Change, Run 3 to Run 7	-28.7	-26.4	-143.2	-14.6	-21.1	-14.1	-377
Percent Change, Run 3 to Run 7	-43%	-41%	-24%	-37%	-72%	-66%	-14%

1/ Run #3 is Maximum PNV without MR's. Run #7 is Maximum PNV with MR's.

A significant decline in allowable sale quantity (ASQ) and long-term sustained yield capacity (LTSYC - see glossary for definitions) occurs when MR's are applied. A primary cause of this decline is the reduction in acres available for timber harvest. This reduction is the result of assigning "no harvest" prescriptions to tentatively suitable lands to provide habitat for those wildlife species that require mature and old growth habitats. Another cause of the reduction in acres available for timber harvest is the "special attention" requirement in the Planning Regulations for riparian zones to protect water conditions and fish habitat. Twenty-five percent of the acres available for timber production in the riparian area were constrained to a "no harvest" prescription to simulate this "special attention".

Another major reason for the decline in timber harvest is the incorporation of the harvest dispersion and water quality MR's. The harvest dispersion constraint was used in FORPLAN to model the dispersion of openings and maximum size limit of clearcut units, required by the Regional Guide. This constraint limits the amount of acres that can be harvested in an allocation zone in each decade. The procedure for meeting water quality MR's developed in the hydrologic cumulative effects analysis constrains the number of acres, by watershed, that are available for final harvest to a level that maintains a watershed in its acceptable condition or allows watersheds in an unacceptable condition to recover to an acceptable level. The complete results of the opportunity cost analysis are found in Appendix B.

Sensitivity Analysis

The sensitivity of timber costs, timber price trends, and the discount rate were also analyzed utilizing the benchmarks. The detailed results of these sensitivity analysis are displayed in Appendix B, Chapter VI. In summary, as timber price trends are increased, LTSYC and PNV increase; however, first decade harvest decreases. Only insignificant (1 percent or less) changes in suitable acres occur as price trends change.

The sensitivity of timber costs utilized in the model were analyzed by increasing and decreasing costs by 20 percent. Timber outputs and PNV increase 10-20 percent as timber costs are reduced 20 percent. Acres selected for intensive timber management increase approximately 50 percent as costs are reduced 20 percent. When costs are increased by 20 percent, timber outputs are reduced 15-20 percent and PNV declines by approximately 10 percent. Acres selected for intensive timber management practices are reduced about 55 percent when costs are increased by 20 percent. Acres suitable for timber production vary by 2 percent or less, as costs are increased or decreased.

The 1980 RPA Program for timber is based on an assumption of substantial reductions of unit costs through improved cost effectiveness and new technology.

Benchmarks (and alternatives) were run using a 4 percent discount rate. To determine the sensitivity of the runs to varying discount rates, PNV, costs and benefits were also calculated using a 7 1/8 percent rate. At the higher discount rate, PNV costs and benefits all decline approximately 45 percent.

C. FORMULATION OF ALTERNATIVES

The alternatives displayed in this FEIS were formulated by the Interdisciplinary Team and the Forest Management team. They used the information developed in the benchmark analysis that defined the decision space, the range within which the Forest has the ability to formulate alternatives to respond to the ICO's. Refer back to Table II-2.

Existing Constraints

There are three categories of existing constraints that limit the range of feasible alternatives that could be developed. The management direction for a significant portion of the Forest is already established through legislation. Congress prescribed the management emphasis for approximately 895,000 acres (52 percent of the Forest) through various acts that designated wilderness, National Recreation Areas, Wild and Scenic Rivers, and the Alpine Lakes Management Unit.

Existing development and use on an additional 184,000 acres (11 percent of the Forest) also constrains the range of feasible alternatives. These include: municipal watersheds, Research Natural Areas, roads, utility corridors, special use authorizations, and recreation and administrative developments.

Finally, habitat necessary to maintain viable populations of wildlife management indicator species (wildlife MR's) was determined prior to the formulation of alternatives. To the extent possible, these habitat areas were placed in areas that had already been encumbered by congressional designation or existing uses and developments.

Mapping and Assignment to A Management Strategy

These three categories of land constraints (congressional designations, existing uses, and MR's) were mapped and assigned to management strategies. The management strategies for these areas are the same in all alternatives but the management intensity (prescription) varies between alternatives.

For example: small municipal watersheds were assigned to a municipal watershed management strategy in all alternatives. However, in an alternative that emphasized timber production, a watershed prescription that included timber harvest was available for selection (by the FORPLAN model). In an alternative that emphasizes unroaded recreation, the analysis areas in the watershed were assigned to a watershed prescription that excluded timber harvest. Note that Alternative NC (No Change) was not formulated using FORPLAN.

Required Alternatives

Several alternatives are required by regulation, Regional, and National direction; these required alternatives are listed and briefly described below.

No Change

This alternative, developed in response to a 1986 appeal, is designed to represent the existing direction in approved plans. The No Change Alternative represents the 1963 Timber Management Plans (as amended); coordination with

other resources is guided by the Ranger District Multiple Use Plans and the Forest Service Directives System. It does not comply with the provisions of the National Forest Management Act.

In this FEIS, Alternative NC is the No Change Alternative.

Current Direction (No Action)

This is the alternative of "No-Action" required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14) and the NFMA regulations (36 CFR 219.12(f)(7)). This alternative will continue the management of the Mt. Baker-Snoqualmie as defined by existing direction in approved management plans; continuation of existing policies, standards, and guidelines; management requirements; current budget updated for changing costs over time; and, to the extent possible, production of current levels and mixes of resource outputs.

In this FEIS, Alternative A is the "No-Action" Alternative.

Emphasis on the RPA Program

This alternative will determine how the 1980 RPA Program distributed to the Forests through the Regional Guide can best be implemented.

In this FEIS, Alternative B is the 1980 RPA Program alternative.

Emphasis on Nonmarket Opportunities

This alternative puts an emphasis on water, fish and wildlife, recreation, and other amenity values. Management for other resources will be consistent with the emphasis on amenity values.

Alternative C is the alternative which emphasizes nonmarket opportunities in this FEIS.

Emphasis on Market Opportunities

This alternative has an emphasis on outputs that have an established market price (timber, livestock range forage, commercial fish, developed recreation opportunities, and minerals). Management for other resources will be consistent with the emphasis on market-oriented outputs.

In this FEIS, Alternative I is the alternative which emphasizes market opportunities.

Additional Alternatives

Additional alternatives, including those necessary to respond to the full range of issues, concerns, and opportunities, were formulated to reflect a broad range of resource outputs and expenditure levels. The regulations, 36 CFR 219.12(f)(1), require alternatives to be "distributed between the minimum

resource potential and the maximum resource potential" to display the "full range" that a Forest could produce.

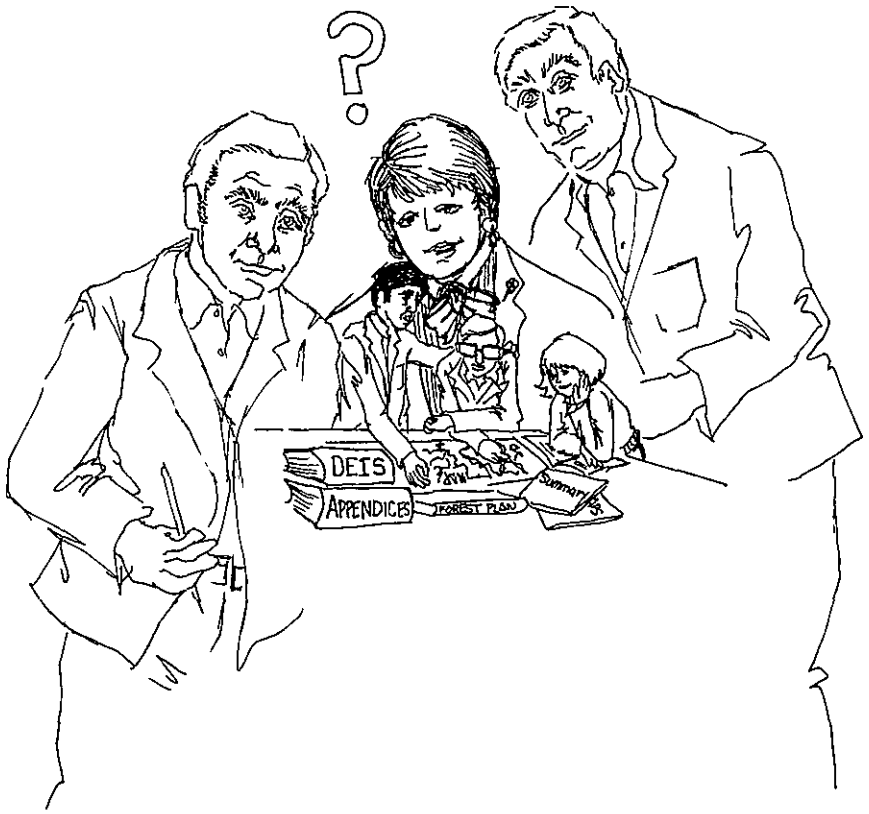
In this FEIS, Alternatives G, H and J are designed to provide a better distribution between the minimum and maximum resource potential.

The Preferred Alternative

A new Preferred Alternative is identified in this FEIS. This alternative was developed considering all comments received on the DEIS. It was selected as the Preferred Alternative only after careful comparison of all the alternatives on the basis of their resource outputs, environmental effects, implementation costs, and the trade-offs among them. The Preferred Alternative is that one alternative which the Forest Service determines best maximizes the net public benefits in an environmentally sound manner, thereby responding to issues.

After the Forest Supervisor reviewed the Interdisciplinary Team's evaluation, and after the Regional Forester and his staff had reviewed the alternatives,

Alternative J is selected as the Preferred Alternative in this FEIS.



D. ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Within the range defined by the benchmarks, an almost infinite number of alternative ways to manage the Forest may be developed. And in the initial formulation of the alternatives, a large number of possible variations were considered.

The criteria used to reduce the number of possible alternatives for development in detail included: obtaining a good distribution of alternatives within the decision space available; responding to public issues (national, regional, and local); recent Congressional legislation; National and Regional direction for required alternatives; public reaction to alternatives presented in the DEIS; and, subjectively, limiting the alternatives to a number that could be reasonably reviewed and comprehended by both the decision-maker and the public. The following alternatives were considered but were not developed in detail.

Alternatives Developed in Detail in DEIS, But Eliminated From Detailed Study in FEIS

Alternatives D, E, E-Departure, F, and H-Departure were developed in detail in the DEIS but eliminated from further consideration because they received very few comments during the public review period and they are not needed to provide a full range of alternatives for analysis. The alternatives eliminated are described below:

Alternative D - The goal of this alternative was to emphasize those resources with an established price in the market. Other resources would be managed at levels that would not reduce the outputs of the market resources. While this alternative was dropped, a new alternative (I) with a similar goal has been added in response to public comment on the DEIS.

Alternative E - The goal of this alternative was to retain a large portion of the existing roadless areas in an unroaded condition, while producing the maximum timber volume on the remaining developed portion of the Forest to reduce the economic impact of retaining the roadless areas.

Alternative E-Departure - The goal of this alternative was the same as Alternative E except for relaxed non-declining flow and harvest utilization standards.

Alternative F - The goal of this alternative was to provide a moderate level of outputs for a number of resources, with some emphasis on unroaded recreation, timber production, and increasing big game populations.

Alternative H-Departure - The goal of this alternative was to provide an emphasis on unroaded recreation; protection of scenic values in the foreground and middleground of heavily traveled highway corridors; increasing big game populations; plus emphasis on timber production on tentatively suitable acres not assigned to other objectives. As a departure alternative, the timber harvest schedule was allowed to depart from non-declining flow.

Alternatives Received From The Public During Response to DEIS, But Eliminated From Detailed Study in FEIS

Several alternatives, or proposals for alternatives, were received from individuals or organizations during the comment period on the DEIS. One was developed as an alternative considered in detail (Alternative I); two others, described below, were considered but not developed in detail.

The Earth First! Alternative - The goal of this alternative was to halt logging and road construction in roadless areas and unfragmented old growth areas; phase out all logging on National Forest lands over a 15-year period; phase out road construction; complete protection of American Indian Religious and Cultural Use areas; recovery of native plant and animal species to historic population levels; rehabilitation in all streams for natural anadromous fish; recommendation of 47 wild and scenic rivers for designation; wilderness recommendations in nine areas; rehabilitation of the North Cascades Ecosystem; and elimination of the mountain hemlock study.

The Earth First! Alternative was not developed in detail. It does not meet the Multiple Use Sustained Yield Act. However, in developing Alternative J (Preferred), some elements of this alternative were incorporated, including rehabilitation of streams for anadromous fish, greatly increased mileage of recommended wild and scenic rivers, and larger, unfragmented areas of old growth.

Alternative C-Modified - This alternative was presented by the Pleasure Walking Horse Club of Washington and included mapped management areas: a blend of DEIS alternatives C and G. The goal of Alternative C-Modified was to minimize clearcutting, with more emphasis on selective cutting; more emphasis on wildlife and wildlife habitat, protection of old growth and rivers; and a harvest level between that of the two alternatives. While Alternative C-Modified was not developed in detail, as presented, in this FEIS, a large number of the components of the alternative were incorporated in the development of Alternative J (Preferred). These included more miles of wild and scenic river recommended, more wildlife habitat protection, increased scenic protection, a lower allowable sale quantity, and fewer miles of new road construction.

Designate Additional Wilderness

The Mt. Baker-Snoqualmie National Forest has over 400,000 acres of land that are unroaded and undeveloped and are suitable for wilderness. Some members of the public believe that additional wilderness recommendations should be considered in the Forest Planning process. An alternative that would recommend additional wilderness designation was considered but not developed in detail.

The primary reason this alternative was not developed in detail was the passing by Congress of the Washington State Wilderness Act of 1984. During deliberations on this Wilderness Act, Congress considered all the roadless areas on the Forest. They received many recommendations from diverse segments of the public. The Act represents their judgement on which areas should be designated wilderness. The Act contains specific language to the effect that the Forest Service is not required to consider wilderness recommendations for those "released" roadless parcels in the first generation of Forest Plans. The

statute does not prohibit the Forest Service from doing so, but for the Mt. Baker-Snoqualmie, it is not considered reasonable so soon after the '84 Act.

Revise Alpine Lakes Plan

The Alpine Lakes Area Management Act of 1976 required development of and periodic revision of the management plan for the Alpine Lakes Management Unit. This is a special plan required by Congress. No special planning criteria or process was specified. The NFMA planning regulations (36 CFR 219.2(b)) provide that, in those cases where a separate special area plan is required, such plan may be incorporated without modification into the Forest Plan.

Based on the fact that the Alpine Lakes Plan (USDA 1981) is relatively new, is consistent with the intent of the NFMA, only minor problems have been encountered in its implementation, and the existing Plan is not a major public issue or management concern, the decision was made to incorporate the Alpine Lakes Plan into the Forest Plan without modification. Thus, alternative management direction for the Alpine Lakes Area was not developed in detail.

Revise the Skagit Wild and Scenic River Management Plan

The Skagit Wild and Scenic River was classified by Amendment to the Wild and Scenic Rivers Act by P.L. 95-625 dated November 10, 1978. The Management Plan for the Skagit System was finalized and Notice of Availability published in the Federal Register on May 10, 1984. The Plan became effective on August 8, 1984.

Based on the fact that the Skagit Wild and Scenic River Management Plan is a recent Plan, that no major problems have been encountered during implementation that would require revision, that the Plan is reasonably consistent with the NFMA Planning regulations, and that it is not a major issue or concern, the decision was made to incorporate the plan into the Forest Plan without modification. Thus, alternative management direction for the Skagit Wild and Scenic River was not considered in detail.

Alternative to Meet RPA Goals

Several FORPLAN runs were made in an effort to produce all of the RPA Targets simultaneously. A departure analysis was made to determine if timber targets could be met for the first five decades. In addition rotation age constraints were relaxed to the point of utilization standards. None of these alternatives resulted in a feasible solution that would simultaneously meet all of the RPA targets. Thus, an alternative to meet all RPA targets could not be considered in detail.

Development of All and None of the Roadless Areas

NFMA Planning Regulations (36 CFR 219.12(f)(1)) require that "alternatives shall be distributed between the minimum resource potential and the maximum resource potential to reflect to the extent practicable the full range of major commodity and environmental resource uses and values that could be produced from the forest."

Regional Planning direction relating to this requirement and the roadless areas suggests a range of alternatives where 100 percent, 75, 50, 25, and 0 percent of the roadless areas remain undeveloped, unless this range does not produce practical alternatives.

Following the formulation of the alternatives, all those to be considered in detail were reviewed to determine whether they met this criterion. Alternatives A through J provide a range of 63 percent to 91 percent of the roadless acres remaining in an undeveloped condition.

An alternative where 100 percent of the roadless areas would remain undeveloped was not considered practical because of the size and location of a number of the individual roadless parcels. Fifty-five of the roadless parcels are less than 1,000 acres in size. These small parcels are generally slivers of roadless areas that remained after Congress established the wilderness boundaries in the Washington State Wilderness Act of 1984.

The character of the roadless parcels can be generally described as high elevation, steep terrain, with difficult or impossible development opportunities, although there are exceptions. These lands are still in an undeveloped condition for these reasons. Past National Forest managers have recognized these limitations and chose to concentrate development activities elsewhere.

A maximum of 36 percent of the roadless areas would be developed in any of the alternatives, due to the lack of resource capability, wildlife habitat necessary to meet MR's, and the character of the terrain.

Develop Benchmarks into Alternatives

The benchmarks were eliminated from detailed study as alternatives because they were not feasible to implement. As discussed above, the benchmarks were developed to study resource maximization potentials for the Forest, by which the decision space or the parameters within which alternatives could be developed was determined. Benchmarks do not consider alternative output combinations which address issues, concerns, or opportunities.

E. ALTERNATIVES CONSIDERED IN DETAIL

The alternatives considered in detail all specify different ways of managing the Mt. Baker-Snoqualmie National Forest. Each is a combination of land uses, management practices, and activity schedules which result in a unique combination of resource outputs, land uses, environmental conditions, and economic and social effects. Each responds to the issues and concerns in different ways.

Together, these alternatives present a broad range of reasonable management alternatives. They were formulated through an analysis process, discussed above, that explored a wide array of possibilities shown in the benchmarks and the required alternatives. A detailed description of the process used to formulate the alternatives can be found in Chapter VII of Appendix B. The following alternatives were selected for detailed study:

Alternative NC (No Change)
Alternative A (No Action)
Alternative B (RPA)
Alternative C
Alternative G-Modified
Alternative H
Alternative I
Alternative J (Preferred)

Elements Common to All Alternatives

A number of resource management programs are treated the same in all the alternatives considered in detail. These are described below and are **not** included in the alternative descriptions which follow.

- The Alpine Lakes Area Management Plan, implemented in 1981, is incorporated into all alternatives except Alternative NC.
- The Skagit Wild and Scenic River Plan, implemented in 1984, is incorporated into all alternatives except Alternative NC.
- The Mt. Baker National Recreation Area, established in 1984, is the same in all alternatives.
- The three existing Research Natural Areas - North Fork Nooksack River, Lake Twenty-two and Long Creek - are retained in all alternatives.
- The foreground of the Mather Memorial Parkway, designated in 1931, is managed to retain its scenic quality in all alternatives.
- The management requirements necessary to integrate the requirements of law and regulation are incorporated in all alternatives except Alternative NC.
- The rights established by the various Indian Treaties are retained in all alternatives. Consultation with Indian Tribal leaders will continue on any proposed projects within sites inventoried in response to the American Indian Religious Freedom Act.

- The acres of designated wilderness are the same in all alternatives. Acres assigned to classes of the Wilderness Recreation Opportunity Spectrum (WROS) do vary by alternative; however, there are no WROS classes in Alternative NC.

- Even-aged management and regeneration harvest through clearcutting are assumed in estimating timber outputs in all alternatives; the use of other systems, however, is not precluded. Refer to Appendix F for a discussion of those situations where other harvest methods are acceptable.

- All alternatives would make full use of vegetation management techniques including herbicides and fire. In 1988, the Pacific Northwest Region, USDA Forest Service completed a final EIS on managing competing and unwanted vegetation (USDA 1988b). That final EIS, the Mediated Agreement, and accompanying implementation direction is incorporated by reference into this FEIS. It will guide vegetation management activities as the Forest Plan is implemented.

- All existing utility corridors, electronic sites, and administrative sites are retained in all alternatives.

Alternative NC (No Change)

The No Change Alternative has been developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's.

The No Change Alternative is designed to continue the level of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1963 Timber Management Plans. 2/ This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA; the alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

Alternative NC: does not use the most up-to-date inventories for assessing effects and estimating outputs; does not use current yield projection methods; its harvest schedule was not developed according to the concepts and philosophy of non-declining flow; and it does not incorporate management requirements, including those designed to maintain viable plant and animal populations.

2/ The 1963 Timber Management Plans (TM Plans) have been amended and updated to reflect major changes in the land base, such as the formation of North Cascades National Park, designation of wilderness, and transfer of administrative responsibility to other Forests. The TM Plans direct timber management activities; coordination with other resources is guided by Ranger District Multiple Use Plans and the Forest Service Directives System.

Design Criteria for Alternative NC (No Change)

Timber: the 1963 Timber Management Plans are the basis for the alternative.

Roads: the Naches Pass road would not be constructed.

Roadless Areas: an estimated 60% of the roadless areas would remain undeveloped; this estimate is based on the acres of commercial forest land assumed to be in the roadless areas.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: no provision for study or protection of potential rivers is included in the TM Plans.

Research Natural Areas: no potential areas recommended.

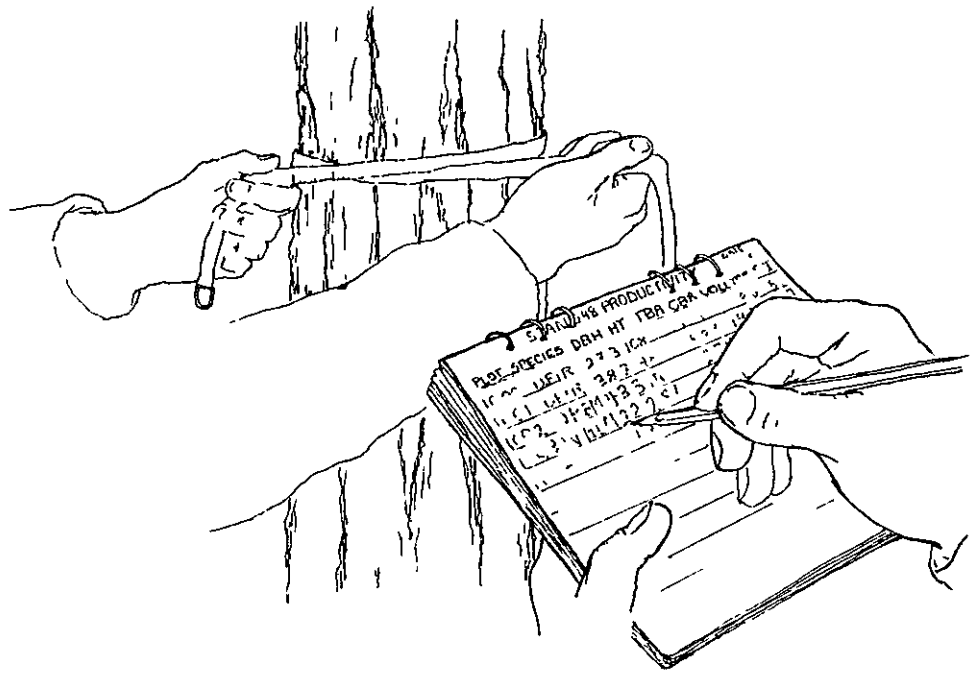
Spotted Owls: no provisions made to protect old-growth habitat for wildlife.

Big Game Habitat: no provisions made for protection of big game habitat.

Cavity Excavators: no provisions made for protection of habitat.

Anadromous/Resident Fish: no provisions made for protection of fish habitat.

Municipal Watersheds: all are managed under current agreements, memoranda of understanding.



Alternative A (No Action)

Alternative A was developed to continue management direction as set out in plans formulated and approved prior to the passage of the National Forest Management Act. The alternative incorporates the requirements of the National Forest Management Act of 1976 (36 CFR 219.12 through 219.27). The goal of Alternative A is to provide maximum timber outputs while maintaining or exceeding existing recreation, wildlife, fisheries, and visual resource outputs.

The plans approved prior to NFMA, plus current laws, regulations, and directions - including MR's - were used to assign management direction to different parts of the Forest. The most recent inventories were used to identify land base features, such as riparian zones and different timber condition classes. The NFMA process of land stratification for timber production was applied to commercial forest lands identified in the 1963 TM Plans. The latest technical processes were utilized to develop growth and yield projections for existing and regenerated timber stands. See the discussion below for more about the relationship of Alternative A (No Action) and the No Change Alternative.

This is the No Action Alternative required by the Council on Environmental Quality Regulations for implementing the National Environmental Policy Act (NEPA).

Design Criteria for Alternative A (No Action)

Timber: an exception to "Elements Common to All Alternatives", in FORPLAN, Alternative A was run with an objective of maximize timber volume for the first five decades, then was rerun to maximize PNV for 15 decades with the same timber outputs as in Decades 1-5. This resulted in some timber prescriptions having less than maximum economic efficiency. Approximately 70 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 26 miles of arterial and collector roads would be built. During that same period, about 330 miles of local roads would be constructed. The Naches Pass road would not be constructed.

Roadless Areas: would be managed under the direction contained in the Ranger District Multiple Use Plans; approximately 82 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: the 15 rivers included in the National Park Service Nation-wide Inventory are recommended for designation as part of the National Wild and Scenic River System. These fifteen rivers include a total of 375 miles, of which 142 miles are within the national forest boundary.

Research Natural Areas: no potential areas recommended.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide.

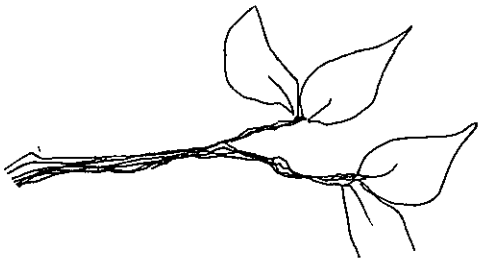
Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: habitat is provided for viable populations at the MR levels; additional habitat for some species in wilderness, RNA, and areas not suited for timber production.

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of their potential population levels.

Anadromous/Resident Fish: current populations are maintained through habitat maintenance or improvement at the MR level (low investment, MA 13A; see below.)

Municipal Watersheds: are managed under current agreements, memoranda of understanding.



Relationship of the No Change Alternative to the Alternative A (No Action)

The following brief section compares the No Change Alternative and Alternative A (No Action). Since Alternative NC is based on the 1963 Timber Management Plans - the only plan of those formulated and approved prior to NFMA that quantifies outputs - the following discussion is limited to the timber resource. Both Alternative A and Alternative NC are useful for comparison with the other alternatives.

Comparisons between the two alternatives are complex. Changes have occurred in the land base available for timber management, technology, timber inventory methods, analysis, and applicable laws and regulations.

One major difference between Alternatives NC and A (and the other alternatives) is the terminology used to express timber outputs. Potential yield (PY), used in the 1963 TM Plans, represents a level of chargeable volume that could be produced. It includes both net live (green) and dead (salvage) volume. Allowable sale quantity (ASQ) - used in Alternative A and the other alternatives - is the output objective that drives the timber program. ASQ includes only net live volume. Both PY and ASQ represent a ceiling on the amount of chargeable volume that could be sold for a given decade. Both are legitimate expressions of outputs.

Table II-6 shows a summary of the major differences between the development of PY and ASQ. Also refer to the narrative accompanying Table II-9b.

Table II-7 compares outputs between the No Change and No Action Alternatives. Timber sale program quantity (TSPQ), a term applicable to both NC and A, is the timber volume planned for sale in any one year. This could be potential yield plus any other volume, or allowable sale quantity plus other volume programmed for sale.

Table II-6
Summary of Major Differences Between Development of Potential Yield in Alternative NC and Allowable Sale Quantity in Alternative A (No Action)

Factor	PY Alt. NC (No Change)	ASQ Alt. A (No Action)
1. Land Base for Determining Timber Production	580,000 acres CFL, of which 33,000 acres are marginal and no yield is calculated, resulting in 547,000 for yield calculation.	597,000 acres tentatively suitable, with 184,000 acres not appropriate for timber production, 1/ resulting in 413,000 acres for yield calculation.
2. Acre Determination	Plot expansion to determine CFL acres.	Acres mapped in place.
3. Utilization Standards	11" DBH to 8" top.	9" DBH to 6" top for mature stands, 7" DBH to 4" top for others.
4. Sampling	No growth samples, mortality sampled on only one District.	Growth and mortality sampled Forest-wide.
5. Yield Calculation	Hanzlik formula used, plus an estimate of merchantable dead included in PY.	FORPLAN analysis used. Merchantable dead not included in ASQ, but is in TSPQ.
6. Commercial Thinning	No estimated yield; amended to include yield.	Included in ASQ.
7. Precommercial Thinning	No estimated yield.	Yield increases ASQ.
8. Genetics	No estimated yield.	Yield increases based on acres planted by area and species. Increases are between 1 and 2 percent.
9. Hardwoods	No estimated yield.	Hardwood volume chargeable to ASQ. 2/

1/ See Tables II-9d and II-9d(1) for a detailed breakdown of these acres.
2/ About 1.7% of inventory volume is in hardwood species.

Table II-7
Comparison of Timber Outputs Between the No Change and No Action Alternatives

Factor	Unit	Alt. NC 1/	Alt. A (No Action)
Land Base for Determining Timber Outputs	M Acres	547	413
LTSYC	MMCF	---	39
Potential Yield			
Yield Per Acre	BF	373	---
FY 85 - 88 Average	MMBF	204	---
FY 79 - 88 Average		230	---
ASQ			
Yield per Acre	BF	---	360
1st Decade	MMBF	---	149
Offered for Sale			
FY 85 - 88 Average	MMBF	252	---
FY 79 - 88 Average		267	---
Harvested			
FY 85 - 88 Average	MMBF	230	---
FY 79 - 88 Average		253	---
TSPQ			
1st Decade	MMBF	220	168

1/ See Table III-11, page III-46, FEIS for a detailed history of performance/ changes in 1963 TM Plans.

There is a 25 percent reduction in the acres used to determine timber outputs from Alternative NC to Alternative A. The two primary reasons are: the timber resource land suitability classification process used to determine lands tentatively suitable for timber production; and wildlife, riparian, and water quality MR's. As there is considerable overlap in acres not suited for timber production and those necessary to meet MR's, the best estimate of the effects of the two factors on the reduction in acres would be to assign 50 percent of the effect to each factor.

A long-term sustained yield capacity (LTSYC) was not calculated for Alternative NC. The average annual PY is lower in fiscal years 1985-88 than the average for the decade because adjustments were made in FY 1980 and FY 1984 to reflect the Rare II decision and the 1984 Washington State Wilderness Act.

The ASQ yield per acre per year - 360 BF (Alternative A) - is 3.5 percent less than PY per acre, 373 BF in Alternative NC, a result of decreased acreage used to determine timber outputs. This decrease would have been greater except for increased utilization standards, precommercial thinnings, and planting genetically improved seedlings. The average annual volume harvested is substantially less than the average sold for the periods shown in Table II-7. The differences are a reflection of the severely depressed timber market in the early 1980's. In Decade 1, projected TSPQ for Alternative A declines about 24% from the estimated TSPQ for Alternative NC. Refer to Table II-9b for comparison with the other alternatives, and to Table II-9n for budget, costs, employment and income outputs and effects.

Alternative B (RPA)

The goal of Alternative B is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation, as specified in the 1980 RPA Program.

The RPA targets specified are:

Timber: annual programmed timber sales (TSPQ)
Decade 1 - 66 MMCF; Decades 2,3 - 69 MMCF; Decades 4, 5 - 70 MMCF
Developed Recreation: in thousand RVD's
Decade 1 - 2,381; Decade 5 - 2,660
Dispersed Recreation (includes hunting, fishing): in thousand RVD's
Decade 1 - 2,910; Decade 5 - 3,930
Wildlife Habitat Improvements: in acre equivalents
Decade 1 - 7,278; Decade 5 - 3,068

Design Criteria for Alternative B (RPA)

Timber: is produced at the highest level possible, while meeting the other goals of the alternative. Approximately 64 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed for timber production. In the first two decades, approximately 28 miles of arterial and collector roads would be built. During that same period, about 280 miles of local roads would be constructed. The option to construct Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 87 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: same as "Elements Common to All Alternatives."

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic designation.

Research Natural Areas: no potential areas recommended.

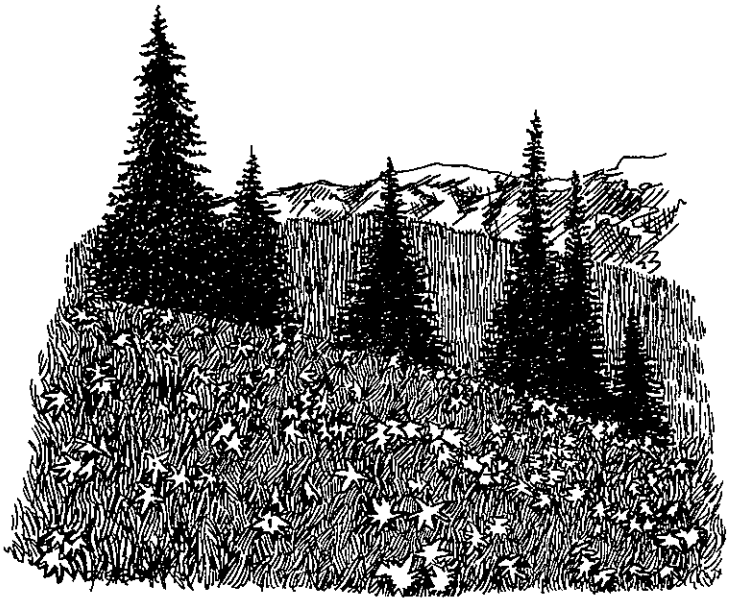
Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 79,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on land suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of their potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.



Alternative C

The goal of Alternative C is to emphasize primitive and semi-primitive nonmotorized recreation (accomplished through retention of existing roadless areas and, over time, reversion of some roaded areas to unroaded condition); protect scenery, fish, and wildlife habitat; and protect sites and areas important to American Indians for religious and cultural use.

Design Criteria for Alternative C

Timber: no production goals set; suitable acres and harvest level will be the lowest of all alternatives considered in detail. Approximately 43 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 300 miles of existing arterial and collector roads. In the first two decades, about 15 miles of arterial and collector roads would be built, and about 180 miles of local roads would be constructed. Construction of the the Naches Pass road is precluded by management of surrounding lands for unroaded dispersed recreation.

Design Criteria for Alternative C (continued)

Roadless Areas: nearly all (97%) of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: high to moderately-high protection of the foreground and middleground of all inventoried primary and secondary viewsheds.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers included is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 36,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat provided to maintain cavity excavators at 60% of their potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, with stipulation that habitat be maintained as old growth when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - closed watershed, exchange NF lands; Others - no timber harvest, limited recreation use.

Alternative G-Modified

The goal of Alternative G-Modified is to emphasize maintenance of natural ecosystems and diversity of native plants and animals, emphasize providing uses not found on private lands, and produce timber in a way that is consistent with the other goals and is non-damaging to soils.

Design Criteria for Alternative G-Modified

Timber: timber production will occur on currently accessed sites first. Maintenance or development of old growth, especially at lower elevations, is emphasized. Approximately 41 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: roads to be closed include approximately 65 miles of existing arterial and collector roads. In the first two decades, approximately 13 miles of arterial and collector roads would be built, and about 145 miles of local roads would be constructed. Construction of the Naches Pass road is precluded by management of surrounding lands for undeveloped recreation.

Roadless Areas: approximately 96% of the roadless area acres are retained in an unroaded condition at the end of the fifth decade.

Visual Resource: the foreground of selected corridors is protected, including the upper end of Mt. Baker Highway, portions of the Cascade River and North Fork of the Cascade, portions of the Mt. Loop Highway, the upper Sauk, lower Sultan, and Mather Memorial Parkway. Integral vistas within and from Class I airsheds and other wildernesses (not yet designated Class I) are protected.

Wild and Scenic Rivers: all 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for designation as part of the National Wild and Scenic River System. The total mileage of rivers include is 786, of which 441 miles are within the national forest boundary.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Twin Sisters, Monte Cristo, Baker Lake, Naches Pass, and along the Mather Memorial Parkway.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide **with additional habitat areas** being protected to meet the objectives of the alternative. Approximately 113,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

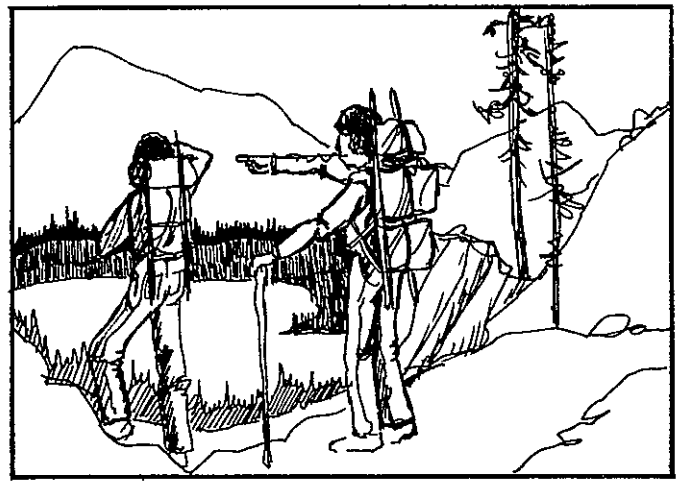
Big Game Habitat: habitat provided for viable populations at the MR levels; some additional habitat for some species in wilderness, RNA.

Design Criteria for Alternative G-Modified (continued)

Cavity Excavators: on lands suitable for timber production, habitat is provided for cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous and resident fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - managed to retain old-growth habitat with stipulation that it be maintained when lands exchanged to City of Seattle; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - managed for a full range of outputs, timber production on suitable lands.



Alternative H

The goal of Alternative H is to provide an increased emphasis on unroaded recreation; protection of scenic values in the foreground and middleground of heavily traveled highway corridors; increasing big game populations; plus emphasis on timber production on tentatively suitable acres not assigned to other objectives.

Design Criteria for Alternative H

Timber: about 60 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. About 20 miles of existing roads, located in areas assigned to unroaded dispersed recreation, will be closed. In the first two decades, approximately 11 miles of arterial and collector roads would be built. During that same period, about 250 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Design Criteria for Alternative H (continued)

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 88 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways.

Wild and Scenic Rivers: the five rivers determined in the DEIS to be eligible for Wild and Scenic River designation are recommended for designation - North Fork Nooksack, North Fork Skykomish, South Fork Skykomish, Tye, and Middle Fork Snoqualmie Rivers, a total of 154 miles, of which 71 miles are within the national forest boundary.

Research Natural Areas: five potential are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 61,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - current direction (exchange NF lands to City of Seattle, no old-growth habitat maintained); Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

Chapter II
Alternatives Considered in Detail

Alternative I

The goal of Alternative I is to emphasize those resources with an established price in the market place: timber production, anadromous fish, developed recreation, and minerals. Emphasis is also placed on enhancement of big game wildlife and fish habitat, and developing/maintaining an extensive trail system to accommodate a wide variety of users on a year-round basis. Other resources are managed at levels that do not reduce the outputs from the market resources.

Design Criteria for Alternative I

Timber: timber production is emphasized. Approximately 65 percent of the acres tentatively suited for timber production are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed, to meet timber production goals. In the first two decades, approximately 34 miles of arterial and collector roads would be built. During that same period, about 290 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: all roadless area acres that are tentatively suitable for timber production are available for assignment to a timber harvest prescription, unless needed to meet MR's. Approximately 86 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual: the foreground of heavily-traveled highways are managed for scenic quality (I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, and Baker Lake Highways).

Wild and Scenic Rivers: high timber goal precludes recommending any eligible rivers for Wild and Scenic River designation.

Research Natural Areas: no potential areas are recommended for designation.

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. About 93,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: alternative designed to increase population levels over time. Acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotation, sale design, smaller clearcuts, etc., provide an optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at the MR level - 20% of potential population levels.

Anadromous/Resident Fish: anadromous fish populations are increased through habitat improvements at a high investment level (MA 13C; see below).

Municipal Watersheds: Cedar River - contains 2 SOHA's, retain NF lands, timber production on suitable lands, maintain old-growth habitat; Green River - high level of timber production, essentially closed to public recreation; Sultan River - retain NF lands, full multiple use; Others - managed for a full range of outputs, timber production on suitable lands.

Alternative J (Preferred)

This is the Preferred Alternative. It is a new alternative and was not displayed in the DEIS. Beginning with the draft EIS Preferred Alternative (H), Alternative J was developed to respond to public comment and new information. Differences between the draft and this Preferred Alternative include: a considerable increase in trail mileage; an increase in the number of rivers recommended for addition to the National Wild and Scenic Rivers System; allocation of three Special Areas (Botanic, Scenic, and Recreation/Education); an increased emphasis on unroaded recreation; and greater protection of scenic values within travel corridors. Timber production is emphasized on suitable acres assigned to a timber harvest prescription. Other resources will be managed at levels commensurate with the objectives of the alternative.

Design Criteria for Alternative J (Preferred)

Timber: about 58 per cent of the tentatively suitable acres are available for assignment to a prescription that includes timber harvest.

Roads: are constructed as needed. Roads to be closed include about 25 miles of existing roads, located in areas assigned to unroaded dispersed recreation. In the first two decades, approximately 15 miles of arterial and collector roads would be built, and about 240 miles of local roads would be constructed. The option to construct the Naches Pass road is retained.

Roadless Areas: areas with a high percentage of tentatively suitable lands are available for timber production emphasis, except where they also have a combination of high values for unroaded dispersed recreation, big game winter range enhancement opportunities, and are inventoried American Indian religious sites. Approximately 91 percent of the roadless area acres remain in an undeveloped condition at the end of the fifth decade.

Visual Resource: the foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality (meet inventoried visual quality levels): I-90, U.S. 2, Mather Memorial Parkway, and Mountain Loop, Mt. Baker, Baker Lake and Crystal Mountain Highways, and Cascade River road.

Wild and Scenic Rivers: 30 of the 47 rivers determined to be eligible for Wild and Scenic River designation are recommended for inclusion in the National Wild and Scenic Rivers System. A total of 452 miles are recommended, with 276 of those miles located within the national forest boundary. This recommendation is a preliminary administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

Research Natural Areas: five potential RNA's are recommended for designation - North Fork Nooksack Addition, Lily Lake, Perry Creek, Green Mountain, and Chowder Ridge.

Special Areas: special interest areas are recommended for designation at Mather Memorial Parkway, Heather Meadows, and Sulfur Creek.

Design Criteria for Alternative J (Preferred) (continued)

Spotted Owls: spotted owl habitat is inventoried, identified, and protected following the direction in the SFEIS amending the Regional Guide. Approximately 54,000 acres of owl habitat in lands otherwise suitable for timber production are in designated Spotted Owl Habitat Areas.

Big Game Habitat: some acres of suitable habitat are assigned to habitat improvement (timber management prescriptions that, through longer rotations, sale design, smaller clearcuts etc. provide optimal mix of thermal, forage, and hiding cover).

Cavity Excavators: on lands suitable for timber production, habitat is provided to maintain cavity excavators at 40% of potential population levels.

Anadromous/Resident Fish: anadromous fish production is increased through habitat improvements at a high investment level (MA 13D; see below).

Municipal Watersheds: Cedar River - initiate negotiations on a new Cooperative Agreement to reestablish goals and management for the watershed; until then, do not enter into land exchanges affecting National Forest lands; Green River - current direction (timber production, dispersed recreation permitted); Sultan River - current situation (exchange NF lands, moderate timber harvest, restricted recreation use); Others - manage for a full range of outputs, timber production on suitable lands.

Mitigation Measures Common to All Alternatives

Some of the proposed management activities in the alternatives would cause significant environmental damage if implemented without means of mitigating the potential adverse effect. Based on research findings, the many years of experience in managing the resources on this Forest, and the professional judgement (and on-the-ground experience) of specialists involved in project design, many adverse environmental effects can be anticipated or predicted.

Activities can be prescribed and designed, in advance, using mitigation measures that will avoid, minimize, rectify, reduce, or compensate for undesirable environmental effects. Mitigation measures are incorporated into alternatives at different levels in several different ways:

- The management area allocations can mitigate potential adverse effects by separating incompatible uses, impacts, and conflicts.

- National Forest Management Act requirements are incorporated into the planning process; they are reflected in the allocations and Standards and Guidelines (refer to FEIS Appendices B, D, H and the Forest Plan, Chapter 4).

- Management activities in all alternatives will be governed by Standards and Guidelines, including Best Management Practices (BMP's). Best Management Practices are specifically designed to protect water quality, as required by Section 319 of the Clean Water Act, as amended by the Water Quality Act of 1987. Appropriate, site-specific BMP's will be selected and tailored for site-specific conditions of each proposed project. See Appendix I, FEIS for a discussion of the process and practices. Also, refer to Forest PLan, Chapter 4, Forest-wide Standards and Guidelines.

- The Forest Plan Monitoring Plan includes provisions for monitoring the effectiveness of mitigation measures; see Chapter 5, Forest Plan.

- Mitigation measures are developed at the site-specific project level of planning, and projects are tiered to other planning level mitigation measures.

- Management requirements established in accordance with Regional direction (1920, 2/9/83) are a major part of mitigation found in all alternatives.

- The standards and guidelines and management area prescriptions in Chapter 4 of the Forest Plan are a fundamental and integral part of the mitigation measures. Following are the Forest-wide Standards and Guidelines that apply to all alternatives.

Mitigation Measures Included in the Forest-wide Standards and Guidelines

The Recreation Resource

Public Information. Many of the recreating public are uninformed or inexperienced in using the forest for recreational purposes. Through ignorance of the Forest ecosystem and thoughtlessness, they often perform acts that are detrimental to their own safety, the enjoyment of the forest by others, or the

forest resource. Examples include: poor disposal of human waste and garbage, fire safety, wildlife harassment, lack of appropriate equipment, and destruction of desirable vegetation.

Past experience with public information and education programs has proved to be an effective way to minimize these adverse effects, but not completely eliminate them.

Off-Road Vehicle Use. Off-road vehicles (ORVs), have the potential to cause user conflicts, destruction of desirable vegetation, stress on wildlife, and adverse effects on soil and water.

Providing facilities specifically designed to accommodate ORV use is effective in reducing adverse effects on soil, water, and vegetation. Seasonal or year-long closures to ORV use are effective in preventing harassment of wildlife, and can protect soil and water when weather conditions are inappropriate for ORV use. User conflicts can be avoided or reduced by providing facilities that are specifically designated for use by ORVS. Recreationists that find ORV use objectionable can avoid these designated areas.

The Visual Resource

Many Forest management activities have the potential to cause adverse or undesirable effects on the visual resource. Activities that modify the landscape and scenery include: construction of roads, administrative or recreation facilities, and utility corridors; timber harvest activities; mining and energy exploration and development; burning wood debris; and fish and wildlife habitat improvements.

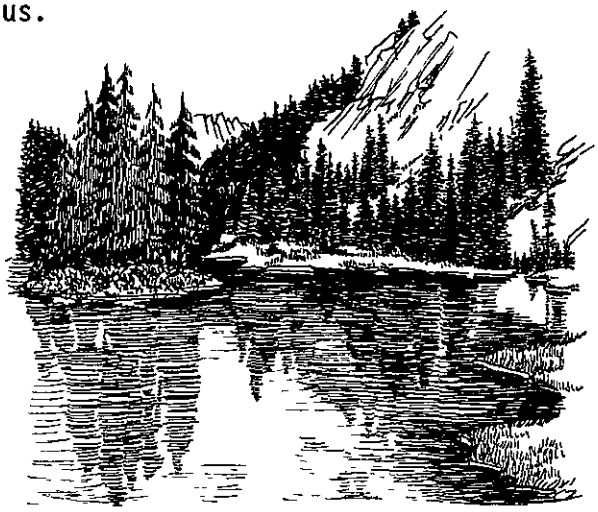
A number of handbooks regarding all aspects of landscape and visual resource management have been developed. These volumes were developed to provide a service-wide approach to National Forest landscape management. The basic concepts and principles are explained in Agriculture Handbook Number 434. The second volume, Handbook 462, describes the practical application of visual resource management concepts in administering various forest resources.

Handbook 462 describes the Visual Resource Management System. The system establishes a means of identifying visual quality objectives for National Forest management activities. All acres on the Forest are managed for an established visual quality objective (VQO). The minimum VQO on this Forest will be maximum modification but many management areas have a higher visual quality level.

Other handbooks describe detailed techniques for meeting visual quality objectives developed for the activities that have the greatest potential to cause undesirable visual impacts. These include utilities (#478), range (484), roads (483), timber (559), fire (608), and ski areas (617).

Wild and Scenic Rivers

Forest-wide Standards and Guidelines state that recommended rivers shall be managed to protect those characteristics that contributed to the eligibility of those rivers at their highest potential classification, until congress formally determines their status.



American Indian Religious and Cultural Use

A professional inventory of religious and cultural use areas and sites on the Forest was completed in 1981 (Inventory of Native American Religious Use, Practices, Localities and Resources, Study Location on the Mt. Baker-Snoqualmie National Forest, Washington State, 1981). Tribal members and the literature were surveyed to identify those sites and areas on the Forest that are important to American Indians for religious and cultural purposes. Confidentiality of these inventoried sites is maintained.

> Prior to planned activities, the Forest presents project information to tribal groups whose religious practices might be affected. Working with tribal religious leaders, National Forest managers attempt to develop mitigation measures. Mitigation may include complete avoidance of the site, delay of the project, redesign of the project, or seasonal restrictions on project activities.

The Cultural Resource

Archaeological & Historical Properties. A complete inventory of all significant sites on the Forest has not been completed. Forest management activities have the potential to adversely affect properties because their presence is unknown.

> A cultural resource inventory (professionally supervised) will be performed on all projects, prior to any ground-disturbing activity or modification or removal of older structures. Cultural properties that are identified will be protected until their significance has been evaluated, through consultation with the Washington State Historic Preservation Office (SHPO) and using the criteria for eligibility to the National Register of Historic Places. When sites are determined significant, mitigation measures will be developed in consultation with the SHPO, Advisory Council on Historic Preservation, and other interested parties, as specified in 36 CFR 800.

The Wilderness Resource

Prohibited Activities. The Wilderness Act and Title 36 of the Code of Federal Regulations (36 CFR) provide for the maintenance of the necessary environmental conditions to preserve the wilderness resource by prohibiting certain activities or uses.

With some exceptions, the following are generally prohibited: commercial enterprises, temporary or permanent roads, cutting of trees, use of motor vehicle, aircraft landing strips, heliports, helispots, landing of aircraft, dropping of materials from aircraft, motorized equipment, motor boats, mechanical transport, structures or installations, use of hang gliders, use of bicycles, and appropriation under the mining act or minerals leasing laws after January 1, 1984.

Recreation Use in Wilderness. Use by people pursuing recreational experiences is the major cause of adverse environmental effects on the wilderness resource.

Estimated carrying capacity has been established for each wilderness, by wilderness recreation opportunity spectrum (WROS) class. In addition, limits of acceptable change (LAC) have been established. Using these measures, recreation use in wilderness will be regulated or excluded when on-site conditions indicate that wilderness resource values are in jeopardy.

Carrying capacity and LAC were developed based on available research; actual wilderness management experience under these concepts is limited. However, both carrying capacity and LAC may be changed, by amending the Forest Plan, if, through experience and monitoring, it is found that they are not providing the desired results.

Any proposed improvements must be necessary for the protection of the wilderness resource and not for the convenience of users, and should be constructed of natural materials, and designed to harmonize with the environment.

Wilderness Vegetation. Natural biotic communities can be destroyed or disturbed if pack and saddle stock feed containing non-native plants is carried into wilderness. In heavily used areas, fragile vegetation can be trampled or destroyed by overuse from livestock or humans. Use of firewood for campfires may occur more rapidly then the accumulation of firewood supplies.

Introduction of non-native plants can be minimized by prohibiting the use of hay and unprocessed grain as supplemental feed for recreation livestock. Limits of acceptable change have been established, as a reference point for initiating closures of heavy-use areas or distributing use to other locations in the wilderness. Campfires are prohibited at many lower elevation, heavy use areas.

Public Information in Wilderness. The use of public information as a mitigation measure can be effective in wilderness. In addition to techniques discussed above (in Recreation Resource), special programs such as "no-trace camping" have proved to be effective in maintaining the wilderness resource.

Fish and Wildlife in Wilderness. Native species of fish and wildlife can be disturbed or destroyed by loss of habitat due to recreation use exceeding carrying capacity and limits of acceptable change (LAC). Species not native to the area also compete for available habitat, thus threatening native species.

Carrying capacity and LAC will be used to regulate use that assures adequate habitat for native species. The Forest Service will also continue to work closely with the Washington Departments of Game and Fisheries in all aspects of fish and wildlife management.

Use of Fire in Wilderness. Aggressive fire suppression actions may alter the natural ecosystems found in wilderness.

To allow fire to play a natural role in shaping vegetative patterns within wilderness, naturally-occurring fires will be permitted to burn in specific areas and under predetermined conditions. Fires will be closely monitored to assure that they continue to burn within those conditions. If the fire burns outside the pre-established conditions, appropriate suppression action will be taken. Considerable research is available on fire behavior and the different parameters that affect that behavior. Forest Service managers also have considerable experience in the use of prescribed fire. This combined research and experience indicate that this mitigation measure will be successful.

The Soil Resource

Some forest management practices have the potential to reduce soil productivity through soil loss, compaction, puddling, changes in soil chemistry, and nutrient loss. Activities that can cause undesirable effects on soils include: timber harvest, road construction, recreation use, and fuels treatment.

The standards and guidelines limit to 20 percent the activity area that can be compacted, puddled, displaced or severely burned. Standards are also prescribed for minimum effective ground cover, both by erosion-hazard class and year after activity. Special considerations - avoidance, smaller projects, more time between activities, use of specialized equipment - are required on and adjacent to soils susceptible to mass movement.

These mitigation measures are based on previous and extensive experience of forest managers and scientists in the field of soil science and hydrology.

The Air Resource

Wildfire and prescribed burning have the greatest potential to cause undesirable effects to the air resource. Suspended particulates introduced into the air reduce visibility. The State of Washington Department of Natural Resources (DNR) administers the State Smoke Management Plan.

> The Forest has established a standard that burning is to be the last resort method of fuel treatment. Good progress has been made in disposing of fuels by utilization of the wood fiber. All prescribed fire is coordinated with the DNR regarding time, location, and volume of material to be burned. In addition, for all wildfires (or prescribed burns if they exceed air quality regulatory standards), a standard has been established that requires suppression.

Under the Federal Clean Air Act (PL 88-206), as amended, the Federal land manager has responsibilities to the State Department of Ecology in the review and approval process involving facilities that may have potential impacts on air quality within Class I areas (wilderness, national parks, etc.). See Chapter III, FEIS, Air and Air Quality section.

> Before the State can grant approval and issue permits, it must have concurrence from the Federal land manager that the emmissions from the proposed facility, as mitigated by the permit requirements, are within acceptable limits and will not adversely affect the Air Quality Related Values, such as visibility, vegetation, water quality, etc. of the Class I areas under Federal jurisdiction.

The Water and Riparian Resource

Forest Management activities have the potential to affect water quality and the adjacent riparian zone. Activities that introduce sediment into the water, change water temperature or chemistry, alter water flows, or change timing of runoff can be detrimental to water quality (and to municipal and industrial use, fish habitat, recreation, and energy production). Changes to streambank stability or to riparian vegetation shading the stream can adversely affect habitat for fish and wildlife.

> Meeting management requirements for water quality and riparian areas (through the procedure developed in the hydrologic cumulative effects analysis) ensures that, along with the mitigation provided by the standards and guidelines, management activities prescribed in the Forest Plan do not result in unacceptable adverse effects on water quality and quantity.
>
> Special attention must be given to management activities within about 100 feet of perennial streams and bodies of water, or at least the area dominated by riparian vegetation. Inventories are not available for the riparian vegetation zone, but during project design, these areas will be identified and mapped. Interdisciplinary team specialists will consider soil, topography, vegetation, climate, and management objectives in specifying the special measures needed to prevent the detrimental damages. Measures that may be used include: avoidance of the riparian area, stream clean out, individual tree marking, directional falling, yarding away from the stream, full suspension of logs, seasonal restrictions on use, and site

hardening or rotation of recreation sites. These mitigation measures have proved effective in past forest management activities.

Standards are included for Class I, II, and fish-bearing Class III streams that state the maximum stream temperatures allowed, to avoid and/or minimized effects on fish.

Implementation of the State Water Quality Plan on lands administered by the USFS is described in a Memorandum of Understanding (MOU) between the Washington State Department of Ecology and the U.S. Department of Agriculture, Forest Service (1979), and in "Attachment A", referenced in the MOU, the Implementation Plan for Water Quality Planning on National Forest Lands in the Pacific Northwest (USDA 1978a). These provide the basis for the interagency agreement whereby the Governor of the State designates the Forest Service as the designated management agency for nonpoint source pollution control on lands under its jurisdiction. The agreement provides for annual meetings between Pacific Northwest Region, Forest Service and DOE to evaluate the program and progress being made and provides the basis for recertification by the Governor.

Available monitoring information is reviewed, revisions or additions to the BMP's are addressed, progress on problem identification and treatment is provided, and reports are written and submitted by the State to the Environmental Protection Agency.

Water Quality Regulations for waters of the State of Washington (Washington Administrative Code Chapter 173-201 WAC) are met through application of Best Management practices (BMP's). The key beneficial uses which BMP's are designed to protect are fish and water for domestic use.

Diversity and Long-term Productivity

Forest management activities have the potential to affect the diversity of plant and animal communities and impact the long-term productivity of forest resources.

In all forest management activities, the management requirement of diversity and long-term productivity will be met. Management area prescriptions plus the Forest-wide standards and guidelines address evaluation of opportunities to maintain or enhance stand, sub-basin, and Forest level components of diversity; provide for a ecologically sound distribution and abundance of plant and animal communities; and maintain large woody and small fine materials on the ground, plus standing dead and green trees (at varying levels, by alternative). Soil productivity and other elements will be monitored to determine the effectiveness of standards and guidelines.

The Wildlife Resource

Viable Populations of Wildlife Management Indicator species. A wide variety of Forest management activities that involve vegetative manipulation have the potential to adversely affect wildlife habitat, and in turn, directly affect wildlife populations. Activities include: timber harvest, fuels management, recreation development, road and trail construction, and water impoundments or diversions.

Wildlife habitat areas have been established to maintain at least a viable population of selected management indicator species (whose habitat is considered limiting). Data necessary to establish numbers and sizes of habitat areas, distribution, and habitat requirements (such as time of year used) for each species have been identified, based on research, available literature, and the experience and judgement of knowledgeable professionals. Sources include: Westside Habitat Relationships (in press), and Pacific Northwest Region Management Requirements for Wildlife, MR Report. Habitat areas will be monitored to determine their effectiveness in maintaining viable wildlife populations.

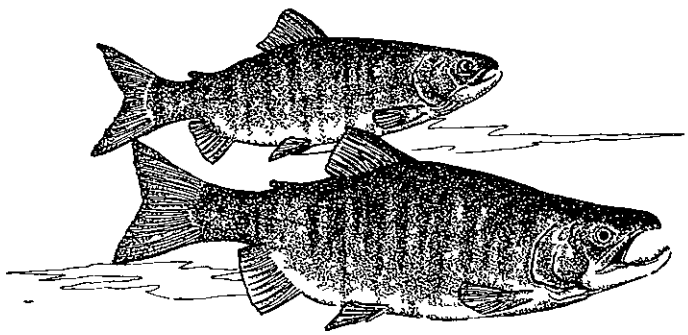
Forest-wide standards and guidelines state minimum levels of live and dead trees, snags, and large, dead and down logs to meet habitat needs.

The Fish Resource

Forest management practices, if conducted improperly, have the potential to cause environmental damage to fisheries habitat. Increases in water temperature, sedimentation, turbidity, loss of aquatic food sources, changes in water chemistry, and physical or velocity barriers to fish migration are examples of effects to fish habitat most commonly associated with forest management practices.

The Clean Water Act as amended by the Water Quality Act of 1987 sets forth a concept of Best Management Practices (BMP's). In part, it is designed to maintain existing populations of both resident and anadromous fish; fisheries habitat will be managed under this concept. It is covered under a 1979 Memorandum of Understanding between the Washington State Department of Ecology and the Forest Service. The implementation of BMP's is detailed in an Implementation Plan for Water Quality Planning on National Forest Lands in the Pacific Northwest (USDA 1978a). The effectiveness of BMP's is periodically reviewed by Environmental Protection Agency, Washington State Department of Ecology, and by Forest Service professionals to insure that application of BMP's is providing the desired results.

In addition, meeting management requirements for water quality and riparian areas, plus the Forest-wide standards and guidelines will benefit in-stream uses, including fish and fish habitat.



Threatened, Endangered, and Sensitive Species

The Endangered Species Act requires Federal Agencies to ensure that their proposed actions do not jeopardize the continued existence of any threatened or endangered (T&E) species or result in the destruction or adverse modification of their critical habitat. Recovery Plans are developed by an inter-agency team of experts and are designed to identify those actions necessary for the eventual delisting of the species from the Federal Threatened and Endangered species list.

When activities are proposed on National Forest lands that are likely to affect T&E species or their critical habitat, consultation with U.S. Fish and Wildlife Service is initiated. Threatened and endangered species habitat has been mapped (where information is available) and, for known habitat, special habitat management areas have been established. Management direction, designed to maintain or improve this habitat, has been developed. The direction is based on Guidelines developed by the U.S. Fish and Wildlife service. Additional habitat necessary to meet the recovery objectives identified in the Recovery Plan has also been identified and is managed using the same guidelines.

When management activities may affect the habitat of a Forest Service sensitive species, a biological evaluation will be completed (Forest Service Manual 2670); habitat for sensitive plants and animals will be managed to ensure that management activities do not contribute to these species becoming threatened or endangered.

The Timber Resource

Management of stands of trees for timber production has the potential to result in undesirable environmental and fluctuating economic effects.

Non-Declining Flow. Widely fluctuating levels of timber sales offered from the National Forest may result in economic hardship to the wood products industries, and can also result in increased consumer prices for timber products. Congress has determined (in the 1976 NFMA) that a relatively even, sustained flow of timber in perpetuity is appropriate public policy for National Forest lands. Congress also recognized that variance (departure) from this non-declining flow policy is appropriate under some circumstances if it meets the overall multiple-use objectives of the plan.

The timber harvest level of the alternatives in this FEIS is determined based on a policy of non-declining flow. Departure was examined in two alternatives developed in detail in the DEIS.

Rotation Lengths. Cutting trees for timber can occur at any time after they reach an age (or size) the tree can be utilized for commercial products. Harvesting very young trees can result in undesirable environmental effects on other resources such as scenery, fish and wildlife habitat, soil productivity, and water quality, or result in harvest of trees too small to be used for boards or plywood.

Timber harvest levels for all alternatives are calculated on the basis that for final harvest, trees will have at least reached 95% culmination of mean annual increment (see glossary). Rotation lengths are longer where other

resources requirements (such as visual corridors, wildlife and fish requirements, and protection of riparian values) permit harvest of trees but require larger sized trees. These rotation lengths are specified in the standards and guidelines for specific management areas.

Regeneration Assurance. Some stands of trees grow under environmental conditions where, if harvested, regeneration of a new stand of trees is difficult or impossible under existing technology. Serious adverse effects to wildlife habitat, scenery, water production and soil productivity could occur if these areas were harvested but not regenerated.

To mitigate these potential adverse effects, a standard has been established that prohibits the cutting of trees for timber production purposes unless there is reasonable assurance that the harvested stands can be reforested within five years.

Created openings. Too large openings in stands of trees, from even-aged harvest methods (such as clearcutting) can cause undesirable environmental effects on wildlife habitat, scenery, water quality, and reforestation success.

A standard has been established to limit the size of harvest units to 60 acres in the Douglas-fir type and 40 acres for other forest types; in the Pacific silver fir zone, units must be less than 40 acres. Exceptions are permitted for catastrophic events such as fire, windstorm, and insect or disease attack. These size-of-opening standards are somewhat arbitrary, so the environmental effects produced will be monitored during implementation of the Forest Plan and recommendations for change will be initiated when warranted.

Suitable lands. Cutting trees for timber production on all lands that support stands of trees could result in adverse environmental effects. Some stands of trees have been assigned, by higher authority, to uses that prohibit timber harvest. Some lands have been assigned to activities where cutting trees is not compatible; other lands have physical or environmental conditions where harvest would result in unacceptable results. A process to classify all lands as to their suitability for timber production has been developed.

All lands that are less than 10% covered by trees are excluded, as are all lands classified by higher authority to a use that prohibits tree cutting, such as wilderness and research natural areas. Lands being used for roads, administrative sites, and utility corridors are also removed. Those lands where soil stability is such that cutting of trees would result in a two-fold increase in mass soil movement, 75% of the time, are classified as not suitable for timber production. Also removed from timber production are those lands which are so rocky or have soil that is so thin that a new stand of trees could not be re-established.

The result of these exclusions is a land base called tentatively suitable for timber production. Only lands that are tentatively suitable are eligible for assignment to a timber harvest prescription. An economic screen of tentatively suitable lands is made during the determination of outputs from the alternatives. The linear program FORPLAN seeks a "solution" for each alternative that maximizes PNV. Those lands not selected for assignment to a timber production prescription because they do

not contribute to a maximum PNV solution are also dropped out of the suitable land base for that particular alternative.

The Mineral Resource

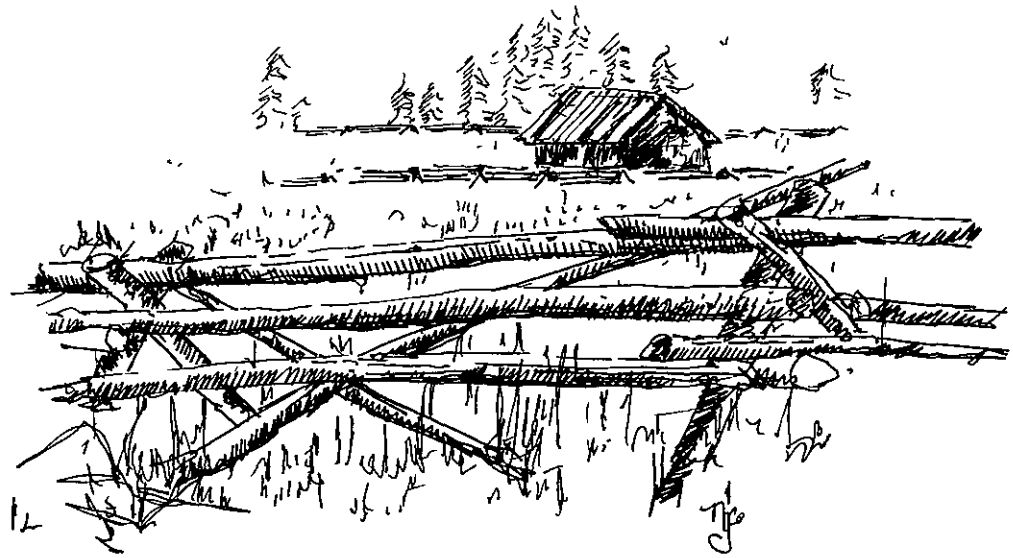
Management of mineralized areas for mining and energy development can potentially result in undesirable environmental effects.

When mining activities are proposed on National Forest lands, appropriate environmental analysis will be conducted to determine the stipulations necessary for the protection of other resources.

Processing and administration of all mineral, oil and gas and geothermal leases, exploration proposals, and development proposals will be in accordance with State and Federal rules, regulations, and standards.

All activities which involve significant disturbance of the surface resources require a notice of intent and/or an operating plan that must be submitted and processed in accordance with 36 CFR 228. Based on an environmental analysis prepared by the applicant, the Forest Service efforts will be directed toward minimizing adverse environmental impacts on the surface resources and toward reclaiming the site. Approval will be given when the Forest Service concerns are mitigated in a responsible and responsive manner.

Operations will be inspected periodically to ensure compliance with approved operation plans. Applications for patent will be investigated and contested when validity determinations reveal invalid claims. Questionable occupancy of mining claims will be investigated and contested where necessary.



F. COMPARISON OF ALTERNATIVES

The purpose of Forest Planning is to identify and select for implementation the alternative that most nearly maximizes net public benefits, while responding effectively to all the ICO's. Net public benefits are defined as the..."overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not - consistent with the principles of multiple use and sustained yield" (36 CFR 219.3).

There is no mathematical formula available to select the preferred alternative. In fact, there are differences of opinion about whether particular effects of alternatives are positive or negative. Therefore, it is necessary to separately identify all the major effects of each alternative as the basis for review, judgement, and an eventual selection.

The following pages summarize, in tables and narrative, the outputs and effects of the alternatives. Alternatives are presented in a manner that allows detailed comparison. Elements presented include:

1. Management Areas - the descriptions - also see the packet of maps;

2. Alternatives At A Glance - figures that graphically compare the outputs activities and uses of the alternatives;

3. Comparison of Resource Outputs, Inputs, and Environmental Effects - a detailed series of tables showing the inputs, yield, and effects of various resources and activities, by alternative; and

4. Economic Tradeoffs Among Alternatives - additional comparisons.

1. Management Areas

Multiple use management will continue to be the overall means of achieving goals of the Mt. Baker-Snoqualmie National Forest. In each alternative, every acre of the Forest will be assigned to a single management area (MA). Management areas are areas of the Forest to which a set of management practices, standards, and guidelines apply. One or more uses may be emphasized in a management area, but management for many other compatible uses will occur in every management area.

On the following pages, two tables show the acres assigned to each management area, by alternative. MA's are identified by a number or number/letter, plus a short descriptive title. The letters are various "intensities" of a broader management area. An example is Management Area 1 **Dispersed Recreation.** The intensities are **1A, 1B, 1C, 1D, 1E,** and **1F;** these are all types or intensities of dispersed recreation, but each has somewhat different management practices, standards, and guidelines. Some management areas, such as **4, 8,** and **19,** have only one intensity.

Note that the title, or descriptive phrase for each MA shows the emphasis of the management area. The section following Tables II-8 and II-8a includes a brief description for each MA (the management practices, standards, and guidelines).

The Management Areas used in the Preferred Alternative (Alternative J) are described in detail in the Forest Plan. Refer to Appendix D, FEIS for the descriptions of all the other MA's or intensities of MA's not used in the Preferred Alternative.

Management Areas and the Maps

Although the number of acres assigned to a management area may be quite similar in different alternatives, the location of those acres may vary by different alternatives. The alternative maps accompanying this FEIS show the on-the-ground location of management areas in each alternative.

Where compatible uses occur, the acres have been assigned and mapped to the set of management practices, standards, and guidelines that cover management for both uses. For example, an area assigned to nonmotorized recreation emphasis (1A or 1B) may also be capable of providing old-growth wildlife habitat (11). In this case, the MA mapped would be 1A or 1B, not management area 11 because old-growth habitat has been "over-ridden" by a management area that is more restrictive, primarily in terms of the appropriateness of road construction. (Roads cannot be built in 1A or 1B; they may be constructed through MA 11.)

In Table II-8, note that the acres for the wildlife MR's (MA 11, 12, 14, and 15A) vary among the alternatives. This is primarily due to "overrides." For example: in Table II-8, Alternative C shows the fewest acres in MA 11 Old Growth Habitat of any alternative, yet C has a goal of emphasizing wildlife habitat. Old-growth habitat is provided at the highest level in Alternative C, but many acres of old growth were assigned to Management Area 1A or 1B, which provide for both wildlife habitat and nonmotorized recreation. The output tables later in this chapter (Tables II-9a through II-9o) help show the differences among alternatives. Also, refer to the Wildlife Resource map.

Alternative NC (No Change)

No Management Areas are assigned in Alternative NC (No Change). However, indirect comparisons between Alternative NC and the other alternatives can be made. This must be done understanding that the 1963 Timber Management Plans, as amended, stratified lands by their availability and suitability for timber harvest, while land in the other alternatives is stratified by its suitability for timber harvest and management strategies, which when combined, equate to Management Areas. Table II-8a provides an indirect comparison of Alternative NC with the other alternatives.

The Order of the Alternatives

In Table II-8 and the tables that follow in this chapter, the alternatives are not arranged alphabetically (A, B, C etc.) but are displayed, from left to right, in order of decreasing acres of land suitable for timber production. This order is useful in understanding how the environmental consequences and effects will vary by alternative. The sequence is strongly correlated to the amount of vegetative management in alternatives. See additional discussion in part 3. Comparison of Resource Outputs, Inputs, and Environmental Effects, page II-75.

1/ Total acres in each alt vary due to rounding MA 9 not used, MA 24 Min Mgt not assigned in any alternative

2/ Applies only to Alt A, includes mostly unroaded, but some roaded recreation, from exisitng Multiple Use Plans

3/ Parcels of the 1926 area that remain outside of wilderness and the Mt Baker NRA are included here

4/ Acres are protected, at varying levels in the alternatives but not shown to protect confidential nature

5/ Includes Cultural-Historic, Geologic, Biologic, Botanic, and Scenic Special Areas

6/ Many acres of riparian zone fall within other MA s and are protected through those management prescritptions

7/ Management Areas 16B Grizzly Bear, 16C American Peregrin Falcon and 16D Gray Wolf have no acres assigned at this time, because no specific habitat has been identified or evaluated

8/ Acres of existing or proposed RNA located within wilderness are included in MA 10 not here

9/ These acres overlap other MA's

10/ Includes acres within the congressionally designated Alpine Lakes Management Unit that are not otherwise assigned to other, compatible management areas (Compatible MA's include 5, 11, 12, 14 15, and 16)

Management Area Descriptions

1 Dispersed Recreation

1A Primitive. The goal of this management area is to provide dispersed recreation opportunities in a primitive ROS setting. Natural habitat for wildlife is also provided. Areas are remote (generally 3 miles from roads) with low concentration of users. No ORV use. The visual quality objective is preservation. No scheduled timber harvest and no roads. The only exception is salvage harvest of catastrophic forest loss for the purpose of limiting further loss; any temporary roads needed for this salvage will be returned to near-natural condition.

1B Semi-Primitive Nonmotorized. The goal of 1B is to provide dispersed recreation opportunities in a semi-primitive ROS setting. Very similar to 1A. Differences include: areas are generally one-quarter to 3 miles from roads. *Snowmobile use is permitted in some areas. The visual quality objective is* retention. As discussed above, no scheduled timber harvest or road construction except to salvage catastrophic loss.

1C Semi-Primitive Motorized. Somewhat similar to 1A and 1B, the goal of this management area is to provide dispersed recreation opportunities in a semi-primitive motorized setting. Areas are generally one-quarter to 3 miles from roads. Dispersed ORV use is permitted. Seasonal ORV closures may be used to protect wildlife or other resources. The visual quality objective is partial retention. As discussed above, only salvage of catastrophic forest loss is permitted; no scheduled timber harvest.

1D Roaded Natural. The goal of this MA is to provide a variety of dispersed recreation uses in a roaded natural setting; natural habitat for wildlife is also provided. Timber harvest is permitted, with silvicultural prescriptions designed to meet MA goals. Longer rotations are scheduled to meet visual quality objectives, which are partial retention along sensitive travel routes, and range from partial retention to modification elsewhere.

1E General Dispersed Recreation. This prescription is used only in Alternative A (No Action). Areas outside of wilderness managed primarily for roadless, dispersed recreation, but some roaded dispersed use, including ORV's, may occur. Natural habitat for wildlife is provided. No scheduled timber harvest is planned, though it is permitted on tentatively suitable lands where MA goals can be met. Any timber volume removed is nonchargeable.

1F Mt. Baker Recreation Area (1926). Includes the remaining parcels of the Mt. Baker Recreation Area, established in 1926, a total of about 6,005 acres. This prescription is used only in Alternative A (No Action). Area managed primarily for recreation and scenic values while also providing natural wildlife habitat. Timber harvest is permitted, however no scheduled harvest is planned and any volume cut is nonchargeable.

2 Scenic Viewshed

2A Foreground. The goal of this management area is to provide a visually appealing foreground landscape as viewed from major travel corridors and use areas, and to provide for recreation, wildlife, timber production, and water resources. The visual quality objective ranges from retention to partial retention. A diversity of tree species and age classes is maintained, with timber managed at less than full yield (about 65% of full yield).

2B Middleground. Similar to 2A, this management area includes the middleground area of visually sensitive landscapes viewed from major travel corridors and use areas. Differences include: visual quality objective ranges from partial retention to modification. A diversity of tree species and age classes is maintained through timber harvest scheduling. Timber harvest yield will be about 86% of full yield.

3 Developed Recreation

3A Public Sector Developed Sites. Includes existing areas such as campgrounds, day-use sites, trailheads, and boating and swimming areas. The purpose is to provide a wide variety of year-round recreation opportunities. Visual quality objectives range from preservation to partial retention. Any silvicultural activities shall meet recreation objectives and reduce risk of public injury. Any incidental timber volume removed is nonchargeable.

3B Potential Recreation Sites. The goal of 3B is to manage potential developed recreation sites to protect their value for future development and use. Potential areas include a full range of recreation sites, as listed in 3A. Management is very similar to that in 3A.

3C Winter Sports Resorts. Included are developed winter sports areas, located at a few selected sites throughout the Forest, that are managed through special use permits. These areas offer alpine and nordic skiing, and snowplay in winter, and horseback riding, tennis, day-use, and other activities in the summer. No timber harvest permitted, except to maintain an attractive, safe setting, or to clear areas for ski runs or other improvements. Any timber volume removed is nonchargeable.

3D Private Sector Sites. Included are organization camps, concession sites, and recreation residences located at a few selected sites. They are operated by the private sector on National Forest land under a special use permit. The goal is to plan and administer these areas to provide suitable, safe, and attractive sites. Any silvicultural activities shall meet recreation objectives; any volume removed is nonchargeable.

4 Mt. Baker National Recreation Area (1984)

The emphasis of this 8,743 acre management area is high-elevation, dispersed recreation and conservation of scenic, natural, historic, and other values. Winter season management emphasizes uses such as snowmobiles and nordic skiing; nonmotorized recreation is emphasized in the summer season. There is limited acreage suitable for timber production; all silvicultural practices are permitted, but long rotations are required to meet visual quality objectives of retention to partial retention. Timber yields are about 70% of full yield.

5 (5A, 5B, 5C) Recommended Wild and Scenic Rivers

The goal is to protect from degradation the outstandingly remarkable values and wild, scenic, and recreational characteristics of rivers and their environment. A suitability analysis, when completed, determines whether a potential river qualifies for inclusion in the National Wild and Scenic River system, and if so, as a Recreation, Scenic, or Wild River. Management activities are most restricted in 5C Potential Wild Rivers, and less restricted in 5A Potential Recreation Rivers, and 5B Potential Scenic Rivers. Timber management is at less than full yield to meet visual quality objectives in 5A and 5B. Timber harvest is not normally permitted in 5C; any volume removed is nonchargeable.

6 Skagit Wild and Scenic River

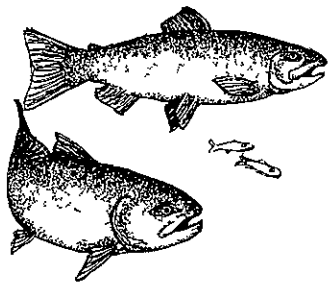
This management area includes the Skagit Wild and Scenic River System: 158.5 miles of designated portions of the Skagit, Cascade, Sauk, and Suiattle Rivers. The area totals 38,939 acres; about 44% are National Forest lands. The area is managed in accordance with the Skagit River Final Management Plan, Volume II, 1984. Management emphasis is to maintain or enhance the characteristics and outstandingly remarkable values for which these rivers were classified. Timber yields are about 65% of full yield.

7 American Indian Religious and Cultural Use Areas

The goal is to make available and protect environmental conditions and resources important to American Indians for religious and cultural uses. Included are all areas identified in the 1981 Inventory of Native American Religious Use, Practices, Localities and Resources. Consultation will be undertaken with the affected Tribes(s) for all projects falling within identified religious and cultural use areas. If adverse effects are found, mitigation measures may be developed through the consultation.

8 Special Areas

Includes areas with unique scenic, historic, biological, botanic, or geological features. Management emphasis is to protect and, if appropriate, foster public use and enjoyment of these areas. The visual quality objective is retention or preservation. Roads, trails, ORV use, and any facilities may be permitted, if they meet objectives of areas. Maintenance and habitat improvement for watchable wildlife or fish is emphasized. No scheduled timber harvest; any incidental volume harvested is nonchargeable.



10 Wilderness

Wilderness includes lands in the following designated wildernesses: Glacier Peak, Mt. Baker, Noisy Diobsud, Henry M. Jackson, Boulder River, Clearwater, and Norse Peak. See MA 27 for Alpine Lakes Wilderness.

The goal of wilderness management is to feature naturalness, provide opportunities for solitude, challenge, and inspiration, and - within these constraints - allow for recreation, scenic, scientific, educational, conservation, and historic uses.

No timber harvest or road construction is permitted. The visual quality objective is preservation. Refer to the Forest Plan, Management Prescriptions, for the specific standards and guidelines.

A number of management uses or emphases are compatible with wilderness, including (but not limited to): American Indian religious and cultural uses; old-growth and mature and old-growth habitat emphasis; deer, elk, and mountain goat winter range; and Research Natural Areas. Where these uses occur, or "overlap" wilderness, the acres will be assigned to wilderness, and on the maps, shown as "10" wilderness.

The total acres assigned to MA 10 will be the same in all alternatives; the acres within the five wilderness intensities discussed below will vary by alternative.

10A Transition. Transition areas within wilderness, in close proximity to popular trailheads and heavily-used trails entering wilderness. Typically, this is the day-use area of the wilderness. Frequent encounters with other users.

10B Trailed. Includes most of the system trails extending beyond the transition class. Visitors must be prepared for overnight camping. Less frequent encounters with other users.

10C General Trailless. No system trails, though some user-made trails may exist. It is characterized by a lack of attractions or destination spots, therefore, there are very infrequent encounters with other users.

10D Dedicated Trailless. These areas are not trailed and will be managed forever trailless. User-made trails are not permitted. Outstanding opportunities for isolation, solitude, and lack of evidence of humans. Cross country travel with very infrequent encounters with others.

10E Special Areas. These include Congressionally acknowledged areas, areas of significant cultural or historic value, areas with special wildlife considerations, and areas with limited management options. Special areas are unique and may not be found in all wildernesses.

11 Old-Growth Habitat (Spotted Owl)

Spotted Owl Habitat Areas (SOHA's). The goal of this MA is to provide and maintain old-growth forest ecosystems as habitat for wildlife species that depend upon or utilize old growth for a significant portion of their habitat. No motorized off-trail use. Road and trail construction may be permitted outside of the core area if habitat objectives can be met. No scheduled timber harvest. Catastrophic tree loss, which results in the area no longer being suitable habitat, may be salvaged as nonchargeable volume under certain conditions. The oldest adjacent stand replaces the acreage salvaged.

12 Mature and Old-Growth Wildlife Habitat (Pine Marten, Pileated Woodpecker)

The goal is to maintain mature and/or old-growth forest ecosystems for those species (such as pine marten and pileated woodpecker) that depend on or utilize such forests for a significant portion of their habitat. Road construction is permitted if objectives for the MA can be met. No scheduled timber harvest. Catastrophic loss, which results in the area no longer being suitable, may be salvaged as nonchargeable volume under certain conditions. The oldest adjacent stand replaces acreage salvaged.

13 Watershed, Wildlife, and Fisheries Emphasis in Riparian Areas

The goal of this MA is to maintain or improve water quality and to produce various levels of potential habitat capability for various species of fish within designated riparian areas. Also, maintain or enhance habitat for riparian associated wildlife species. A broad range of recreation permitted, while maintaining riparian resource values. Minimize activities that cause ground or water channel disturbance. These areas support a diversity of plant species and contain a variety of resource values: water, fish and wildlife habitat, and productive soils. Hardwood trees are common; there is a variety of ages of vegetation, including dead trees, standing and down. All silvicultural practices are permitted, with the objective of maintaining or improving riparian habitats. There is a variety of rotations, from extended rotation (160+ years), to normal rotation, to no-harvest, due to unstable soils or to maintain or improve riparian and aquatic habitats. Small harvest units will be widely distributed. Timber is managed at about 63% of full yield.

13A Management Requirements. The goal of this MA is maintain or improve riparian and aquatic ecosystems and maintain anadromous and resident fish at Level I (existing, MR). Requires the lowest investment to implement.

13B Level II Anadromous, Existing Resident Fish Habitat Capability. The goal of 13B differs from 13A in the special emphasis on rehabilitation or restoration of lost or degraded anadromous fish habitat. Anadromous fish habitat capability is increased to Level II, requiring a moderate investment level. Existing resident fish habitat capability is maintained.

13C Level III Anadromous, Existing Resident Fish Habitat Capability. In 13C, natural and degraded anadromous fish habitat is enhanced to Level III, requiring a high level of investment to implement. Existing resident fish habitat capability is maintained.

13D Level III Anadromous, Potential Resident Fish Habitat Capability. In addition to the goals of 13C, this MA emphasizes resident fish as well as anadromous. Natural and degraded habitat is enhanced, requiring a high level of investment.

14 Deer and Elk Winter Range

The goal for this management area is to provide improved winter range habitat for deer and elk. Improvement of the range is emphasized. A variety of improvement techniques are used, including planting desirable forage species, fertilization, thinning, and design of timber harvest units, with emphasis on a distribution and specified ratio of habitat types for forage, thermal/hiding cover, and optimal thermal cover. Seasonal road closures and restrictions on other activities are used. Timber harvest is scheduled to first, meet optimal thermal cover acreage; if met, then schedule harvest to meet forage requirements. Timber yields will be about 85% of full yield.

15 Mountain Goat Habitat

15A Management Requirements. The goal of this management area is to provide habitat, including winter range, for a viable population of mountain goat. Habitat includes some mature and old-growth forest, steep rocky cliffs, pinnacles, ledges, and talus slopes. Seasonal restrictions on ORV's are used. No new road constructed to access winter range; road closures may be used. No scheduled timber harvest. Any salvage of catastrophic timber loss shall be designed to maintain mountain goat habitat; any salvage volume is nonchargeable.

15B Emphasis on Habitat Improvement, Mountain Goat. This MA is similar to 15A but improvement of the mountain goat habitat is emphasized. ORV, trail, and recreation use, plus road use and construction are seasonally restricted. Road closures may be necessary. A variety of goat habitat improvement techniques, such as prescribed fire to increase forage, will be used. A maximum of 5% per decade of suitable lands may be harvested. Small, long, and narrow timber harvest units will be encouraged. Harvest is seasonally restricted to avoid conflict with goat habitat use. Timber yields will be about 70% of full yield.

16 Threatened and Endangered Species

For all intensities: the goal is management of existing habitat to provide for the long-term needs of the species, plus identification of potential habitat and management to enhance long-term viability of the species consistent with recovery objectives and for eventual delisting.

There are four threatened and endangered species: Northern bald eagle, grizzly bear, American peregrine falcon, and gray wolf. Large numbers of bald eagles winter on the Forest; one active nest site is known. Most sightings of grizzly bear have been in the Glacier Peak Wilderness, where management direction is compatible with protection of habitat and consistent with the Grizzly Bear Recovery Plan. The American peregrine falcon is an infrequent visitor; there are no areas on the Forest known to have been recently inhabited. Habitat for the gray wolf has not been identified or evaluated.

16A Northern Bald Eagle. Included as dedicated habitat are one existing and two potential nest sites, and two communal roost sites. There are additional acres of existing and potential feeding habitat that are managed for the eagle but assigned to MA's 13, 6, and perhaps others with compatible management direction. There is no scheduled timber harvest in dedicated areas. Timber yields in the managed portion of the eagle habitat will vary. Specific restrictions apply to almost all Forest activities in the dedicated areas. Some activities are prohibited, others are restricted, either by season or distance from the nest or roosting area. Some restrictions also apply to managed areas.

16B Grizzly Bear. Proposed timber harvest and other activities in or near potential grizzly bear habitat will be evaluated for their effects. Developed and dispersed recreation use will not degrade important potential habitat. No acres have been assigned to 16B at this time.

16C American Peregrine Falcon, and 16D Gray Wolf. No specific habitat has been identified or evaluated; no acres are assigned at this time. Meet Forest-wide Standards and Guidelines, Threatened, Endangered, and Sensitive species direction if use is discovered.

17 Timber Management Emphasis

For all intensities: the goal is to provide for the production of timber products on suitable lands. Also provided: unroaded and roaded dispersed recreation, including ORV use, opportunities for gathering firewood, and other forest uses. A number of large dead and down logs, plus live and dead trees will be left for primary cavity excavators; exact numbers vary by alternative. Wildlife and fish habitat enhancement may be permitted if timber production is not impaired. A number of silvicultural practices will be applied, including clearcutting, thinning, and planting. Timber harvest is full yield.

There are eight intensities in MA 17. The one selected for any acre assigned to MA 17 will vary with site productivity, timber type, accessibility by road and other objectives. Intensity 17H (plant, precommercial thin, option for three commercial thinnings, final harvest, genetic stock, and extended rotation) will actually be applied in other MA's (such as Scenic Viewshed), to meet specific objectives.

17A Natural Regeneration - Final Harvest. Natural reforestation is supplemented by planting to meet Forest minimum stocking standards. This is a minimum investment intensity.

17B Natural Regeneration - Precommercial Thinning - Final Harvest. Reforestation is natural, supplemented by planting to meet Forest minimum stocking standards. Precommercial thinning is planned. Release, growing stock protection measures, and fertilization may be prescribed. This intensity may be applied to existing reforestation condition classes. There are no location or species constraints.

17C Plant - Final Harvest. Reforestation is by planting. Release and growing stock protective practices may be prescribed.

17D Plant - Final Harvest - Genetic Stock. Reforestation is by planting, using genetically improved stock when available. Release and growing stock protective practices may be prescribed.

17E Plant - Commercial Thin (1) - Final Harvest - Genetic Stock. Reforestation is by planting, using genetically improved stock when available. Release, growing stock protection measures, and fertilization may be prescribed. Commercial thinning harvest is planned 10 to 20 years before regeneration (final) harvest. MA 17E may be applied to stands that have not been precommercially thinned. Commercial thinning permitted in timber stands accessible by road, in which 50% of the trees are Douglas-fir.

17F Plant - Precommercial Thin - Final Harvest - Genetic Stock. Reforestation is by planting, using genetically improved stock when available. Precommercial thinning planned. Release, growing stock protection measures, and fertilization may be prescribed. This intensity may be applied to existing reforestation condition classes. There are no location or species constraints.

17G Plant -Precommercial Thin - Commercial Thin (1) - Final Harvest - Genetic Stock. This intensity is designed to obtain the maximum timber production possible while meeting the Forest-wide and Management Area Standards and Guidelines. Every applicable approved practice should be used to increase production. Reforestation is by planting, using genetically improved stock when available. Precommercial thinning is planned; commercial thinning is permitted, as in 17E. This intensity may be applied to existing reforestation condition classes. Maximum rotation length is at the age volume production is equivalent to 100% culmination of mean annual increment (see Glossary).

17H Plant - Precommercial Thin - Commercial Thin (3) - Final Harvest - Genetic Stock - Extended Rotation. This intensity is designed to produce and maintain a portion of managed stands with a good range of large to very large trees, to meet visual quality requirements or other resource objectives. The basic rotation length is 200 years, with three intermediate thinning harvests; however, different rotation lengths may be prescribed. Reforestation is by planting. Precommercial and commercial thinning at 30 year intervals are planned. Release, growing stock protection practices, fertilization, or planting genetic stock may be prescribed. This intensity may be applied to existing reforestation condition classes.

18 Research Natural Areas

This management area includes existing Research Natural Areas and those proposed for designation as part of the Research Natural Area Program. The goal is to reserve typical or distinctive natural ecosystems for scientific and educational use. Management directed toward perpetuating natural processes, protecting natural features, and preserving naturally-occurring ecosystems in an unmodified environment. Only authorized scientific research and educational uses allowed. Recreation activities not encouraged. Existing use and trails will be allowed as long as they do not degrade the qualities for which the area was established. No scheduled timber harvest.

19 Mountain Hemlock Zone

The goal of this management area is to provide an opportunity for administrative study of regeneration harvest techniques within the Mountain Hemlock Zone. Acres assigned to MA 19 are located on the Mt. Baker, Darrington, and Skykomish Ranger Districts; the primary overstory species is mountain hemlock. These areas have been classified "not suited" for timber harvest because there is no reasonable assurance they can be reforested within 5 years after final harvest. A total of 250 acres of this management area may be harvested (in 25 plots of approximately equal size) to test various silvicultural systems to determine what portion of mountain hemlock forest can be successfully reforested, and thus returned to the tentatively suitable land base. Any timber harvested is nonchargeable. No new system roads constructed.

20 Cedar River Municipal Watershed (City of Seattle)

For all intensities: the goal of this management area is to provide municipal water for the City of Seattle at a level of quantity and quality that, with adequate treatment by the purveyor, will result in a satisfactory and safe water supply. The watershed contains 90,495 acres, with National Forest land intermingled with City of Seattle and private lands. Intensities 20A, 20B, 20C, and 20D apply to the National Forest lands.

20A Current Direction, Exchange NF Lands to City of Seattle. The goal of 20A is continuation of the current direction, defined in the 1962 Agreement with the City of Seattle. Management emphasis is timber production to the extent the water quality goal is met. Recreation use is limited; City and private lands are closed to public use, with no road access to interior NF parcels. No specialized wildlife habitat areas are left for old-growth dependent species. The long-term objective is exchange of all NF lands to the City to consolidate NF holdings elsewhere. All mature timber on available commercial land will be sold within about 30 years; land exchanges, about every 5 to 10 years, will occur after the timber is harvested. The entire watershed will be owned by the City of Seattle in about 35 years. Timber harvest on suitable lands is full yield, using the minimum investment intensity: 17A.

20B Exchange NF Lands, City of Seattle Maintains Old Growth Habitat. The goal of 20B is similar to 20A with one major exception. Habitat for old-growth dependent species necessary to meet viable population levels will be identified; these lands would then be exchanged to the City, with the stipulation that the old growth be maintained. Land exchanges of other NF lands will proceed as in 20A, after the old growth harvest. If a designated habitat area is destroyed (from blow down, etc.), the land exchange process will be halted until a suitable substitute area is acquired by the City, if available. Timber harvest will occur at a faster rate, though fewer acres will be harvested than in 20A, due to old-growth habitat areas. The watershed will be owned by the City in about 25 years. Timber harvest is full yield, using the minimum investment intensity, 17A.

20C Retain NF Lands, Maintain Old Growth Habitat. The goal of this management area is very different from 20A and 20B. There will be no further exchange of NF land; the Forest will pursue acquisition of public rights on roads leading to NF lands within the watershed. All other conditions of the 1962 Agreement remain in effect. Dispersed day-use recreation is emphasized.

No ORV's and water-related recreation is discouraged. Wildlife habitat for old-growth dependent species will be maintained. Timber management is emphasized on suitable lands not maintained as wildlife habitat, and to the extent the water quality goal is met. Timber harvest is full yield, using all investment intensities, 17A through 17G.

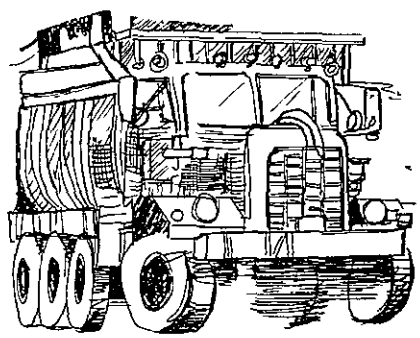
20D Negotiate a new Cooperative Agreement. The Forest Service will initiate negotiations on a new Cooperative Agreement between the City of Seattle and the Forest Service to reestablish goals and objectives for management of the watershed. Until a new agreement is negotiated, the Forest Service will not enter into new land exchanges affecting National Forest lands within the watershed. Pending a new agreement, the 1962 Cooperative Agreement will remain in effect. When a new agreement is reached, the Forest Plan will be amended to incorporate its goals and objectives.

21 Green River Municipal Watershed, City of Tacoma

For all intensities: the goal of this management area is to provide municipal water for the City of Tacoma at a level of quantity and quality that, with adequate treatment by the purveyor, will result in a satisfactory and safe water supply. The watershed contains about 142,000 acres of private, municipal, and National Forest land. The NF lands - about 35,828 acres - are intermingled with private lands in the east end of the watershed. The two intensities in this MA, 21A and 21B, apply only to the NF lands.

21A Current Direction, Timber Harvest and Dispersed Recreation Permitted. The goal of 21A is continuation of the current direction, as defined in the 1984 Memorandum of Understanding with the City of Tacoma. Timber production with dispersed recreation in a primarily roaded modified setting is emphasized, to the extent the water quality goal is met. Emphasis on public firewood cutting continues. Wildlife habitat is provided. About 9,000 acres of National Forest land will be exchanged; as exchange is completed, public rights on roads not needed to access NF land will be relinquished. Timber harvest on suitable lands is full yield, using all investment intensities, 17A through 17H.

21B Timber Harvest Permitted, Most Recreation Prohibited. The goal and management direction for 21B is similar to 21A, but most public recreation is prohibited except for persons authorized to participate in special, controlled big game hunts, and users of the Pacific Crest National Scenic Trail. All other aspects of this intensity are the same as 21A. Timber harvest on suitable lands is full yield.



22 Sultan River Municipal Watershed, City of Everett

For all intensities: the goal of this management area is to provide municipal water for the City of Everett at a level of quantity and quality that, with adequate treatment by the purveyor, will result in a satisfactory and safe water supply. The three intensities apply to 16,779 acres of National Forest land within the watershed.

22A Closed Watershed, Except for Production of High Quality Water and Hydropower; Exchange NF Lands. The long-term objective of this intensity is to exchange National Forest lands to some other ownership. The Forest will relinquish all rights except those necessary to administer the Federal Power Withdrawal. The management goal is production of high quality water and hydropower, with emphasis on improving water quality. The watershed will be closed to recreation, with no new trails or roads. All existing recreation sites and facilities will be closed. Once current timber sale contracts are completed, no new timber sales permitted.

22B Current Situation, Exchange NF Lands, Moderate Timber Harvest, Restricted Recreation. The land exchange objectives are the same as 22A. Management emphasis is on maintaining current high quality water, with moderate levels of timber harvest, fish and wildlife habitat improvement, and recreation. Watershed values are protected beyond legal requirements. General dispersed recreation is discouraged but not prohibited. Developed recreation sites will be distributed around Spada Lake, but water contact sports prohibited. Sanitation facilities provided at the lake and trailheads. Wildlife and fisheries habitat improvement encouraged; 20% of forest lands in the watershed maintained as old-growth habitat. Timber harvest from suitable lands will be full yield, using low investment intensity, 17D.

22C Retain NF Lands, Full Multiple Use. In this intensity, NF lands are retained. The management emphasis is meeting Washington State minimum legal standards for water quality and producing high levels of wildlife and fisheries habitat, recreation use, and timber products. Recreation site development is encouraged; dispersed recreation permitted. Habitat improvement projects are encouraged. Suitable forest lands will produce full yield, using all investment intensities, 17A through 17H.

23 Other Municipal Watersheds

For all intensities: provide water at a level of quality and quantity which, with treatment by the purveyor, will result in a satisfactory and safe water supply. This MA applies to the municipal watersheds not included in MA's 20, 21, and 22. They are located throughout the Forest, ranging in size from 84 acres to 30,100 acres. A total of 60,100 acres are included.

23A Timber Harvest, Moderate Recreation Opportunities. The management emphasis of 23A is a varying mix of timber, recreation, wildlife, and other outputs, while meeting legal standards for water quality. A variety of recreation is provided, including ORV use. New trails and roads will be located and constructed to meet water quality objectives. Timber production will be full yield using the low investment intensity, 17D.

23B No Timber Harvest, Limited Recreation Opportunities. The management goal of 23B is production of quality water for human consumption. There is no timber harvest and limited recreation. Water contact sports are discouraged. No developed sites (unless needed to protect water quality), no overnight use, and no ORV's. No new trails; new roads limited to those needed to access lands beyond the watershed. No scheduled timber harvest; any salvage of catastrophic timber loss is nonchargeable.

24 Minimum Management

The goal of this management area is to meet basic stewardship responsibilities at minimum costs. These include: protect life, health, and safety of incidental users; prevent unacceptable resource damage to NF or adjoining lands or downstream areas; administer non-Forest Service special uses, leases, and permits; and retain NF lands in Federal ownership and protect from theft and damage. No acres are currently assigned to this MA.

25 Special Uses

25A Utility Corridors. The goal of this management area is to provide utility corridors for effective and economical transmission facilities, with the least impact on natural resources. Utility corridors are located throughout the Forest, and vary in width and length from local water pipelines to major cross-state power transmission lines. Recreation opportunities may be provided (ORV use, hunting, gathering forest products, etc.); edge habitat for wildlife is provided. Similar special use development will be encouraged within existing corridors when use is compatible. No scheduled timber harvest; salvage and brush control for safety purposes is encouraged.

25B Electronic Sites. The goal of 25B is to provide for electronic sites for effective and economic transmission facilities, with the least impact on natural resources. Existing sites are located at a few selected sites on the Forest. Jim Creek Naval Station is 1,000 acres in size; others are quite small. Recreation and trail construction are not encouraged. Other types of special uses are discouraged. No scheduled timber harvest; salvage and brush control for safety is encouraged.

26 Administrative Sites

The goal of this management area is to provide appropriate sites and facilities for administration of the Forest. Included are: Ranger Stations, public service centers, engineering zone compounds, road maintenance compounds, seed orchards and seed production sites, scale stations, guard stations, and lookouts, where permanent facilities and utility systems are constructed. Older buildings will be renovated or replaced to maintain their functionality; improvements will be integrated into existing facilities. Appropriate recreation information, displays, and services provided at major administrative sites. No scheduled timber harvest. Hazard tree removal, salvage, and special cutting for safety or improvements permitted. Forest tree improvement is the primary goal of seed production areas and seed orchards.

27 Alpine Lakes Management Area

The goal of this management area is to provide for the administration and management of the Alpine Lakes Areas in accordance with the Record of Decision, Selected Alternative, Alpine Lakes Area Land Management Plan Final Environmental Impact Statement, November 2, 1981. Five management units were created (Special Areas, Dispersed Recreation, Developed Site, Scenic Forest, and General Forest). Timber harvest permitted in Scenic Forest (at about 70% of full yield) and in General Forest (full yield.) No scheduled harvest elsewhere. The FEIS and Management Plan provided for inclusion of the following Management Areas within the Alpine Lakes Area:

5 Potential Wild and Scenic River
11 Old Growth Habitat (Spotted Owl)
12 Mature and Old Growth Wildlife Habitat (Pine Marten, Pileated Woodpecker)
14 Deer and Elk Winter Range
15 Mountain Goat Habitat
16 Threatened and Endangered Species

Brief description of allocations in the Selected Alternative, 1981 FEIS:

Developed Site. Areas are substantially modified for campgrounds, boating, ski areas, summer home tracts, administrative sites, etc. Sights and sounds of people are evident; concentration of users is often high. Roads, trails, and parking are managed to provide access to the site, with emphasis on nonmotorized activity on the site. No scheduled timber harvest. Vegetative manipulation only for the enhancement or protection of the area.

Dispersed Recreation. Managed primarily in an unroaded condition with emphasis on dispersed recreation, scenic, wildlife or other amenity values. No new road construction. ORV use permitted, depending on the ROS class. No scheduled timber harvest. The only exception is salvage harvest of catastrophic forest loss for the purpose of limiting damage on adjacent lands. Visual Quality Objective is Retention and Partial Retention. Concentration of recreation users is low; relatively minimal contact with other users. If no alternative road access available for intermingled lands, access may be granted for a non-public minimum standard road.

General Forest. Timber harvest occurs, with a full range of silvicultural prescriptions used on suitable lands. The visual quality objective ranges from Retention to Modification. Dispersed recreation sites are common; encounters between recreationists may be numerous. Motorized activities are common. Rustic facilities may be provided. Land in this allocation is generally accessible by road. Road and trail standards range from optimum, for high-volume mixed traffic, to closed after project completion.

Special Area. Areas protected for their uniqueness and natural conditions, and, where appropriate, to foster public use, enjoyment, or study. Each Special Area has a specific management direction. Refer to FEIS, Alpine Lakes, 1981. No scheduled timber harvest. Roads, facilities (such as parking, picnic areas, and interpretive sites, etc.) will enhance and protect the area. Other resource manipulation, including removal of trees, will occur only for the enhancement or protection of the area.

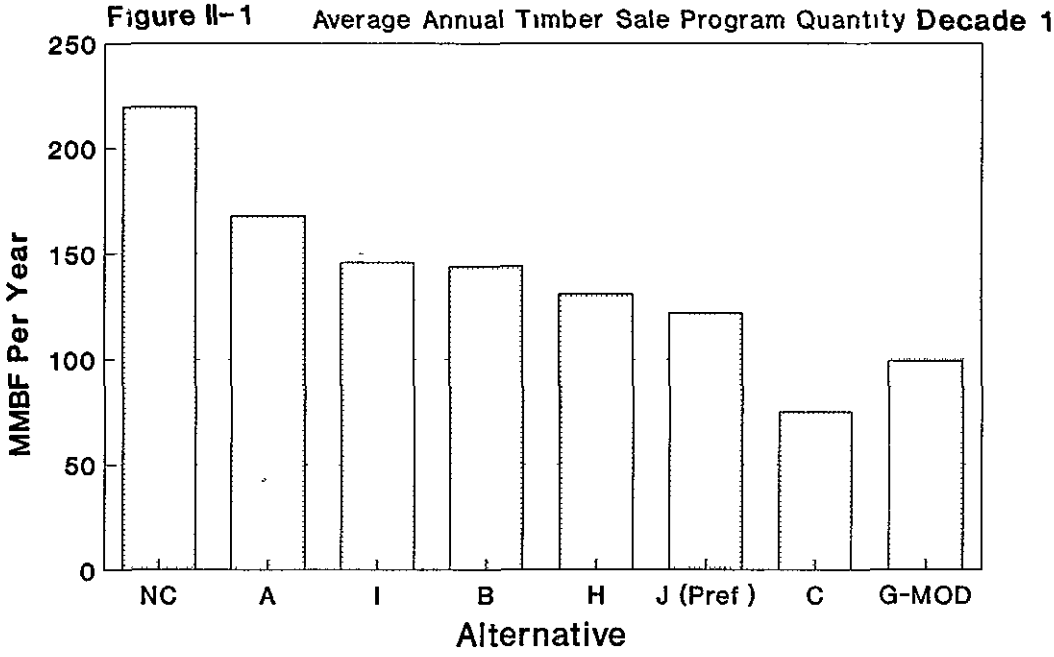
Scenic Forest. The objective is to retain or enhance viewing and recreation experiences. Developments and use in the seen area from recreation sites, roads, and trails within Scenic Forest will meet visual quality objectives. Use will be integrated with the natural landscape. Timber harvest permitted; a full range of silvicultural prescriptions will be used to meet the visual and recreational objectives.

Note: the wilderness portion, Alpine Lakes Wilderness managed in accordance with the Record of Decision Selected Alternative, Alpine Lakes Area Land Management Plan Final Environmental Impact Statement, November 2, 1981.

2. Alternatives At A Glance

The following figures show how the alternatives compare to each other in just a few of the Forest activities or resource outputs. The graphs tie to the detailed output tables in the next section (where other outputs are displayed). Again, the alternatives are arranged in order of decreasing acres of land suitable for timber production. Alternative NC (No Change) was not modeled in FORPLAN, therefore not all outputs for this alternative can be reasonably estimated. Refer to the text and footnotes for each figure.

Figure II-1 shows average annual timber sale program quantity (TSPQ) for Decade 1 (in million board feet). TSPQ includes live (green) wood, plus salvage, fuelwood, and other non-industrial wood. Figure II-2 shows the acres of final timber harvest, each decade, for Decades 1, 2, and 5. Refer to Table II-9a for more comparisons.



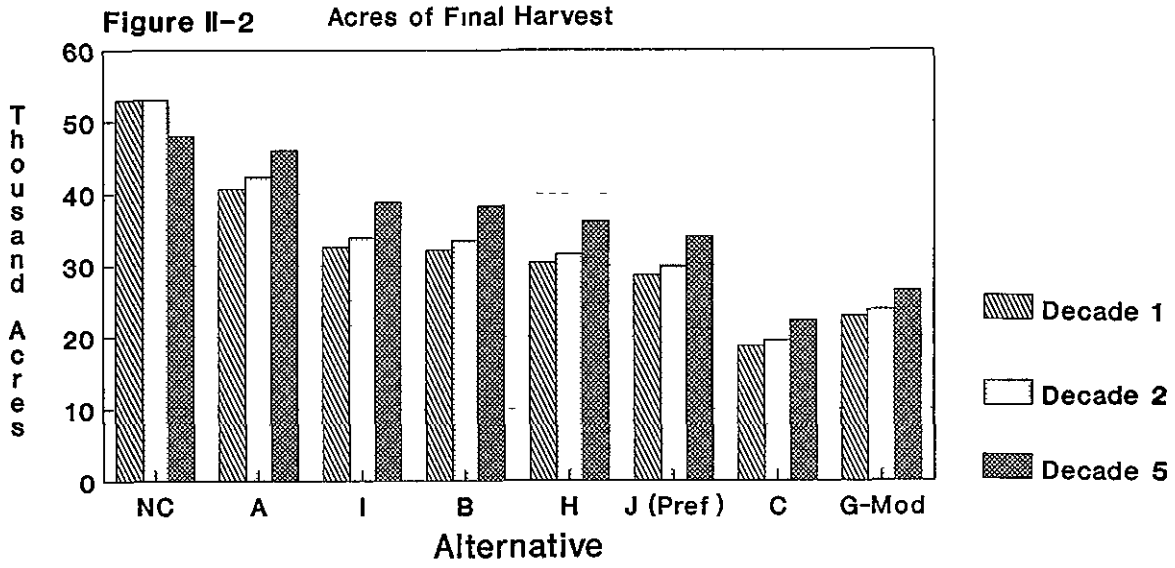


Figure II-3 shows the total amount of old-growth forest remaining, which includes old growth located in wilderness and other no-harvest areas. The starting point is the beginning of plan implementation. The figures then show acres remaining at the end of Decades 1, 2, and 5. Refer to Table II-91.

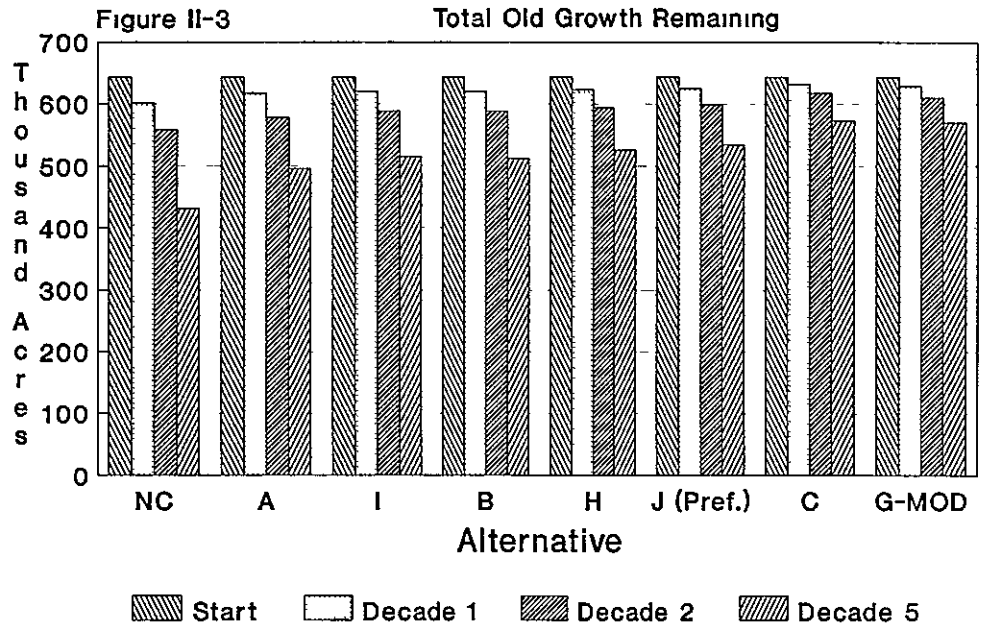

Figure II-4 shows total road construction, in miles per year. Most of the miles are local (timber purchaser) roads. For example; in Alternative J (Preferred), 0.8 miles of arterial/collector roads and 12.6 miles of local roads will be built per year in the first decade. In all alternatives, all arterial and collector road construction, but not all local road construction, will be completed by Decade 3. In Alternative C, about 300 miles of arterial and collector roads are closed starting in Decade 1; about 65 miles are closed in Alternative G, about 20 miles closed in Alternative H, and about 25 miles closed in Alternative J (Preferred).

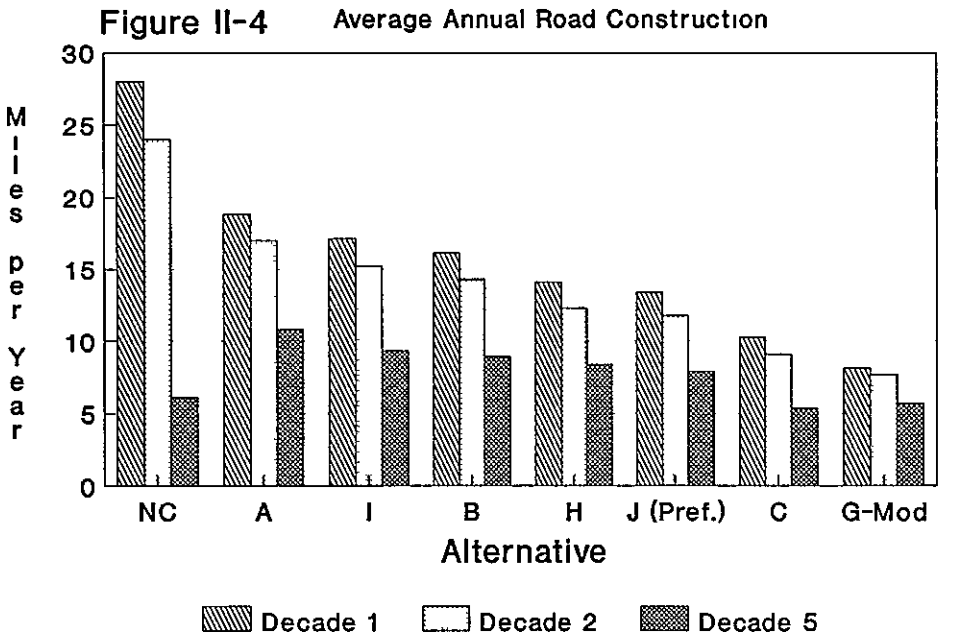

Figure II-5 shows the disposition of the 402,930 acres of roadless areas: the percent remaining undeveloped at the end of Decades 1, 2, and 5. No data can reasonably be estimated for Alternative NC. In the first 10 to 15 years, from 1% to 7% would be developed, depending on the alternative. The acres shown for Alternative A are an estimate; refer to the text accompanying Table II-9g.

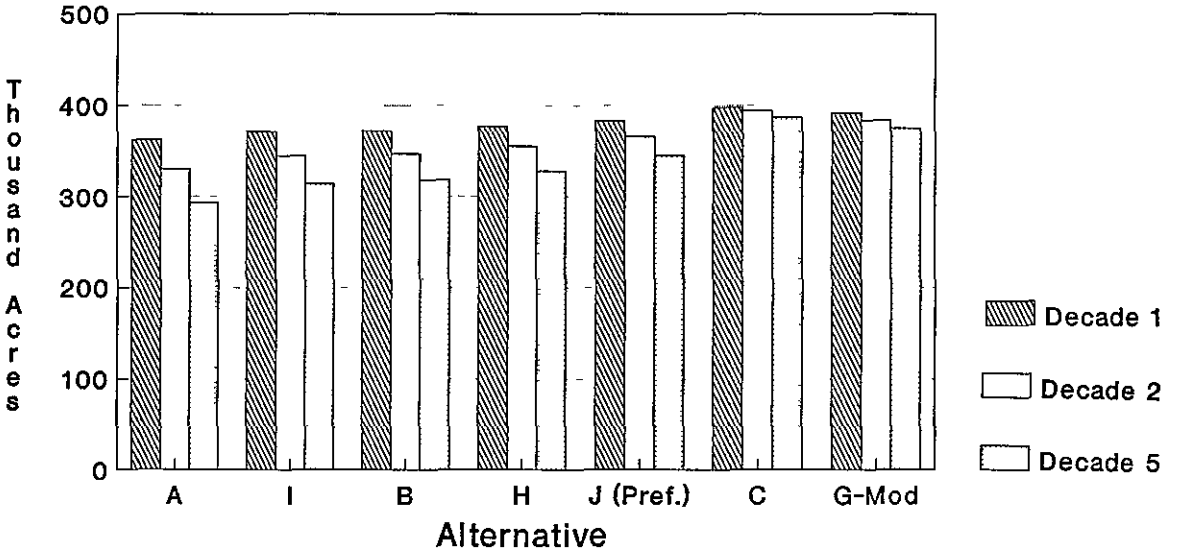
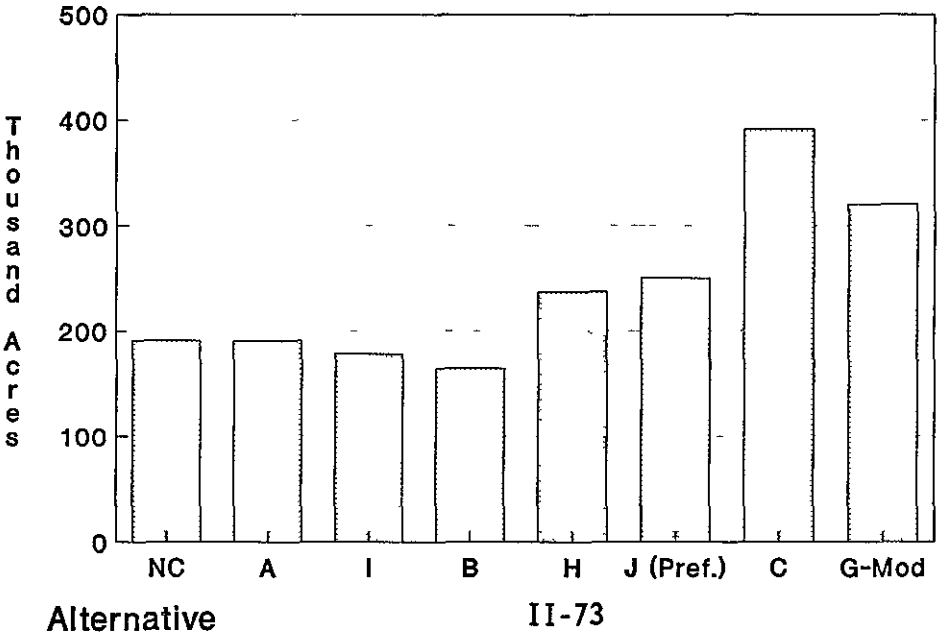
Figure II-5 Acres of Roadless Areas Remaining Undeveloped
Decades 1, 2, & 5



Does not apply to NC Alt

Figures II-6, below, and II-7, on the next page, show the acres of dispersed recreation by ROS classes. Alternative NC is estimated to be similar to Alternative A. The term "reached by Decade 4" is used because, as an alternative is implemented, land allocated to MA's, and standards and guidelines applied, the recreation setting will slowly change toward the desired future condition. The figures show the expected ROS acres after four decades of implementing each alternative.

Figure II-6 Unroaded ROS Acres Reached by Decade 4



While no alternative can meet future demand for unroaded dispersed recreation, Alternatives C and G-Modified come the closest. Alternative B cannot meet the RPA target for dispersed recreation. Looking at Figure II-7, the alternatives with more timber harvest activities and associated road construction (NC, A, and I) provide the most roaded dispersed recreation; however, much of this recreation will occur in landscapes that have been heavily altered.

Figure II-7 Roaded ROS Classes Reached by Decade 4

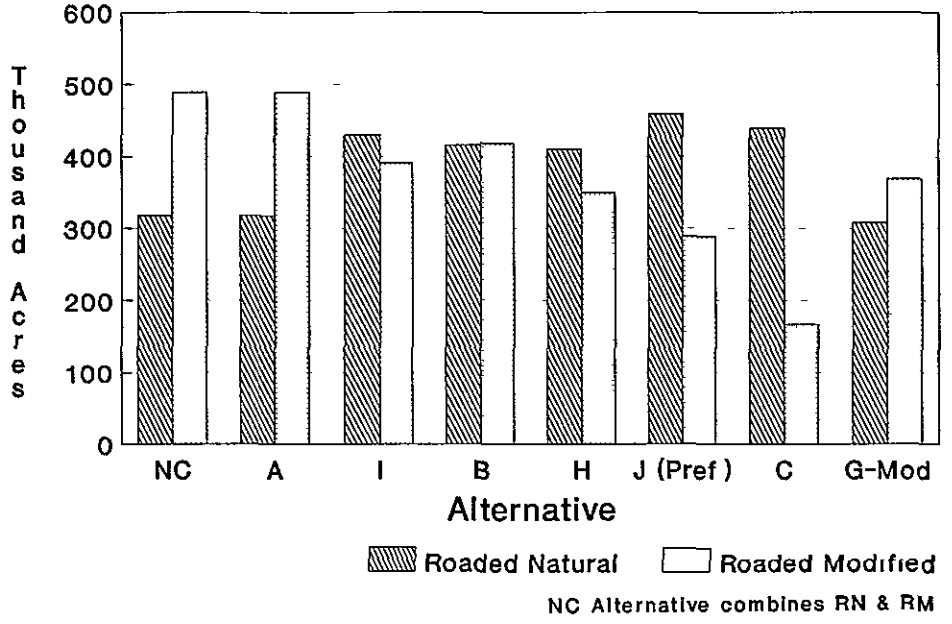


Figure II-8 shows the pounds of anadromous fish available for commercial harvest. The differences between alternatives are a function of investments in habitat improvements: a higher level of investment and more restoration/ enhancement results in more available fish. Alternative NC is similar to A. While not shown in this figure, resident fish habitat is also improved/enhanced in Alternatives C, G-Modified, and J (Preferred).

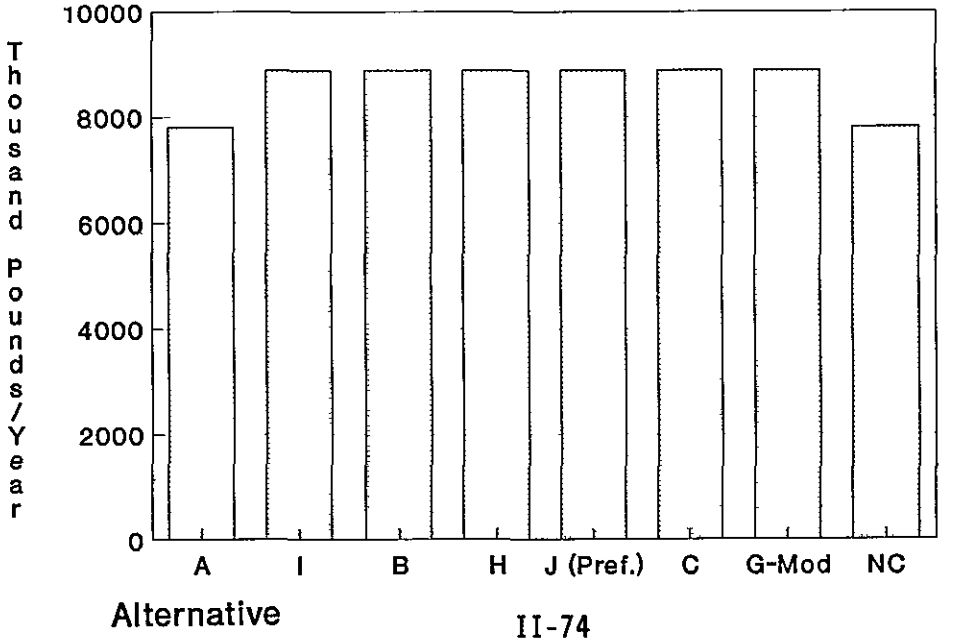
Figure II-8 Anadromous Fish for Commercial Harvest



3. Comparison of Resource Outputs, Inputs, and Environmental Effects

The following pages of tables show the inputs, yields, and effects of various resources and activities, by alternative. The numbers in the II-9 Tables and in Table II-10 are derived primarily from analysis completed in the FORPLAN model, or in a few cases, from analysis done outside of the model. Table II-10 is a narrative comparison of outputs and environmental effects that are qualitative in nature; also refer to the quantitative II-9 tables.

As mentioned earlier in this chapter, the alternatives are displayed, from left to right, in order of decreasing acres of land suitable for timber production. This order is useful in understanding how the environmental consequences and effects will vary by alternative. The sequence is strongly correlated to the amount of vegetative management in the alternatives. Total suitable acres also correlate with the objectives of each alternative. For example: Alternative I (emphasis on timber/other resources with established market prices) has a large number of suitable acres and a high allowable timber sale quantity (ASQ). Alternative C, near the other end of the spectrum, emphasizes primitive/semi-primitive dispersed recreation; it has the second-lowest number of acres suitable for timber harvest and the lowest ASQ.

The first set of data is presented in sub-tables: Table II-9a through II-9o. Outputs and effects that are generally related, such as timber/roads/sediment or recreation/wilderness/scenery, are grouped and displayed together. Please refer to the narratives preceding each sub-table for information to help understand the tables, and the differences among the alternatives.

Alternative NC (No Change) is based on the 1963 Timber Management Plans. These Plans were not integrated resource plans, and consequently did not address all resource uses and outputs. Data for Alternative NC is presented as available. Refer to the footnotes for each table.

Although these tables show outputs and effects over the long term, the results of this planning process will apply for only 10 to 15 years, the life of the Forest Plan.

Long-term Timber, Water, and Sediment Inputs and Yields (Table II-9a)

Table II-9a compares, by alternative, the long-term yields, effects, and activities related to the timber, water, and soils resources. With few exceptions, as suitable acres increase, the following increase: the amount of vegetative management (all aspects of timber harvesting: reforestation, timber stand improvement, fuel treatment, and regeneration harvest), miles of road construction and reconstruction, and finally, the environmental effects from these activities.

To put the allowable sale quantity for the five decades in perspective, the potential yield for the 1963 TM Plans (as amended), plus the average annual cut and sold volume for 1975-1988 are shown. Potential yield for the Mt. Baker-Snoqualmie was last reduced to reflect the 1984 Washington State Wilderness Act, from 259.4 MMBF to the current level: 203.8 MMBF. TSPQ was also reduced. The PY and TSPQ for Alternative NC (No Change), which are based on the TM Plan, are also shown in Table II-9a. More information about outputs in the timber resource can also be found in Tables II-9b through 9e.

1/ The TM Plans upon which the No Change Alternative is based were developed in 1963. The outputs and effects are generated from previous inventories. All other alt. outputs and effects were calculated using updated inventories and yield tables and the latest method of calculating timber harvest levels For Alt NC, tentatively suitable lands were not determined and standard plus special commercial forest land is shown as lands suitable for timber production

2/ ASQ· Quantity of timber that may be sold, from suitable land. Includes only chargeable, live (green) not salvage, fuelwood or other non-industrial wood. Potential yield from the TM Plan is shown for Alternative NC.

3/ Potential yield is a ceiling on amount of chargeable timber volume that can be sold; includes both net live and salvage volume Current potential yield equals 203.8 MMBF/yr. Potential Yield 1975-1979 = 240.9 MMBF/yr ; 1980-1983 = 259.4 MMBF/yr., 1984-1988 = 203.8 MMBF/yr. See Table III-11 for further explanation on potential yield values.

4/ Includes ASQ, nonchargeable mortality volume, volume not meeting utilization standards, and volume used for other than board products from lands suitable for timber production, and volume from unsuitable lands Includes PY and all other volume for NC

5/ The fuelwood conversion is 95 cubic feet per cord. Volumes are estimated as a % of submerchantable timber outputs associated with regeneration harvest. This volume is included above in Timber Sale Program Quantity and in 1975-84 Cut and Sold It is not included in ASQ or PY.

6/ Acres shown are those planted with seedlings; however all acres regeneration harvested (see Table II-6c) are reforested by planted or natural seedlings.

Acres of reforestation are determined by the mix between natural and planting reforestation intensities in each alternative. However, in all alternatives, most acres will be reforested by planting by hand, rather than through natural reforestation. Estimates for Alternative NC are based on reforestation by planting. The acres of timber stand improvement shown in Table II-9a are acres of precommercial thinning.

The soil sediment index is a reflection of the amount of new timber harvest and road construction/reconstruction, plus the amount of background sediment (from old roads and other acres of previously-disturbed ground, and natural sediment). The index increases as total suitable acres increase.

The Forest annual water yield shows no change, by alternative; research has shown the effects of management activities on annual yield to be unmeasurable.

Acres of improved watershed conditions reflect planned improvement/rehabilitation of watersheds damaged either by natural or human-caused disturbance.

Comparison: Past, Present, and Alternative Timber Outputs (Table II-9b)

This section is included in Chapter II to give the reader an idea of the differences between the 1963 Timber Management Plans (the basis for Alternative NC) and the projected outputs and effects of the Forest Plan alternatives. Also included is a brief history of the timber sale "performance" of the recent past for the Mt. Baker-Snoqualmie, and some of the economic and social impacts.

These comparisons are similar to material presented earlier: "The Relationship of Alternative No Change to Alternative A (No Action)" on page II-29. Also, refer to Chapter III for more information about timber supply and demand.

Table II-9b shows timber outputs for: the actual annual timber sold (average for 1979 through 1988) under the 1963 Plans; potential yield for Alternative NC; and first decade allowable sale quantity projected for each alternative.

Discussion of Table II-9b

The potential yield (PY) exceeds the allowable sale quantity for all alternatives; even if salvage volume is subtracted from PY, it still exceeds ASQ for all alternatives. The percent decrease in ASQ from PY ranges from -27 percent in Alternative A to -67 percent in Alternative C. Alternative J (Preferred) is 47 percent below the 1963 Plans potential yield.

The commercial forest land base for the 1963 Timber Management Plans is larger than the suitable land base of all alternatives. However, all alternatives have a higher per acre yield, primarily due to increased utilization standards; increased yields from precommercial thinning and use of genetically improved stock; and inclusion of hardwood volumes.

The timber sale program quantity for each alternative is also less than in the existing 1963 plan, though the decrease is less than for ASQ (primarily because salvage volume for each alternative is included in TSPQ.) In all alternatives except Alternatives A and NC, timber sale program quantity includes volume from the study plots in MA 19 Mountain Hemlock Zone (a total of up to 250 acres in 25 plots of approximately equal size).

Table II-9b

Footnotes appear on the following page

Footnotes for Table II-9b

1/ ASQ for Alternative A (No Action) was calculated by modeling direction from the 1963 Timber Management Plans, projected into the future. New, scientific information was used, such as improved yield tables, land suitability classification for timber production, and FORPLAN analysis.

ASQ includes only live (green) volumes resulting from the yield projections of FORPLAN. ASQ is obtained from lands designated as suitable for timber production under NFMA standards. ASQ volumes meet utilization standards in the Regional Guide. When sold, the volume is called "chargeable", and is used to determine achievement of planned allowable sale quantity goals.

2/ Potential Yield from the 1963 Timber Management Plans (upon which Alternative NC is based) is shown in parenthesis to distinguish from ASQ; it includes both net live (green) and dead (salvage) volume.

3/ Meets utilization standards in the Regional Guide, but is not considered "chargeable" against the planned ASQ goals.

4/ Sawtimber from lands designated unsuitable for timber production. This volume is estimated based on the incidental volume of timber that will be sold from lands not designated for timber production.

5/ This dead (salvage) volume from suitable lands was not included in yield tables in FORPLAN.

6/ The estimated timber volume that does not meet utilization standards in the Regional Guide, but which could be utilized for products other than sawtimber. It is not considered "chargeable" against planned ASQ goals.

7/ Fuelwood volume in parenthesis is not added to Total Submerchantable, Nonchargeable Volume, or to the TSPQ to avoid "double counting." There are two reasons: in the first two columns, nearly all of the 6.4 MMBF of fuelwood sold is already included in nonchargeable Other Sawtimber or submerchantable volume remaining in timber harvest sale areas. In the alternative projections, fuelwood is estimated as a percentage of submerchantable timber outputs associated with regeneration cutting. An unestimated volume of fuelwood may be available from other activities, e.g. commercial thinning.

8/ TSPQ includes the allowable sale quantity for Decade 1 and estimated additional volume planned for sale during the first decade, such as fuelwood.

Differences in Terminology. One major difference between the 1963 TM Plans and the Forest Plan alternatives is the terminology used to report timber outputs. Both potential yield (PY) and allowable sale quantity (ASQ) are legitimate expressions of outputs. Refer to the discussion of Alternatives NC and A, page II-29, and to the glossary. Both PY and ASQ represent a ceiling on the amount of chargeable volume that could be sold for a given decade; in this context, the terms are comparable. PY includes both net live (green) and dead (salvage) volume, while ASQ includes only net live (green) volume. **Table II-9b(1)**, on the following page, shows major differences between calculation of PY (1963 Plans) and ASQ (Alternative J (Preferred). It is similar to Table II-7, on page II-31, which displayed the differences between PY for Alternative NC and ASQ for Alternative A.

Table II-9b(1)
Major Differences - 1963 TM Plans PY and Forest Plan ASQ (Alternative J)

Factor	PY 1963 TM Plans	ASQ Forest Plan (Alt J)
Land Base for Determining Timber Production	Consider available forest land producing 20 or more CF per acre per year	All forest land considered in Land Suitability for Timber Production Process
	CFL classified available for timber production (Timber Key Value Areas & Special, Modified Cut)= 579,800 acres Of these, 33,300 acres are Marginal CFL or Modif cut, currently not economically or technologically feasible to manage for timber prod Result 546,500 acres can be managed for timber production	Land classified Tentatively Suitable for Timber Production = 597,000 acres Of these, for Alt J, 175,000 acres are proposed for other resource uses that preclude timber prod FORPLAN analysis determines that, for Alt J, another 76,000 acres are not cost-efficient in meeting alt objectives or cannot be scheduled for harvest in the next 150 years Result 346,000 acres are suitable for timber production (in Alt J
Inventory, Utilization Standards		
-Mapping	Identified broad Timber Key Value & Modified Cutting Areas	In-place ecoclass mapping of entire Forest (lattr'75)
-Acre Determination	Plot expansion to determine total CFL acres (USDA 1960)	Data base extract of mapped in-place acres
-Utilization Stds		
Existing Mature	11 inch DBH to 8 inch top	9 inch DBH to 6 inch top
Commercial Thin	No standards specified	7 inch DBH to 4 inch top, for Decade 1
All Stands Except Existing Mature	NA	7 inch DBH to 4 inch top, after Decade 1
-Sampling	No growth samples taken Mortality sampled on only one Ranger District	Growth and mortality sampled Forest-wide
Yield Calculations	LTSYC undetermined	LTSYC calculated in FORPLAN
-Annual Regeneration Harvest Yields	In Timber Key Value CFL Yield calculated by dividing total live timber volume over rotation age by 100-year rotation, plus estimated ann growth in Key Value CFL less than rotation age	In Suitable lands Net live timber volume from timber yield tables entered into FORPLAN where analysis determines yields Included in ASQ
	Added estimate for merchantable dead (the volume per acre x estimated acres clear-cut annually) Included in PY	Same calculation, but dead volume is not included in ASQ
	In Marginal CFL, No Yield	In suitable lands where reduced timber yield provides other resource opportunities, yield is calculated as in suitable above Included in ASQ
	In Special CFL, Gross growth is estimated yield (excluded mechantable dead volume) Is included in PY	
-Commercial Thinning Yields	No estimated yield	Net live timber volume, yield calculated as in suitable land, above
-Pre-commercial Thinning	No estimated yield	Yield reflected in timber yield tables
-Genetics	No estimated yield	Yield increases based on acres planted by area and species Increases are between 1 and 2 percent
-Hardwoods	No estimated yield	Hardwood volume is chargeable to ASQ Only 1 7% of inventory is hardwoods

The Effects of the Previous Decade

In order to understand some possible effects of the projected ASQ for the alternatives, the events of the previous decade can add some perspective. Both the performance of the Mt. Baker-Snoqualmie National Forest and the performance of the timber industry in the Puget Sound area are summarized. Refer to Chapter III, Commercial Timber section for more detailed information.

Past Performance Under the 1963 Timber Management Plans. The average annual PY sold during the ten year period 1977-88 was 235.8 MMBF; the average annual PY planned for this period was 229.8 MMBF. The PY sold in any fiscal year may exceed the PY in effect that year, but the cumulative total chargeable sell cannot exceed the cumulative total planned chargeable sell during the fiscal years the plan has been in effect.

Through fiscal year 1988, the cumulative total chargeable volume sold (5,822.1 MMBF) was 9.8% less than the total cumulative total planned chargeable sell (6,452.4 MMBF) over the 25 year plan period. 3/ This is a good record, especially in view of the changing land base, the return to the government of 87 timber sales under the Federal Timber Contract Payment Modification Act of 1984 in contract defaults, and the fact that the 1963 TM Plans were issued as "interim" five-year plans. 4/

The actual cut volume in any fiscal year, averaging 200.6 MMBF per year between 1979 and 1988, is a function of log market prices and other factors, rather than the volume sold that year.

A general recession in the Northwest in the early 1980's and severely depressed timber markets resulted in the return to the government of a number of timber sales. Purchasers who bought timber in the late 1970's at high stumpage rates elected to not harvest this volume and sell it at the prevailing low rates of the early 1980's. During an eight month period on this Forest (Nov. 1985 - June 1986), a total of 87 unharvested timber sales were returned to the government, with a volume of 640.7 MMBF (592.3 MMBF chargeable.) Sixty-nine of the 87 sales were authorized under the Federal Timber Contract Payment Modification Act of 1984, and 18 were returned through contract defaults. Most of this volume has been resold, or will be sold in the near future.

Adjusting the PY for the ten year period, 1979-1988, for the chargeable volume returned to the government for resale produces an actual PY sold of 1850.4 MMBF for the period. 5/ This compares to the planned PY sell volume of 2297.5 MMBF for the period. The Forest has undersold the planned PY sell volume by 447.1 MMBF for the time period, or 19.5 percent less than planned.

3/ Volume sold values based solely on the Forest "Timber Management Control Record - Sell" for the timber period.

4/ The PY was amended to reflect wilderness designation in 1964, 1976, and 1984; creation of the North Cascades National Park and Recreation Area and designation of Wild and Scenic Rivers in 1968; and the roadless area reviews.

5/ This volume can be termed the "effective" PY sold during the period, in that only 185.0 MMBF of timber was effectively available to the timber industry and the area economy, not the 235.8 MMBF per year actually sold.

This volume - 185.0 MMBF - falls between the ASQ of the alternatives and the PY of the 1963 Plans (203.8 MMBF) and is only 9.2% less than the latter. See Table II-9b.

Comparing effective sold to the planned sell for the 1963 through 1988 period, the Forest sold 630.3 MMBF less than was planned. 6/ All except 38 MMBF of the difference can be accounted for by the 87 sales returned to the Government (592.3 MMBF) and, in fiscal year 1985, underselling the planned PY by 2.5 MMBF. Some reasons for the 38 MMBF difference are:

- o appropriation and national policy affected the sell;
- o from 1963 through fiscal year 1979, the Forest undersold the planned PY by 118.7 MMBF, while during 1975 through 1984, the Forest oversold the PY by 60.6 MMBF. The Forest undersold the PY during five fiscal years since 1971 (1972, '74, '82, '83, and 1985);
- o market or recession lows in 1967, 1969, 1971, and 1981-82 partly accounted for less sold than planned;
- o designation of wilderness, wild and scenic rivers etc.; the growth of the conservation movement during this period; and a tremendous increase in concern for wildlife and the preservation of old growth have all affected the timber sale program. Timber sales were not planned, were canceled, or delayed in certain areas because of pressure from special interest groups or pending legislation.

Timber Mill Situation. A direct effect of the 1981-82 recession was a decline in the number of mills. From 1972 through 1978, the total number of mills in the State of Washington, excluding the export industry, increased 35.7%. From 1978 to 1982, the number of mills decreased 29.6%. The number of mills in the Puget Sound area (excluding export) dropped 20 % in two years - 1980-82. Part of this is due to increasing mill efficiency: by 1982, mills utilized 97 percent of wood and bark residue.

Between 1982 and 1984, another 18 percent of the mills in the Puget Sound area closed; another 11 percent shut their doors by 1986. In all, the recession and restructuring of the wood products industry saw Puget Sound area mills (not including export operations) decrease by almost half. Yet, there were major improvements in productivity among the remaining mills. For instance, lumber mills, which had dropped by 23 percent in number by 1986, were producing 9 percent less lumber than in 1978.

In the Puget Sound area in 1986, 49 of the 87 mills (excluding the 35 export mills) were not dependent on National Forest timber; 11 mills were dependent for 1-33% of their log supply; 6 were dependent on National Forest timber for 34-66% of their supply; and 21 were 67-100% dependent on National Forest log supply. As discussed in detail in Chapter III, Commercial Timber section, this situation is expected to continue for at least the next decade.

6/ The cumulative planned chargeable sell from 1963 to 1988 was 6,452.4 MMBF. The effective sold was 5,822.1 MMBF.

Timber Resource Management Data, By Alternative (Table II-9c)

Table II-9c on pages II-86 and 87, and the accompanying narrative compares timber-related information for the alternatives and two of the benchmarks. The benchmarks selected, Maximum Timber and Maximum PNV with management requirements (MR's), represent the "benchmark ceilings" or maximum timber resource outputs that could be achieved on the Mt. Baker-Snoqualmie National Forest, while meeting the NFMA requirements. The columns in Table II-9c are numbered to help the reader track information, and the narrative below is organized by these columns.

Some data is not shown for Alternative NC (No Change). The alternative is not directly comparable with the other alternatives, due to differences in inventory, land classification, modeling, etc., previously discussed in this chapter.

Some general comparisons for the data in Table II-9c are as follows. The remainder of the narrative for this table will focus only on the inter-relationship of Alternatives A (No Action) and J (Preferred) and the two benchmarks.

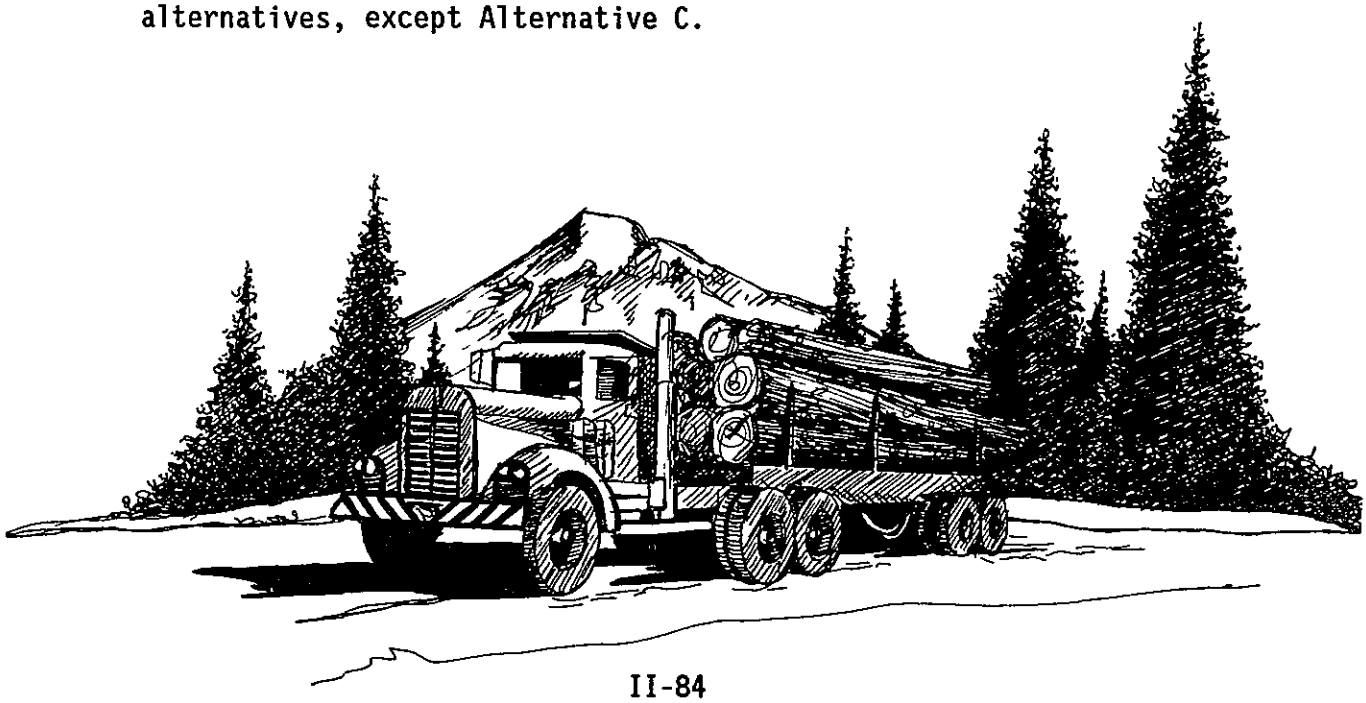
Suitable Acres, Column (1): see footnote 1, Table II-9c.

Inventory, Columns (2), (3), (4): was determined for Alternative NC using inventory data for the 1963 (amended) TM Plans and current standard and special (suitable acres).

Average Annual ASQ, Columns (5), (6), (7): previously compared in this chapter.

Area and % of Suitable Lands by Yield Level, Columns (14) through (19): standard lands have full yield. Special lands have 50-99% yield.

Regeneration Harvest in 1st Decade, Columns (20) through (23): clearcut acres are the greatest, reflecting the highest timber output of any alternative. Percent of suitable acres harvested is smaller than all other alternatives, except Alternative C.



Suitable Acres, Column (1)

The acres suitable for timber production include lands where timber management activities will occur; they are a reflection of the different multiple-use objectives of each alternative or benchmark. In the two benchmarks, multiple-use objectives are limited to those needed to meet minimum policy and legal requirements. Alternatives must meet these requirements, plus additional objectives to meet the goals of the alternative. Thus total suitable acres in the alternatives are much lower than in the benchmarks.

Suitable acres decrease from Alternative NC to Alternative G-Modified. This decrease reflects the acres in each alternative that are tentatively suitable for timber production (except Alternative NC) but, to meet the multiple resource objectives of the alternative - including timber resource objectives - were not assigned suitable for timber production. Some of these acres were assigned to MA's that do not allow scheduled timber harvest (see Table II-9d), and others are not cost efficient in meeting the management objectives of the alternative or were not scheduled for harvest during the 150 year planning horizon. (see Tables II-9d and 9d(1)).

Inventory (on Suitable Lands), Columns (2), (3), and (4)

These columns show the inventory volume of growing stock trees on suitable lands, calculated from timber yield tables in FORPLAN. Column (2) shows inventory at the beginning of the first decade, before any timber harvest. The inventory is generally proportional to the total suitable acres; the mix of timber age classes also affects inventory volume. For example, 61 percent of the beginning inventory volume of Alternative J (preferred) is made up of mature sawtimber age classes (age 100 and above). Alternatives G-Modified and C have the lowest beginning timber inventory, reflecting their management objectives: more emphasis on nonmarket and amenity values.

Column (3) shows the average volume per acre of the beginning inventory; it is calculated by dividing Column (2) by Column (1).

It is apparent in Column (3) that Alternatives B and I have the highest volume per acre. These alternatives have objectives that included high timber outputs and have a high proportion of mature sawtimber acres in suitable lands. These alternatives develop the most acres of unroaded lands, which have 76% of tentatively suitable acres in the mature sawtimber age classes compared to only 46% mature sawtimber in roaded areas. Both of these alternatives have approximately 62 percent of their beginning inventory, suitable acres, in mature sawtimber. Alternative B has the most management area acres with emphasis on enhancement of big game wildlife habitat. Acres in these MA's have proportionately more mature sawtimber for big game thermal cover and winter forage. The beginning per-acre inventory of Alternative B is 2.5% higher than Alternative J (Preferred) and 0.8% higher than Alternative I. This difference is attributed to the mix of age classes; Alternative B has 0.7% more acres of mature sawtimber than J (Preferred), and 0.3% more than Alternative I in its suitable base.

Table II-9c

Timber Resource Management Information by Benchmark and Alternative

1/ Tentatively suitable lands for all benchmarks is 604 800 acres for all alternatives is 597,000 acres, except Alt NC (tentatively suitable lands were not determined for Alternative NC) The reduction in suitable lands between benchmarks and alternatives resulted from correcting data base boundaries updating for land exchange and better defining recreation site area

2/ Some standard volume does not appear in the inventory and growth columns All volume that has reached utilization standards is included

3/ The Forest-wide cubic foot site class is 4 a natural growth potential of 85-119 cubic feet per acre per year

4/ Region 6 NFI statistics, corrected, 5/20/78, unpublished, show 33 7 CF/Ac/yr growth on 685,658 acres of poles and larger inventoried, growth applied to the total CFL (834,939 acres) inventoried in 1976 equals 27 7 CF/Ac/Yr

5/ Elements of the 1963 TM Plans upon which the No Change Alternative is based include

a) Potential yield 203 8 MMBF 41 7 MMCF

b) Average annual chargeable volume sold Through FY 1988 (23 years) 232 9 MMBF, or 47 6 MMCF including an adjustment reducing total volume sold

c) Total acres of standard and special CFL lands used to develop the potential yield, the 547,000 CFL acres are comparable to suitable lands

Column (4) is the inventory of growing stock trees at the midpoint of Decade 15, after fourteen decades of harvest, growth, and inventory have been projected over the planning horizon. This ending inventory is controlled by a constraint (ending inventory constraint.) It's purpose is to assure that enough timber volume remains at the end of the planning horizon to continue management, at the long term sustained yield level, indefinitely. See the discussion for Column (9).

Alternative G-Modified has the lowest ending inventory volume (Column 4) of all the alternatives; it has the second lowest growth total, only Alternative C is lower (Column 13); and it has the greatest growth rate of all the alternatives (Column 12). The high per acre growth rate is due to the selection of high intensity prescriptions and a small overall suitable base.

The volume in all timber yield tables in FORPLAN was reduced to provide sufficient numbers and sizes of hard snags per acre to maintain varying viable population levels of primary cavity excavators, thus meeting part of the NFMA requirement to maintain viable wildlife populations (36 CFR 219.27(a)(6)). Yield tables were reduced 1.5% for the two benchmarks, Alternatives B, I, and G-Modified; reduced 3.0% for A, H, and J (Preferred); and reduced 4.5% for Alternative C.

Average Annual Allowable Sale Quantity, Columns (5), (6), and (7)

Columns (5) and (7) show the first decade average annual allowable sale quantity (ASQ), in cubic feet and board feet. With a few exceptions, ASQ is a direct function of the number of suitable acres and the timber management prescription intensities assigned in FORPLAN. Generally, ASQ decreases as suitable lands decrease. The ASQ in the alternatives is also reduced by prescriptions that project less-than-full timber yield on suitable lands, to provide for multiple-use opportunities for other resources.

The two benchmarks have the highest number of suitable acres plus fewer multiple-use objectives; therefore, they have a higher ASQ. The Max PNV benchmark has a lower ASQ than Max Timber because the objective was to select the most cost-efficient prescriptions in achieving maximum PNV. The Max Timber benchmark, with the highest ASQ, was run in FORPLAN twice: first, with the objective of maximizing timber output without regard to cost efficiency; then, to select the most cost-efficient timber prescriptions while still achieving those maximum timber outputs.

Allowable sale quantity for the alternatives decreases in order of decreasing suitable acres, with a few exceptions. Some of the decline in ASQ is due to high allocations of suitable acres to reduced yield: 50-90% of full yield. (See Columns (16) and (17).) Alternative G-Modified had some unique constraints, which resulted in higher ASQ's than might be expected from its suitable acres.

Alternatives B, C, G-Modified, H, I, and J (Preferred) were run in FORPLAN with an "objective function" of maximizing PNV over 15 decades. 7/ However, the ASQ for Alternative A (No Action) was determined from a combination of FORPLAN runs maximizing timber output and PNV.

Alternative A (No Action) was first run to maximize timber over the first five decades without regard to cost efficiency. The alternative was then re-run with an objective function to maximize PNV with an absolute constraint to meet the same timber outputs as the first run.

The ASQ for Alternative G-Modified is higher than Alternative C even though Alternative C has more suitable acres than Alternative G-Modified. Alternative G-Modified has more acres assigned to Management Area 17 with its higher timber intensities than Alternative C, thus a higher output from these lands contributing to the ASQ in Alternative G-Modified.

Column (6) shows the relationship of the first decade ASQ to the beginning inventory: Column (5) divided by Column (2) multiplied by 100.

Long-Term Sustained Yield Capacity (LTSYC), Columns (8), (9), and (10)

Column (8) shows the annual long-term sustained yield capacity (LTSYC); column (9) shows the relationship of LTSYC to the ending inventory: Column (8) divided by Column (4), multiplied by 100. Column (10) shows the decade in which the average annual allowable sale quantity equals or exceeds the LTSYC.

In FORPLAN, the LTSYC is calculated through the use of a LTSYC coefficient. A coefficient is calculated for each prescription by summing all the harvest volumes and dividing by the rotation age. The LTSYC for an alternative is calculated by summing the products of the LTSYC coefficient for each prescription times the suitable acres assigned to that prescription.

The LTSYC varies directly with suitable acres and management intensities in the timber prescriptions. LTSYC is best compared when expressed as yield per acre, per year (Divide Column (8) by (1)). 8/

Although FORPLAN had wide latitude in selecting timber management intensities, the multiple-use objectives of each alternative affects the timber yield per-acre (through minimum rotation lengths and the percent of the suitable lands in certain management areas that could be harvested each decade.)

In Alternative C, which has the lowest per-acre yield (77.7 CF/ac/yr) and the most acres with emphasis on management for high visual quality, the timber minimum harvest rotation in the foreground viewshed management areas is 200 years, and harvest is limited to only five percent of the area per decade.

7/ In addition, all alternative runs were subject to common constraints plus unique constraints to meet the multiple-use objectives of each alternative.

8/ LTSYC, expressed in cubic feet per acre, per year equals: Max Timber and Max PNV Benchmarks - 118.7 and 93.8 CF/ac/yr; Alternative G-Modified - 95.9 CF/ac/yr, followed by Alternatives A - 93.7; I - 89.1; H - 88.6; B - 87.9; J - 87.8; and C - 77.7 CF/ac/yr.

The LTSYC expressed as a percent of ending inventory, Column (9), is very similar for all alternatives except C, which is somewhat lower and A which is larger. This reflects the fact that timber management intensities in Alternative C average the lowest timber production per acre of any alternative. It also reflects the timber management intensities in Alternative A which has the second highest growth rate of all alternatives.

All alternatives except A (5th decade) and B (7th decade) achieve or exceed LTSYC in the eighth decade (Column 10). The time needed to achieve or exceed LTSYC is determined by three major factors in each alternative: 1) the number of acres allocated to prescriptions allowing timber management; 2) the selection of acres for harvest based on the economics of the prescription; and 3) the scheduling of prescriptions over the planning horizon. The combination of these three factors result in the LTSYC being reached by all alternatives except A at or after the seventh or eighth decade.

Alternative A reaches LTSYC in the fifth decade. Here, the large number of suitable acres (highest of all alternative); large number of acres assigned to Management Area 17 (timber emphasis) with shorter rotations; and few acres assigned to extended rotations produce few conflicts in scheduling, thus a shorter time period to reach LTSCY.

Average Annual Net Growth, Columns (11), (12), (13), and (13a)

Columns (11) through (13) show information about net timber growth on the Forest. Average annual net growth is a reflection of age class distribution, site productivity mixes, and timber production intensities on suitable lands.

Average annual net growth - Columns (12) and (13) - is the change in net inventory volume of growing stock between decades, adjusted for harvest. For example, if total inventory change equaled harvest, then ASQ and net growth between two decades would be the same. Growing stock volume is represented in timber yield tables in FORPLAN.

Yield tables in FORPLAN are slightly different for existing mature stands and regenerated (managed) stands because different utilization standards apply. Existing stands 20 years old or less are treated as managed stands. Utilization standards (refer to Regional Guide) for existing pole and larger stands are 9 inches DBH to a 6 inch top, while regenerated stands have a utilization standard of 7 inches DBH to a 4 inch top. Thinnings from existing stands have a utilization standard of 7 inches DBH to a 4 inch top.

Yield tables are developed for each timber management intensity that has been selected for use.

In the FORPLAN yield tables, no volume is shown prior to the time that a particular intensity produces trees that meet the utilization standards: no volume is shown for managed stands until they equal or exceed an average stand diameter of 7 inches, or for existing pole and larger stands until they equal or exceed an average diameter of 9 inches.

All existing pole or larger stands (in the FORPLAN model) already exceed 9 inches DBH (the utilization standard), therefore all volume is represented. For regenerated stands, the volume of the stands less than 7 inches in diameter is not stated. This volume is not "lost" for the purposes of calculating

timber outputs. It accumulates from the time the stand begins to grow until it reaches utilization standards. At that time, the total volume appears in the yield table.

Since no volume is represented in the yield tables for age classes below utilization standards, the inventory at any given time is understated by the volume in those stands between 5 and 7 inches DBH. This understatement of growth cannot be calculated from the information in the FORPLAN model.

The unstated volume in the yield tables has no affect on the LTSYC (see LTSYC discussion above) or on ASQ. ASQ is the sum of the volume in yield tables representing growing stock at the time of harvest. The unstated inventory volume and the growth thereon is reflected in the harvest volumes making up the ASQ, therefore, the unstated volume below utilization standards has no affect on ASQ.

Old growth has a lower net growth than younger, fast-growing stands; old growth has a net growth of about 12 cubic feet/acre/year. As the old-growth stands on suitable lands are harvested and "converted" to younger, fast-growing age classes, the Forest-wide per acre growth rate increases. In 1966, the Forest-wide net growth on commercial forest land was estimated at 21.3 cubic feet/acre/year. By the 1976 timber inventory, the growth rate had increased 30 percent, to 27.7 cf/ac/yr, Column (11).

Net growth will continue to increase for 4 to 6 decades in all alternatives; subsequently net growth alternately decreases and increases through the planning horizon. The growth rate increase from 1976 to 2030, Column (12), ranges from 371 percent in Alternative G-Modified to 271 percent in Alternative C. At some future date, when the age-class distribution on suitable lands is fully regulated, LTSYC and net growth will be the same, indefinitely.

The average annual net growth in the alternatives, Column (12), decreases as the percent of suitable lands in the alternative decreases and/or the number of acres producing less-than-full timber yield, Column (17), increases. There is one exception, which is explained below.

Alternative G-Modified has the highest average annual net growth of all the alternatives, yet it is in the middle of the range of the suitable acres going to less than full yield timber prescriptions (Column 17). It has the highest percentage of suitable acres assigned to Management Area 17 when compared to suitable acres. Management Area 17, with its full yield prescriptions and higher yield less-than-full yield prescriptions, produces more wood fiber than other management areas that provide for timber production. This selection of high yield prescriptions combined with a small number of suitable acres produces the highest level of growth per acre at LTSYC.

Column (13a) shows the decade in which net growth for each alternative meets the long-term sustained yield capacity. Alternatives B, C, H, I, and J (Preferred) meet or exceed the LTSYC in decade 6. Alternative A meets or exceeds LTSYC in the 5th decade.

Alternative G-Modified growth reaches the LTSYC first because it has the highest proportion of suitable acres (35%) in young timber stands - 10 to 20 years - and the lowest proportion of old growth (33%). In this alternative, inventory meeting utilization standards and growth in the young age classes is

picked up earlier (Decades 2 to 4) than in regenerated age classes (Decades 3 to 5).

Area and Percent of Suitable Land by Yield Level, Columns (14), (15), (16), (17), (18), and (19)

These columns report, in acres and percent, the suitable lands producing full timber yield or less-than-full yield for each alternative based on growth potential, mean annual increment of timber prescription by type. Most are discussed above. No suitable lands are producing less than 50 percent of full yield even when extended rotations are considered.

Regeneration Harvest in 1st Decade, Columns (20), (21), (22), and (23)

The acres of regeneration harvest in the first decade, Columns (20) - (23), generally vary with the ASQ. Planning projections were made using clearcutting which is the most commonly appropriate harvest cutting method on this Forest. The actual harvest cutting method will be selected on a site specific basis, as identified in the project environmental analysis. Appendix F, FEIS, describes selection criteria and rationale for selection of the harvest cutting method. The Forest Plan will include some sales where miscellaneous acres of shelterwood or selection regeneration harvest methods will be selected as the harvest cutting method.

Those alternatives that have the most acres assigned to Management Area 17 relative to their suitable base and have more flexibility in selecting a harvest schedule - A, and G-Modified - achieve a higher first decade ASQ volume per acre. Based on the area harvested, it would require from 103 to 105 years (Alternatives A and G-Modified respectively) to 134 years (Alternative C) to cut-over the suitable lands at the first decade harvest rates.

The percentage of suitable acres harvested in decade one, (Column 23), does not appear to reflect a pattern among alternatives that relates to the other resource objectives of the alternative except for Alternative C. A lower percentage of suitable acres is harvested in Alternatives C because the harvest rate is reduced by the entry rate and rotation constraints of the reduced yield acres, (Column 16) and a reduced suitable acre base (Column 1). Maximum entry rates and minimum rotation lengths of 160-200 years constrain 152,000 acres of the reduced yield acres in Alternative C.

It should be noted that all alternatives have approximately the same conversion period, 103 to 119 years. Two exceptions are Alternatives NC and C. In Alternative NC, it will take 130 years to harvest all of the commercial forest lands. This is the largest land base on which harvest could occur; 33 percent higher than Alternative A. In Alternative C, it will take 134 years to harvest all of the suitable acres. This can be attributed to the large number of acres assigned to timber prescription with extended rotations of 160-200 years needed to meet other resource objectives.

Comparison of 1963 Timber Management Plans and Alternative J (Preferred).

Timber management data from Table II-9c for the 1963 Timber Management Plans (TM Plans) land base and Alternative J (Preferred) are summarized below.

Standard and special areas in the TM Plans are comparable to suitable acres in the Forest Plan, because both have timber production. No yield is calculated for marginal lands. Standard, special, and marginal are defined and discussed in detail in the planning records.

The potential yield (PY) of the 1963 Timber Management Plans is 86.2% greater than the allowable sale quantity (ASQ) of Alternative J (Preferred). The land base for timber production in the 1963 TM Plans (the standard and special components) is 58.1% greater than the suitable land base for Alternative J (Preferred).

Table II-9c(1)
1963 TM Plans and Alternative J (Preferred) Timber Data

Plan	PY	ASQ	Suitable Lands	CFL Components		
				Standard & Special	Marginal 1/	Total
	..MMCF/Year..			.....Thousands of Acres.....		
1963 TM Plans	41.7			547	33	580
Alt. J (Pref.)		22.4	346			

1/ Marginal acres are comparable to not suited forested lands or tentatively suitable lands that were determined unsuitable because they were not cost efficient (not appropriate) for managing timber in meeting the objectives of a plan alternative.

Although the 1963 TM Plans have a larger land base with timber yield (547,000 acres), Alternative J produces a greater annual timber yield per acre by the fifth decade. The figures are: 87.9 CF/Ac/yr for J compared to 76.2 CF/Ac/yr in the TM Plans. The difference is due primarily to changes in planning methods and tools since 1963: managed yield tables were developed, using the latest techniques, and were used in FORPLAN. Increased yield from planting genetically improved stock was incorporated into the managed yield tables. FORPLAN calculated nondeclining timber yields over a 150-year planning horizon, selecting suitable acres and the most cost-efficient timber management prescriptions from a large number available. See Table II-1. Prescription rotations in timber emphasis MA's ranged from 70 to 120 years.

These methods compare to those used in the 1963 TM Plans, where full yield is based simply on available over-mature volume per year for 100 years, plus an estimate of growth. The dead timber salvaged within regeneration harvest units

was also included in PY, but only net live timber volume is included in the ASQ for the alternatives. In the TM Plan, reduced yields were estimated as a percentage of full yield. There were no provisions included to increase yield from timber stand improvement practices, or from planting with genetically improved seedlings.

The 1963 Plans originally had an "annual allowable cut", a term similar to ASQ. It was calculated using a forest land base stratified into "timber key value areas" for the standard component, and "timber modified cutting areas" for the special component (for such areas as landscape management areas, where visual quality is the management emphasis.) The area of these components was determined by plot expansion; 9/ and the Hanzlick process (Davis 1966) was used to determine annual regeneration harvest yield: it equals over-mature timber volume divided by a 100 year rotation, plus estimated growth.

Administrative changes in terminology amended the annual allowable cut to potential yield (PY) in 1973, and labeled the land base standard, special, and marginal commercial forest land. The PY for the 1963 TM Plans is not exactly the same as the PY calculated for Region 6 Forests during the 1970's, when computer program models were used to calculate yields.

Since 1963, there have been notable official changes in the land base, most discussed earlier.

The PY has been amended six times, changing from 60.7 MMCF (296.9 MMBF) in 1963, to 41.7 MMCF (203.8 MMBF), effective October 1, 1983. 10/ The amendments were made on a proportional basis of CFL added or subtracted; each acre had the same effect. There was no in-place map showing exact boundaries of the standard, special, and marginal components. The RARE process added more uncertainty to the amendments because the source of determination of CFL varied between land management planning and timber inventory records.

9/ Inventory plots are located over the entire Forest on a systematic grid; each plot represents so many acres of the total.

10/ This discussion compares the 1963 TM Plans with a similar administrative unit in 1963. The 60.7 MMCF excludes portions of the Mt. Baker-Snoqualmie in the 1963 unit now administered by the Wenatchee, Gifford Pinchot, and Okanogan National Forests, and the National Park Service.

Comparison of Allowable Sale Quantity and Long-Term Sustained Yield Capacity

The figures below compare, by alternative (except Alternative No Change), the allowable sale quantity (ASQ) over the fifteen decades of the planning horizon with the long-term sustained yield capacity (LTSYC). In general, both ASQ and LTSYC are a function of the number of suitable acres and the timber management prescription intensities assigned in FORPLAN. No LTSYC was calculated for Alternative NC. Refer to the text that accompanies Table II-9c for more discussion.

In all alternatives, long-term sustained yield capacity appears as a constant line over the decades. Alternative A has the highest LTSYC of all the alternatives because of large numbers of suitable acres and higher management intensities in the timber prescriptions. Alternatives B, H, I, and J (Preferred) have approximately the same per acre and annual LTSCY value. This is the result of a combination of similar suitable acres, mix of full yield and less-than-full yield timber prescriptions (see Table II-9c). Alternative C has the lowest per acre and annual LTSYC value. This is due to a combination of few suitable acres, long rotations to meet other resource objectives, and less-than-full yield prescriptions. Alternative G-Modified has the second lowest annual LTSYC, but the highest per acre value. This is attributed to the high percentage of acres that are managed for timber production at full yield or at the upper end of the less-than-full yield category on a small total suitable acre base (see Table II-9c).

ASQ equals or exceeds LTSYC in the eighth decade in all alternatives except A and B. In Alternative B, LTSYC is reached one decade earlier. Alternative A reaches LTSYC three decades earlier in the fifth decade, earliest of all alternatives. This is due to the larger number of acres allocated to Management Area 17, full yield prescription. (See Table II-9c).

Disposition of Tentatively Suitable Acres (Table II-9d)

Table II-9d shows the disposition, by alternative and management area, of all acres that are tentatively suitable for timber production but, in the alternatives, were not assigned to suitable. Alternative NC is not shown, as it has no tentatively suitable acres.

As shown in the first part of Table II-9d, some of these acres were assigned to "no-harvest" MA's because timber production on those acres is inconsistent with other objectives of the alternatives. In the second part of II-9d, the tentatively suitable acres which are not cost-efficient in meeting the objectives, including timber production, of an alternative or not scheduled for harvest during the 150-year planning horizon - classified not suitable for timber production - are summarized for the management areas listed. The last three lines of Table II-9d show the total not suitable acres; added to the suitable acres for each alternative, these equal the total tentatively suitable acres (597,000).

The "no cut portion" of MA 13, Watershed, Wildlife, and Fisheries Emphasis in Riparian Areas, is the estimated number of acres that will remain uncut in each alternative to meet the standards and guidelines. Also included are tentatively suitable acres in MA 13 that are not cost-efficient - over the planning horizon - in meeting alternative objectives, including timber production.

Total Tentatively Suitable Acres	597	597	597	597	597	597	597

1/ Alternative NC not shown as it has no tentatively suitable acres.
2/ 36 CFR 219.14(c) Lands not appropriate for timber production
3/ The estimated number of no-harvest acres to meet standards and guidelines.
4/ The portions of MA 13A-D where timber harvest prescriptions apply.

With the exception of Alternative G-Modified, the allowable sale quantity decreases as the not-suitable acres increase.

Table II-9d shows that Alternative G-Modified contains the fewest suitable acres of all alternatives. This, in combination with the heavy emphasis on intensive timber management prescriptions results in the second lowest ASQ while achieving the highest per acre outputs of all alternatives (Table II-9c, Columns 5 and 12). Alternative C has the second lowest suitable lands but the lowest ASQ of all alternatives. This can be attributed to the emphasis on nonmarket values including dispersed recreation, scenery, and wildlife.

Alternative B has the most suitable acres assigned to minimum level intensity (not cost-efficient or not scheduled in the 150 year planning horizon); more than 8,000 acres more than Alternative I, the second highest. This is the result of one of the goals of Alternative B: high levels of habitat improvement for commonly hunted big game species. Constraints to extend rotation ages and dispersion of harvest units to provide the mix of successional stages to meet the forage and cover requirements of these management areas were applied. These constraints reduce timber production on some analysis areas to the point that they do not make a positive contribution to PNV, thus are not cost efficient or are not scheduled during the 150-year planning horizon. See Appendix B, Chapter VII for more information.

Alternative A has the lowest number of suitable acres assigned to a minimum level intensity of all the Alternatives. Alternative G-Modified has the second lowest number.

Tentatively Suitable Acres Assigned to Timber Production, Reduced Yield (Table II-9d(1)

Table II-9d(1) shows the disposition of tentatively suitable acres, by alternative, to: 1) nontimber objectives; 2) no yield; 3) timber harvest at full yield; 4) timber harvest at 50-99% reduced yield; and 5) timber harvest at 1-49% reduced yield. Alternative NC (No Change) is not shown because tentatively suitable acres were not determined for that alternative. The total suitable acres by yield category for each alternative also appears in columns 14, 16, and 18 of Table II-9c.

Effects of Alternatives on Aggregated Timber Supply (Table II-9e)

Puget Sound Area mills are expected to face a fluctuating timber supply over the next five decades. Projections indicate that the supply of non-National Forest stumpage will increase approximately 22 to 24 percent (over the 1980-84 level) in the next two decades, and then begin to decline until, by the fifth decade, it is only 1.6 percent greater than the 1980-84 supply.

Table II-9e shows the average total Puget Sound Area harvest volume for the 1980-84 period and the expected volume for the next five decades under each alternative. The assumption is made that the Mt. Baker-Snoqualmie National Forest's contribution to this total area harvest is equal to the Timber Sale Program Quantity for each alternative.

In all alternatives, except NC, the aggregate timber supply level falls short of the high level of the estimated demand range for the next five decades. Alternative NC exceeds the high level in Decade 1. In Decade 1, in all alternatives except Alternative C, the projected supply levels exceed the low range demand levels.

During the second decade, Alternatives NC and A supply levels would fall between the upper and lower estimated demand levels. All other supply levels would fall below estimated demand levels.

By the third decade, when non-National Forest supply levels start to decline, only Alternative NC produces high enough timber outputs so that the aggregate supply level falls within the estimated demand range. The aggregate supply level is below the lower limits of the estimated demand for all other alternatives.

During the fourth and fifth decades, as non-National Forest Supply levels continue to decline, all alternatives fall below the estimated demand range.

Recreation, Wilderness, and Related Inputs and Outputs (Table II-9f)

Table II-9f compares the effects and activities of the various alternatives upon the recreation, wilderness, and other amenity resources.

The first five subheadings include current use and current capacity figures, as well as projected future capacity and future demand. For this Forest, capacity means practical, or realistic capacity not the theoretical maximum. 11/ Future demand is expressed as a range (±10% from the absolute figures developed in the analysis process). As demand is an expression of public desire, it is the same for all alternatives in a given decade. The planned future capacity reflects the management response of the various alternatives to recreation, and the ability to meet the expected demand.

An assumption concerning the relationship between future recreation capacity and demand is the key to understanding Table II-9f. It was assumed that projected recreation use will not exceed the estimated capacity for any particular activity. It is expected that use will be limited by a combination of direct management actions by the Forest Service (such as permits, area closures, etc.) and by the users themselves: as use of a particular site or area approaches the capacity level, users will begin to shift, and substitute other activities or move their activities to other lands, if they cannot satisfy their expected recreation experience on the Forest.

This assumption has major significance in the discussion of recreation economic benefits later in this chapter. Since it is assumed that no use will occur above the estimated capacity, no economic benefits are assigned above this level.

Developed Recreation

Currently, the demand for developed recreation (which is primarily alpine skiing and developed campgrounds) is well below the Forest capacity. Alpine ski areas currently have more than enough capacity, and are now expanding to meet a market demand for a higher quality skiing experience. Developed campgrounds are operating well below capacity, except for selected summer weekends, and in certain geographic areas.

Depending on the actual demand in later decades, the alternatives may or may not have enough developed recreation capacity. Alternatives H, I, and J will have the greatest future capacity. Also, see Table II-9f(1) on page II-108, which shows new day-use and campground construction, by alternative.

See page II-106 for further narrative for Table II-9f.

11/ Theoretical capacity is an estimate of the maximum use of the Forest, assuming all facilities are 100% full, all days of the maximum use season. Practical capacity recognizes physical and social limitations, such as low mid-week use and periods of unfavorable weather, when use declines.

5/ Includes 721,600 acres of preservation VQO in wilderness, which is the same in all alternatives.

6/ The visual quality terms here were not in use in 1963. Modified cutting areas termed "Landscape Management Areas (LMA) were managed to protect other resource values. These LMA's included "Present Occupency Areas" (e g Mather Memorial Parkway and developed recreation sites); "Proposed Occupancy"; and roadside, streamside, lakeside, and buffer zones where reduced timber harvest was part of the regulated PY. Terminology amendment to the 1963 Plan termed the CFL in LMA's as Special or Unregulated Actual acres assigned to VQO cannot be reasonably estimated, but would be similar to Alternative A.

7/ VQO for these acres was assigned by the 1981 Alpine Lakes Land Management Plan. These acres vary by alternative depending upon the amount of wildlife habitat assigned in that alternative.

8/ RARE II roadless areas released by the 1984 Washington Wilderness Act.

9/ System roads tentatively closed to all travel are not included.

Roaded Non-wilderness Dispersed Recreation

Current capacity for roaded dispersed recreation far exceeds the current use. Future capacity will be able to accommodate expected demands on the Forest until the fourth decade, when population growth begins to affect all recreation sectors.

Since the dominant use in this sector is "driving for pleasure," those alternatives with the most new road construction (A, B, and I) will best meet expected demand. Any future expansion of the Interstate Highway system could also increase roaded dispersed recreation, since a high proportion of this use is made up of people driving through Forest areas on public highways. A doubling of the number of traffic lanes would greatly increase the future capacity for roaded dispersed recreation on this Forest.

Unroaded Non-wilderness Dispersed Recreation

Unroaded dispersed recreation use currently exceeds the capacity of the Forest. The result, at present, is a reduction in the quality of the local experience, or a displacement to another location to satisfy current demand. With future population growth, this situation will not improve. All alternatives show a decline in the ability of the Forest to supply this form of recreation. Under no alternative will capacity ever meet projected demand. The amenity alternatives merely come closer, for a longer period of time, than commodity-oriented alternatives.

Wilderness Recreation

Use data is based on: 1983 Alpine Lakes and Glacier Peak use plus an estimate for the wilderness acreage added by the 1984 Washington Wilderness Act; and 1986 use data for all eight wildernesses (RIM 1986). Total wilderness acres on the Forest are 721,716.

As can be seen in Table II-9f, wilderness on this Forest is nearing its practical capacity, due in large part, to its proximity to the Puget Sound metropolitan area. By the second decade, projected demand will have exceeded capacity in all alternatives. Capacity is increased in some of the alternatives (I, B) by building trails in currently trailless areas.

Total Recreation Use

Currently, the Forest is operating at about 60% of practical capacity, primarily due to the large existing reserve of developed capacity in alpine ski areas and campgrounds. It overshadows the existing deficit in unroaded dispersed recreation. Demand will exceed capacity sometime in Decade 4 in all alternatives. However, the differences in the ability of each alternative to meet future demand is probably less statistically significant than the error factor in projecting recreation demand so far into the future.

Fish and Wildlife Use

The recreation visitor days of fishing, hunting and nature study are included within the figures reported for wilderness and roaded and unroaded dispersed recreation. These RVD's cannot be added with other subheadings for a Forest total recreation use figure. The figures for WFUD's are based on preliminary data. Current trends predict large increases in non-consumptive and fish use with a smaller gain in hunting. These figures will be updated when more accurate data becomes available.

Visual Quality Objectives

As the visual quality objectives in wilderness (preservation) and the Alpine Lakes Management Unit (varied) remain the same in all alternatives, these acres are not included in Table II-9f. The acres shown also do not total, by alternative, due to wildlife designations overlapping with the Alpine Lakes Management Unit. The overlap differs by alternative, and was not corrected here.

The acres of retention shown in Alternative A differ significantly from the other alternatives due to the general dispersed recreation management area (1E), which is used only in A. Acres in this management area were assigned a prescription of partial retention instead of the retention VQO used in other dispersed recreation MA's (1A,1B) in the rest of the alternatives. Alternative A, thus has the greatest number of acres in partial retention.

Alternatives B and I, with higher timber harvest levels, show significantly more acres of modification and maximum modification. Conversely, Alternative C, with an emphasis on visual quality and unroaded recreation, shows the greatest acres in partial retention and retention.

Unroaded Areas

Because of its unique design, Alternative A merits a brief discussion. In Alternative A, under the existing Multiple Use Plans, most of the roadless areas fall within the Upper Forest Resource Zone (and are assigned to MA 1E). While generally not a high timber producing area, this zone does allow an unspecified amount of development. In Alternative A, it is estimated that about 30 percent of the roadless area acres would be developed.

New Day-Use Sites and Campground Construction (Table II-9f(1))

For some additional comparison among the alternatives, Table II-9f(1) shows the planned new day-use sites and campgrounds, by alternative. Construction would be completed over a period of five decades.

Table II-9f(1)
New Day-Use Sites and Campground Construction Over 5 Decades

Roadless Area Disposition, By Alternative (Table II-9g)

Table II-9g shows a summary of the disposition of the roadless areas on the Forest, by alternative. For each area, the table shows the acres assigned to MA's allowing development and acres that will remain undeveloped. Roadless area information was not determined for Alternative No Change; see footnote number 2 in the table.

As can be seen in the preceding table, II-9f, not all the acres assigned to a development prescription will be developed within the next 15 years. For example: in Alternative J, 93,716 total roadless acres are allocated to development. However, 61,598 of those acres (or 66%) will **not** be developed in the next 15 years.

Alternative A is unique, because most of the roadless acres fall into the existing Multiple Use Plan's "Upper Forest Resource Zone." In mapping Alternative A, these acres were assigned to MA 1E, General Dispersed Recreation, a prescription that matches that of the Upper Forest Zone. While this is generally not a timber harvest area, it allows an unspecified amount of mostly moderate development - some roaded dispersed recreation, including ORV use, but no scheduled timber harvest. In Alternative A, an estimated 30 percent of the total areas will actually be developed.

A maximum of only 155,739 acres, 39 percent of the total roadless acres, are tentatively suitable for timber harvest in any alternative. The acres assigned to development are not limited to lands suited for timber production but may also include non-timber related activities, such as wildlife enhancement. Further information on each separate roadless area can be found in Appendix C, FEIS.

1/ The Timber Management Plans upon which the No Change Alternative is based were developed in 1963. They are not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot reasonably be calculated. However, based on the existing vegetation, it is unlikely that more than 50% of the total roadless area acres would be developed in the foreseeable future.

2/ Estimate. Alternative A is unique because an unspecified amount of development is permitted in Upper Forest Resource Zone. See the description of MA 1E, earlier in this chapter.

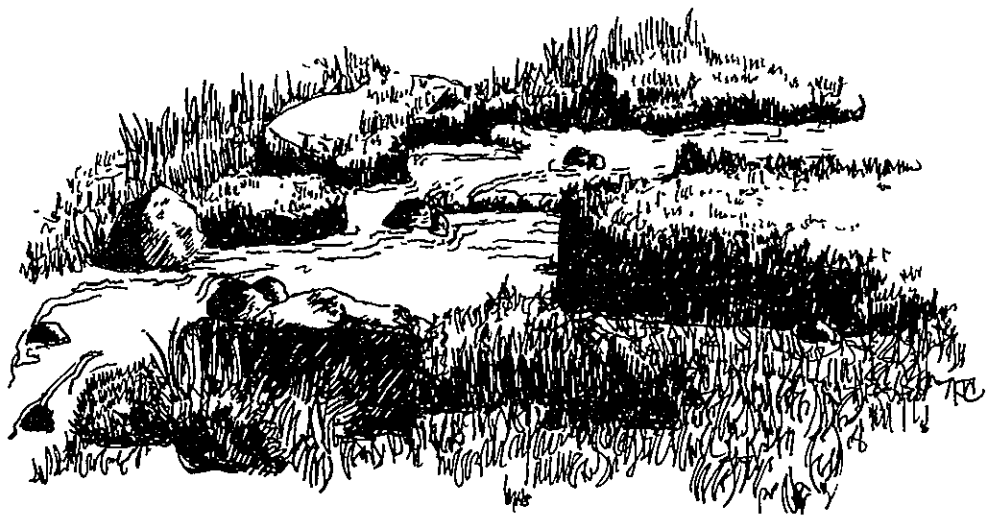
Wild and Scenic Rivers Eligibility and Suitability (Table II-9h)

There are 47 eligible wild and scenic river segments on the Mt. Baker-Snoqualmie National Forest. The suitability and potential classification of these river segments varies by alternative. The variation is based on the amount of roading, vegetative manipulation, or other development activities that would occur within and adjacent to the eligible river corridor.

Table II-9h provides information about the rivers found eligible for inclusion in the National Wild and Scenic Rivers System. The first three data columns display for each river the miles, by classification type (Wild, Scenic, or Recreation), found eligible for classification. Following the eligibility determination information are the results of the suitability study made for each river for each alternative. This part of the table shows those rivers found suitable for recommendation for inclusion in the National Wild and Scenic Rivers System for each alternative.



Footnotes for Table II-9h:

1/ Only upper three segments recommended: 3.0 miles Scenic, 2.3 miles Wild, and 4.3 miles Scenic.

2/ Only 42.8 miles recommended.

3/ Only lower 12 miles recommended: Scenic.

4/ Recommended for Recreation River.

Research Natural Areas (Tables II-9i and II-9j))

There are three established Research Natural Areas (RNA's) on the Mt. Baker-Snoqualmie National Forest. Five potential additions to the system have been identified. The existing and potential Research Natural Areas are listed in listed in Table II-9i

Table II-9j Displays which potential RNA's are recommended for designation in each alternative.

Table II-9i

Name	Acres	Principle Features
Established		
N.F. Nooksack River	1,407	Douglas-fir, western hemlock forests.
Lake Twenty-two	790	Western redcedar, western hemlock forests and subalpine lake.
Long Creek	640	Western hemlock forest, climax red alder forest.
Potential		
Addition to North Fork Nooksack RNA	2,460	Example of Douglas-fir, 75 year old burn. Also includes wide array of subalpine meadow communities found in existing RNA.
Lily Lake	800	Represents high-elevation mountain hemlock-Pacific silver fir forest. Lake is typical of mid-to-high-elevation subalpine lakes.
Perry Creek	2,066	Represents unique assemblage of rare fern species. Also has Alaska cedar (in stand with mountain hemlock and subalpine fir) and heather-huckleberry community.
Green Mountain	2,060	Represents subalpine parkland mosaic, heather-huckleberry communities, and subalpine lush herbaceous communities.
Chowder Ridge	1,920	Alpine community mosaic with Krummholz tree groups.

Fish and Wildlife Inputs and Outputs (Table II-9k)

Table II-9k shows inputs and outputs for anadromous fish and selected wildlife species at the end of Decades 1, 2, and 5, by alternative.

Anadromous Fish

Commercial harvest of anadromous fish is related to the anadromous fish habitat improvement (and the level of investment). Commercial harvest will not vary through time. Improvements completed in Decade 1 will remain and be maintained through Decade 5, thereby providing the same amount of additional fish production each decade. Alternative NC production is similar to Alternative A.

Management Indicator Species

The wildlife species shown are the majority of the indicator species for the Forest. Population estimates are shown, as a measure of habitat capability. These population estimates are based on the maximum available habitat in each alternative for the decade shown. Reliable population inventories are not available for most species; numbers shown are based on current estimates projected into the future, based on expected changes in habitat (from management activities, etc.). Trends in populations should be given more weight than the actual numbers. Data for Alternative NC cannot be reasonably estimated.

Bald eagle numbers are derived from recovery plan population objectives for pairs in breeding territories. (There is currently one active nest.)

Two other management indicator species, the American peregrine falcon and grizzly bear, are not included in the table. Occasional sightings of these species have been recorded but no habitat capability or population estimates have been developed, due to lack of data.

Mature and Old-Growth Habitats

Wildlife populations that primarily use mature and old-growth habitats (northern spotted owl, marten, pileated woodpecker) decrease over time in all alternatives, primarily due to harvest of these timber age classes.

Population estimates for mature and old growth management indicator species exceed the MR population levels in all alternatives, except Alternative NC, for all time periods. In alternatives other than NC, population levels will approach MR levels in those portions of the Forest where timber harvest occurs, but will remain above MR levels in the undeveloped portions of the Forest.

Acres of spotted owl habitat, by land classification include:

Acres in Reserved Areas:	166,200 acres (1989)
Acres Not Suited for Timber Production:	137,037 acres
Acres Suited for Timber Production Outside of SOHA's	146,000 acres
All Acres of Suitable Habitat	499,237 acres

Primary Cavity Excavators

On lands suitable for timber production, habitat will be provided for varying percents, by alternative, of the total population potential for primary cavity excavators. Alternative NC is estimated is to similar to Alternative A (No Action). Potential populations are based on home ranges, vegetative types, and other factors (Brown 1985 and others). Also, refer to Chapter III, FEIS, Wildlife. Forested areas with no timber harvest will generally have higher populations.

Big Game Species

Thermal cover on big game winter range is reduced in all alternatives. However, winter range habitat capability for deer and elk increases from the current situation (which supports 9,140 deer and 470 elk) through the first decade, a result of increased forage from timber harvest activities. In the second decade, habitat capability declines as winter thermal cover becomes limiting. By the fifth decade, habitat capability again increases due to improving forage/cover ratios, from habitat improvements implemented in the first decade. Summer deer and elk populations increase due to forage production in timber harvest areas.

Mountain goat habitat provides both winter and summer range, so the populations are limited by winter range capability.

Wildlife habitat improvements result in additional habitat capability for some of the above species - big game - as well as for other wildlife, such as osprey and waterfowl.

Consultation with U.S. Fish and Wildlife Service

A biological assessment of the effects of the Forest Plan alternatives on Federal threatened and endangered species was completed and submitted to the USDI Fish and Wildlife Service. The finding of this assessment was that, under all alternatives, federally-listed species would not be affected detrimentally. These species will receive special management under Forest-wide Standards and Guidelines and the standards and guidelines for individual species. The Forest will confer with the Fish and Wildlife Service on any future actions which may affect a listed species.

1/ Values for wildlife species other than bald eagle and primary cavity excavators are population estimates based on maximum habitat potential.

2/ The TM Plans upon which the No Change Alternative is based were developed in 1963. They are not integrated resource plans and consequently did not address all resource uses and outputs.

3/ Populations would be expected to decline at a rate faster than Alternative A because no specific provision is made in Alt. NC to maintain viable populations and more of the old growth is suitable for timber harvest and will be fragmented.

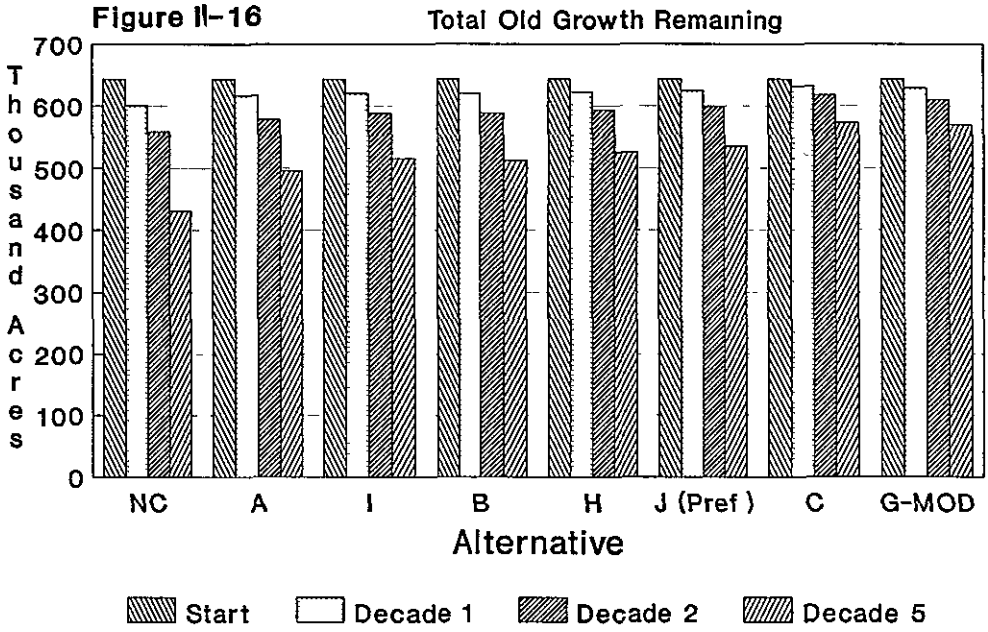
4/ On acres suitable for timber harvest. Percentages are higher on other portions of the Forest.

Old Growth Forest (Table II-91)

Old growth timber stands are valued as wildlife habitat, for their contribution to ecosystem diversity, and for their aesthetic qualities. Old growth is also valued as a timber resource to supply mills. The acres of old growth remaining varies by alternative; the acres of old growth inside wilderness and Research Natural Areas will not change by alternative. Refer to Table II-91. Management requirements are included in every alternative except Alternative NC and retention for ecosystem diversity and aesthetics is considered in each alternative.

Figure II-16 is a duplicate of Figure II-3, on page II-72 of this chapter. Figure II-17 shows acres of old growth remaining on lands suitable for timber production. At the end of five decades, Alternatives C and G-Modified will have the most old growth remaining and Alternatives A (No Action), I, and B the least.



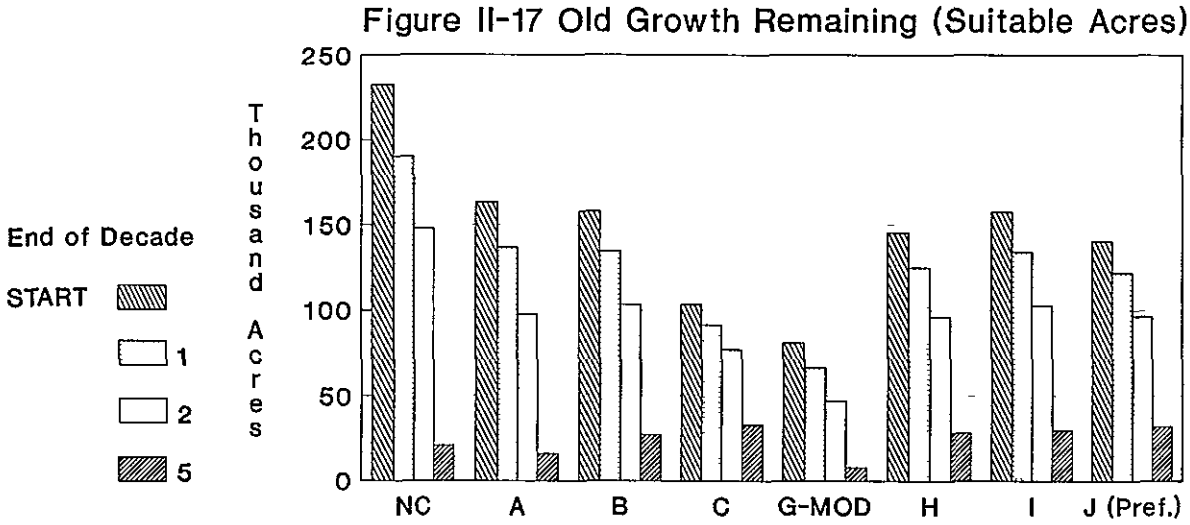


Table II-91

Old-Growth Acres by Alternative 1/

Alternative	Old Growth in Wilderness	Non-wilderness Not Suited for Timber Production Because of Other Resource Objectives 2/	Non-wilderness Not Suited for Timber Production Because of Potential Irretrievable or Irreversible Resource Damage	Non-wilderness, Suited for Timber Production and Allocated to a Prescription Allowing Timber Harvest			
				Start	End Decade 1	End Decade 2	End Decade 5

C	232,500	173,393	134,400	103,245	91,396	77,180	33,134
G-Mod.	232,500	195,946	134,400	80,692	66,491	47,228	7,824

1/ The total acres of old growth, at the starting point, wilderness and non-wilderness = 643,538 No reasonable estimates for Alt NC.

2/ Other resource objectives include allocations such as wildlife MR's, riparian MR's, or non-motorized dispersed recreation, etc These vary by alternative, depending upon the objectives or goal of the alternative.

Grazing, Minerals and Energy Yields (Table II-9m)

Table II-9m compares, by alternative, the long-term yields for range and minerals, and the acres available for mineral exploration. The current low demand for domestic livestock range is expected to continue.

The acres available for mineral exploration do not vary much between alternatives, ranging from 53.7 percent to 50.1 percent of the total Forest, in Alternatives A and G-Modified, respectively. Alternative NC is similar to A. Alternative G-Modified is lower due to the acres assigned to Special Areas (Management Area 8).

Energy mineral production varies according to location and access to areas prospectively valuable for energy minerals, especially geothermal energy. Outside wilderness, MA prescriptions that restrict access and/or mineral development were assigned to 41 percent and 35.8 percent of the Forest in Alternatives C and G-Modified, respectively. Alternative H has similar restrictions on 32.2 percent to 28.7 percent of the total Forest outside wilderness. Significant production of oil, gas, or coal in the Forest during this period is not expected.

Non-energy minerals include salable minerals (stone or gravel) and locatable minerals. It is assumed that production of salable minerals will continue to meet off-Forest demand in all alternatives; Forest Service demand is generally proportional to road construction and reconstruction.

Production of locatable minerals depends on a number of factors: technology, demand, location relative to withdrawn areas, and management emphasis of the selected alternative. Commodity-oriented Alternatives B and I have the least decrease in production from the present, followed by H.

The U.S. Bureau of Mines data (USDI 1985) indicates demand for non-energy mineral commodities from this Forest is expected to increase at the rate of 2 percent per year through the year 2000, with no prediction beyond that year.

1/ The 1963 Timber Management Plans, upon which Alternative No Change is based, were not integrated resource plans, and consequently did not address all resource uses and outputs.
2/ Two sheep allotments with an estimated capacity of 950 AUM's, have been in non-use status the past 5 years.
3/ Area other than Wilderness where MA prescriptions call for withdrawal These acres include Mt. Baker National Recreation Area, 8,743 acres, which is withdrawn from geothermal entry.

Budget, Costs, and Social and Economic Outputs and Effects (Table II-9n)

Table II-9n presents, by alternative, the projected total budget and costs for Decades 1, 3, and 5. Also included are a number of social and economic outputs and effects.

The total budget is made up of operational costs plus capital investment costs. Operational costs include all salaries and expenses (excluding capital investment costs) dispersed in managing the Mt. Baker-Snoqualmie National Forest and producing outputs. Capital investment costs include costs for road construction and preconstruction engineering (such as location, survey, and design of a road), plus campground and/or facility development.

Returns to the Treasury include: all receipts from timber stumpage (a marketing term, meaning the dollar value assigned to timber still standing in the forest - "on the stump" - rather than its value in the mill, etc.); recreation fees; special use permits; or other permits or sales minus timber purchaser road credits.

Timber Purchaser Credits. The appraised price of timber sales sold is calculated as if roads needed to remove the timber were already constructed. If roads are required in the sale, timber purchaser credits are paid to the timber sale purchaser (or applied to stumpage). If the sale appraised at $100 per MBF and roads cost $10 per MBF, the purchaser could receive $10 per MBF purchaser credit for completing all roads; thus, only $90 of the $100 per MBF appraised price would be returned to the Treasury. If the purchaser bid more than $100 per MBF to buy the sale, additional dollars would be returned to the Treasury.

In Table II-9n, the payments to counties shown are higher than the 25 percent of Returns to the Treasury, as the figure includes 25 percent of the purchasers road maintenance and fuel treatment payments, which, in the planning process, were excluded from Returns to Treasury.

The human resource program includes various programs operated by the Forest that provide employment, training, and experience to members of the community. These programs accomplish work that would not otherwise be accomplished. Programs included are: the Senior Community Employment, the Forest Volunteer, Touch America Project, and Youth Conservation Corps. Demand for these programs is high, however the Forest is limited in its ability to utilize these programs by personnel and funds needed to train, supervise, and manage people in the programs. For this reason, the program is projected to be the same for all alternatives.

The last outputs shown in Table II-9n are the direct, indirect, and induced jobs and income generated by alternative outputs. Jobs and income generated by average Forest outputs for the periods, 1985-86 and 1977-86, are inserted into the table for comparison with jobs and income projected for each alternative. All calculations relative to timber outputs are based on Timber Sale Program Quantity (TSPQ), assuming timber sold and harvested will be equal.

1/ The 1963 TM Plans, upon which Alternative NC is based were not integrated resource plans, and consequently did not address all resource uses and outputs Alternative NC was not modeled in FORPLAN, information in this table was calculated outside of FORPLAN

Inventoried American Indian Religious and Cultural Use Sites (Table II-9o)

Table II-9o shows, by alternative, an approximate percentage of the inventoried American Indian religious and cultural use sites protected by management areas that generally preclude or limit ground-disturbing activities. The percentages given in Table II-9o should be viewed as only an approximation as some use sites and areas were not identified in the Inventory, but were included in a larger "buffer" area by tribal respondents. Therefore, the degree of actual protection in each alternative can only be estimated.

Inventoried use sites and areas are not mapped as MA 7, American Indian Religious and Cultural Uses in order to protect the confidential nature of the areas as authorized by the Archeological Resource Protection Act (P.L. 96-95), the National Historic Preservation Act (P.L. 89-665), and exemptions to the Freedom of Information Act (P.L. 93-502).

In the table, the difference between "high" and "moderate" protection is derived from the expected frequency of human encounters. There is no timber harvest or road construction in either. All cemeteries have high protection. Management Areas 1A, 10B through 10E, 11, 12, 15A, and 18 afford high protection. Management Areas 1B, 5C, 10A, 16, and 23B afford moderate protection. Not all of the inventoried acres are currently in an undeveloped state.

The actual protection of all sites will be determined using the Forest-wide Standards and Guidelines for the mapped Management Areas (see Chapter 4, Forest Plan) and through the consultation process. Consultation will be conducted with appropriate tribes before initiating any field activity that may affect these areas or sites. It is this process that will determine the actual level of on-the-ground protection for religious and cultural use areas and sites.

The percentage of "high" protection provided for each type of site (except cemetery sites) does not vary much between alternatives. While the number of acres "protected" in one of the above listed MA's versus another varies considerably among the alternatives, the overall percentage does not vary much.

Alternatives C and G-Modified provide the highest percentage of management area acres providing moderate protection for all types of religious and cultural sites. There is a much wider variation between alternatives in the percentage of moderate protection provided, excluding cemeteries. This is because there is a much wider range between alternatives in the combined total acres of assigned MA's affording moderate protection (MA's listed above).

Because of goals and the design criteria of the alternatives, overall protection is highest in Alternatives C and G-Modified. These alternatives would show higher percentages of high protection in Table II-9o if the MA's affording high protection were not "over-ridden" by MA's that provide moderate protection (e.g. 1B and 10A "over-riding" MA's 11, 12, and 14).

Table II-9o

1/ The 1963 TM Plans, upon which Alternative NC is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated because, except for cemeteries, the percentages were developed by overlaying inventoried areas with MA's; no MA's were assigned in Alternative NC.

Qualitative Resource Outputs and Environmental Effects (Table II-10)

Table II-10 displays selected qualitative resource outputs and environmental effects that could not be adequately shown in the II-9 tables. Again, the alternatives are discussed in order of decreasing acres of land suitable for timber production. This order is strongly correlated to the amount of vegetative management in each alternative, and is useful in understanding how the environmental consequences and effects will vary by alternative.

Alternative NC (No Change) is based on the 1963 Timber Management Plans; they were not integrated resource plans and consequently did not address all resource uses and outputs. Data for this alternative is presented, or estimated, as available.

Note: although the outputs and effects occur over the long-term, the results of this planning process will apply for only 10 to 15 years, the life of this Forest Plan.

Refer to Chapter IV, Environmental Consequences, for a complete discussion of the effects of implementing the alternatives on the physical, biological, social, and economic environments.

Table II-10 Page 1 of 6
Qualitative Resource Outputs and Environmental Effects

Archaeological and Historical Properties

NC (No Change)	Estimated to be similar to Alternative A (No Action), by highest frequency of resource damage.
A (No Action)	High frequency of resource damage in developed areas, with high mitigation costs. Information gained through site discovery and recovery.
I	Intermediate frequency of resource damage in developed areas, with high mitigation costs. Some information gained.
B (RPA)	Similar to Alternative I in developed areas.
H	Similar to Alternative I in developed areas.
J (Pref)	Similar to Alternative I, with more potential for information gain and interpretation.
C	Has the fewest adverse effects on cultural and historic resource, but also fewer opportunities for information gained through site discovery and interpretation
G-Mod	Only Alternative C has fewer adverse effects. Somewhat less opportunity for gaining information.

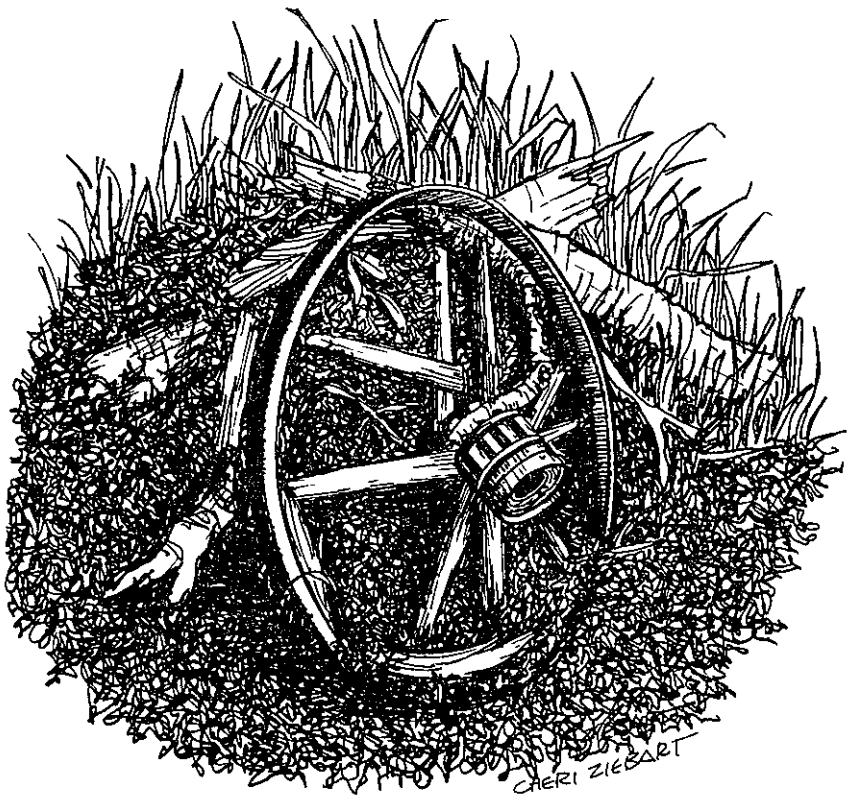

Table II-10 Page 2 of 6

Visual Quality

Same in All Alternatives: Visual quality in Alpine Lakes Management Area (which includes Snoqualmie Pass and Stevens Pass Highways) and Skagit Wild and Scenic River will be managed as prescribed in approved plans, except where overridden by wildlife MR's. Wilderness is Preservation in all alternatives.

NC (No Change	The foreground of Mather Memorial Parkway is managed as a scenic corridor; timber harvest permitted but not scheduled. Effects of NC on other areas of the Forest are estimated to be similar to Alternative A.
A (No Action)	With emphasis on timber harvest at low elevations, coinciding with many heavily used rec. areas, there would be some conflict between commodity production and scenic quality. The cumulative effect of Alt. A would be a "moderately" altered character even in highly scenic areas. Only the foreground of Mather Memorial managed as scenic corridor.
I	With an emphasis on managing tentatively suitable lands for timber production, only the foreground of heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Parkway, Mtn. Loop Highway, Mt. Baker Highway, Baker Lake Highway, and North Cascades Highway 20. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily-altered state.
B (RPA)	With high emphasis on managing all tentatively suitable lands for timber production, scenic quality will deteriorate for almost all lands accessible by road. Only the foreground of Mather Memorial Pkwy will be managed as scenic area; only sites unsuitable for timber production will remain roadless.
H	The foreground and middleground of five heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Pkwy, Mtn. Loop Hwy, Mt. Baker Hwy, Baker Lake Hwy, and North Cascades Hwy 20. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily altered-state.
J (Pref)	The foreground and middleground of 7 heavily traveled corridors will be managed to retain high visual quality: Mather Memorial Pkwy (MA 8, Special Area), Mtn. Loop Hwy, Mt. Baker Hwy, Baker Lake Hwy, North Cascades Hwy 20, Cascade River road, and Crystal Mtn. Hwy. Outside these viewsheds and the roadless areas, the Forest will be managed at a moderately to heavily altered-state. Wild and scenic river recommended (30 rivers) will add to visual quality.
G	With low level of timber harvest and emphasis on retaining old growth and wild and scenic rivers, many foreground areas will be visually unaltered. Some scenic acres assigned: upper end of Mt. Baker Hwy, portions of Cascade and N. Fk. Cascade R., portions of Mtn. Loop Hwy, upper Sauk, lower Sultan, and Mather Memorial Pkwy. Middleground views will be "moderately altered". Roadless areas will be undisturbed.
C	Nearly all existing roadless areas will remain roadless and be visually undisturbed. Both primary and secondary recreation corridors will be managed as scenic viewsheds. Opportunities for roaded and remote scenic viewing are high.

Table II-10

Water and Riparian Resources

NC (No Change	Emphasis for water quality similar to Alt. A. Some riparian values protected via land stratification in TM Plan (no regulated harvest on Marginal). Mitigation measures - similar to Alt. A.
A (No Action	Emphasis on maintaining water quality. Riparian values managed at MR level. Intensive mitigation measures needed to mitigate effects of high road construction and vegetation disturbance from timber harvest.
I	Water quality maintained or improved slightly from Alternative A. Riparian values managed with special emphasis on enhancement. More intensive mitigation measures than in Alternative A, required to mitigate direct effects of roads and timber harvest on soils which result in sedimentation.
B (RPA)	Water quality will improve slightly over Alt. A due to longer harvest rotations in large areas managed for wildlife habitat improvement. Riparian values managed with special emphasis on enhancement. Fewer acres harvested and miles of road constructed/reconstructed than in Alt. A require less mitigation of direct effects of road construction and timber harvest.
H	Water quality improved over Alt. A due to fewer acres harvested and fewer new roads. Management of riparian values and mitigation measures needed are similar to Alt. I.
J (Pref)	Water quality improved over Alt. A due to fewer acres harvested and fewer new roads. Management of riparian values and mitigation measures needed are similar to Alt. I.
G-Mod	Water quality will improve significantly over Alt. A due to fewer developed areas, reduced road construction and timber harvesting, and closure of about 65 miles of existing road. Riparian values managed with special emphasis on enhancement. Lowest mitigation costs except for Alt. C.
C	Water quality will improve significantly over Alt. A due to reduced timber harvest, road construction, plus closure of 300 miles of existing road. Riparian values managed with the highest emphasis on enhancement of any alternative. Least mitigation required.

Diversity of Plant Communities

Same in All Alternatives: Timber harvest or the lack of timber harvest, will have a great effect on the kinds and distributions of plant communities found on the Forest. On those areas where timber harvest is precluded, natural processes will continue uninterrupted and more late successional communities will prevail. These areas will be dominated by large diameter trees of advanced age and other plant species associated with this condition.

In those areas where timber harvest occurs, there will be a transformation from the late successional communities to early successional communities. These areas will be dominated by small to medium size trees of relatively younger ages, less than 160 years old, and other plant species associated with this condition. These plant communities will take on a mosaic appearance because of the schedule of harvest activities and their distribution across the landscape. In addition, there will be intermingled areas of late successional communities. The amount and distribution of these intermingled older communities will depend on the theme of the individual alternative.

NC (No Change	There will be an increase in early successional plant communities on all commercial forest lands. By the end of the 5th decade, approximately 435,000 total forested acres will be in successional stages 100 years or less in age.
A (No Action	Late successional plant communities will be found on 739,000 forested acres (480,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 147,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 370,000 total forested acres in successional stages 100 years of age or less.
I	Late successional plant communities will be found on 744,000 forested acres (486,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 128,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 351,000 total forested acres in successional stages 100 years of age or less.
B (RPA)	Late successional plant communities will be found on 744,000 forested acres (486,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 130,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 353,000 total forested acres in successional stages 100 years of age or less.
H	Late successional plant communities will be found on 757,000 forested acres (450,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 117,000 acres will have been converted to earlier successional stages. This combined with the starting acreage

of stands in successional stages under 50 years of age (223,000 acres) produces a total of 340,000 total forested acres in successional stages 100 years of age or less.

J (Pref) Late successional plant communities will be found on 763,000 forested acres (503,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 108,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 331,000 total forested acres in successional stages 100 years of age or less.

C Late successional plant communities will be found on 806,000 forested acres (540,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 70,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 293,000 total forested acres in successional stages 100 years of age or less.

G-Mod Late successional plant communities will be found on 832,000 forested acres (563,000 acres in age classes 240 years plus) not scheduled for harvest. By the 5th decade, 73,000 acres will have been converted to earlier successional stages. This combined with the starting acreage of stands in successional stages under 50 years of age (223,000 acres) produces a total of 296,000 total forested acres in successional stages 100 years of age or less.

Civil Rights

Same in All Alternatives: Various Civil Rights, Affirmative Action, and Equal Employment Opportunity Acts require that Forest Service hiring, supervisory, and contracting practices be conducted in a manner conducive to meeting established Regional and Nation-wide goals in these areas. In all alternatives, positive steps are included to ensure that facilities, sites, and activities will not be denied to any individual on account of race, color, creed, religion, sex, marital status, age, handicap, or National origin.

Table II-10

Social Environment

Same in All Alternatives: There is no measurable effect on urban communities. See Table II-9n for the economic effects. Jobs lost/gained will often affect residents in the rural and agricultural communities east of the Interstate Highway 5 corridor.

NC (No Change)	Lifestyle and minority employment: estimated to be similar to Alternative A (No Action).
A (No Change)	No apparent changes in lifestyle. Some of the employment generated in Decade 1 will be filled by minorities.
I	Opportunities increases for individual pursuing roaded recreation experiences, although these people will encounter strong evidence of altered landscapes. The most favorable alternative for minority employment.
B (RPA)	Similar to Alt. D; less favorable than the current situation for minority employment.
H	No apparent changes in lifestyle would occur. Less favorable than the current situation for minority employment.
J (Pref)	No apparent changes in lifestyle would occur. Less favorable than the current situation for minority employment.
G-Mod	Opportunities are enhanced for those who seek leisure or work in a more natural environment, and diminished for those pursuing roaded recreation experiences. Less favorable than the current situation for minority employment.
C	Opportunities increase for those pursuing activities in a natural setting and decrease for those pursuing roaded recreation experiences. Least favorable for minority employment.

4. Economic Tradeoffs Among Alternatives

Present Net Value (PNV) is an estimate of the potential economic effectiveness of managing the Forest. Since each alternative is a different way of managing the Forest, each alternative has its own PNV. By comparing PNV of the alternatives, the economic effectiveness of the alternatives can be compared.

As discussed in the first pages of this chapter, PNV is defined as the discounted dollar value of all priced outputs, less the discounted cost of all expenditures for management and investments. Discounting is a way of combining current and future values to show them in todays terms; values are expressed in terms of 1982 dollars and the discount rate used is 4%. A more complete discussion of PNV is included in Appendix B.

Priced outputs include resource outputs with a market price and those non-market resource outputs that have an assigned price (commensurate with market prices). Market resources include: timber, developed recreation, commercial anadromous fish, minerals, and special uses for which fees are collected. The displayed economic benefits for market resources include actual dollar receipts plus additional assigned dollar benefits for developed recreation. Non-market resource benefits are dollar benefits assigned to dispersed recreation, wilderness, and wildlife and fish-dependent recreation. The purpose of assigning dollar benefits is to reflect the full economic benefit, even though none, or only part, of that benefit associated with particular resources is actually collected as fees under current laws and policies. Economic benefits associated with market and non-market resources are displayed in detail in Appendix B, Table B-16.

As discussed in the text preceding Table II-9f, an assumption made concerning the relationship between recreation capacity and use has a significant effect on the economic benefits of recreation discussed here. It was assumed that recreation use will be limited to estimated capacity. Under this assumption, no use would occur above capacity levels; therefore, no economic benefits were assigned above that level.

If this assumption is incorrect and recreation use occurs to the level of predicted demand, recreation benefits have been underestimated by $698 million to $801 million, depending on the alternative. This potential underestimation would increase PNV by approximately one-third.

Since projected demand in Decade 1 is below estimated capacity for all classes of recreation - except non-wilderness unroaded dispersed, 6 percent of total demand - the possible underestimated economic benefits would not occur until after the first decade, or beyond the life of this plan.

Costs

Two types of costs are included in Forest management: operation and maintenance, and capital investment.

Operation and maintenance costs are the costs of activities required to plan and manage outputs, and maintain existing capital assets at standard levels. These include fixed costs such as general administration, and variable costs

which vary with different levels of outputs. Fixed costs are constant across all alternatives, while variable costs differ among the alternatives.

Capital investment costs are the costs of creating or enhancing capital assets, such as roads, trails, or fish habitat improvement structures. Road construction costs are a main component of capital; they are a direct function of the timber program. Other capital investment costs, such as fish and wildlife, vary independently of the timber program.

Table II-11: PNV, Discounted Costs and Benefits of Alternatives

Table II-11 summarizes the economic information used to determine PNV for each alternative, except Alternative NC, and for the Maximum PNV, with MR's Benchmark. This benchmark is not considered to be a viable alternative for the reasons discussed earlier in this chapter; it is shown as a reference point. The alternatives are ranked in order of decreasing PNV.

Discounted costs are the sum of all the costs which would be incurred to implement the alternative, discounted to their present value at a four percent interest rate. Discounted benefits are the sum of all the benefits produced by an alternative, discounted to their present value using a four percent interest rate.

The "change" is the difference in either PNV, discounted costs, or discounted benefits between successionally ranked (in descending order of PNV) pairs of alternatives. The incremental changes in PNV are a measure of the net economic benefits of the priced resources that would be foregone if a lower ranked alternative were to be selected over the preceding one. These priced resources that would be foregone would have to be weighed against the response to public issues and any net difference among the non-priced outputs.

As a general rule, PNV declines because benefits decline faster than costs, mainly due to a decline in timber benefits, although recreation benefits also fall. There are, however, some exceptions to this general rule.

When comparing Alternative A (No Action) to Alternative J (Preferred), Alternative A has markedly higher discounted costs (30%) and benefits (10%) than Alternative J (Preferred) but only slightly higher (1%) PNV. The objective function (in FORPLAN) for Alternative A is to maximize timber outputs in the first five decades. As a result, Alternative A has higher timber outputs with accompanying increased benefits, but these increased outputs are achieved at the cost of less efficient investments in timber management practices, which increases cost. Alternative A has the highest road construction program of any of the Alternatives, which also increases costs.

Another general trend: as roaded dispersed recreation use declines, so does PNV. Again, there are some minor exceptions. All alternatives have the same roaded dispersed recreation use in Decade 1, as capacity exceeds demand, thus limiting the benefits of roaded recreation to actual use.

Although there is a strong correlation between roaded dispersed recreation and PNV, this relationship is attributable to timber outputs and the accompanying road construction program. Thus, timber outputs are the real driver of PNV.

Table II-11

Present Net Values and Discounted Costs and Benefits of Alternatives

Alternative/Benchmark	PNV	Change	Discounted Costs	Change	Discounted Benefits	Changes
Benchmark	.....	.....	Millions of Dollars.....			
Max PNV with MR's (run #7)	2590.7	-247.5				
Alternatives						
B (RPA)	2343.2	-0.3	1091.5	3.9	3434.7	3 6
I	2342 9	-59.4	1095.4	178.3	3438.3	118.9
A (No Act.)	2283.5	-23.5	1273 7	-242.4	3557.2	-265.9.2
H	2260.0	-1.2	1031 3	-46.9	3291.3	-48.1.9
J (Pref.)	2258.8	-261.8	984.4	-156.2	3243.2	-418.0
G-Mod.	1997.0	-26.1	828.1	-103.9	2825.1	-130.0
C	1970.9		724.3		2695.2	
NC (No Change)	NA	NA	NA	NA	NA	NA

Table II-12: PNV, Discounted Benefits and Costs By Resource Group

In Table II-12, the total costs and benefits for each alternative are assigned to selected major accounting or budgeting categories. A complete and exact relationship between the dollar benefits associated with a particular priced output and the cost figure assigned to it should not be assumed. Forest-wide production of any specific priced output is generally supported by complex combinations of input costs. As an example, some recreation and wildlife benefits are joint outputs of timber management.

In Table II-12 the total discounted costs and benefits have been disaggregated into the broad resource groups of timber, recreation, and other. "Timber" benefits include sawtimber and fuelwood. "Recreation" benefits include dispersed and developed recreation, and wildlife and fish use. Benefits for commercial fish are included under "other." Discounted costs for roads are shown as a separate entry, since it is very difficult to accurately separate these costs into the resource groups. Costs shown under "other" include fish habitat improvement investments, share-cost road maintenance, and fixed costs.

Table II-12 indicates that almost all of the variation in PNV discounted costs and discounted benefits is due to the variation in timber outputs of the alternatives. First decade timber outputs vary by 125% between Alternative C (13.8 million cubic feet) and Alternatives A (31.0 million cubic feet). The discounted costs and discounted benefits for timber follow the same general trend as timber outputs with some minor exceptions: as timber outputs decline, so do discounted costs and benefits.

Discounted costs and benefits for recreation change very little from one alternative to another. This is partly due to the fact that current recreation use is very close to capacity on the forest for most types of recreation except roaded dispersed. There is little opportunity to significantly increase recreation supply in wilderness or primitive, semi-primitive nonmotorized, or semi-primitive motorized outside of wilderness. Although there is some variation between alternatives in these dispersed recreation capacities, it is a very small percentage of the current capacity and affects discounted recreation benefits only about 6% between the alternatives. Discounted recreation benefits exceed discounted timber benefits in all alternatives.

Alternative C has the lowest discounted recreation benefits of all the alternatives but the highest levels of primitive and semi-primitive nonmotorized recreation capacity. This inverse relationship is true throughout all the alternative rankings. Although primitive and semi-primitive nonmotorized recreation use has a higher value per RVD than motorized use, it has a lower RVD per acre coefficient. The result is that on a per acre basis, motorized use is more valuable than nonmotorized use.

Table II-12

Present Net Values and Discounted Benefits and Costs by Resource Group

Alternatives	PNV	Discounted Benefits			Discounted Costs			
		Timber	Recreation	Other	Timber	Roads	Recreation	Other
		Millions of Dollars						
B (RPA)	2343.2	1384 3	1904.2	146.2	746.8	147.2	34.8	162.7
I	2342.9	1400.0	1892.1	146.2	754.1	146.9	35.2	159 2
A (No Act.)	2283.5	1643.5	1880.0	33.7	916.2	165 1	34.8	157.6
H	2260.0	1288.6	1856.5	146.2	693.3	144.2	34.7	159.2
J (Pref)	2258.8	1204.8	1892.1	146.2	650.3	136 2	35.2	162.7
G-Modified	1997.0	940 8	1805.4	78.9	523 1	110.9	34.9	159.2
C	1970.9	760.5	1788.5	146.2	420.5	106.8	34.2	162.7
NC (No Change)	NA	NA	NA	NA	NA	NA	NA	NA

Table II-13: Average Annual Cash Flows, Non-cash Benefits

In Table II-13, the alternatives are ranked in order of decreasing net receipts; all alternatives show a positive cash flow (net receipts) to the treasury in Decade 1 except Alternative C. Alternative A has the highest cash flow, with $6.5 million, while Alternative C has the lowest with a ($0.2) negative flow. There is an almost identical ranking of the alternatives in terms of cash flow and ASQ, because timber receipts make up nearly all of the total receipts on the Forest.

All of the alternatives have a positive cash flow in the fifth decade. Again the ranking of the alternatives in terms of cash flow mirrors the ranking of alternatives by ASQ.

Net receipts increases from Decade 1 to Decade 5 in all alternatives. In the first decade, the water quality and riparian management requirement result in reduced acres of harvest in some watersheds and thus lower receipts than in later decades when the HCE management requirement allows increased harvest. Alternative A net receipts increase most ($23.1 million) and Alternative G-Modified the least ($8.9 million) between the first and fifth decade.

From Decade 1 to Decade 5, total receipts in Alternative J (Preferred) increase approximately 121%. At the low end, Alternative G-Modified total receipts increase approximately 67%, and at the high end Alternative C total receipts increase approximately 182%.

Non-cash benefits increase from first to fifth decades in all alternatives. This is a function of increased recreation benefits that are valued as demand increases in Decade 5. By the fifth decade, development will have converted more lands from nonmotorized recreation opportunity to motorized recreation. Motorized recreation is more valuable on a per acre basis than nonmotorized. This also explains why Alternative C has the lowest non-cash benefits, as it maintains more land in a nonmotorized condition than any of the other alternatives.

Table II-13

Average Annual Cash Flows and Non-cash Benefits
Decades 1 and 5, By Alternative

Alternatives	Decade 1 Net Receipts	Decade 1 Total Costs	Decade 1 Total Receipts	Decade 1 Non-Cash Benefits to Users	Decade 5 Net Receipts	Decade 5 Total Costs	Decade 5 Total Receipts	Decade 5 Non-Cash Benefits to Users
	Millions of Dollars Per Year							
A (No Action)	6.5	15.3	21.8	60.9	29 6	16 7	46.3	85.2
I	5.8	14.3	20.1	61 3	25 6	15 4	41.0	85 5
B (RPA)	5.3	14.4	19.7	61 0	24.8	15 4	40.2	86.8
H	4.8	13.6	18.4	60 5	24.1	14.9	39 0	83.8
J (Preferred)	3.4	13 6	17.0	61.2	23.1	14.6	37 7	85.5
G-Modified	2.1	12 4	14.5	60 6	11.0	13.2	24 2	80.2
C	-2.4	11 8	9.4	60.7	14.1	12.4	26.5	78.8
NC (No Change) 1/	NA	NA	NA	NA	NA	NA	NA	NA

1/ The 1963 TM Plans, upon which the No Change Alternative is based, were not integrated resource plans, and consequently did not address all resource uses and outputs. Since Alternative NC was not modeled in FORPLAN, economic measures comparable to the other alternatives were not determined.

G. MAJOR TRADEOFFS AMONG ALTERNATIVES

This section summarizes the relationships among the economic values (discussed in detail above) and the differing responses of the alternatives to selected issues, concerns, and opportunities (ICO's). The purpose is to highlight major economic tradeoffs and public issue-response tradeoffs and non-economic trade-offs (or combinations of differences) that can be quantified, through the use of indicators of responsiveness to ICO's, as a means of comparing the alternatives. However, a complete understanding of differences among alternatives requires reading all of this chapter and Chapter IV. The ICO's are discussed in detail in Chapter I and Appendix A.

To provide a partial framework for assessing tradeoffs, the long-term resource demands of the nation, region, and local economic area are briefly summarized. In part two, selected economic values and quantified indicators of responsiveness to major ICO's are tabulated (Table II-14). Finally, differences and similarities among individual alternatives are summarized in terms of major tradeoffs among competing objectives or responses to expressed public issues, management concerns, and resource use and development opportunities.

1. National, Regional, and Local Overview

National (RPA) planning estimates that total national demands will rise for all outputs of the National Forest. At the same time, there is a strong demand to protect and enhance the quality of the environment. Many people view the production of goods and services from the National Forests as competing with protection and enhancement of a quality environment.

Demands and prices for commodity products are generally determined in regional and national markets. The nation benefits most when supplies are provided from the most efficient sources of production.

The Mt. Baker-Snoqualmie National Forest is an efficient supplier of timber products. The 1980 RPA program assigned approximately 2.5 percent of the total projected timber outputs for the National Forest System in 1990 to the Mt. Baker-Snoqualmie National Forest. The Forests' share of the projected Regional outputs in 1990 is approximately 6 percent. The Mt. Baker-Snoqualmie produces about 15 percent of the logs consumed in the Puget Sound area; forest industry and other private owners are the major producers of logs consumed in the area. Nearly all (97%) of the logs produced on the Forest are processed in the local economic area (Larsen and others 1983). The resulting products are consumed primarily in the Western U.S. market.

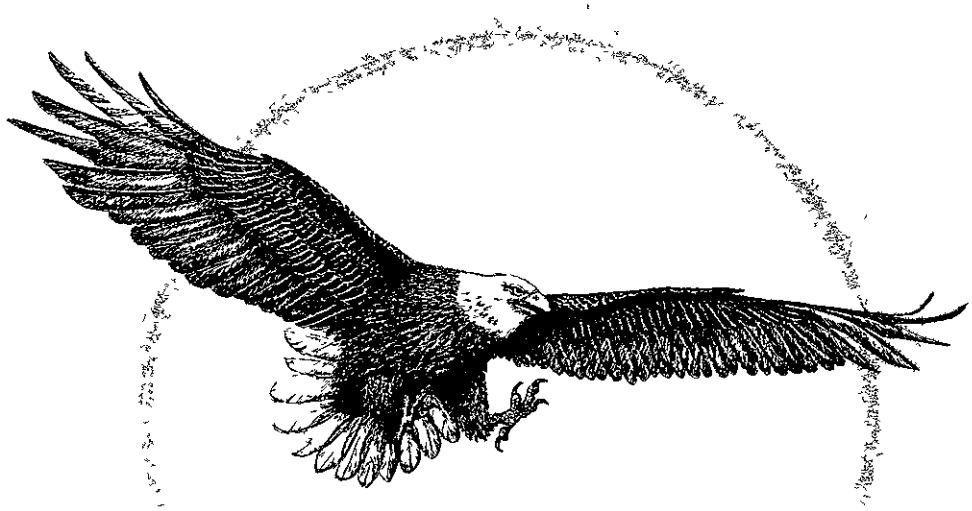
The Forest has extremely low capability to produce economically efficient forage for commercial grazing of domestic livestock.

Demands on the Forest for outdoor recreation uses are more localized than the regional and national demands for timber. Most of the Forest recreation users reside in the major population centers along the Interstate 5 highway corridor.

Recreation use and the demand for recreation of many types is growing, and at a rate faster than the population growth of the Puget Sound area. Total recreation use increased approximately 40 percent on the Forest in the 10 year period from 1975-1984. In a similar time period, the population of the five county area of the Forest increased approximately 20 percent. The fastest growing segment of the recreation spectrum is wilderness use: + 145 percent, compared to an increase of 65 percent in developed recreation use. Wilderness use represents approximately 4.5 percent of the total recreation use on the Forest for the period 1975 to 1984.

The Mt. Baker-Snoqualmie National Forest is a major supplier of National Forest wilderness in the Pacific Northwest and the nation. The Forest contains 16 percent of the National Forest wilderness in the Pacific Northwest Region and 2.2 percent of the total National Forest wilderness system. Available data collected in the late 1970's and early 1980's indicates that 82-94 percent of wilderness use on the Forest originated from Washington State, and 49-65 percent of the users are from the Puget Sound area. Several of the Forest wildernesses are among the most heavily used in the nation.

Salmon, by a large margin, is the most valuable fish or wildlife species, as measured by the market value of the harvest. An estimated 50 percent of the harvest of naturally produced (as opposed to hatchery produced) salmon for the Puget Sound area are produced from Mt. Baker-Snoqualmie National Forest water systems.



2. *Economic Values and Responses to Major ICO's*

The main reason that alternatives differ is that each alternative is designed to respond differently to the major issues, concerns, and opportunities (ICO's) identified for this Forest. The following section and Table II-14 summarize many of those differences in response by defining indicators of those responses that can be quantified. In addition, indicators of central concern to the nation as a whole are discussed. Appendix A fully discusses each of the ICO's; also refer to Chapter I, pages I-10 through I-20. Additional information about the effects and tradeoffs is displayed earlier in this chapter and in Chapter IV. The ICO's and indicators of responsiveness found in Table II-14 include:

- **Development versus Nondevelopment of the Forest Issue:**

  Existing Roadless Areas Allocated to Nondevelopment
  Roadless Areas Assigned to a Roaded Management Prescription, But Not Developed in the Next 15 Years

- **Timber Supply Issue:**

  Timber Harvest Level
  Long-term Sustained Yield Capacity
  Lands Suitable for Timber Production
  Employment: Jobs Supported by the Alternative
  Payments to Counties

- **Old Growth Ecosystems and Fish/Wildlife/Plant Diversity Issue:**

  Total Old Growth Remaining, at the end of Decades 1 and 5
  Old Growth Remaining on Suitable Acres, at the end of Decades 1 and 5
  Anadromous Fish Production
  Low-Elevation Old Growth Habitat for Wildlife
  Suitable Winter Range for Deer and Elk, Decade 1

- **American Indian Religious and Cultural Use Issue:**

  Percent of Inventoried Use Areas with High or Moderate Protection

- **Recreation Opportunities Issue:**

  Demand Satisfied for Wilderness, Primitive and Semi-Primitive Nonmotorized Recreation, Decades 1 and 5
  Roads Open to Public Use, Passenger Car
  Trail Construction, Reconstruction, Decade 1
  Lands Managed for High Visual Quality Level, Meeting a Visual Quality Objective of Retention, Partial Retention

- **Wild and Scenic Rivers Issue:**

  Recommended for Designation as Wild and Scenic River

- **Management of Municipal Watersheds Issue:** (see note below)

  Timber Harvest Level (see note below)

- **Effects of Timber Management and Related Activities Issue:**

  Timber Harvest Level (see note below)
  Old Growth Remaining on Suitable Acres, Decades 1 and 5 (see note below)
  Annual Road Construction, Decade 1
  Sediment Produced from All Sources, Annually, Decade 1

- **Adjacent and Intermingled Lands Issue:** (see note below)

  Timber Harvest Level (see note below)

Note: Two issues - Management of Municipal Watersheds and Adjacent and Intermingled Lands - are not listed separately in the table, but their indicators are included in other ICO's. When an indicator is used to measure responsiveness for more than one ICO, the indicator is displayed only once.

In addition, the indicators of national interest include the following; they are listed in the first three columns of Table II-14:

- **National Concerns:**

  Present Net Value
  Net Receipts
  Noncash Benefits

Table II-14
Response, By Alternative, to Major Issues and National Concerns

	National Concerns			Development Vs Nondevelopment Issue 1/			Timber Supply Issue					
	Average Per Year for Decades 1/5											
Alternatives	Present Net Value	Net Receipts	Noncash Benefits	Existing Roadless Areas Allocated to Nondevelopment		Roadless Areas Assigned to a Roaded Mgt Prescription But Not Devel in Next 15 Yrs. NC 3/	N/A	N/A	N/A	NA	NA	NA	45 0	(220)	N/A	547	30.1	9.5

1/ Roadless Areas refer to the 402,930 acres of remaining RARE II parcels

2/ This is an approximate figure. Alternative A is unique because an unspecified amount of development is permitted in the Upper Forest Resource Zone. See description of Management Area 1E

3/ The TM Plans upon which Alternative NC is based were developed in 1963; they are not integrated resource plans, and consequently did not address all resource uses and outputs. Missing data in this table (NA) cannot be reasonably estimated, since the TM plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect standards in the NFMA regulations, or are otherwise inappropriate.

3. Economic Benefit and Issue Response Tradeoffs Among Alternatives

The alternatives were designed to respond to specific major issues, or a combination of issues. In responding to one set of issues, some potential benefits or responses to other issues may be limited or "traded off". This section discusses the incremental changes in indicators of response of the alternatives as economic efficiency (PNV) declines. This is only one systematic way of examining tradeoffs. It should be noted that there are tradeoffs among indicators of response to the issues as well as with economic benefits.

The alternatives are discussed in order of highest PNV to lowest. Following the discussion of the changes in each alternative from the one with the next highest PNV, is a display that shows which indicators increase in value and which decrease, and the magnitude of the change. These indicators of response are also displayed in Table II-14.

Alternative B

The goal of this alternative is to simultaneously produce high levels of timber, anadromous fish, commonly hunted species of big game, and dispersed unroaded recreation as specified in the 1980 RPA Program. With this goal, this alternative results in the highest PNV of all alternatives: $2343.2 million. Net receipts of $5.3 MM in the first decade increase to $24.8 MM by the fifth decade, reflecting the increase in ASQ between the first and fifth decade.

Noncash benefits (primarily dispersed recreation) of $61.0 MM in the first decade increase to $86.8 MM in the fifth decade, as more roaded recreation is valued as a result of increasing demand.

As a result of the emphasis of this alternative, a timber sale program quantity (TSPQ) of 29.8 MMCF is provided on a suitable land base of 380,000 acres. The long-term sustained yield capacity (LTSYC) is approximately 33.4 MMCF. An average of 16 miles of road construction annually is required in the first decade to support the timber harvest level. This high harvest level results in one of the three highest levels of jobs, income, and payments to counties of all the alternatives.

Of the 447,000 acres inventoried for American Indian Religious and Cultural Use, 43% are afforded a high level of protection (no timber harvest or road construction) and 7% are afforded a moderate level of protection (no timber harvest or road construction, but increased probability of human contact). The acres afforded high protection change very little among alternatives; there is more change between alternatives in percent of acres afforded moderate protection.

This alternative would satisfy 76% of the primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation demand anticipated in the first decade and 34% of anticipated demand in the fifth decade, based on currently defined standards for capacity. This decline over time is a result of increasing demand and slower increases in supply, as more of the currently undeveloped areas become developed. There is little change among the alternatives in the Forests ability to meet this demand, due to low per acre yield of this type of recreation. This indicator is not further discussed in the other alternatives.

Alternative B has 287,000 acres assigned to a management prescription that meets the Visual Quality Objectives (VQO) of retention; another 285,000 acres will meet partial retention VQO. The amount of acres managed to meet retention is in the lower part of the range of all alternatives reflecting less emphasis on managing the scenic foreground along travelways. However, the amount of land managed for partial retention is in the higher part of the range for all alternatives reflecting a recognition of the need to maintain a relatively high level of scenic quality forest-wide.

Effective acres of wildlife habitat for mature and old growth management indicator species are reduced by 82,000 acres, or 26% during the first five decades. A total of 225,000 acres of inventoried big game winter range is managed to provide an optimal mix of thermal and forage habitat.

Total old growth remaining at the end of Decade 5 is 513,000 acres, a reduction of approximately 20% over the five decades. This reflects the relatively high level of harvest in this alternative.

Alternative B has a high level of investment in anadromous fish habitat improvements (MA 13C); 8,874 M pounds of fish will be produced.

Alternative I

The PNV for Alternative I is $2342.9 or $0.3 MM lower than PNV for Alternative B. Annual net receipts in Decade 1 are $0.5 MM higher than those in Alternative B, primarily because of the higher timber outputs. Net receipts in Decade 5 are $0.8 MM higher than those of Alternative B, again because of the higher timber outputs.

Alternative I has 6,000 acres more land suitable for timber production than Alternative B, primarily attributable to the emphasis of the alternative on those resources with an established price in the market place. The higher number of suitable acres result in a Decade 1 TSPQ that is 0.3 MMCF above that of Alternative B; LTSYC is 0.8 MMCF higher.

The slightly higher timber harvest levels in Decade 1 in Alternative I also requires a small increase (over Alternative B) in road construction of 1 mile annually. This alternative provides essentially the same levels of jobs, income, and payments to counties.

The acres of American Indian Religious and Cultural Use afforded high levels of protection remain the same in Alternative I while those acres afforded a medium level of protection decrease by 5%. This change reflects an increased probability of human contact as a result of the additional access provided in Alternative I.

Alternative I would satisfy 18% more of the first decade demand for primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation and 11% more of the fifth year demand than Alternative B. This reflects a higher emphasis on dispersed recreation than in Alternative B

Alternative I has 79,000 fewer acres than Alternative B that will meet a VQO of retention, but 26,000 acres more that meet a VQO of partial retention. The shift in VQO is due to the slight increased in acres suitable for timber production.

Alternative I has about the same amount of roadless areas remaining in a roadless condition as Alternative B.

Since there is less emphasis on management of deer and elk habitat in Alternative I, old growth available for indicator species in the fifth decade is 3,000 acres more than in Alternative B; however, there are 28,000 fewer acres managed for big game winter range.

Alternative I has essentially the same amount of old growth included in the land base suitable for timber harvest. The rate of old growth harvest is approximately the same so that at the end of the fifth decade, about the same amount of old growth suitable for timber production will be left in both alternatives.

Alternative I has the same level of investment in anadromous fish habitat improvements and therefore provides the same level of fish production as Alternative B.

Summary of Alternative I

Indicators That Increase From Alternative B

- Decade 1 annual net receipts, +$0.5 MM
- Decade 5 annual net receipts, +$0.8 MM
- Decade 1 annual noncash benefits, +$0.3 MM
- Decade 1 annual TSPQ, +0.3 MMCF
- LTSYC, +0.8 MMCF
- Lands suitable for timber production, +6,000 acres
- Decade 1 annual road construction, +1 miles
- Acres meeting VQO of partial retention, +26,000
- Acres of Old Growth for indicator species in Decade 5, +3,000

Indicators That Decrease From Alternative J (Preferred)

- PNV, -$0.3 MM
- Decade 5 annual noncash benefits, -$1.3 MM
- Acres meeting a VQO of retention, -79,000
- Acres managed for deer/elk winter range, -28,000

Alternative A (No Action)

The PNV for Alternative A is $2283.5 or $59.4 MM lower than PNV for Alternative B. Although Alternative A has a high level of timber outputs, timber harvest prescriptions were selected on the basis of their volume contribution, rather than their contribution to PNV. The high cost of these prescriptions offsets the high timber output contribution to PNV. Annual net receipts in Decade 1 are $0.7 MM higher than those in Alternative I, primarily because of the higher timber outputs. Net receipts in Decade 5 are $4 MM higher than those of Alternative I, again because of the higher timber outputs.

Alternative A has 26,000 acres more land suitable for timber production than Alternative I, primarily attributable to the maximize timber objective function used in the formulation of this alternative. The higher number of suitable

acres plus the higher timber production prescriptions result in a Decade 1 TSPQ that is 4.9 MMCF above that of Alternative I; LTSYC is 4.6 MMCF higher.

The higher timber harvest levels in Decade 1 in Alternative A also require an increase (over Alternative I) in road construction of 2 miles annually.

Compared to Alternative I, Decade 1 jobs are 200 higher, income is $5 MM higher, and payments to counties are $0.5 MM higher in Alternative A, also a result of the higher timber harvest levels.

Alternative A has 88,000 fewer acres than Alternative B that will meet a VQO of retention, but 31,000 acres more that meet a VQO of partial retention. The shift in VQO - from retention to partial retention - is due to the emphasis on visuals in the upper resource management zone of the current multiple use plans, along with the protection of all rivers included in the National Rivers inventory (except Jim Creek), both of which have a VQO of partial retention.

Alternative A has 7% more roadless areas allocated to nondevelopment than Alternative I.

Since there is little emphasis on management of wildlife habitat in Alternative A, old growth available for indicator species in the fifth decade is 22,000 acres less than in Alternative I. There are 112,000 fewer acres managed for big game winter range.

Alternative A has 3,000 acres more old growth remaining in the suitable land base after the first decade. Old growth is harvested at a faster rate than in Alternative I, resulting in Alternative A having 19,000 fewer acres of total old growth in the fifth decade.

Alternative A maintains the current level of investments in anadromous fish habitat improvements (MA 13A), resulting in a production of 1,065 M fewer pounds than Alternative I.

Summary of Alternative A (No Action)

Indicators That Increase From Alternative I

- Decade 1 annual net receipts, +$0.7 MM
- Decade 5 annual net receipts, +$4.0 MM
- Decade 1 annual TSPQ, +4.9 MMCF
- LTSYC, +4.6 MMCF
- Lands suitable for timber production, +26,000 acres
- Decade 1 annual road construction, +2 miles
- Decade 1 annual jobs, +200
- Decade 1 annual income, +5 MM
- Decade 1 annual payments to counties, $0.5 MM
- Acres meeting VQO of partial retention, +31,000
- Acres of old growth in suitable lands end of Decade 1, +3,000

Indicators That Decrease From Alternative I

- PNV, -$59.4 MM
- Decade 1 annual noncash benefits, -$0.4 MM
- Decade 5 annual noncash benefits, -$0.3 MM

- Acres meeting a VQO of retention, -88,000
- Acres of old growth in suitable lands in decade 5, -14,000
- Total acres of old growth in decade 5, -19,000
- Annual anadromous fish production, -1,065 M pounds
- Acres of old growth for indicator species in Decade 5, -22,000
- Acres managed for deer/elk winter range, -112,000

Alternative H

The PNV of Alternative H is $23.5 MM less than Alternative A. While the TSPQ is 7.7 MMCF lower than Alternative A, the timber prescriptions were selected on the basis of their contribution to PNV rather than to volume (as in Alternative A), so the decrease in PNV is not large. In addition fewer miles of road construction in H compared to A result in cost savings that mostly offset the benefits foregone from the reduced timber harvest.

First decade net receipts are $2.3 MM less and fifth decade net receipts are $5.5 MM less than Alternative A primarily as a result of reduced timber sale harvest levels.

Alternative H has 53,000 acres less land suitable for timber production than ALternative A. This reduction in suitable land is the result of increased emphasis on dispersed recreation, Wild and Scenic River recommendations, and more more emphasis on scenery and diversity. The TSPQ in the first decade is 7.7 MMCF lower than Alternative A and the LTSYC is 6.8 MMCF lower. The reduced timber harvest and the emphasis on dispersed recreation results in 5 miles less road construction per year in decade one compared to Alternative A.

Compared to Alternative A, there are 400 fewer jobs, $11 MM less income, and $1 MM less in payments to the counties in this alternative.

Alternative H has 287,000 more acres that will be managed to meet the VQO of retention and 161,000 less acres managed to meet the VQO of partial retention. This shift from partial retention and addition of retention reflect the increased concern of Alternative H for scenic values.

Alternative H has 3,000 more acres of old growth remaining after the first decade, and the total old growth remaining on all lands at the end of the fifth decade is 29,000 acres more than in ALternative A.

Anadromous fish habitat improvement investments are increased with a resultant increase in production of 1,065 thousand pounds per year more than Alternative A.

Summary of Alternative H

Indicators That Increase From Alternative A

- Acres meeting VQO of retention, +287,000
- Total acres of old growth at the end of Decade 1 and 5, +3,000/29,000
- Annual anadromous fish production, +1,065 M Lbs.

Indicators That Decrease From Alternative A

- PNV, -$23.5 MM
- Decade 1 annual net receipts, -$2.3 MM
- Decade 5 annual net receipts, -$5.5 MM
- Decade 1 annual noncash benefits, -$0.4 MM
- Decade 5 annual noncash benefits, -$1.4 MM
- Lands suitable for timber production, -53,000 acres
- Decade 1 TSPQ, -7.7 MMCF
- Decade 1 annual road construction, -5 miles
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$11 MM
- Decade 1 payments to counties, -$1.0 MM

Alternative J (Preferred)

The PNV for Alternative J (Preferred) is $1.2 MM lower than Alternative H. Annual net receipts are $1.4 MM less in the first decade and $1.0 MM less in the second decade. These reductions are all a result of the reduced timber harvest levels of Alternative J (Preferred) compared with Alternative H. The reduced levels of timber harvest also results in a reduction of road construction of 1 mile per year.

Noncash benefits increase in the first decade by $0.7 MM and in the fifth decade by $1.7 MM. These increases reflect the increased emphasis on non market resources from Alternative H.

Alternative J (Preferred) has 13,000 acres less land suitable for timber production than Alternative H. This reduction is primarily the result in increased emphasis on dispersed recreation, Wild and Scenic Rivers, and scenic values.

Compared to Alternative A, there are 400 fewer jobs, $11 MM less income, and $1 MM less in payments to the counties in this alternative.

Alternative J (Preferred) would satisfy 12% more of the first decade demand for primitive and semi-primitive nonmotorized wilderness and non-wilderness recreation and 7% more of the fifth year demand than Alternative H. This reflects a higher emphasis on dispersed recreation than in Alternative H

Alternative J (Preferred) has 10% more roadless areas remaining in a roadless condition than Alternative H. Again this reflect a higher emphasis on dispersed recreation.

Alternative J (Preferred) has 3,000 less acres of old growth included in the suitable land base for timber production and the total old growth remaining on all lands at the end of the fifth decade is 10,000 acres more than in Alternative H.

Summary of Alternative J (Preferred)

Indicators That Increase From Alternative H

- Decade 1 annual noncash benefits, +$0.7 MM
- Decade 5 annual noncash benefits, +$1.7 MM
- Total acres of old growth at the end of Decade 5, +9,000

Indicators That Decrease From Alternative H

- PNV, -$1.2 MM
- Decade 1 annual net receipts, -$1.4 MM
- Decade 5 annual net receipts, -$1.0 MM
- Lands suitable for timber production, -13,000 acres
- Decade 1 TSPQ, -1.8 MMCF
- Decade 1 annual road construction, -1 miles
- Decade 1 annual jobs, -100
- Decade 1 annual income, -$4 MM
- Decade 1 payments to counties, -$0.3 MM
- Acres of old growth on suitable lands, Decade 1, -3,000 acres
- Acres of old growth for indicator species in Decade 5, -0,000 acres

Alternative G-Modified

Alternative G-Modified has a strong emphasis on the maintenance of natural ecosystems and diversity of native flora and fauna. The retention of existing ecosystems reduces the acres suitable for timber production and the TSPQ. Although less road construction is required than in Alternative J (Preferred), PNV is reduced by $261.8 MM.

The reduction in TSPQ of 5.1 MMCF from Alternative J (Preferred) results in net receipts declining by $1.0 MM in the first decade. Fifth decade net receipts decrease by $12.1 MM over Alternative J (Preferred).

Noncash benefits decline by $0.6 MM in the first decade and by $5.3 MM in the fifth decades.

Lands suitable for timber production decline by 99,000 acres from Alternative J (Preferred). Alternative G-Modified has 21% more roadless areas remaining in a roadless condition than Alternative J (Preferred). This reflects the objectives of maintaining natural ecosystems and diversity.

The reduced timber harvest in the first decade of Alternative G-Modified results in 400 fewer jobs than in Alternative J (Preferred), $10 MM less income, and $0.8 MM lower payments to the counties than in Alternative J.

Due to the emphasis on retention of natural ecosystems and the management of larger acres of currently developed lands in an undeveloped condition, the acres meeting a VQO of retention will increase by 178,000 over those in

Alternative J (Preferred). Acres meeting a VQO of partial retention will be 148,000 less than in Alternative J (Preferred).

The emphasis on maintaining the natural diversity on the Forest will result in an increase of 25,000 acres of old growth for management indicator species in Decade 5; 167,000 fewer acres would be managed for big game winter range compared to Alternative J (Preferred).

Alternative G-Modified would have 56,000 acres less old growth in the suitable timber land base and 36,000 acres more total old growth by Decade 5 than would Alternative J (Preferred).

Summary of Alternative G-Modified

Indicators That Increase From Alternative J (Preferred)

- Acres meeting a VQO of retention, +178,000
- Acres of old growth for indicator species, +25,000
- Total acres of old growth at the end of Decade 5, +35,000

Indicators That Decrease From Alternative J (Preferred)

- PNV, -$261.8 MM
- Decade 1 annual net receipts, -$1.0 MM
- Decade 5 annual net receipts, -$12.1 MM
- Decade 1 annual noncash benefits, -$0.6 MM
- Decade 5 annual noncash benefits, -$5.3 MM
- Decade 1 annual TSPQ, -5.1 MMCF
- LTSYC, -6.8 MMCF
- Lands suitable for timber production, -99,000
- Decade 1 annual road construction, -5 miles
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$10 MM
- Decade 1 annual payments to counties, -$0.8 MM
- Acres meeting a VQO of partial retention, -148,000
- Acres of old growth in suitable lands in Decades 1/5, -56,000/-24,000
- Acres managed for deer/elk winter range, -167,000

Alternative C

The emphasis of Alternative C includes the non-market outputs of undeveloped dispersed recreation, visual quality, and fish and wildlife habitat. As a result, it has the lowest PNV of all the alternatives: $26.1 MM below that of Alternative G-Modified.

Alternative C has 9,000 more acres of land suitable for timber production than Alternative G-Modified. However, 62% of the total suitable acres produce timber at less-than-full yield to provide for visual quality and wildlife habitat. In combination, these result in a first decade TSPQ that is 4.6 MMCF lower than Alternative G-Modified.

The low level of timber outputs and the constraints on the rate of harvest of the available old growth result in first decade net receipts that are $0.3 MM less than Alternative G-Modified. A 15% increase in the TSPQ by the fifth

decade, along with a higher percentage of the harvest coming from old growth stands results in an increase in net receipts of $4.1 MM over that of Alternative G-Modified.

The reduced timber harvest level in the first decade results in 400 fewer jobs, $11 MM less income, and $1.2 MM lower payments to the county than Alternative G-Modified.

The strong emphasis on visuals in Alternative C results in 46,000 more acres meeting a VQO of retention and 88,000 more acres meeting a VQO of partial retention than in Alternative G-Modified.

Habitat available for old growth management indicator species is the same in Alternative C as in Alternative G-Modified. There are 168,000 more acres of deer and elk winter range managed in Alternative C.

Alternative C has 25,000 acres more old growth in the suitable land base than Alternative G-Modified. Alternative C will have 2,000 acres more total old growth in Decade 5 than Alternative G-Modified.

Summary of Alternative C

Indicators That Increase From Alternative G-Modified

- Decade 5 annual net receipts, +$4.1 MM
- Decade 1 annual noncash benefits, +$0.1 MM
- Lands suitable for timber production, +9,000 acres
- Decade 1 annual road construction, +2 mile
- Acres meeting a VQO of retention, +46,000
- Acres meeting a VQO of partial retention, +88,000
- Acres of old growth in suitable lands Decade 1 and 5, +25,000 and +25,000
- Total acres of old growth in Decade 5, +2,000
- Acres managed for deer/elk winter range, +168,000

Indicators That Decrease From Alternative G-Modified

- PNV, -$26.1 MM
- Decade 1 annual net receipts, -$0.3 MM
- Decade 5 annual noncash benefits, -$1.4 MM
- Decade 1 annual TSPQ, -4.6 MMCF
- LTSYC, -3.7 MMCF
- Decade 1 annual jobs, -400
- Decade 1 annual income, -$11 MM
- Decade 1 annual payment to counties, -$1.2 MM

Alternative NC (No Change)

Alternative NC is based on the Timber Management Plans developed in 1963. The Plans are not integrated resource plans and consequently do not address all resource uses and outputs. The data applicable to this alternative was not incorporated into a FORPLAN model; therefore, PNV was not calculated.

The No Change Alternative emphasizes the timber resource. As a result, the acres of land suitable for timber harvest and first decade TSPQ are the highest

among the alternatives: an increase of 291,000 acres and 29.2 MMCF per year over that of Alternative C.

The harvest level involves more road construction, increases employment and income, and generates more payments to counties in Decade 1.

Recreation demand satisfied decreases. In addition, the total acres of old growth remaining in Decade 5 decrease from 573,000 in Alternative C, to 432,000 acres in Alternative NC.

Alternative NC continues the current level of investments in anadromous fish habitat capability; production is similar to Alternative A, which is 7,809 M pounds of fish per year, a decrease of 12% from Alternative C.

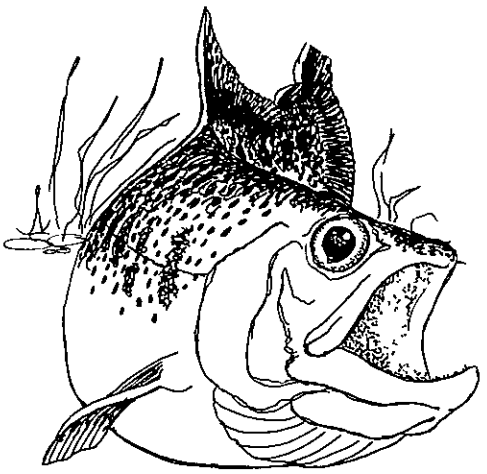
Summary of Alternative NC

Indicators That Increase From Alternative C

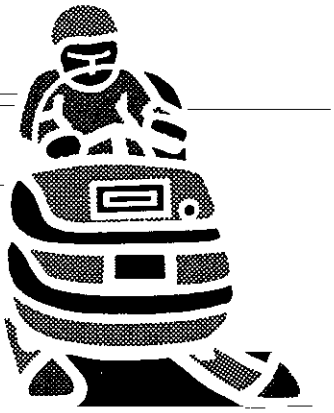
- Decade 1 annual TSPQ, +29.2 MMCF
- Lands suitable for timber production, +290,000 acres
- Decade 1 annual road construction which is +19 miles over Alternative C.
- Acres of old growth in suitable lands in Decade 1, +129,000 acres

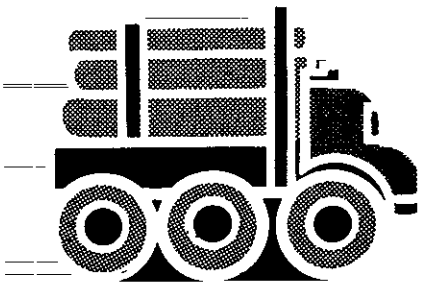
Indicators That Decrease From Alternative C

- Total acres of old growth remaining in Decade 5, -141,000
- Annual anadromous fish production, similar to Alt. A, -1,065 pounds



Chapter II





CHANGES BETWEEN DRAFT AND FINAL - CHAPTER III

Based on public response to the draft EIS and new data and information, there have been a number of changes in Chapter III. Major changes include:

- Additional information on snow-on-rain events, groundwater, and the condition of Forest watersheds has been added to Soil and Water.
- Elements of diversity have been specifically identified and discussed together, including the riparian environment, plant communities, and threatened, endangered, and sensitive plants. In addition, Wildlife and Fish Elements of Diversity have been added.
- New information has been added to the Old Growth section.
- Timber cut and sold information has been updated.
- The Wildlife section has been updated to reflect changes in MR's, the SFEIS Record of Decision, and new information.
- Fish Resources section has have been extensively revised and updated, with revised values and demand and supply section. A discussion of the Forest experience with the cumulative effects in watersheds on fish/fish habitat has been added.
- More discussion of the State Comprehensive Outdoor Recreation Plan has been added, plus additional recreation demand data.
- The Trails discussion has been moved out of "Facilities" and now follows the Recreation section.
- Wilderness capacity coefficients were recalculated.
- The roadless area acres were updated.
- The list of rivers studied for wild and scenic river status was adjusted; also refer to Chapters II, IV, and Appendix E.
- The Cedar River Watershed discussion has been updated.
- More discussion has been added to the Air Quality, Broadcast Burning, and Fire discussions, including cooperation with other agencies.
- Updated data was included in Special Uses, Land Ownership, miles of roads, and elsewhere.

CHAPTER III - AFFECTED ENVIRONMENT

Chapter III describes the area affected by Forest management and addressed in this FEIS and the Forest Plan. The Mt. Baker-Snoqualmie encompasses a number of very complex physical and biological systems. A basic understanding of these ecosystems and their interrelationships is essential to understanding the issues and concerns and the effects on the environment of implementing any of the alternatives.

The Mt. Baker-Snoqualmie National Forest occupies portions of Whatcom, Skagit, Snohomish, King, and Pierce Counties, as shown in Figure III-1. These five counties are considered to be the general zone of influence for forest planning. The National Forest includes land from the Canadian border south, 130 miles, to the northern boundary of Mt. Rainier National Park. The Forest also adjoins the North Cascades National Park Complex and the Wenatchee National Forest. The Forest is located in Congressional Districts 1, 2, and 8.

LAND OWNERSHIP

There are a total of 1,983,774 acres of land within the Mt. Baker-Snoqualmie National Forest boundary. Most - 87 percent - are National Forest land. The remaining 259,545 acres are in private or other public ownership.

Most of the intermingled lands are located in the southern ranger districts of the Forest. Principle owners of adjacent and intermingled lands are: Weyerhaeuser Company, Plum Creek Timber Company, The City of Seattle, Scott Paper Company, Georgia Pacific Corporation, and Washington State Department of Natural Resources.

The following table shows the legal acres, as of February, 1990. These are the land currently administered by the Mt. Baker-Snoqualmie National Forest and covered in this Plan. The acre figures used for much of this planning effort are generated by a computer mapping system (R2MAP), and they will not necessarily equal the legal national forest acres.

Table III-1
Forest Legal Acres By Ranger District - Includes Water

Ranger District	N.F. Land	Other Ownership	Gross Acres
Mt. Baker	524,719	20,527	545,246
Darrington	562,124	10,099	572,223
Subtotal - North	1,086,843	30,626	1,117,469

CLIMATE

A general description of the climate in the vicinity of the Mt. Baker-Snoqualmie National Forest is included here to give perspective to the effects of management activities on air quality, timber blowdown, naturally occurring fire, etc. and to briefly describe the temperature and precipitation as it affects the vegetation and growing season on the Forest.

Topography has a marked influence on climate in the region. The Cascade and Rocky Mountains shield Western Washington from the cold air masses that travel south across Canada in the winter. The Olympic Mountains and the Coast Range on Vancouver Island effectively protect the Puget Sound area from most intense winter storms from the Pacific Ocean. The Strait of Juan de Fuca and the Strait of Georgia provide passage for maritime air, which has a moderating effect on climate both summer and winter. Winters are wet and mild; summers are cool and relatively dry (Pacific N.W. River Basins Commission 1970). The mountain ranges east and west of the Forest and the low elevation passage through Puget Sound results in unique wind patterns. Generally, the prevailing direction of the wind is from the south or southwest in winter and from the west or northwest in summer. However, during the winter there are periods of low pressure off the coast combined with cold air from Canada, resulting in outbreaks of strong northeasterly winds over the northern part of the Forest. It is not unusual to have strong southeasterly winds over the southern portion of the Forest at the same time.

Extreme wind velocities (30 feet above the ground) can be expected to exceed 55 mph once every two years, 90 mph once in 50 years, and 100 mph once in 100 years (Pacific N.W. River Basins Commission 1970). Some trees are blown down each year; an estimated 100 million board feet of commercial timber was blown down in November, 1977.

A common occurrence from late spring through fall are short periods of warm, dry easterly winds. They are usually associated with very low, relative humidity and high temperatures. The result is an extremely high forest fire danger. About once every 20 years, a catastrophic fire or fires will occur. (See Fire, Chapter III, this document.) During these periods, smoke carries into the populated areas to the west of the Forest.

Precipitation is light in the summer and heaviest from October through March. The annual precipitation ranges from 35 to 50 inches over the lowlands, increasing to 75 inches in the foothills, and from 100 to 200 inches near the crest of the Cascades.

Between 1,500 and 3,500 feet, both rain and snow are common during most winters. Rapid melting of snow during rain-on-snow conditions in this elevation range is the cause of many landslides and road maintenance problems. Above 3,500 feet in elevation, most winter precipitation falls as snow. The total snowfall is 75-100 inches in the foothills and 300 to 500 inches in the high mountains. The precipitation and heavy snowfall affects the growing season of vegetation. The amount of snow in a given year can greatly affect recreation use, especially downhill skiing. Trail and road maintenance and construction is also affected by the weather and amount of snowfall.

The temperatures in the Forest area range from the 60's in the summer at higher elevation to the upper 70's in the foothills. Winter highs range from the

upper 30's to mid-40's in the lowlands; below freezing temperatures occur almost every night in the mountains. Temperature is a very important environmental factor in terms of plant growth. Soils in the upper elevations warm very little until the snowpack is gone and the cool fall rains resume a short time after. This creates a very harsh environment for mountain hemlock and other high elevation vegetation to germinate and grow (Henderson and Peter 1981).

GEOLOGY AND TOPOGRAPHY

The Forest is located along the west side of the crest of the Cascade Mountains. The Cascade Mountains can be separated into two distinct geological regions, with the approximate division occurring at Interstate 90 Highway. The differences, north and south of I-90, in geology, topography, bedrock, and soils are important because many components of the natural environment are influenced by the character of the geologic material.
The mountains north of I-90 consist of metamorphic rocks intruded by granitic batholiths. Uplifting and geologic erosion has produced a very rugged and steep topography. Vertical distances may exceed over 4,000 feet from the valley floor to the adjacent peaks. Many peaks exceed 5,500 feet and contain perennial snow and ice. The volcanic peaks of Mt. Baker and Glacier Peak rise above other rugged peaks and ridges. Common features include long, steep slopes containing timber, intermingled with talus slopes, rock outcrops, and meadows. The high alpine scenery is impressive, with serrated, rocky ridges and numerous meadows and small glacial lakes (Snyder and Wade 1972).

South of I-90, the mountains are primarily of volcanic origin. Although often steep and dissected, these mountains lack the size and are less impressive than those to the north. The mountains on the southern half of the Forest are generally lower in elevation, with only a few peaks exceeding 4,500 feet. They are often completely covered with trees.

Much of the present configuration of the Cascades is a result of glacial activity that began about one million years ago. Continental glaciers are believed to have advanced into and withdrawn from the Puget Sound region at least four times during the Quaternary Period; the last glacier retreated about 10,000 years ago (Pacific N.W.River Basins Commission 1970).

Glacial ice, a powerful agent of erosion, abraded and scoured the topography at an accelerated pace. Valley floors were broadened and deepened and valley walls were over-steepened. Many predominant features of the landscape were caused by glacial activity: jagged peaks, cirque basins, lakes, and hanging valleys. The retreating glaciers left surface deposits of till, outwash, and lacustrine (lake-laid) deposits of varying thickness and composition in the valleys and on many lower sideslopes. Till's compact character favors runoff and does not "hold" water well (River Basins Commission 1970).

The rugged topography resulting from glacial modification is most pronounced north of I-90. Glaciation was more extensive here and the hard bedrock has remained relatively resistant to non-glacial erosion. South of I-90, the less-resistant volcanic rock has been weathered and eroded from stream action, slides, surface erosion, and other natural processes.

For further detail, refer to the minerals section in this chapter.

SOILS

Soil is a basic resource. It absorbs and stores water, releasing it slowly over time; soil supplies the nutrients for vegetation which, in turn, supplies habitat for wildlife and resources for people's use and enjoyment. Soil is essentially a non-renewable resource, because soil formation occurs very slowly over a long period of time. Soil loss or damage (from erosion, compaction, etc.) can have a significant effect on soil productivity, and all the resources that are dependent on the soil. Refer to the Diversity section of this chapter.

The soils of this Forest are complex and varied. An inventory of the Mt. Baker National Forest soils was completed in 1970; the Snoqualmie Soil Resource Inventory was finished in 1972 (Snyder and Wade 1970, 1972). There are over 200 different soil mapping units on the two forests, based on soil type, geologic type, and topographic shape. However, these soils can be categorized into several broad groups that have similarities in texture, depth, parent material. There are also differences in soils in the north half and the south half of the Forest, due to the differences in bedrock and the extent of glaciation and/or volcanism.

North Half of the Forest

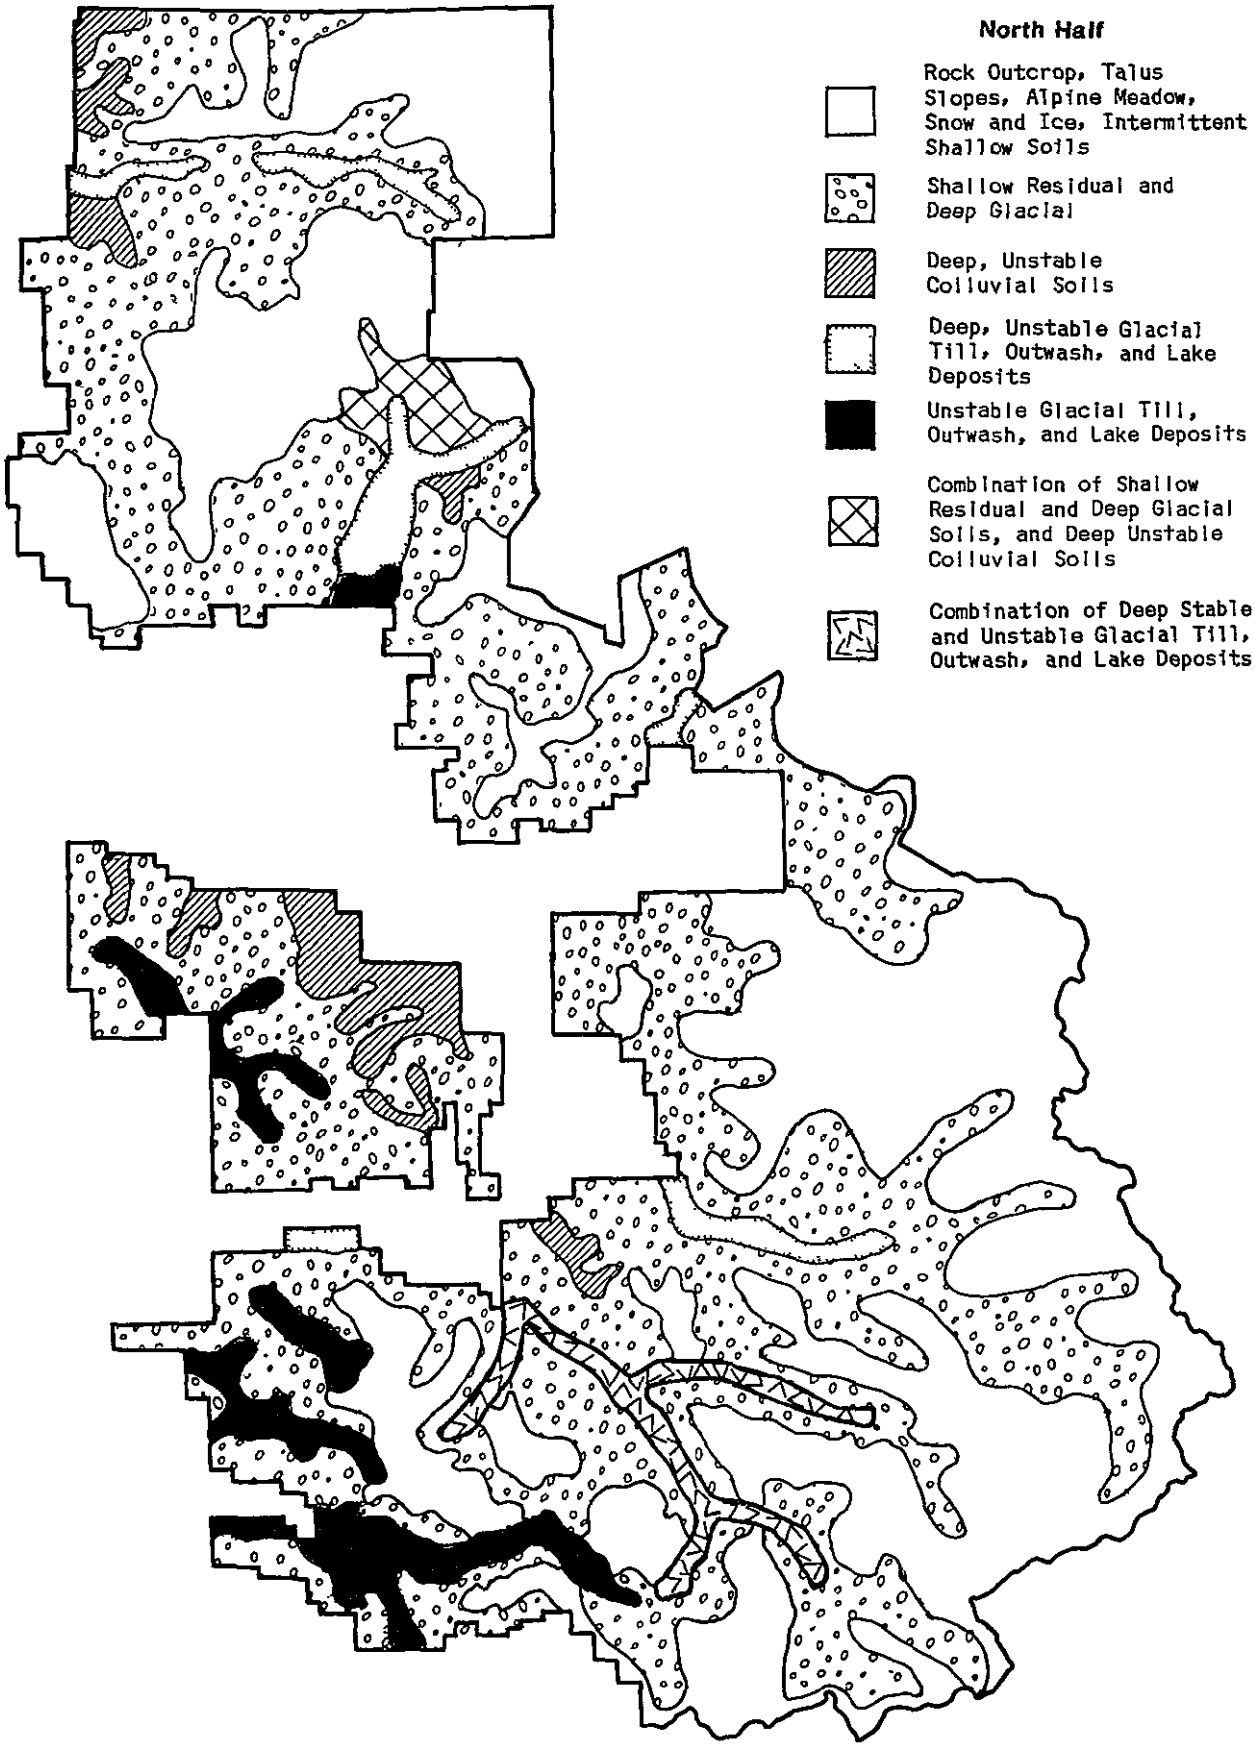
This area is one of the most unstable in the Pacific Northwest, and the soils are quite complex. This is, in part, due to the wide range of geologic rock types and the extensive glaciation on this part of the Forest. Glaciers greatly modified the pre-glacial landscape and deposited till, outwash, and other materials throughout the area. Because of this, it is common to find similar soils occurring on a variety of landscapes (Snyder and Wade 1970). Rocks of one type were frequently deposited over bedrock of another type, resulting in soil that is very different in texture from that which would be expected. Some ridges and sideslopes have been scraped clean of till, from either glacial action or mass wasting. These areas now contain shallow, gravelly soils that were derived from the local bedrock. Other slopes exhibit a mixture of shallow residual soils and deep glacial soils (Snyder and Wade 1970).

The soil types in the soil inventory have been placed into five broad soil areas as shown on the generalized soil map, Figure III-2a, for the north half of the Forest. Within each area are some broad similarities of landforms and soil characteristics. At the highest elevations, rock outcrops, talus slopes, alpine meadow, and permanent snow and ice are common. The soils that are found are shallow and fragile, lacking the soil structure to resist erosion, especially if the vegetation is removed. Much of this area lies above the conifer forest zones; the sedges, grass, and small shrubs found in the high elevations have a low tolerance to resist trampling, and are easily destroyed (Snyder and Wade 1970).

A large portion of the north half of the Forest contains long steep slopes, ridges, and narrow valleys with both shallow residual soils and deep glacial soils. Because of the complex bedrock and glacial geology of the area, soils occur in complex patterns and arrangements. In general, shallow soils are more predominant above 3,000 feet, while deep glacial soils occur more frequently below this elevation (Snyder and Wade 1970). High precipitation and steep

Figure III-2a

Generalized Soil Map



slopes plus weakly structured soils in these areas have resulted in a high potential for surface erosion. Many of the shallow soil types are resistant to water infiltration; rainwater often runs over the surface, rather than infiltrating. The potential for erosion is high. Refer to Snyder and Wade (1970) for further information.

The remaining soil areas occur in more localized portions of the north half. One is comprised of deep, unstable colluvial soils occurring on steep toeslopes and midslope drainages throughout the entire Forest (Snyder and Wade 1970). The soils tend to be gravely or silt and sandy loam with clay, gravel and sand textures in the subsoils. Combined with highly weathered bedrock, steep slopes, and subterraneous water, the soils in these areas are very unstable. Deep-seated mass movement (slumps etc.) occur even on virgin landscape.

Another soil area also contains unstable soils; glacial till, outwash, and glacial lake deposits are found in a number of valleys in the Phinney Block, the South Fork of Canyon Creek, and the North and South Forks of the Sauk River. The 1984 massive slump and failure at Deer Creek occurred in these soils. (See Special Conditions, below.) The natural instability is caused by a combination of steep slopes, fine textured "plastic" subsoils, wet weather, and subterraneous water. Slumps and slope failures with resulting sedimentation to streams (and damage to fisheries and other resources) have occurred in virgin landscapes; the problems are accelerated with roading, logging, or other ground disturbances.

A soil area comprised of stable glacial till and outwash occurs on the bottom and toeslopes of major valleys, including portions of the North Fork Nooksack, Suiattle, Sauk, Whitechuck, and other rivers. Gentle slopes are common and these soils are well suited to most management activities.

Finally, as shown in the north half generalized soil map, there are two areas with combinations of these soil types; both are quite localized.

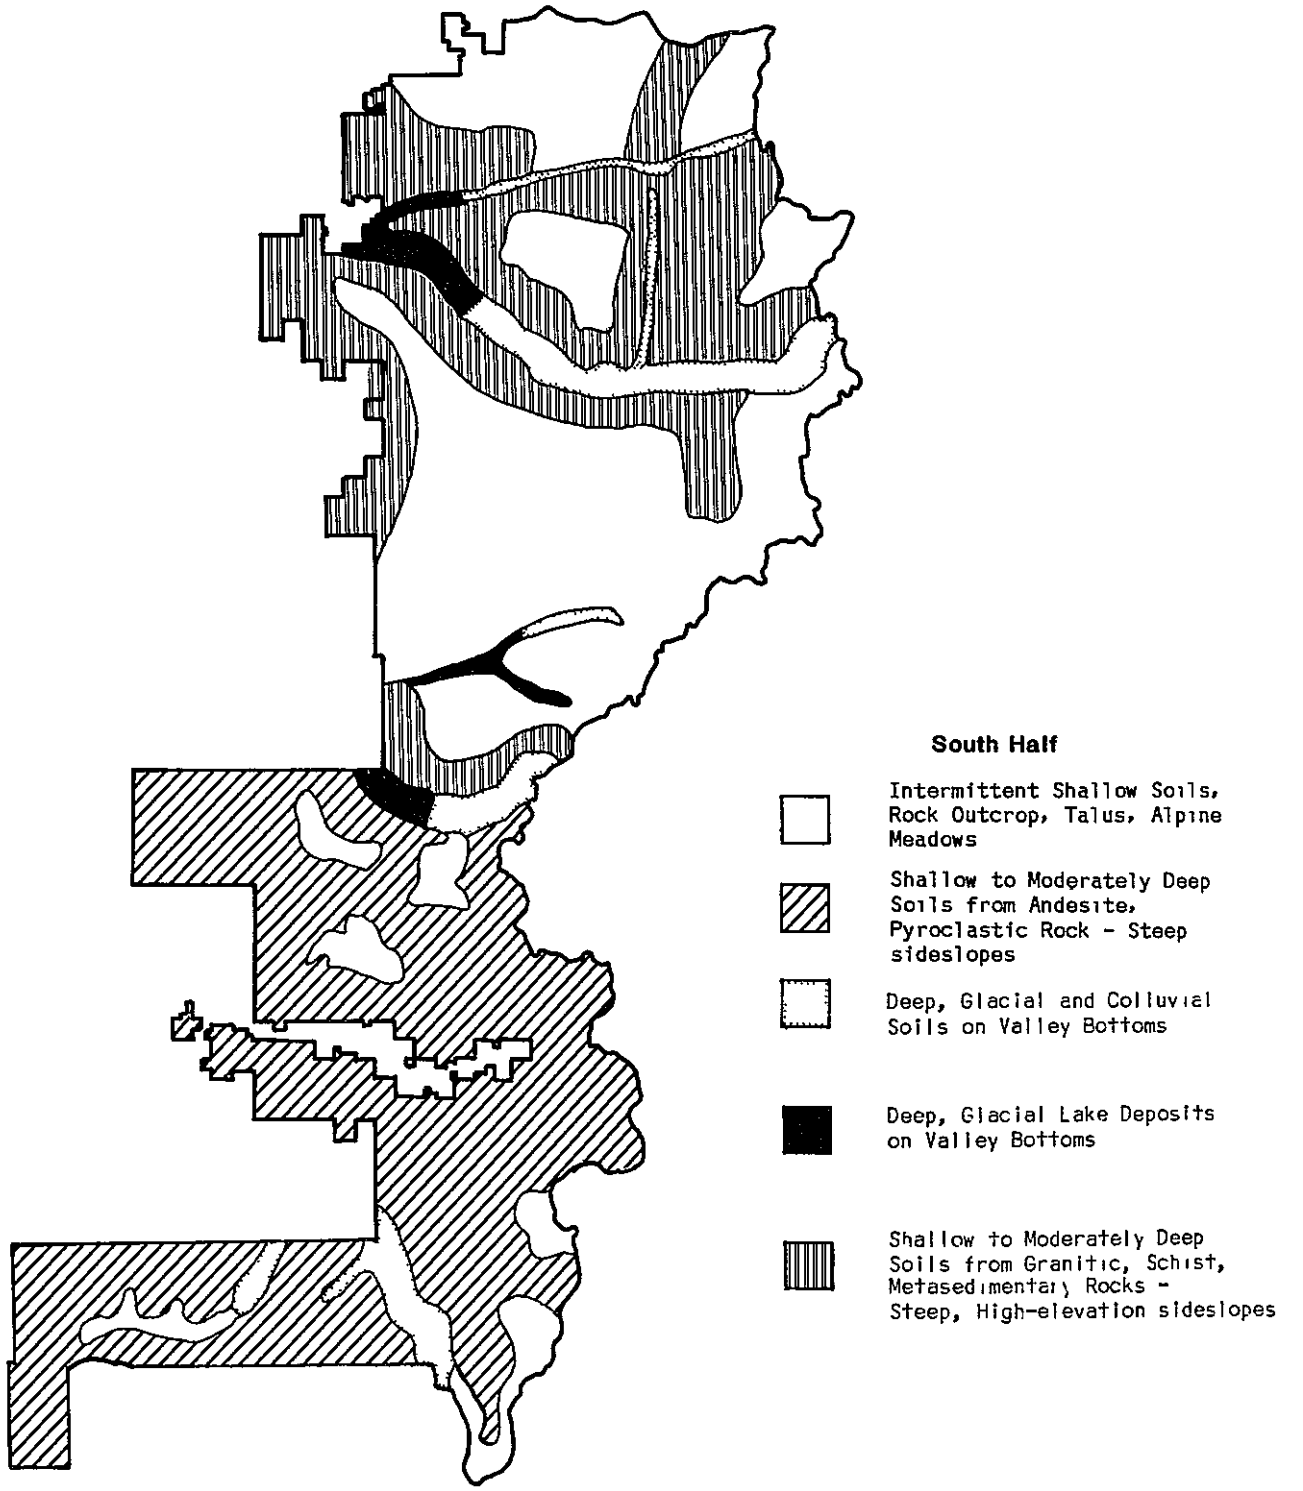
South Half of the Forest

The south half of the Forest, particularly the area south of I-90, is strikingly different. Rather than the numerous bedrock types of the north, the dominant bedrock is volcanic (andesites and pyroclastics). Glaciation was a minor influence and affected only the major valley bottoms and toeslopes. These differences in bedrock and glaciation have produced more subdued topography. Mountains are more ridgelike in nature, and while commonly steep and dissected, they lack the size and grandeur of their northern counterparts.

These differences in bedrock, glacial history, and topography also cause differences in soil types and their amount. The generalized soil area map, Figure III-2b, shows the soil areas which occur in the south half.

Many of the soil areas which occur on the north half also occur on the south half, but they occur to a much lesser extent. A common soil condition on the south half is shown as "shallow to moderately deep soils from andesite, pyroclastic rock." This area most characteristically contains soils that are well drained, moderately coarse textured and occur on steep sideslopes. The underlying bedrock is most commonly volcanic south of I-90 and intrusive or metasedimentary north. These soils are generally stable with the exception of

Figure III-2b
Generalized Soil Map



the areas adjacent to many of the stream channels. These soils can generally absorb the effects of management activities with little or no productivity loss provided that Best Management Practices (BMP's) are done.

Special Conditions

Approximately 39,850 acres of forest land containing commercial tree species, and having a productivity of at least 20 cubic feet of wood fiber, per acre, per year, are considered to be technically unsuitable for timber harvest due to irreversible soil damage. These soils are so unstable that timber removal results in a 75 percent probability of a doubling of mass soil movement (Boyer Memo 1980, Snyder 1981). Even use of technologically advanced logging systems, such as balloon or helicopter logging, cannot reduce the risk. These "irreversible damage" acres represent 2.3 percent of the Forest acres.

An additional 55,626 acres of highly unstable soils contain vegetation other than commercial tree species or produce less than 20 cubic feet of wood per acre per year. The total - 95,476 acres of unstable soils - equals nearly six percent of the Forest. In addition, a number of acres in riparian areas, the number varying by physical condition, will not be harvested because of other watershed, fishery, and wildlife management objectives.

While soils in this extremely unstable category occur forest-wide, they are predominant on the Darrington and Mt. Baker Ranger Districts, in the northern half of the Forest. The unstable soils are either glacial lake-deposited (Lacustrine) found on very steep toe slopes, or deep colluvial soils, deposited on very steeply dissected side drainages. In addition, there are many locations where the underlying bedrock is very weathered and incompetent, adding to the probability of slides and slumps.

Several large drainages on these two Ranger Districts contain highly unstable soils that are particularly sensitive to any management activities, such as cutting trees, road building, etc. Among them are Canyon Creek (Mt. Baker), Canyon Creek (Darrington), and Deer Creek (Mt. Baker.) The Deer Creek drainage contains about 40 percent unstable deep glaciolacustrine and colluvial soils. This drainage is very sensitive to disturbances. In the past years, numerous slumps and slides, both natural and human-caused, have had serious effects on the fisheries, water quality, and scenery of Deer Creek.

The majority of the watersheds on the Mt. Baker-Snoqualmie National Forest are in an acceptable condition and fully meet the requirements of the beneficial uses, which most often is fisheries. However, in recent years there has been an increasing concern among Forest Service professionals and members of the public that a number of the watersheds were showing evidence of deteriorating conditions, resulting from past management activities, and that these watersheds may not be in an acceptable condition. These deteriorated watersheds are more common on the northern half of the Forest, where there are numerous deep, unstable glacial soils. Indicators of watershed deterioration include: unstable stream channels, unstable streambanks, poor pool/riffle ratios, and streams that either lack large woody debris or contain unstable large woody debris.

Refer to Chapter IV, Table IV-4 for a list of watersheds that were evaluated and rated in the hydrologic cumulative effects analysis (which is documented in

Appendix H, FEIS). Appendix H describes the process used on the Forest to evaluate watershed conditions in order to meet the management requirements for water quality and riparian areas.

Watershed Improvement Needs Inventory

A watershed improvement needs inventory was completed for the Mt. Baker-Snoqualmie about six years ago. It is now outdated and has limited use for the Forest Plan. The need for an updated inventory is recognized, but due to budget and personnel restrictions, inventories will be conducted in only a few critical watersheds, such as Deer Creek and Canyon Creek. Work began in 1986; refer to the Watershed Rehabilitation Schedule, Appendix I, Forest Plan.

WATER

Water is one of the most abundant and valuable resources on the Forest. There are over 14,000 miles of streams and rivers on the Mt. Baker-Snoqualmie and over 13,600 surface acres of lakes within the Forest boundary.

Water is a key component of the environment. A complex interplay of the aquatic resources, climate, soils, and topography have created a climate especially favorable to coniferous vegetation (Franklin and Dryness 1973). The numerous lakes, streams, and rivers provide a high quality spawning and rearing habitat for anadromous fish, and habitat for resident fish. Habitat areas adjacent to streams, lakes, ponds, springs, marshes, etc. are the most heavily used by wildlife. The streams and rivers of the Forest provide high-quality water for municipal use by over 1.4 million people in the Puget Sound area, and for agriculture and industrial purposes downstream from the Forest boundary. Water is of primary importance for recreational activities; many are directly or indirectly water-based, such as fishing, boating, camping, and sightseeing. In one way or another, the cultural and natural environment is affected by, and in turn effects, the water resource.

Lakes

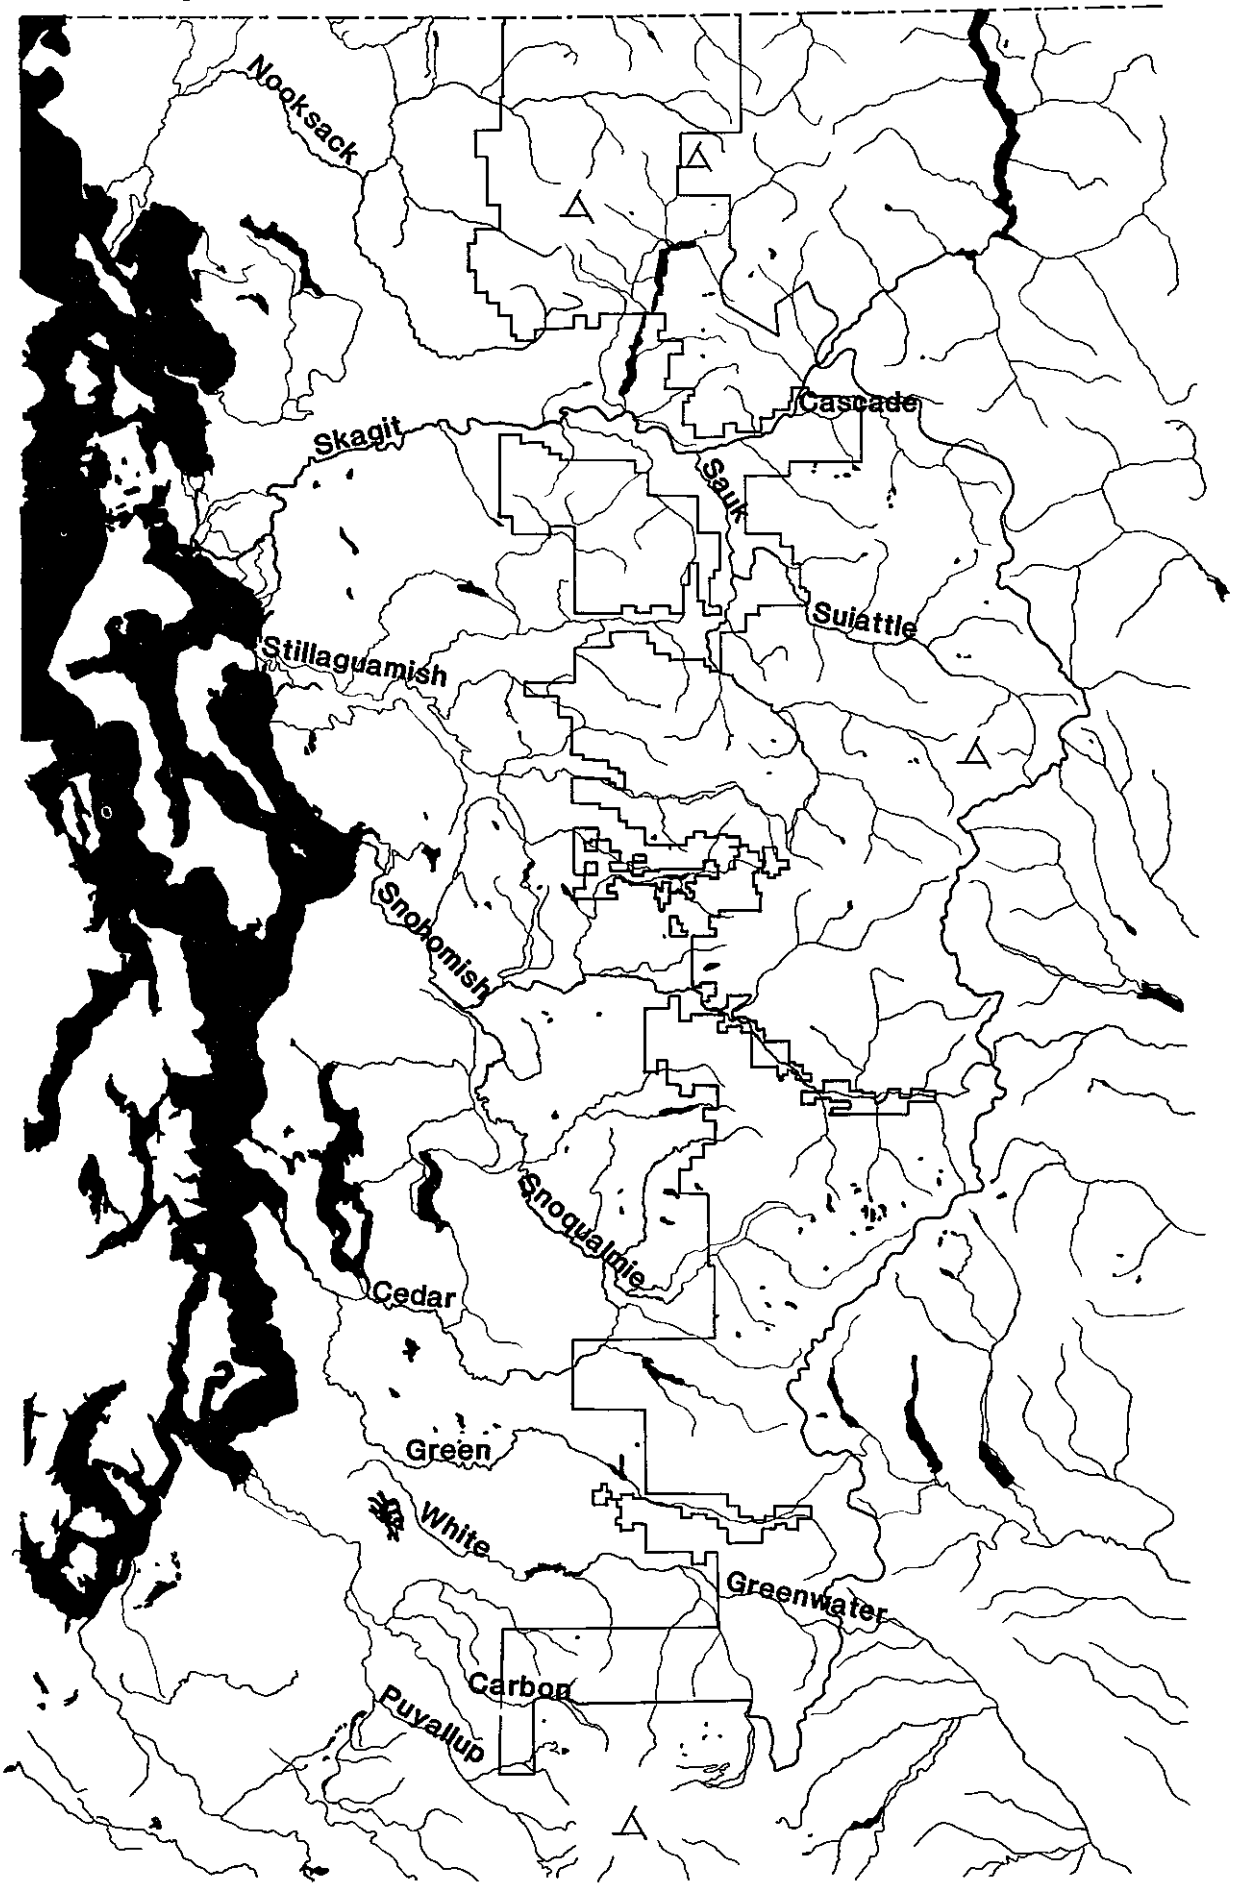
There are over 650 lakes on the Forest, ranging in size from alpine tarns less than one acre in size, to the Upper Baker Lake Reservoir (5,238 acres) and Sultan Basin Reservoir (Spada Lake, 5,300 acres.) Over 60 percent of the lakes are within wilderness. About 120 lakes are 20 acres or larger in size: Snoqualmie Lake is 126 surface acres; Marmot Lake, 135 acres; Blanca Lake is 179 surface acres; and Lake Dorothy is 290 acres. The lakes and reservoirs of the Forest provide habitat for resident fish; their shores contain rich, riparian habitat (refer to the discussion following); and many are important in maintaining stream flow year round. Many of the 650-plus lakes are important recreation resources for camping, fishing, and general sightseeing. Forest recreation trails often have a lake as a destination point. Problems of overuse, soil compaction, and loss of vegetation (from campers and horses) are among the overuse concerns.

River Systems

The streams and rivers of the Mt. Baker-Snoqualmie National Forest contribute to seven of the ten largest river systems (largest annual runoff) draining into Puget Sound. These include: the Nooksack River; the Skagit River system, including the Cascade, Suiattle, and Sauk Rivers; the Stillaguamish River; the Snohomish River, including the Skykomish and Snoqualmie Rivers; the Cedar River; the Green River; and the Puyallup River, including the White, Greenwater, and Carbon Rivers (Pacific N.W. River Basins Commission 1970). These major rivers are shown in Figure III-3, on the next page.

The runoff from these rivers, over the last thirty years, averaged over 30 million acre feet annually (Pacific N.W. River Basins Commission 1970). There are few places in the nation where the runoff is so great. This figure represents about 31 percent of the State's total annual runoff. Over half the water running into Puget Sound comes from just two river systems: the Skagit and the Snohomish.

Figure III-3
River Systems



The Mt. Baker-Snoqualmie National Forest portion of these seven rivers has an annual runoff of 15.5 million acre-feet of water. This equates to approximately 8.96 acre feet of water for each acre of forest land. In comparison, the yield for the Olympic National Forest is 6.3 million acre feet per year, or 9.69 acre feet of water per acre of forest land. The water yield from forests located east of the Cascade Mountains is considerably lower; the Umatilla yields 2.5 million acre-feet or 1.178 acre feet/acre and the Wenatchee, 4.5 million acre-feet per year, or 2.10 acre feet/acre.

Stream Class and Streamside Management Units (SMU's). A stream classification system (see the Glossary) on National Forest lands has been designed to provide graduated management protection of the national forest drainages based on their individual water quality requirements. Class I streams are the direct source for domestic water and/or are used by large numbers of fish. Class I streams are the highest or most protected class. Class II streams generally have moderate fish use and/or contribute to Class I streams. The Forest contains approximately 1,600 miles of Class I and II streams.

Class III streams are divided into "deeply incised" and "lightly incised", depending on streambank slope, soil stability, and other factors. (This is a local refinement of the Pacific Northwest Region stream class criteria). On the Mt. Baker-Snoqualmie, 70 percent of the over 3,500 miles of Class III streams are deeply incised. Deeply incised and lightly incised Class III streams are a Forest refinement of the Pacific Northwest Region stream classification system. Class IV streams include all others not meeting the above criteria.

Streamside Management Units (SMU's) are Forest Service-applied boundaries to that portion of the land lying between the aquatic and terrestrial ecosystem - the riparian zone. Refer to the section on Diversity in this chapter. The width of an SMU varies with the terrain and the management goals for each type of stream.

Streamflow, Flooding

Two distinctive low streamflow periods typically occur in the Western and Northwestern Cascades. The winter period varies, but usually corresponds to clear, cold weather periods in late winter. It is most pronounced in the higher elevation watersheds dominated by heavy snowpack and glacial ice. The summer low flow period is closely related to the summer/early fall low rainfall climatic pattern. Streamflow begins to decline in June and low flows persist into late September and early October. Streamflow from high elevation watersheds remains higher longer into the summer season as the snowpack recedes. Streamflows dominated by glacial icemelt remain at relatively high levels throughout the summer season and are closely associated with warm weather periods, fluctuating widely through daylight and night-time hours.

Larger streams in forested areas maintain at least a minimal flow level throughout the dryer summer season. Adequate water is usually available for all wildlife needs. Extremely low streamflow and accompanying warm temperatures may impact fisheries habitat, however, particularly rearing habitat for both trout and anadromous species.

Coniferous tree growth is well adapted to the usual summer dry period, as tree roots penetrate into ample stored subsurface soil moisture supplies. Shallower

rooted, newly planted trees can suffer for moisture, however, particularly when the dry period begins in early June and persists for weeks without cloudy, cool weather and light rainfall breaks.

History of High Streamflows, Flooding

High streamflows and extreme flood flow events occur during the fall/winter precipitation period especially in November and December. Persistent rain and rain-on-snow events often produce large increases in peak flows, that often pose a threat to downstream lives, property, and aquatic habitat.

There is 20 years of documentation of the occurrence and frequency of these events, especially for the watersheds on the north half of the Forest. In some watersheds, such as Canyon Creek, Finney Creek, and Deer Creek, rain-on-snow events have occurred numerous times over the past 20 years. These events have repeatedly caused major channel damage and adverse fish habitat changes, resulting in degradation of water quality and reduction in fish species numbers or diversity.

On this Forest, these storms are known to cause or trigger mass wasting events, such as debris torrents, debris floods, and earthflows. Such events have occurred at least once a year in three north-end Forest watersheds (Canyon Creek, Deer Creek, Finney Creek) during 1951, 1959, 1962, 1971, 1975, 1977, 1979, 1982, 1983, 1986, and 1989. Heavy timber harvesting and road building activities in these watersheds - over the past 30 years - along with the natural instability and steep slopes, has aggravated the damage and degradation resulting from these peak flow or flood events.

Groundwater

Research studies indicate timber harvesting generally increases annual water yields. This is due primarily to reduced evaportranspiration. Harr (1983) developed a regression equation for use in estimating potential increases in annual water yield, which can be expected from clearcutting in western Oregon and Washington, based on research results in experimental watersheds. Initial on-site increase of up to 20 inches are predicted, though they completely disappear in about 27 years. The equation predicts a smaller annual water yield increase when annual precipitation is less.

Harr estimated that sustained increases in water yield from most large watersheds in western Oregon and Washington subject to sustained forest management are, at best, three to six percent more than flows from an undisturbed forest. Kattelmann et al. (1983) estimated similar maximum potential increases in Sierra Nevada watersheds if minimum standards for all applicable laws were followed. However, they concluded that the typical increase in a large watershed drops to approximately one percent when constraints are imposed to meet other resource demands. A similar scenario is expected in Pacific Northwest Region National Forests due to multiple-use considerations. Flow increases on these Forests have already been realized due to past harvesting, so there is little or no potential for increasing yields in most large watersheds.

This is especially true on the Mt. Baker-Snoqualmie, as timber harvest levels of the past (over 300 million board feet annually) have dropped; refer to Table III-11, Timber Sold and Harvested, later in this chapter. Other factors which

further minimize potentials to effect changes in streamflow are high natural variability, lack of flow measurement accuracy (within five percent, at best, so potential changes are less than what is measurable in large watersheds), and the fact that most of the flow increases occur when they are least needed or useable - during spring runoff on the eastside, and during fall storms on the westside.

Research generally shows increases in summer flow result on site immediately after harvest in western Oregon. However, studies in the Rocky Mountains (Troendle 1983) showed no change in late summer streamflow following timber harvest, despite annual increases. (These increases occurred during spring snowmelt.) In large watersheds subject to sustained yield harvesting, summer flow increases are temporary and not expected to be measurable at downstream locations.

Effects of harvesting timber on groundwater recharge and aquifers are similar to effects on streamflow, except for timing differences; eg., aquifer responses are typically slower and fluctuate less than streamflow.

Water Quality, Temperature, Turbidity

All waters on the Forest are classified by the State of Washington as Class AA Excellent. (WAC 173-201 (12-19-99)) As discussed in Chapter IV, Forest-wide mitigation measures, water quality standards for the State are met through application of Best Management Practices (BMP's); water for domestic use and fish are key resources protected by BMP's.

In terms of natural chemical components, it will usually meet U.S. Public Health Service drinking water standards and provide an excellent medium for aquatic organisms and spawning and rearing resident and anadromous fish.

A periodic exception may be streamflow composed primarily of glacial icemelt. Water in these streams, in addition to being highly turbid, is generally neutral in pH, soft, and dominated by either calcium bicarbonate or acid sulfate. This latter component has been associated with intermittent volcanic steam activity around Mt. Baker. One stream, Boulder Creek, following an increase in volcanic activity in 1975, registered a relatively low pH, high conductivity, and an increase in sulfate concentrations. These components are now essentially back to pre-activity levels.

Stream conductivities, as a measure of mineral salts in solution, will vary seasonally. Low values typically occur during higher flows, particularly during the spring and early summer snowmelt runoff period. Higher concentrations occur during the summer low or base flow period.

Turbidity and Suspended Solids

The majority of headwater streams on the Forest are almost sediment-free in their natural state, with the exception of winter storms when some sediment likely occurs. The glacial-fed streams originating on the slopes of Mt. Baker, Shuksan, and Glacier Peak have a milky appearance and contain suspended sediments derived from melting glaciers (Pacific N.W. River Basins Commission 1970). They tend to be particularly sediment laden during periods of high runoff.

Temperature

Among the water quality attributes that affect water use by fish, temperature can be a concern. Removal of streamside vegetation usually increases summer water temperatures in direct proportion to the amount of increased sunlight on the water surface (Chamberlin 1982). Small canopy openings on some streams can promote aquatic production. Changes in water temperature begin to have a detrimental effect on fish/fish habitat when a threshold amount, or percent, of streamside vegetation that provides shade is removed within a watershed or basin. Mitigation, in the form of limiting removal of vegetation along streams, etc. (discussed fully in Chapter IV) has generally been successful in the past.

Water Uses

Primary uses for the water flowing from Forest lands include municipal water, downstream hydroelectric power generation, fish habitat, and irrigation. There is no direct diversion for irrigation from the Forest and water used by off-Forest fish hatcheries is minimal. However, water for municipal and industrial use is valued at $135 per acre foot, or for the watersheds on the Mt. Baker-Snoqualmie, $25,448,158 per year. Water is also used for generating power. When valued at $8.00 per megawatt hour, water from the Forest used for power generation totals a value of $26,428,160 per year. Total water values from the Forest exceed $51,876,000 - a considerable amount.

Municipal Watersheds

A significant portion of the watersheds supplying the cities of Bellingham, Everett, Seattle, and Tacoma is located within the boundaries of the Forest. A number of smaller municipalities, ski areas, and other recreation sites also obtain their water from the Forest. About 135,600 acres (7.9 percent) of the Forest land base, supply water for municipal watersheds (USDA Forest Service 1982). Table III-2 shows the cities served and their watersheds.

Only one water supply impoundment is located on National Forest land: Spada Reservoir, on the Sultan River. It supplies municipal water for the City of Everett. Chester Morse Lake is located within the Forest boundary but the City of Seattle water supply intake is located downstream, on the Cedar River. Several other large municipal supply reservoirs are located downstream from National Forest lands; Eagle Gorge supplies Tacoma from the Green River and the Tolt Reservoir supplies Seattle from the South Fork Tolt River.

There are a number of issues and concerns regarding the watersheds, including water quality, recreation use, timber harvest, and management of wildlife habitat and old growth ecosystems. These concerns are not limited to the large watersheds supplying Seattle and Tacoma. The issues are discussed in both Chapter I and Appendix A of this FEIS.

Table III-2
Municipal Watersheds on the Mt. Baker-Snoqualmie National Forest

Watershed Name	Service Area or Municipality	Type of Water	Population Served	Daily Consumption -gallons	Acres N F.	Acres Other	Acres Total	Water Treatment: Disinfectant	Water Treatment: Filtration	Water Treatment: None

1/ The population served by both the Cedar and South Fork of the Tolt Watersheds is 992,000.

The Cedar River Watershed

This large watershed is managed under a 1962 Agreement between the Forest Service and the City of Seattle. The agreement provides for timber harvest on a sustained yield basis (see Glossary) within the watershed. As National Forest lands have been cut, they are exchanged to the City for City lands located elsewhere. In 1989, the City of Seattle established Ordinance 114632, which changes the emphasis for city land management. This Ordinance may, in the future, cause the 1962 Agreement to be amended. Refer to the land ownership and land use sections of this chapter for additional information. Public access on roads on National Forest lands within the watershed is restricted. The Cedar River Watershed is inaccessible to recreation use except for existing peripheral use at some sites (City of Seattle, USDA Forest Service 1979). All National Forest land in the South Fork of the Tolt are open to recreation use, but access from the west is closed to the public. Money Creek road, to the east, provides the only access to National Forest lands in this watershed.

The Green River Watershed

This watershed is managed under a 1984 Memorandum of Understanding between the Forest Service and the City of Tacoma. Timber harvest is permitted. National Forest land in the Green River Drainage is open to public recreation use; however, the intermingled private lands west of the town of Lester are closed to such use by agreements between the City of Tacoma and private landowners. Access into the watershed is from the east, through Stampede and Tacoma Passes.

The Sultan River Watershed

This watershed is managed under a 1963 Memorandum of Understanding between the Forest Service, the City of Everett, and the Snohomish county Public Utility District. The provisions of the Federal Energy Regulatory Commission (FERC) license for Project 2157 - The Sultan Basin Hydroelectric Project - also contain management direction for the watershed. Developed recreation use is permitted along Spada Reservoir, but no water contact activities are allowed. Timber harvest is permitted with a long-range goal of disposal of all National Forest lands within the watershed except those necessary for the FERC project.

Other Watersheds

No formal agreements exist for other municipal watersheds. These watershed vary in size and population served (refer to Table III-2); timber harvest has occurred in the past as well as most recreational activities.

Hydroelectric Power

Because of the mountainous topography of much of the Forest, there are many potential sites for generating hydroelectric power. Table III-3 shows the existing power plants on or near the National Forest. It should be noted that installations downstream from the Forest get much of their water from watersheds on the Mt. Baker-Snoqualmie.

Table III-3
Developed Hydroelectric Power Plants

Hydroelectric Power Supply

There is a renewed interest in hydropower on a National scale, due to a combination of factors, including legislation in the mid-1980's. The National Energy Act (NEA), the Energy Security Act, and the five bills composing the NEA (one of which is the Public Utility Regulatory Policy Act of 1978) provided additional economic, regulatory, and tax incentives to developers of hydroelectric power through the end of the year, 1985. This contributed to a substantial increase in the number of filings for preliminary permits and licenses for sites which have the potential for producing not more than 15 megawatts of power. They are generally located on smaller rivers and streams, with no storage potential.

A large number of small hydroelectric power applications have been received, mostly for sites on the Mt. Baker, Darrington, and Skykomish Ranger Districts. The rate at which new applications are received will diminish over time as economically feasible and environmentally sound sites are identified, construction completed, and speculative projects are eliminated.

The Forest Service's present role is as an advisor to The Federal Energy Regulatory Commission (FERC). Through Section 4(e) of the Federal Power Act, the Forest Service makes recommendations on hydropower License applications. These comments, conditions, and stipulations are made a part of the License if the License is issued by FERC. A Licensee constructing a hydroelectric

powerplant, electric transmission line, or related facilities will be authorized to occupy National Forest System land through a special use permit.

These projects have the potential to affect timber harvesting, fish and wildlife habitat, particularly anadromous and resident fisheries, scenery, cultural resources, roadless areas, and recreation setting.

The Sultan Basin Project is the only on-going, major hydroelectric project on the Forest. The project was started in 1961 by the Snohomish County Public Utility District; a dam and storage area were constructed on the Sultan River to provide domestic water for the city of Everett. Construction of the second phase has raised the dam height, increased the water storage area, and will provide Everett 95 megawatts of power annually.

Demand

The demand for energy in the Puget Sound area is expected to grow at an average annual rate of between one and two percent through the early 1990's. Predictions beyond this period show a wide variability, based on the difficulty in forecasting demographics and the economy.

While the area is currently operating with surplus power - Bonneville Power Administration estimates a surplus through 1994 - new energy sources will be needed in the future. The inclusion of the Skagit River in the Wild and Scenic Rivers System and the large number of acres in designated wilderness will affect the location and future construction of potential hydroelectric sites.

Small hydroelectric projects may become more feasible due to possible limitations on the expansion of major dams on the Columbia River (to increase flows for downstream salmon migration and for additional irrigation).

National Surface Water Survey

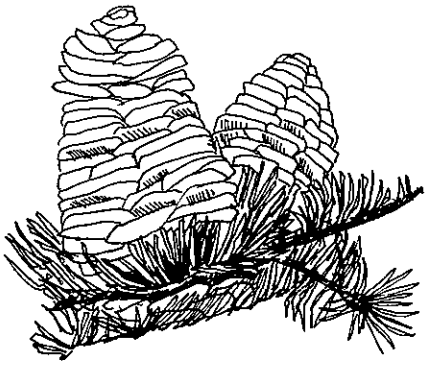
In the fall of 1985, a total of 26 lakes (twenty within designated wilderness) on the Mt. Baker-Snoqualmie National Forest were sampled to assess their sensitivity to acidic deposition (acid rain). The survey is part of the National Surface Water Survey and was mandated by Congress. The Environmental Protection Agency and the Forest Service are jointly conducting the survey.

Acid rain occurs when oxides of nitrogen and sulfur are emitted into the atmosphere. The major man-made source is the combustion of fossil fuels in power plants, automobiles, factories, and smelters. Acid deposition can cause serious environmental problems. When pollutants enter lakes and streams, they may change the chemistry of the ecosystem; they have the potential to destroy small aquatic organisms which support fish and may kill the fishery as well (U.S. Environmental Protection Agency 1985).

Lakes and streams, with their surrounding watersheds, vary in their sensitivity to acidic deposition. Some lakes, naturally, are able to handle more acid deposition without becoming damaged; others have very little "buffering capacity" or ability to withstand the pollutants (Environmental Protection Agency 1985). The national survey will identify how many lakes may already be acidic and how many others are potentially sensitive to deposition. It is not expected that the results of this study will affect the alternatives.

DIVERSITY

Introduction



Diversity, as described in NFMA, refers to the distribution and abundance of plant and animal species and communities on the Forest. Elements of diversity include, but are not limited to:

- viability, distribution, and abundance of wildlife and plant species;
- structure, composition, and distribution of ecosystems;
- the role of perturbations such as fire, wind, and insects;
- long-term productivity; and
- fragmentation and reduction of scarce community types.

The regulations (36 CFR 219.27) require that management prescriptions, where appropriate and to the extent practical, preserve and enhance the diversity of plant and animal communities, including endemic and desirable naturalized plant and animal species. "Diversity" of these communities and species should be at least as great as those expected in a "natural" Forest. The diversity of tree species should be similar to that existing in the forested planning area. Reduction in diversity may be prescribed only where needed to meet overall multiple-use objectives.

Detailed discussions of individual elements that comprise diversity are included in other sections of this chapter, including soils, wildlife and fish, and fire management. To avoid repetition, discussions of biological diversity elements presented here have been summarized and cross-referenced, where appropriate.

Biological Processes and Long-term Productivity

Ecosystems

Ecosystems are more than their component parts; they are also the processes that link these parts together. These processes include reproduction, growth, energy flow, and succession. One reason diversity is valued so highly is the belief that by preserving the parts (the kinds of plant and animal species and communities), we also preserve the processes, which are essential to the maintenance of the health and productivity of the ecosystem. By ensuring that diversity is maintained, we protect the habitats of animals and plants, and ensure the productivity and viability of future ecosystems.

Soil

Soil is a basic, nonrenewable resource and is the foundation on which diversity is maintained. All plant and animal life on the Forest is either directly or indirectly dependent on maintenance of long-term productivity of soils. By definition, the components of long-term soil productivity include:

- surface litter and topsoil layers;
- soil organic matter and its replacement;
- soil organisms and biological systems and;
- soil porosity, structure, drainage and aeration.

As discussed earlier in this chapter, the soils of the Mt. Baker-Snoqualmie are complex, with over 200 mapped categories (based on soil type, geologic type, and topographic shape). These can be grouped into several broad groups that have similarities in texture, depth and parent material. There are differences in soils in the north half and the south half of the Forest. Unstable soils occur Forest-wide, but are found primarily on the north half of the Forest, where there is a high potential for surface erosion, slides and slumps. (See Soils, this chapter.)

Natural and Human Influences

In addition to soils, long-term productivity can be described as the ability of the forest to withstand impacts from both biotic and abiotic influences. Insects, diseases, wildlife, atmospheric deposition, silvicultural treatments, and harvesting practices are examples of influences that can have both positive and negative effects on the health of the forest, and thereby, on long-term productivity. Fire has played a major role in creating the vegetative conditions found at present on the Forest. The natural ecosystems are characterized by a long-term fire cycle of very infrequent but high-intensity, stand-replacement fires. Livestock grazing has been of very-low intensity. Pollutants in the air may affect vegetation; refer to Air Quality in this chapter. Also, see the section later on this chapter on insects and disease.

From 1983-88, the Forest harvested around 230 MMBF in timber sales annually, with most of this volume removed from clearcut harvest units. About 3,000 acres were precommercially thinned each year. The roadless area issue resulted in the concentration of timber sales in approximately one-half of the Forest land base. Approximately 87 percent of acres harvested are planted, although even these planted sites also have some natural seeding and survival of residual trees. Planted stock is increasingly coming from seed of "genetically superior trees," trees with better resistance to disease, better juvenile survival and improved growth form, from a forest products perspective. A small percentage of the planted acres receive "release" treatment, which involves removal of competing vegetation from young conifer plantations. About 100 acres each year receive intermediate harvest, or commercial thinning. (See Vegetation - Timber, this chapter.)

The Role of Research Natural Areas

Preservation of ecosystems that are substantially undisturbed is one of the objectives of the Research Natural Area program. This is one element of preserving diversity. Three such areas have already been established on the Forest the North Fork Nooksack, Lake Twenty-two, and Long Creek Research

Natural Areas. See Research Natural Areas, this chapter, for a discussion of existing and potential RNA's.

Vegetation and Diversity of Plant Communities

Vegetation is a major resource on the Forest. Grasses and forbs, shrubs, and trees are the source of food and cover for wildlife and livestock. Timber is produced from the trees of the forest. Recreational and aesthetic values come from the forests and meadows of the Mt. Baker-Snoqualmie. Cedar bark and certain plants are important to Native Americans for religious, cultural, and ceremonial purposes. Vegetation also serves to hold the soil mantle in place (Henderson and Peter 1985). Diversity of plant communities forms the base for diversity in animal communities.

Requirements were set in the National Forest Management Act to maintain native and desired introduced plant and animal species and communities. All seral stages of terrestrial and aquatic plant associations are to be provided for, and the long-term integrity and productivity of these communities is to be maintained or enhanced. Because some species and communities are abundant and well-distributed on the Mt. Baker-Snoqualmie (and are likely to continue to be) the emphasis in managing for diversity is place on those plant and animal species and communities which are rare, or less common (or could become so). Of particular concern are those species and communities which are fragile or easily affected by human activity. Species whose habitats are poorly distributed are especially susceptible to genetic risks, which may affect their viability.

Current Vegetation Distribution

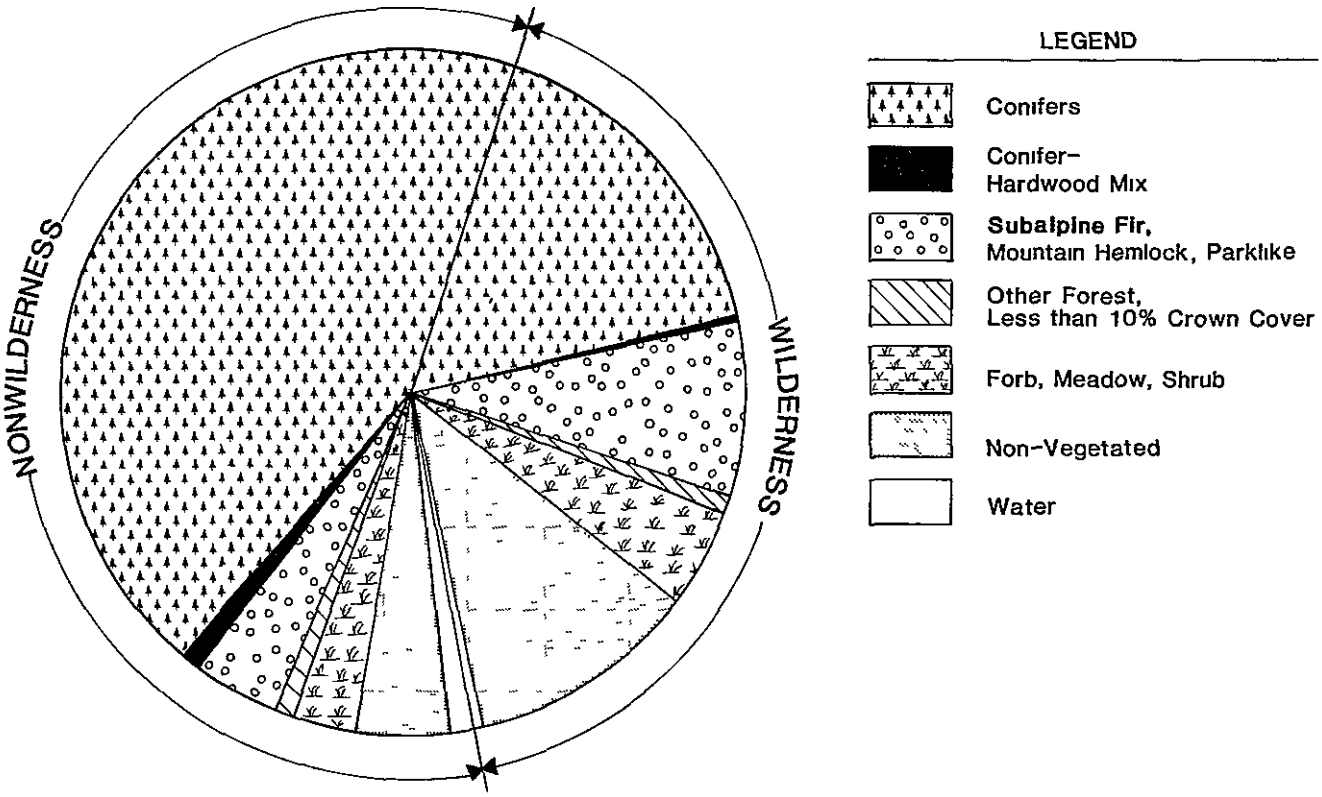
Nearly 85 percent of the lands managed by the Mt. Baker-Snoqualmie National Forest are covered by vegetation; conifers are by far the most prevalent vegetation. Table III-4 and Figure III-4 show the vegetative mix, both for wilderness and nonwilderness lands.

Table III-4
Current Vegetative Distribution - Percent

	Wilderness	Nonwilderness	Total
Forest			
Conifers 1/	16.4	43.6	60.0 %
Conifer-Hardwood Mix 1/	0.1	3.0	3.1
Subalpine Fir, Mountain Hemlock, Park-like 1/	8.2	4.0	12.2
Other Forest 2/	0.9	0.9	1.8
NonForest			
Forb, Meadow, Shrub	4.8	3.0	7.8
Non-vegetation 3/	11.0	3.2	14.2
Water	0.4	0.5	0.9
TOTAL	41.8	58.2	100.0

1/ Productivity is 20 or more cubic feet per acre per year (cf/ac/yr).
2/ Productivity is less than 20 cf/ac/yr.
3/ Rock, snow, ice, talus, developed for administrative sites, roads, etc.

Figure III-4
Current Vegetative Condition



Much of the riparian zone on the Forest contains a mixture of hardwoods and conifers, including red alder, bigleaf maple, vine maple, black cottonwood, Douglas-fir, western redcedar, and western hemlock. Associated plants include Devil's club, swordfern, herbs, and others that require large amounts of free standing water or sites that are more moist than usual (Oakley and others 1985). Refer to the Diversity - Riparian discussion, below.

The largest amount of land that is essentially non-vegetated is located within the the 721,718 acres of designated wilderness. Included are rock, snow and permanent glacier fields, and talus slopes. Outside of wilderness, most of the acres of non-vegetation are roads, administrative sites, and other developed areas on which the vegetation has been removed by human activity.

Forest Series on the Mt. Baker-Snoqualmie National Forest

On this Forest, there are three main forest series: western hemlock, Pacific silver fir, and mountain hemlock. The area of ground where these series occur is called a zone. Franklin and Dryness (1973) also identify a fourth zone, the subalpine meadow zone. It occurs above 6,000 feet in elevation, above timberline, for most of the Forest.

The table below shows, very generally, the major series or zones on the Forest, including some of the more common understory trees, shrubs, and grasses. For a more complete description, refer to the Preliminary Plant Associations and Habitat Types, Henderson and Peter, for each Ranger District.

Where the subalpine fir series occurs, the fourth zone, subalpine fir is the major tree species, with mountain hemlock and Alaska yellowcedar subdominant. In any of these series, stand succession takes place over time, leading to the

climax species. Once reached in the succession - and if no natural catastrophe occurs - the climax species will be in a continuum of replacing itself.

Table III-5
Forest Series and Major Plant Associations on the Forest 1/

Western Hemlock Series

Zone begins in the foothills and extends to about 2,600 feet in elevation.

Major Tree species: western hemlock, Douglas-fir, western redcedar, alder, and some Pacific silver fir.
Common understory vegetation: swordfern, salal, devils club, Alaska huckleberry, Oregon grape, vine maple, foamflower.

Pacific Silver Fir Series

Zone extends from about 2,000 to 4,000 feet in elevation, slightly lower on north aspect slopes and slightly higher on south aspect.

Major Tree species: western hemlock and Pacific silver fir co-dominate, with Douglas-fir, mountain hemlock, some noble fir and western redcedar.
Common understory vegetation: Alaska huckleberry, swordfern, herbs, big huckleberry, salal, devils club, foamflower, vine maple.

Mountain Hemlock Series

Zone is the highest coniferous forest zone, ranging from about 4,000 to 6,000 feet; it extends down to about 3400 feet in wetter areas.

Major Tree species: mountain hemlock co-dominates with Pacific silver fir; Alaska yellowcedar, subalpine fir; some western hemlock, Dougals fir, noble fir.
Common understory vegetation: Alaska huckleberry, big huckleberry, herbs, red heather, blueleaf huckleberry, mountain ash, bear grass.

1/ Henderson and Peter 1981 through 1985.

Diversity and Successional Stages

The diverse vegetative communities of the Mt. Baker-Snoqualmie National Forest are a result of extremes in elevation, aspect, soil depth, and climate. Fire, wind storms, avalanches, insect and disease, and the harvest of timber over the years have also contributed to the character and diversity of vegetation on the Forest. In the pristine forest, not all lands are naturally in an old-growth condition. Grass and forb communities are often the result of recent forest fires and timber cutting. The proportion of young tree stands in drainages reflects the patterns of past forest fires. The amount of moisture on a particular site, in combination with slope, elevation, temperature, and soil nutrients all affect the composition of communities.

Vegetation occurs over the landscape as a complex mosaic of various plant communities at different stages of development (Henderson and Peter 1985). The structure and composition of these communities is constantly changing with time (Odum 1971). Trees grow, plants die, the distribution of trees of various ages changes; the death of a large tree leaves a hole in the "canopy" of the forest that will be filled in with younger individuals, often of a different species. This natural process is known as succession (Golley 1977, Hall and others 1985a).

Diversity and Succession in Natural Stands

Succession generally follows a particular sequence. The time periods are relative; several stages may be spanned in the first 50 years of succession, following a disturbance (such as fire or timber harvest). Vegetation communities in the later stages will change slowly.

A pioneer stage of grass and forbs lasts from 2 to 5 years and occasionally as long as 50 years. An early seral stage of shrubs and saplings often lasts 3 to 10 years but may remain for 20 to 100 years if tree regeneration is delayed, either by natural or man-caused events. At this stage, trees in the area are generally under 10 feet tall. A young forest condition follows, with saplings and poles over 10 feet tall. The forest "canopy" is still fairly open (less than 60 percent closed) and the understory vegetation, commonly, is dominant. This stage may last from 8 to 20 years, depending on tree crown closure (Hall and others 1985a).

In most situations, forest stands have a tendency to be single-layered as they grow through their juvenile or early stages. The stands generally stay in a single canopy layer until a point in time where disease, insects, and weather begin to introduce mortality. With this mortality, holes appear in the crown canopy, allowing new seedlings to become established. Over time, these seedlings will become components of the canopy, providing for a multiple-layered canopy. The most shade-tolerant species in these stands are the likely stand replacement species.

As the tree crown cover closes, understory vegetation becomes sparse. This closed sapling-pole-sawtimber condition may last from 40 to 100 years. Succession continues through old-growth forest and finally to the "climax" stage of succession (Hall and others 1985a).

The size classes of trees in unmanaged stands will vary, depending upon the specific site, and the frequency of interruptions in the sequence. In most situations, older dominant trees in the western hemlock and Pacific silver fir series can be expected to exceed 26 to 30 inches in diameter. Trees at higher elevations will be smaller. When maturity is reached, a broad range of tree sizes will be found in a stand.

If natural succession is not interrupted by fire, changes in climate, timber harvest, or other disturbances, one stage of vegetation succession will be considered the "climax" stage (Henderson and Peter 1985). Technically, the community of plants that would develop within a time period of about 1000 years represents the climax stage (Henderson and Peter 1985). The climax stage, or "series" of vegetation, has one (or more) dominant overstory species, used to identify the series (Henderson and Peter 1985).

Should a catastrophic event occur, it may set the successional sequence back, allowing for subclimax species to replace the climax species and re-starting the successional sequence toward climax conditions. Mortality from disease, insects, windthrow, and wildfire tend to produce uneven edges and a mosaic of affected and unaffected trees or patches of trees. (This is in contrast to the the managed stand, discussed below.) The structural diversity in these natural stands will remain high and will continue to develop as the stands age.

Table III-6 shows the tree species found in each series or zone, in a natural stand. The tree species includes the dominant or major species found, plus other (minor) species; shade-tolerant species will be found in lower canopies.

Table III-6
Tree Species in A Natural Stand, by Series (or Zone)

	.....	.....	Series or Zone.....	
Species	Western Hemlock	Pacific Silver Fir	Mountain Hemlock	Subalpine Fir
Western hemlock	**Major**	**Major**	**Major**	
Douglas-fir	**Major**	Minor	Minor	
Western redcedar	Minor	Minor		
Pacific silver fir		**Major**	**Major**	
Noble fir		Minor	Minor	
Mountain hemlock		Minor	**Major**	Minor
Alaska yellowcedar		Minor	Minor	Minor
Subalpine fir				**Major**

All forested acres on the Mt. Baker-Snoqualmie that are **not** tentatively suitable for timber production will retain a high structural diversity, which will continue to develop as the stands age. Most of these acres are currently in the mature and older age classes. Refer to the Timber section later in this chapter.

Succession and Diversity in Managed Stands

When human activity interrupts the natural succession of vegetation, diversity changes. The harvesting of timber by clearcutting or shelterwood cutting - along with natural catastrophes such as fire or changes in climate - can interrupt the sequence discussed above.

When trees are removed by harvesting, the opened areas tend to be more regular in shape and size (typically, units are 10 to 60 acres); in addition, trees are removed evenly over the unit, as compared to the irregular "look" of a natural stand that has suffered mortality, disease, or fire.

After trees are removed, grasses and forbs invade. These species may differ from the ground vegetation found under a mature stand. This stage of succession in managed stands generally lasts two to five years, and sometimes up to 10 years. During this time, which is shorter for a managed stand than a natural stand, tree seedlings and shrubs become established. In a natural stand, the species of young trees re-establishing themselves after a catastrophic event will depend upon the species of trees left in openings

(residual trees) and/or seed-fall from adjacent trees. Tree replacement in a managed stand is pre-determined by the interdisciplinary planning team, following a particular silvicultural prescription which determines the species and number to be planted.

Replanting a Managed Stand. When the management emphasis for an area is timber production, the species selected by the silviculturalist is generally that with the highest commercial value, found naturally within the area, and that will perform well on a particular site. Often a species mix will be planted. Managed stands are normally artificially planted. Several species will usually regenerate in a cut-over areas, from seeds from residual or adjacent trees; thus, the planted managed stand will have a mixture of tree species. In areas where the management emphasis is other than timber production, the species mix planted may be selected to emulate the natural tree diversity. The resulting mix may or may not be similar to what would regenerate naturally (when a stand would regenerate gradually and continually, a few trees at a time). For example: in the western hemlock series, Douglas-fir is normally found, but it is a relatively shade intolerant species, needing bare soil to establish itself from seed. Western hemlock, on the other hand, is a shade tolerant species which can establish itself on top of the duff layer.

In addition, managed stands may be thinned prior to commercial harvest (to reduce the number of young trees on an acre, benefitting those remaining), which again interrupts the sequence of succession. Pre-commercial thinning usually results in the planted species dominating the stand. The natural fill-in species often comprise just 30 to 40 percent of the stand.

In a managed stand, climax conditions may not be reached. The maximum stand size (diameter of the trees) may be limited by the rotation assigned to the area and there will typically not be as broad a range of tree size classes in the stand, compared to a natural stand. Refer to the discussion later in this chapter for the acres available for timber harvest.

RIPARIAN ZONES

The riparian zone or habitat is that area that lies between the aquatic and terrestrial ecosystems. Riparian areas usually contain high water tables and have vegetation that requires large amounts of free or unbound water or conditions that are more moist than usual. (Brown 1985) Riparian areas occur along rivers, streams, lakes, ponds, reservoirs, and springs. They can occur through an entire drainage, and may extend inland for a considerable distance (Oakley and others 1985). Riparian zones may differ greatly in topography. Those with a broad, shallow profile receive more sunlight and wind and have more diversity of vegetation than those zones with steep slopes and a narrow profile (Oakley and others 1985).

Wetlands are areas that are permanently or intermittently flooded. The water table is normally at or near the surface; the land may be covered with shallow water (Oakley and others 1985). Vegetation needs saturated or seasonally saturated (hydric) soils to survive. Marshes, bogs, seeps, wet meadows, and shallow ponds are examples of wetlands found on this Forest. They occur Forest-wide but are more numerous on the north half of the Forest.

Riparian zones occupy only areas adjacent to approximately 11,641 miles of the rivers and streams on the Forest, but they are a critical source of diversity within the forest ecosystem (Oakley and others 1985). Riparian areas have a greater diversity of plants and trees than do upland areas. Riparian zones and wetlands provide some of the most important wildlife habitat. Wildlife species use riparian areas disproportionately more than any other type of habitat (Carothers and others 1974; Kelley and others 1975; Thomas and others 1977; Brown and others 1977; Riparian Habitat Technical Committee 1985). Most riparian areas contain all the major requirements for life - water, food, and cover (Oakley and others 1985). Many species are dependent on the riparian habitat for feeding and/or reproducing. See Chapter III Wildlife.

Riparian zones are important for many other uses as well. Highly productive timber sites frequently occur along streams and around lakes or wetlands. Riparian zones have often been used for road locations. Mining may have direct or indirect effects on the riparian zone. Recreation use is concentrated in the riparian zone, where scenic values are high. The riparian zone is a preferred location for many types of developed sites, from campgrounds and picnic areas to recreation residences and administrative sites. Because of this great variety of use and the fragile nature of riparian zones, they are recognized as a critical area for planning (Oakley and others 1985).

Riparian Zones and Planning

For the purposes of Forest planning, the width of the riparian areas on the Mt. Baker-Snoqualmie National Forest is at least 100 feet back from the water's edge on both sides of all perennial streams (36 CFR 219.27 (e)). Not included are intermittent streams that do not directly supply domestic water; are not used by fish; or do not contain enough water to be a major contributor to streams that contain these characteristics.

There are a total of 11,641 miles of streams with associated riparian ecosystems on the Forest. This figure is derived from the R2MAP data base (discussed in Chapter I, FEIS) and is slightly less than the total stream miles

on the Forest. Forty-one percent of the stream miles with associated riparian ecosystem are located within designated wilderness. As the width of these riparian ecosystems varies depending on the topography, acres of riparian zones have not been calculated for this level of Forest Planning.

Riparian zones, by nature, are especially susceptible to natural and human-caused disturbances. The long, narrow shape of the zone plus its extensive interface with both the aquatic and terrestrial systems make the riparian zone highly vulnerable to impacts from major upslope events (Oakley and others 1985). Natural erosion and deposition is common and may create additional diversity. Floods accelerate erosion and deposition, inundate streamside vegetation, and uproot and destroy riparian vegetation; but, they may also create new riparian zones or wetlands as stream courses change. Wildlife rarely impact or destroy riparian vegetation.

Many of the 39,850 acres of forested land that are technically unsuited for harvest due to irreversible soil damage are located in riparian zones. These acres are discussed in detail above, in the soils section. (In addition, there are a varying number of acres, depending upon physical conditions, in the riparian areas that will not be harvested because of watershed, fishery, and wildlife management objectives.)

Human-caused alteration of riparian zones include but are not limited to road and trail building, harvesting trees, recreation use, dam construction, and mining activities, especially of salable minerals such as sand and gravel.

Private lands within the National Forest boundary and downstream from the Forest also contain riparian lands. Much of the non-Federal land within the boundary tends to be located along stream and river valleys, in intermingled, "checkerboard" patterns. Disturbances on these lands can impact fragile riparian zones on National Forest land.

Logging by private owners in "checkerboard" lands has often resulted in the accelerated harvesting of entire square-mile sections of land. Harvest standards may also vary. Since these streams also flow through National Forest lands, protection of the watershed values needs to take in to account conditions and management patterns on private areas in order to maintain acceptable watershed conditions.

OLD GROWTH

Introduction

One of the elements of diversity is old growth. Biologically and politically, many people have more interest in old growth than in other successional stages. Old growth is an important value in its own right (W.O. letter October 1989). In addition, old growth provides wildlife habitat, gene pools for plants and animals, opportunities for research on natural systems, aesthetics, recreation, fish habitat, and commercial timber.

Old growth management is a major public issue on the Mt. Baker-Snoqualmie National Forest. Retaining old growth for wildlife habitat, ecosystem diversity, aesthetics, and the use by Native Americans for religious, cultural, and ceremonial purposes are all facets of the issue. From a timber management standpoint, these old-growth trees have a high market value. The net growth of these trees is less than 20 cubic feet per acre per year; if the old growth were cut and young trees replanted, the same sites could potentially produce in excess of 170 cubic feet per acre per year, in an intensive management regime.

The Definition of Old Growth

Old-growth stands can be defined by age, by stand condition, by diameter, by ecological characteristics, or by a combination of some or all of these factors (USDA Forest Service 1988c). The most recent timber inventory completed on the Mt. Baker-Snoqualmie (1976) was based on tree species and size.

Recently, the public and scientific community have focused on a definition of old growth based on the structural components of the stand. Several structural components are believed to be of key importance in an old-growth stand, including: individual, live, large trees; dead and down logs in streams; standing dead trees or snags; large, dead, down logs on the land; and multi-storied canopy of mixed species. These structural features are unique to an old-growth forest ecosystem, setting it apart from young growth and, especially from managed stands. Most of the distinctive compositional and functional features of old-growth forests can be related to these structural features. These structural components make possible much of the uniqueness of the old-growth forest in terms of flora and fauna - including microorganisms and species of fungi - (its composition) and the way in which energy and nutrients are cycled (its function). This complex system is only partially understood at this time.

There are a number of definitions of old growth. Franklin et al. (1986) establishes numerous characteristics to define old growth; the stand characteristics vary by species. The Pacific Northwest Regional Guide (1984) defines old growth, also varying by species. Neither of these definitions could be used on this Forest, when the planning process began; the 1976 inventory did not include enough information about understory and dead and down logs to allow a direct translation into either the definition from the Regional Guide or Franklin et al. (1986).

Old-growth and mature forest inventories are being updated as quickly as possible, to reflect new concepts of older forest values and importance. A landsat inventory is underway, which will give broad mapping capability of old

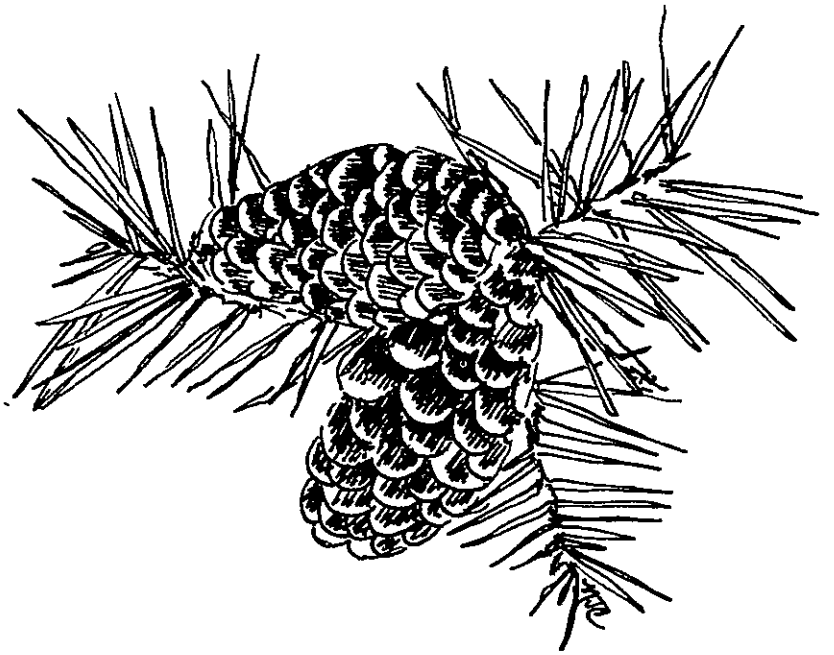
growth. This portion of the new inventory should be completed by 1991. Total Resource Inventories are replacing the older timber inventories; they are based on many more characteristics than tree size and class. With this new inventory, there will be the flexibility to identify and map acres of old growth can be determined and/or mapped, regardless of the definition used.

Existing Situation

At present, old-growth forest covers nearly 37 percent of the National Forest land on the Mt. Baker-Snoqualmie, approximately 643,500 acres. 1/ For the purposes of this plan, old growth is defined as those stands containing mature and large sawtimber, with trees that are at least 21 inches in diameter at breast height (DBH), or 4-1/2 feet from the ground. The mean age for mature, large sawtimber on the northern half of the Forest is 241 years; on the southern half, it averages 257 years. Refer to Appendix B for a discussion on how old growth was handled in the FORPLAN model.

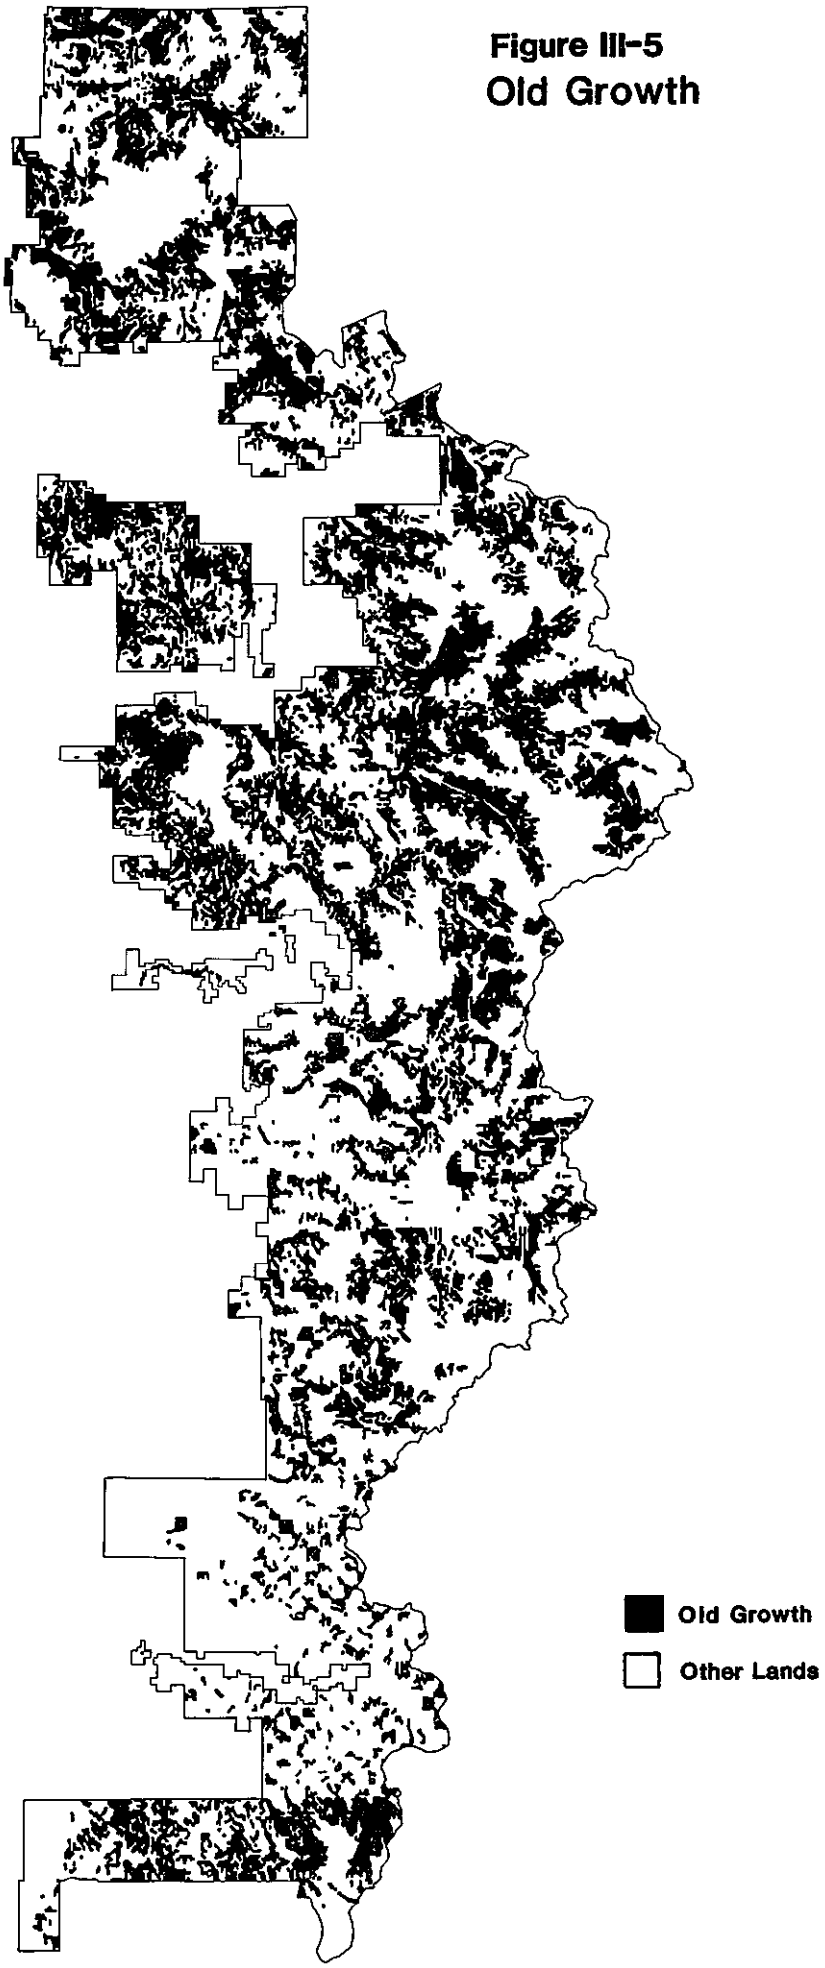
A total of 232,500 acres (36 percent) of the old growth is found in wilderness. An additional 134,400 acres outside of wilderness are considered to be unsuitable for timber harvest. These acres are either withdrawn from timber production (example: Research Natural Areas) or they are unsuitable because of highly unstable soils and difficulty in reforesting the area with trees if the timber is cut. An estimated 276,600 acres of old-growth forest are tentatively suitable for timber harvest (1989).

Figure III-5 shows the general location of acres of all old growth on the Forest, based on the above description.



1/ Currently, there are about 224,000 acres of forested lands which are in the grass-forb and seedling-sapling stages. These are areas which have been harvested (or, in a few cases, burned) and which are undergoing reforestation. Immature tree stands total approximately 222,300 acres on the Forest.

Figure III-5
Old Growth



THREATENED, ENDANGERED, AND SENSITIVE PLANTS

There are no federally-listed threatened or endangered plant species which have been found on the Forest. Twenty-six species from the Pacific Northwest Region Forest Service list of Sensitive Plants are known to occur on the Forest, and another fifteen are suspected to occur; see Table III-7 below. Sensitive species are not protected under the Endangered Species Act. However, Forest Service policy requires that these plants by managed to avoid a need for placing them on the Federal list. Potential impacts to these species must be evaluated prior to a final decision on any specific, proposed project.

Two sensitive plant species, suspected but not known to occur on the Forest, are Category 2 candidates for federal listing. They are Calamagrostis crassiglumis and Castilleja cryptantha.

The list of plant species will continue to change, as inventories produce more information on the occurrence, numbers, and distributions of species. Species may be removed from the list based on additional information which shows that they are not as rare as once thought, or as management plans are developed to ensure their viability. Species may also be added to the list, as they are discovered to occur on the Forest, or if they are more rare than presently thought.

Table III-7

COMMERCIAL TIMBER

Commercial timber species on the Mt. Baker-Snoqualmie National Forest include Douglas-fir, western hemlock, Pacific silver fir, noble fir, western white pine, western redcedar, grand fir, Alaska yellowcedar, sitka spruce, red alder, big leaf maple, and cottonwood. The table below shows the distribution of commercial tree species on tentatively suitable lands on the Forest. Suitability is discussed below.

Table III-9
Commercial Tree Species on Tentatively Suitable Forest Lands
1976 Inventory

Species	Percent
Western hemlock	32.8
Douglas-fir	26.1
Pacific silver fir	22.5
Western redcedar	9.4
Other Conifers 1/	7.5
Hardwoods 2/	1.7
TOTAL	100.0

1/ Includes: mountain hemlock, subalpine fir, Alaska yellowcedar, grand fir, noble fir, sitka spruce, and western white pine.
2/ Major species are red alder, bigleaf maple, and black cottonwood.

Timber Suitability

Of the 1,724,229 (legal) acres of National Forest land on the Mt. Baker-Snoqualmie, approximately 597,000 acres, or 35 percent, are tentatively suitable for timber harvest. Tentatively suitable forest land is capable of producing industrial wood and, 1) has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service (for wilderness etc.); 2) existing technology and knowledge is available to ensure timber production without irreversible damage to soils, productivity, and watersheds; 3) there is reasonable assurance that, given current technology, the lands can be restocked with trees within five years of cutting; and 4) there is adequate information to project the response of the environment to timber management activities (FSH 2409.13). Once forest lands are assigned to a timber production prescription in an alternative, they are identified as suitable, rather than tentatively suitable.

Table III-10, on the following page, shows the process for determining which lands are tentatively suitable for timber harvest. The process is graphically portrayed in Figure III-6. On the following page, Figure III-7 shows the general location of all tentatively suitable acres on the Forest. A more detailed discussion of the determination of timber suitability is included in the planning records, available at the Forest Supervisor's office.

Table III-10
Land Suitability for Timber Production 1/

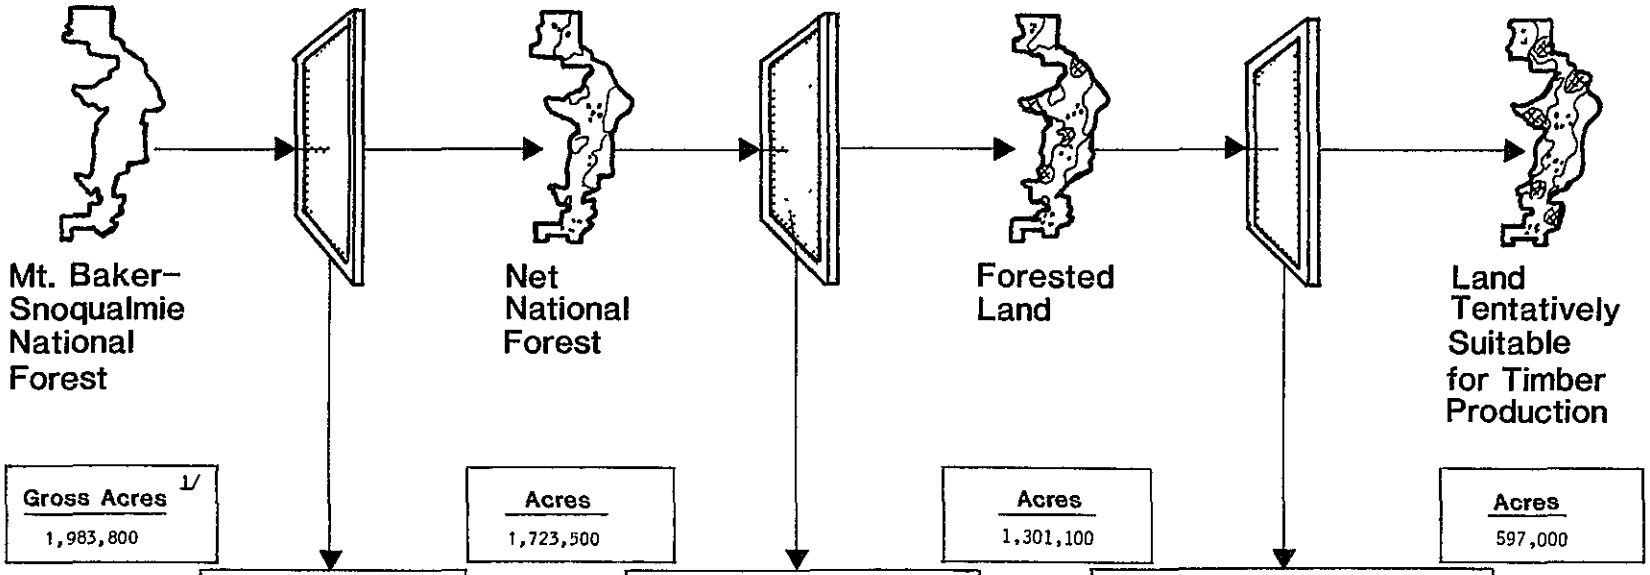
3/ Long Creek Research Natural Area is included in Wilderness
4/ Inadequate Response Information There is not adequate information available, based on current research and experience, to project responses (growth or yield) to timber management practices (FSH 2409 13-21).

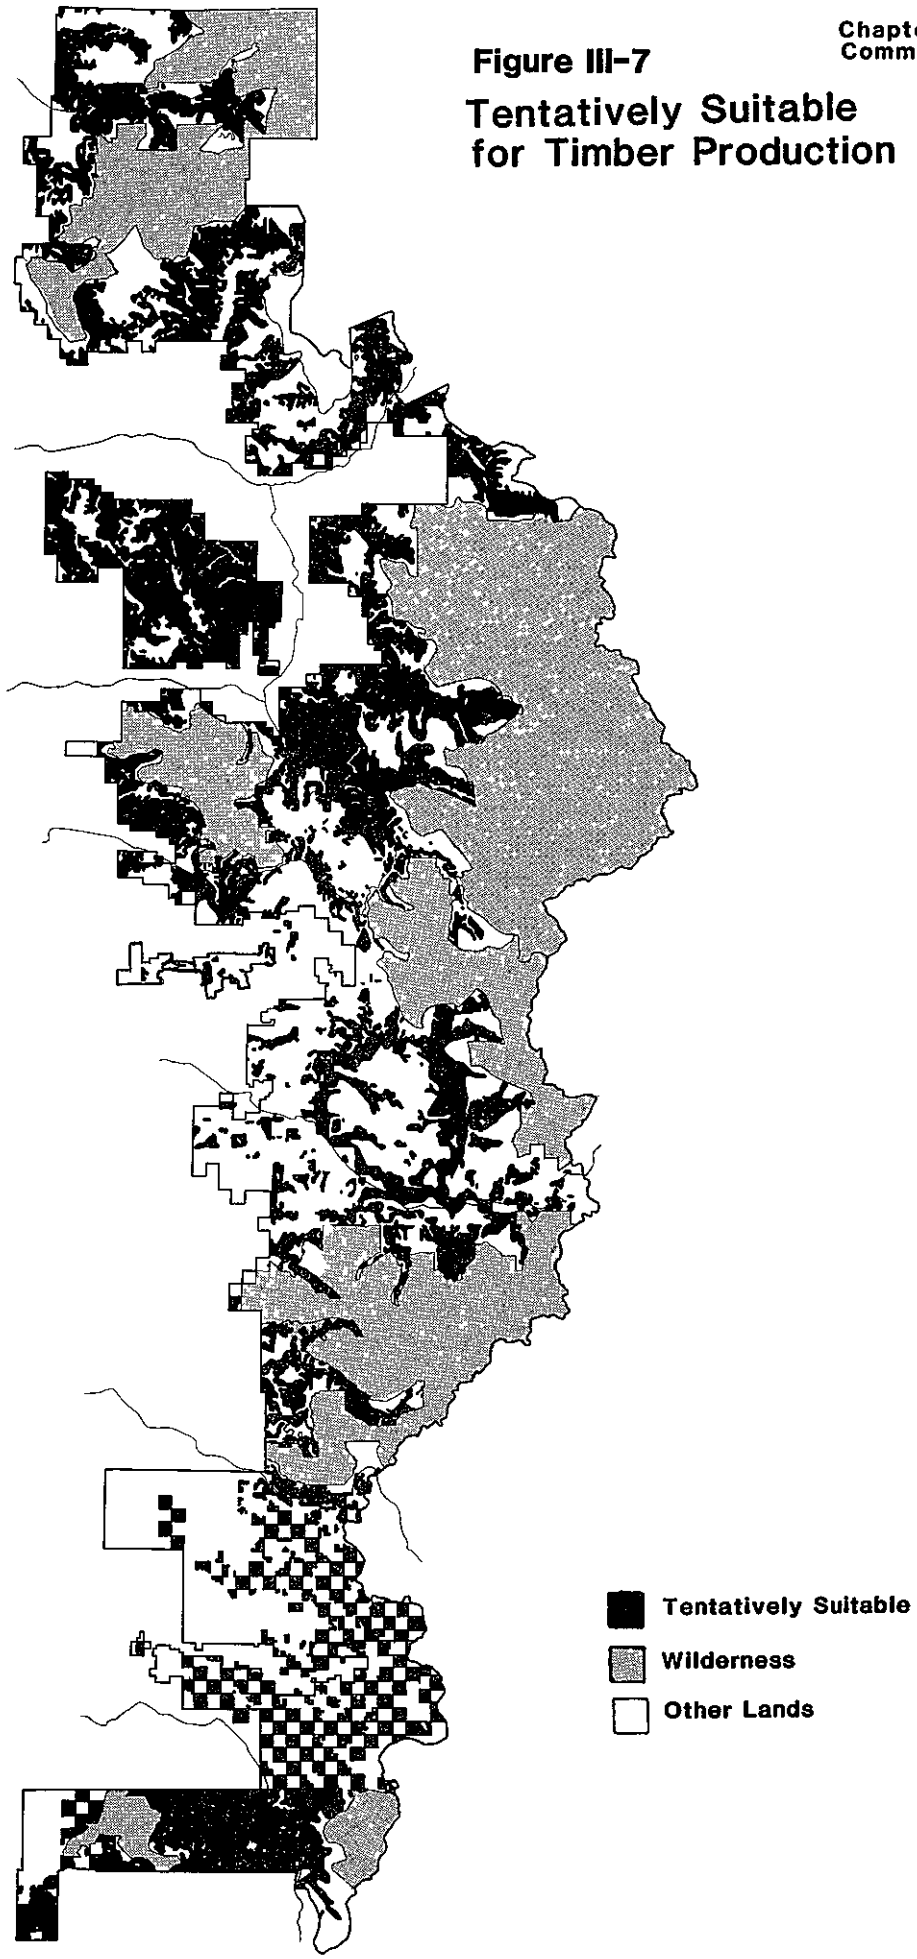
Figure III-6

Determination of Land Suitability for Timber Production



1/ Legal acres, all other acres are R2Map Data Base. To calculate the tentatively suitable acres, subtract from the 1,723,500 Net National Forest acres.

Figure III-7
Tentatively Suitable for Timber Production



Regeneration Difficulty Lands

Approximately 159,700 acres of forest land have been identified as not suitable for timber production because of regeneration difficulty. (Forest land includes acres outside of wilderness and Research Natural Area, at least 10 percent stocked by live trees, or land formerly having such tree cover and not currently developed for non-forest use.) At this time, there is no reasonable assurance that these acres could be reforested within the prescribed time period of five years. Refer to Appendix B for more information.

Slightly over 75,900 of the regeneration difficulty acres contain stands dominated by mountain hemlock. These acres occur at higher elevations - generally above 4,200 feet - in the Mountain Hemlock Zone, and are found in the three northern Districts.

These lands are generally not very productive for growing commercial trees. Growth occurs slowly, over a long period of time - some stands are over 800 years old - a result of high elevation, deep winter snow pack, poorly developed, shallow soils, and especially the temperature regime. Cold soil temperatures in the tree rooting zone for much of the year create a poor environment for plants to germinate and become established. The usual cold soil temperatures are compounded by occasional high soil surface temperatures, adding to the harshness of the environment (Henderson and Peter 1985).

Trees in these mountain hemlock stands are averaging a growth rate (a Mean Annual Increment, MAI) of 35 cubic feet per acre per year. The culmination, or age at which average growth is the greatest (CMAI) for these trees occurs at approximately 240 years. This compares to a Forest-wide average productivity of 115 cubic feet/acre/year and a culmination of MAI of 80 years.

Past timber management activities on these lands, both National Forest and private, has been limited. Although examples of regeneration success can be found, the conditions under which this success occurred cannot be documented because of lack of information on stand make-up, harvest systems, post-harvest activities, and conditions under which regeneration was attempted. Although these lands eventually are reforested, the conditions and timing of reforestation have not been documented. In general, reforestation does not occur within 5 years of harvest, but occurs over an extended time period.

Timber Management Plans

Timber management activities on the Forest are based on the July, 1963 Timber Management Plans for the Mt. Baker and Snoqualmie National Forests. These plans have been amended and updated to reflect major changes in the land base, including the formation of the North Cascades National Park complex, transfer of administrative responsibility to other National Forests, the Alpine Lakes Area Management Act, the Roadless Area Review and Evaluation (RARE I and II), and the Washington State Wilderness Act of 1984. Recent amendments extended the effective date of these plans through Fiscal Year 1990.

As discussed in the Diversity section, the most recent timber inventory of the Forest was completed in 1976. A Timber Resource Management Plan Draft Environmental Impact Statement, based on that inventory, was released in 1979. As the Forest Planning process began, late in 1979, a decision was made to

integrate the timber plan into the Forest Land and Resource Management Plan. A final EIS, Timber Resource Management Plan was never completed.

THE FOREST TIMBER SALE PROGRAM

Historical Perspective

The 1979 Draft EIS and Timber Management Plan proposed a preferred alternative - Intensive Management - and gave an annual potential yield of 422 million board feet (MMBF), including: 40 MMBF of salvable dead timber; 6 MMBF full marginal CFL yield; and 22 MMBF earned harvest yield from intensive management practices, such as precommercial thinning. The preferred alternative had a chargeable average annual programmed harvest level of 330 MMBF. Data from this Plan was used to develop the Forest 1980 RPA Timber Sale Targets. (See the Glossary, FEIS for definitions of these terms.)

The roadless area issue (1972-1984) resulted in a long-term concentration of the forest timber sale program on approximately one-half of the land base. In 1982, the Mt. Baker-Snoqualmie National Forest negotiated with the Regional Forester and an annual programmed harvest level of 265 MMBF was set for fiscal years 1983-1985, or until the Forest Plan is completed. The 265 MMBF programmed harvest level is equivalent to approximately 244 MMBF of chargeable volume and 21 MMBF of nonchargeable volume. At the time of negotiation, the 1963 Plans had been amended to reflect a chargeable volume of 259.4 MMBF.

The programmed harvest level of 265 MMBF is based on a management intensity requiring 5,578 acres of precommercial thinning per year. Precommercial thinning accomplishments in the last seven years have averaged about 2,500 acres per year.

The November 1984 amendment to the 1963 Timber Management Plan (effective October 1984) includes an Annual Potential Yield of 203.8 MMBF, reflecting the impact of the Washington State Wilderness Act. Although terminology has changed and the method of calculation differs, this 203.8 MMBF may be compared to the 1979 annual programmed harvest level of 330 MMBF, reduced to 302 MMBF for marginal CFL yield and earned harvest. These latter yields are not included in the 203.8.

Forest Industry Performance

During the 1979-88 period, the average annual cut on the Forest averaged 229.6 MMBF; 200.6 MMBF of this volume was chargeable to the potential yield. This compares with the "effective adjusted PY sell" of 185.4 MMBF discussed above.

The 15.2 MMBF difference between the actual chargeable cut and adjusted chargeable sell is minor and the adjustment masks the effects of the recession. During the 1979-88 period, average annual timber purchased was 266.8 MMBF, including 235.8 MMBF chargeable to PY. The average annual cut during the period, 229.6 MMBF, was 13.9% below the average volume purchased. The major reasons purchasers did not cut more of the volume sold: market or recession lows and overbidding during 1979-84; and the large backlog of volume under contract not cut due to recession. This backlog volume under contract but not cut had shrunk to 147.7 MMBF by the start of FY 1989.

The effects of the 1981-82 recession - with high interest rates - depressed the housing market, resulted in a general slowdown in the economy, and sent timber prices and demand crashing. Timber harvest in fiscal year 1982 on the Forest declined to 124.5 MMBF, the lowest level since World War II. In fiscal year 1984, the cut increased to slightly above the 1980 cut; a higher percentage of harvesting was done on National Forest and State lands and less on private lands. This reflected an effort by industry to stay competitive by harvesting sales purchased at the lowest rates, especially those purchased in 1982-84. After 1985, harvest increased on all ownerships, with harvest activities (cut volume) out pacing sold volume on national forest lands in 1987 and 1988 by 22.8 MMBF per year. This was a reflection of the high demand for wood products from all ownerships, as the economy recovered from the recession, housing demand increased, and log exports from State and private lands rose dramatically.

The Mill Situation

A direct effect of the 1981-82 recession was a decline in the number of mills (lumber, veneer and plywood, pulp, shake and shingle, and post/pole/piling). From 1972 through 1978, the total number of mills in the State of Washington, excluding the export industry, increased 35.7%. From 1978 to 1982, the number of mills decreased 29.6%. The number of mills in the Puget Sound area (excluding export) dropped 20 % in two years - 1980-82. Part of this is due to increasing mill efficiency: by 1982, mills utilized 97 percent of wood and bark residue.

Mills continued to close: between 1982 and 1984, another 18 percent in the Puget Sound area closed. An additional 11 percent shut their doors by 1986. In all, the recession and restructuring of the wood products industry saw Puget Sound area mills (not including export operations) decrease by almost half.

However, there were major improvements in productivity among the remaining mills. For instance, lumber mills, which had dropped by 23 percent in number by 1986, were producing only 9 percent less lumber than in 1978.

In the Puget Sound area in 1986, 49 of the 87 mills (excluding the 35 export mills) were not dependent on National Forest timber; 11 mills were dependent for 1-33% of their log supply; 6 were dependent on National Forest timber for 34-66% of their supply; and 21 were 67-100% dependent on National Forest log supply. This is discussed further, under "supply" in this section of Chapter III.

Situation as of 1988

The planned Programmed Harvest for fiscal year 1988 was 231 MMBF; this is approximately equivalent to a chargeable volume of 209 MMBF and 22 MMBF of nonchargeable.

Table III-11, on page III-46, shows the history of the amount of timber sold and harvested during the period of the current Timber Management Plan (Fiscal Year 1964-88). The remarks column includes explanations of significant amendments to the plan. Note that forested federal lands remained part of the land base used to calculate potential yield until transferred to other

jurisdictions (National Park) or specially designated (wilderness or research natural area).

For the entire period - 25 years - the cumulative total potential yield was undersold by about 3 percent (7,452.2 MMBF - 7,256.2 MMBF equals 196.0, divided by 7,452.2 x 100). This undersell is somewhat less than actually occurred, because some potential yield volume returned to the Government was resold in Fiscal Year 1986 through 1988, thus sold and counted twice.

The total harvest over the period was just less than 1 percent of the total sold (7,977.1 MMBF - 7,883.4 MMBF equals 93.7, divided by 7,977.1 x 100). It is interesting to note that there was only one fiscal year before 1975 (the year 1972) when total harvest did not exceed total sold. This reflects (1) high demand for timber, (2) that the timber purchasers were heavily involved in harvesting the 1962 blowdown from the Columbus Day Storm, and (3) sell of potential yield was less than planned, due to the priority of salvaging the blowdown or other factors.

From 1975 to 1986, the trend opposed that of preceding years, with more volume sold than harvested. This represents a lower demand for timber off of National Forest lands, combined with the speculative nature of the timber industry during that period. The trend peaked in 1984, when many sales were returned to the Forest under Congressional legislation, or by default. In 1987 and 1988, the amount harvested again exceeded the volume sold, a function of increased demand for wood, the restructuring of the timber industry, reduced programmed sale levels on this Forest, and the harvesting of timber timber contract but not cut from previous years.

Footnotes for Table III-11

1/ Termed annual allowable cut in the 1964 plans. Plan amendment effective 7/1/73 changed the term to potential yield. See discussion in Chapter II.

2/ PY sold is from the Forest Timber Mgt. Control Record-Sell. Exceptions:Naches-Tieton WC, Snoqualmie NF, was estimated for FY 1964, 34.5 MMBF; FY 1965, 96.5 MMBF; and FY 1966, 49.1 MMBF. PY sold for FY's 1967-68 were estimated for the Tieton Ranger District portion of Naches-Tieton WC. This volume is chargeable to the PY.

3/ Total sold is from the Forest TM Control Record-Sell; FY's 1964-66 from R-6 Cut and Sold Report; includes both chargeable and nonchargeable volume.

4/ Total Harvested is from the Forest Timber Management Control Record-Cut. This includes both chargeable and nonchargeable volume.

5/ Changes in TM Plans are made by plan amendment approved by the Regional Forester. Amendments on file: Forest Supervisor's and Regional Offices.

6/ Only those CFL acres used to calculate the regulated PY are included in this table.

Table III-11

Timber Sold and Harvested During the Period of the Current Timber Management Plan

Fiscal Year	Potential Yield 1/	Potential Yield Sold 2/	Total Sold 3/	Total Harvested 4/	Remarks 5/
		MMBF			
1964	392.9	382.1	418.7	436.2	Includes seven working circles in Snoqualmie National Forest with a PY of 228 6 MMBF, and two working circles in Mt. Baker National Forest with a PY of 164.3 MMBF CFL 6/ of the two plans totaled 1,056,663 acres
1965	392.9	428.6	416.3	483.7	PY sold in Naches-Tieton WC, Snoqualmie NF, estimated for PY 1964, 34 5 MMBF; 1965, 96.5 MMBF, and 1966, 49.1 MMBF.
1966	392.9	359.7	385.3	470.1	
1967	413.9	322.3	345.4	362.0	Effective 7/1/66 a new Timber Management Plan for the Naches-Tieton working circle increased the PY 21.0 MMBF, and reduced CFL 31,469 acres The remaining six Snoqualmie National Forest working circles were combined into Snoqualmie working circle
1968	413.9	413.1	426.1	462.3	
1969	377.6	240.9	283.6	410.5	Effective 7/1/68 the two Mt Baker NF working circles were combined into Mt. Baker working circle and the PY was reduced by 36 3 MMBF as a result of The North Cascade National Park and Recreation Act of 1968. The North Cross State Highway Corridor was transferred to administration of Okanogan NF Reduction in CFL was 49,273 acres.
1970	377.6	374.2	446.4	452.8	
1971	342.3	258.0	301.4	308.8	Mineral Ranger District portion of Snoqualmie working circle was transferred to administration of the Gifford Pinchot NF effective 7/1/70. The Snoqualmie working circle PY reduced 35.3 MMBF and CFL reduced 70,613 acres
1972	342.3	305.2	327.4	325.8	
1973	342.3	359.9	380.4	455.2	
1974	342.3	313.0	338.7	412.9	
1975	240.9	268.0	315.7	206 0	Effective 7/1/74, plans amended for Chief's Wilderness Study Area (RARE I study) resulting in reduction in PY of 19 7 and CFL of 49,350 acres The Naches-Tieton working circle was transferred to the administration of the Wenatchee NF resulting in a reduction in PY of 81 7 MMBF and CFL of 253,814
1976	301.1	312.4	346.2	271.4	Fiscal year 1976 includes an additional 60 2 MMBF PY, more sold and more harvest to account for the transition quarter to change the federal fiscal year from 7/1 - 6/30 to 10/1 - 9/30
1977	240.9	289.9	299.9	281 5	
1978	240.9	270.8	277.1	247 7	
1979	240.9	302.5	319 3	267 6	
1980	259.4	262.9	294 1	228.5	Effective 10/1/79 the PY was amended to reflect the results of the RARE II study; PY increasod 18.5 MMBF and CFL 38,557 acres
1981	259.4	271 7	307.3	211.8	
1982	259 4	230.5	266.3	122.5	
1983	259.4	194.6	221.2	216 6	
1984	203.8	218.8	250.9	235 6	Effective 10/1/83, Plans amended to reflect the results of the Washington State Wilderness Act of 1984, PY reduced 55.6 MMBF and CFL reduced 94,201 acres.
1985	203.8	201.3	231.1	210.9	
1986	203.8	245.1	279.9	259.0	Sold includes volume returned to Government under the Federal Timber Contract Payment Modification Act of 1984, and volume from defaulted sales cancelled.
1987	203.8	221.5	266.8	295.9	..... same as 1986.. . . ..
1988	203.8	209.2	231.6	248.1	.....same as 1986, 1987 ....
TOTALS	7,452.2	7,256.2	7977.1	7883.4	

Reforestation

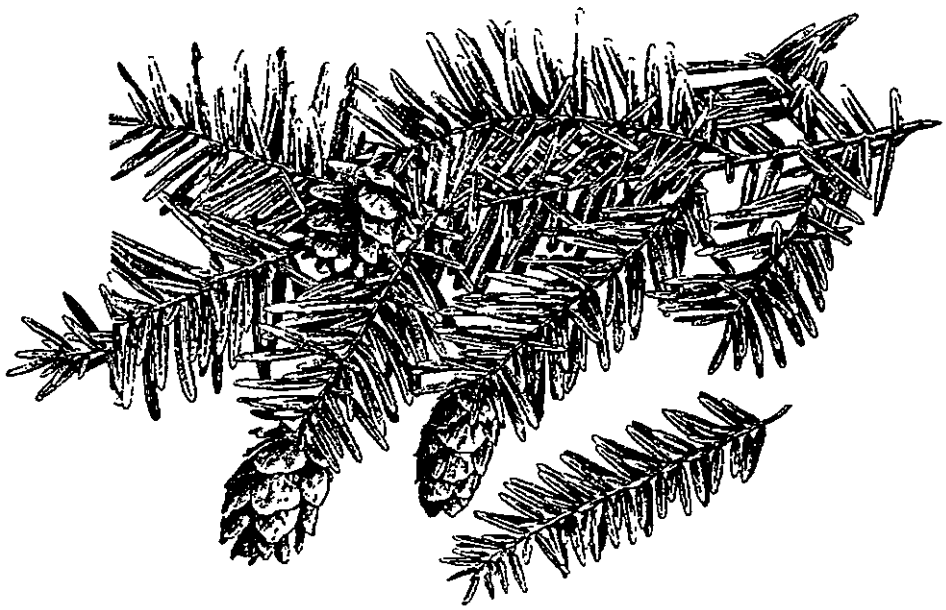
By law, the Forest Service is charged with reforestation of all harvested acres. Based on the history of planting previously harvested areas (areas generally located in the western hemlock and Pacific silver fir zones), reforestation on the Forest has not been difficult. Approximately 87 percent of all acres harvested are planted. An average of 5,122 acres per year were planted between 1978 and 1988. About 93 percent of the planting stock was bare-root; containerized seedlings were used where special reforestation problems existed. The remaining acres (13 percent) are reforested through natural seeding and from residual trees remaining after harvest.

The species planted varies considerably from year to year and from site to site; Table III-12 shows the approximate species composition. The actual stand composition of plantations may vary because of residual trees remaining after harvest and the natural regeneration that occurs.

Table III-12
Species Planted 1/

Noble fir	28%
Douglas-fir	43%
Silver fir	27%
Western redcedar	1%
Grand fir, hemlock, western white pine	1%

1/ Source: File 2490 Records and Reports.



Tree Improvement

The goal of tree improvement is to provide seed for reforestation which will produce trees genetically superior in form, juvenile survival, and growth. An additional trait under selection for western white pine is resistance to white pine blister rust.

Two procedures are presently being used. In the first, tree selections are made throughout the breeding zone, seed or scion is collected, and the trees are planted or grafted into the orchard. This system is being applied to Pacific silver fir, western white pine, and western redcedar. Western white pine trees, in addition, undergo blister rust resistance testing. In the more intensive scheme, tree selection is followed by seed collection and scion collection. Seedlings from the selected trees are tested in evaluation plantations and the scion is grafted into the orchard. Test results are used to select the trees with desirable characteristics. These selections are retained in the orchard and a breeding design is used to produce material for the next generation. Douglas-fir and noble fir are under the intensive program.

Table III-13
Trees Selections by Species - 1987 Data

Species	Number
Pacific silver fir	360
Noble fir	370
Douglas-fir	657
Western white pine	124
TOTAL	1,511

All evaluation plantations will be planted by 1992. There are two centralized seed orchard on the Forest. The Captain Moses Seed Orchard, in Darrington, will produce Pacific silver fir, Douglas-fir, and western redcedar. The R. Nevan McCullough orchard (White River Ranger District) is scheduled to produce nobel fir, Douglas-fir, western white pine, and western redcedar. Completion of these orchards is expected by 1992.

Timber Stand Improvement

Timber stand improvement (TSI) is the removal of unwanted trees to improve the growing conditions for the remaining trees. Foresters can control the number of trees growing on an acre (stocking level), the species of trees grown, and can remove competing brush and weeds to create better growing conditions for commercially grown conifers such as Douglas-fir, which need sunlight.

Thinning can benefit wildlife habitat as well as improve growing conditions for trees (Witmer and others 1985). Several factors affect the forage and habitat quality of an area for various species. Precommercial thinning can extend the grass-forb, shrub, or open sapling-pole condition of the forest, thus adding habitat for species using open conditions for reproduction and foraging. The

amount and disposition of slash can affect the amount of forage that is accessible to animals. The timing of thinning and the condition of adjacent stands of trees all effect the amount of forage, access, hiding cover, and thermal cover available for different animals.

On the Mt. Baker-Snoqualmie National Forest, about 3,300 acres of young conifer plantations receive some type of TSI annually. Approximately 75 percent of this TSI is precommercial thinning, 20 percent is fertilization, and five percent is release (see below).

Precommercial thinning is done when the trees are 10 to 15 years old. There is little slash left after the cutting is completed, as the tree stems are still fairly small. The thinning contractor may choose to sell or utilize the residue. Some thinned material is piled near roads, where it is available for firewood. Some debris is chipped, some is piled and burned, and some is left in place for nutrient recycling and for habitat for those wildlife species that utilize down material. Refer to the wood residue section, below, for further discussion.

Over the last seven years, the Forest has applied fertilizer to an average of 700 acres, annually. Most was applied on timber stands that were 70 percent or more Douglas-fir, on soil types that show a positive response to fertilization.

A small number of acres (estimated 165 acres annually) receive a type of vegetation management called "release." Hardwoods and other competing vegetation are removed from young conifer plantations, thus improving the growing conditions for these small trees. Competing vegetation may be removed by hand, by mechanical means, or through application of herbicides. This Forest has traditionally used only small amounts of herbicides. Over a decade, an annual average of 200 acres were treated with herbicides; treatment is not needed every year. About 300-400 acres total over a ten-year period are released by hand.

The Mt. Baker-Snoqualmie vegetation management program was assessed in a site-specific environmental analysis and documented in an environmental assessment (EA) in May, 1980. Addendums were prepared for each year after 1980 to reflect the existing program. There was considerable public involvement during that decade, regarding vegetation management and herbicides use on this Forest. Various groups and individuals were invited to join the Interdisciplinary Team to develop the 1980 EA. Public meetings were held to gather response and explain the program. There were several active protest groups near Bellingham and Glacier (but none in the south half of the Forest) in the late 1970's; some residual of these groups remain.

A Pacific Northwest Region programmatic EIS was approved in 1981 (Methods of Managing Competing and Unwanted Vegetation, Final Programmative EIS, June 1981); an update of that document has been several years in completion.

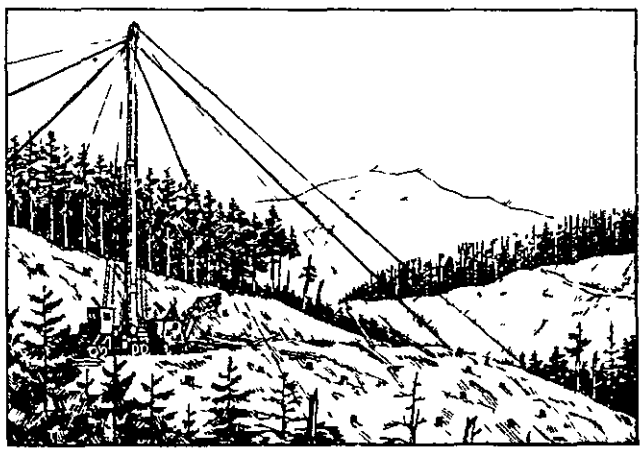
In March 1984, the Federal District Court enjoined the Forest Service from the use of all herbicides in National Forests in Oregon and Washington until the requirements of the court order can be met. The injunction is the result of a lawsuit brought by the Northwest Coalition for Alternatives to Pesticides and others. Since then, all removal of brush, weeds, and other unwanted vegetation has been done by hand or mechanical means, or has not been done.

Chapter III
Commercial Timber

The Regional Forester, Pacific Northwest Region signed the Record of Decision (ROD) for the updated programmatic environmental impact statement on vegetation management: Managing Competing and Unwanted Vegetation, Final Environmental Impact Statement, Pacific Northwest Region, December 1988.

The Federal District Court injunction was removed in May, 1989, except for herbicide use in nurseries. Additionally, a Mediated Agreement was completed. The Forest Service is curently under an administrative stay, imposed by the Chief of the agency, against the use of herbicides. When the stay and the remaining Court injunction are lifted, the Mt. Baker-Snoqualmie will follow the direction in the 1988 FEIS, the Mediated Agreement, and implementation direction. Until such time, herbicides will not be used.

It is assumed, for the purposes of planning (and FORPLAN modeling), that herbicides will be available. (See Forest-wide Standards and Guidelines.) However, because the herbicide program on the Mt. Baker-Snoqualmie is so small, there will be very minor changes in costs or outputs if herbicides are not available. Refer to the Built Environment - Roads section of this chapter, for more information on vegetation management.



Timber Harvest Methods

Intermediate harvest involves cutting some trees from a stand prior to the time the trees reach the age for regeneration harvest. On the Mt. Baker-Snoqualmie, some intermediate sanitation cutting (salvage), is done to remove dead, dying, and defective trees. Intermediate harvest timber may be sold commercially. About 100 acres annually are commercially thinned. Commercial thinning is designed to remove merchantable size trees from a timber stand that has not yet reached final harvest age; it is usually done at 40 to 70 years.

The final harvest of trees is called regeneration harvest, as the trees are cut with the intention of reforesting the area, either through natural seeding or by planting young seedlings. Most timber harvesting on this Forest is done by clearcutting. A miscellaneous amount of shelterwood and/or selection cutting have also occurred. Refer to Appendix F for a discussion of harvest methods.

Four types of logging systems have been used: Tractor (8% of total volume cut is logged by this method); high-lead (58%); skyline (34%); and helicopter (1%). Helicopter and skyline systems completely suspend the cut log, from the woods to the landing. One end of the log drags the ground with the highlead system, and the entire log may drag the ground with tractor logging.

Timber Harvest and Soils

The amount of soil disturbance and its significance varies widely and depends on a number of factors. These include steepness and configuration of the slope, the natural sensitivity of the soil, the thickness of the duff and slash, and the type of harvest equipment used. Disturbance can lead to erosion again, depending on a number of factors. Some disturbance, when erosion is not a factor and the surface soil has not been degraded, is beneficial for tree seed establishment.

Timber harvest causes changes in the nutrient cycling process within soils. These nutrient relationships involved in removing trees for commercial timber are complex and highly interrelated. In the majority of conifer stands on the Forest, growth is limited by insufficient available nitrogen. Most nitrogen on a site is contained in the soil, but is in living organic matter or organic residue. Each year, as organic material decomposes, a fraction of it is mineralized to inorganic nitrogen, which is available to plants and competing micro-organisms. Silvicultural practices affecting nutrient cycling and site productivity vary with the site. Sites with thin or shallow soils and small amounts of organic residue have less tolerance for nutrient and organic matter (and will be less productive for conifers) than do sites with deep soils and large nutrient capitals.

Site Preparation

Prior to planting commercial tree seedlings, "site preparation" is done. Most simply, enough brush and left-over residue from logging is removed to allow planting of the young trees. Ten years ago, on the Mt. Baker-Snoqualmie, nearly every acre of harvested land was broadcast burned prior to planting. Broadcast burning was considered a necessity to meet the old wood debris standards and to maintain low potential fuel levels for wildfires. While this method removes most of the wood residue, a hot fire will volatilize large amounts of nitrogen and other essential elements, transform elements to soluble forms that are lost through leaching, destroy organic matter, alter soil structure, and may affect the ability of the soil to retain water. These effects all combine to cause soil to be more susceptible to erosion and possibly less productive.

Today, with emphasis on utilizing wood residue, very few acres are burned. There is no need to remove every piece of debris, as the fire hazard on the Forest is low. In the Pacific Silver Fir Zone, burning is the exception rather than the rule. In the Western Hemlock Zone, where much of the Douglas-fir seedlings are planted, about 80 percent of the planted acres are "site prepped" by hauling (yarding) residue to the landing. The other 20 percent are broadcast burned. Refer to the discussion on wood residue and fire, in this chapter, for more information.

Chapter III
Commercial Timber

TIMBER SUPPLY AND DEMAND

Regional Timber Supply and Projections

The principal projections used in developing long-range plans and programs for management of the National Forests are contained in the Forest and Rangeland Renewable Resources Planning Act (RPA) Assessment, the 1984 Update and the FEIS for the 1985-2030 RPA Program. These projections focus on the long-term picture - 50 years - for the States of Oregon and Washington; they do not necessarily recognize current, short-term regional fluctuations. The following pages summarize those projected RPA trends for timber supplies through the year 2030.

General

The current balance between growth of wood and its removal show that the hardwood forests and eastern softwood forests can support additional timber harvests. This balance is likely to change; future harvest, especially beyond the year 2000, could vary over a wide range. Nonetheless, if commercial timberland owners continue to respond to price and inventory changes and manage much as they have in the recent past, then timber harvest can be increased in most geographic regions during the next few decades.

Hardwoods

Hardwood supplies are projected to almost triple from 3.2 billion cubic feet in 1980 to 9.4 billion in 2030. The largest increases will be in the South (USDA Forest Service 1986). Hardwood markets are changing rapidly as technology evolves. For instance, in recent years use of alder for pulp and for furniture has increased rapidly, creating a growing commercial market for what used to be considered a "weed" tree. This has significant implications for the Pacific Northwest, where alder is abundant. While still accounting for only 3 percent of total Oregon and Washington wood output, harvest tripled during the 1980's (Clark 1990).

Softwoods

By the year 2030, the total projected softwood (roundwood) harvest will rise 24 percent, from 9.6 billion cubic feet in 1980 to 11.9 billion cubic feet in 2030. Although the national outlook calls for increased softwood harvest, there are important differences among the major softwood timber-producing regions.

In the Douglas-fir subregion, the projected annual harvest is 2.3 billion cubic feet from 1980 to 1990. The annual harvest then declines to about 2 billion cubic feet per year, through the rest of the 50-year projection period (USDA Forest Service 1986).

In the South, the other major softwood-producing region, previous forecasts showed an expected increase in production, from about 4.1 billion cubic feet in 1980, to 7.3 billion in 2030. However, most recent forecasts are now showing a downward modification in the rate of supply. The South may be shifting to a slower rate of increase, over present levels, until 2030. Much of the current expansion of hardwood and softwood production in the South is a result of

diversification within the wood-products industry, especially compared to other regions of the country.

Short- and Long-Term Demand Trends

Over the next 10 years, the demand for timber from the Pacific Northwest region will grow, but slowly. Although there is a backlog of unfulfilled housing demand, that backlog is shrinking. The future will depend primarily on the continuing strength in personal income and the availability of affordable housing and financing. An aging population (particularly the "baby boom" cohort) is leading to a slowdown in housing starts. As a result, there will be a declining trend in the construction sector, particularly in single-family residential housing. Structure remodeling and replacement, rather than new construction, will come to characterize the market. The projections for increases in demand may be described as considerably restrained and cautious (Nomura 1981).

Projections of forest product exports to the Pacific Rim countries show a continuing slow economic growth. Log exports have ballooned over the past three years, and have been the major source of growth in the forest products industry in the Northwest over that time. But exports are expected to decline by as much as 20 percent over the next decade or so because of increasing competition from foreign sources, particularly radiata pine (Adams 1989).

The ability to sustain a moderate increase in demand on a long-run basis is linked to the critical issue of cost. For the Pacific Northwest, cost is a limiting factor for increasing market share compared to other producer regions. The Northwest is a higher-cost timber producing region, particularly compared to the Southeast, and will likely remain so because of land ownership patterns, and higher stumpage, transportation and labor costs (Northwest Power Planning Council 1989; Adams 1989).

The short-term demand for timber and wood products appears strong. However, long-term trends in housing demand, the growing popularity of construction methods that use less wood, availability of wood substitutes, increased competition from international producers, and a shift in business management strategies and methods all contribute to a potential shift in longer-term future demand (Haynes and Adams 1985).

Wood supply continues to be an issue in that it is highly dependent on the ability of producers to lower costs to be competitive with wood substitutes (Schallau 1985). Although overall current timber supply levels in the Pacific Northwest region may be capable of meeting future demand, there are some problems within the subregional market areas. There is a shifting of industry within the region, and a shifting emphasis on the types of wood products produced, as well as the ability of the subregion to supply the various kinds of wood needed. The Pacific Northwest wood products industry can regain much of the previous strength, but new vision and a concerted effort by the industry to broaden the economic base are needed. This will still take time.

Approaches to rebuild the industry include development of a more flexible regional basis for stabilizing wood supplies and new wood-fiber management methods. This will allow the Pacific Northwest region to better utilize opportunities to increase exports to international markets. The forest products industry will need to learn the workings of a different market system

and provide more products in the form demanded (Campbell and others 1983). In addition, actions by industry, such as modernizing facilities, adopting state-of-the-art technology, reducing costs, and diversifying into other sectors of production (similar to what the Southern region has done) could help to rebuild and stabilize the wood-based sectors of the regional economy (Schallau 1985).

Private and Public Land Interrelationships

Canada and the southern states of the U.S. are currently supplying part of the timber formerly supplied by the Pacific Northwest region. This situation in Canada is expected to change, with supply dropping off within the next 6 years or at least in 15 years. It is projected that Canada will experience a drop in supply capability of 30 to 50 percent, down from the current high levels.

The South should be able to maintain or slowly increase its harvest because of the remaining inventory plus some substitutions of hardwoods. However, both the economic and physical supply of southern hardwoods may begin to show a decline by the year 2030.

Within this same time-frame, the wood supply on private lands in the Pacific Northwest should once again be at a high. As the supply from Canada and the South falls off, the private lands in the Pacific Northwest could become a major source of softwoods to meet national and international demand. Further, during the interim period - 6 to 15 years ahead - and before private forest lands in the region grow to full potential, the public forests will be looked upon as a major, relatively stable source of wood fiber (Schallau 1985).

Local Timber Supply and Demand Projections

Potential timber supply and demand is difficult to project on a Forest or economic area basis. Adequate data are not available for many significant variables such as exports and imports from outside the area, harvest strategies of other owners, and future interest rates.

In making supply and demand projections, a number of assumptions are made where data are unavailable. The major assumptions used are included throughout the following discussion. This overview is a portion of a general evaluation of the economic base for the Forest influence area. This evaluation provides a basis for anticipating pressures on resource use in the future.

Supply

Supply needs to be discussed from two perspectives: physical/biological, and economic. It is possible to calculate timber inventories by ownership for the Puget Sound area, and potential yield can be estimated given current known levels of output, management intensities, and constraints on the various ownerships. This gives an estimate of the potential physical/biological supply of timber for the area. However, it is almost impossible to translate that physical/biological supply estimate into a meaningful quantitative projection of actual wood that will be harvested and sold into the Puget Sound market, or into the regional market, for the next several years or decades.

The amount of wood actually harvested and sold into the market is the economic supply of timber. The economic supply of roundwood from the Puget Sound area is affected by local, regional, national and international economic trends, demands, markets and prices. Changes in any of these factors may change the amount of wood actually supplied to the market. Higher prices may elicit greater supply response. For instance, in the past several years, a booming export market has encourage the State and private timberland owners to accelerate their rates of harvest. More wood has been supplied as well by the nonindustrial private forest owners, both in absolute terms and as an increasing relative share of the market.

On the other hand, a recession or a slump in the housing construction market can bring down wood products prices. In this case, the economic supply of wood will drop, as owners either cannot recover costs of harvest and reforestation, or because they hold their timber off the market until prices cycle back up. The recession of the early 1980's was an excellent example of economic conditions affecting the regional and local economic supply of timber.

The Puget Sound area is one part of a much broader regional forest products market. The amount of roundwood supplied to and consumed within the area is more a function of the existing and utilized mill capacity (and export levels) at any given time than it is a function of the amount of timber cut within or near the area. Utilization of local mill capacity will vary depending on the broader regional demand for wood products and prices, with little regard to the amount of wood that is, or could be, harvested within the area at that time.

Conversely, the amount of timber cut in the Puget Sound area does not rely solely on the existing mill capacity in the area. The market area is large enough that logs cut in one county may end up several counties away to be processed. And finished wood products move over much larger areas. Therefore,

the regional market situation is much more appropriate for supply and demand analyses than any particular locality.

Economic factors related to characteristics of the timber and its location and markets for wood products determine the economic supply. These economic factors change over time, and lead to changes in economic supply. For example, changes in processing technology may change the limits on size of material used or species suitable for processing. This can cause the economic supply to shift from currently valuable species and size classes to a different mix. This causes both a change in the value of timber stocks held by various owners and shifts between regions. The general effect of technology is to increase supply and reduce scarcity.

Pulp and Paper

Supply of chips to the pulp and paper industry is a portion, though not a major one, of the total wood fiber supply picture in the Puget Sound region. Regionally, pulp and paper manufacturers derive only about 30% of their total fiber input from roundwood. The balance comes from residues generated mostly at primary processing plants. Over the past decade or so, about 5% of the annual harvest from the Mt. Baker-Snoqualmie has gone to Puget Sound area pulp mills, which represented about 7% of the mills' roundwood consumption.

In the past, prices for pulpwood have not escalated in the same manner that stumpage prices have. Available substitutes among sources and types of chips and residue, along with continuing technological innovations, have kept the real prices of pulp relatively constant over the long term. In addition, final prices of paper and board products made from pulp are much less susceptible to changes in wood fiber prices, as compared to finished lumber price sensitivity to changes in stumpage costs. The reason is that wood fiber costs are a much smaller percentage of manufacturing costs for paper and board, with chemicals and energy comprising significant portions of the total costs.

Timber Base

Potential physical supply of timber is a function of several factors. Major factors include the available timberland base, the intensity of management on these lands, harvest scheduling strategies, and institutional and legal constraints imposed.

Major timber producers in the Puget sound economic area can be grouped into four landowner classes: National Forest, State, Forest Industry, and other private. Factors affecting potential timber supply vary considerably by landowner class. Each landowner class is displayed/discussed separately for the factors affecting potential timber supply.

Table III-14, below, shows the timberland base, by ownership class, for the Puget Sound Area, as of 1980. Data for National Forest have been updated to reflect the 1984 Washington Wilderness Act. The inventory is fairly evenly distributed among the four owner classes. Forest Industry and the State and Other Public have generally younger, faster growing stands. The National Forests have the bulk of the old growth and lower net growth. National Forest inventories have the heaviest losses from annual mortality.

Table III-14
Characteristics of the Timber Resource, Puget Sound Area, By Ownership 1/

	National Forest	State/Other Public	Forest Industry	Other Private	Total
Timberland Acres (1000 acres)	19% (605)	19% (629)	31% (998)	31% (1001)	100% (3233)
Volume of Growing Stock (Net) & Sawtimber (Scribner)	29	21	25	25	100
1980 Annual Growth of Growing Stock & Sawtimber (International 1/4-Inch)	4	26	34	36	100
1980 Average Annual Mortality of Sawtimber (Interntl. 1/4-inch)	58	12	15	15	100

1/ Adapted from Timber Resource Statistics for the Puget Sound Area, Washington PNW-96, March 1982.

The available timberland base is not static. It is expected to decline over time due to urban expansion, additional road and utility rights-of-way, and recreation and commercial enterprise uses. Larsen and Wadsworth in their Washington Forest Productivity Study (1982) made some projections about withdrawals from the commercial forest land (CFL) base in Western Washington for the next 50 year time frame (1980-2030). Table III-15 shows that the heaviest withdrawals are likely to occur on the Other Private lands, in both absolute and relative terms. Total withdrawals are projected to be about 6 percent.

Table III-15
Projected Acreage Withdrawals from Commercial Forest Land
by Ownership, Western Washington, 1980-2030 1/ (Thousand Acres)

Ownership Class	CFL Base (1980)	Projected Withdrawals	Percent Withdrawn
National Forest	2,256	67	3.0
State	1,252	0	0
Other Public	423	35	8.3
Forestry Industry	3,544	118	3.3
Other Private	2,328	360	15.5
All Owners	9,803	580	5.9

1/ Adapted from Larsen and Wadsworth, Washington Forest Productivity Study, Phase III, Part II, Department of Natural Resources, 1982.

In Table III-15, the withdrawal projections assumed that only the acres recommended for wilderness by President Carter would be withdrawn from the National Forests. The Washington State Wilderness Act (1984) actually reduced the commercial forest land base on the Mt. Baker-Snoqualmie National Forest alone by 125,000 acres. This is almost double the amount assumed by Larsen and Wadsworth for all of Western Washington National Forest lands.

The productivity of the land and the age class distribution of existing stands are important factors in predicting the supply potential of forest lands. Table III-16 displays how these factors vary between the landowner classes in Western Washington. It is assumed that Western Washington data is representative of the Puget Sound economic area.

Table III-16
Age Class and Site Class Distribution, W. Washington Conifer Lands
By Ownership Class 1/ (Percent)

Owner Class	Cubic foot Site Class 165 and above	Age Class 60 years and younger
National Forest	19 %	34 %
State	20	70
Other Public	25	73
Forest Industry	49	82
Other Private	23	70

1/ Adapted from Larsen and Woodsworth, DNR 1982.
Forest industry lands are generally located at lower elevations than other owner class lands, and are more productive. National Forest lands have a much lower percentage of lands in the younger age classes than any of the other owner classes, due to longer deferral of harvesting and slower rates of harvest.

Management Intensity

The management intensity applied to timber stands can substantially influence future timber supplies. Intensive management regimes (which include planting, pre-commercial thinning, fertilization, and commercial thinning) on site III lands (120-164 cubic feet/acre/year) with a harvest age of 55 years provide a 36 percent increase in yield over a regime that includes only planting (Larsen and Wadsworth, 1982). These estimates reflect just the biological potentials; economic conditions must be favorable to justify these investments in intensive management.

Decisions about management intensities vary by landowner class based on management objectives, capital available for investments, and site class of the available land base. The outlook contained in 1985 RPA (increasing softwood demands and decreasing supplies in the Douglas-fir subregion, resulting in significant increases in price) would establish a favorable climate for intensive timber management. Forest Industry and the State, who have high site lands and a high percentage of land in the younger age classes, have current intensive management programs underway. National Forest lands, which tend to be lower site and older age classes, are likely to be managed less intensively in the near future, as most harvest will come from old-growth stands.

In the Washington Forest Productivity Study, Larsen and Wadsworth made some assumptions about the management intensity most likely to be utilized by landowner class following harvest (Table III-17).

Table III-17
Management Regime Assumed Most Likely to Occur
By Owner Class, Conifer Acres (Percent) 1/

Management Regime	National Forest	State	Other Public	Forest Industry	Other Private
Natural	0%	0%	35%	2 %	35 %
Plant	10	0	20	8	20
Plant & PCT 2/	10	15	10	15	10
Plant & PCT & CT 2/	40	15	10	7	10
Plant & PCT & Fert 2/	10	15	10	33	10
Plant & PCT & Fert & CT	30	55	15	35	15
Total	100	100	100	100	100

1/ Adapted from Larsen and Woodsworth, Washington Forest Productivity Study, DNR, 1982.
2/ PCT = Precommercial thinning, CT = Commercial Thinning, Fert = Fertilization

The assumptions displayed in Table III-17 project that other public and other private landowners will use the more intensive management regimes on many fewer acres than National Forest, State, and Forest Industry managers.

Recent experience has led to some reconsideration of the extent of intensive management practices that are planned for forest lands, both public and private. Questions have been raised, even on industrial lands, whether the experienced gains in yields and returns are matching the expected gains, and if the high level of investments originally planned can continue to be justified.

The expected future supply conditions are very important in terms of making decisions today to invest in intensive management regimes. Projections by Adams (1989) and others indicate a large increase in available timber supply after 2010, both from domestic and international sources. Accompanying that increase will be a leveling off of real stumpage prices. This future pattern makes high levels of current investments in intensive management regimes somewhat more problematic vis a vis expected returns. Shorter rotations on higher-site lands will tend to support more intensive management investments than will longer rotations on lower-site lands. Thus, industry will tend to have a higher proportion of its lands under intensive management than will the National Forests.

Harvest Flow Scheduling

Harvest flow scheduling refers to the scheduling of timber harvest and whether annual or periodic fluctuations are permitted, and if so to what degree.

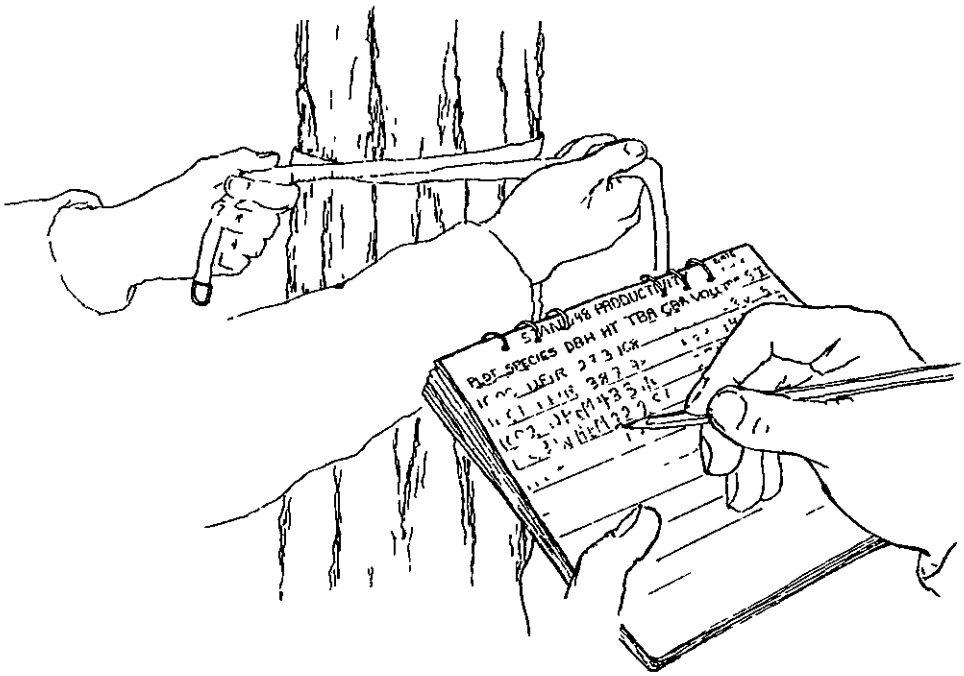
National Forest. Harvest schedules on National Forest lands are generally developed on the basis of a non-declining yield (NDY), although departures from this schedule are permitted by Congress and are examined under certain circumstances provided for in the Secretary of Agriculture Regulations. A departure schedule includes constraints on the amount of variation and/or the length of time departure is permitted. A departure from NDY generally results in increased outputs in the early years with a decrease in subsequent years to Long Term Sustained Yield (LTSY), and sometimes temporarily below LTSY.

State. State lands are managed to provide continuous harvest without major prolonged curtailment or cessation. The policy of nondeclining yield, or evenflow, is not applied, although the amount of variation permitted is restricted. The State manages and schedules its annual timber sales so as to sell more during periods of high prices and less during weaker market conditions. Upper and lower limits of 25 percent deviation from the sustainable harvest level are permitted. Nearly all the remaining old growth on State lands is scheduled for harvest before 1994.

Forest Industry. Forest Industry harvest flow scheduling varies considerably among individual firms. Generally, Industry harvests fluctuate with market conditions to the extent that timber is available. Most Forest Industry managers increase harvest during times of high prices and decrease harvests in periods of low prices. Some Forest Industry landowners have actually made major harvest reductions or even stopped harvesting for a period of time. Nearly all old-growth timber on Forest Industry lands has been harvested or will be within the next few years.

Other Public and Other Private. Harvest flow scheduling in these landowner classes varies so widely that no general characterizations can be made. Some landowners have liquidated their entire inventory and no harvest will be possible for many years. Others have made no harvest cuts; for some owners, current objectives include no explicit plans to harvest in the future. Still

others seem to be scheduling periodic harvests on an intermittent basis. However, the overall share of total harvest in Western Washington and Oregon (the Douglas-fir subregion) has been increasing since the early 1980's (Adams, 1989).



Institutional and Legal Constraints

National Forest. Legal and institutional constraints that affect timber production levels on National Forest lands are primarily Federal laws, Secretary of Agriculture Regulations, and policy statements developed to implement laws and regulations. Two of the most important laws in terms of determining timber production potential from National Forest lands are the Multiple-use Sustained Yield Act (USDA 1960) and NFMA. The Multiple-use Sustained Yield Act directs that the National Forests shall be administered for outdoor recreation, range, timber, watershed, and wildlife and fish purposes, so that they will best meet the needs of the American people, without impairment of the productivity of the land, and not necessarily for the combination of uses that will give the greatest dollar return or the greatest unit output.

The National Forest Management Act and the Secretary of Agriculture's implementing regulations, as they effect timber production, include: requirements for determination of lands suitable for timber production; that timber stands will generally have reached the culmination of mean annual increment before harvest; and resource integration requirements for all the resources.

These legal and institutional constraints have the general effect of limiting timber management investments and outputs to levels below the biological

potential of the forest. Economic considerations have the same influence not only on National Forest lands, but on all ownerships.

State. The Washington Department of Natural Resources (DNR) is designated as the manager of State Trust lands. As such, the DNR has certain constitutionally-mandated financial obligations to the beneficiaries of the trusts, primarily schools and other public entities. The basic objective is to generate income for the support of the designated institutions. In addition, the Legislature has directed the Department to employ the concept of Multiple Use Management when compatible with fulfilling the financial obligations of trust management.

The DNR has also been directed to manage State forest lands on a sustained yield basis when compatible with other legislative directives. DNR operates on a policy of relative even-flow, which permits year to year variations from the sustainable harvest level up to ± 25 percent. The State-wide sustainable harvest level for the period 1984-1993 is 777 MMBF a year. However, in 1986, the Board of Natural Resources approved an accelerated harvest level of 880 MMBF a year for the period 1986-2002 to sell a backlog of defaulted sales.

State lands are also subject to several other general Federal and State statutes such as the Clean Water Act, Clean Air Act, Endangered Species Conservation Act, State Environmental Policy Act, State Forest Practices Act, State Hydraulics Act, and the State Shoreline Management Act. Many of these acts establish minimum levels of management performance. The State finds in its own best interest to exceed these minimums.

Forest Industry. Institutional constraints on the Forest Industry vary widely from one company to another, but most practice, at least to a certain degree, a "good neighbor" policy. This policy is exhibited through such things as public access to their private lands, allowing and in some instances facilitating recreational use, support of administrative studies and research, and cooperation with adjacent land owners. The degree to which the timber industry practices this "good neighbor" policy as it affects timber management is made on an individual basis after weighing the perceived benefits against the costs.

Legal constraints that have the greatest effect on timber outputs are the State Statutes, discussed in the last paragraph on State institutions. Many of the Forest Industry land owners exceed the minimum management performance standards established in these statutes and related regulations.

Other Private. Other private forest land owners include farmers, woodlot owners, and other non-forest industry individuals and firms who own forest land for a variety of reasons. Timber management varies widely on these lands, from intensive management to no management other than harvesting and natural regeneration. Some owners of these lands are not interested in the production of commercial forest products. Legal constraints on other private lands are the same as those applicable to Forest Industry lands.

Summary of Timber Supply

Some estimated trends in potential supply by landowner class can be made, considering the timberland base, likely management intensities, harvest flow scheduling, institutional and legal constraints, and historical trends in harvesting. These are summarized, by ownership, below.

National Forest. Future timber supply from suitable lands on the Mt. Baker-Snoqualmie National Forest will be approximately 108 MMBF annually over the next decade, according to the Forest Plan Preferred Alternative. Although the Forest has a large inventory of old growth that could be harvested in the immediate future, institutional and legal constraints will limit rapid liquidation of this inventory.

The upper end of the decision space for allowable sale quantity is the benchmark, Maximum PNV, With Assigned Prices, which includes non-declining yield, rotation at 95 percent culmination of mean annual increment, and management requirements. This benchmark indicates an ASQ of 239 million board feet. This is considered the upper end of the decision space, except for possible temporary departures. Other alternatives considered in the FEIS project varying levels of timber supply below this level.

Between 1970 and 1984, all National Forest lands provided approximately 16 percent of the logs consumed in the Puget Sound area. From 1972 to 1984, the National Forest contribution ranged between a low of 13% (1978) to 18% (1972). Absolute volumes consumed in the Puget Sound area from all National Forest lands were at a high in 1972 with 431 MMBF, and at a low in 1982 with 252 MMBF. In 1986, the volume was midrange, at 367 MMBF, but the percentage of all logs consumed in the Puget Sound region rose to a new high of 21%, as total log consumption in the area declined.

State. The State has a current Forest Land Management Program. The Board of Natural Resources has authorized a sales program above the sustainable harvest through the year 2002. From 1970 to 1984, State Lands contributed approximately 11 percent of the logs consumed in the Puget Sound Economic Area, ranging from a high of 13 percent in 1978 (294 MMBF) to a low of 7 percent in 1974 (171 MMBF). In 1986, State harvest for the area rose to a new high of 371 MMBF and a 21% share.

Other Public. Since 1970, the Other Public owner class has supplied approximately 1 percent of the logs consumed in the Puget Sound Economic Area. The assumption is made that log supply to the Puget Sound Area from their lands will average 18-20 MMBF annually over the next 5 decades. This assumption is based on the current inventory and announced harvest plans of some of the major landowners in this owner class.

Forest Industry and Other Private. These two owner classes together have been the major producers of logs consumed (including export) in the Puget Sound Economic Area since 1970. During the 1970's, forest industry and other private owners produced 74 percent of the logs consumed in the area, and during the early 1980's, 71 percent. However, by 1986, that share had dropped to 56%. This follows a Statewide trend during the 1980's of a declining percentage share of logs consumed being provided by this sector.

These two owner classes have large acreages of young forests that are assumed to reach harvest age in the near future. These lands include some of the best timber growing sites in the Puget Sound area. The landowners are relatively unconstrained by institutional constraints and respond more rapidly to changes in demand than do the public owner classes.

Currently, industrial forest landowners in the Northwest are experiencing an inventory gap in age classes, resulting in about a 10-20 year period during

which harvests from industrial lands are declining 15%-20% from averages of the previous 25 years or so. In about 15-20 years, young stands currently growing will reach merchantable age, and industry harvest will rise again.

Other private (nonindustrial) owners also have a large percentage of inventory in younger classes, but can still support the current, or somewhat increasing, level of harvest over the next 20 years. The current harvest level from these lands is low enough that the existing inventory structure does not leave any gap in merchantable acres (Adams, 1989).

Average volume of logs supplied for consumption in the Puget Sound area by various ownerships between 1970 and 1986 are shown in Table III-18, below; the relative shares are shown in Figure III-8 on the facing page.

As can be seen, the private sector share has dropped over that period relative to other ownerships. In addition, the total roundwood consumed in the area dropped over time. This reflects closing of several mills during the recession of the early 1980's.

Table III-18
Log Consumption by Ownership, Puget Sound Economic Area
Annual Volumes, Million Board Feet

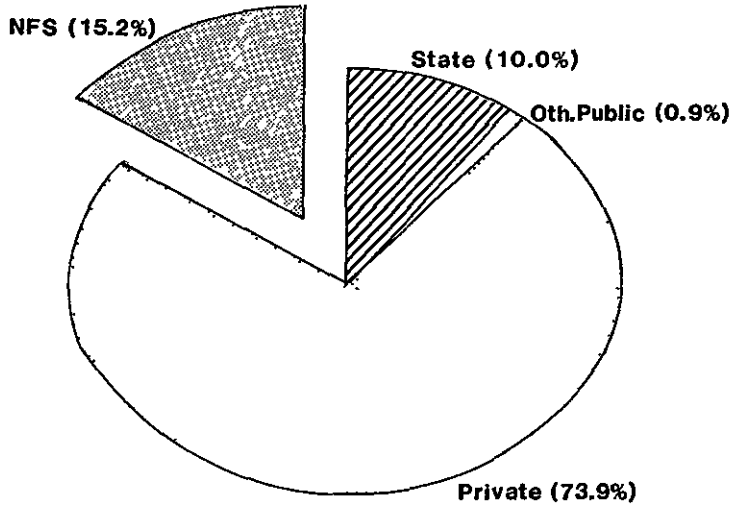
Period	State	Other Public	Timber Industry & Other Private	Total Non-National Forest	National Forest	Total
1970-'78	233	20	1726	1979	356	2335
1980-'84	216	18	1314	1548	292	1840

Without attempting to put numbers on the projected timber supplies over the next several years or decades, one can make some fairly reasonable estimates about harvest trends by ownership categories. These estimated trends would apply to the regional market (e.g., Western Washington) along with the Puget Sound area. They are estimates of trends in economic supply, and are predicated on an economy that continues to grow, but at a moderate pace, with no major recessions similar to that of the early 1980's.

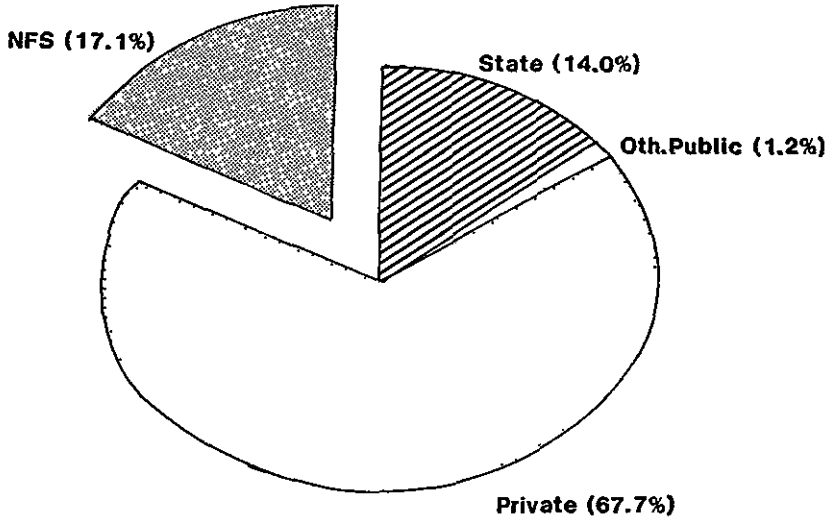
Forest Industry. Timber harvest from private industrial forest lands will fall, perhaps 15%-20%, over the next two decades from the high levels of the 1960's, 1970's, and latter 1980's, partly due to a gap in merchantable age classes in the existing inventory, and to a lesser degree because of flattening demand in the housing markets. By about 2010, as new inventory comes of age, industry will once again begin to increase harvest levels (Adams, 1989).

Figure III-8

**Origin Of Puget Sound Log Consumption
By Ownership (1970-1978)**



**Origin of Puget Sound Log Consumption
By Ownership (1980-1986)**



State. Timber harvest from State lands will decline significantly from current levels over the next two decades as remaining old growth is cut and/or pressures are successful to meter out the old growth harvest, or even protect some stands completely. The State DNR is currently revising its Forest Land Management Program and the associated sustainable harvest calculation. Included is consideration of the recent report and recommendations by the State's Commission on Old Growth Alternatives for Washington's Forest Trust Lands, which recommends protecting old growth in the State's experimental forest on the Olympic Peninsula. The tentative harvest level estimates for the time being show that harvest levels from State lands will probably be in the neighborhood of 200 MMBF annually over the next two decades (Washington DNR, 1990). This is toward the lower end of the harvest range experienced over the past 20 years.

National Forest. National Forest harvest levels will be lower than the highs of the 1970's and late 1980's. Over the past two decades, National Forests have accounted for about 15% of the total harvest in Western Washington. It is expected the absolute amount of timber supplied from National Forests will decline somewhat over the next two to three decades with the adoption of final Forest Plans. However, a report prepared by the Regional Office in Portland (USDA Forest Service, 1989) estimated that, in total, changing harvests from National Forests would have a price effect of only a few percentage points over the next decade or two. These would disappear as markets adjusted and more inventory comes on line in about 20 years.

Other Private. Harvests from nonindustrial private forest lands are less predictable than from other ownerships. These harvests have risen in recent years. If they are responding to price, the declines in harvest over the next two decades from other ownerships could keep those prices up (assuming no major decrease in demand), and continue to elicit more supply from the nonindustrial private lands. This source of supply, then, could serve as a moderating factor to keep prices from rising even more rapidly over the next two decades until inventories and potential supply once again begin to increase on other ownerships.

Demand

Demand for timber stands at the local and regional levels is derived from markets for processed wood products at the regional, national, and international levels. The relationship between supply cost and demand price at the local/regional level is determined by the ability of individual firms to compete in these wider markets. Important factors in this ability to compete are: the cost of raw materials facing the firm; the technology available to it to convert the raw materials to manufactured products; and its ability to compete for markets. Information about these factors for individual firms is not revealed, as it is vital to the firms for both competing for raw materials and for markets.

Demand for lumber and wood products from the Puget Sound Economic Area followed the trends of the Pacific Northwest, with a drastic decline in the early 1980's compared to the highs during the 1970's. Production of wood products in the period 1980-84 was slightly less than 80 percent of that experienced during the 1970's. The structure of the wood products industry in the Puget Sound Area

put it at a competitive disadvantage with imports from Canada and Southern U.S. production.

The pulp and paper industry avoided the deep declines in demand and production of the early 1980's. Strong demand for paper, domestically and abroad, helped pull that sector of the wood products industry through the recession in fairly good shape. Over the past decade, the number of pulp and paper mills in the Puget Sound area has dropped by almost 20%, but the installed capacity of the remaining mills has increased by about 10%. This is similar to the structural changes found in other sectors of the industry. As of 1986, about 5% of the Forest's annual harvest went to Puget Sound area pulp mills, which represented about 7% of the mills' roundwood consumption. Regionally, roundwood consumption represents only about 30% of the total fiber input for pulp production.

The restructuring of the timber industry in the Northwest during the early 1980's was a response to the declining market share and an attempt to regain market share. The projected future decline in production from Canada and a continuing growth in exports to the Pacific Rim Countries are likely to result in a shift in demand for Puget Sound Economic Area logs. The timing and magnitude of this shift in demand, however, are speculative. Increased production from Puget Sound Area mills during the past three years is an indication that the industry is improving the efficiency of its wood processing and thus improving its ability to compete for market share nationally and internationally.

The supply/demand situation in other economic areas around the state also influences the availability of timber in the Puget Sound area. The Puget Sound area mills (including export facilities) consume more logs than are harvested in the area. During the 1980's, approximately 66 percent of the logs consumed in Puget Sound originated from Puget Sound; approximately 26 percent came from the Olympic Peninsula; 5 percent from Central Washington; and 3 percent from other areas, including out of State. A similar pattern of imports into the area occurred during the 1970's.

While the Puget Sound area has historically imported approximately 35% of the logs needed for its mills, it has used about 95% of the wood harvested in the are within the region. Only about 5% of the harvest from the Puget Sound area is going to processing elsewhere. (Exporting logs overseas is considered part of the local processing industry.) So the Puget Sound area is a net importer of logs, which come from other parts of Western Washington, along with a minor amount from the east side of the Cascades.

Depending on markets, mill capacity, price and local harvest level fluctuations, one part of the State may have a greater demand for logs at any given time than another. The relative demand for logs among processing areas may change seasonally, or from year to year. Prices in the areas with a greater need for logs will tend to float upward, drawing more supply to that area. As that need is met and prices stabilize, a shift may occur to another region. Prices serve as the leveling agent to direct the log supply to the areas with greatest demand. In extreme cases, prices may not be able to go high enough to bring in the needed lumber and a structural shortage of logs may develop for an area. If that continues for any length of time, mills in that area will be faced with closure. Competitive mills will tend to survive such periods, but marginally efficient mills may drop out. The changing of prices

to moderate log flows have to operate within limits, which are set primarily by the prices of finished wood products in the regional market.

Because of the local and regional interactions in the roundwood markets, it is difficult to make quantitative estimates of future demand for logs from the Puget Sound area. One can not really assume that the consumption by the Puget Sound mills is a measure of the demand for Puget Sound logs, when other regions may assert a need (as reflected through relative prices) for those logs as well. However, estimates of relative levels and trends in demand for timber can be made, given what is known about current consumption patterns, expected changes in regional, national and international demand for wood products, and projected physical/biological supply.

Demand Over the Next 20 Years

For the next 20 years, demand for wood products is expected to grow, but slowly. This is based on a continuing, though not rapidly expanding, need for wood for new construction and for remodeling and repair. Export markets will decline somewhat over that time period, but will still remain very active. Canadian wood imports will continue to decline from the high levels they held in the early 1980's because of decreased competitiveness and increasing restrictions on logging in Canada. In all, given no economic shocks, the demand for roundwood will stay at least at current, to somewhat higher, levels.

In the face of this demand, available inventory from private industrial forest lands will be declining, as will harvests from National Forest lands, particularly in Northwestern Washington. Other private land harvests may come up somewhat, but probably not enough to offset the declines in these two ownerships. And after the mid-1990's, almost all old growth timber that is still harvested will come from National Forest lands. Therefore, it appears the next 20 years will find fairly tight physical/biological supplies juxtaposed with demand that stays at least at current levels. The expected result will be fairly rapidly rising prices in the range of 1.5 to 4 percent per year (Adams, 1989), but no timber supply "crisis," as prices play a moderating effect - eliciting more supply from the private nonindustrial forest lands, and dampening final demand for wood products by consumers because of increased cost.

The declining inventory of sawtimber of harvestable age in the next two decades will have less effect on the pulp and paper sector than on the lumber and plywood sectors. Pulp mills can use much smaller material, chipped either in the woods or at the mill, than can sawmills. Thus, the age-class gap in the inventory will not be as limiting for pulpwood supply. Other economic factors, though, may combine to place an increasing squeeze on pulp prices. Better log utilization and on-site use of residues by the primary manufacturers leaves less low-cost residue available for pulp. Declining harvests regionwide and in western Canada will also reduce residues available. If the export demand for chips remains strong, additional pressure will be placed on prices.

Over the next decade or two, these supply and demand factors may put the Northwest pulp producers at a greater cost disadvantage than East Coast or Southeast producers, who already produce the major portion of pulp and paper products in the country. Mitigating factors for the industry are likely to be continued technological changes, allowing more use of species little utilized to date, and greater use of recycled paper as feedstock. Supply changes from

the Mt. Baker-Snoqualmie National Forest are expected to have little effect on the local area or regional pulp and paper sectors.

Bidding History

Table III-19, on the following page, summarizes data for 863 timber sales sold on the Mt. Baker-Snoqualmie National Forest between January 1, 1979 and September 30, 1988.

During the timber sale auction process, timber purchasers may increase the cash received from a sale by bidding more than the appraised value. The analysis of the 1979-88 bidding history for the Forest, shown in Table III-17, reveals that on a Forest-wide basis, purchasers bid over twice the appraised value for timber in the first five years of this comparison. In 1984 the average bid was only 1.2 times the appraised price, and in 1985 the bid ratio dropped to just 1.15. However, as the economy began to recover from the recession, bid values began once again to climb relative to appraised values. By 1988, purchasers were again bidding almost twice the appraised values for timber.

It is interesting to note that the changes in bidding procedures and requirements implemented in the early 1980's, after the speculative bidding problems of the late 1970's and subsequent "buy back" of default volume, have apparently had some effect. Even with the rapid increase in stumpage prices in 1988 (and 1989), the bid ratio has stayed just under 2.0, compare to ratios running 2.4 to 2.8 under similar economic conditions a decade ago.

The total volume sold during this period was 2,651.39 MMBF, having an appraised value of $193,794,016. The weighted average overbid was $78.95 per MBF with a total overbid of $209,316,760.

Demand was such that bidders were willing to bid the price for wood up to an average of 2.08 times the appraised price (weighted average bid) during that time period. There was also competition for the timber sales being offered, with an average of six bidders per sale.

Table III-19
Summary of Timber Volumes Sold - Advertised and Bid Values, 1979-1988

Fiscal Year	Total Bid $	Total Appraised $	Total Overbid $	No. of Sales	Total Volume MBF 1/	Average Bid $/MBF	Average Appraised $/MBF	Average Overbid $/MBF	Bid Ratio 2/

4/ Includes period of calendar year 1980 from Jan 1, 1980 to Sept 30, 1980 only

Timber Sale Costs and Returns

A recently highlighted national issue is popularly called below cost timber sales. The issue involves whether or not the Forest Service should offer timber sales in which the revenues generated are below the costs of selling the timber.

Differences exist as to what costs and what benefits should be included in such a determination. There appears to be general agreement that below cost sales are, by and large, undesirable. However, Schuster and Jones (1985) build a case that individual timber sales should not be evaluated on their own, and that below cost sales may be necessary and desirable in maximizing net public benefits. They also argue that below cost sales cannot be evaluated apart from the managerial context within which the Forest Service operates.

This managerial context is spelled out in the policy and procedures associated with the National Forest Management Act of 1976 (NFMA). NFMA calls for

integrated land management. Timber sales should be evaluated as to how they fit into a comprehensive program of management for an entire National Forest, and not solely on whether or not they are below cost.

Harvesting trees may, in some cases, be the best, most efficient way to achieve other objectives. For example, on some portions of the Forest, land at the optimal elevation for deer and elk winter range is covered with young, second growth stands. These dense stands, unlike old growth or shrubs and saplings, have almost no forage for deer. By cutting timber, open areas are created. Grasses dominate for the first five years after harvest, but as forbs, shrubs, and replanted conifers come in (years 6 to 30 after harvest), the land can provide forage (though limited cover) for deer winter range. Costs related to these sales may exceed receipts, but the timber sale is the most efficient way to produce the desired winter range.

Timber Sale Cost Accounting

The Forest Service does not have an accounting system that permits tracking the costs of an individual timber sale. Costs related to timber sales are accounted for on the basis of expenditures made during a particular fiscal year, and include costs incurred for all timber sales that were in any stage of preparation or administration during that year. Receipts from a timber sale are rarely received in the same year that all of the costs were incurred.

Timber sale costs are commonly incurred for several years prior to the time that receipts are generated. Costs such as sale planning, road survey and design, volume estimation, and appraisal all occur prior to the time a sale is offered. After the sale is sold, the successful bidder begins harvest operations and makes payments for the timber as it is cut. During the harvest operation, costs are incurred for contract administration. After all the timber has been harvested, costs are also incurred for post sale activities, such as reforestation and timber stand improvement.

Timber Sale Program Information Reporting System (TSPIRS). In 1984, Congress responded to popular concern about below cost sales and the lack of an accounting system to track timber sale costs and benefits. The Forest Service was directed to design a new accounting system to report all costs and benefits of the timber sale program. After two years of cooperative effort between the Forest Service and the General Accounting Office (GAO), TSPIRS was developed. Prior to formal adoption, the system was tested nationwide for two years (fiscal years 1987 and 1988) with changes and fine tuning made as necessary. The first official reporting year was FY 1989.

The TSPIRS produces three major reports:

- "Statement of Timber Sale Revenues and Expenses" which displays an annual financial record of timber sale revenue and expenses for the current fiscal year;
- "The Economic Account" which provides an economic, as opposed to a strictly financial, long-term view of all resource costs and benefits associated with timber sale areas harvested in that fiscal year;
- "The Employment, Income and Program Level Account" which displays estimates of employment and income in the local economy supported by

the timber sale program, as well as timber-related program accomplishments for the current fiscal year.

The first report is similar to a corporate annual report. It reflects the cash flow position of the Forest, with longer-term investment costs pooled and distributed on an annual acres harvested basis. This is similar to the amortization of costs done by corporations in their financial reports, and was developed in accordance with generally accepted accounting principles. (For more detail on TSPIRS see the annual TSPIRS report for the Forest for fiscal years 1989 or following, or see the Final Instruction Package for FY 89 or following years, as released by the Washington Office.)

Timber sale cash flows are comprised of the dollars the government receives from a timber purchaser minus the costs the government incurs, such as sale planning, appraisal, contract administration, reforestation, etc., to carry out the timber sale and associated timber management. TSPIRS does not measure the costs and benefits of individual sales, but rather of a Forest's sale program in the course of one year. There is still no accounting system to track costs of individual sales. Also, since sale costs occur over several years, and sale revenues may also be received over a different period of years, an annual cash flow statement related to individual sales would not have any real meaning.

The value of the timber on a particular sale is primarily determined by the species present and the size of the logs. Species such as Douglas-fir and western redcedar have more value than species such as alpine fir and red alder. Larger trees are more valuable than smaller trees because they produce a higher percentage of clear wood (free from defects, such as knots).

The costs related to a particular timber sale can vary widely. Factors that affect costs include roading, logging systems required, harvest unit size and shape, volume per acre, distance from a manufacturing facility, environmental constraints included, and mitigation work necessary. All these factors, combined, determine the appraised value, or the minimum that the Government will accept for the sale when it is sold.

Summary cash flow statements for the Mt. Baker-Snoqualmie from TSPIRS are shown in Table III-20 for fiscal years 1987-89. Although the first two years were test years, the figures are comparable for all three years in the financial statement.

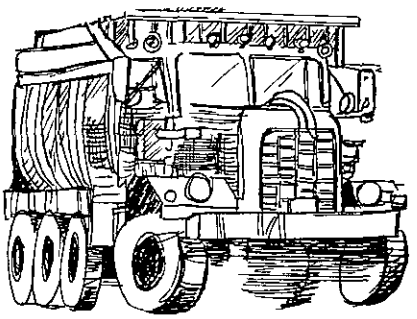

Table III-20
Timber Sale Financial Statement Summaries - MBS TSPIRS Reports

	FY87 (M$)	FY88 (M$)	FY89 (M$)
Total Revenues 1/	29,378	36,245	35,060
Total Operating Expenses 2/	16,989	13,422	14,462
Gain/Loss Before Payments to States	12,389	22,823	20,598
Payments to States	7,021	8,014	8,293
Net Gain/Loss from Timber Sales	5,368	14,809	12,305
Volume Harvested (MBF)	295,953	248,127	188,742

1/ Includes purchaser road credits established.
2/ Includes prorated annual share of long-term investment costs.

All fiscal years compared show a positive cash flow from the timber sale program for the Forest. In fiscal year 1989, net cash flow stayed up (and higher than in fiscal year 1987) even with a significant drop in volume harvested. This was because of a rapid rise in revenue per MBF as prices rose during 1989. Timber prices, which had dropped to low levels during the early 1980's, have risen as the economy has recovered, with prices rapidly increasing in the past two years as demand has remained high and log supplies have begun to tighten. Even during the recession years of the early 1980's, the Forest still showed a positive cash flow from timber sales, although the numbers are not exactly comparable to those developed through the TSPIRS process.

The positive cash flows from the timber program on this Forest are not surprising because of the predominance of high value old growth timber in the harvest mix. It is for this reason that below cost timber sales have not been a major issue on the Forest.

Road Costs Related to Timber Sales. Road construction costs for permanent roads related to timber sales, whether from appropriated or purchaser credit funds, are included in the total costs reported under TSPIRS, but they are prorated over time. (Costs for temporary roads that serve only the timber sale and will be obliterated at the end of the sale are included without proration in the annual timber sale expenses.) It is a generally accepted principle of accounting that long-term investments are prorated or amortized over some extended time period, and only one year's prorated or amortized value is counted in cash flow financial reports for that year.

Under TSPIRS rules, these permanent road costs, along with other long-term investment costs such as for backlog reforestation from appropriated funds, timber stand improvement, and genetic tree improvement, are accumulated in a

"growth activity allowance" pool from year to year. The costs are expensed to the current year timber sale program in the same proportion that volume harvested in that year is to the total volume available to be harvested in one "average" rotation on all suitable lands on the Forest.

Purchaser road credits established are included as part of the gross income calculations for the TSPIRS financial report. The prorated portion of the accumulated road costs are included in the current year expenses, as described above. Essentially, road costs are included on both sides of the cash flow equation, resulting in an appropriate accounting in the cash flow calculation.

Road costs related to timber sales have declined nearly 50 percent over the past decade. This reduction is due primarily to two factors. The first is the reduction, in the latter part of the period, in the number of sales located in roadless portions of the Forest. Since most of the sales were located in areas of the Forest that were already developed, less construction of arterial and collector roads took place. The second factor was a concentrated effort to reduce road costs through changes in design, location, and road standards.

FIREWOOD

Prior to 1974, free-use firewood was an incidental program on the Forest, considered by most managers to be a low priority. Demand was primarily limited to citizens in more rural areas who had traditionally burned wood for home space heating. The 1974 oil crisis caused many Washingtonians to view wood as an insurance policy for use in conventional fireplaces.

Demand declined after the 1974-75 oil crisis and by 1977 had approached the pre-1977 level. By 1979, energy prices for home heating began to increase rapidly and demand for firewood again increased through 1982. A decline in 1983 was observed. Part of this decline was due to the greater availability of commercial firewood from sources other than the National Forest. The more recent declines in firewood sales from the Mt. Baker-Snoqualmie have followed publicity from local air-pollution jurisdictions, regarding the the contribution wood smoke was making to the overall particulate levels in urban areas. Stricter regulations have affected the number of days wood stoves and fireplaces can be used. This has diminished their appeal, and firewood demand has dropped accordingly. The combined total of personal use and commercially cut firewood removed from the Forest appears to have leveled off, or may be declining.

Table III-21
Firewood Permits and Volumes 1/ - 1975 to 1983

Year	Number of Permits	Cords	MCF	MBF
1975	10,514	21,028	1,998	9,769
1976	5,374	10,748	1,021	4,993
1977	3,249	6,498	617	3,019
1978	3,375	6,750	641	3,136
1979	8,550	17,100	1,625	7,944
1980	10,733	21,466	2,039	9,971
1981	10,826	21,652	2,057	10,059
1982	10,253	20,506	1,948	9,525
1983	4,561	9,122	867	4,240
1984	3,658	10,300	1,057	5,171

1/ Assumes 2 cords removed per permit issued; 95 cubic feet solid wood per cord (USDA 1982, Methods for Evaluating Energy Effects of Forest Management Alternatives); 4.89 board feet per cubic foot.

Table III-22
Personal Use and Commercial Cutting, Firewood - 1984 to 1988

Year	Personal Use Number of Permits	Personal Use Volume MBF	Personal Use Volume MCF 1/	Commercial Cutting Volume MBF	Commercial Cutting Volume MCF 1/
1984	3658	5171	1057	944	193
1985	2368	2458	503	1357	278

1988	1535	1584	324	1206	247

1/ Source Quarterly Cut and Sold Reports.
2/ Conversion ratio is 4.89 board feet per cubic feet.

Historically, most firewood on the Forest came from cull material that had been yarded to a landing to meet fuel treatment and silvicultural objectives. On more gentle terrain, firewood on these landings was completely cleaned up. However, firewood seekers were reluctant to harvest material that had to be moved uphill.

Recently with innovative approaches toward increasing the firewood supply, firewood gathering habits have changed. Firewood gatherers are willing to cut and remove small material from pre-commercial thinnings as well as remove undesirable species from regenerated stands. Techniques such as spreading material on the landing following logging and hauling firewood to central locations where it can be safely utilized have been effective in maintaining the supply of firewood.

The demand for firewood is expected to fluctuate as prices of other energy sources change. There may be a slight increase in overall demand that will follow the increase in population in the Puget Sound area, but the concerns over air quality and the cost of efficient clean burning stoves will moderate increases in firewood demand due to population growth. The Mt. Baker-Snoqualmie will continue to supply the firewood demand of the rural communities, but other commercial sources - mostly private landowners - will supply the urban areas for the immediate and foreseeable future.

Supply

As discussed below (wood residue section), each acre of old-growth forest contains about 12,500 cubic feet of wood fiber. Of the material unsuited for marketing, about 1500 cubic feet, per acre, can be yarded to a landing and used as firewood. Currently, between 3,500 and 4,000 acres of mature timber are harvested annually. Assuming 1,500 cubic feet per acre of residue suitable for firewood or fiber, the Forest has the potential to supply between 5 and 6 million cubic feet of fiber per year for the next 20 to 30 years. This is considerably more that the current demand.

Increasing utilization efficiency and resource requirements to leave some of the woody material on the harvested site, to maintain long-term site productivity and wildlife habitat will increase the competition for material suitable for firewood. The future of firewood availability for the public depends largely on: competition for small-sized material from pulpwood manufacturers; the rate of development of commercial firewood markets; and the rate at which harvest activities move from old-growth stands to managed stands - which contain much less wood residue.

WOOD RESIDUE

Dead and down woody material, whether the result of the natural tree mortality or the wood debris left after logging, clearing for campgrounds, and other activities, is an important resource. The stumps, root wads, bark, limbs, and logs play an important role in nutrient cycling within the forest ecosystem (Bartels and others 1985). Large portions of some nutrients are stored in branches and foliage; larger logs and branches serve as sites for nitrogen fixation. Logs may protect a site from the loss of nutrients through surface erosion (Bartels and others 1985).

The effect of nearly total residue removal on long term nutrient availability is complex and only partially understood. Soil nutrient supply and productivity change relatively slowly; therefore, harvesting practices can be selected from rotation to rotation without serious risk of decline in soil productivity (Wells and Jorgensen, 1979). Most researchers generally agree that normal harvest of most of the stem will not deplete the soil of nutrients, but that short rotations and whole tree harvests have the potential to remove nutrients and accelerate other outputs to a rate that will decrease the systems supply of nitrogen, potassium, phosphorus, calcium, and possibly other elements. The quantitative aspects of the biological, chemical, and physical processes in the soil are not sufficiently known to predict the long term effect of intensive harvest on the soil or on soil productivity.

Wood debris creates a structure and diversity of habitats that are valuable to a great many wildlife species (Maser and others 1979, Bartels and others 1985). Dead and down material is used by 149 terrestrial wildlife species in the western Cascades, as a primary or secondary component of their habitat requirements (Bartels and others 1985). Logs and root wads can be placed in streams to channel water or create pools for spawning and rearing fish.

Logs may serve as favorable sites for regeneration of some species of trees; western hemlock is especially tolerant and will grow on and over downed logs. Wood residue can also be utilized for firewood or sold for pulp chips for a growing variety of new products.

An average acre of old-growth forest on the Mt. Baker-Snoqualmie contains approximately 12,500 cubic feet of wood fiber. If the trees on this acre are harvested, about 60 percent of the wood is removed as merchantable logs; another 15 percent is removed as cull or under-sized material. Of the remaining 3,000 cubic feet, about half is left on the site to meet nutrient cycling, erosion protection, and wildlife needs. There is an estimated 1,500 cubic feet that is excess to these resource management needs, that is disposed of through a variety of techniques.

In the past, the need for wood residue for nutrient recycling and wildlife habitat was recognized, but generally, this material was viewed as fuels that created a fire hazard and debris that hampered planting seedlings. (Douglas-fir, often the selected reforestation species, is very intolerant and requires a "clean" site and lots of sunlight to grow.) Nearly all logging debris was burned, either in place or in piles near the landing.

In the past five years on this Forest, more and more of this resource is being used rather than burned. This is a result of more aggressive marketing of small-sized wood residue, better silvicultural practices, increased use of wood for home heating, a growing international market for innovative wood and paper products, and the cost savings in utilization versus burning. The cost to "clean" yard after timber harvest, and make the material available for sale, is approximately $300 per acre. Burning this residue (either broadcast burn in place or piled and burned) averages about $400 per acre.

Table III-23 shows the trend in acres broadcasted burned, over the past ten years.

Table III-23
Acres Broadcast Burned, Tons of Material Burned

Year	Acres Burned	Tons Consumed
1980	3,411	129,600
1981	3,010	105,400
1982	1,295	41,000
1983	422	14,900
1984	598	14,200
1985	626	22,000
1986	453	11,700
1987	193	7,400
1988	167	4,800
1989	252	8,300

More commercial firewood operators are operating today than ever before. This new business provides an option for the home wood-gatherer: firewood that is cheaper than that available in the urban area yet is more accessible than wood offered by cutting permit from the Forest Service. Refer to the subsection on firewood.

The demand for pulp chips for both domestic use and export is increasing as the market demand for paper products and structural panel increases. There are a number of new products that can be manufactured from residue material, ranging from various types of fuels to a type of interply plywood.

The Mt. Baker-Snoqualmie is one of several forests in the Pacific Northwest with an aggressive program to promote the utilization of wood residue. Major objectives of the program include: inventory of available and potential wood fiber residues; development of new markets, including international markets; coordination with local manufacturing firms in developing potential new markets, and resolution of Forest Service internal barriers and other external barriers to increased utilization.

A key question is determining the proper balance between cost-effective utilization of wood residue and retaining downed woody material to benefit soils, fish, and wildlife habitat.

FOREST INSECTS AND DISEASE

Insect damage on the Forest is calculated only for any losses to commercial timber species. Estimated loss has been relatively minor; for 1981, wood lost to insect damage totaled 431,000 board feet, a small percent of the forest-wide timber volume. The annual loss in the State of Washington is approximately 108.7 million board feet (USDA 1981). Table III-24 shows estimated loss for 1981.

Table III-24
Estimated Loss From Insects - 1981

Insect Species	Acres Affected	Board Feet
Mountain Pine Beetle		
Western white pine	2,120	287,000
Lodge pole pine	60	6,000
Douglas-fir beetle	380	99,000
Douglas-fir engraver	1,320	21,000
Fir engraver	230	18,000
Balsam woolly aphid	280	minor - not estimated
TOTAL	-	431,000

Commonly found root rots are: laminated root rot, Phellinus weirii, Armillaria root disease, Armillaria ostoyae, and Annosus root and butt rot, Fomes annosus. No precise root disease losses have been compiled for the Mt. Baker-Snoqualmie National Forest. However, in Douglas-fir forests in western Oregon and Washington, laminated root rot has caused an estimated annual loss of 32 million cubic feet of timber. It is present on at least five percent of the Douglas-fir forest type. It is believed that root rots may cause significant losses in commercial timber species. Early harvest of infected trees and planting less-susceptible tree species on infected sites are the most common approaches used to reduce loss (Hadfield and Johnson 1977).

Bole rots, especially in Pacific silver fir, western hemlock, and mountain hemlock, are a problem on the Mt. Baker-Snoqualmie. Most of the rots are associated with damage or wounds to trees. Damage from bole rots is reduced by minimizing wounding trees during harvesting, removing trees with large wounds and/or existing decay, and establishing rotation ages of less than 150 years. Old-growth stands of Pacific silver fir and western hemlock have a high incident of bole rots. Because the disease spreads through root grafts and external wounds, intermediate commercial thinning in these stands will be prescribed only when external wounding of remaining trees can be minimized.

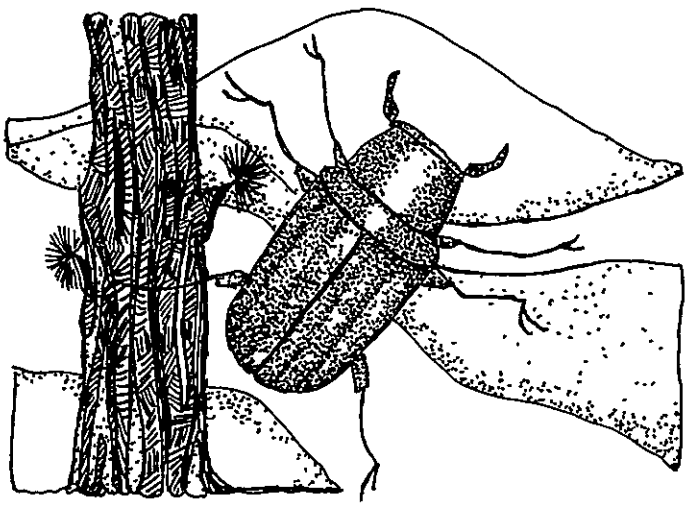
Dwarf mistletoe is a parasite which stunts tree growth and may, eventually kill the tree. Only three species are of any significance on the Forest. Hemlock dwarf mistletoe (Arceuthobium tsugense) is the most common. Douglas-fir dwarf

mistletoe (A. Douglasii) is also found, but to a much lesser extent. There is some dwarf mistletoe found on Pacific silver fir. Precommercial and commercial thinning present opportunities to reduce the level of dwarf mistletoe infection by removing selected, infested trees.

Animal Damage to Commercial Trees

The most serious animal damage occurs from bears stripping bark from young trees in regenerated stands. The bears' favorite species is Douglas-fir, at 7 to 9 inches diameter (measured at 4'6" from the ground, or diameter at breast height - dbh). Damage is heaviest in localized drainages in the Darrington area, although some damage is found Forest-wide. In the areas most impacted, as much as 80 percent of the stands has been lost. A co-operative control project was initiated with the Washington State Department of Wildlife. Some form of bear control may be required in future years.

There is some damage to commercial tree plantations from mountain beaver and lesser amounts of damage from deer, elk and small rodents. Tree mortality is rare.



FORAGE VEGETATION - LIVESTOCK MANAGEMENT

Forage for grazing animals is available, to some degree, throughout the Mt. Baker-Snoqualmie National Forest as a component of all vegetation types. As discussed above, approximately 85 percent of the Forest is covered with vegetation. Each stage of vegetation growth, or stand condition, provides different habitat and forage for animals (Hall and others 1985).

The demand for grazing range for domestic livestock has been very low on the Mt. Baker-Snoqualmie National Forest. Portions of two sheep grazing allotments are located on the Forest. Both are located primarily on the east side of the Cascade Mountains and have historically been administered by the Wenatchee National Forest. The Mt. Baker-Snoqualmie portion contains 10,000 acres, of which 4,000 are suitable for grazing. The two permits have an estimated carrying capacity of 950 animal unit months. (See the glossary in this document for a definition of these terms.) Neither permit has been used in the past five years.

There is a small amount of free grazing by recreation livestock, plus a few paid temporary permits for commercial packing. Most of this use occurs along the Pacific Crest National Scenic Trail.

In 1978, a temporary permit was issued to graze a band of sheep on transitory range in clearcut timber harvest units. The animals lost weight and the damage to planted tree seedlings in the clearcuts was unacceptable. Since this 1978 trial, the demand for transitory range has been low to nonexistent.

The supply of transitory range has not been inventoried. After a timber harvest unit is cut, the grass-forb condition lasts 2 to 5 years and occasionally as long as ten years (Hall and others 1985). Thus, it is assumed that a clearcut unit could provide range for approximately five years. If it is assumed 4,000 acres are clearcut annually, a total of 20,000 acres of transitory range could be available at all times.

WILDLIFE ELEMENTS OF DIVERSITY

Management of vegetation for the production of goods and services, other human uses of the Forest, and natural succession result in constant changes in the abundance and distribution of plants and animals on the Forest (Odum 1971). Maintenance of diversity of wildlife and their habitats is essential to the long-term goals of the Forest. The diversity of habitats on the Forest has changed from historic times to current conditions, and will continue to change. Wildlife community diversity is affected both by the amount and kinds of habitats on the Forest, and by the amount and distribution of successional stages. Wildlife-related diversity elements include:

- viability, distribution, and abundance of animal populations - this includes maintaining viable populations of all threatened, endangered, and sensitive wildlife and fish and not eliminating any species from an area;
- structure and composition of forested habitats, including diversity of tree species, and numbers of horizontal layers of vegetation at the ground, shrub, understory tree, and overstory tree levels;
- maintaining long-term productivity of habitats, including the factors which form the basis for these habitats, such as maintaining soil productivity, dead and down trees, and a duff layer; and
- fragmentation and reduction of scarce or fragile habitat types, such as old growth, riparian communities, cliff, cave, and talus habitats, and hardwood communities.

(Also refer to the previous discussions on Soil, Diversity of Vegetation, Diversity - Old Growth, the above text on wood residue, and the Fire section later in this chapter.)

WILDLIFE

The abundance and distribution of animal species is a key element of diversity. Typically, animals are dependent upon or frequently use certain vegetation types or successional stages that have been previously discussed. Consequently, managing for the maintenance of diversity of vegetation is the foundation for maintaining diversity of wildlife. This is the general means of ensuring the continued existence of healthy populations of species. However, some wildlife species are, for a variety of reasons, low enough in numbers that special management emphasis and protection are necessary to maintain or recover their populations. These are species which are on the Federal list of threatened and endangered species, or which are on the Forest Service's sensitive list for the Pacific Northwest Region. These are discussed below.

Significant differences in elevation and climate create a natural and diverse mosaic of habitats within the Forest boundary. These habitats provide for approximately 276 wildlife species. Some are residents, others migrate through the Forest. There are 29 species of reptiles and amphibians, about 174 bird species, and 73 species of mammals (Guenther and Kucera 1978).

One Federally designated threatened species, the bald eagle, and three Federally designated endangered species, American peregrine falcon, grizzly bear, and gray wolf, occur on the Forest.

Big game species include black-tailed deer, Roosevelt elk, black bear, cougar, and mountain goat. Upland game species include blue and ruffed grouse, cottontail rabbit, and band-tailed pigeon. Predators on the Forest are bobcat, coyote, and raccoon. Nongame species include reptiles, amphibians, birds of prey (raptors), other birds, and small mammals.

Wildlife habitat is directly related to the vegetative condition and species mix occurring in a particular habitat. The natural process by which one plant community or stand condition changes into another is known as succession (Hall and others 1985a). Edges are places where plant communities or geomorphic features (water, cliffs, etc.) meet or where successional stages within plant communities come together. Induced edges result from disturbance factors and tend to be relatively short-lived (e.g. wildfire, flooding and erosion, disease and insect outbreaks, timber harvest, planting) (Logan and others 1985). These areas are usually richer in number of species of wildlife than adjoining plant communities or stand conditions.

Habitat For Management Indicator Species

To help determine the effects of management activities on wildlife, several species and groups of species were chosen as management indicators. One type of indicator species represents a number of other wildlife species that depend on or prefer similar habitats. Species selected generally require the largest amount of a habitat type, so that managing the larger habitats should provide for those species that require smaller amounts of the same habitat or certain components of that habitat.

Management indicator species (MIS) are designated and monitored as one way of assessing the effects of management activities (timber harvest, road construction, etc.) on the viability of all vertebrate wildlife populations on

the Forest. If the MIS populations remain viable under planned activities, it is a good indication that all other species' populations are also remaining viable.

Environmental factors that influence wildlife use of a specific habitat type include species composition of the plant community, the successional stage of the surrounding stand, elevation, the condition of the habitat type, the proximity to water, and the wildlife species present.

Management indicator species were selected for three habitat types with special management concerns: 1) old-growth and mature forest; 2) snags and dead and defective standing and down tree habitat; and 3) big game winter range. In addition, all threatened and endangered species are indicator species. Monitoring the effects of forest management activities on these species is critical to ensuring their protection. Threatened, Endangered and Sensitive Species are discussed in detail, below. Table III-25 displays the habitats and their associated indicator species. (Each MIS species is then discussed, in order.)

Table III-25
Wildlife Management Indicator Species
Ecological Indications Species

Habitat Type	Indicator Species
Threatened and Endangered Species Habitat	Bald Eagle, American Peregrine Falcon, Grizzly Bear, Gray Wolf
Old-Growth and Mature Forest	Northern Spotted Owl, Pine Marten, Pileated Woodpecker
Snags and Downed Logs	Primary Cavity Excavators
Big Game Winter Range	Black-Tailed Deer, Roosevelt Elk, Mountain Goat

Threatened and Endangered Habitat and Occurrence

Threatened and Endangered animals occurring on the Mt.Baker-Snoqualmie are the bald eagle, American peregrine falcon, grizzly bear, and gray wolf. There are no known federally-listed plants on the Forest.

Bald Eagle

Washington State has the largest population of wintering bald eagles in the lower 48 states, over 2370 birds in 1988, with 267 occupied nesting territories and a total of 322 territories (occupied or not) with one or more nests (Washington Natural Heritage Data Base 1988). Most of the birds are found in forested areas west of the Cascade Mountains. The 1988 Washington Midwinter Bald Eagle Survey (coordinated by the Washington Department of Wildlife) shows an increasing trend in bald eagles wintering in Washington, with a consistent percentage of immature eagles.

Much of the bald eagle activity takes place on lands outside the National Forest boundary. Several communal night roosts occur on state and private lands. Within the Forest boundary, the most significant bald eagle activity occurs near the town of Skykomish; this includes feeding, nesting, a staging area and communal night roosts. Each of the five Ranger Districts has several identified or suspected roost and perch tree areas that receive use during some years.

The habitat needs of the bald eagle vary with the birds' activities and behaviors. Individual eagles exhibit variable patterns of use yearly, by area and season. Eagles may be absent from a certain area one year and then return, in variable numbers, in successive years (Steenhof 1978). Apparently, eagle distribution at any one time is determined largely by availability of food over several entire river basins. Consequently, foraging, perching and roosting habitat may be properly identified only after several years of investigation. Nesting, roosting and perching habitats are more apt to be adversely affected by human activities than are foraging habitats (Stalmaster and others 1985).

Bald eagles spend a large portion of the day perching (Stalmaster and others 1985). Eagles usually perch on the tallest tree on the edge of stands; snags are ofter preferred. Foraging habitat is almost always associated with water and preferably is in large areas with a wide visual field.

The following subsections describe bald eagle wintering and nesting habitats on the Forest.

Bald Eagle Wintering Habitat. During the winter, bald eagles often roost in large groups; non-breeding eagles may roost together in the spring and summer (Stalmaster and others 1985). Roosting areas are usually used only at night, although some eagles may remain there throughout the day. The eagles may congregate in specific trees, or staging areas, before flying to the roost area (Stalmaster and others 1985). Winter roost sites may be located in coniferous forests, which offer the most protection from the weather, or in deciduous forests, especially in riparian habitat (Stalmaster and others 1985). Roost trees are usually larger than other trees in the stand and are mature or old growth. Selected trees may be Douglas-fir, black cottonwood, western redcedar, big leaf maple, or snags (Stalmaster and others 1985).

The largest concentration of wintering eagles in the State occurs on the Nooksack River system; bald eagles also gather along the Skagit, Sauk, Suiattle, and Skykomish Rivers (Stalmaster 1983). Feeding along these rivers is related to the salmon spawning in the lower reaches of the rivers and the availability of salmon carcasses. As many as several hundred bald eagles winter on the forest, approximately 15 percent of the State total.

Disturbances, including vehicular traffic, aircraft, and winter recreation (mostly winter river boating), may affect the large winter concentrations of bald eagles on the Forest. Avoidance flights caused by human disturbances alter eagles' behavioral patterns, restricting habitat use and wasting energy in flight (Stalmaster 1981). Vegetative buffers between eagles and humans usually reduce the effect of minor noise disturbances (Stalmaster and others 1985). The USDA Forest Service, Pacific Northwest Research Station is currently conducting a study to determine the significance of the effects of recreation activities on wintering bald eagles on the Skagit River.

Bald Eagle Nesting Habitat. Bald eagles prefer old growth or mature second growth for nesting (Stalmaster and others, 1985). Bald eagle nests are usually built in trees that dominate the surrounding forest and have large horizontal branches. Trees selected for nesting are usually near water, for easy access to food. Osprey nesting habitat is similar, except that nest trees are usually snags or broken top trees, often interspersed in bald eagle habitat.

Bald eagle productivity during nesting may be adversely affected by human presence. Even temporary abandonment of a nest, due to disturbance, may result in chilling or overheating of, or predation on eggs or young. However, the eagles' responses to disruption are inconsistent among pairs (Stalmasters and others 1985). Guidelines for acceptable activities around, and minimal distances of project activities from, active nests sites provide protection for nesting eagles. There is one known active bald eagle nest site which has been observed for the past two seasons and three potential (not active) nest sites (two of the nest sites are in one pair territory). An interagency management plan, the Final Pacific States Bald Eagle Recovery Plan, was approved in 1986. It calls for a buffer of at least 660 feet around the nest tree(s) of these sites; the eniter buffered area is to receive protection and special management.

A study of bald eagles on the Skykomish District was conducted during the winter of 1977-78. The study objectives were to determine the population dynamics and habitat requirements of bald eagles wintering along the Skykomish River and to determine the compatibility of bald eagles with Forest Service activities. The Mt. Baker, Darrington, and Skykomish Ranger Districts, in conjunction with the USDI Fish and Wildlife Service, the Washington State Department of Wildlife, the Nature Conservancy, and citizen volunteers, are conducting multi-year surveys of eagle winter feeding and roost areas in the Skagit, Sauk and upper Cascade River drainages.

American Peregrine Falcon

The American peregrine falcon, an endangered species, is currently showing a low reproductive rate in the Pacific Northwest (Larrison 1981). Peregrine falcons are most numerous along the Washington coast and less common in interior Washington (Larrison and Sonnenberg 1968). They prey on nesting colonies of water birds, migrating waterfowl and shorebirds, songbirds, and other birds. Peregrines usually nest on ledges or in small caves on high vertical cliffs overlooking plains or bodies of water (Welty 1975). They forage over adjacent tideflats and beaches in coastal areas and over marshes and prairies in interior areas (Larrison 1981). Peregrine falcons are mainly found in open country at other times of the year (Larrison 1981).

The peregrine falcon is an infrequent visitor to the Forest during spring and fall migration. At present, there is one historical and one potential nest site on the Forest. There are no known active nest sites at present. The "Pacific Coast Recovery Plan for the American Peregrine Falcon" (1982) is currently being revised.

Grizzly Bear

Grizzly bear occurring on the Forest are part of the North Cascade Grizzly Bear Ecosystem (NCGBE) as described in the "Grizzly Bear Recovery Plan" (1982).

The grizzly bear is omnivorous and is a very mobile and secretive animal. The habitat types and conditions selected by grizzlies is highly variable, influenced primarily by their search for food. Data indicates that the grizzly bear prefers small interspersed openings and meadows for feeding, in close association with forest cover for resting and hiding (Ruediger and Mealey 1978). These preferred habitat types include lower elevations, riparian areas, drainage bottoms, avalanche chutes, and big game winter ranges during early spring. As the seasons progress to late spring, summer, and fall, grizzly bears follow the receding snows to higher elevations to feed on succulent herbaceous materials in wet meadows and openings. Grizzlies will also feed on berries, small mammals, and carrion if available (US Department of the Interior, Fish and Wildlife Service 1982).

Presently, the USDI Fish and Wildlife Service, USDI Park Service, the Washington State Department of Wildlife, and the Forest Service are working together to evaluate habitat suitability and capability, habitat use information and population estimates for the North Cascades Ecosystem, which includes portions of the Mt. Baker-Snoqualmie National Forest. This is a five-year project which includes public information, education and input. The Department of Wildlife's portion of this is an attempt to validate whether there is a resident population of grizzly bears in the North Cascades. These projects are due to be completed in December 1990.

The number of bears utilizing the NCGBE or the number using Forest lands is not known. The Forest has documented 36 grizzly bear observations from the mid 1850's to 1983. Thirty-three of these 36 observations, 92 percent, were on lands currently designated as wilderness; 2 of the remaining 3 were in unroaded areas and 1 sighting was in roaded lands. In 1989, grizzly bear signs were confirmed at two sites by Department of Wildlife biologist Jon Almack: one on the Wenatchee National Forest, and one in the Ross Lake National Recreation Area. Most sightings on the Forest have been in the Glacier Peak Wilderness.

Grizzly bear occurrence on the Forest probably does not represent an established population, but wandering single bears in search of food.

The combination of diverse plant communities, inaccessible topography, and remote locations have facilitated the maintenance of habitat characteristics attractive to the grizzly bear.

Gray Wolf

The gray wolf (Canus lupis) once roamed over most of North America. It is now found only in limited areas of Alaska, Canada the northern portions of Washington, Idaho and Montana. The gray wolf is an extremely adaptable animal, but its numbers are greatly diminished due to human predation, loss of habitat to development and loss of suitable prey - especially deer and elk - due to reductions in big game habitats.

The gray wolf is a social animal; it lives in packs of 2 to 15 animals, formed primarily of family members and relatives (Whitney 1942). The wolf mates for life. Unlike many mammals, wolves do not make regular use of shelters. A den is constructed or occupied only for the birth and care of the young, a period of about two months. Dens are usually located on slopes, ridges, or other high ground, and near a source of water.

There have been 16 probable and possible wolf sightings reported on or near the Forest, dating as recently as 1988 (Laufer and Jenkins 1989). Geographical concentrations of the reports are found near Baker Lake on the northern part of the Forest, and near Mount Rainier, the southern-most portion of the Forest. Sightings have also been reported on Darrington District. Laufer and Jenkins (1989) report a total of 83 wolf sightings in the North Cascades since 1946; 49 since 1973. Of the reports since 1973, they classified nineteen of them as probable wolf sightings. Another concentration of sites is near Ross Lake, east of the Forest. Many other portions of the Forest are also likely to be good habitat for the gray wolf.

There is no formal recovery plan for the species in the Pacific Northwest. The Washington Wolf Project acts as a clearinghouse for information on gray wolves. The land managing agencies in the area are considering a study to determine whether or not reintroduction or recovery of the species is feasible in the North Cascades.

Candidates for Federal Listing

Five Pacific Northwest Region Sensitive animal species are candidates for federal listing. Category 2 candidate species are the bull trout, the marbled murrelet, Townsend's big-eared bat, the California wolverine, and the North American lynx.

Proposed for Federal Listing

The northern spotted owl is a classified Pacific Northwest Region Sensitive species and is proposed for Federal Threatened and Endangered listing. A decision on listing is expected from U.S. Fish and Wildlife Service in 1990. The northern spotted owl is discussed in more detail in the next sub-section.

Old-Growth and Mature Forest

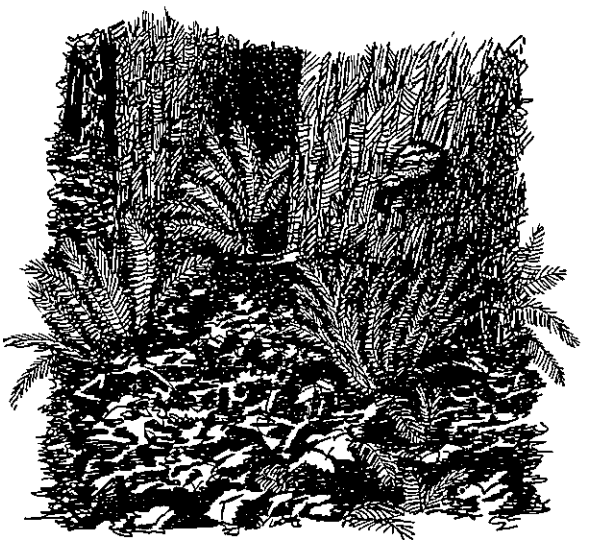
As discussed in Diversity - Old Growth, earlier in this chapter, the old-growth coniferous forest is a habitat ecosystem of particular concern. Depending on the site, 175 to 250 years are needed for a natural old-growth coniferous forest to develop. The loss of old-growth forest or changes in use patterns of the remaining old growth have significant effects on the wildlife that use it.

It is necessary to define old growth forests in terms of multiple criteria, rather than a single characteristic, such as size as age of trees (Franklin et al 1986). Old-growth stands have the following characteristics: mature and overmature trees in the overstory that are well into the mature-growth stage; a multi-layered canopy and trees of several age classes; standing dead trees and down materials are present; and evidence of human activities may be present but do not significantly alter the other characteristics (USDA Forest Service 1984b). (For more information, see Franklin 1981.)

The size of an old-growth stand affects its function as an ecological unit. Patches of smaller sizes may be dominated by edge effects - effects of being close to younger stands or disturbed areas - and they are vulnerable to major disturbances such as windthrow (Franklin et al 1986).

At present, there are about 643,500 acres of old growth on the Mt. Baker-Snoqualmie; these acres contain mature and large sawtimber, 21 inches and larger in diameter (see discussion on Diversity - Old Growth, this chapter). Of the total, 232,500 acres are located within designated wilderness. A total of 276,600 acres (43 percent) are tentatively suitable for commercial timber harvest.

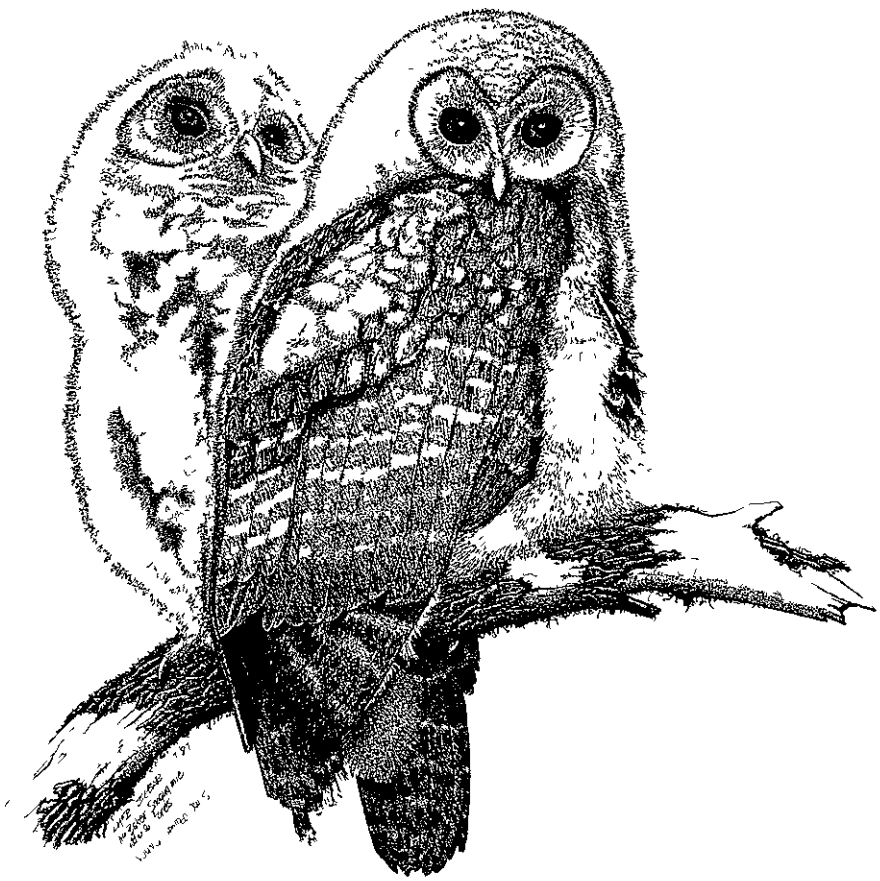
Though few plant and animal species are totally dependent on coniferous old-growth ecosystems, many find optimal habitat in old growth and mature forests; these include species such as great blue blue heron, osprey, goshawk, and numerous species of woodpeckers. The northern spotted owl is a species closely related to old-growth habitat, generally under 4,000 feet in elevation. The spotted owl is a Washington State-listed endangered species, a Pacific Northwest Region Sensitive species, and is proposed for federal listing. (See Current Situation, below.)



Northern Spotted Owl

The spotted owl is a medium-sized, nocturnal bird which inhabits mountainous, forested regions of the West. Three subspecies have been described. One, the northern spotted owl, was once common in the extensive old-growth coniferous forests of Washington, Oregon and northern California. Northern spotted owls live primarily in dense, mature and old-growth forests, commonly dominated by Douglas-fir, although other forest types and occasionally, younger age stands are used. Mature and old-growth forests contain the structural characteristics and type of vegetation that best provide spotted owls with food, cover, nest sites, and protection from weather and predation. Northern spotted owls usually nest in cavities created by broken tops of large, old trees, and forages in older stands in the winter (USDA 1988a).

Radio-telemetry studies of a small sample of spotted owls indicate that the average size of an individual spotted owl's home range in Washington is 7,300 acres. The average amount of mature and old-growth forest within this home range is 4,200 acres. There is some overlap in areas used by some adjacent pairs of owls (USDA 1988a). Extensive reviews of existing information on the spotted owl can be found in U.S. Fish and Wildlife Service (1989) and USDA (1988).



Habitat. The older forest habitat used by spotted owls is characterized by the presence of multi-layered stand structure, dense tree canopy closure, large trees with cavities or broken tops, and abundant standing and down dead trees (U.S. Fish and Wildlife Service 1988). In different portions of the owl's

range, the forest stands which provide these characteristics may vary. The suitable habitat definition used in this Forest Plan is displayed in Table III-26.

Table III-26
Definition of Spotted Owl Suitable Habitat, Mt. Baker-Snoqualmie NF

Physical Attributes		
	Elevation	less than 4,200 feet (Darr/Sky/N. Bend RD) 1/ less than 5,000 feet (White R. RD) 2/ less than 4,000 feet (Mt. Baker RD)
	Patch (or block) Size	greater than 21 acres
Vegetation Attributes		
	Overstory Characteristics	
	Dominant Tree Species	Douglas-fir Western hemlock Western redcedar
	Age and Condition	Old Growth and Mature, older than 230 years
	Understory Characteristics	Multi-layered, Uneven Aged
Structural Attributes		
	Live Trees	
	Tree Size	greater than 21 inches DBH 3/; 17 to 20 inches DBH but contains trees over 21 inches DBH 2/
	Tree Density	more than 15 trees per acre
	Canopy Closure	greater than 70% closed
	Dead and Down	
	Snag Size	greater than 21 inches DBH
	Snag Density	more than 3 per acre
	Down Logs	high density of down logs

1/ Darrington, Skykomish, and North Bend Ranger Districts
2/ Mt. Baker-Snoqualmie habitat that did not meet all of the characteristics but in which northern spotted owls were found more than a single time during daylight hours.
3/ Diameter at breast height (4'6" from ground).

This definition is very similar to that used on the Gifford Pinchot National Forest. The Mt. Baker-Snoqualmie has included elevational adjustments for different parts of the Forest, based on the area's stands structure and type, and records of adult spotted owl occurrence. Spotted owl habitat on the Wenatchee National Forest, adjacent to this Forest and east of the Cascade Mountain crest, has somewhat different attributes. There are differences between the two Forests in primary overstory tree species, typical minimum age for stands, and diameter of overstory trees; there also appear to be differences in primary prey species. On the Wenatchee National Forest, spotted

owls sometimes nest on mistletoe platforms in trees of smaller diameter than the nest trees on the Mt. Baker-Snoqualmie N.F. (USDA 1989; USFWS 1988).

Current Situation. There are currently about 499,200 acres of suitable spotted owl habitat on the Mt. Baker-Snoqualmie; refer to the wildlife resource map, in the packet of maps accompanying this FEIS. Some of these suitable habitat acres are so fragmented that their primary contribution to spotted owl habitat may be as islands of dispersal habitat between reproductive pair habitat areas.

Tools used to define suitable spotted owl habitat for this plan and for identifying a network of spotted owl habitat areas were:

- vegetation information from the Total Resources Information System;
- aerial photography;
- ground-checking of potentially suitable habitat areas;
- stand examination information;
- personal knowledge of district personnel of characteristics of areas.

As Landsat information on vegetation and a Geographics Information System become available to the Forest, and as further vegetation surveys are collected - which include more detailed structural information on forest stands - the definition and mapping of suitable habitat will be refined.

The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (FSEIS) (USDA 1988a) - that addressed northern spotted owls - estimated present spotted owl habitat capability on the Forest at 121 pairs.

As mentioned above, a decision from USDI Fish and Wildlife Service on federal Threatened and Endangered listing for the northern spotted owl is expected in 1990. An Interagency Scientific Committee was established, under the authority of an interagency agreement (August 1988) between USDI National Park Service, USDA Forest Service, USDI Bureau of Land Management, and UDSI Fish and Wildlife Service to address the conservation of the northern spotted owl. This Committee recommended a conservation strategy in April, 1990. Section 318 of the 1990 Interior Appropriations Act directs the Forest Service to consider the recommendations of the Committee in reviewing and revising the 1988 FSEIS decision regarding the species. A new decision on management direction for the spotted owl decision is expected in 1990.

Northern Spotted Owl Sightings. Between 1980 and 1989, there have been sightings of 55 pairs of spotted owls and 177 individuals on the Forest. It is difficult to establish an exact number, since it is often not possible to know whether pairs in subsequent years or in adjacent areas are the same owls. During a fairly intensive surveying and monitoring effort in 1989, a total of 100 spotted owls were detected: 15 pairs with a total of 28 young, 12 pairs with no young, and 46 individuals which were not paired or not known to be paired. Fifty-four of these individuals (18 of the pairs) are believed to be owls not located in previous years. The remainder are likely to be repeat sightings of spotted owls from previous years, or pairs or individuals which replaced owls located in previous years.

Management Requirement. Also refer to Chapter II, development of management requirements, Appendix B and Appendix H of this document. Under FSEIS direction, a network of spotted owl sites was established to meet management requirement for spotted owls. This MR network consists of 76 habitat areas;

about half are located on lands tentatively suitable for timber harvest (the actual number on lands suitable for timber harvest varies by alternative). The remaining half are on reserved lands, not available for timber harvest.

Within 20 designated habitat areas (MR habitats on lands suitable for timber harvest) that were monitored in 1989, 85 percent had one or more owls present; 50 percent had pairs of owls, and 88 percent of those pairs produced young which fledged from the nest. A total of 39 percent of the network sites monitored fledged spotted owls. Spotted owls evidently do not breed every year (USDA 1989; USDI 1988) and reproduction appears to occur at a lower rate on this Forest than on many others.

Within the current 39 designated habitat areas, 94 percent have had spotted owl presence at some time in the last decade; 62 percent are known to have had pairs and 43 percent are known to have fledged young. Ninety-four percent of these areas have been checked for owl presence at this time. Of the total known pairs on the Forest in the last decade, 63 percent are within the spotted owl MR network, and 73 percent of the reproductive pairs are in the network. Some of the spotted owls outside of the network are older sightings which have not been confirmed recently.

SOHA Size. Standards and guidelines from the FEIS set spotted owl habitat areas (SOHA) size at 2200 acres, with SOHA's to be smaller only where fewer acres of habitat remained and the site was needed to maintain the species' distribution on the Forest or to provide connections between network sites. All habitat areas within reserved areas are at least 2200 acres in size. Of the designated network sites on the Forest, 78 percent have 2200 or more acres of suitable habitat within a 2.1 mile radius of the center of the soha; 89 percent have at least 2000 acres; 95 percent have over 1,650 acres and 97 percent have at least 1000 acres of suitable habitat.

Relationship Between Spotted Owls, Other Owls. Barred owls have been found in some of the spotted owl network sites, and great horned owls have been located in a few. Barred owls began to extend their range into the forested areas west of the Cascade Crest in the early 1980's. The relationship between the two species is not well understood, although behaviors have been observed which indicate that barred owls may sometimes be able to displace spotted owls from higher-quality habitat, and great horned owls may prey upon young spotted owls (USDA 1989). Barred owls can use a relatively wide range of habitats, including spotted owl habitat. A better understanding of these relationships may result from studies which are part of the USDA Forest Service Pacific Northwest Research Station's Old Growth Research project, and the Region 6 Forest Service monitoring of spotted owl habitat areas.

Pine Marten and Pileated Woodpecker

Habitat needs for the pine marten and the pileated woodpecker can be met in mature and old-growth forest. However, the optimum habitat for these species is probably old growth. These species were selected as indicators for mature and old-growth habitat.

Pine martens primarily inhabit dense coniferous forests where soil conditions support the understory vegetation required by voles, the pine marten's preferred prey species (Koehler and others 1975). Stands of mature to overmature coniferous forest comprised of at least 40 percent fir, having a canopy closure greater than 50 percent, with 20 to 50 percent of the ground surface covered with dead and down woody material, provide near optimal pine marten habitat during the winter months. The pine marten relies on uncut and partially cut coniferous stands in winter but is able to tolerate and make use of extensive areas of re-generating clearcuts (Stevenson 1982). During summer months, pine martens sometimes forage in open rock slides, brush fields, and meadows (Marshall 1951).

The pileated woodpecker is dependent on snag habitat for nesting, roosting, and feeding. Generally, large snags, 25 inches DBH on the west side of Washington, are used for nesting (Neitro and others 1985). The foraging habitats of this predator of forest insects results in a need for dead wood in snags, logs, and naturally created stumps. As the woodpecker preys on insects, it also creates holes for a variety of other cavity-dwelling wildlife. As a result, lack of adequate habitat for the pileated woodpecker seriously effects the diversity and stability of the ecosystem (Bull and Meslow 1977).

The present habitat capability for pine marten, in 634,500 acres of habitat, is about 3,688 females and 922 males - a total of 4,610 pine marten. The same area provides habitat to support 922 pileated woodpecker pairs. It is unlikely that all potential habitats are occupied at any one time, so the actual number, though unknown, is likely to be slightly lower.

Snags and Downed Logs

Large standing dead and/or defective trees (snags) and downed logs are important to the total makeup of the coniferous old-growth ecosystem (Franklin and others 1981). Snags in the forests of western Oregon and Washington are used by nearly 100 species of wildlife, of which at least 53 species (39 birds and 14 mammals) are cavity-dependent (Neitro and others 1985). Snags are used for nesting, roosting, foraging, and other functions, such as protection from adverse weather (Neitro and others 1985). A number of woodpeckers, owls, sapsuckers, and others are dependent on snags. Snags distributed over a larger area is important (Mannan 1983); isolated snags are not utilized as much as clumps of snags for nesting and feeding (Raphael and White 1984).

Dead and down woody material, in the form of stumps, root wads, bark, limbs, and logs not only are important in mineral cycling, nutrient mobilization, and natural forest regeneration but, also, create structure and diversity of habitats that are valuable to a great many wildlife species (Maser and others 1979, Bartels and others 1985). Dead and down material is used by 149 terrestrial wildlife species in the western Cascade forest, including the pine marten (Bartels and others 1985). Past silvicultural treatments involving

clearcutting have depleted many acres of old growth and eliminated most dead and defective trees. Since 1979, the Forest has actively planned for retention of standing and down wildlife trees as a part of timber harvest activities.

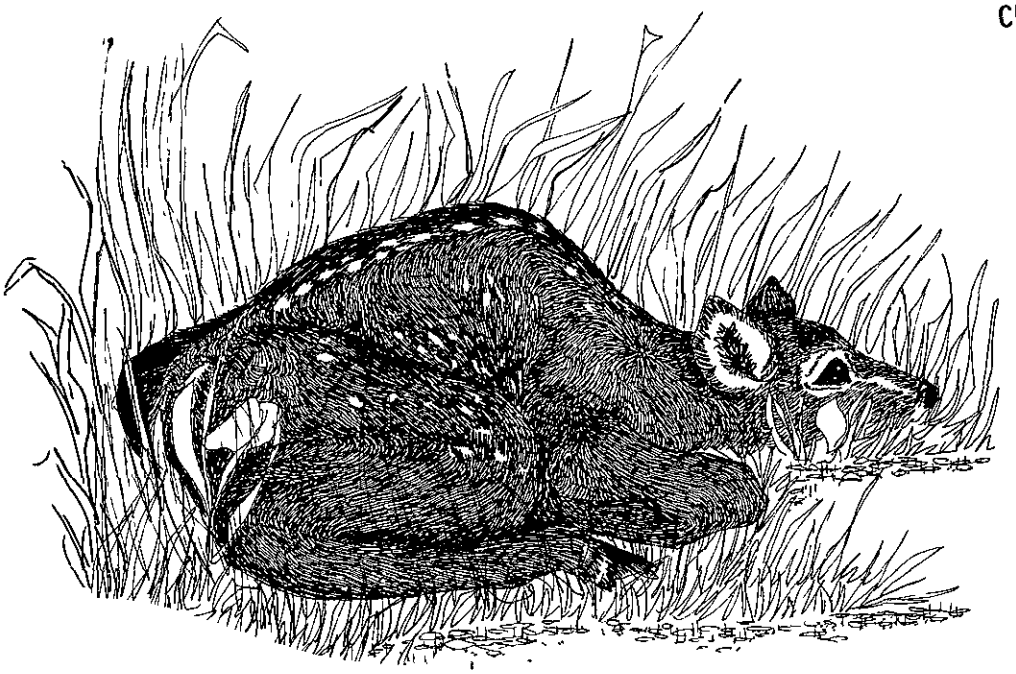
Research documented in The Seen and Unseen World of the Fallen Tree, Maser, C and J.M. Trappe, Gen. Tech. Rep. PNW-164, indicates that large woody material plays and important role in soil productivity. Subsequent research (Coarse Woody Debris in Douglas-fir Forests of Western Oregon and Washington, Spies, T.A. and J.F. Franklin, Ecology, June 1988) determined the amount of dead and down logs typically present in the forests of western Washington and Oregon. Large woody material was lowest on dry sites where fire was more common, and highest on moist sites where fire played less of a role in the history of the stand. It also varied from north to south and from the Cascades to the coast. It averaged 4500 cu ft (55 tons) per acre in both old growth forests and young natural stands. Mature stands (second growth) had approximately half the volume of dead and down logs as old growth stands or young stands. Much of the large wood from the previous stand had decayed but the current stand had not yet begun to break up so no new logs had fallen to replace them.

Franklin and Spies concluded that "Forest management activities greatly reduce coarse woody debris below minimums typically encountered under natural ecosystem dynamics... Our research suggests that if managers plan to maintain even moderate amounts of coarse woody debris in managed forests, substantial changes are required in current harvesting and silvicultural practices, and management guidelines will need to take into account successional, site, and geographic variation." The best available model for maintaining long term productivity is the natural forest ecosystem.

Dead and defective trees, standing and downed (logs) are present over the 77 percent of the Mt. Baker-Snoqualmie that is forested. The conifer and conifer-hardwood mix portions (66%) have a high level of snags - enough to support 80-100 percent of the potential populations of cavity excavators, except for those acres of the Forest which have been harvested in the past. Fourteen percent of the Forest is in high-elevation or low-productivity sites, with a more open, park-like canopy and, consequently, with fewer dead trees and downed logs. Habitat remains for high densities of cavity excavators and species dependent on dead and down logs on 65 percent of the Forest.

Big Game Winter Range

Black-tailed deer and mountain goat are found throughout the Forest. Roosevelt elk are concentrated primarily in three distinct groups. The White River group near Mt. Rainier National Park, the Snoqualmie group on the south end of the Forest, and the Nooksack group on the northern portion of the Forest. These indicator species are important as hunted and viewed wildlife, and they represent other species, like cougar and blackbear, which use a mixture of optimal cover, openings, and other stages which are affected by human activities.



Winter range areas are essential to maintaining deer, elk, and mountain goat populations. During mild to average winters, these animals find forage and cover up to 3,000 feet in elevation. Important winter range, which generally occurs below 2,200 feet, provides needed food and cover to maintain big game herds during severe winters. Figure III-9, on the next page, shows the general locations of deer, elk, and mountain goat winter ranges on the Forest.

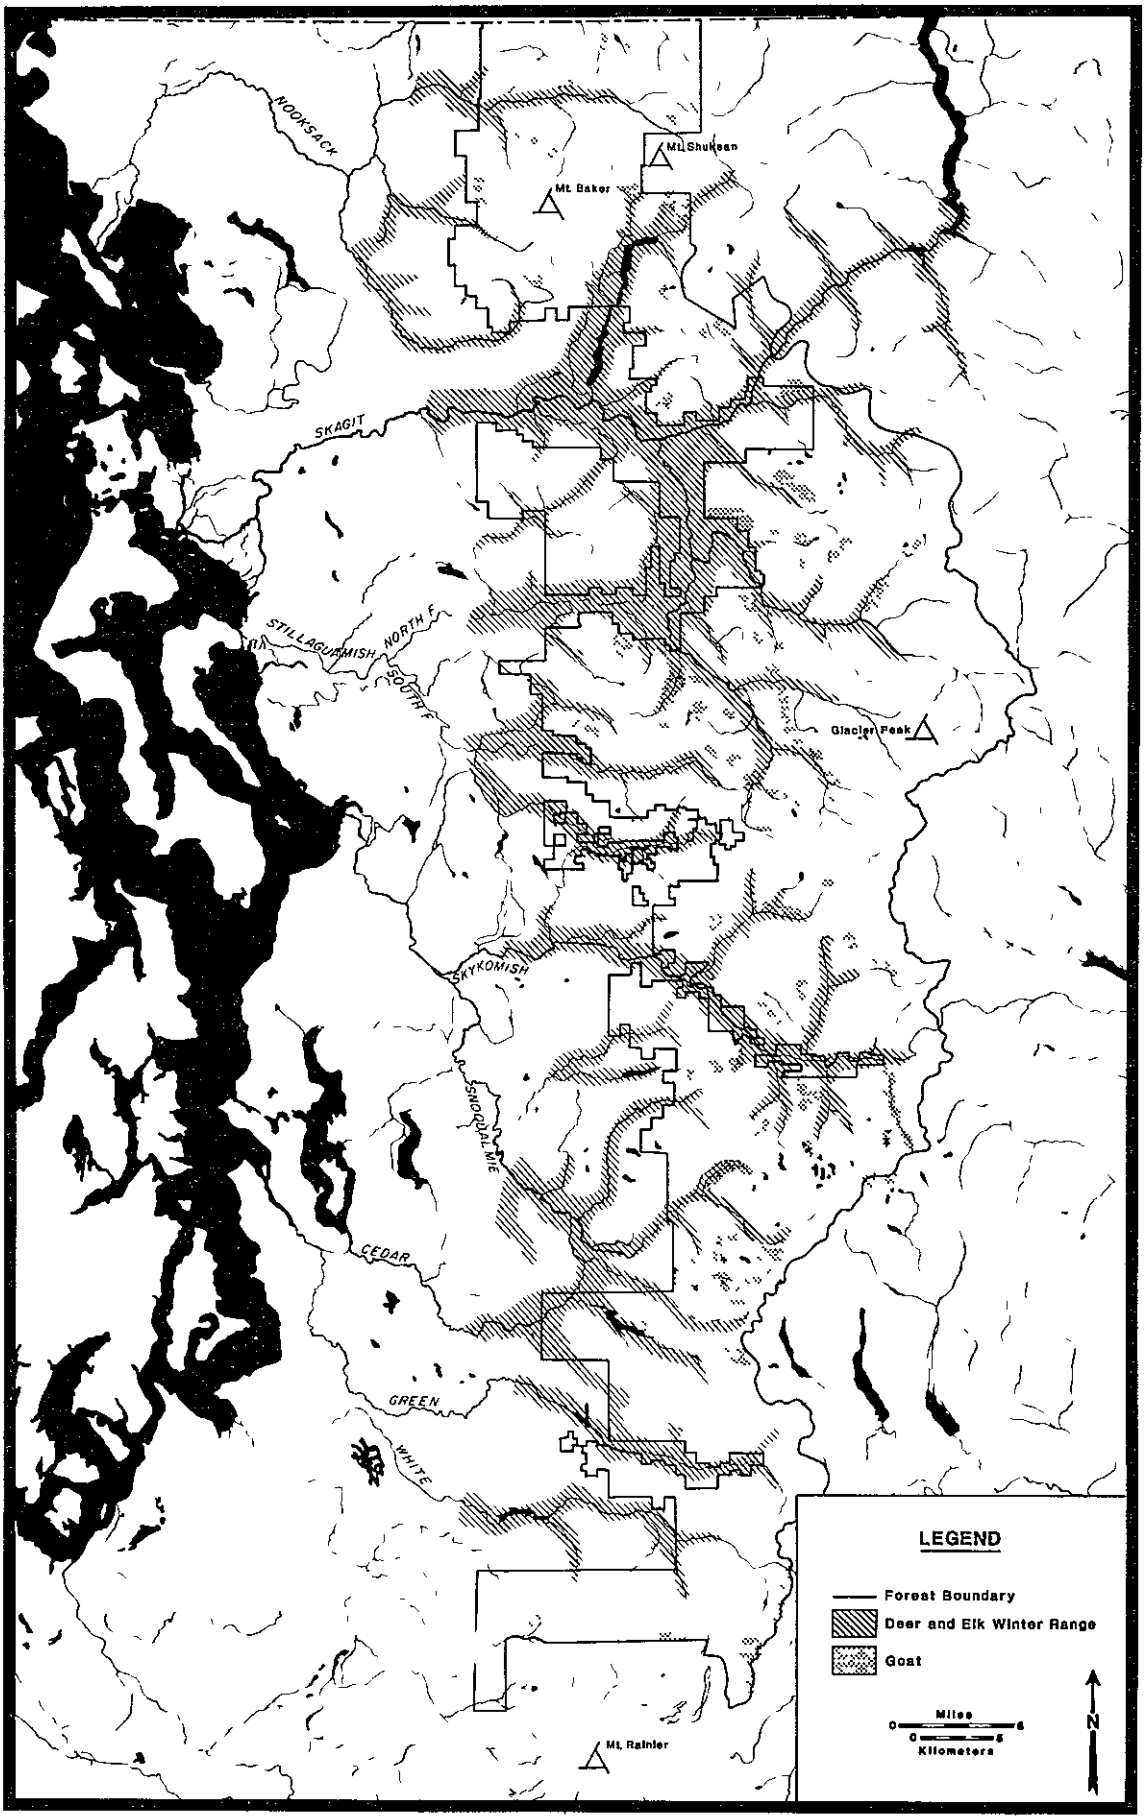
Thermal cover is considered to be the most critical component of big game winter ranges. Old growth is optimal thermal cover, providing cover along with maintenance forage (Jones 1974, Taber and Hanley 1979).

Approximately 173,300 acres of suitable deer and elk winter range occur on the Forest. Based on the habitat capability model used by this Forest, this would support about 13,330 deer and 682 elk. Deer and elk winter ranges on the Forest are generally associated with drainages and their adjacent riparian areas which provide necessary cover and forage at the lower elevations. The relationship of the Forest to private and State-owned lands is such that, in winters of heavy snowpacks, elk and deer winter on a greater portion of the range off the Forest. Development for recreation, agricultural, residential, and commercial uses on public lands is decreasing the quality and quantity of wintering areas. As off-Forest winter ranges decrease, more emphasis will be placed on improved management of the Forest winter ranges.

Mountain goat winter ranges are generally steep, rocky slopes of 40 degrees or more, adjacent to forage and cover. During periods of heavy snowfall, mountain goats are forced to migrate to lower elevational winter ranges with mature and old-growth timber. These areas modify the harsh environmental factors by intercepting wind, rain, and snow, in conjunction with providing tree lichens, mosses, grasses, and shrubs used as forage. There are about 113,800 acres of land identified as mountain goat habitat on the Forest, estimated to currently support about 1,300 mountain goats.

The habitat capability for goats, based only on vegetation condition, is currently estimated to be 1,450 goats; however, the current population is estimated to be about 1,300. Parasites, over-hunting, and human disturbance have been suggested as possible causes of this difference (Welch and Raedeke 1990).

Figure III-9 Deer and Elk Winter Range / Mountain Goat Habitat On or Adjacent to the Forest



Sensitive Animal Species

It is Forest Service policy to protect the habitat of federally listed threatened and endangered species, and Forest Service sensitive species from adverse modification or destruction, as well as to protect individual organisms from harm or harassment as appropriate (FSM 2670.32). All Forest Service projects, programs, and activities are reviewed for possible effects on threatened, endangered, and sensitive (TE&S) species. Should any of these species be added to the Federal Threatened and Endangered Species list, they would be managed according to the provisions of the Endangered Species Act.

Table III-27
Pacific Northwest Region Sensitive Species

	Scientific Name	Common Name	Classification
	Salvelinus confluentus	bull trout	Candidate 1/
*	Gavia immer	common loon	Sensitive
*	Strix occidentalis caurina	northern spotted owl	Candidate 2/
*	Brachyramphus marmoratus	marbled murrelet	Candidate 1/
*	Plecotus townsendii townsendii	Townsend's big-eared bat	Candidate 1/
	Gulo gulo luteus	California wolverine	Candidate 1/
*	Felis lynx canadensis	North American lynx	Candidate 1/

1/ Candidate for Federal listing; further information needed
2/ Proposed for Federal listing; decision due June, 1990.

Bull trout: Habitat consists of large rivers and their tributaries both above and below anadromous barriers. Bull trout tend to be more resident than anadromous. They seem to prefer very cold and still water, especially for spawning. According to the Washington Department of Wildlife (Johnston pers. comm.), this species is expected to occur in many of the rivers and streams on the Forest. Due to their similarity to Dolly Varden (Salvelinus malma), this species is difficult to identify.

Common loon: Common loons have been observed during non-winter months. They typically winter along the coast and in coastal estuaries. Nesting habitat consists of bodies of water large enough for take-offs, deep enough for escape-diving, and relatively free of human disturbance. They prefer to nest on islands. There have been 19 reports of common loons (totalling 55 animals) on the Mt. Baker District since 1984. (Habitat requirement information sources: McIntyre 1975; Terres 1980.)

Marbled murrelet: Marbled murrelets are robin-sized seabirds which are distributed along the Pacific Coast from the Aleutian Islands south to central California. They feed on the ocean and nest on land. The breeding ecology and habitat requirements of this species are poorly understood. In northern Alaska, they nest on the ground, but from southeast Alaska to central California, they have been found nesting in large trees that are part of old-growth or mature forest stands. They have been observed 35 miles (56 km) inland. Little is known of their habitat requirements but marbled murrelets are reported to use large trees with moss or lichen covered branches for nesting. (Pacific Northwest Region, Forest Service 1989).

Fewer than 15 nests have been identified for this species within its range (Marshall 1988). Washington's breeding population is estimated at 1900 - 3500 pairs (Speich and Wahl 1987). There have been reports of marbled murrelets on Mt. Baker and Darrington Districts, including the finding of a dead murrelet chick on Darrington District in 1989. The Department of Wildlife coordinated volunteer surveys of a limited amount of inland murrelet habitat in 1988 and 1989. At this time, an estimate of the murrelet population on the Forest is not possible. An intensive study of murrelet habitat and use on portions of Darrington District, funded by the the Forest Service, the Department of Wildlife, and also supported by volunteer individuals and organizations, will begin in 1990. The objective of this project is to identify marbled murrelet inland habitat requirements.

Townsend's big-eared bat: These bats characteristically utilize caves or cave-like structures as hibernacula during the winter. They are highly susceptible to human disturbance during those months. During non-winter months, they also use caves or cave-like structures as nursery sites and as day-roosting habitat. They have also been observed to roost under bridges on the District. As with many bats, they utilize open areas of standing water along streams for feeding on insects. A Forest Service survey by Perkins (1988) found only two occurrences of this species on the Forest, both on Mt. Baker District. Suitable wintering and nursery habitat is limited on the Forest.

Wolverine: The usual habitat of the wolverine is remote timbered areas (Hornocker and Hash 1981; Wilson 1982). According to Hornocker and Hash (1981) radio-telemetry relocation data from Montana showed that dense, young timber stands were least used and that burned-over areas and wet meadows were rarely used. Preliminary results from Oregon (Utzinger unpublished data) indicate that wolverines would most commonly be found above approximately 3500 feet elevation in northern Washington. They may utilize lower elevations during winter months to feed on ungulate carrion. Little is known about the habitat requirements of this secretive animal; but wet areas, freedom from regular human disturbance, and areas that normally have winter snow appear to be important elements (Hornocker and Hash 1981; Wilson 1982). The Forest does not have the information at this time to determine the size of its wolverine population.

North American lynx: Lynxes are typically associated with extensive tracts of dense boreal forest interspersed with rocky outcrops, bogs, and thickets. They are also dependent on the availability of suitable prey. Their primary prey species is snowshoe hare but they also consume small rodents and ground-dwelling birds. (Habitat requirement information sources: McCord and Cardoza 1982.) The Forest does not yet have an estimate of its lynx population.

Other Wildlife Habitats

Overall Deer, Elk, and Mountain Goat Habitat

The current wintering habitat capability of the Forest is 682 elk and 13,330 deer. There is a higher summer habitat capability of 1,233 elk and 19,600 deer. Herd sizes are probably limited by wintering capability. The Forest currently has habitat capability capable of supporting 1,450 mountain goats.

Forage and cover are the main habitat components for big game animals. Grasses and shrubs are important forage for deer, elk, and mountain goats. Thermal cover is forest vegetation with at least 70-percent crown closure. If any part of a created opening is greater than 600 feet from cover, elk, deer, and mountain goats may not fully utilize the newly developed forage or may abandon the area altogether (Barteleme 1981, Witmer and others 1985).

There are two broad habitat types of primary importance to elk, deer, and mountain goats: winter range and summer range. A third habitat type, transitional range, joins the winter and summer ranges together. Within each of the three ranges, specialized habitat may occur. These include riparian zones, natural openings, old growth, and reproductive habitat. Over most parts of the Forest, the abundance and quality of wintering habitat is more limiting to herd sizes than summer range.

A balance of habitat components within each of the three ranges must be maintained so overuse does not occur on any single range. For example, if emphasis is given to optimizing winter range without maintaining usable cover and forage on summer range, animals that normally migrate to summer range will stay on or return to the winter range during the summer. Animals may then use forage during the summer months that is needed for winter survival. Overuse and a lack of forage during the winter causes animals to starve or become too weak to successfully reproduce (Taber 1973).

Migration routes, and fawning, calving, and kidding areas are specialized habitat areas. Fawning and calving areas, which generally are near quality forage and water, do not receive full use if adequate cover is not maintained. Large down logs are often used as cover during birth of the young (Maser and others 1979a, Thomas and others 1979a).

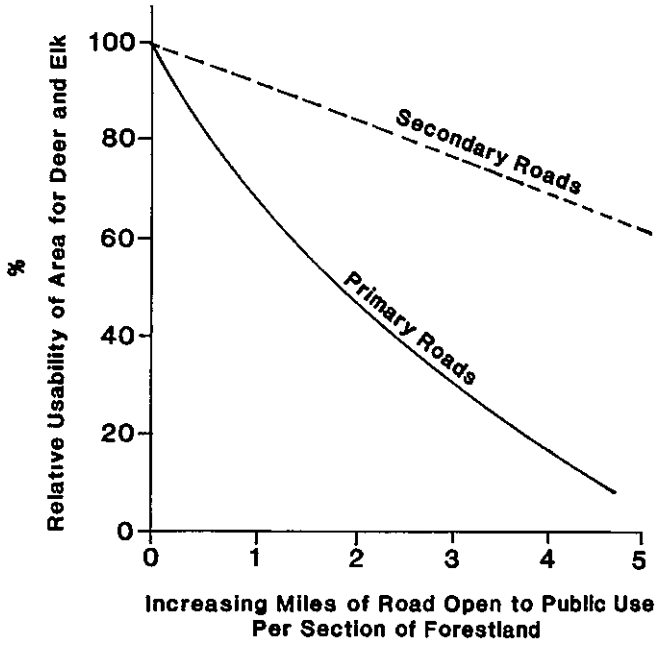
Near-optimal habitat arrangements and conditions for deer and elk contain: 10 to 15 percent forage; 40 to 45 percent thermal/hiding cover; and 37 to 45 percent optimal thermal cover.

A number of studies document the effect of roads and associated traffic on deer and elk habitat use. Generally, increased road density and traffic volume results in decreased usability of adjacent deer and elk habitat (Witmer and others 1985). Decreases in habitat use occur within the 1/4- to 1/2-mile zone on either side of roads with constant traffic (Thomas and others 1979a). Current road density on the Forest is approximately 3.0 miles of road per square mile (640 acres), which results in up to a 30-45 percent reduction in potential carrying capacity for deer and elk (discussed above). Winter range closures of roads in certain areas are used to decrease this impact.

As new roads are constructed for timber and other resource management, habitat effectiveness decreases. Road closures, however, significantly reduce disturbances to deer and elk, and may benefit the species as travel corridors and forage areas. Figure III-10 illustrates the influence of open roads on deer and elk habitat use (Witmer and others 1985). In response to Washington State Department of Wildlife requests, the Forest has cooperated in implementing road closures, reducing adverse effects on important deer and elk habitat.

Figure III-10

Generalized Influence of Increasing Open Road Density on Otherwise Usable Deer and Elk Habitat



The Washington State Department of Wildlife has established statewide big game population objectives, for 1989, as follows:

1. Black-tailed Deer - 230,000 (a 5 percent increase from the Statewide population mean 1970-79 of 218,500).

2. Roosevelt Elk - 36,000 (11 percent increase from the Statewide population mean 1970-79 of 32,000).

3. Mountain Goat - 7,700 (9 percent increase from the Statewide population mean 1970-79 of 7,000).

Department of Wildlife objectives have not been broken down to determine the Mt. Baker-Snoqualmie's share.

Special or Unique Habitats

Many species find adequate breeding and foraging habitat in a variety of habitat types found in abundance on the Forest and outside the National Forest boundary. Some species find optimal habitat in special or unique habitat types. Table III-28 shows the species that find optimal breeding and/or feeding habitat in four unique habitat types found on the Forest: 1) old growth; 2) caves, cliffs, and talus; 3) snags and downed logs; and 4) riparian.

Table III-28
Wildlife Use of Special and Unique Optimal Habitats 1/

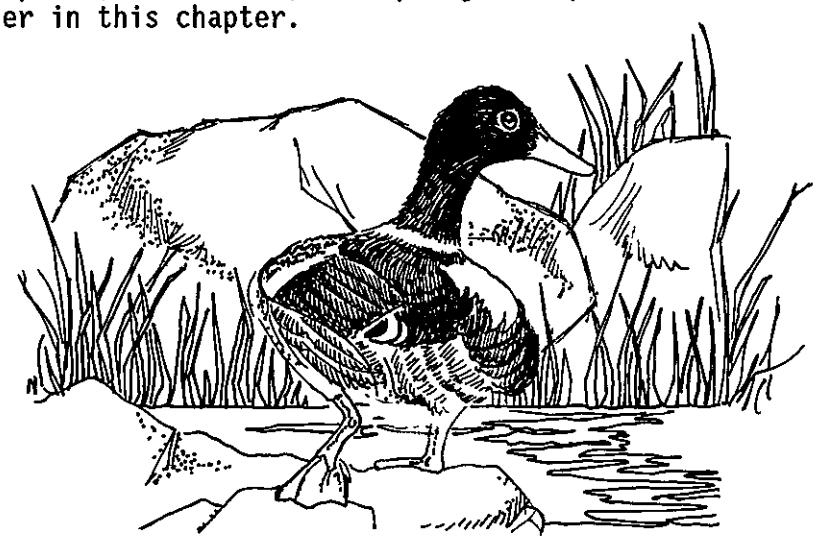
Habitat Type	Number of Wildlife Species 2/					
	Reptiles/Amphibians		Mammals		Birds	
	Breed	Forage	Breed	Forage	Breed	Forage
Old Growth	3	8	22	12	46	37
Caves, Cliffs, Talus	3	3	26	5	19	5
Snags and Downed Logs	6	11 3/	18	4	39	6
Riparian Zones	17	19	26	39	37	69

1/ Adapted from Brown 1985.
2/ There is overlap between the number of species that breed and/or forage.
3/ Data extrapolated from Nussbaum and others 1983.

Riparian Zones and Wetlands

Riparian zones and freshwater wetlands are among the most heavily used wildlife habitats occurring in forest lands of western Oregon and Washington (Oakley and others 1985). Numerous mammals, birds, and amphibians inhabit the diverse, water-influenced riparian zones and wetlands.

Riparian habitat lies between the aquatic and terrestrial ecosystems. These areas usually contain high water tables and have vegetation that requires large amounts of free or unbound water or conditions that are more moist than usual (Oakley and others 1985). Riparian zones occur along rivers, streams, creeks, sloughs, lakes, ponds, reservoirs, and springs. Riparian zones are further described earlier in this chapter.



Riparian zones generally are the most varied, abundant, and productive of any habitat type, providing water, food, and cover. The density and diversity of vegetation combine with a variety of landforms, and create edges and microclimates that provide an almost infinite number of habitat "niches" for wildlife. Wildlife use riparian zones disproportionately more than any other habitat type (Brown and others 1977, Carothers and others 1974, Kelley and others 1975, Riparian Habitat Technical Committee 1985, Thomas and others 1979b).

The Riparian Habitat Technical Committee (1985) estimates that 68 species of mammals, birds, amphibians, and reptiles require riparian areas to satisfy a vital habitat need during all or part of a year. They contain natural migration routes/travel corridors for many wildlife species. Riparian areas are important for ruffed grouse, beaver, muskrat, mink, river otter, wood duck, bald eagle, osprey, songbirds, small snag birds, several amphibians such as the Pacific giant salamander and Cascade's frog, and other species.

Wetlands are covered by shallow water or are periodically saturated with the water table at, near, or above the soil surface (Oakley and others 1985). These areas include ponds, marshes, swamps, bogs, seeps, and wet meadows.

Caves, Cliffs, and Talus

Some geological features create habitats in which the primary elements are nonvegetative. These are "unique" habitats found in the Cascade Mountain range that provide refuge for many wildlife species (see Table III-25), some of which are so dependent on these geomorphic features that they are found nowhere else. Ordinarily, caves, cliffs, and talus slopes are more resistant to change than plant communities. Though their structure may not change, human activities regularly alter the ecosystems within which these unique habitats occur (Maser and others 1979, Scharpf and others 1985).

Caves. Caves provide a more stable environment of temperature and moisture than do most terrestrial habitats (Barr 1964, 1967; Nichols 1955). Many animals inhabiting caves, such as bats, are extremely dependent upon this stability to maintain their body functions. The Townsend's big-eared bat is on the Forest Service Pacific Northwest Region Sensitive species list and on the State of Washington Threatened List. It roosts and locates its nursery colonies in caves, and is very sensitive to human disturbances. These tunnels, abandoned mine adits, and buildings sometimes replicate cave-like habitat for some species. In 1987 and 1988, a survey for bats on the Mt. Baker-Snoqualmie included investigating two caves, one tunnel, and nine mine sites (some with several adits) for bat use. Bridges with under-structures providing roost habitat were also examined. Bats were found at a number of bridges, including two bridges, each with one Townsend's big-eared bat. There are few naturally-occurring caves on this Forest; most of the cave-like habitat is provided by abandoned mine adits.

Other species that use caves simply as a matter of preference or convenience, such as the bobcat, depend on this stability to a lesser degree, but it is still an important habitat element. Raptorial birds like owls use shallow caves for roosting and sometimes nesting.

Small changes in the transport of biological material into or out of the cave, could lead to drastic changes in resident species (Wilson 1978). Even

alterations in wind currents around a cave entrance can affect the delicate balance of the micro-environment within the cave. Changes in forest structure and productivity around a cave may influence wildlife that use caves (McAlpine and Reynolds 1977).

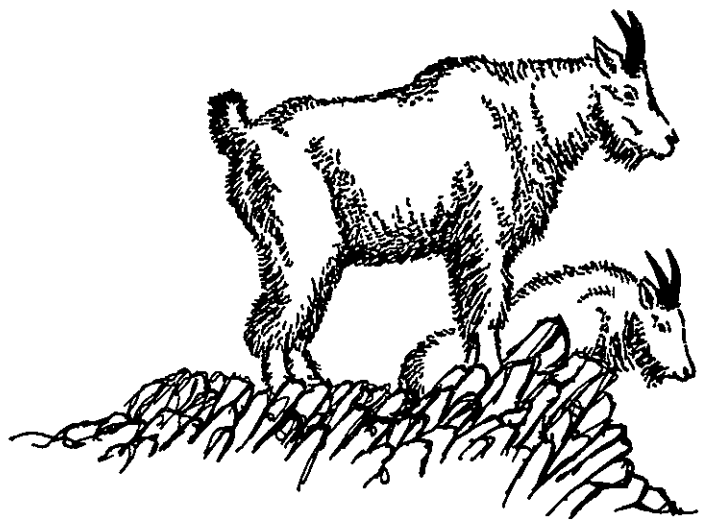
Cliffs. A cliff is a steep vertical or overhanging face of rock. Many animals utilize the features of cliffs and use the security found in cracks and ledges of the cliff face to escape from predators. Birds build their nests and small mammals make dens along rocky ledges. Many raptors prefer cliffs for nesting and roosting.

Talus. Talus is a sloping mass of dislodged rock fragments that accumulate on slopes or at the base of cliffs. Talus areas occupy a relatively small portion of the land base yet concentrate wildlife species, including birds and small mammals.

Caves, cliffs, and/or talus are important habitat for such animals as mountain goat, marmot, pika, bats, golden eagle, American peregrine falcon, and small birds such as cliff swallows and black swifts. There are only a few known caves on the Forest and the other areas occur incidentally throughout the Forest. This habitat type represents acreage that has been identified as not suitable for timber production. However, the available and suitable acres of forest that form the edge for these openings are very important as cover for species such as the mountain goat.

Habitat Connections

Connections of habitat areas by travel or dispersal corridors are important linkages in maintaining viable populations of animal species. This avoids the isolation of habitat into geographic isolation. Connecting habitat provides species access across drainages and elevation gradients (ridgeline to valley floor and over passes). Requirements for connecting habitat vary among wildlife species, but are for areas of some to full suitable habitat. The higher the suitability of the habitat for a species, the less risk it incurs in moving through an area. Usually, connecting habitat is made up of mid-and-later seral stages.



Chapter III
Fish

FISH ELEMENTS OF DIVERSITY

The abundance and distribution of fish species on the Forest is another important element of diversity. As is true for wildlife, some fish species are - for a variety of reasons - low enough in numbers that special management emphasis or protection is necessary. These species are on the Pacific Northwest Region , Forest Service Sensitive Species list, or are under review for federal listing. Refer to the discussion on threatened, endangered, and sensitive species later in this section.

Overview - Historical Perspective

As discussed in the Forest Overview in Chapter I, the Puget Sound region contains approximately 13,355 square miles. Dominant physical features of the region include the North Cascade Mountains, and the waters of Puget Sound, with its many islands, bays, channels, and tributaries. The principal river systems draining into Puget Sound from the North Cascade Range are the Nooksack, Skagit, Stillaguamish, Snohomish, Cedar, Green, and the Puyallup-White Rivers. Some of these systems are fed by glacier melt water and are discolored during the summer months.

Ownership along these seven river basins includes private, county, state, and federal holdings. The Forest encompasses most of the land mass at the higher elevations of the seven river basins.

Each of these basins supports more than two species of anadromous fish populations, fish populations that migrate upstream to make use of National Forest land.

The abundance of fish and wildlife resources, plus the maritime climate of Puget Sound historically has supported various tribes of Native American Indians. The 1800's marked the arrival of the first white settlers; by 1877, over 45 canneries were established. Exploitation of the anadromous fish resource continued until the 1930's, by which time some of these fish populations were over-harvested to the point of being depleted. Agricultural use and timber harvesting in the river basins displaced or destroyed some of the habitat used by fish populations. The two factors (agriculture and timber) forced local and federal resource managers to develop and implement anadromous fish regulations and management strategies to insure the viability of these economically, culturally, and biologically important species. Fish hatcheries were developed in the 1950's and 1960's to mitigate and/or augment the natural production of anadromous fish.

Today, a multitude of land and water uses occurs along and in each of the Puget Sound river basins: timber harvesting, land development, recreation development, small hydro development, agriculture, etc. Anadromous fish production has and continues to be impacted by each of these activities.

The Forest Contribution

The waters of the Mt. Baker-Snoqualmie National Forest provide a significant contribution to the freshwater fishery and aquatic resources in the Puget Sound region. Commercial and sport fisheries depend upon the Forest ecosystem to provide spawning and rearing habitat, as well as a source of high quality water

for downstream fishery resource uses. Puget Sound Treaty Tribes (Medicine Creek, Point Elliott, and Point-No-Point Treaties) continue to rely heavily upon this natural production and high water quality to support and maintain their subsistence and commercial fisheries. Maintenance, protection, and the improvement of this habitat and related water quality is a very significant issue and management concern of the public, State and Federal resource managers, and with the Tribes.

Over 1,500 miles of fish-bearing streams and over 12,000 acres of fish-bearing lakes serve as both seasonal and year-round habitat for five species of salmon, three species of sea-run trout, and numerous other cold, freshwater species. These streams and lakes drain into seven major Puget Sound river basins.

The actual portion of Puget Sound anadromous fish naturally produced on the Forest is unknown. However, using river miles of habitat accessible to anadromous fish as a rough approximation, 16 to 58 percent of the total anadromous habitat of five of these river basins lie within the Forest boundary. Of the estimated 1100 miles of anadromous fish habitat found within the Nooksack, Skagit, Stillaguamish, Snohomish, Green, and White River systems, roughly 315 miles are located within the Forest boundary. In addition, approximately 278 miles of anadromous habitat lie directly outside or adjacent to the Forest boundary and are directly influenced by Forest management activities.

The Forest's aquatic systems also support high quality, resident fish habitat. Many of these stream systems are lake-fed and support one or more species of resident trout, whitefish, and two or more cottid species.

Table III-29 displays anadromous and resident fish miles by major river basin. Table III-30 shows the fish, by species, found on the Mt. Baker-Snoqualmie.

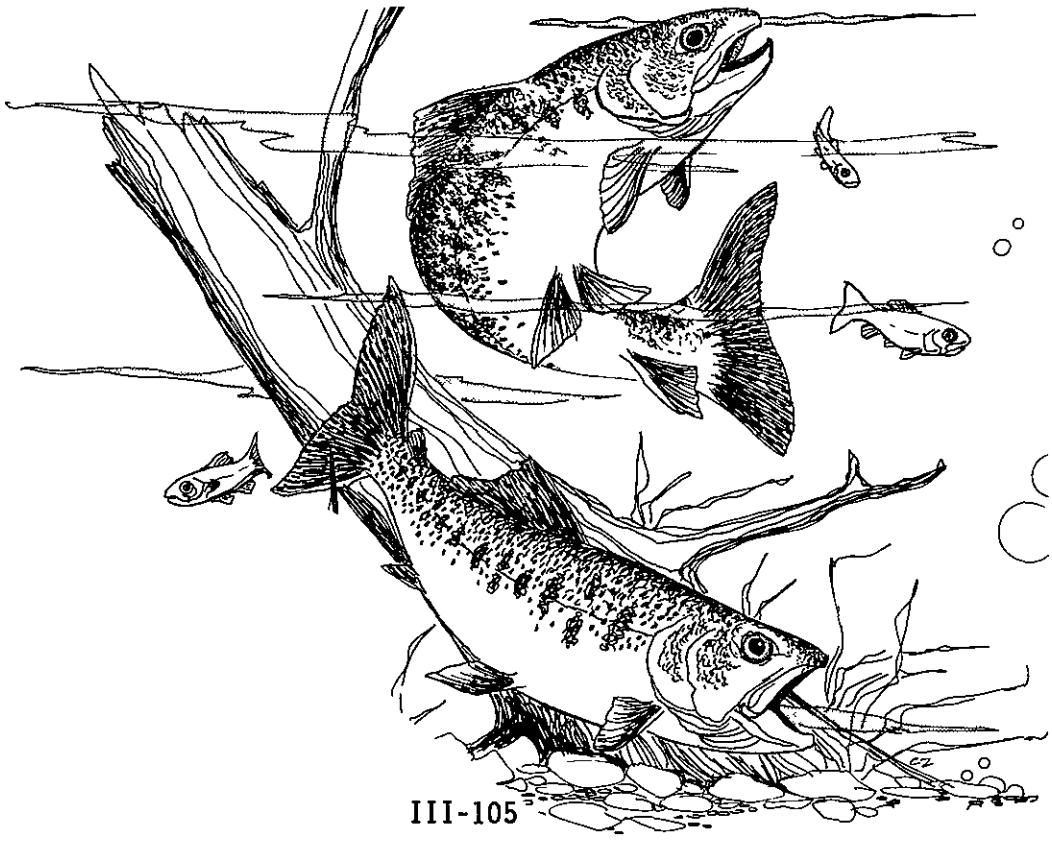


Table III-29
Anadromous and Resident Fish Miles by River Basin 1/

River Basin	Anadrom. Fish Habitat Total Miles	On-Forest Anadrom. Fish Habitat Miles	Anadrom. Fish Habitat Forest Influenced	On-Forest Resident Fish
Nooksack	236.0	17.0	59.0	103.0
Skagit	470.0	135.0	66.5	487.0
Stillaguamish	295.0	45.0	135.0	295.0
Skykomish	246.0	78.0	3.0	311.0
Snoqualmie	152.0	0.0	0.0	135.0
Green	61.0	5.0	8.0	100.0
White	142.0	40.0	14.0	75.0
TOTAL	1,602.0	320.0	285.0	1,506.0

1/ Stream mileage derived from the WDF Catalog of Fish Streams supplemented by District data and information. Stream mileage within the Forest boundary derived as described above and from stream surveys completed over the past 8-10 years. On-Forest habitat includes aquatic systems where hatchery-spawned fry are planted back out in fresh waters habitats to imprint and rear.

Miles of off-Forest habitat influenced by Forest management are estimated from known, recorded, or observed data/information on each river basin. Major influences on the spawning and rearing habitats of anadromous fish populations within these river basins.

Table III-30
Fish Species Found Within the Forest Boundaries

Anadromous	Resident	
Chinook Salmon	Rainbow Trout	Cutthroat Trout
Coho Salmon	Eastern Brook Trout	Golden Trout
Pink Salmon	Artic Grayling	White Fish (spp)
Chum Salmon	Bull Trout	Kokanee
Sockeye Salmon	Sculpin (Coast Range, Shortland, Torrent and Mottled)	
Steelhead	Largescale Sucker	
Sea-Run Cutthroat Trout	Dace (sp)	
Sea-Run Dolly Varden		

Management Indicator Species

Chinook, coho, pink, chum, and sockeye salmon, along with steelhead and resident trout, were selected as the Forest's aquatic habitat Management Indicator Species (MIS) for inclusion in the Forest Plan. These species, and their viability, are sensitive to environmental change.

Threatened, Endangered, and Sensitive Species

There are, at the present, no federally-listed threatened or endangered salmon species known to utilize aquatic habitat located within the Forest boundary.

Bull trout is currently listed as a Pacific Northwest Region, Forest Service Sensitive species. This species may be uniquely adapted to cold, relatively unproductive waters. As a result of specific adaptation, the bull trout could probably provide production from a niche that cannot be effectively used by any other species. Loss of individual stocks could represent a net loss that cannot be mitigated. Loss in some cold rivers may represent loss of the only "large fish" production possible.

The bull trout is known to have adfluvial, fluvial, and resident life history patterns. The nature and variation in life histories among Forest drainages is unknown. Some stocks appear to have very specific adaptations in timing of migrations. Such migrations may result in movements past seasonal barriers and use of otherwise empty habitat. They use habitat differently from other fish, particularly cutthroat trout which are present throughout most of the range. Bull trout are typically associated with the bottom rather than the water column or three-dimensional cover. The degree to which angling, habitat loss, and other factors control bull trout populations are not well known. Habitat loss is probably important in population declines, but bull trout - like other long-live species - are much less resilient to exploitation than other fish (Kramer 1984; Fraley and Shepard 1989).

Preliminary inventory and data collection on the Mt. Baker-Snoqualmie indicates that bull trout is widely distributed across the majority of the Forest watersheds, especially on the north end.

Value of Species

The value of the fish species found within the Mt. Baker-Snoqualmie National Forest boundary to the various commercial, sportfishing, and Tribal subsistence uses in and around the Puget Sound region is significant. Salmon and sea-run trout produced or influenced by aquatic systems within the boundaries of the Mt. Baker-Snoqualmie contribute to Puget Sound as well as West Coast commercial fisheries. 2/ Substantial numbers of steelhead and sea-run trout along with chinook, coho, pink, and chum salmon produced from Forest waters are also caught in the ever-growing and highly popular Puget Sound and Washington coast sport fisheries. Another important value and use of these anadromous species is the commercial and subsistence harvest by the Puget Sound Treaty Indian Tribes. Each of the seven Puget Sound river basins originating and flowing across the Forest falls within one or more of the Tribes' Treaty ceded areas.

The Forest's rich and diversified resident fish habitat offers another significant sportfish value. The 1,500 plus miles of stream and 12,000 acres of lake produce cutthroat, rainbows, eastern brook trout, dolly varden char, whitefish, and grayling. These species are sought after by a million-plus Forest visitors and users each year.

2/ Note that natural production of anadromous fish within the Forest boundaries include fish that migrate beyond the boundary to spawn and rear, as well as hatchery fry that are outplanted to these areas to imprint and rear.

For biological and ecological reasons, the Forest's fishery resource values are also very important. Within and adjacent to the Forest boundary exist some of the last remaining miles of optimum anadromous fish habitat, capable of producing and sustaining wild populations of spring chinook, coho, pink, and chum salmon, as well as summer and winter-run steelhead. This kind and quality of habitat is in short supply in Washington State and in even shorter supply along the West Coast. Pure, wild runs of salmon and sea-run trout are almost lost, or have been lost, in this country as well as in other parts of the world.

Trends

The following trends will play an increasing part in Forest fish management over the next few years on each of the seven Puget Sound river basins:

1. Demand (commercial plus sport) will dramatically increase for anadromous fish (salmon and sea-run trout) produced from each river basin over the next five to ten years.

2. The U.S.-Canada Salmon Treaty will help fuel this demand, but it should also play a much larger role by influencing the supply of anadromous fish.

3. With limited dollars available for increasing anadromous fish production, restoring/enhancing fish habitat (through natural production methods) will be given primary funding consideration over artificial operation.

4. Puget Sound Treaty Indian Tribes will continue to become more directly involved in our land management activities, including our fish habitat management programs and planning.

5. Over the next 5 to 10 years, there exists as much opportunity in habitat restoration or rehabilitation as there is in habitat enhancement.

6. With limited funding and personnel resources to carry out a complete anadromous fish improvement or enhancement program by any one agency, coordinated and integrated planning and implementation of such programs by all concerned parties (agencies, public citizens, groups) will become more and more common.

7. State and/or Tribal existing, on-going fishery management plans or programs within the seven river basins need to be either incorporated in, or coordinated with, the Forest's fishery habitat management program. An example of this includes the on-going Watershed Planning-Proposed Enhancement Plan between the Tribes and the Washington Department of Fisheries.

8. The demand for recreational sport fishing experiences on the Forest will dramatically increase over the next 5 to 10 years, due to current and projected growth and development in the Tacoma-Seattle-Everett region.

Supply (Production)

Assessing the current or existing supply (or production) of anadromous fish and the resident fish which can be attributed to the aquatic systems within and adjacent to the Mt. Baker-Snoqualmie boundaries is difficult. To make these assessments, a number of assumptions are made for each species group. As more fish and fish habitat inventory data and research results become available, these Forest assessments will be updated and become more reliable.

There is only a very small sockeye salmon run that originates on the Forest, coming from Baker Lake. This run is too small for significant commercial or sport opportunities, and adequate data are not available on either harvest or production to carry forward into production and value estimates. Sea-run cutthroat trout are included in Table III-37, Values; however, there is not sufficient data to include quantified production estimates in the other tables (Washington Department of Wildlife 1989).

The Forest Watersheds

The Forest is divided into 88 allocation zones (defined by watershed boundaries, in most cases) for forest planning purposes. Some watersheds are located completely within the Forest boundary, others are only partially located within the forest boundary. Estimates of fish supply or production are keyed to these 88 watersheds. All of these watersheds fall within the seven major river basins. (See FEIS, page III-12.) Both anadromous and resident fish production occurs in all of these river basins.

Most of the anadromous and resident fish produced within the Forest's watersheds is natural production. This means a portion or the entire life cycle of these species occurs within the watersheds. Natural production of a rich diversity of salmonids requires substantial areas of high quality habitat and high water quality.

The amount and quality of habitat and water in the Forest's watersheds is affected by the geologic and climate conditions inherent for each watershed. In addition, habitat and water quality are influenced by the amount and type of any timber harvesting and road construction activities occurring within the watersheds. Forest fish habitat conditions that are affected or impacted by management are: stream channel stability; streambank stability; pool condition; and large woody debris (its presence or absence).

On the Mt. Baker-Snoqualmie, there is documentation and evidence that watersheds with moderate to heavy amounts of timber harvesting and road construction - combined with the presence of unstable soils and steep slopes - have a history of major and minor peak-flow events (floods or rain-on-snow events). Debris torrents, avalanches, or earth flows have led to stream channel instability, streambank erosion, scouring-out or filling-in of pools, and the loss of large woody debris. Fish habitat has been lost or degraded. These habitat conditions have resulted in the degradation of water quality and/or the reduction in fish species numbers or diversity.

Forest watersheds that have experienced this degradation and resulting habitat/fish reductions include: Canyon Creek (North Fork Nooksack), Deer Creek (North Fork Stillaguamish River) and Canyon Creek (South Fork Stillaguamish River). In total, 19 watersheds on the Forest are currently in

an unacceptable condition. For further discussion, refer to Chapter IV, FEIS, effects of implementing the alternatives on soils and water. Also, see Appendix H, FEIS.

Supply - Anadromous Fish

Determining the amount of anadromous fish produced within the National Forest boundary is complicated by the location of the Forest in relation to the river systems of Puget Sound, and the reliability of existing sub-regional or basin fishery data. Estimating production figures for those river systems outside of the Forest boundaries but influenced by upstream Forest management activities is even more difficult. In most of these basins, only the upper portions are within Forest boundaries; in some cases, the entire main stream corridors are managed by the state or privately owned. Because of these factors, it is difficult to determine the contribution of the Forest's waters to overall production of various species of anadromous fish in the seven river systems.

Two types of anadromous fish production presently occur within or immediately downstream of the Forest boundary: hatchery and natural. All hatchery production occurs off Forest, usually downstream from the Forest boundary. Most of these are State or Tribal hatchery facilities and are used to spawn adult fish and incubate eggs. But, in some river basins (Nooksak, Stillaquamish, Green, and White), the hatcheries require the use of Forest aquatic environments (side channels, beaver ponds, rearing ponds) for the imprinting and rearing of chinook, coho salmon, and steelhead trout.

Natural anadromous fish production also occurs within or adjacent to the Forest boundary. Natural production presently occurs in all the major river basins, except the Snoqualmie. Anadromous fish production estimates for this FEIS are displayed by adult production and smolt production.

Smolt production has been selected as the indicator of anadromous fish spawning and rearing capabilities of the Forest portion of these river basins. The Forest has defined three broad categories of smolt production, either occurring presently or having the potential to occur within the Forest boundary:

Smolt Production Level I - The estimated amount of smolt currently produced (by species) within the Forest boundaries. This estimate reflects the past and current condition of habitat on the Forest, plus the past and existing escapement of adult spawners to the Forest.

Smolt Production Level II - The potential smolt production with habitat restoration (both spawning and rearing habitat), and assuming that there is adequate adult escapement to the Forest.

Smolt Production Level III - The potential smolt production within the Forest with full habitat restoration in place and full implementation of all natural fish enhancement opportunities. This level also assumes full escapement to the Forest.

The assumption regarding spawning escapement (from Forest streams out to the ocean) in Levels II and III was made to address the external management problems of over-harvesting and migration barriers (both natural and human-caused). The Forest cannot manage non-National Forest lands, therefore only the capabilities of the Forest are displayed. Level I production does not

assume adequate spawning escapement; production at this level is based on actual, existing escapement.

Existing Production - Level I. In order to estimate the current or existing anadromous smolt production attributed to Forest's aquatic systems, current adult production occurring on the Forest was examined. By estimating adult production, it is then possible to calculate the various survival rates from adult to fry stages to obtain smolt production figures. This is currently the only method of obtaining these figures, as information and data on smolt production by species and river basin does not exist for this Forest.

Table III-31 shows recent Washington Department of Fisheries and Washington Department of Wildlife estimates of fish production (harvest plus escapement) from Forest waters in the major Puget Sound river basins. From this table of existing, estimated production of adult salmon and steelhead attributed to on-Forest production, an estimate can be made of the existing smolt production attributed to the Forest. Table III-32, on the next page, shows the estimated existing anadromous smolt production by species and major river basins.

Table III-31
Anadromous Fish Production (Escapement and Harvest) from Within MBS Boundary 1/
Production Level I - In Numbers of Fish

River Basin	Chinook	Pink	Coho	Chum	Steelhead	Remarks
Nooksack	26,460	60,660	10,270	27,000	1,260	Natural production. Chinook & Coho augmented by the straying of hatchery fish. Recent estimates for chum are much higher. Steelhead escapement is not documented.
Skagit	5,417	469,225	35,100	34,100	8,580	
N.F. Stillaguamish	4,430	55,160	22,930	5,840		
S.F. Stillaguamish	5,000	69,000	25,475	6,640	9,040	This production est. includes steelhead produced in the Snohomish R. system: NF & SF Stillaguamish, Skykomish, & Snoqualmie
Skykomish	5,550	75,440	48,560	2,790		
White	2,290	13,830	10,070	1,220	190	These est. may be high given current condition of the river.
Snoqualmie & Green	No Natural Salmon Production on NF				2,790	Green River only.
TOTAL	97,900	743,315	152,400	77,590	21,850	TOTAL = 1,093,000

1/ Salmon estimates from WDF, Olympia office, April 1989.
Steelhead estimates from WDW, in response to DEIS, April 1989.

Table III-32
Estimated Existing Anadromous Smolt Production from Forest Portion of Major Puget Sound River Basins, in Numbers of Fish - Production Level I 1/

River Basin	Chinook	Pink	Coho	Chum	Steelhead	Remarks
Nooksack	69,200	844,000	32,500	940,000	8,000

Green	No Natural Salmon Production on Forest				8,400	
White	9,700	212,700	3,500	11,000	3,720	Est. may be high given the present condit.
TOTAL	231,800	12,450,000	1,290,000	2,000,000	125,510	

OVERALL TOTAL = about 16,000,000 smolt

1/ Smolt production for each species obtained by converting existing adult escapement to smolt production using the following smolt to adult survival coefficients: for North Puget Sound - Chinook .05, pink .018, coho .02, chum ,.02, steelhead .08. For South Puget Sound - Chinook .03, pink .015, coho .02, chum .018, steelhead .05. Data from WDF, 1980.

Potential Production - Levels II and III. The potential exists for producing more anadromous fish from the Forest's aquatic systems. During the past ten years, the Forest has directed much time and effort to either restoring degraded habitat or improving existing habitat conditions. The quantity and/or quality of both spawning and rearing habitats, and improving access to these habitats has been the focus of Forest work, in an effort to protect, maintain, or increase natural anadromous fish production.

Over the next 10 to 15 years, there is great potential for the Forest to raise the natural production of chinook, pink, coho, and chum salmon and steelhead trout in the major Puget Sound river basins by protecting and maintaining existing optimum habitats, and by continuing to rehabilitate, restore, or improve habitats that have been destroyed or degraded due to either natural or management-related events.

Maintaining, protecting, and increasing the natural anadromous fish populations in the major Puget Sound river basins is a significant management goal of both the State of Washington and the Puget Sound Treaty Tribes. The Forest is a significant contributor to this goal because a sizable portion of the natural production in these rivers occurs within the Forest boundaries or is influenced by Forest activities (refer back to Table III-29). For the Mt. Baker-Snoqualmie, there are various approaches to maintaining, protecting, or improving the anadromous fish habitat capability in these river basins. Included are a mix of land allocations, use of management standards and guidelines, application of management requirements, development of site-specific Best Management Practices (project level), and capital investments in specific areas.

Maintaining and protecting existing anadromous fish habitat capability (Level I) is the first priority. This can be accomplished both through land allocations and application of measurable standards and guidelines.

Increasing the Forest's anadromous fish habitat capability above the existing level requires a sizable capital investment in fish habitat restoration and/or watershed rehabilitation. This Level II production potential assumes adequate escapement to the Forest. Level II production potential - measured as smolt production - is shown in Table III-33; it covers a potential production after a 10-year investment period.

The Forest has additional potential to increase natural production of salmon and steelhead in those river systems where there are opportunities to improve or enhance the existing habitat. This is production Level III. These opportunities are usually limited to only a few of the river systems; the majority of the habitat work in all rivers is to restore or rehabilitate degraded or destroyed spawning/rearing areas.

Table III-34 displays increases smolt production that is possible at a Level III over a ten year period.

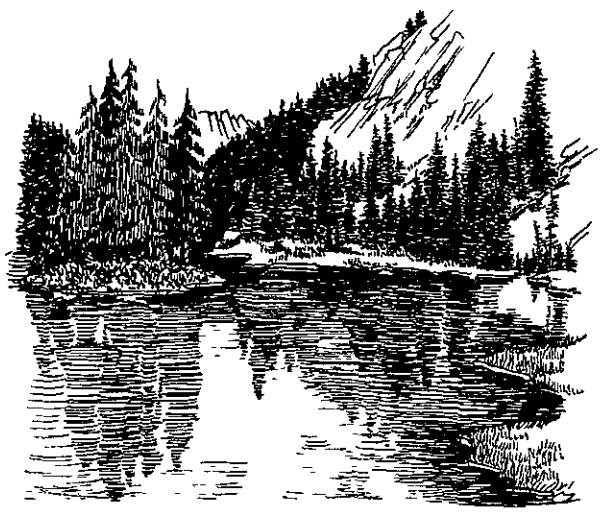

Table III-33
Potential Anadromous Fish Production (Smolts) From Forest Ownership of Each River Basin Over Next 10 Years, with Habitat Restoration, In Numbers of Fish - Production Level II 1/

River Basin	Chinook	Pink	Coho	Chum	Steelhead	Remarks
Nooksack	89,960	1,000,000	35,750	1,081,000	9,200

OVERALL TOTAL = 18,015,370

* denotes no increase from Production Level II, Table III-33.

Supply - Resident Fish

All of the 88 watersheds on the Forest contain resident salmonid habitat, as shown by the amount of known resident fish stream miles; refer back to Table III-29.

Information and data on species presence, utilization, and population density for the 1,500 stream miles and 12,000 acres of fish-bearing lake habitat is very spotty and in some cases unreliable. The Forest data base for resident fish habitat and existing populations is almost non-existent. This gap has been identified as a major information inventory need; refer to Chapter 2, Forest Plan.

Resident trout species are either known or suspected to occur in almost all of the Forest's watersheds. These species include rainbow and cutthroat trout; trout populations are found both in streams and lake systems. The larger stream and river systems contain small populations of whitefish and one or two species of cottids. Almost all of these populations are native, wild, naturally-produced fish. A few isolated Forest lakes contain native runs of Artic grayling.

Hatchery-produced trout populations are found in fewer watersheds across the Forest. These species include Eastern brook trout, Kokanee, and brown trout. Most of these introduced species are found in lowland and high lakes, in both wilderness and non-wilderness areas.

Most of the larger Forest watersheds are suspected of containing the habitat to support unknown populations of Dolly Varden/bull trout or the hybrid of these two species. The bull trout is a species of management concern; it is presently on the USDA Forest Service, Pacific Northwest Region's sensitive species list and is being considered for listing on the State of Washington's threatened and endangered species list. New information and data suggests that both bull trout and Dolly Varden char utilize overlapping habitat areas within the Forest in all river basins.

Demand (Harvest)

The existing demand or harvest of anadromous and resident fish produced within the Forest boundaries, or the off-Forest production which is influenced by Forest management activities, cannot be estimated directly.

Estimates can only be made in general terms because reliable harvest data and information does not currently exist. The Forest's contribution to the following fisheries is not well known: anadromous commercial fishery (Washington coast), anadromous coast and Puget Sound sport fishery, Puget Sound stream and lake recreational sport fishery, and the Indian Treaty Tribes subsistence fishery. This information need is noted in Chapter 2, Forest Plan. The Forest's contribution to each of these harvests or demands is suspected to be significant due to the known or suspected production attributed to Forest aquatic systems.

Demand - Anadromous Fish

The existing natural production of anadromous fish from the Forest's aquatic systems contribute to three fish harvesting sectors. Salmon and steelhead produced from on- and off-Forest rivers and streams are harvested by the Washington coast commercial fishery, the Puget Sound sport fishery, and by the Puget Sound Treaty Tribes subsistence fishery.

Table III-35 shows this estimated commercial and sport fishery demand - that is the estimated salmon and steelhead commercial harvest that is attributed to production occurring within or adjacent to the Forest.

The salmon harvest estimates include both treaty and non-treaty harvests. No attempt is made to separate the two distinct demands because both the State and the Treaty Tribes have not yet agreed upon a method for allocating harvests.

The major points of disagreement are: 1) the applicability of all-citizen fish; 2) net "dropout"; 3) sport fish bias; 4) stock compensation in mixed-stock areas; and, 5) lack of information on the true past-season catches (Washington Department of Fisheries memo to Forest, 4/13/89).

The steelhead harvest figures include both sport-fish catch and Treaty Tribes' subsistence harvest: average, annual harvest values for 1984 to 1989. In total, the annual estimated harvest of salmon and steelhead produced from Forest aquatic systems is approximately 780,890 fish. In addition, there are other anadromous fish produced in Forest rivers and streams that are caught in smaller sport fisheries. Sea-run cutthroat trout and Dolly Varden char production occurs within the Forest; the actual production and the demand or catch are both unknown.

Table III-35
Estimated Anadromous Fish Harvest That is Attributed to Escapement and Production Occurring within the MBS, By River Basin of Origin, In Numbers of Fish 1/

River Basin	Chinook	Pink	Coho	Chum	Steelhead	Remarks
Nooksack	23,000	46,000	9,620	8,200	620	
Skagit	48,000	337,000	27,000	17,000	3,810	
N.F. Stillaguamish	4,000	37,000	19,000	3,700		
S.F. Stillaguamish	4,500	42,500	21,000	4,200	5,377	This harvest est. for all steelhead produced from NF land in Snohomish R. system
Skykomish	5,000	47,000	40,000	2,000		
Snoqualmie	No Natural Salmon Production on Forest					Snoqualmie R.
Green	No Natural Salmon Production on Forest				2,360	
White	2,000	10,000	10,000	1,000	4	
TOTAL	86,500	519,500	126,620	36,100	12,171	
OVERALL TOTAL =	780,891					

1/ Salmon harvest estimates from WDF, Olympia office, April 1989. No attempt was made to separate Indian treaty and non-treaty harvest. See text. Steelhead sport fishing harvest from WDW, in response to DEIS April, 1989. Harvest also includes treaty harvest.

Anadromous Fish - Future Demand

The local, regional, and national demand for commercially-caught salmon, and sport-caught steelhead will continue to increase. There will be increasing management pressure from the State, Tribes, and concerned environmental groups to protect, maintain, and actually increase the natural production of these anadromous fish populations from the river basins of Puget Sound. This matches the short- and long-term goals for the U.S.-Canada Salmon Treaty. In addition, the Puget Sound Treaty Tribes subsistence fishery will continue to rely heavily upon natural production methods in order to meet their harvest requirements.

Meeting this increasing future demand will depend heavily on the protection, maintenance, and, when possible, the improvement of the natural production capabilities of anadromous habitat on the Forest over the next ten years.

Demand - Resident Fish

The existing demand or the recreational sport fishing pressure on resident fish produced in the Forest's lakes and streams is not known. Some estimates of this current demand were developed using recent data and information gathered by the Washington Department of Wildlife for their management area Region 4 (Puget Sound).

A 1986 study by the Department on the resident sport fishery in the State of Washington shows that there were 243,800 licensed anglers residing in the WDW's Region 4 (which encompasses all of the Puget Sound area, including the Mt. Baker-Snoqualmie National Forest.) These licensed anglers spent over 5 million days fishing for trout and/or salmon in 1986.

The statewide sport fish demand includes seven different fishing interest areas: lowland lake-trout, warmwater, steelhead, resident streams and beaver ponds, high lakes, sea-run cutthroat/Dolly Varden streams, and sea-run cutthroat/Dolly Varden marine. For the Mt. Baker-Snoqualmie, there is a demand for and opportunities provided for all of these except warm-water fishing, and marine fishing for sea-run cutthroat/Dolly Varden. The most popular type of sport fishing for Puget Sound anglers is lowland, lake trout, as shown in Table III-36, below. Note that the table includes juvenile, non-licensed anglers as well as adult anglers; juveniles comprise 20-30% of the anglers in each of the different fishing interest areas. In 1986, it is estimated that anglers spent over 1.3 million days on the Forest fishing for resident game fish, or about 16% of the angler days in WDW's Region 4 and 1% of the Statewide angler days.

Table III-36
Estimated Angler Use (in Angler-Days) in Various Sport fish Interest Areas
Statewide, Puget Sound Region 4, and on Forest - 1986 1/

Sport Fish Interest Area	Statewide Total Angler Days	WDW Region 4 Total Angler Days	Estimated for MBS Total Angler Days 2/
Lowland Lakes Trout	4,689,300	2,588,400	258,840 (.10) 2/
Warmwater	3,438,900	1,658,300	no opportunities
Steelhead	2,895,900	1,332,100	266,400 (.20)
Resident Streams and Ponds	1,690,500	933,000	373,200 (.40)
High Lakes	793,800	438,200	140,200 (.32)
Sea-run Trout/Dolly Varden Streams	779,800	358,400	107,520 (.30)
Sea-run Trout/Dolly Varden Marine	352,800	162,300	no opportunities
TOTAL	14,640,000	7,985,000	1,146,100

1/ Includes all anglers: licensed and non-licensed juveniles. Source: Washington Department of Wildlife Report, June, 1988.
2/ Estimated demand for each interest area calculated using a percent, shown in ( ), of that area in WDW Region 4.

Additional information from the 1986 survey shows that 95.8% of the anglers surveyed preferred to fish for trout and steelhead. A majority indicated that hatchery fish were very important to the lowland trout-lake fishery, while wild fish were more important to the trout-stream, high lake, and steelhead fisheries. Over 70% said that their reasons for going fishing were not related

to actually catching fish; more important were the social and aesthetic aspects of the sport. As the Mt. Baker-Snoqualmie is located in some of the nation's most scenic mountains and contains over 1,500 miles of fish-bearing streams and 13,600 acres of lakes, the Forest provides a setting to meet this existing demand.

Resident Fish - Future Demand

Given the current and projected population growth and development in the Puget Sound area, the demand for a quality resident fishing experience will increase. Outdoor recreational experiences in the Cascades will continue to be a key part of the "Northwest Lifestyle." The Mt. Baker-Snoqualmie, along with the State Department of Wildlife, will need to develop comprehensive management plans for high use areas, especially in high lakes and resident trout stream and pond systems. This will become a high priority management item for the Forest over the next ten years, and will be implemented under the Forest's Rise to the Future Action Plan. Rise to the Future is a nationwide initiative, developed by the Forest Service in 1986. This bold new program was created to promote public awareness and to direct future management of the fishery resources on National Forest lands. In meeting the first step of this initiative, each Forest prepared a multi-year Fish Action Plan; refer to the Forest Plan, Chapter 4, Resource Summaries for additional information.

Fish Values

The existing value of the Forest's production of anadromous and resident game fish is not well established. Estimates have been made to establish the current annual value of this production to the local and regional commercial and recreational fishing economies. Based upon these gross estimates, the existing annual value of the fish resources produced on the Mt. Baker-Snoqualmie is approximately $23 million, annually. Refer to Table III-37.

This annual value is the sum of commercial salmon (treaty and non-treaty) harvest ($4,332,000), the salmon sport fish value ($8,177,000), the resident game fish value ($4,256,800), and sea-run trout and steelhead values ($6,533,500).

Maintenance and protection of the fish habitat on the Forest will be needed to realize these annual values. Through capital investment opportunities, such as watershed rehabilitation and/or fish habitat restoration, the Forest has the potential to increase these annual values. Increases of 10 -15 percent over the existing values could be realized over a 10-year period with capital investment. Ongoing watershed rehabilitation and fish habitat restoration activities will be needed in some of the more sensitive watersheds to maintain the current production and to eventually increase production of salmon and steelhead. Opportunities exist throughout the Forest to increase resident trout production (sea-run and Dolly Varden) through habitat improvement and access management. With capital investment in habitat restoration and improvement, plus watershed rehabilitation, the Mt. Baker-Snoqualmie could increase the annual Forest fishery value by $2.4 to 3.0 million over the next ten years.

Table III-37
Current, Annual Estimated Non-Treaty Commercially Caught and Sport Caught
Values for Salmon and Steelhead Attributed to Production on the Forest

Species	Estimated Existing Harvest (CF/SF) 1/	CF/SF 2/ Catch Ratio	Commercial Value 3/ Value/Fish	Commercial Value 3/ Total Value	Sport Fish Value 4/ # of Angler Trips of Days	Sport Fish Value 4/ Value of Angler Day	Sport Fish Value 4/ Total Value	Total Value by Species 5/
Chinook	54,495/32,005	63/ 37	$47 00	$2,561,265	74,172	56.55	$4,194,400	$ 6,755,600
Pink	514,305/5,195	99/.1	$ 1.82	$ 936,035	Negligible	Negligible		$ 936,000
Coho	96,231/30,389	.76/ 24	$ 2 82	$ 271,371	70,427 (WFUD)	56 55	$3,982,600	$ 4,254,000
Chum	36,100/0	100% CF	$12.00	$ 433,200				$ 433,200
Steelhead	0/12,171	100% SF	N/A		75,217	56.55		$ 4,253,500
Trout: Lowland Lakes					97,065 (WFUD)	14.70		$ 1,426,800
Trout· Streams & Ponds					139,950 (WFUD)	14.70		$ 2,057,200
Trout: High Lakes					52,575 (WFUD)	14.70		$ 772,800
Sea-Run Trout & Char					40,320 (WFUD)	56 55		$ 2,280,000
			Total	$4,332,000				$23,169,100

1/ Estimated Existing Harvest (Commercial fish/Sport fish harvest. this figure obtained from Table III-37. Harvest then divided between CF/SF by ratio in column 2

2/ CF/SF Ratio is determined by WDF 4/89.

3/ Commercial Value: Value/fish is retail value of each species (WDF 4/89), Total value = Value/fish x number of fish caught commercially.

4/ Sportfish value # of angler trips or days is the effort required to catch /fish and measured in wildlife/ fish user days (WFUD) and various according to type of sport fishery. WDW and WDF angler day use data converted to USFS's WFUD's Value of a Angler Day or WFUD is the RPA (1980) value assigned to that type of use; for anadromous fish = $56 55 per day, resident fish = $14.70 per day.

5/ Total Value by Species = Combined commercial and sportfish value for a particular species

HUMAN COMMUNITY

The Puget Sound region is one of the faster growing areas in the United States. The population, though far from uniform, tends to be young and well-educated, with incomes above the national average. The economy is highly diversified. Manufacturing is led by the aerospace industry. While that industry does not dominate the region quite so much as it has in the past, a recent study showed that one out of six jobs in the State of Washington is still dependent, directly or indirectly, on spending by the aerospace industry (Pascall and others 1989). With most of the direct employment in aerospace manufacturing found in the five-county area, the relative health of that sector is felt throughout the area.

Linkages with the Pacific Rim countries make wholesale and retail trade important employers. Exporting services outside of the region is an emerging facet of that sector (Beyers and others 1985). Trade and the broadly-based service industry are the fastest growing segments of the region's economy. Financial services have also grown as the area becomes an increasingly important regional finance center. Other major sources of employment include agriculture (especially in Skagit County), the forest products industry, and tourism.

For the purposes of Forest Planning, a five-county zone of influence has been defined. This zone includes Whatcom, Skagit, Snohomish, King, and Pierce Counties. British Columbia, Canada is a secondary zone of influence, as the Forest is an important recreation resource for the residents of Vancouver, B.C.

Population

Over one-half of Washington State's population resides in the five-county area. The 1988 population for the zone was almost 2.6 million; an addition 3.0 million people reside in British Columbia, Canada (Washington State OFM 1988). The entire area has experienced significant population growth, averaging almost 1.5% per year since 1970. Snohomish County has in recent years experienced one of the highest growth rates of any county in the country. Skagit County population has also been growing at over 2% per year since 1970.

Table III-38
Population

County	1960	1970	1980	1988	Percent Change 1970-88
King	935,014	1,159,375	1,269,898	1,413,900	22.0%
Pierce	321,590	412,344	485,667	547,700	32.8%
Skagit	51,350	52,381	64,138	70,800	35.2%
Snohomish	172,199	265,236	337,720	409,500	54.4%
Whatcom	70,317	81,983	106,701	119,100	45.3%
Zone of Influence	1,550,470	1,971,319	2,264,124	2,561,000	29.9%
Washington State	2,853,214	3,413,250	4,132,353	4,565,000	33.7%
Zone as Percent of State	54.3%	57.8%	54.8%	56.1%	---

	1970	1979	1988	Percent Change 1970 - 88
B.C. Canada	2,128,000	2,566,900	2,983,800	40.2%

Population Composition

King, Pierce, and Snohomish Counties are more urbanized and have younger populations, with fewer people in the over-65 age group than the State average. In fact, Snohomish County has the second lowest percentage of over-65 population of all counties in the State. Skagit and Whatcom Counties have larger numbers of residents over 65 years of age, reflecting the in-migration of retirees and the declining population of a number of rural communities, particularly as younger people move away to take jobs in more metropolitan areas. Projections made for Snohomish, King, and Pierce Counties indicate that some shifts in population composition can be expected, including an expansion of the youngest age group and more people in the 35-65 group, as the "baby-boom" group has children and ages (OFM 1986).

Minority Populations

The population of the Forest's zone of influence is predominately white; in 1980, 12 percent of the 5-county area's population was non-white. However, the majority of the State's Black and Asian populations live within the Seattle-Tacoma metropolitan area. Just under half of the State-wide Hispanic population lives in the metropolitan area. Slightly less than half of the State's Native American people live within the five counties. The area's non-white population increased from 7.8% to 12% between 1970 and 1980. That percentage is expected to show another increase after the 1990 census is completed, and will likely continue to increase over at least the next decade.

Table III-39
Selected Ethnic Population - 1980

County	Spanish Surname	Black	Indian	Asian	Other
King	27,080	55,275	13,353	62,744	9,669
Pierce	13,242	30,026	5,611	16,158	5,943
Skagit	2,010	99	1,217	399	1,524
Snohomish	5,500	2,523	5,089	5,518	1,976
Whatcom	1,957	244	3,071	846	779

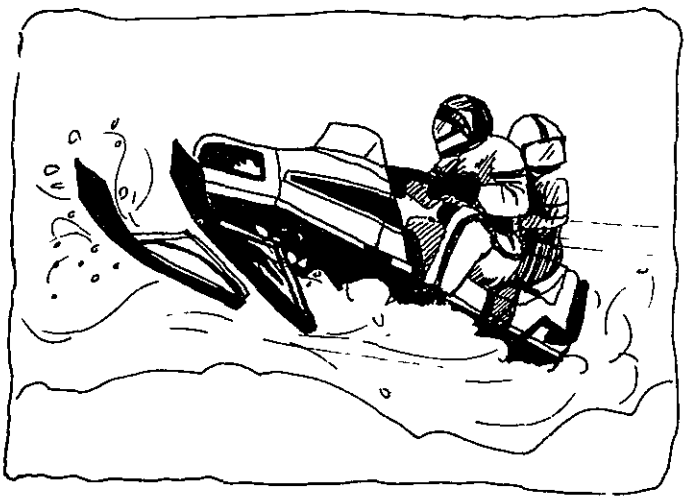
Projected Population Growth

Projections for future population in the Puget Sound area vary considerably. Two different projections were considered in the planning process, covering a range of population growth that may likely be expected, given the economic and demographic history of the region: Washington State Office of Financial Management (OFM) 1989; and Puget Sound Council of Governments (PSCOG) 1988.

The PSCOG projections are only available for three of the five counties. Both forecasts take into account the recession of the early 1980's, the subsequent economic recovery and growth since 1984, and the slowing of growth expected into the 1990's.



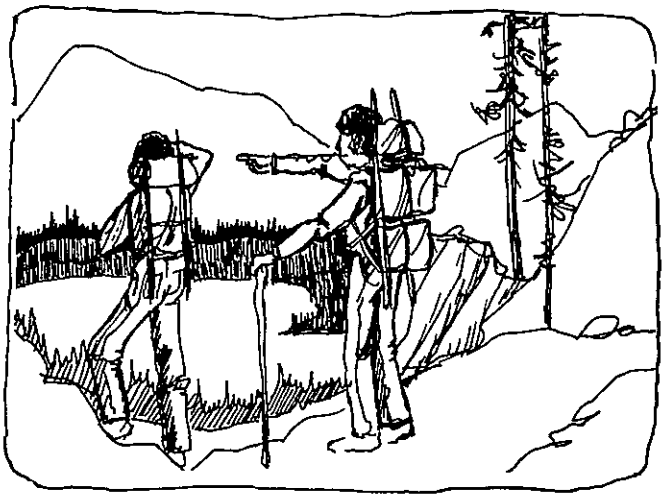


Table III-40
Projected Population 1/
1980 - 2000

County	1980		1990	% Change	2000	% Change
King	1,269,898	(OFM)	1,474,947	16.2	1,693,787	14.8
		(PSCOG)	1,461,000	15.3	1,697,500	16.2
Pierce	485,667	(OFM)	570,066	17.4	656,079	15.1
		(PSCOG)	565,700	16.5	672,100	18.8
Skagit	64,138	(OFM)	73,692	14.9	82,694	12.2
Snohomish	337,720	(OFM)	444,748	31.7	563,106	26.6
		(PSCOG)	429,000	27.0	555,900	29.6
Whatcom	106,701	(OFM)	123,822	16.1	137.389	11.1
Five-Co. Area	2,264,124	(OFM)	2,687,275	18.7	3,133,055	16.6
State	4,132,353	(OFM)	4,738,833	14.7	5,367.202	13.3

1/ Washington State OFM 1989; U.S. Department of Energy 1979; PSCOG 1988.

Although the State grew faster than the five-county area during the 1970's, that relationship reversed during the 1980's. Through the year 2000, growth in the five-county area should be faster overall than for the State as a whole. Forecasts for the area's population gains range about 18% percent from 1980 to 1990, and somewhat less than that in the decade 1990 to 2000. In spite of the recession of the early 1980's, King, Pierce and Snohomish Counties recovered and went on to experience a faster growth rate during the 1980's than in the 1970's. Skagit and Whatcom Counties, on the other hand, grew more slowly than in the 1970's. That pattern is projected to continue during the 1990's.

The central cities and older suburban areas in the five counties should remain relatively stable. Population growth has been, and will likely continue to be concentrated in several subareas, such as the towns and suburbs east of Bellevue, southeast King County, and south Snohomish County.

Income

When adjusted for inflation, real per capita personal income increased about 29 percent in the five-county area between 1970 and 1978. The increase in real per capita income dropped to about 10% from 1978-1987, following national and state trends. The recession of the early 1980's had a negative effect on relative income growth during that period. Income in the area is expected to increase within this range of rates through the year 2000, averaging 1.7 percent increase per year, as compared to 2.7 percent from 1960 to 1980 (PSCOG 1984).

Table III-41
Per Capita Personal Income
1970-1987

	1970 (1970 $)	1978 (1978 $)	1987 (1987 $)	Nominal % Change 1970-78	Real % Change 1970-78	Nominal % Change 1978-87	Real % Change 1978-87 1/
King	$4,601	$10,064	$19,511	118.7	31.0	93.9	15.9
Pierce	3,923	7,881	14,008	100.9	20.4	77.7	6.2
Skagit	3,653	8,269	14,301	126.4	35.6	72.9	3.4
Snohomish	3,649	7,625	15,511	109.0	25.2	103.4	21.6
Whatcom	3,599	7,773	13,595	115.4	29.4	74.9	4.5
Washington State	3,997	8,494	15,642	112.5	27.3	84.2	10.1

1/ Income deflated by implicit price deflator for personal consumption expenditures. Inflation by this measure was 66.9% from 1970-1978, and 67.3% from 1978-1987.

Employment

The five-county area accounts for over 60% of all wage and salary employment in the State of Washington and over 65% of all wages paid in the State. The Seattle-Tacoma-Everett metropolitan area is the dominant commercial center in the State and in the Pacific Northwest. It is a major center for finance, trade - especially to the Pacific Rim countries - transportation, administration, and government. Seattle is the regional headquarters for many Federal agencies.

As shown in Table III-42 and Figure III-11, wholesale and retail trade, manufacturing, services and government are the largest components of the area's economy. While the percentage of workers employed by the manufacturing sector has declined in recent years, manufacturing is still a major employer in the area. Transportation equipment manufacturing, primarily related to aerospace, employs about seven percent of the area's work force. Resource-based industries, including forest products, food products, fisheries and mining, have a long-standing prominent historical role in the economies of the Puget Sound area and of the State. These sectors currently employ about four percent of the five-county work force.

The forest products industry is the second largest manufacturing sector, both Statewide as well as in the regional economy, though it is still a small portion of the overall employment picture. Because of the manufacturing related to metals and to machinery manufacturing in the metropolitan area, lumber and wood products employment in the five-county area is just about on a par with these other sectors. Lumber production has the greatest local significance in Skagit County, where it provided over four percent of the wage and salary jobs in 1988. In Whatcom, Pierce and Snohomish Counties the figures

were between two percent and three percent in 1988, while it was less than one percent in King County.

Other industries which have major significance throughout the study area include agriculture (especially in Skagit County), trade, and the service sector. Jobs supported by tourism are somewhat hidden in the data for trade, services, and other sectors. Tourism and travel may be the third-largest industry in terms of sales and employment.

Table III-42
Wage and Salary Employment By Sector - Five-County Area 1/

Sector	Persons Employed 1979	1984	1988
Agriculture, Forestry, Fisheries 2/	9,475	12,488	16,142
Mining	694	634	804
Construction	56,686	47,682	63,001

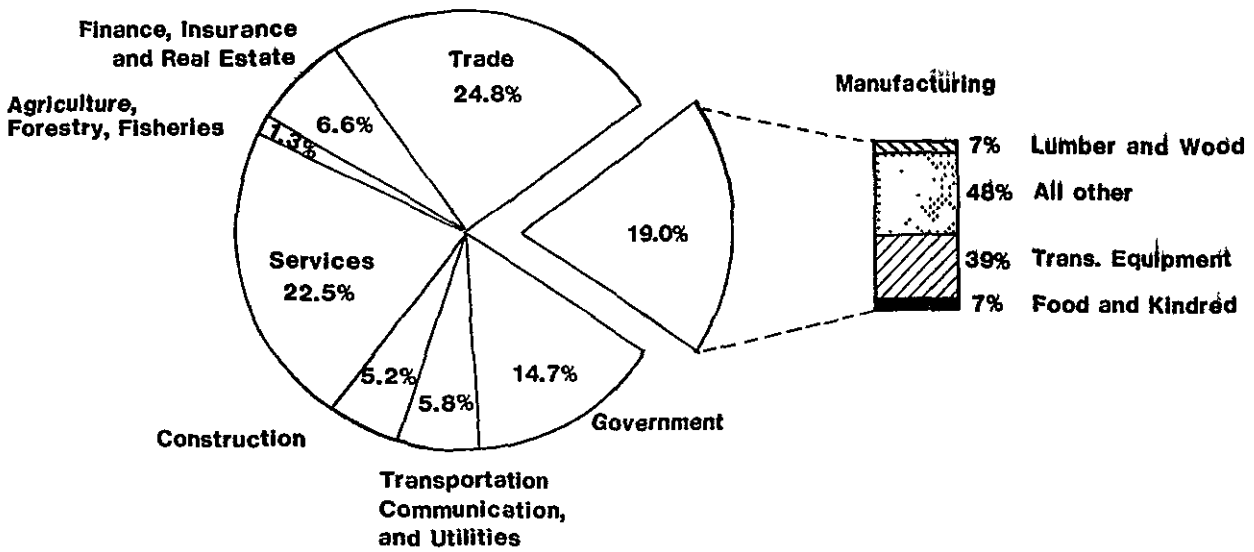
TOTAL	922,391	986,206	1,204,393

1/ Employment covered by Washington Employment Security Act, which covers in excess of 85% of total employment in the State. Does not include self-employed.

2/ Fewer than 5% of jobs in this sector are in the Forestry Services SIC Group.

Figure III-11
Employment by Sector



Note: Mining employment is 0.1% and does not show in the figure.

Wages Paid

In 1988, more than 1.2 million persons were employed in the five-county area. (Not included are self-employed persons, as well as workers not covered by the Washington Employment Security Act - another 10 to 15 percent of the total.) Almost $27 billion dollars in covered wages were paid in that year.

Table III-43 shows the total wages paid in several economic sectors. It also shows the average wage per job. Figures were calculated based on covered wages and employment for 1988 and do not include self-employed. While these figures are only averages, it can be seen that the average salary per job in some of the growing segments of the economy - retail trade, services, etc. - are substantially lower than wages paid in manufacturing.

Table III-43
Employment and Payrolls for 1988 - Five-County Area 1/

Economic Sector	Wages Paid (In Million $)	Jobs	Annual Wages per Job ($)
Agriculture, Forestry & Fisheries 2/	316.8	16,142	$ 19,627
Mining	23.3	804	28,970
Construction	1,488.5	63,001	23,627
Manufacturing	7,004.0	228,421	30,663

Transportation Equipment	3,224.2	88,316	36,507
All Other Manufacturing	3,001.1	108,818	27,579
Transportation, Communications & Utilities	2,087.7	69,783	29,918
Wholesale Trade	2,039.6	75,718	26,936
Retail Trade	2,819.5	222,942	12,647
Finance, Insurance, & Real Estate	2,028.5	79,799	25,420
Services	4,828.4	270,319	17,862
Government (All Levels)	4,273.1	177,464	24,079
TOTAL/AVERAGE	26,909.4	1,204,393	$ 22,343

1/ Employment covered by Washington Employment Security Act, which covers over 85% of total employment in the State. Does not include self-employed.

2/ Fewer than 5% of jobs in this sector are in the Forestry Services SIC Group.

Forest Payments to Counties

By law, twenty-five percent of the revenues collected by the Forest Service from timber sales, recreation, mineral, and other land-use charges are returned to the counties within which those national forest lands are located. Also included are collections for reforestation and amounts allowed to timber purchasers for road construction. Timber sales generate most of the revenues.

The funds are used for public schools and roads. Each state establishes a distribution formula. In Washington, fifty percent of the total receipts are forwarded directly to the counties for use on public schools or roads; the remaining dollars are distributed to the General Fund. The 50 percent given to the counties is split equally between roads and schools.

For the period 1980 to 1989, the Mt. Baker-Snoqualmie annually returned between $4.3 million and $8.9 million to the five counties. In 1989, the payment to counties per acre of National Forest land was about $2.45 for the Mt. Baker portion; for the Snoqualmie, it was $6.91. As a comparison, two other west-side forests in the state returned $4.94 and $12.78 per acre in 1989 (USDA

Forest Service 1989). The monies returned to counties are higher in Oregon, with several individual counties receiving over $10 million in 1989. State-wide, the federal payments to counties supply approximately 15 percent of the state funds for roads and streets. In comparison, one county in Oregon (Lane) depends on receipts for 75 percent of the county's road construction and maintenance. Table III-44 shows the returns to counties, by county, for the past ten fiscal years (a fiscal year is October 1 through September 30). The figure below shows the total returns from all five counties.

Table III-44
Returns To Counties

County	FY80	FY81	FY82	FY83	FY84
King	$1,437,231	$1,419,189	$ 851,310	$ 988,049	$1,068,133

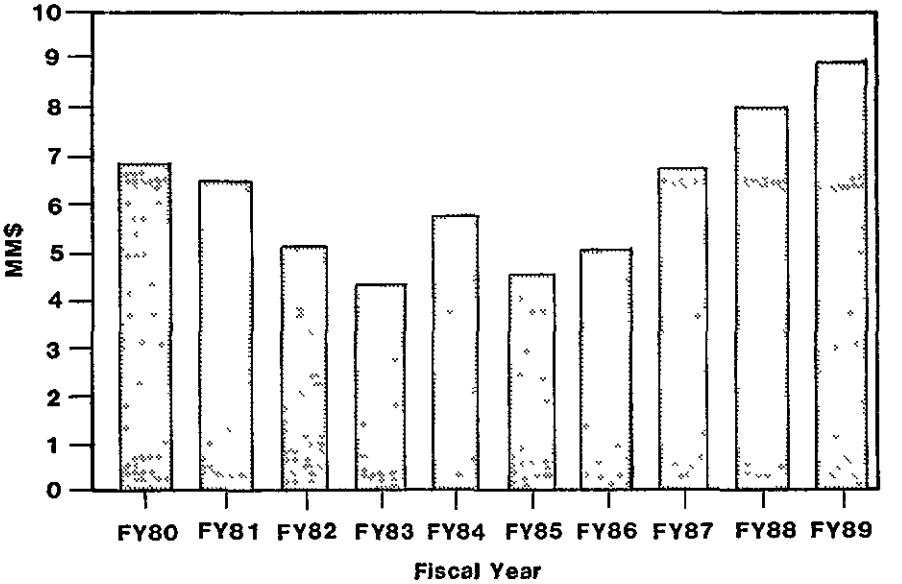
Figure III-12
Returns To Counties



Employment Growth

The Puget Sound area economy is quite diverse today, although it is still relatively dependent on aerospace employment and spending (Pascall and others 1990). National economic trends have and will continue to affect the area. Housing starts are now up from the slump of the early 1980's, but are expected to stay fairly level over the next decade. The trade and services sectors are expected to continue growing. The forest products industry has already experienced major changes over the last decade. A shakeout of marginal mills and more extensive modernization, coupled with new products and expanding markets, have led to high levels of wood products outputs in the past three years, but with about 25 percent fewer employees than required for similar output levels in the late 1970's.

Future manufacturing growth will likely be in the high-technology industries. Aerospace employment has begun to stabilize and is expected to stay slightly below its historic high for the next several years. Basic industries - food products, lumber and wood products, etc. - and government are projected to grow relatively little through the year 2000. In fact, forest products employment is expected to continue to decline over time as modernization and productivity gains continue to be made (NWPPC 1989). Non-manufacturing jobs should increase about 2.5 percent per year, compared to manufacturing, with projected annual employment growth of about 1.3 percent. However, the output of the manufacturing sector will continue to grow due to greater labor productivity and new technology (PSCOG 1984).

The areas location, lifestyle amenities, educated work force, and the many land and water resources should provide the base for continued economic growth in the future, though likely at a more modest rate than in the late 1980's, which has been a period of fairly rapid economic expansion.

Future Trends - Lifestyle

While most of the five-county areas population is concentrated in the low-lands along Interstate Highway 5, growth in the entire area reflects the national trends. Migration into the area is expected to continue. Most residents will live in urban-suburban areas, although growth in smaller towns and "bedroom" communities - reverse migration - is occurring. People regularly commute to jobs in Everett-Seattle-Tacoma from Carnation, Duvall, North Bend, and Enumclaw. Rural population centers like North Bend and Enumclaw - those within commuting distance of the Everett-Seattle-Tacoma metro area - are growing at a faster rate than the area as a whole.

The spread of knowledge, technology, and new values has shifted the metropolitan part of the Puget Sound area from an economy based on resource extraction to one based more on diversified manufacturing, trade, finance, tourism, and government. This same shift is now beginning to take place in the more rural portions of the area. The shift from resource extraction to services tends to place increasing emphasis on public goods such as developed and undeveloped recreation, clean air and water, and preservation of scenery.

Darrington and Granite Falls, plus Concrete, Skykomish, Sedro Woolley, and a few others are the remaining towns close to the Forest with residents who place

more value on resources than amenities, though the environment and lifestyle of the area are important to them. But, with mass communication and migration, the up-river areas are exposed to modern technology, knowledge, and values. Many new residents of the smaller, less urban communities have had little direct experience with the resource extractive uses of the Forest.

In the future, the decline of the traditional rural community is expected to continue, though overall population will increase. The changing local population composition, including greater numbers of people over age 65, a diverse regional economic base, and growth of regional industrial areas is likely to change the occupational patterns and value structures of many smaller towns. The rate of change can be expected to be faster in towns closer to the metropolitan area, including Sedro Woolley, North Bend, and Enumclaw. Those towns further away, including Darrington, will experience this change more slowly.

AMERICAN INDIAN RELIGIOUS AND CULTURAL USES

The resources of the Mt. Baker-Snoqualmie National Forest are significant to the Native American people who live in the Puget Sound area. The First Amendment to the Constitution and the American Indian Religious Freedom Act of 1978 (USDA 1978) protect their right to practice traditional religions by providing for access to religious sites, and use and possession of sacred objects, and the protection of areas important to these practices. Other uses, such as the right to collect roots and berries, are guaranteed by the Medicine Creek and Point Elliott treaties.

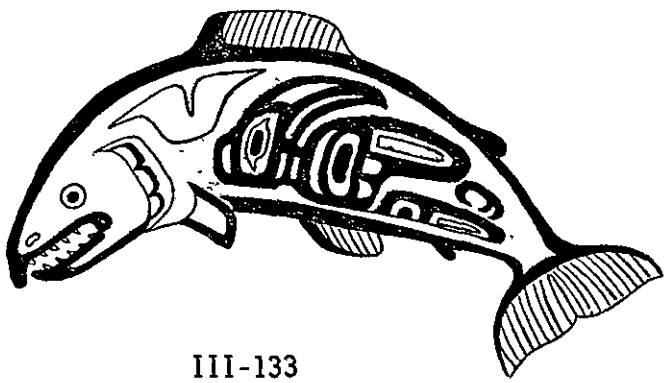
At least fifteen tribal groups currently use the Forest for traditional religious uses: Lummi, Nooksak, Swinomish, Samish, Upper Skagit, Sauk-Suiattle, Stillaguamish, Snoqualmie, Tulalip, Duwamish, Puyallup, Muckleshoot, Nisqually, and Cowlitz. This represents a potential user group of approximately 25,000 Indians (Department of Commerce 1980). This figure is slightly under one percent of the total population for the five-county area of influence, but for many of the Indian people, the National Forest has been, and remains, a vital resource for the continuous practice of their traditional religion.

Traditional religion is a significant component of the social and community structure of Puget Sound tribes. The religion teaches good and correct character and behavior, contributing to the smooth functioning of personal and group relationships. Further, proper religious practice ensures success in life. Those who are successful become role models and authority figures within the community. Disruption of religion can therefore destroy personal sense of worth, interpersonal relations, and tribal leadership.

The Inventory

The Mt. Baker-Snoqualmie is currently one of the few National Forests with an inventory of Indian religious sites. A growing concern among the tribes for present and future availability of resources and access to important sites and areas resulted in the 1981, The Inventory of Native American Religious Use, Practices, Localities and Resources (Blukis Onat and Hollenbeck 1981).

Five categories of use areas and sites were mapped and described in the Inventory: cedar areas, ceremonial flora areas, spirit quest sites, legend sites, and cemeteries and archaeological sites. Some sites cover less than one acre; others average between 3,000 and 15,000 acres. A total of approximately 450,000 acres were identified as sites and areas important for religious and cultural practices. Identified use areas and sites are located throughout the Forest, but are concentrated in the northern half, between the Snoqualmie River and the Upper Skagit River. There is some use in the Nooksack River drainage.



Environmental and Religious - Cultural Relationships

For certain uses, the condition of the area and the integrity of the relationship of vegetation, water, wildlife, and fish is important. Any area of the forest containing old-growth cedar and/or clean streams and/or plants used for medicinal or ceremonial purposes is a potential religious use area. Areas where these resources co-occur are especially important (Blukis Onat and Hollenbeck 1981).

About 34 percent of the inventoried acres are located within designated wilderness - close to 139,084 acres. One-third of the use sites and areas within wilderness contain old-growth trees. Over half of the inventoried sites and areas outside of wilderness contain stands of old growth; 75 percent of these stands are tentatively suitable for commercial timber harvest. Refer to the discussion on tentatively suitable land in Vegetation, Chapter III. At this time, data showing the acres of old growth overlapping with clean streams and/or important plants is not available.

Anadromous fish have been a traditional and principal means of income for many Native Americans living in the planning area. Protection and enhancement of the habitat for anadromous fish is a major issue.

Indian religious practitioners prefer privacy for rituals, without intrusion of visual or audible disturbances. Some religious use may require isolation, privacy, and purity of environment. The degree and nature of uses or management activities (such as recreation use or the harvest of timber) that are compatible with Native American religious use depends on the kind of use, and the condition of the environment. Semi-primitive and primitive recreation may be compatible. Timber harvest, road construction, and hydropower development can damage the value of a site for ceremonial use.

Spirit quest and legend sites are the most sensitive areas of religious use and practice. The sounds of cars, trucks, and voices can disturb religious practice. Sudden intrusions from hikers, cross-country skiers, kayakers, etc. can be disturbing to practitioners. Timber harvesting, small hydroelectric power developments, and other evidence of secular activities can detract from the isolation, privacy, and purity of these areas.

Cedar is used for a variety of purposes, and is an important component of the environmental setting for religious practices. A variety of age classes are used. Old-growth cedar is valued for use in canoes and long houses. When cedar is of "saw log" size, its bark is most suitable for gathering for use in baskets and other items. Through the consultation process (discussed below), it appears that the need for isolation, privacy, and purity is somewhat less than in spirit quest sites.

Over 75 species of medicinal and ceremonial plants have been identified in the 1981 inventory. The rights to gather some of these plants are provided for in the American Indian Religious Freedom Act and in the Treaties of Point Elliott and Medicine Creek. Like cedar, the extent to which isolation, privacy, and purity are important to the setting from which plants are gathered is not been known.

Historic and currently used cemeteries will be protected in all alternatives. Archaeological sites are discussed in the following section.

The Consultation Process

During the scoping phase of project environmental analyses, Inventory data are reviewed by the Forest Service project leader and the Forest Archaeologist. When a project overlaps inventoried use areas, officials and known religious leaders of the affected Tribe(s) are notified, and their comments sought. If adverse effects are identified, meetings may be held to identify potential avoidance or mitigation measures. These are incorporated into the environmental document and considered in the selection of a preferred alternative and its mitigation measures.

In 1987, the Forest contracted for the development of an improved consultation process. The results of this contract will be used as a starting point for an update of the Inventory, scheduled for 1991 (Forest Plan, Appendix D, Cultural Resource Implementation Schedule). The update will identify changes in religious use since 1980, and specify consultation procedures appropriate for specific tribes.

The Future

Native American religious and ceremonial use of the Forest and its resources is likely to increase. Numerous investigators predict increased involvement in traditional rituals and ceremonies. There are an estimated 3,000 active "Spirit Dancers" in the Native American community. The traditional religion continues to satisfy needs that often go unmet by non-Indian society (Suttles In: Blukis Onat 1981).

The Forest will offer the majority of the remaining unmodified natural environments in the Puget Sound area, increasing the demand beyond that attributable solely to growth in the number of practicioners.

ARCHAEOLOGICAL AND HISTORIC PROPERTIES

There are a wide range of archaeological and historic properties on the Mt. Baker-Snoqualmie National Forest. Almost 1000 have been reported on or near the Forest. To date, only about 200 have been adequately investigated and reported, because of the difficulty of survey and site location in the rugged terrain and dense vegetation of the Cascades. Also, the focus of survey efforts - proposed project areas - has limited opportunities to record many sites.

Properties include prehistoric or archaeological sites containing a diverse range of artifacts and historic buildings and groups of buildings. They also include extensive linear features, such as historic trails, wagon roads, and railroad grades. Properties may also include a large "district", like the Stevens Pass Historic District, which contains a network of rail lines, tunnels, trestles, switchbacks and snowsheds, linking townsites and remains of railroad construction camps.

Cultural resources represent tangible evidence of human history. Some also contain irreplaceable scientific data. As land development outside of the Forest boundary continues and more cultural resources are destroyed, the proportion of cultural resources in the Puget Sound area that are located on Federal land will increase. As time goes on, the value of the cultural resources on the Mt. Baker-Snoqualmie is expected to increase. Concurrently, there may be increased conflicts with other, more consumptive uses, such as timber harvesting, road building, recreation developments, and others.

The Forest Service is charged with the responsibility to identify, evaluate, protect, interpret, and enhance archaeological and historic properties. In accordance with the National Historic Preservation Act of 1966 (USDA 1966), amended in 1980, the effects of management activities on significant cultural resources must be considered. The Forest is directed to complete an inventory of all cultural resources and evaluate them for possible inclusion on the National Register of Historic Places.

On the Mt. Baker-Snoqualmie National Forest, inventories have generally been conducted on those acres where projects are planned, such as timber sales, road or trail construction, campground construction, or on acres which are proposed for transfer from Federal ownership. As of 1985, about 170,000 acres or 10 percent of the Forest have been inventoried.

Cultural and historic properties will be discussed in three sections: archaeological sites, including cemeteries, historic buildings and structural remains, and linear cultural features.

Archaeological Sites

Archaeological evidence indicates that Native Americans have occupied western Washington for at least 10,000 years (Gustafson and others 1979). The earliest evidence for occupation and use of upland areas dates to 6,000 years (Hedlund 1979). At this time, there are 20 known prehistoric sites on the Forest; only one of these sites has been investigated and, as yet, none have been dated.

Archaeological sites on the Forest often escape early detection. The difficulties of reliably identifying potential buried archaeological sites in the dense, forested environment of the western Cascades is widely acknowledged (Aikens 1976, Connolly and Baxter 1983, Darsie and others 1985, Pettigrew 1985, Wessen 1985). The thick understory vegetation, layers of decaying plant litter on the forest floor, and fallens trees obscure the ground surface. Even surface sites can be disguised under the dense vegetation; they are often only exposed in a few localized places, such as cut banks or upturned trees (Carter 1978).

The wet, cool climate of the Forest is very destructive to artifacts. In prehistoric sites, organic artifacts (baskets, wooden tools, clothing, etc.) deteriorate rapidly (Baenen 1981, Blukis Onat 1981, Gordon and Buikstra 1981, White and Hannua 1983). Usually only stone tools are durable enough to withstand the climate through the years.

Other factors related to the difficulty of identifying archaeological sites include the techniques used to explore in this area and the subtlety of the deposits, especially compared to other parts of the country. Subsurface "shovel-testing" has not been used to search for sites on this Forest, though it is a technique used elsewhere (Chartkoff and Chartkoff 1980). This is likely due to the large size of proposed projects (timber sales, campgrounds, road and trail construction, etc.), the labor involved, and the low rate of site discovery in proportion to the labor.

Additionally, deposits are likely to be of a more subtle type than found in other parts of the nation. Prehistoric occupation of the Forest might result in limited campsites or use areas with the remains consisting of a scatter of chipped stone tools, a buried fire hearth, or soil stains to reflect the presence of structural remains. These are much harder to detect than the extensive shell midden sites on the Olympic Peninsula or cliff dwellings in the southwestern portion of the United States.

The value of archaeological sites lies in their contribution to our knowledge of prehistory and history, insights not available in any other form. The "context" of artifacts is important. This is the exact location of artifacts in the soil profile, their spatial relationship to other artifacts or features in the site, associated "ecofacts" like food remains, and more. If the soil has not been disturbed and an artifact is located "in situ" or in its original place, it may be possible to determine the age and use of the artifact, and describe and explain the behavior which it represents.

Archaeological resources are not limited to prehistoric sites; some historic sites physically remain in archaeological context only. These sites are valued for the information they contain about our history.

Archaeological sites may also be of value to contemporary communities (for example, Indian Tribes) as documentation of that community's role in history.

Historic Buildings and Structural Remains

The earliest recorded explorations of the Forest by Euro-Americans occurred in the early 1800's. Explorers and fur trappers were soon followed by miners, the military, lumbermen, and homesteaders. These early residents found the forest

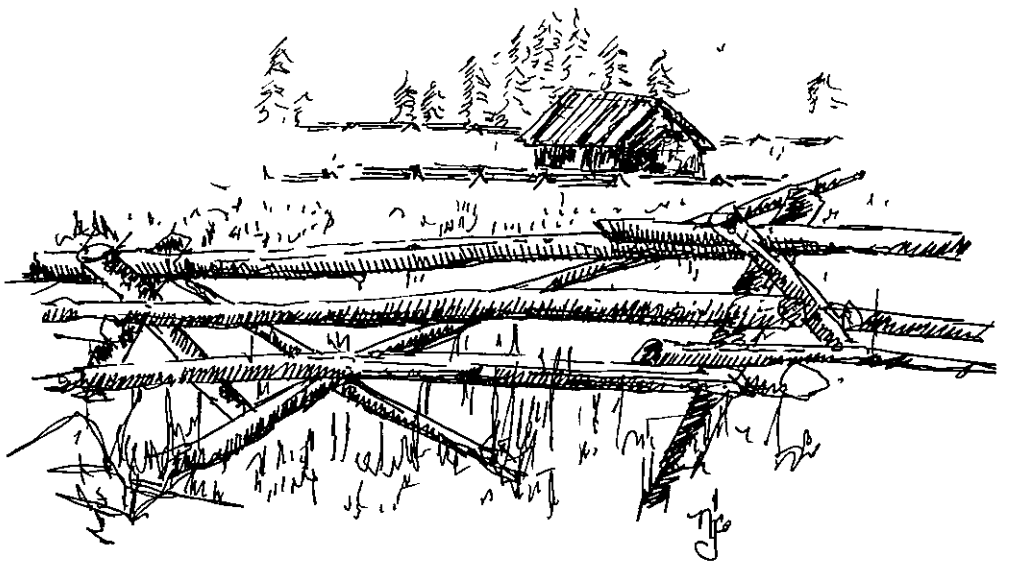
environment less desirable than the flatlands, river valleys, and shorelines of Puget Sound. The forest resources in the Cascades were reached by Indian trail and later by mine- and timber-to-market roads and railroads. As access improved and exploitation of forest resources was easier, settlers moved closer to the mountains.

Several major historic themes, important in the history of the Pacific Northwest, are represented on the Mt. Baker-Snoqualmie National Forest. These include, but are not limited to: exploration and settlement, early mining, historic logging, development of trans-Cascadian and trans-continental transportation and communication, and Forest Service administrative history.

Sites and features representative of the historic period include old townsites, homesteads, isolated cabins, campsites, and associated domestic remains; mining camps and equipment, mill sites, tramlines, and mine shafts; logging camps, skid roads, sawmills, chutes, dams, and early logging machinery; tunnels; and trestles. Early Forest Service history is represented by guard stations, fire lookouts, recreation developments, trails, and Depression-era administrative compounds.

Historic buildings rarely occur in isolation but are usually part of larger patterns of development, including roads and trails, railroads, camps and towns (see below). These networks of cultural features can cover a considerably larger area than the structure itself. Cultural features are often found in currently used recreation sites, simply because places that attracted human use and occupation in the past also attract contemporary use.

Historic buildings and structural remains tend to be more visible and recognizable than archaeological sites. Also, archival information can be used to locate them. Because of these factors, there is a greater chance that historic buildings and remains will be discovered prior to any ground disturbing activity. However, dense vegetation can disguise or cover them.



Historic buildings and remains are especially vulnerable to weathering and deterioration from wind and rain, insects, falling trees, fire, and trampling by wildlife. On the Forest, most of the inventoried wood frame or log structures (aside from administrative sites still under use) have experienced substantial deterioration. Besides the natural elements of destruction, man can cause damage or collapse of old buildings and structural remains. Refer to Chapter IV for more specific effects.

The principal value of historical resources are their associations with the past - with broad patterns in history, with historic persons, or with characteristic modes of technology and construction. These are also the same values that make linear features important.

Linear Cultural Features

Linear cultural features are the remains of historic routes of communication and/or transportation. They include trails, wagon and military roads, mine-to-market roads, railroad lines and grades, early corduroy logging roads, ditch lines, and early Forest Service trails and telephone lines. On the Mt. Baker-Snoqualmie National Forest, specific linear features include the Naches Trail, the 6,649 acre Stevens Pass Historic District, Snoqualmie Pass Wagon Road, Yakima Pass, and the Huckleberry Mountain Indian Trails.
Current travel and communication routes often follow the historic routes; Interstate 90 or the North Cascades Highway over Washington Pass are examples. Ridges have been travelways for both man and animals; river corridors (and associated riparian areas) have long been used for access by both.

Because linear cultural features can extend for miles or cover a large area, complete avoidance by current users of the forest is impossible. As segments of the linear cultural feature are damaged, the integrity of the whole feature is diminished. There may be conflicting demands placed on historic trails by different user groups, from hikers to ORV users to horseback riders. However, because of their size and accessibility, linear cultural features can provide great opportunities for aesthetic and educational experiences for visitors.

The Future

The historic preservation community has demonstrated continued interest in management of cultural and historic properties. Many of the Forest's cultural properties were first recognized by these organizations, who in turn nominated them to the National Register. Some groups and individuals have taken on the responsibility of protecting and maintaining historic fire lookouts; others have been active in protecting the Naches Pass Trail.

Archaeological research, in the past, has concentrated on the coastal areas of Western Washington (Archaeological Research Services, Inc. 1981, Blukis Onat 1981, Geo-Recon International 1981) and upland forest areas have received little attention (Hedlund 1979, Hedlund and others 1978, Moura and Kennedy 1981). At this time, the academic community is becoming more aware of the exceptional value of the cultural and historic properties located on National Forest land. Many sites on the Mt. Baker-Snoqualmie have escaped human disturbance and they represent some of the most pristine examples of archaeological sites in the region. Their research value in reconstruction of

prehistoric and historic lifeways is recognized (Blukis Onat and others 1980, Carter 1978). There will also be an increased level of protection and preservation of these properties.

Management decisions concerning cultural resources will be made in a context of increasing public interest and involvement, with growing public appreciation of these resources contribution to community economies and identity. In response to these concerns, the amount of inventory not tied to specific development projects will increase, to equal or surpass the amount of inventory for development projects.

SCENERY

The Mt. Baker-Snoqualmie National Forest contains some of the nations most scenic forest landscapes. The Forest contains a broad spectrum of landforms and a wide variety of visual settings or scenes.

Lush, low-elevation forests contrast sharply with the glaciated peaks and ridges of the North Cascade Mountains. Major mountain peaks located within the Forest boundary, or visible from the Forest include Mt. Baker, Glacier Peak, Monte Cristo Peak, Mt. Index, and Mt. Rainier. These are dominant focal points for the forest visitor. Adding to the visual variety are the eight major river drainages that dissect the Cascades, and the broad Puget Sound Basin visible to the west of the Forest.

Contrasting with this natural landscape are human modifications, including roads, rockpits, utility corridors, ski areas, and the activities associated with timber harvesting. The linear road corridors and geometrically-shaped clearcut patterns resulting from past timber harvest are the most visually evident. However, natural appearing environments exist on much of the Forest, even where extensive timber harvest and other activities are occurring.

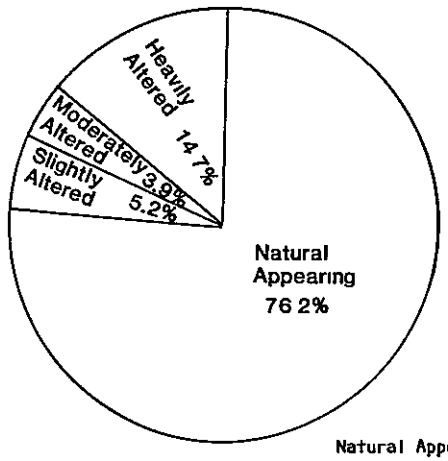
Classifying Visual Conditions

The visual resources of the Forest have been inventoried using the Visual Management System (USDA Forest Service 1974). The Existing Visual Condition of the Forest, including wilderness, was inventoried and mapped in 1979. This inventory is a survey of the actual visual condition of various forest landscapes at a point in time. As shown in Figure III-13, on the next page, most of the Forest is natural in appearance. Approximately 15 percent has been heavily altered by activities such as cutting commercial timber, road construction, and other projects.

This current condition is a result, in part, of the Roadless Area Review and Evaluation (RARE) process. From 1972 until the RARE Final Environmental Impact Statement was issued in 1979, up to 45 percent of the Forest was essentially unavailable for timber harvesting or roaded activities. Timber harvest and reforestation was concentrated in accessible, low-elevation areas. The schedule between "entries" to harvest timber in an area was also shortened. Designated wilderness and the roadless areas remained natural appearing.

The large amount of heavily altered land is also attributable to the intermingled land ownership pattern on some parts of the Forest. When viewed in the context of the visible landscape, roads and timber harvesting on private land adjacent to the Forest have influenced the visual condition on National Forest lands.

Figure III-13
Forest-Wide Existing Visual Condition
1979



Natural Appearing Area appears untouched by man; changes not visually evident.

Slightly Altered Changes may be noticed by the average visitor but do not attract attention. Natural appearance dominates minor disturbances.

Moderately Altered - Changes are easily noticed by the average visitor and may attract attention Disturbances are apparent.

Heavily Altered - Changes are strong and obvious to the average visitor. Changes dominate the landscape but may resemble natural patterns when viewed from a distance of 3 to 5 miles. Disturbances are major.

Viewsheds

Recreation experiences are a combination of activity at the use area and the visual perceptions of the landscape as viewed during travel on the Forest and at the recreation site. One of the largest recreation activities is driving through the Forest, for pleasure. Most forest visitors travel through or recreate on only a small portion of the Forest. The "seen" landscape visible to most visitors are those acres seen from roads, trails, rivers, and recreation areas. These "viewshed" corridors have been inventoried and mapped, using the current recreation and transportation patterns.

To establish a framework for planning emphasis, the Forest had been divided into 56 viewsheds. A viewshed is the portion of the landscape "seen" by most visitors from roads, trails, rivers, or recreation areas. Most are corridors one-quarter mile to 2 miles wide on either side of a road, trail, or river. The viewsheds are further subdivided into 25 highly sensitive, or Primary Viewsheds, that are viewed from primary travel routes, and 31 moderately sensitive, or Secondary Viewsheds.

The Existing Visual Condition of the 56 viewsheds is shown in Table III-45. This visual condition is a summary rating of the overall impression a visitor would have of each viewshed, at the present time. It should be noted that a higher percentage of acres (29 percent) within viewsheds is heavily altered, than in the acres outside of the viewsheds (13 percent).

Table III-45
Existing Visual Conditions Within Viewsheds, 1983 1/

Condition	Acres	Percent of Total Viewsheds
Natural Appearing	96,591	46.3%
Slightly Altered	53,047	25.4
Moderately Altered	11,765	5.6
Heavily Altered	47,316	22.7
TOTAL	208,719	100.0 %

1/ Recently acquired lands have not been inventoried for EVC, thus the acres shown here are less than the total viewshed acres shown in Table III-46.

Figures III-14a and 14b - maps of the viewshed corridors for the north half and south half of the Forest - show the approximate location of the individual viewsheds. Table III-46, on page III-146 and 147, shows the name, acres, and existing condition of the viewsheds.

Visual Quality Levels

Visual Quality Levels have also been mapped for the entire Forest, by viewsheds. Visual quality is classified according to the scenic variety of an area and how often it is seen by the viewing public. The levels are defined in Table III-47.

Table III-47
Existing Visual Quality Levels
1984

Visual Quality Level	Description	Acres	% of Forest
Preservation (P) 1/	Areas in which only ecological change has taken place, except for trails needed for access. Land appears to be untouched by human activities.	729,507	42.3 %
Retention (R)	Areas in which changes in the landscape are not visually evident to the average person unless pointed out. Land appears to be natural.	261,744	15.1
Partial Retention (PR)	Areas in which changes in the landscape may be noticed by the average forest visitor but they do not attract attention. The natural appearance of the landscape still remains dominant. Changes appear to be minor disturbances.	422,345	24.5
Modification (M)	Areas in which changes in the landscape are easily noticed by the average forest visitor, and may attract some attention. Changes appear to be disturbances but resemble natural patterns.	307,016	17.8
Maximum Modification (MM)	Areas in which changes in the landscape are strong and would be obvious to the average forest visitor. These changes stand out as dominant, yet they may resemble natural patterns when viewed from 3-5 miles or more distant. They appear to be major disturbances viewed at closer distances.	4,729	0.3

1/ Preservation is generally reserved for areas that have been Congressionally or administratively established, such as wilderness.

Visual Quality Levels (VQL) vary by alternative in this FEIS. The existing VQL provides a basis for measuring the effects of each alternative on the scenery. Visual Quality Levels are Visual Quality Objectives in the Forest Plan.

Supply and Demand

The Existing Visual Condition, indicating the current degree of alteration from a strictly natural condition, constitutes the supply of visual resources. The 293,901 acres of land in a heavily altered condition will require long-term special designs and scheduling of projects to decrease the effects of past activities and to "move" these acres to a less altered Visual Quality Level.

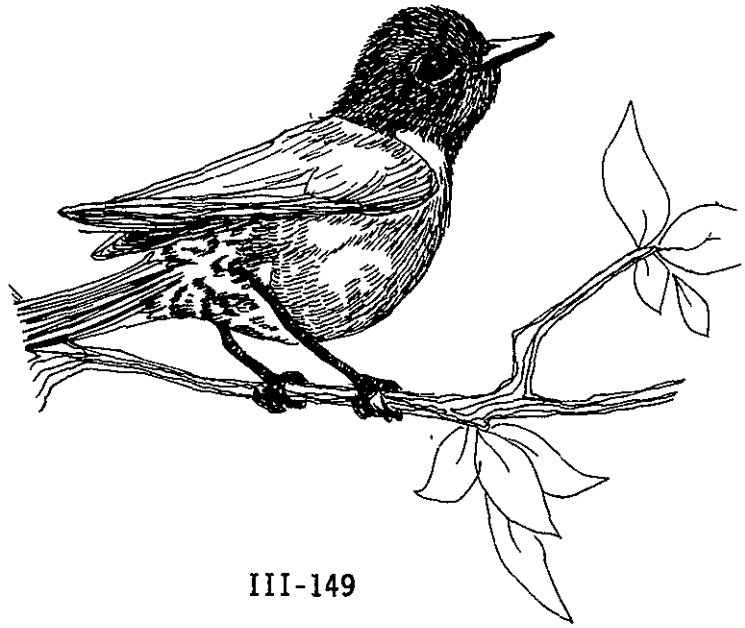
Regardless of the alternative selected in the Forest Plan, the visual pattern currently existing within the heavily altered areas will be evident for fifty to eighty years, assuming no additional management activity occurs. As shrubs and trees "green up" old harvested areas, the linear patterns of roads become less evident and disturbances begin to blend into the natural environment. In addition, special designing of future timber harvest can soften the hard edges of older clearcut units.

The demand for landscape management or scenic beauty comes from several sources. Nationally, concerns were vocalized in the late 1960's and early 1970's, primarily over clearcutting practices in the Monongahela, Bitterroot, Bridger-Teton, and Tongass National Forests. Several major pieces of legislation resulted. Scenic quality is also closely associated with recreation opportunities; the Recreation Opportunity Spectrum classes are tied to and reflect the appearance of the landscape.

Scenic Byways

The National Forest Scenic Byway designation acknowledges scenic drives where the combination of forest setting, recreation, and interpretive opportunities provide a quality pleasure driving activity.

The Mt. Baker Highway was designated a Scenic Byway in 1988. It includes over 24 miles along State Road 542. The Mountain Loop Highway and Stevens Pass Highway will be nominated in 1990.



RECREATION

Introduction

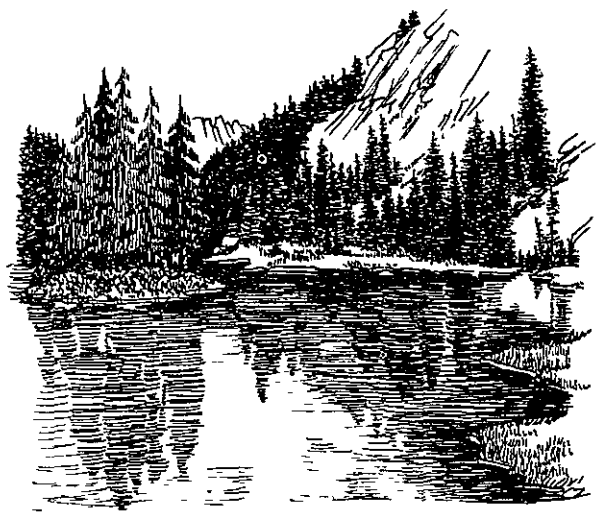
The Puget Sound area is rich in recreation opportunities, from National Parks (the Olympic, North Cascades, and Mt. Rainier) to urban, county, and state facilities. The Mt. Baker-Snoqualmie National Forest is a key component, complementing available recreation use on other public and private lands.

The Forest is located within a one-half days drive for over 2.5 million people in the five-county area of influence. An additional 3.0 million persons live in the Vancouver, British Columbia metropolitan area. No other Forest in Oregon or Washington is closer to such a large recreation market. The Forest contains some of the nations most scenic and primitive country; also available are opportunities to enjoy many types of developed and dispersed recreation.

The importance of the recreation resource of the Forest has been recognized in several acts of Congress in recent years. The Alpine Lakes Area Management Act of 1976 (PL 94-357) found the area to have "...opportunities for great diversity of recreational use and enjoyment during all seasons of the year" (USDA 1976). The Wild and Scenic Rivers Act of 1968 (PL 90-542) declared the Skagit River to "...possess outstandingly remarkable scenic, recreational values...to be preserved and protected for the benefit and enjoyment of present and future generations" (USDA 1968).

The Washington State Wilderness Act of 1984 (PL 98-339) found that "...many areas of undeveloped National Forest System lands possess outstanding natural characteristics which give them high values as wilderness" (US 1984). Finally, the National Park Act (PL 90-544), which designated the North Cascades National Park recognized the establishment of a vast, contiguous recreation complex in the State of Washington and provides a clear, legislative mandate for the management of "...National Forests adjacent to the park" (US 1916).

Between four and five million recreation users visit the Mt. Baker-Snoqualmie each year, making it one of the most heavily visited National Forests in the country. This figure includes a number of Canadian visitors. Table III-50 shows the recreation use of three Washington State National Forests, including the Mt. Baker-Snoqualmie, and the three National Parks in the State.



National Forests received 78 percent of the total recreation use, compared to 22 percent in the three Parks; the Mt. Baker-Snoqualmie received 37 percent of the total use. The Mt. Baker Snoqualmie National Forest provides 30.5 percent of the backcountry recreation use in northwest Washington.

Table III-48
1988 Recreation Use On Federal Lands - Northwest Washington - RVD's

	Total Recreation	Wilderness/Backcountry (USFS) - (NPS)
National Forests		
Mt. Baker-Snoqualmie	5,196,300	455,500
Olympic	1,526,110	89,500
Wenatchee	4,409,800	485,500
Subtotal	11,132,210	1,030,500
National Parks		
Mt. Rainier	1,409,500	98,100 1/
North Cascades	419,800	84,300
Olympic	1,246,900	278,300
Subtotal	3,076,200	460,700
TOTAL	14,208,410	1,491,200

1/ The National Park Service reports backcountry use by overnight visits; for the purpose of this table it was assumed that the average stay was approximately 40 hours. Refer to the Glossary for other definitions.

Recreation use is heaviest in the summer months, but occurs in all seasons of the year. In the early spring, hikers, horse users and mountain bikers flock to low elevation trails. These recreationists follow the melting snows upward during the summer until fall storms begin to push users back down into the valleys. Scenic highways and forest roads are equally attractive to visitors, and driving for pleasure is a popular public recreation use of the Forest. Although a majority of this use occurs of federal and state highways crossing the National Forest, such as I-90 over Snoqualmie Pass. In 1989, there were 45 campgrounds and 11 picnic sites offering visitors an outdoor experience for a few hours or for several days.

Water is one of the focal points for recreation on the Forest. Dozens of rivers and creeks begin in melting snows and glaciers and flow down through forested valleys to Puget Sound. Hundreds of lakes and tarns dot the alpine highcountry; several large lakes offer recreation opportunities in the mid- to lower elevations of the Forest. Water-oriented recreation includes fishing, swimming, boating, and river rafting.

Upland birds and deer hunting season mark the beginning of hunting season and ends with deer and elk seasons in late fall and early winter. Since some of the state's largest herds of deer, elk and goat populations are found within the Forest, thousand of hunters take to the woods each fall.

Downhill skiing is the major focus of winter use, and continues to increase steadily in popularity at seven ski areas. Snowmobiling use grew in the 1960's and leveled off in popularity in the late 1970's. However, snowbound forest roads, groomed snowmobile trails, and areas of open terrain continue to attract hundreds of snowmobilers on winter weekends. Cross-country skiing has exploded in popularity in recent years; skiers take advantage of Forest roads as well as

several ski trails developed through scenic forest terrain with volunteer labor. Parking is provided by state snowplowing at seven "sno-park" sites located throughout the Forest.

National Recreation Strategy

The National Recreation Strategy emphasizes strengthening and rounding out multiple-use management on the National Forest System lands. An aim of the National Recreation Strategy is to find creative and innovative ways to take advantage of outdoor recreation opportunities on the Forest by working with individuals, organizations and associations. The ultimate goal is customer satisfaction with high quality recreation services and facilities.

Applicable Existing Plans

Several approved plans provide existing management direction for recreation on the Forest:

Plan	Year Approved	In Forest Plan
Glacier Peak Wilderness Plan	1976	Superceded by Plan
Off-Road Vehicle Management Plan	1977	Updated in the Plan
Trail Management Plan (Interim)	1979	Updated in the Plan
Alpine Lakes Area Management Plan	1981	Incorporated in Plan
Skagit Wild and Scenic River Final River Management Analysis and Plan	1984	Incorporated in Plan

Recreation Opportunity Spectrum

The Forest provides recreational settings that range from Congressionally designated wilderness to intensively managed forest lands. Any recreational setting actually consists of three kinds of settings - physical, social, and managerial:

- The physical recreational setting of an area is defined by its size, the presence and extent of environmental changes caused by human activity, and the presence or absence of human sights or sounds.
- The amount and type of contact occurring between individuals and groups using an area constitutes it social setting.
- An area's managerial setting refers to the number and kind of regulations used by the Forest Service to manage use in that area.

Different combinations of these three settings provide recreationists with different kinds of recreational experiences. Such combinations range from extremely isolated, pristine natural surroundings with very few visitors and management regulations, to intensively developed surroundings like ski resorts used by large numbers of people, who are highly regulated. To assist in the inventory and management of recreational resources, the Forest Service developed the Recreational Opportunity Spectrum (ROS), which classifies recreational surroundings in terms of their physical, social, and managerial settings.

Mt. Baker-Snoqualmie National Forest lands have been evaluated for the recreational settings they currently provide, using six Recreation Opportunity Spectrum (ROS - see the glossary) classes. These classes are: Primitive (P), Semi-Primitive Nonmotorized (SPNM), Semi-Primitive Motorized (SPM), Roaded Modified (RM), Roaded Natural (RN), and Rural (R).

The acres of wilderness on the Forest have been inventoried using a different ROS scheme; wilderness ROS is discussed later in this chapter. Each Forest acre has been assigned to one of the ROS classes. A more complete definition of the Recreation Opportunity Spectrum may be found in the 1986 ROS Book (USDA, Forest Service 1986).

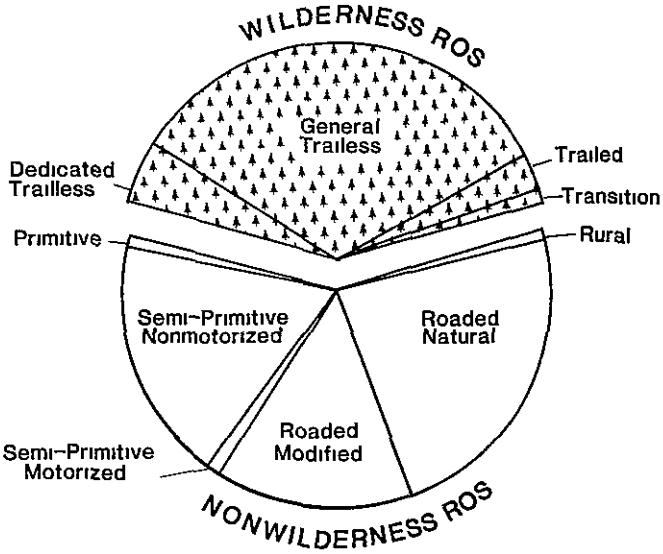
The table and figure below show the distribution of the acres of the Mt. Baker-Snoqualmie National Forest by ROS class, for the current situation.

Table III-49
ROS Acres - Nonwilderness and Wilderness - Current Situation

Nonwilderness ROS	Acres 1/	% of Nonwild.	% of Total Acres
Rural	4,540	0.5%	0.3%
Roaded Natural	399,326	39.7	23.2
Roaded Modified	248,077	24.7	14.4
Semi-Primitive Motorized	9,714	1.0	0.6
Semi-Primitive Nonmotorized	327,334	32.5	18.9
Primitive	16,683	1.6	0.9
Subtotal Nonwilderness	1,005,674	100.0	58.3
Wilderness ROS		**% of Wild.**	**% of Total Acres**
Transition	12,067	1.7%	0.7%
Trailed	44,356	6.1	2.6
General Trailless	585,326	81.1	33.9
Dedicated Trailless	80,000	11.1	4.6
Subtotal Wilderness	721,749	100.0	41.8
TOTAL	1,727,423	100.0	

1/ R2MAP acres may vary from other totals elsewhere in this document.

Figure III-15
ROS Acres
Wilderness and Nonwilderness Current Situation



The lands surrounding the Mt. Baker-Snoqualmie National Forest offer recreation opportunities ranging from urban to primitive. To the west of the Forest lie thousands of acres of rural and roaded natural opportunities. Land east of the Forest, in the 684,000 acre North Cascade National Park Complex, and to the south, in Mt. Rainier National Park, generally offer primitive opportunities. Wenatchee National Forest lands to the east offer opportunities ranging from primitive to developed.

Current General Recreation Use and Past Trends

Recreation use on the Mt. Baker-Snoqualmie increased from 3,100,500 Recreation Visitor Days (RVD's) in 1975 to 5,181,800 RVD's in 1989, an increase of about 67 percent. These trends are similar to recreation use trends reported by other public recreation agencies throughout the Pacific Northwest. For instance, visits to Park Service managed sites increased by 24 percent between 1983 and 1988, surpassing the national visitation increase of 16 percent. Additionally, while "backcountry" overnight stays declined nationally 37 percent during those years, overnight use of this regions' National Parks increased 17 percent (WS ICOR 1990).

Figure III-16, opposite, shows the general trends from 1975 to 1989. Despite a couple of low-use years, the surge in popularity of outdoor recreation (which began in the 1960's) has continued. The growth in recreation use is considerably greater than the 19.8 percent rate of population growth in the Puget Sound area (1970 to 1983). Table III-50 shows the actual RVD's.

Figure III-16
Recreation Use 1975 - 1989

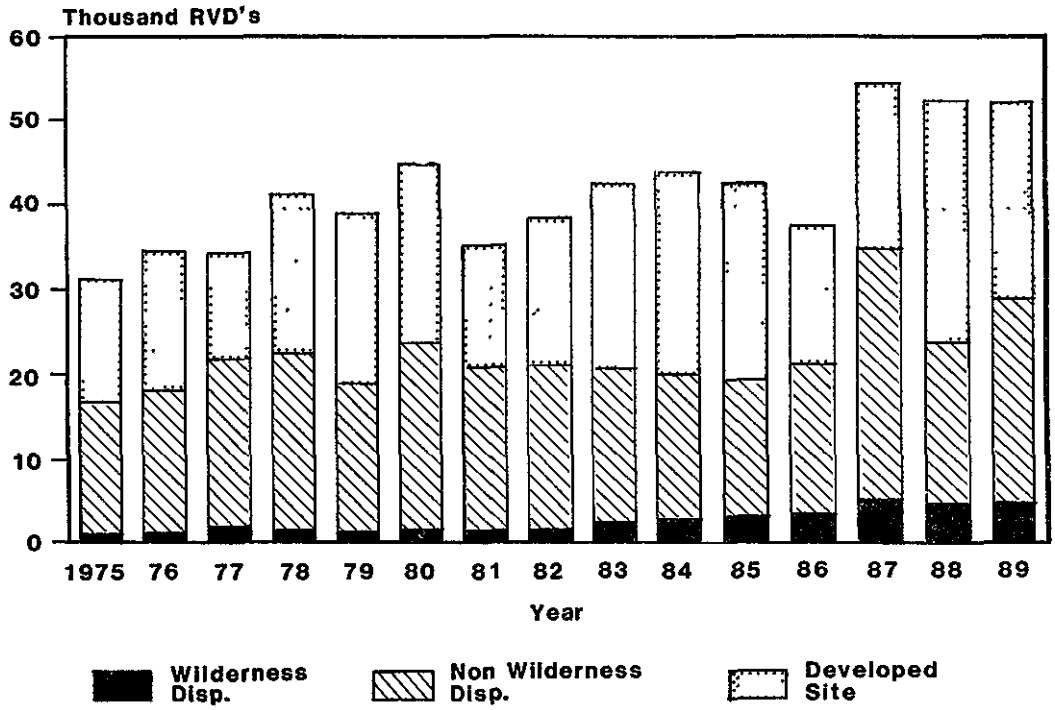


Table III-50
Recreation Use 1975-1989 1/

Year	Wilderness Dispersed	Nonwilderness Dispersed	Developed Site	Total
1975	111,800	1,554,600	1,434,100	3,100,500
1976	116,800	1,672,500	1,660,300	3,449,600
1977	192,000	1,966,100	1,261 600	3,419,700

Chapter III
Recreation

Recreation use depends on a number of factors. Key among them are real personal income, resource attractiveness, regional population growth, and weather patterns. Several factors moderated the rate of recreation growth from 1975 to 1989. Slight decreases in use may be due to regional and national economic factors, such as rising gasoline prices in the middle 1970's. Also, recreation use in the Pacific Northwest is very responsive to weather conditions, especially for certain activities, such as alpine skiing. In 1977 and 1981, the Pacific Northwest received very little snow. The dry winters and, consequently, limited alpine skiing (the largest component of developed use), are reflected in the low RVD's for developed site use in 1977 and 1981. Increased dispersed use for those two years is a reflection of the exceptionally clear, dry summers.

Visitor use data for 1975 and 1983 for various recreation activities is shown in Table III-51, on the next page. During the nine year period, use in various activities changed at different rates. Automobile travel (much of it travel over the cross-Cascade highways) and viewing scenery remains one of the largest recreation activities on the Forest. Alpine skiing, dispersed and developed camping, and hiking and walking continue to receive large amounts of use.

Other activities are growing, including off-road bicycling, nordic skiing (which, with snowshoeing, has increased 471 percent since 1975) and river rafting (a component of Other Boating). Some activities are decreasing in use: trailbiking, swimming, and horseback riding.

Recreation Demand - All Activities

Recreation demand, as used here, is expressed demand - use that is manifested by participation in an activity. Projected demand is subject to uncertainties of supply of the opportunity, costs of participation, and availability of time to participate.

There are other uncertainties: changes in recreation use due to new technology, change in the regional or national economy, or new legislation. The forecaster's resources are records of past use, population and other social projections, and indicators of the future supply of opportunities. The further into the future these extend, the more tenuous they become.

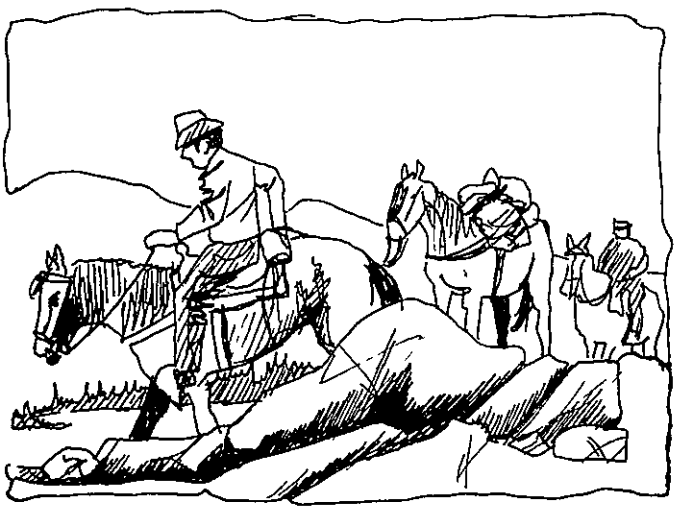

Table III-51
Recreation Use, Selected Activities 1/ - Thousand RVD's

Recreation Activity	1975	1983		Percent Change
Alpine Skiing	514.9	649.6	2/	+26
Nordic Skiing, Snowshoeing	7.0	40.0		+471
Snowplay	33.0	44.0		+33
Riding Lifts	18.2	125.0		+587
Snowmobiling	14.0	17.0		+21

Nature Study	18.7	33.0		+76
Auto Travel, Viewing Scenery	767.3	903.0		+18
Visitor Information Activities	38.0	84.0		+121

1/ USDA Forest Service, Recreation Information Management System (RIM).
2/ Lift ticket purchases, which are assumed to closely represent actual number of skiers. This figure is lower than ski area use, shown in Table III-56.
3/ 1984 figure.

Recreation demand may be projected by activities or by ROS classes. Many activities require specific conditions - topography, vegetation, facilities, special natural features, etc. - so that demand is strongly related to land, resource, and budgetary allocations. Demand is also very strongly related to weather conditions, especially for developed camping and alpine skiing.

Underlying the demand for recreation in the Puget Sound area is one assumption: demand will increase with a growing population and a growing awareness and appreciation of recreation values. The population in the Puget Sound area is expected to grow at a faster rate than the overall State population, with increases of 16 to 26 percent from 1980 to 1990 and increase another 15 percent by the year 2000. Population growth will be

disproportionate, that is some counties will grow faster than 15 percent; Snohomish County is expected to grow by 26 percent between 1989-2000 (OFM, 1989). The area's expected population in 2000 is 2.8 to 3.3 million. The demand for recreation is expected to grow at a rapid rate through the end of the century, based on past correlations between population growth and increased recreation demand.

Figure III-17 shows actual and projected total recreation use for the Forest to the year 2030. A regression analysis was used to develop recreation projections, considering past recreation use and population data. Figure III-18 shows projected recreation use by ROS class. The ability of the Forest to meet this demand, in the ROS classes, is discussed in the Recreation Supply section of this chapter.

Figure III-17
Total Recreation Use - Wilderness and Nonwilderness
Actual and Projected

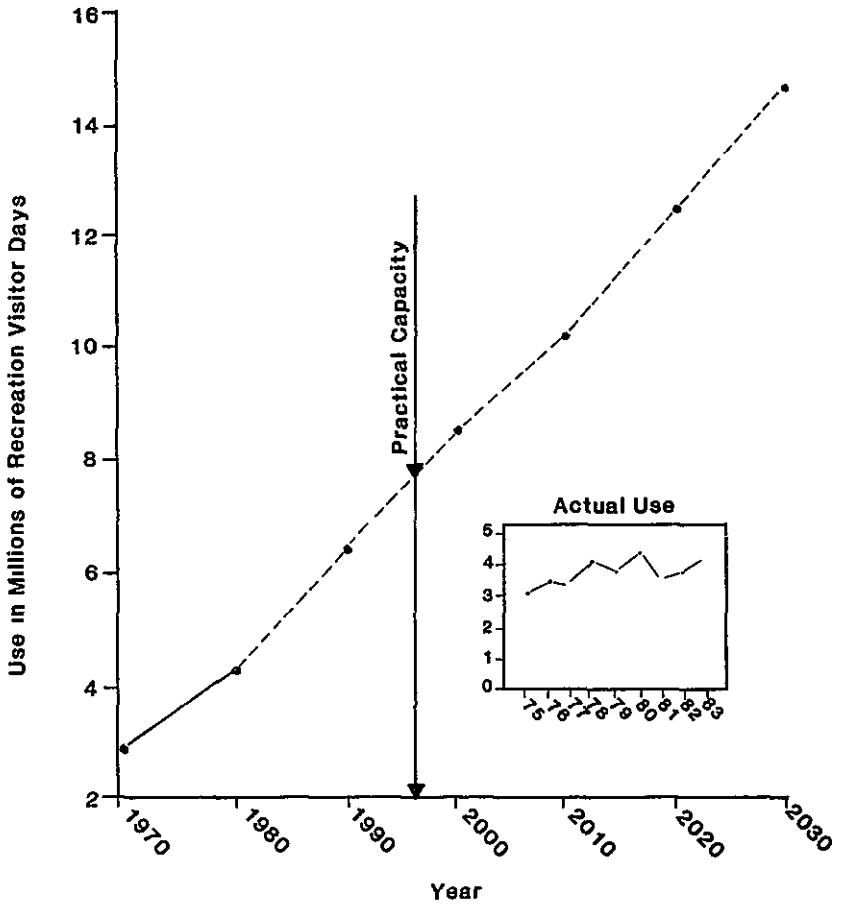

Figure III-18
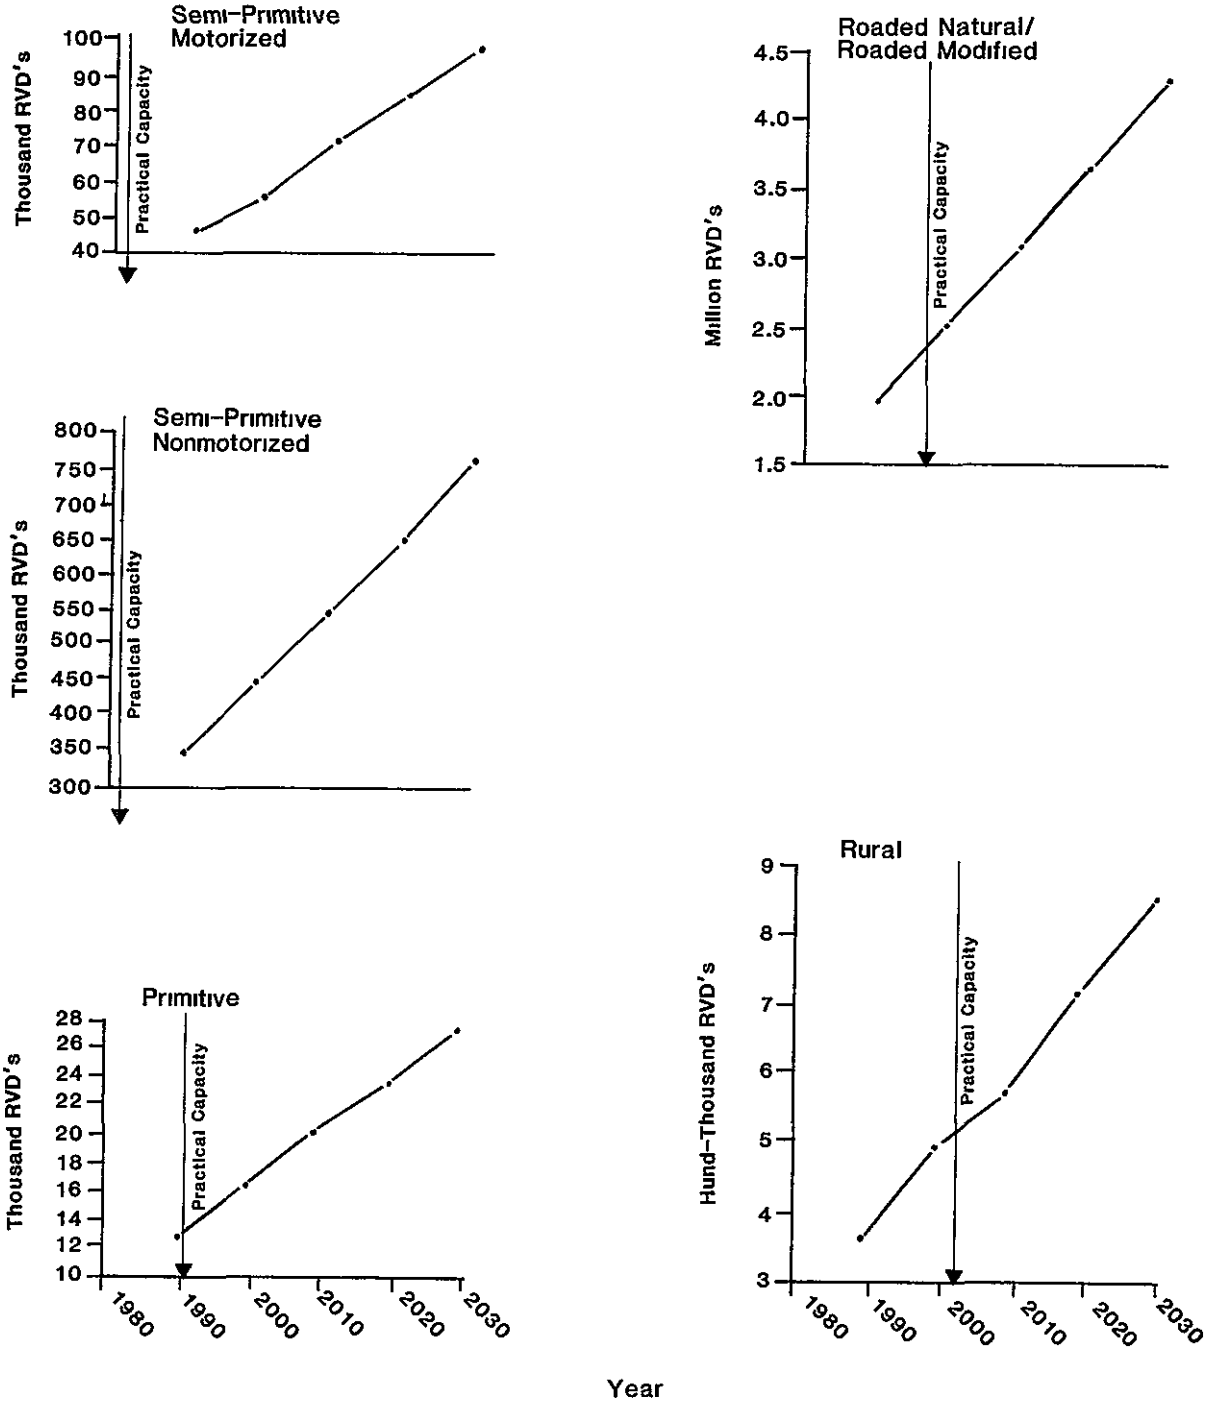
Projected Forest Wide Recreation Use by ROS Class
(Does Not Include Wilderness)



Capacity

The capacity of the Forest to provide recreation can be measured in two ways. The "maximum theoretical capacity" assumes every acre of the Forest is full of a maximum number of people, throughout a maximum season - weekdays, weekends, rain or shine. While this maximum theoretical capacity provides an upper limit to the physical and/or social capacity of the Forest, it seldom represents a realistic or "practical" maximum. Practical capacity recognizes physical and social limitations on user density as well as weather and weekend/weekday patterns of use. "Practical" capacity is the effective upper limit because it recognizes factors that are always present and that significantly affect recreation participation patterns. Practical maximum capacity provides values that can be used in most planning analyses; this approach was used in the FEIS.

Pacific Northwest Regional Recreation Committee Recreation Demand Study

Outdoor recreation demand, as expressed by the behavior and preferences of Washington residents, was measured in a study conducted by the Pacific Northwest Regional Recreation Committee (PNRRC). This study examined outdoor recreation participation in four geographic regions around the state. Each district is composed of planning districts grouped according to bio-physical and social criteria.

Estimates of 1987 recreation participation and projections of participation in 2000 were made for many recreation activities. Activity participation is expressed in terms of household trips. A household trip can include one or all members of a household. Some activities last longer than others. Other activities, such as boating, are broken down into specific settings or styles.

At this time, it is difficult to apply the information from this study specifically to the Mt. Baker-Snoqualmie, since the Forest is located in two planning districts. It is difficult to determine the amount of these activities occurring on the Forest. It is valuable, however, to look at the trends for these two planning districts for those activities which can be supplied by this Forest.

Table III-52 shows the 1987 household trips and projected trips for the year 2000 for those activities provided by the Forest. It is interesting to note that many of those activities which the Forest has historically been managed for appear high on this list.

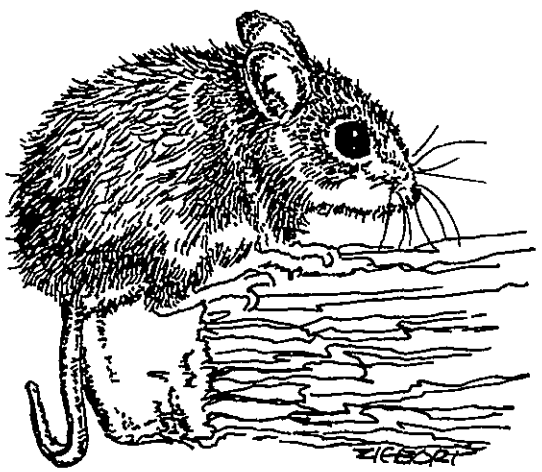


Table III-52

Household Trips for 1987 and
Projected Growth to 2000 For Assorted Recreation Activities - Thousand RVD's

Activity	1987	2000	% growth
Day Hiking	2376	3156	41%
Wildlife Observation	2262	3156	40%

Recreation Supply

An important step in the Forest Planning process is estimating recreation supply, or capacity. These estimates, expressed in annual visitor days of use by ROS Class, are important in later stages of the planning process, particularly in measuring outputs and effects of the alternatives.

Table III-53, on the following page, shows existing nonwilderness recreation use and practical capacity by ROS. Acres of water are not included, therefore the totals may vary from other R2MAP acres used elsewhere in this document.

Table III-53
1983 Nonwilderness Recreation 1/
Existing Use and Practical Capacity by ROS (Water Excluded)

ROS Class	Acres	.....RVD's..... Existing Use	Practical Capacity	...RVD's Per Acre.... Existing Use	Capacity
Rural	4,450	2,086,855	4,632,100	460.0	1,020.0
Roaded Natural & Roaded Modified	638,617	1,577,342	2,504,563	2.46	3.92
SP-Motorized	9,714	80,395	33,554	8.3	3.45
SP-Nonmotorized	326,447	306,263	188,126	.93	.58
Primitive	16,683	0 2/	1,340	0 2/	.08
TOTAL	995,911 3/	4,050,855	7,358,343	-	-

1/ Source: Recreation Information Management System (RIM).
2/ Only five miles of trail exist in the Primitive Class; no new construction is planned (1979 Interim Trail Management Plan).
3/ Differences between numbers in this table and Table III-49 are due to R2MAP rounding and the inclusion of water acres in Table III-49.

Demand/Supply Discussion by ROS Class

Rural. The 4,450 acres of Rural ROS are less than one percent of the Forest acres. Included in Rural are developed sites and some small communities along highways. The demand for rural recreation opportunities will continue to increase in the future. Currently, the Forest has the capacity to handle twice the existing use in the Rural class, easily meeting future demand until after the year 2000. By expanding developed sites and increasing the capacity of the ski areas, the capacity of this class can be greatly expanded.

Roaded Natural - Roaded Modified. Roaded Natural and Roaded Modified contain over 64 percent of the nonwilderness acres on the Forest. There were 1,577,342 RVD's in RN and RM in 1983; practical capacity is 2,504,563 RVD's. Driving for pleasure and dispersed camping are the largest activities in RN/RM. Demand for opportunities in these ROS Classes is expected to continue to grow. Under the current management situation, practical capacity will be reached by the early 1990's. This situation is very distorted by the number of driving for pleasure and viewing RVD's which occur on the Interstate and State Highways across Stevens and Snoqualmie Pass. Discounting this use, there is enough capacity in the RN and RM classes to last into the fourth decade. If more of the Forest is converted from an unroaded to a roaded condition, the supply of Roaded Natural/Roaded Modified opportunities will increase. Intensive management will convert more acres to Roaded Modified; currently, over 60 percent of the RN/RM acres are in Roaded Natural.

Semi-Primitive Motorized. The Mt. Baker-Snoqualmie National Forest has very few acres of this ROS Class. The current supply for off-road motorized use is only 9,714 acres, less than one percent of the nonwilderness land base. Demand has already exceeded capacity by 141 percent. Current practical capacity is about 33,600 RVD's; the 1983 SPM use was over 80,000 RVD's.

While the current use of trailbikes, 4 x 4, three-wheeled ORV's, and snowmobiles is less than other dispersed activities (such as hiking, fishing, and hunting), use of all types of off-road vehicles is growing. If more nonwilderness acres are converted to a roaded condition, overuse in this ROS Class will be worse in the future. There is no substitute for Semi-Primitive Motorized acres on the Forest. Users will be forced to recreate in the Roaded Natural Class (not a Semi-Primitive experience) or go elsewhere.

Semi-Primitive Nonmotorized. About 32 percent of the nonwilderness acres on the Forest are Semi-Primitive Nonmotorized. Demand far exceeds supply in this ROS Class; 1983 use in SPNM was about 306,300 RVD's and current capacity is only 188,000 RVD's. Activities occurring on Semi-Primitive Nonmotorized lands include hiking, fishing, hunting, dispersed camping, viewing scenery, and non-consumptive wildlife use.

Many acres originally in this class have become wilderness. The SPNM class will be reduced in size if more acres of the Forest are roaded, converting presently unroaded land to Roaded Natural or Roaded Modified. Conversely, the acres of SPNM can be increased by road closures in Roaded Natural areas. Capacity could be increased in this zone with the construction of new trails on the acres remaining unroaded.

Primitive. The 1984 Washington Wilderness Act substantially decreased the amount of Primitive land outside of wilderness. There are only 16,600 acres of Primitive ROS on the Forest. Most of the original acres in this class are now inside the wilderness. Recreation use in nonwilderness Primitive is almost non-existent, as these areas contain few attractions. Forest use is over practical capacity in this class due to the very few acres available.

Winter Dispersed Recreation - Supply and Demand

Winter recreation capacities and use were calculated separately. Table III-54 shows the total capacity on the Forest for winter dispersed recreation: approximately 249,000 RVD's. Practical capacity could be increased by adding more plowed parking or developing more snowplay areas.

Table III-54
Winter Dispersed Recreation - Existing Use and Capacity - 1983

Activity	Opportunities	Existing Use in RVD's	Practical Capacity In RVD's
Nordic Skiing	386 miles	39,600	139,423
Snowmobiling	285 miles	16,900	88,494
Snowplay (Winter Sports Sites)	10 sites	5,000	23,779
TOTAL	-	61,500	248,987

Developed Recreation

A wide variety of developed recreation opportunities are available on the Forest. The majority of these sites are located within the current Rural and Roaded Natural ROS class. Nearly half of the 4.2 million RVD's in 1983 occurred in developed recreation areas. The largest developed recreation activity is alpine skiing. With seven ski areas and a total of 51 lifts, ski areas contributed over 852,000 RVD's in 1983, or 20 percent of all recreation use on the Forest. After alpine skiing, camping in developed sites (both group and family campgrounds) is the largest developed site activity. Table III-55 shows 1983 developed site use, along with the annual practical capacity for various activities (RIM 1983 data).

Table III-55
Selected Developed Recreation Sites - Use and Capacity - 1983

Type	No. Sites	1983 Use RVD's	Annual Practical Capacity 1/
Observation	10	12,100	6,800
Interpretive 2/	16	34,700	6,700
Information	3	5,700	1,000
Boating	6	13,000	2,700
Swimming	1	500	900
Picnic	12	35,700	17,600
Family & Group Campgrounds	74 3/	420,900 4/	615,700
Organization Camps (Pvt.)	24	187,500	455,600
Hotels, Lodges, and Resorts	4	376,600	348,900
Recreation Residences	7	221,800	213,100
Winter Sports Sites 5/	4	5,000	15,200
Alpine Skiing	7	852,300	3,436,300 6/

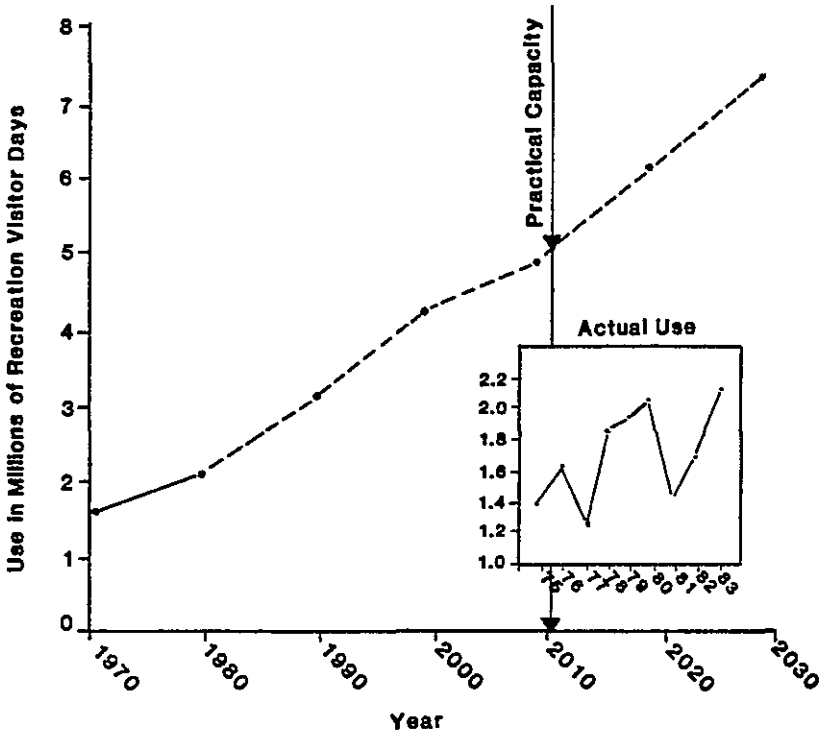
1/ Refer to discussion on previous pages regarding capacity.
2/ Includes minor and administrative sites.
3/ 74 available sites (1983 figure) are used to calculate capacity. Refer to the discussion on campgrounds on page III-170, below.
4/ This figure includes all use occurring at developed campsites; some may be day use, thus this figure is higher than that reported in Table III-52.
5/ These are snow play areas.
6/ Alpine skiing capacity calculated only on existing facilities and permit acreage. Increased capacity exists at some areas; see following discussion.

Based on Table III-55, the following developed site activities exceeded capacity in 1983: observation, interpretive, and information sites, boating sites, and picnic areas.

Some caution must be exercised in interpreting these use figures, especially boating and picnic activities. These facilities are often built next to a campground complex. During high use periods, recreationists disperse to adjacent areas; the total use is counted, but overnight use may be occurring on day-use sites. Use in these developed sites is over capacity, but the exact numbers may not be accurate. Hotels, lodges, and resorts and recreation residences were slightly over capacity in 1983.

Figure III-19, on the next page, shows actual and projected developed site recreation for all activities. Practical capacity will be exceeded by the year 2010.

Figure III-19
Actual and Projected Developed Site Use



Alpine Skiing

Downhill skiing is the largest developed use on the Mt. Baker-Snoqualmie. Table III-56 shows skier visits for recent years. Table III-57 shows the skier visits for the 1988-89 ski season broken down by ski area on the Forest.

Table III-56
Skier Visits - 1975-1983

Year	Skier Visits - RVD's	Year	Skier Visits - RVD's
1975	514,900	1982	1,031,500
1976	553,800	1983	1,123,000
1977	370,400	1984	1,089,500
1978	928,700	1985	1,259,500
1979	1,008,000	1986	1,115,000
1980	1,087,000	1987	1,395,000
1981	465,000	1988	1,481,000

Table III-57
1988-89 Skier Visits by Area

Mt. Baker	137,738
Stevens Pass	393,409
Crystal Mountain	375,000
Ski Lifts	536,005
Pacific West	39,000
Total	1,481,152

The growth rate of skiing is slower than in the early 1970's. As the ski industry matured during the 1970's, overall growth tapered off to ten percent. Participation has now leveled off at a steady rate of incremental growth of approximately three per cent per year. While this growth appears to be small, the ski industry has proven to be largely recession-proof over time. Recent improvements in snowmaking capabilities have also helped to insure reliable snow cover, thereby reducing the effects of poor weather conditions and contributing to continued steady growth in use. The transition from explosive growth in the eighties is the result of many forces, including an aging population, longer work weeks, and decreasing leisure time.

Two overriding trends become apparent when viewing current recreation patterns. First, changing demographic patterns in the United States are steadily leading to a decline in the number of younger skiers, who have traditionally represented the bulk of frequent skiers. At the same time, the numbers of middle-aged and older Americans are increasing. Despite their numbers, these age groups are typically less-frequent skiers than teenagers and young adults.

A second important trend is related to the frequency and durations of vacations. The two week "family vacation" is fast becoming a thing of the past; many people are taking shorter, more frequent trips. As an example, the 1987 study, The Contribution of Skiing to the Colorado Economy, published by Colorado Ski Country USA, indicates that the average length of stay at a Colorado resort is now four to five nights, compared to six or seven nights a decade ago (Frick 1987). With the increase in three to five day vacations, more emphasis is being placed on destinations closer to home and on convenient air travel to more distant locations.

Successful ski areas have catered to the changing demands of the skier population by providing a greater service orientation, and a more refined ski experience through the use of faster and more comfortable ski lifts, the provision of machine made snow, increased slope grooming, and more pleasurable day lodges. These developments have led to an overall improvement of standards and a higher level of expectations among the skiing public.

Ski Area Capacity. While skiing capacity is defined by the downhill capacity of each area (skiable acres x skier density by level of skiing ability), the uphill or lift capacity is usually the limiting factor.

The maximum annual capacity of the existing ski facilities is 3,400,000 RVD's. This assumes all areas operating at capacity, daily, for the entire use season. However, ski area use is not even throughout the week and at the present time, not all seven ski areas operate every day. Overuse occurs primarily on peak days: weekends and holidays. To meet demand, ski areas on the Forest have the capability to increase practical capacity by an additional 1,600,000 RVD's, an increase of 47 percent. It should be noted that since the Forest ski areas are operated by the private sector, excess or uneconomic capacity will likely be avoided.

All of the areas on the Forest except Snoqualmie Summit have the potential to expand, though expansion is not currently needed to meet demand. Ski areas are now proposing expansion to disperse skiers more evenly and access new terrain (to attract new skiers to the area). Also, improvements in technology, especially improved slope grooming equipment, can increase capacity without expanding the permit area. Development of overnight facilities at the base may spread out use - increasing mid-week use - and attract more skiers.

Table III-58 shows the seven alpine ski areas on the Forest, plus current and potential capacity.

It is realistic to expect an increase in demand of between 1.2 and 1.6 million RVD's by the year 2000. The terrain is available in all areas on the Forest, except Snoqualmie Summit, to meet almost any amount of future demand.

Table III-58
Ski Area Capacity - Existing and Potential

Area	No. Lifts Existing	Existing Uphill Capacity SAOT 1/	Existing Downhill Capacity SAOT	No. Potential New Lifts	Additional Potential Downhill Capacity SAOT 3/	Total Downhill Capacity (Existing plus Potential) SAOT

1/ Skiers at one time
2/ Persons per hour.
3/ Potential capacity within the existing permit area

Ski Areas - Future Trends

Skier visits to the ski areas on the Forest are comparable to other day use areas in the nation. However, while most upslope terrain nation-wide is under permit from the Forest Service, their base facilities are located on private land, thus allowing a wider range of overnight accommodations, condominiums, etc.. The Northwest Ski Area Association estimates approximately 500,000 skier visits are lost each year to destination ski resorts in the Rocky Mountain Region.

There is evidence that the Cascade Ski Areas suffer some amount of competitive disadvantage without the ability to offer overnight accommodations. There is a market for local ski area vacationing, not as a substitute for the preferable weather of the Rockies, but to serve the skiers who might otherwise vacation in Oregon, Idaho, and British Columbia. Forest Service policy does not oppose overnight accommodations in ski areas, but it does oppose financial arrangements that compromise the concept of full public access to such accommodations (Deaver Memo 1985).

Developed Camping

During the 1983 season, recreation use in 61 developed campgrounds was approximately 420,900 RVD's. This figure is slightly lower than the average for the period 1975-1983, during which 74 sites were operated. Developed campground use has remained fairly constant over this period, with use fluctuating between 414,000 and 514,000 RVD's. In 1977, campground use reached 558,000 RVD's. The weather that year was particularly dry, which may explain the increase in use.

Table III-59
Visitor Use in Developed Campgrounds - RVD's
Family and Group Campgrounds

Year	RVD's
1975	464,100
1976	514,400
1977	557,800
1978	502,000
1979	460,900
1980	509,500
1981	414,000
1982	420,300
1983 (61 sites operated)	420,900

Location and Capacity. In 1983, there were 74 available developed campgrounds with a practical capacity of 615,716 RVD's; 61 campgrounds were operated that year. In 1986, as a result of reduced budgets and supply greatly exceeding demand, 38 campgrounds were available, but only 28 were operated. The capacity of these sites is 546,243 RVD's. Eleven other campgrounds may be rented by groups, but are not generally available.

These reductions in the number of campgrounds available were the result of a detailed study made in 1984. The goal of this study was to better utilize available budgets during a time when the use of developed campgrounds was well below capacity. The CHUNK Study identified opportunities for improving campground management and fee collection. The Forest was divided into major geographic areas or corridors ("chunks") and the developed site opportunities within each "chunk" were analyzed.

The study recommended altering 43 percent of the sites, to realize a 30 percent increase in efficiency: 7 sites would be converted to fee sites, bringing the total fee sites to 13; 8 sites would be reduced in service level; and a total of 21 sites would be converted to dispersed use sites where most comfort facilities are removed and the site restored to a natural setting. Most of the converted sites had fewer than 10 camping units, thus the overall campground capacity of the Forest was not greatly impacted.

Demand. Demand for developed site camping has remained fairly stable over the last decade; this trend is expected to continue. The Forest is currently operating at 75 percent of maximum practical capacity of the 38 available sites. Developed site camping is one of the largest recreation activities on the Forest, second only to alpine skiing. Whether this level of use will be sustained will depend partly upon public reaction to increased fees, but more importantly on their preference for camping facilities that are predominately in the more primitive end of the development spectrum. Users now choose between the more highly developed sites in State, County, or National Parks and the more rustic sites available in the National Forests. Additionally, the Forest can affect demand by altering prices.

Supply. Generally, developed site use, both current and historic, has remained well below capacity. Developed use occurs mainly on weekends, while developed

capacity is calculated over an average use season, including low-use weekdays. If capacity were to be calculated based only on weekend use, the Forest would constantly utilize most of the capacity, with some days approaching 100 percent. This trend is present on most forests, but is greatly accentuated on those near large urban areas. These forests must plan for future peak-day use instead of average use.

The supply of developed camping will likely meet future demand; however, as stated, most campgrounds may reach capacity on sunny weekends. A dozen potential campsites have been located; some are new sites, others are extensions of existing campgrounds. It is questionable that these potential sites would ever be developed, due to the high construction costs incurred vs. the returns. Most investments will be made in those sites needing reconstruction (most sites were built prior to 1950 and the facilities have deteriorated).

Potential Developed Sites

The National Forest Recreation Site survey (completed in 1964) identified potential sites for developed recreation. Many of these sites are still available for development as recreation sites, based on current land-use. In total, the potential developed sites equal approximately 350 acres. The Forest has the potential to increase its total developed site capacity by 3,365 persons at one time (PAOT's).

Table III-60 displays 19 of these potential developed sites that appear be viable for future construction. Note that at Stoney Flat, there are three potential sites - a campground, swimming site, and boating site. However, the capacity figure of 850 PAOT's includes all three sites. This is also true for the two sites at Sandy Creek.

Table III-60
Potential Developed Sites

District	Name	Site Kind	PAOT
Mt. Baker	Stoney Flat	Campground	850
	Stoney Flat	Swimming	incl.
	Stoney Flat	Boating	incl.
	Sandy Creek	Campground	700
	Sandy Creek	Swimming	incl.
Darrington	Gold Basin	Campground Exp.	108
	Sunnyside	Campground	125
	Big Four	Picnic Exp.	144
Skykomish	Chicago Flat	Campground	125
	Gravel Flat	Campground	108
	East Creek	Campground	108
North Bend	Mountain View	Campground	250
White River	Evans Creek	Campground Exp.	150
	Lonesome Lake	Campground	25

	Silver Creek Gd. Stat.	Information	30

Dispersed Recreation - Nonwilderness and Forest-wide

Over the last decade, use of dispersed recreation areas has averaged over half of the total recreational use. In wilderness and nonwilderness, undeveloped areas, there has traditionally been a plentiful supply of dispersed recreation opportunities. This supply has facilitated rapid growth of such activities as hiking and walking, climbing, nordic skiing, and snowmobiling during the last 20 years.

Competing and often conflicting uses on the land base now pose a serious threat to the recreation resources of the Forest which depend on natural settings. Activities like resource extraction and its associated road building displace existing and potential recreation uses. Natural places to recreate are becoming more and more scarce, both on and off the Forest. This trend makes the dispersed recreation lands of the National Forest more valuable.

Forested lands used for timber production cannot at the same time supply semi-primitive or roadless settings. As this continues, roaded acreage will

increase. In the long run, this conversion means that access will also increase, facilitating popular activities such as visiting interpretative sites, outdoor photography, picnicking and sightseeing. At the same time, however, popular roadless area activities like backpacking, hiking, and motorcycling will suffer.

There is enough capacity to satisfy projected demand for roaded dispersed recreation through the fourth decade of this plan. Unroaded dispersed recreation is already over-capacity with resulting reduction in recreational experience for those choosing to use these lands.

The State of Washington has recognized that the demand for primitive recreation is exceeding capacity in National Park and Forests. The Draft 1990 SCORP for the state recommends that there should be no net loss of acres currently providing semi-primitive recreation opportunities.

The 1990 SCORP also claims that recreation needs on Forest Service lands in roaded modified settings are often not given equal consideration in integrated resource management decisions. The State encourages a balance of recreation with commodity extraction in these settings

Nonmotorized Dispersed Recreation

This form of recreation includes hiking for long trips, or day hikes and afternoon strolls. Recreationists may spend time utilizing a well built and maintained trail or they may travel cross-country following their own inclination. This category also includes hunting and fishing and all the variations of those activities. In addition, dispersed recreation includes such varied activities as berry picking, photography, mountain climbing, and simply relaxing.

Hiking and Horse Use. Hiking is the principle use of the forest trail system, accounting for about 252,000 RVD's of use in 1983. This activity has shown steady growth in the past, and the demand should continue. A significant portion of all hiking and walking is day-use; this has created overuse in some areas, especially during peak use periods.

Horse use has also grown steadily over the past decade. Use dropped sharply in 1983 to 27,300 RVD's, down from 55,300 RVD's the previous year. This may be a reporting error, as dispersed horse use was 34,000 RVD's in 1984.

Hiking and walking are strongly correlated to the trail system; approximately one-third to one-half of the horse use occurs on trails. During the 1970's, the demand for trails for hiking and horse use was met by a plentiful supply of trails on the Forest. There are currently (1989-90) a total of 1,384 miles of system trails; 42% are located in wilderness. The location of most of these trails (higher elevation) means that many miles are usable only in the summer and early fall.

Meeting the demand for dispersed trail use will be a challenge in the next few decades. Wilderness capacity will be reached early in the 1990's. If more of the Forest becomes roaded, the size of the trail system in the Semi-Primitive zone will diminish unless special efforts are made to retain existing trails. The Roaded Natural portion of the Forest is still available for new trails,

though the user experience, physical and social, will differ from more primitive settings. See the Trails discussion later in this chapter.

Nordic Skiing. Nordic skiing is one of the fastest growing recreational activities. In 1983, there were nearly 40,000 RVD's of use, an increase of 22 percent in three years. Use occurs on 13 miles of wilderness trails and on 136 miles of nonwilderness trails; use also occurs on over 200 miles of Forest Service roads.

Although the potential supply of nordic skiing opportunities is immense, avalanche hazard and a lack of maintained access points, plowed parking, and maintained trails limits the readily available supply. Practical capacity for this sport has been calculated at 139,500 RVD's. This figure is probably high, given the current limitations of parking, access, and maintained trails. Demand should continue to grow, although many local skiers travel to eastern Washington to find better facilities, as well as better skiing conditions.

Motorized Dispersed Recreation

Motorized, dispersed recreation ranges from pleasure driving on forest roads, off-road vehicle (ORV) use of Forest roads and trails, to motorized river tours. ORV use includes motorcycles, four-wheel drive jeeps and trucks, and three and four-wheeled all terrain vehicles. In addition to summer use, motorized recreation during the winter includes the use of snowmobiles, ATV's, and recreationists driving into and through the Forest.

Unless specifically prohibited by a formal closure or Congressional designation (e.g. Wilderness), all roads and trails are available for motorized recreation. Some roads are not maintained for use by sedans, and some roads have such heavy use by log trucks that they are hazardous for non-commercial vehicles. The Forest Road Management Plan contains the road management objectives for each road. The maintenance level of the roads changes from year to year, depending on the land management activities on adjacent National Forest lands. Most trails were originally built to a standard for use by hikers or horses. If motorized use has been a gradual development over the years, then the trail is probably not built to the standards necessary to accommodate motorized use.

Off-Road Vehicles. ORV's are one of the fastest growing of the dispersed uses. Trail bikes, 4-wheel drive (4 x 4), and three-wheel vehicles all place increasing demand on the trails, roads, and accessible off-road areas of the Forest.

Off-Road vehicle use has been severely limited by a lack of opportunities. Only about five percent of the existing trail system is open for trailbike use and most of that mileage is poorly maintained. Most of the Forests 2,829 miles of roads are open to motorized recreation. The Naches Pass Wagon Road, Evans Creek ORV Area, and sites in the Greenwater drainage, all on the White River Ranger District, provide some of the only off-road terrain available to four-wheel drive vehicles.

The vast majority of the Forests motorized use occurs on the White River District, on the south end of the Forest. Table III-61 shows 1984 use for the White River Ranger District. It should be noted that these figures differ significantly from those reported in RIM, due to errors, and that much of the entire ORV use on the Forest occurs on this District - the numbers may not be applied to the other Districts.

Table III-61
White River Ranger District Off-Road Vehicle Use

Season	Type of Use	RVD's
Summer	4 x 4	48,000
	Trailbikes, 3-wheel	64,000
Winter	Snowmobiles	36,000
	4 x 4, 3-wheel	12,000

There is very limited opportunity to increase the available supply for off-road vehicles. Most of the Forests trails are simply not suitable for ORV use. Many contain steep terrain with fragile soils and vegetation; conflicts with existing heavy hiking use and trail construction and maintenance standards that cannot accommodate ORV use are other problems.

In addition, most of the Forest that is currently unroaded or trailed is not well suited to cross-country vehicle use; obstacles include dense vegetation in the low and middle elevations, fragile vegetation in the high country, and universally rugged terrain.

Because of the real and/or perceived conflicts between motorized and nonmotorized users, the most likely area for future development of this activity lies in the Roaded Natural ROS Class.

Snowmobiles. Another of the faster growing recreational activities, snowmobiling recorded nearly 17,000 RVD's in 1983. Actual use is most likely higher. The majority of this use occurred in the Greenwater Drainage near Stampede Pass, in the Mt. Baker National Recreation Area (NRA), and in the Mountain Loop highway area. A total of 168 miles of forest roads and trails

are available for this use, plus an unknown number of acres. The largest of the unroaded snowmobiling areas is within the Mt. Baker NRA.

The Forest-wide capacity for this activity is nearly 86,000 RVD's. The current supply exceeds demand, although much of this potential supply contains less desirable terrain and conditions. Other potential snowmobiling areas on the Forest require plowed parking to facilitate use. With increasing use, conflict between nordic skiing and snowmobiling is likely.

Opportunities Under the National Recreation Strategy

The National Forest can become a leader in providing customer service and satisfaction by:

- Enhancing existing recreation opportunities;
- Providing a broad spectrum of outdoor recreation opportunities, including a variety of developed sites, to accommodate a variety of customer preferences;
- Providing a broad spectrum of trail opportunities to accommodate the increasing variety of trail oriented recreation activities;
- Expanding winter recreation opportunities;
- Expanding customer information, education and interpretative opportunities.

The Mt. Baker-Snoqualmie National Forest can encourage, establish, and sustain a diverse spectrum of recreation opportunities, services and facilities in recreation service partnerships with outdoor recreation and user groups; other recreation providers; and groups representing ethnic minorities, elderly, disabled, economically disadvantaged and youth.

Timber sales, K.V. funds and recreation mitigation for hydroelectric projects can be used to provide a variety of recreation opportunities and facilities.

Recreation Use Conflicts

The location of the Forest, close to the growing Puget Sound metropolitan area, is a key factor in the often conflicting demands for use of the National Forest. As the recreating population grows, the demands on a finite resource also continue to grow. Some recreation uses are incompatible; others cause resource damage because of the level or type of use. The ability of the Forest to supply opportunities for all types of recreation - and resolve use conflicts - is a major issue in the planning process. Some of these conflicts are highlighted below:

1. Overcrowding of popular areas, especially when weekends and holidays coincide with good weather.
2. Overuse of winter and summer, motorized dispersed areas: snowmobiles, 4-wheel drives, and three-wheelers all use areas such as the Greenwater Drainage (White River District), leading to overuse and user conflicts.

3. Increased winter dispersed use is leading to conflicts between motorized and nonmotorized users in such areas as Tonga Ridge (Skykomish District) and Canyon Creek, and Glacier Creek (Mt. Baker District).

4. Growth in nordic skiing has resulted in use of marginal and unsuitable areas - a growing avalanche safety hazard.

5. Winter ORV use conflicts with use of available deer, elk, and mountain goat winter range.

6. Water recreation is conflicting with bald eagle winter forage on the Skagit River System and, to a lesser degree, on the Nooksack and Skykomish Rivers. A study of the effects of river rafting on eagle populations on the Skagit has been funded.

7. Growth of hunting and the greater density of road networks has lessened the quality of the hunting experience on the Forest. Selective road closures have been instituted during hunting season to allow for deer and elk escapement and to improve the quality of the hunt.

8. The Forest is nearing the point of probable conflict between proposed hydroelectric power plants and recreation use/American Indian use areas.

9. Changes in classification, such as the designation of an additional 350,000 acres of wilderness in 1984, can effectively decrease the available acres for some types of recreation. Both summer and winter ORV use are now restricted to a smaller, available area.

FOREST TRAILS

There are currently 1,384 miles of system trails on the Mt. Baker-Snoqualmie National Forest. Some trails receive very heavy use. In 1988, the total trail system received over 373,000 recreation visitor days of use. Table III-64 shows the existing system trail inventory, both wilderness and nonwilderness trail, by user type.

Table III-62
Existing System Trail Inventory - In Miles

Primary Objective	Wilderness	Nonwilderness	Total
Hiker	202	245	447
Pack and Saddle 1/	330	183	513
Mountain Bike	0	26	26
Motorbike 2/	0	71	71
Snowmobile 3/	0	168	168
Cross-Country Ski 4/	13	106	119
Barrier Free	0	9	9
Interactive	0	5	5
Jeep (4X4) 5/	0	26	26
TOTAL	545	839	1384

1/ Also open to hikers.
2/ Also open to hikers and pack and saddle use.
3/ Open to all users.
4/ Separate from snowmobile trails.
5/ Primarily in Evans Creek Area.

Hikers, horse riders, and recreationists with motorized equipment all utilize the Forest trail system. The steep slopes and unstable soils of much of the Forest, plus the short duration of the dry summer season, limit trail use. About 32 percent of the trails are designed exclusively for the primary objective of hiking. Motorized use occurs on only 7 percent of the trail system, primarily on the Mt. Baker and White River Ranger Districts.

The earliest trail builders were American Indians, prospectors, and pioneers. When the Forest Service began trail construction for administration and fire suppression in the early part of the century, many trails followed the old trade and market routes. Trail location was the shortest distance between two places and trails were often excessively steep.

In recent decades, trail use has changed. Recreation, rather than protection, is the dominant use. Trail location and design standards take into consideration the recreationist's experiences, including convenience and scenic vistas. Trails may be located to protect fragile terrain. This is in sharp contrast to the earlier trails. A number of miles of older trails are still in use, however, many (nearly one-third) are inadequate for present day use.

With current use levels, the damage to older trails has become a problem for both the visitor and the manager. Poorly designed and improperly located

trails now need reconstruction or relocation. An estimated $7,000,000 is needed to bring the estimated 493 miles of inadequate trails up to standard.

Backpackers and climbers continue to informally expand the trail system as they search out new routes in trailless areas. Many of these new way-trails will require management in the future to prevent further resource damage. The Forest will begin to actively manage some of these areas to retain their trailless characteristics.

Special Classification

Approximately 106 miles of trail have been given national recognition for outstanding scenic or recreation value. The longest is the Pacific Crest National Scenic Trail, designated by Congress in 1968. The trail winds for about 96 miles within the forest boundary, along the crest of the Cascade Mountains. Four other trails have been designated as National Recreation Trails, as shown in Table III-63.

Table III-63
Trails of National Recognition

Trail Name and Number	Ranger District	Miles
Shadow of the Sentinels #623	Mt. Baker	0.5
Ice Caves Trail #723	Darrington	1.2
Deception Falls Nature Trail #1078	Skykomish	0.5
Skookum Flats Trail #1194	White River	7.6
Pacific Crest Trail #2000	Darrington, Skykomish, North Bend, White River	96.0

Demand

Trail use is a large portion of the total recreation use on the Forest. Hiking and walking are the largest trail use activities, and both continue to grow. Until the last two years, horse and trailbike use remained fairly stable over the last decade, each accounting for about 10 percent of the total trail use. Use in these two activities has dropped in the last few years. Trail construction and reconstruction (for all types of users) is a major public issue on the Mt. Baker-Snoqualmie National Forest.

Supply

The opportunity to increase the supply of trails on the Forest is available. The 1979 Interim Trails Management Plan proposed 56 new trails or trail extensions, the current (1983) cost of implementing this plan is approximately $1,550,000 (construction and reconstruction only). An updated trail plan is included as part of the Forest Plan, Appendix E.

Not all currently trailless areas of the Forest are available for trail development. Sizeable areas will be managed without trails for one or more of the following reasons: high elevation; area is already accessed by informal "high route" or way-trails and capacity will be reached without trail access; or the desire to retain some areas in a pristine, trailless condition.

WILDERNESS

The wilderness preservation system, established under provisions of the Wilderness Act of 1964, seeks to create and preserve areas in an unimpaired condition. Management of wilderness, therefore, is aimed at protecting ecosystems in a natural condition and this takes precedence over human and recreational use. Washington State contains just over 12 percent of the wilderness in the lower 48 states; about 10 percent of the state is wilderness. While these figures appear large, nearly all of this land is virtually inaccessible due to steep, mountainous topography; also, snow precludes recreation use of most primitive areas eight months of each year.

All of the National Forests and the three National Parks within the State contain wilderness. The Mt. Baker-Snoqualmie administers eight wildernesses, a total of 721,781 acres (R2MAP acres, which may differ from legal acres, or acres reported in this FEIS). Nearly 42 percent of net Forest acres are wilderness. Fifty-five percent of the state's population resides within a one-hour drive of wilderness on the Mt. Baker-Snoqualmie.

These areas contain some of the most rugged and beautiful country in the Pacific Northwest. Majestic old-growth forests are represented, as are alpine meadows, glaciers, high rock peaks, and hundreds of lakes. The variety of scenery and topography truly provide outstanding opportunities for solitude and primitive recreation.

Table III-64
Wilderness - Net R2MAP Acres - 1984

Wilderness	Net Acres
Mt. Baker	122,676
Glacier Peak	282,267
Noisy-Diobsud	15,015
Boulder River	50,388
Henry M. Jackson	75,836
Alpine Lakes	145,358
Clearwater	14,255
Norse Peak	15,923
TOTAL	721,718

Current Vegetation Condition

The plant communities within the wilderness areas have developed generally with minimal human influence. Over the centuries, most have been subjected to some form of periodic natural disturbance, such as fire, wind storms, avalanche, or insect epidemic. The most significant of these is fire. The plant communities on the western slopes of the Cascade Mountains have developed under a regime of periodic, high intensity, stand-replacement fires. An interval of 400 to 500 years between stand-replacement fire on a given acre is not uncommon. Fire does occur, however. For the past several hundred years, wilderness on the Forest has been subjected to numerous lightning storms each year. Most have been small, self confining fires that burn only small areas. It is only during

very specific combinations of weather and topography that conditions are such that fire starts will spread rapidly over large areas.

Within wilderness, the only natural phenomenon that man has had any influence on has been fire. Aggressive fire suppression programs within wilderness have been in place for over 75 years with little apparent affect on the natural ecosystems. The plant communities and accumulation of dead material existing in the wilderness today is not the result of past fire protection efforts.

Of the total wilderness acres, 61 percent (440,196 acres) are forested with trees. There are 284,922 acres with a productivity of 20 cubic feet per acre per year - 40 percent of the total wilderness acres (and 61 percent of the forested acres). The standing volume of these 284,922 acres is estimated to be 11,564.95 MMBF (2,309.38 MMCF) by 1995.

There are specific, isolated areas with the individual wilderness areas where soil compaction and trampling of native vegetation by human overuse has resulted in modification of the native plant communities. Some of these are identified in the wilderness use conflicts section below.

Wilderness Descriptions

Mt. Baker Wilderness

Mt. Baker Wilderness, designated in 1984, has a rich cultural heritage. Native Americans named the 10,778 foot volcanic mountain "Komo Kulshan," meaning White, Steep Mountain (Easton 19xx). They still consider the volcanic peak a spiritual place and use the area for traditional religious purposes. Mountain climbing expeditions became popular in the 1920's. Today, skiing, mountain and rock climbing, and snowmobiling still bring thousands of recreationists to Mt. Baker each year. State Highway 542 which ends at the Heather Meadows Area is a major access corridor that brings visitors to the core of the wilderness. The area receives considerable recreation use from Canadian visitors.

The 122,676 acre wilderness is located on the western slopes of the Cascade Crest and extends from the Canadian border to Twin Sisters, just north of State Highway 20. It is adjacent to the North Cascades National Park, the newly designated Mt. Baker National Recreation Area, and the Mt. Baker Ski Area.

The Wilderness contains heavily forested slopes of western red cedar, Douglas fir, and western and mountain hemlock. There are over 10,000 acres of permanent glaciers on Mt. Baker and other peaks. The terrain is extremely rugged, with steep slopes and numerous ridges, dissected by small streams. Mt. Baker periodically exhibits thermal activity.

Figure III-20

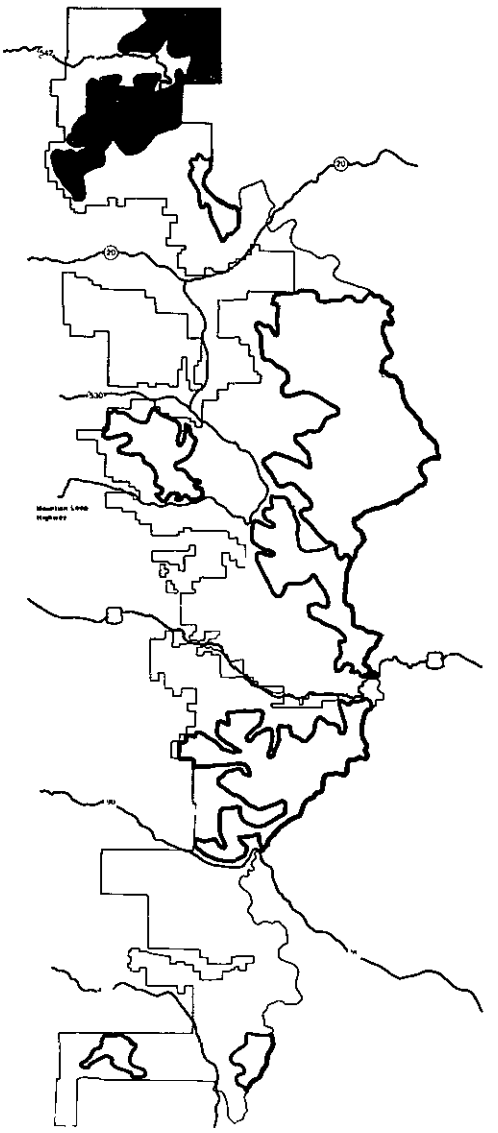

Figure III-21

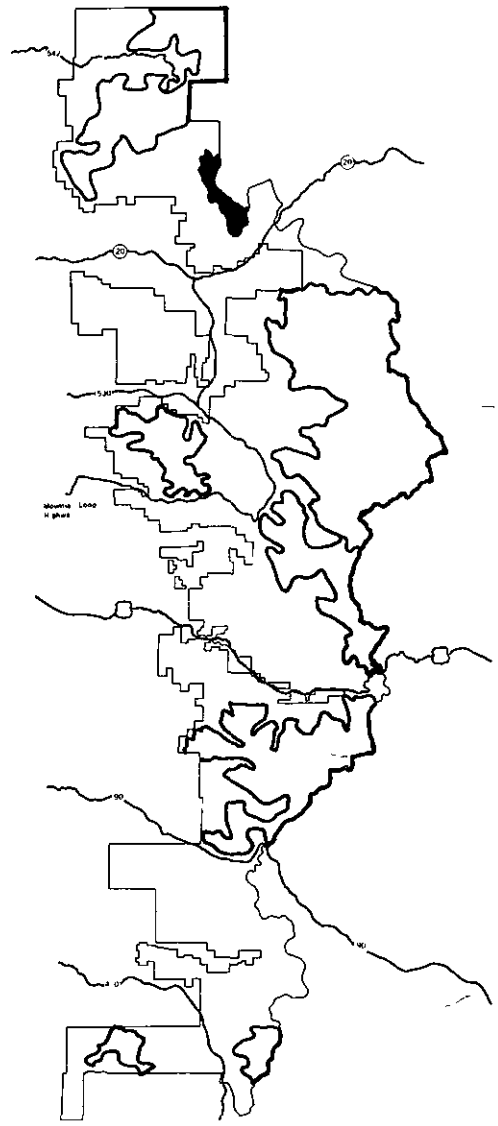


Noisy Diobsud Wilderness

The 15,015 acre Noisy-Diobsud Wilderness is adjacent to the North Cascades National Park. The topography, however, creates a physical separation from the Park. The terrain, dominated by Mt. Watson, is extremely rugged; steep slopes and ridges dominate the area. Noisy Creek dissects the northern portion; Diobsud Creek flows through the southern portion of the Wilderness.

Vegetation cover is typical of the western slopes of the Cascades: cedars, Douglas fir, true firs, western and mountain hemlock, and, at higher elevations, alpine meadows.

Climbing is popular and there is heavy recreation use at Watson Lakes. There are few trails or other popular destinations. The area contains important Native American traditional religious use sites as well as other historic sites and artifacts.

Glacier Peak Wilderness

The Glacier Peak Wilderness was designated in 1964; additions were made in 1968 (12,721 acres added to the Mt. Baker-Snoqualmie portion) and in 1984 (55,793 acres).

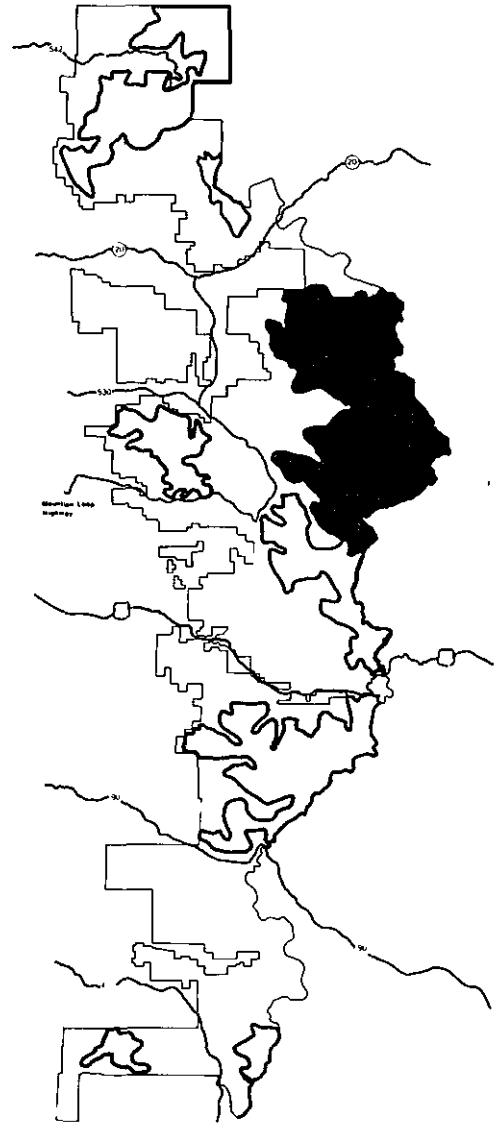
The central feature of the wilderness is 10,541 foot Glacier Peak, one of the five volcanic peaks in the Washington Cascades. The wild country surrounding Glacier Peak is among the largest untouched expanses of mountain terrain in the Northwest. The topography is very rugged, with peaks rising 5,000 to 8,000 feet above the valleys. Nearly all of the higher peaks support ice fields and over 90 glaciers are found within the wilderness.

Glacier Peak also contains heavily forested valleys and the headwaters of several major river systems, including the Skagit and the Skykomish. There are over 400 miles of trails, including 47 miles of the Pacific Crest National Scenic Trail, in Glacier Peak Wilderness.

The U.S. Geologic Survey completed an economic geology survey in 1983, finding only low-grade deposits; most important is a large, low-grade copper-molydenum deposit at Glacier Peak Mine.

Much of the area is known to have been used by Native Americans for seasonal food gathering.

Figure III-22



Boulder River Wilderness

Boulder River Wilderness - 50,388 acres - was designated in 1984. It is located west of Glacier Peak and south of the town of Darrington.

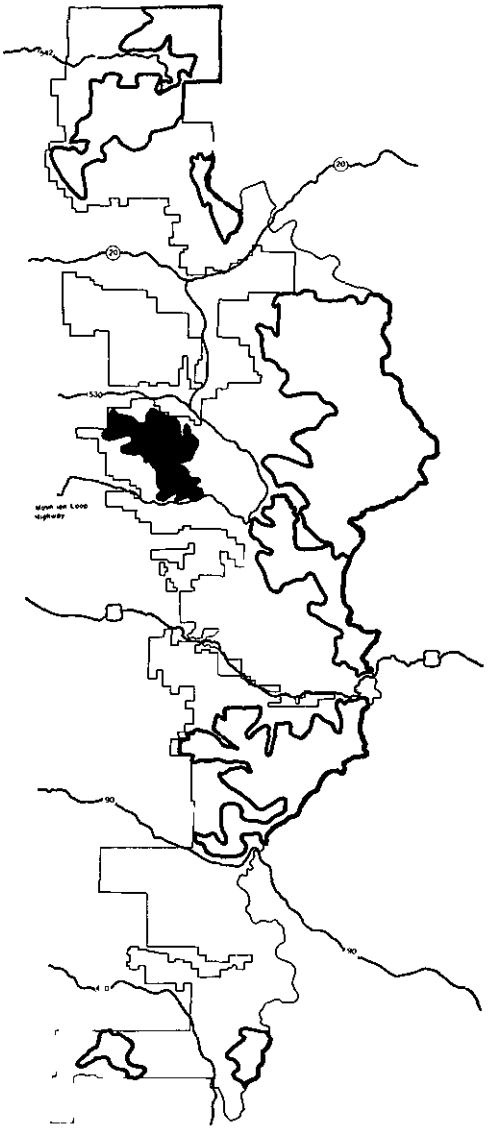
The Wilderness encompasses the magnificent Boulder River Valley and the surrounding peaks, ridges, and high alpine meadows of Whitehorse Mountain and Three Fingers. Elevations range from 1,200 feet in the valleys to nearly 6,900 feet on Three Fingers. The Boulder River valley provides a fine example of old growth forest consisting of Douglas fir, western red cedar, and western hemlock.

Boulder River Wilderness provides easily accessible terrain for year-round recreation use; relatively snow-free winter hiking trails are rare in wilderness. Present recreation use is concentrated on Boulder River, Goat Flats, and the surrounding alpine area.

The Long Creek Research Natural Area (RNA) is located within the Boulder River Wilderness; its principal feature is a western hemlock forest.

Historical sites and artifacts exist in the Wilderness; the area also contains sites and materials of importance to Native Americans.

Figure III-23



**Chapter III
Wilderness**

Henry M. Jackson Wilderness

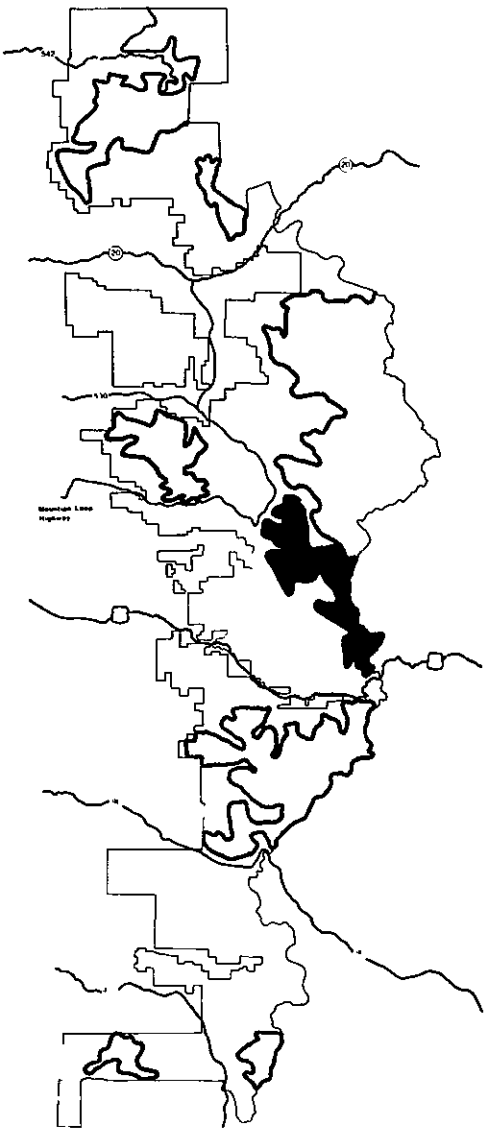
Designated in 1984, the Henry M. Jackson Wilderness includes favorite hiking areas of the late Washington State Senator. The Wilderness is adjacent to Glacier Peak Wilderness and is located on the Mt. Baker-Snoqualmie and Wenatchee National Forests. Of the 103,600 acres in the Wilderness, 75,836 are located on the Mt. Baker-Snoqualmie.

The terrain is very rugged and steep, dominated by a number of peaks, including Monte Cristo, Bedal, and Sloan. Vegetation includes western red cedar, Douglas fir, true firs, spruce, and hemlock. There are approximately 30 lakes in the Wilderness.

A number of trails in the Wilderness cross the Cascades at prominent gaps in the crest. Some of these routes date to very early Indian and pioneer exploration days. There are artifacts and several unconfirmed historic sites in the Wilderness. The area is also important to Native Americans for current practice of traditional religion.

There is substantial and varied recreation use in Henry M. Jackson Wilderness. Climbers, hikers, fishermen, and horsemen frequent the area. The Pacific Crest National Scenic Trail crosses the southern portion of the Wilderness.

Figure III-24



Alpine Lakes Wilderness

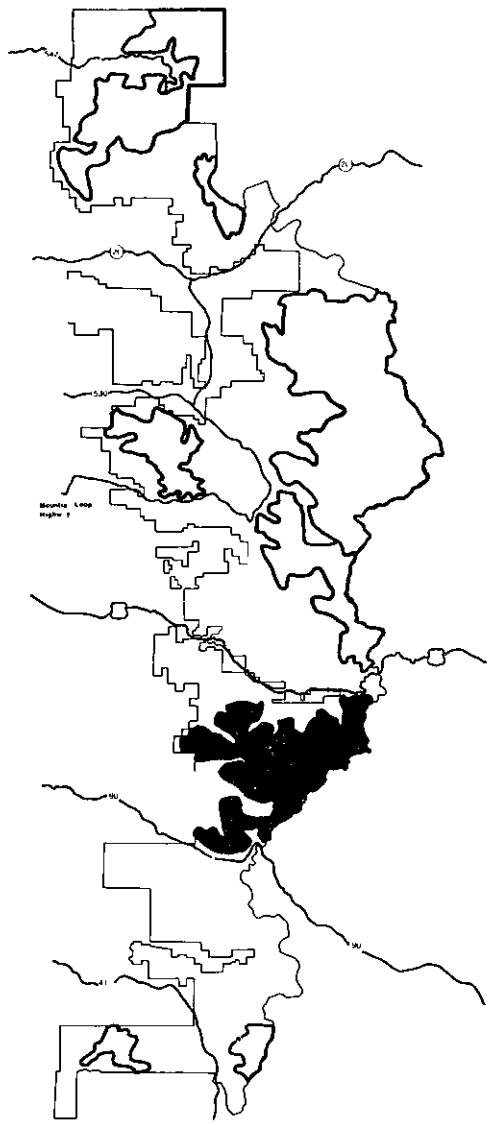
The Alpine Lakes Wilderness takes its name from the over 700 mountain lakes nestled among the glacial cirque basins, high rocky peaks, and heavily forested valleys of the Wilderness. Alpine Lakes Wilderness was designated in 1976.

The Wilderness is located in the central Cascade Mountains, in portions of the Mt. Baker-Snoqualmie and Wenatchee National Forests. It is one of the most popular wildernesses in the nation and one of the most accessible: half of the State's population lives within a one-hour drive. The two major cross-state highways border the area: U.S. Highway 2, at Stevens Pass, to the north, and Interstate 90, at Snoqualmie Pass, to the south.

The Mt. Baker-Snoqualmie portion of Alpine Lakes Wilderness contains over 90 miles of trails, including the Pacific Crest Trail, and 15 trailheads. Alpine Lakes receives considerable day-use, due to its proximity to major highways.

Recorded mining claims are located primarily in West Fork Miller River, Coney Basin, the Middle Fork Snoqualmie drainage, and near the Miller River-Lennox Creek drainages. The Dutch Miller mine is promising for high-grade copper ore. These mines represent potential acquisition issues in the future.

Figure III-25



Clearwater Wilderness

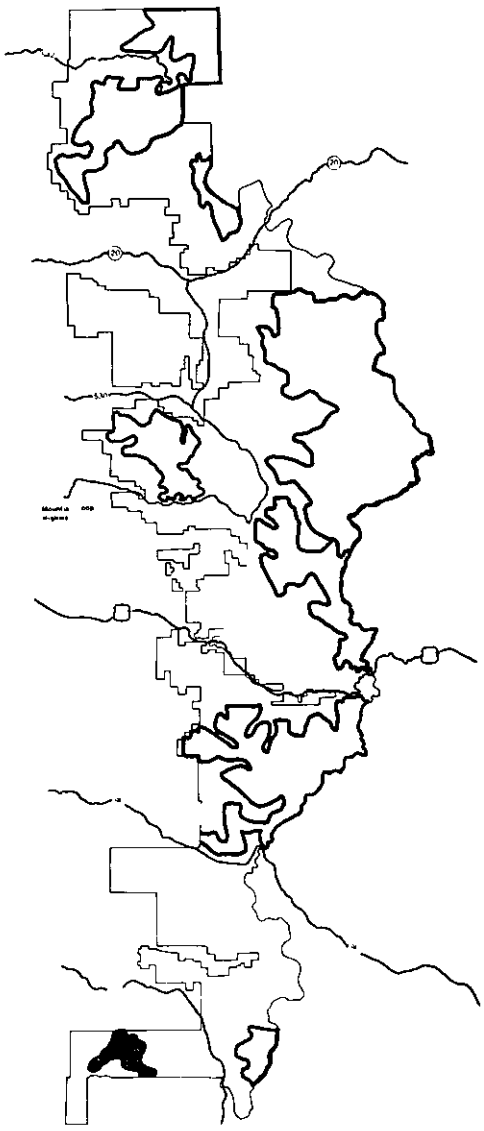
The 14,255 acre Clearwater Wilderness is adjacent to the northern boundary of Mt. Rainier National Park. The Clearwater was designated wilderness in 1984.

The terrain is moderate, interspersed with some steep and rocky sections. The headwaters of the Clearwater River are located within the Wilderness. Vegetation is typical of the western slopes of the Cascades, with fine representation of several coniferous species. Large, old growth timber is present in the lower elevations of the Clearwater valley.

A potential Research Natural Area, Lily Lake, lies within the Wilderness. There are several other small lakes in the Clearwater. These are popular day-use sites, as there is good road access up to the wilderness boundary.

The Clearwater Wilderness contains areas which are significant to Native Americans for traditional religious use. Cultural resources are also present.

Figure III-26



Norse Peak Wilderness

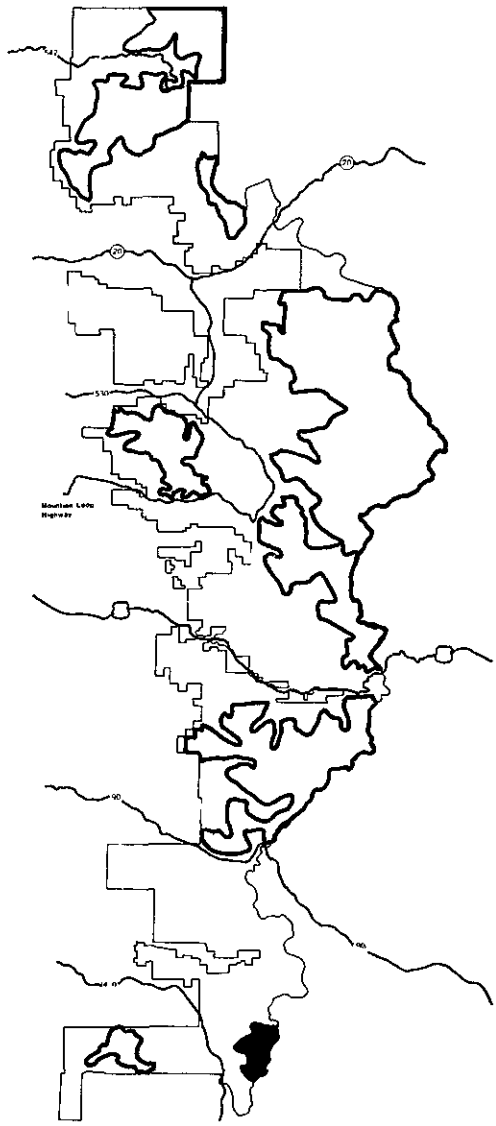
The Norse Peak Wilderness, designated in 1984, contains 50,923 acres between Chinook and Naches Pass on the Mt. Baker-Snoqualmie and Wenatchee National Forests. The Mt. Baker-Snoqualmie administers 15,923 acres. The southwest corner of the Wilderness abuts Crystal Mountain Ski Area.

The topography is generally steep, with rocky high-elevation terrain, narrow valleys, mountain lakes, and open, park-like basins. Norse Peak is the predominant peak. The Wilderness contains a unique geologic feature, Arch Rock. Vegetation includes Englemann spruce, Douglas fir, true firs, western and mountain hemlock, ponderosa, white, and lodgepole pine, larch, and western red cedar.

The Pacific Crest National Scenic Trail crosses the Wilderness from the Crystal Mountain area to Naches Pass. Norse Peak Wilderness is popular for recreation, particularly hiking and horse use. Easy access to Corral Pass and Government Meadows has led to severe overuse in some areas of the Wilderness. Portions of Norse Peak have been favorite motorized use areas for snowmobiles, 4-wheel drive, and trailbikes. Some of this use continues illegally.

The Wilderness contains areas deemed significant by Native Americans for traditional religious purposes.

Figure III-27



Wilderness Capacity

The potential use capacity for wilderness is based upon the subdivision of the wilderness into Wilderness Recreation Opportunity Spectrum (WROS) classes. The central notion of the spectrum is to offer recreationists alternative settings in which they can derive a variety of experiences. There are five mapped WROS classes: Transition, Trailed, General Trailless, Dedicated Trailless, and Special. These terms are defined in the Glossary. Within each class certain activities, settings, and management standards can be expected. These are discussed in detail in the Forest Plan, Standards and Guidelines.

Table III-65 shows the acres of the wilderness by WROS class; Table III-68 shows acres of WROS for each wilderness. Most of the wilderness acres are trailless; there is some potential to build additional trails in the General Trailless WROS class. This potential is discussed in the supply section, below.

In Table III-66, only the Glacier Peak Wilderness has acres in Dedicated Trailless. In the current situation and until the Forest Plan is implemented, only Glacier Peak has a Wilderness Management Plan that includes these acres. No acres of Special Area have yet been identified.

It is worth noting that, while the Trailless component of the WROS contains a large percent of the wilderness acres, only a small percent of the wilderness recreation can occur here. Much of the Trailless Class contains steep slopes and permanent, or long-lasting snow cover. Only 4.3 percent of the wilderness land is less than a 35 percent slope in the eight wildernesses.

Wilderness can accept only a low amount of use - compared to other dispersed areas and uses - due to the non-degradation policy and the fact that recreation is only one of the resources for which wilderness is managed. The wilderness of the Forest also provides for high quality watersheds, wildlife habitat, biological diversity, opportunities for research, and the preservation of unaltered ecosystems.

Table III-65
Wilderness ROS Acres - Current Situation

ROS Class	Acres 1/	% Wilderness
Transition	12,067	1.7
Trailed	44,356	6.1
General Trailless	585,326	81.1
Dedicated Trailless	80,000	11.1
Special	0	0
TOTAL	721,749	100.0

1/ R2MAP acres.

Table III-66
WROS by Wilderness, Current Situation 1/ - Acres

Wilderness	Transition	Trailed	General Trailless	Dedicated Trailless
Mt. Baker	5,470	5,005	112,203	
Noisy-Diobsud	190	0	14,825	
Glacier Peak	1,140	17,866	183,197	80,000
Henry M. Jackson	634	5,301	69,965	
Boulder River	211	2,428	47,748	
Alpine Lakes	2,302	11,235	131,820	
Clearwater	1,352	1,816	12,777	
Norse Peak	760	1,330	12,143	
TOTAL	12,059	44,981	584,678	80,000

1/ Only Glacier Peak has a Wilderness Management Plan with Dedicated Trailless acres at this time. All acres for this table are estimated.

Current Wilderness Use

There were 459,500 Recreation Visitor Days of wilderness use in 1989. In 1988, Alpine Lakes and Glacier Peak were the most heavily used wilderness areas in the Pacific Northwest. As shown in Table III-67, use increased sharply from 1976 to 1977, due to the designation of Alpine Lakes Wilderness. A similar increase occurred with the inclusion of the eight new wildernesses in 1984.

Use continues to grow with the increasing population of the Puget Sound area. The wilderness use on the Forest is among the heaviest in the nation.

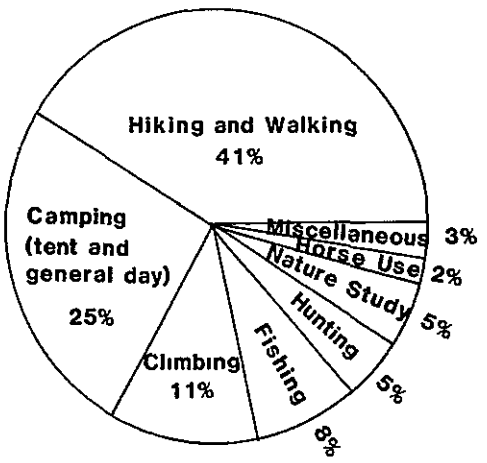
Table III-67
Wilderness Use - 1975-1989 - RVD's

1975	111,800
1976	116,800
1977	192,000
1978	156,100
1979	140,500
1980	170,200
1981	153,200
1982	147,600
1983	245,700
1984	274,500
1985	313,200
1986	340,000
1987	497,500
1988	455,517
1989	459,517

Over 40 percent of wilderness use is hiking. A majority of this hiking is day-use, a reflection of the accessibility of the wilderness. Camping, both tent and general day camping, accounts for another 25 percent of the wilderness RVD's. Hunting and fishing in wilderness receive less use. Norse Peak and Henry M. Jackson Wildernesses are popular horse use areas, however actual numbers for this activity are not available.

Figure III-28 shows relative wilderness use by activity, based on data from Glacier Peak and Alpine Lakes Wilderness. This chart shows the primary reason for going to the wilderness, or primary activity, not the absolute numbers engaged in that activity. Obviously, those engaged in camping had to arrive there by foot or by horse.

Figure III-28
Wilderness Use By Activity



1984 Data
Alpine Lakes and Glacier Peak

According to the 1984 Regional Guide for the Pacific Northwest Region, "the region does not currently have the capability to meet projected demand for wilderness use within the system." This use can be expected to increase, not only as a result of rapid population growth, but also as use in presently unroaded areas is displaced by other resource activities.

An analysis of wilderness capacity and use on the Forest shows that several wildernesses are over capacity in at least one WROS class; others are nearing capacity. Alpine Lakes, Glacier Peak, and the Clearwater were estimated to be over capacity in 1989. Boulder River and Henry M. Jackson are nearing capacity.

Most of these areas are within a two-hour drive of the Seattle-Tacoma metropolitan area. Easy access from major highways has resulted in severe overuse of some portions of Alpine Lakes, Clearwater, and Norse Peak Wildernesses. Much of this use is day-use hiking and walking; it is concentrated on a few, very popular trails (within Transition WROS zone). Refer to Chapter IV, FEIS for more discussion of capacity.

Wilderness Use Conflicts

Many current and potential conflicts of use exist in the wilderness. One of the most severe is overuse at specific locations. Roads and major highways near the wilderness boundary provide easy access, leading to overuse at some sites. Examples include I-90 and U.S. 2, Alpine Lakes Wilderness; the Corral Pass road up to Norse Peak Wilderness; and private roads that terminate at the Clearwater Wilderness boundary near Cedar and Lyle Lakes. Other sites experiencing overuse include:

Wilderness	Site
Mt. Baker	Lake Ann, Chain Lakes, Heliotrope Ridge, Hannegan Pass, and and Mazama Park.
Noisy-Diobsud	Watson Lakes.
Glacier Peak	Slide Lake, Lime Ridge, Miners Ridge, Kennedy Hot Springs, Lake Byrne, White Pass, Blue Lake, Cub Lake, Boulder Lake Green Mountain, Meadow Lake, Crystal Lake, Granite Lake, and Kool Aid Lake.
Boulder River	Boulder River, Kelcema Lake, Canyon Lake, and Goat Flats.
Henry M. Jackson	Goat Lake, Glacier Basin, Silver Lake, and Twin Lakes.
Alpine Lakes	Snow Lake, Gravel Lake, Upper Necklace Valley, Talapus and Olallie Lake, Pratt Lake, West Foss Valley, Dorothy Lake, and Fisher Lake.
Clearwater	Summit Lake, Cedar Lake, and Lyle Lake.
Norse Peak	Quinn and Lost Lakes, Arch Rock, and Echo Lake.

Other problems and conflicts include:

-Historical ORV and snowmobile use in Norse Peak Wilderness, especially near Corral Pass. Several popular routes are now inside the wilderness boundary.

-Horse use early in the season in the Norse Peak Wilderness.

-Snowmobile use overlapping from the Mt. Baker NRA into the Mt. Baker Wilderness. Historic snowmobile use in the upper reaches of Canyon Creek, now within the Mt. Baker Wilderness boundary.

-Historical use of Mt. Baker by large climbing parties, sometimes up to 100 people.

-Aircraft noise in wilderness, especially military aircraft in Alpine Lakes, Glacier Peak, and Mt. Baker.

-Potential designation of Class I airsheds in the new wildernesses may effect activities outside the wilderness.

ROADLESS AREAS

This section includes a brief overview of the roadless area situation. Refer to Appendix C for a detailed, site specific analysis of each roadless area parcel. Each of these areas has been analyzed for their wilderness potential.

Roadless areas are defined by nationally established criteria as tracts of land 5,000 acres of larger, with no engineered roads or other substantial development. They may also be smaller areas that are adjacent to existing wilderness areas. They are relatively undisturbed tracts of the Forest's ecosystem which have been neither set aside as wilderness, nor altered by road building, timber harvesting, or campground development. Although old wagon trails, primitive roads, cabins, camps, and other minor evidence of human endeavor can be found in these areas, they still resemble the untouched forest first viewed by western settlers. There are approximately 402,930 acres of such lands on the Mt. Baker-Snoqualmie National Forest.

There are 101 separate roadless area parcels located throughout the Forest; the majority are located north of U.S. Highway 2. Individual parcels range in size from 30 to 51,000 acres. Twelve roadless areas remain in their entirety, with no wilderness designation of any of the originally inventoried acres. The largest of these are Eagle Rock (33,177 acres), Higgins Mountain (13,127 acres), and Pressentin (15,057 acres). Some parcels are small "fringes" less than 100 acres in size. Others, such as the western Tomyhoi-Silesia portion of Mt. Baker, the Dickerman portion of Boulder River, and portions deleted from Noisy-Diobsud, Henry M. Jackson, and Glacier Peak Wildernesses contain substantial acres.

These lands, inventoried in the Roadless Areas Review and Evaluation - RARE II - (USDA 1979), were not designated wilderness by the Washington State Wilderness Act of 1984 (US 1984). Roadless areas equal about 24 percent of the net acres of the Forest.

These areas provide diverse, undisturbed habitats for fish and wildlife, and can be especially important for species sensitive to human disturbance or dependent of such limited habitat components as old-growth conifers. For the recreationist, roadless areas offer opportunities for solitude and physical challenge not available in more developed settings. Streams in roadless areas are often a source of high-quality water for communities within the Forests zone of influence. Many of the Forest's roadless areas contain extensive acres of old-growth forest, which is valuable to local and regional economies.

Large or small, these roadless parcels were excluded from wilderness designation because of other resource values, or to create a more identifiable or manageable wilderness boundary. Wilderness designation for these roadless parcels will not be considered in this Mt. Baker-Snoqualmie Forest Plan. Areas remaining roadless will be studied again in the next round of planning. All resources, including wilderness, will be evaluated to determine how the areas are to be allocated and managed.

The commercial forest land within the roadless areas has been calculated in the forest annual allowable harvest totals, but this timber has had limited availability for harvest since the beginning of the RARE I process in 1972. An adjusted programmed harvest level was negotiated in 1982; a 1984 revision

further reduced the allowable sale quantity to reflect the Washington Wilderness Act.

Following transmission of the RARE II Final Environmental Impact Statement to EPA and the public in January 1979, the Forest began limited selling of timber within the roadless areas. Initially, blow-down just inside the roadless area boundaries was targeted for salvage. Later entries focused on those areas identified in the Forest 5-year timber sale program. These entries reflected management direction in the Ranger District Multiple Use Plans.

From fiscal year 1979 through fiscal year 1988, 72 timber sales with an estimated volume of 263.4 MM board feet were sold within the roadless areas. These sales ranged in size from 3 to 274 acres; most were under 100 acres in size. Road construction has been very limited. Slightly more than half of these sales involved road construction; mileage was generally 1 1/2 miles or less.

These areas also remained available for dispersed recreation, wildlife habitat, and other uses.

A number of the RARE II areas were designated as wilderness in 1984; however, the allocation and management of the roadless areas remains a major issue. Substantial public comment on the future of the roadless areas was received in response to the DEIS. Many comments favored keeping the roadless areas in their natural state; many other respondents strongly favored opening the roadless areas to motorized use.

Many areas possess scenic attractions, wildlife habitat, and contain a variety of recreation opportunities. Some areas contain sizeable acreage of old growth forest, valued for wildlife habitat, timber production, and aesthetics. About 42 percent of the acreage is considered tentatively suitable for timber production. Table III-68 shows some summary information about the roadless areas. Figure III-29 shows the general location of the roadless areas.

Table III-68
Summary Table - Roadless Areas

Total Acres	402,930
Total Number of Parcels	101
No. Parcels Less Than 100 Acres	14
No. Parcels 100 to 999 Acres	42
No. Parcels 1,000 to 4,999 Acres	24
No. Parcels 5,000 Acres and Larger	21
Total Acres of Tentatively Suitable 1/	161,175
Total Acres of Old Growth 1/	203,538
Primitive and Semi-Primitive Nonmotorized ROS Acres	260,346

1/ These acres include overlaps.

Figure III-29
Roadless Areas

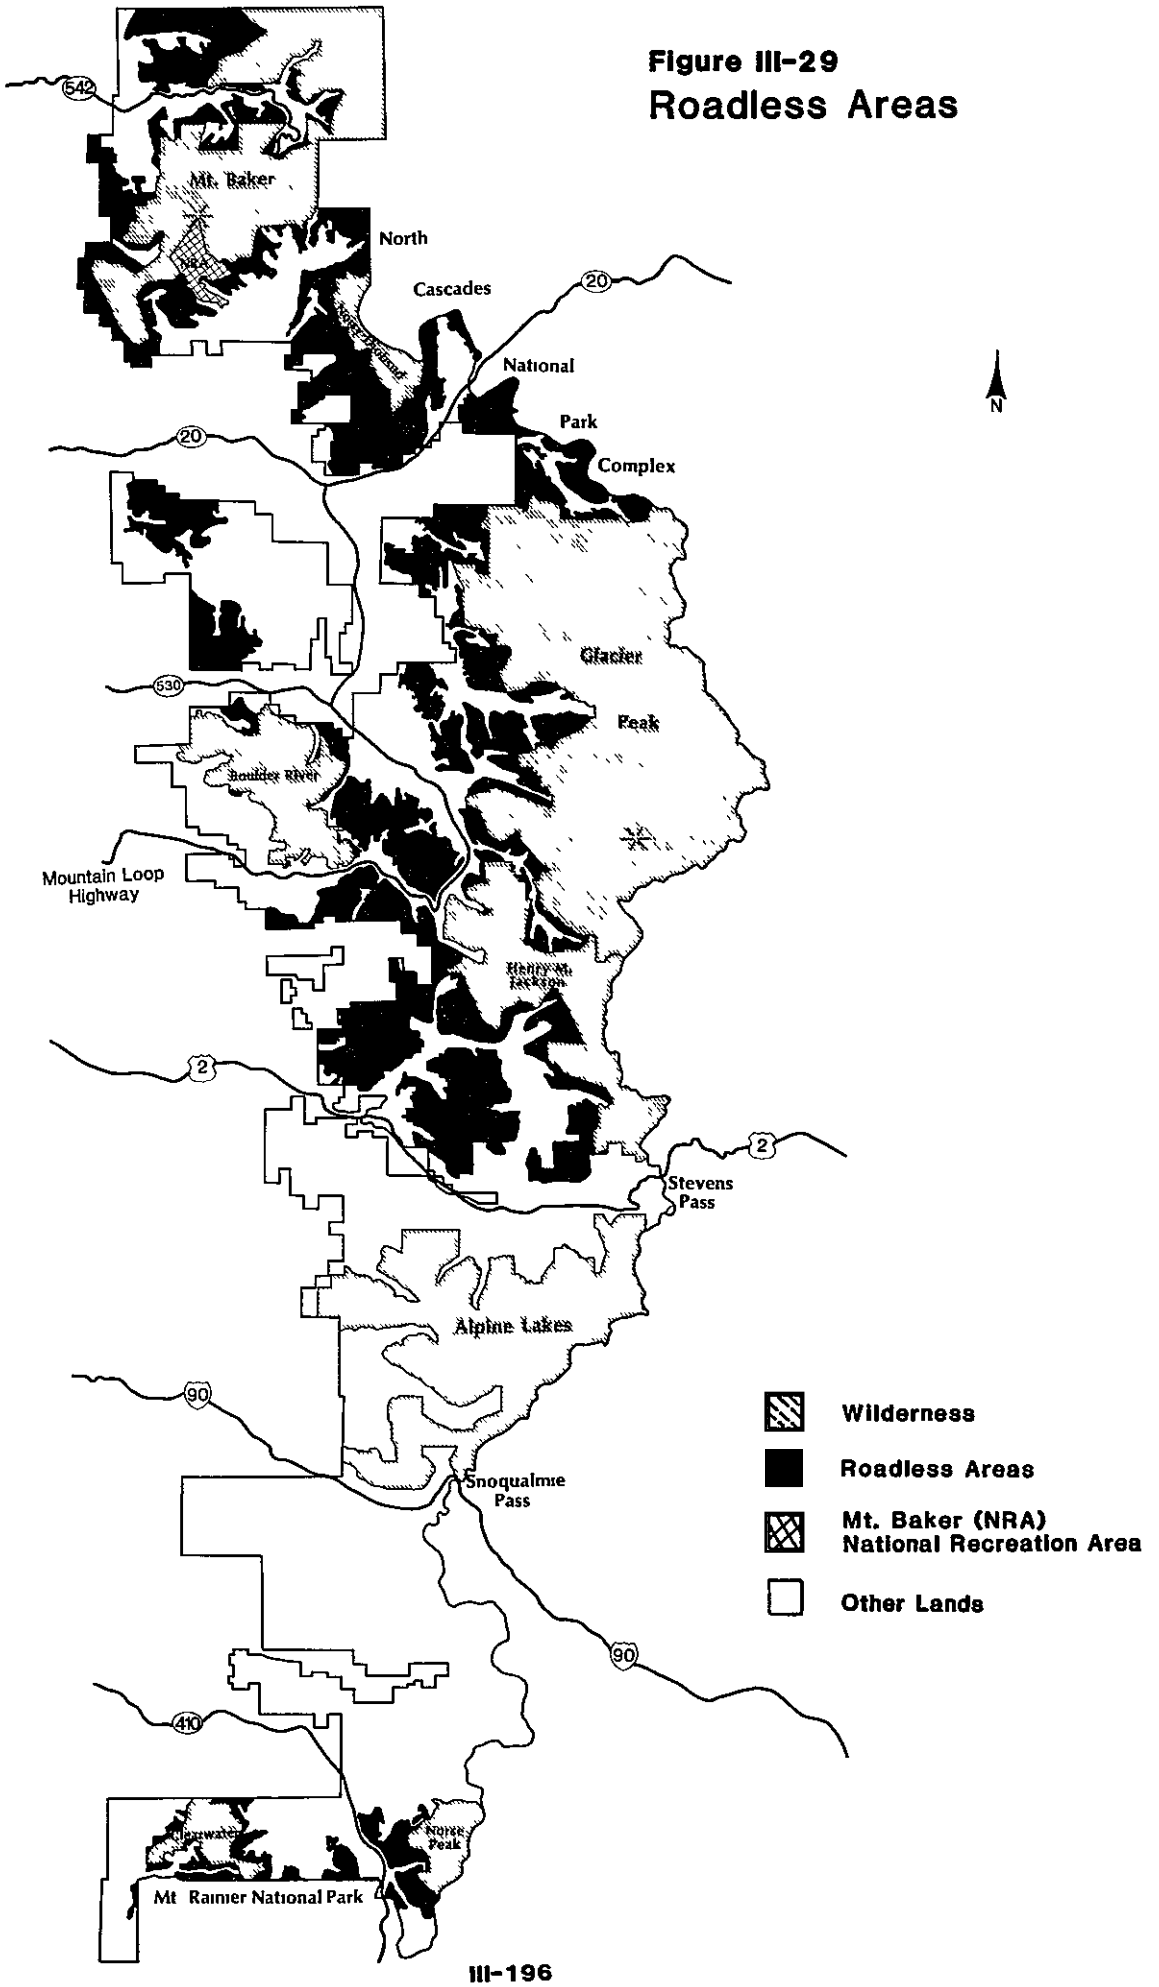


Table III-69 - in two parts on the pages below - provides a summary of the attributes for each of the inventoried roadless areas. Wilderness characteristics and key resource values are identified by area. The individual parcels have been grouped into geographically similar areas for this table. The detailed legend for Table III-69 provides descriptions of each of the attribute ratings used in the table. For more information on each parcel, refer to FEIS, Appendix C.

Legend for Table III-69 - Roadless Area Attribute Ratings

Ratings = High, Medium (shown as Mod), Low, and None or Negligable (0).

Manageability and Boundaries - Ability to manage and protect the area's natural character considering such factors as size, shape, and position (including boundary location) relative to external influences.

High - Inherently protected through excellent topographic positioning, favorable external influence (i.e. land allocation, physical conditions), or very limited hazards/risks to natural character.

Mod - Part of area subject to external influences, or overall positioning and physical conditions are at some risk.

Low - Considerable portions at risk or subject to external influences; manageability highly dependent on degree of protection provided in areas outside unroaded part.

0 - Protection largely unattainable due to present activities and conditions that are not inherently mitigated. Risks to natural character and processes high.

Natural Integrity - Extent to which long-term ecological processes are intact and operating, or are free of disturbances; consideration of extent to which human influences have altered natural conditions and are apparent to user.

High - Extremely limited, or not apparent.

Mod - Small portions of area affected by human activity, or recovery of past impacts approaching natural state and not perceived by user.

Low - Considerable area impacted, or perceived recovery of past change incomplete or apparent to user.

0 - Much of present ecosystem is primarily a result of recent or past activity by man; or major portion is directly or indirectly (from periphery) influenced by human activity; readily noticed by user.

Opportunities for Solitude - Area's feeling of solitude (how it provides for remote and backcountry setting).

High - Most of area free of external influence and provides a strong feeling of remoteness and solitude.

Mod - Fringes influenced by sight and/or sound of human activity; solitude aided by vegetative or topographic conditions.

Low - External influences persist over much of area; vegetation and topography generally only aid to providing solitude.

0 - Most of area within sight or sound of human activity; topography and vegetation provides only limited relief.

Opportunities for Primitive Recreation - Opportunities for primitive and unconfined types of recreation activities; how well the area provides outstanding opportunities for unusual adventures or excitement.

High - Varied type (more than those associated with foot travel only); unique experience, or experience of adventure/excitement.

Mod - Varied type (good mix of foot travel associated activity); potential for adventure exists.

Low - Limited type; adventure or challenge related to topographic difficulty and distance from nearest roaded access.

0 - Type and adventure not different than much of adjacent lands.

Special Features - Unique, abundant, or varied flora, fauna, historic, scientific, and physiographic features; where protection from nonconforming activities would enhance management of unusual or sensitive species or features.

High - Existence over much of area or very unique.

Mod - Existence of species or features over much of area that would be enhanced; limited extent of unique or sensitive elements.

Low - Limited enhancement opportunity; unique or sensitive elements limited to very small areas, or other allocations, standards or guidelines afford adequate protection.

0 - Species and features not different than surrounding areas.

Table III-69
Summary of Roadless Area Attributes

Roadless Area	RARE II Number	Capability: Manage-ability	Natural Integrity	Opportun. Solitude	Primitive Rec. Opp.	Challeng. Exper.	Special Features

Based on the attributes and ratings of Table III-69, six roadless areas on the Forest have demonstrable wilderness potential. All six consistently rating "high" in a majority of the attributes.

They include:

- Canyon Creek Block of the Mt. Baker Roadless Area - 25,046 acres
- Noisy-Diobsud Block of the Mt. Baker Roadless Area - 51,400 acres
- Alma Copper - 8,193 acres
- Glacier Peak, Parcel I - 12,755 acres
- Higgins Mountain - 13,127 acres
- Eagle Rock - 33,177 acres

Again, refer to FEIS Appendix C for more information.

Roadless Area Supply and Demand

One measure of demand for roadless areas is reflected in the demand for recreational opportunities within semi-primitive nonmotorized (SPNM) ROS settings and similar settings within wilderness. As discussed in the recreation section of this chapter, demand for this type of recreation already exceeds supply in the non-wilderness areas, and will soon exceed supply in the wilderness.

Of the 402,930 acres of inventoried roadless areas, all or portions of any of the 101 roadless parcels could be left in their existing condition in order to preserve their wilderness potential. From the above, six of the Forest's roadless areas have greater potential for wilderness than the other areas described and evaluated in Appendix C.

WILD AND SCENIC RIVERS

There is one designated Wild and Scenic River on the Forest and 47 potential river additions to the National System on the Forest. This discussion briefly summarizes the situation on the Forest. Refer to Appendix E for a detailed description of each potential river, including maps and a list of attributes.

The Skagit Wild and Scenic River was designated in 1978 (PL 95-625). It contains 58.5 miles of recreational river, all on the Skagit River, and 100 miles of scenic river: 21.8 miles on the Cascade River, 50.8 miles along the Sauk River, and 27.4 miles on the Suiattle River. Just over 50 percent of the 38,939 acres within the management corridor are State or privately owned. The Skagit Wild and Scenic River system is managed under the 1984 Final River Management Analysis and Plan.

The Skagit drainage provides a variety of recreation use, including one-third of the total river rafting occurring on the Forest (RIM). Nature study and viewing wildlife are also very popular, as the Skagit is the winter home for the largest population of eagles in the lower 48 states. The river is renowned for its steelhead sport fishing. Recreation use of the system is growing, and the potential exists for conflicts between wintering eagles and recreation use. Several research projects are currently evaluating this situation.

The Skagit drainage basin provides habitat for a vigorous, diverse fishery of national significance, including five species of salmon, three species of sea-going trout, and a diversity of resident fish. Approximately 30 percent of the young anadromous fish entering Puget Sound are hatched in the Skagit River System. This fishery has an estimated commercial value of $17 million during odd-numbered years, when the pink salmon migrate upstream, and $6 million during even-numbered years. The Skagit is also the principle fishery for three American Indian tribes. As mentioned above, the fishery and its associated habitats make the Skagit River a principal wintering area for the bald eagle. These birds are protected under the Threatened and Endangered Species Act.

Potential Additional Rivers

The Wild and Scenic Rivers Act established criteria for the addition of other rivers to the National System. The National Park Service (formally Heritage Conservation and Recreation Service) conducted an inventory of potential rivers. Portions of the sixteen rivers on that inventory are within the Forest boundary.

Besides the sixteen rivers on the inventory, other rivers have been considered in this planning effort. A total of 51 rivers were identified and studied for their eligibility as Wild and Scenic Rivers; 47 rivers were determined to be eligible. Eligibility is determined by applying the critieria cited in Section 1(b) and 2(b) of the Wild and Scenic Rivers Act, as interpreted by the USDA-USDI Guidelines. To be eligible for inclusion, a river must be free-flowing or restored to a free-flowing condition and possess one or more "outstandingly remarkable" values, including: scenic values, recreational value, geologic value, fisheries or wildlife value, historic value, cultural values, or other, including ecological values. The table below shows the list of 47 rivers that were determined to be eligible. These rivers will be protected so as not to lose their eligibility until Congress makes their determination.

Table III-70

Rivers Studied for Potential Eligibility

Inventoried River	Total Miles	Inside Wilderness	Inside National Park	Inside Forest Boundary	Outside Forest Boundary	% Inside Forest Boundary
			miles			
Silesia Creek	11 3	6 8	4 5	6 8	4 5	60%

Other Designations

Portions of the Skykomish River system have been designated by the State of Washington as a Scenic River under the provisions of the State Scenic River System Act (RCW 79.72). This designation applies only to city, county, and State lands. This river features substantial runs of anadromous fish, bald eagle feeding and perching areas, and communal roost sites. Portions of the river, especially outside the Forest boundary, support a variety of boating opportunities including white-water rafting.

In 1988 the State of Washington released the Washington State Scenic River Assessment. This report documents the evaluation of several outstanding rivers in the state, and identifies 18 rivers which possess the natural, cultural, and recreational values that would make them suitable additions to the Washington State Scenic River System. The Carbon, Nooksack and Stillaguamish Rivers are the rivers included in this lists which cross the Forest.

RESEARCH NATURAL AREAS

Research natural areas are part of a national network of field ecological areas designated for research and education and aid in maintaining biological diversity on Forest lands. Research natural areas are established to preserve a wide spectrum of pristine natural communities or ecosystems, or those having special characteristics of scientific importance. They maintain biological diversity, serve as reference areas for the study of long-term ecological change, and offer scientists, biologists and others the opportunity to study plant communities and ecological processes in unmodified conditions (Franklin and others, 1972). Besides the Forest Service, the Bureau of Land Management, the National Park Service, the U.S. Fish and Wildlife Service, and the Department of Energy have classified land as research natural areas.

Along with study, research, and educational purposes, RNA's provide a baseline area against which the effects of human activities in similar environments can be measured. They also provide gene pool preserves for plant and animal species, especially rare and endangered types (Franklin and others 1972).

Each involved agency has developed similar regulations for management of RNA's and to protect the scientific and educational values of each area. Ideally, areas are sufficiently large to protect the feature of interest from significant unnatural influences. Logging activities are not permitted. Recreation and other public use is not a recognized use of RNA, although it may be allowed so long as it does not alter the features for which a given area was set aside. Deliberate manipulation of the area, however, may be authorized under certain circumstances in order to preserve the vegetation for which the area was created.

As of 1986, there were 102 research natural areas in Oregon and Washington, 39 of which are in Forest Service jurisdiction. The Mt. Baker-Snoqualmie National Forest has three established research natural areas, totaling 2,837 acres. They are listed below in Table III-71.

Table III-71
Established Research Natural Areas

Name of RNA	Principle Features	Date Established	Acres
N.F. Nooksack River	Douglas-fir, western hemlock forests	1934	1,407 1/
Lake Twenty-two	Western redcedar, western hemlock forests and subalpine lake	1947	790
Long Creek	Western hemlock forest, climax red alder forest	1947	640

1/ The area was initially 1,495 acres, but in 1973, 88 acres were subtracted to allow removal of danger trees along the highway.

Research Natural Area Needs

The Western Slopes and Crest Province has a need for examples of ecosystems or habitats that might be found on the Mt. Baker-Snoqualmie National Forest. They include:

Ecosystem or Community

Douglas-fir less than 75 years old (old burn)
Douglas-fir 100-150 years old
Old-growth western redcedar forest, northern portion of province
Red alder forest
Mountain hemlock-Pacific silver fir forest, northern province
Subalpine parkland mosaic (tree groups with a variety of meadow types)
Heather-huckleberry communities
Subalpine lush herbaceous communities, including Valeriana-Veratrum and Rubus-parvifolium-Pteridium types
Alpine Community Mosaic with Krummholz tree groups
Low elevation lake and drainage basin temperate forest
Subalpine lake and drainage basin (with fish)
Large upwelling cold spring
Typical hot spring

Potential Research Natural Areas - Supply

A study was completed to determine if the Mt. Baker-Snoqualmie National Forest had areas meeting the above description that would be suitable for an RNA. Areas for consideration were identified; further investigation indicated five candidate areas that were potentially suitable. Table III-72 gives these areas, with a brief description, along with a priority for RNA listing. Figure III-30 shows the general location of existing and potential RNA's on the Mt. Baker-Snoqualmie Forest.

Three potential RNA are located within designated wilderness: North Fork Nooksack Addition (Mt. Baker Wilderness), Chowder Ridge (Mt. Baker Wilderness), and Lily Lake (Clearwater Wilderness). Approximately 80 percent of the Green Mountain potential RNA is located inside the Glacier Peak Wilderness. There is established recreation use at Green Mountain and at Perry Creek.

Wilderness designation precludes any use of motorized equipment within the wilderness boundary. While there is limited active research occurring within the three existing RNA's, location of research natural areas within wilderness imposes some limitations to the type and extent of research that could conceivably take place. Some feel the dual designation of RNA and wilderness will ensure protection of the natural ecosystems of the RNA and further preserve its environments and species.

The North Fork Nooksack River Research Natural Area is located in the northern-most Ranger District of the Forest, off the Mount Baker Highway, and just five miles from the Canadian border. It is the least accessible of the three research natural areas and the topography is very steep. The highway bounds the RNA for about three miles, and a short nature trail has periodically been opened. Otherwise, there is little human disturbance.

Lake Twenty-two Research Natural Area is located near Pilchuck Mountain and east of the small town of Verlot. This RNA is easily accessible from the Mountain Loop Highway; a 2.5 mile trail leads to glacier-created Lake Twenty-two. Despite its low elevation (about 2,500 feet), permanent snowfields are found in the lake basin (Franklin and others 1972). Heavy recreation use is well established, especially at the north end of the lake and along the trail.

The Long Creek RNA is located two miles northeast of Lake Twenty-two, within the Boulder River Wilderness. The RNA was established some years before the Boulder River Wilderness was designated in 1984. Long Creek RNA contains two-thirds of the Long Creek drainage; there is little or no recreation use.

All three research natural areas have been named potential National Nature Landmarks.

Demand for Research Natural Areas

While there are currently 102 research natural areas in Oregon and Washington, additional areas are continually being sought to provide needed representation of major forest, range communities, and aquatic features, as well as for unique and rare species. All the agencies involved, plus the Pacific Northwest Research Natural Area Committee, search for suitable areas to protect. The Pacific Northwest Region uses Research Natural Area Needs in the Pacific Northwest (Dyrness and others 1975) to identify specific needs in the two states. These needs are listed by physiographic provinces. The Mt. Baker-Snoqualmie is in the "Western Slopes and Crest Province, Washington Cascades." The Washington Natural Heritage Plan also contains an updated source of specific research natural area needs.

Within this province, there is need for 31 terrestrial and 18 freshwater sites. The three existing RNA's on the Mt. Baker-Snoqualmie National Forest satisfy some of the needs as do other RNA's administered by other Forests or agencies on the western slope of the Cascades in Washington.

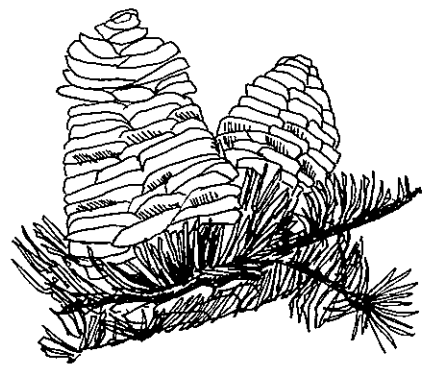

Table III-72
Potential Research Natural Areas 1/

Area	Approx. 2/ Acres	Need/Cell 3/	Priority 4/	Possible Alternate Sites
Addition to North Fork Nooksack RNA 5/	2,460	Example of Douglas-fir, 75 year old burn, (Terrestrial cell = 1). Also includes wide array of subalpine meadow communities found in existing RNA.	Low	Token representation elsewhere.
Lily Lake 5/	800	Represents high-elevation mountain hemlock-Pacific silver fir forest (Terrestrial cell = 16). Lake is typical of mid-to-high-elevation subalpine lakes (Aquatic cell = 8).	Low-moderate	North Cascades Park may be alternate for cell 16 Lake Twenty-two may suffice for example of lake (cell 8).
Perry Creek	2,066	Represents unique assemblage of rare fern species (plant cells = 13, 14, 17, 25, 26) Also has Alaska cedar (in stand with mountain hemlock and subalpine fir. (Terrestrial cell = 19) and heather-huckleberry community (Terrestrial cell = 21)	High	None for ferns. Possible alternate sites in North Cascades Park for Alaska Cedar and heather-huckleberry communities.
Green Mountain 6/ 7/	2,060	Represents subalpine parkland mosaic, heather-huckleberry communities, and subalpine lush herbaceous communities. (Terrestrial cells = 20, 21 and 22)	Medium-high	Possible alternate sites in North Cascades Park.
Chowder Ridge 5/ 6/	1,920	Alpine community mosaic with Krummholz tree groups (Terrestrial cell = 24).	Medium	Possibly found in Mt Rainier and N. Cascades Parks.

1/ Research Natural Area Needs in the Pacific Northwest (Dyrness and others 1974).
2/ Acres digitized from map and may differ from R2MAP
3/ A cell is an ecosystem or organism which needs to be represented and protected by a RNA.
4/ Priority represents the urgency of placing a sample ecosystem in RNA status. Urgency is determined by measuring the risk of losing all examples of the ecosystem to other uses. (Dyrness and others 1974).
5/ Located in wilderness.
6/ Potential National Natural Landmark
7/ Partially located in wilderness.

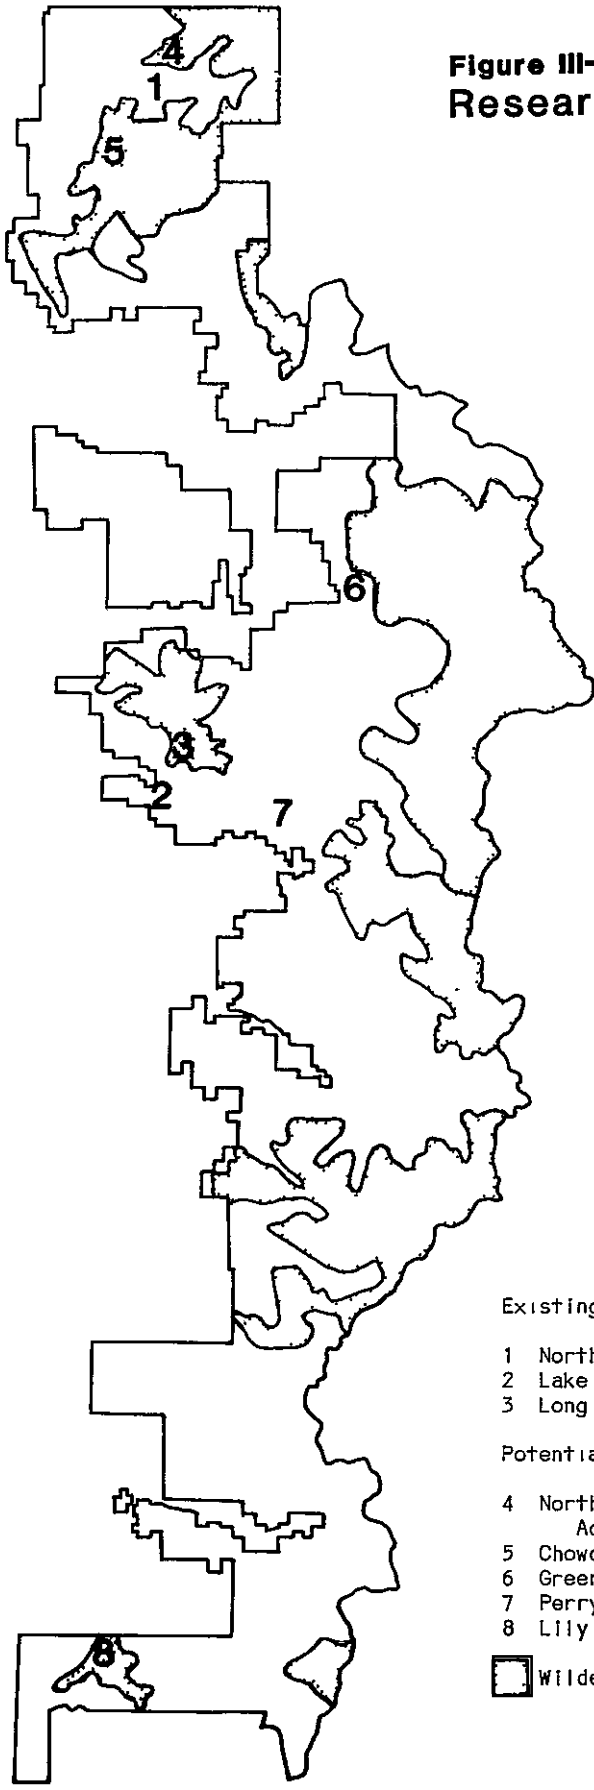

Figure III-30
Research Natural Areas

Chapter III
Air, Fire

AIR

Along with soil and water, air is an essential component of the Forest Ecosystem (Huston, 1979). In addition to being a physical resource, air is also an aesthetic resource; the visual experience has value to the forest visitor and to the people who reside in the area (Washington State Department of Ecology, 1985). Both nature and humans can cause changes in air quality including visibility. Natural phenomenons such as fog, smoke from lightning caused fires, pollen and windblown dust all may affect air quality. Aerosols such as oxides of nitrogen, hydrocarbons, sulfur dioxide, and carbon monoxide have the potential to damage forest resources and impair visibility. What begins as air pollution often ends up in the soil and water and can affect the health and vigor of the ecosystem.

Air Quality

The air quality is generally good over the Forest area. Limited monitoring of the regulated pollutants by local pollution control agencies indicate concentrations decline to the east of the developed metropolitan area around Puget Sound. However, levels of these pollutants are well under Federal and State ambient air standards necessary to protect human health.

The only continuous monitoring program currently on-going is of Total Suspended Particulate (TSP) levels at a site near the Tolt Reservoir by the Puget Sound Air Pollution Control Agency. Data collected since 1980 indicates a fairly constant annual geometric mean of TSP of around 10 microns per cubic meter of air, well below the state standard of 60 microns/cubic meter. For comparison: values measured in the metropolitan areas near Seattle are in the 35-45 micron/cubic meter range. Peak daily concentrations are less than the annual average concentrations of the urban areas.

Previous monitoring efforts of other pollutants within the Forest by the Washington Department of Ecology and the Federal Environmental Protection Agency have been discontinued because of low ambient levels. This supports the estimate that minimal rates of atmospheric deposition are occurring.

Traffic on Interstate 90 and U.S. Highway 2 are the heaviest of any roads within the Forest. Though not measured within the Forest boundary, it is felt that the current levels of carbon monoxide, sulphur and nitrogen emmissions are well below current State and Federal standards.

Ozone is found in the Puget Sound region in concentrations approaching State and Federal standards. The highest concentrations normally occur during the summer months, and are due to the solar heating. The photochemical processes that produce ozone in the atmosphere take time to complete. As a result, the highest concentrations of ozone normally occur 15 to 25 miles downwind of the sources of the pollution. In the past, ozone concentrations in the area to the west of the Forest have exceeded State ambient air standards, but increased controls on hydrocarbons in the metropolitan areas have lowered concentrations to acceptable levels.

It should be noted that most monitoring to date has centered around the pollutants themselves, to compare their concentrations with standards for human health. Considerably less has been done on monitoring the effects, if any, of

airborne pollutants on forest ecosystem components. Currently, the Forest Service has funded a Federal Environmental Protection Agency research effort called the Western Conifers Project to evaluate the ways and extent that air pollution may affect forest vegetation. Results of this research are just now beginning to be published. One finding that may impact future forest resource management: the low pH levels measured in fog water near Mt. Rainier and Mt. Baker that has precipitated from air masses that stagnated over urban areas. What happens when these acidic air masses intercept forested areas of the Forest is not completely understood, but the findings do raise a potential for serious impact (Basabe, 1989).

Monitoring visibility is another current project now underway. This is part of a regionwide effort to characterize the quality of visibility in the Class I areas of the Region. Baseline data is currently being developed for a series of sites throughout the Northwest, including one just south of Stevens Pass near the Alpine Lakes Wilderness. The data from that site are insufficient to show any trends to date, but they do give an indication that visibility, when expressed as mean average standard visual range, is among the best in the Region (Air Resource Specialists, 1989).

Prescribed Burning

Prescribed burning is the practice of using fire under prescribed conditions to accomplish a variety of resource management objectives. Among these are:

- disposal of unutilized material resulting from road, trail, or other construction projects;
- disposal of residue resulting from harvest or cultural treatments to mitigate fire hazards;
- modifying vegetation to improve habitats for certain wildlife species;
- treating infested areas to prevent further spread of disease and/or insects;
- allow natural processes to prevail in wilderness areas;
- prepare sites for regeneration.

Prescribed burning may involve burning as it occurs on the ground (broadcast burning) or burning material that has been piled by machine or hand (pile burning). A key element in the application of all prescribed fires is a site specific prescription that establishes that parameters for fire use.

Prescribed burning on National Forest land is accomplished under the guidelines of the Washington State Smoke Management Plan, a part of the State Implementation Plan required by the Federal Clean Air Act, and the Final EIS on Managing Competing an Unwanted Vegetation, Pacific Northwest Region, Record of Decision. (See discussion earlier in this chapter, in Commercial Timber). The Smoke Management Plan is administered by the Department of Natural Resources. It considers the potential for smoke dispersion, the likelihood of smoke drift to sensitive population centers or Class I areas, and the amount to be burned, etc. There may be days that no burning is permitted, or that burning is severely restricted. No burning is permitted on weekends during the period from July 1 through Labor Day. Most prescribed burning on the Forest is done outside that window. Generally, broadcast burning is done in the spring and burning of piled debris is done in the fall.

Trends

The Vegetation Management EIS (USDA 1988b) requires that prevention of the need to burn is a preferred alternative. The Forest has taken an active position in reducing the amount of prescribed burning and to encourage utilization as an alternative to disposal. Refer to the wood residue section, page III-77, in this chapter.

Tighter merchantability specifications have resulted in more material being removed by the timber purchasers, thus reducing the amount left on the site for disposal. In addition, an increased awareness of the role that woody debris plays in maintaining long-term site productivity and wildlife habitats has resulted in the need to leave more material on the site. Analysis has shown that the contribution logging residue plays in fire protection needs has been overstated on the Forest (Richter, 1987 and Kapral, 1986). Alternatives that eliminate the need to use prescribed burning are preferred in all project-level analyses.

During the period from 1980 to 1989, the amount of prescribed burning done on the Forest declined from an average of 3,500 acres per year to approximately 250 acres per year. This represents a shift from broadcast burning of almost 55 percent of the harvested areas to burning approximately 10 percent. The current level of prescribed burning will continue into the future.

Burning of organic material has been identified as a major source of fine particulates in the Puget Sound area. In order to protect human health and achieve Federal goals to improve visibility where it had been impaired, the Washington Department of Ecology (in their 1985 Revision to the State Implementation Plan for Visibility Protection) has established a goal of a required 35 percent reduction in emissions of TSP from prescribed burning by 1990. The baseline for this reduction was calculated from the historical average for the period 1976-1979. The entire Puget Sound area averaged 155,900 tons of suspended particulates per year from prescribed burning sources; 57,000 tons or 37 percent were attributed to prescribed burning activities on the Mt. Baker-Snoqualmie.

Since the establishment of the baseline data, less broadcast burning has been done on the Forest, and emissions from prescribed burning dropped dramatically. Prescription parameters and ignition techniques have reduced consumption (thus particulate emissions). Post ignition mop-up has been more aggressive, reducing the smoldering phase (the period with the highest emission rates).

Prescribed burning of natural vegetation for wildlife habitat improvement or wilderness management purposes will generate considerable levels of particulate emissions. Since this a relatively new practice on the Forest, actual emissions rates are unknown. It is felt that 7.5 tons per acre burned is a reasonable estimate.

Class I Airsheds

The Forest has two federally designated Class I airsheds: Glacier Peak and Alpine Lakes Wilderness. The remainder of the Forest is designated as a Class II airshed. Mandatory Class I Federal areas are defined as all international parks, all national wilderness areas and memorial parks exceeding 5,000 acres

in size, and all national parks over 6,000 acres in size (Section 169A of the Clean Air Act, 1977 Amendments). Visibility protection within these areas is required.

The Washington State Department of Ecology must obtain Federal land manager concurrence that any proposed facility with pollution potential will not have any unmitigated impacts on the Air Quality Related Values in Class I areas. Values that may be considered include: visibility within the wilderness, water quality in high-elevation lakes and streams used by anadromous fish, any threatened or endangered plants that may be present in the area, etc. These will not vary by alternative, nor should management under any alternative affect the impacts from any off-Forest developments.

Visibility within the Class I areas of the Forest is usually good, though there are periods when visibility is temporarily impaired by smoke from prescribed burning, campfires, or from urban pollutants. Other adjacent Class I areas, administered by the National Park Service, may also be impacted by activities occurring on the Forest.

The areas added to the Wilderness System by the Washington State Wilderness Act of 1984 remain designated as Class II under the Clean Air Act. Redesignation of these wildernesses to Class I must be recommended by the State and analyzed by the Forest Service. To date, no recommendations have been made; any analysis would be outside the scope of this Forest Plan.

Recent research and field investigation have examined the possibility of acid deposition occurring on the Forest. During the month of September, 1985, samples were taken from 26 lakes on the Forest. These will be analyzed to determine how many lakes are already acidic and how many others are potentially sensitive to deposition (EPA 1985). Refer to the Water section of this chapter.

FIRE

Wildfires started by lightning have always been a part of the natural cycle affecting the structure of plant communities over broad acres of forest land. These fires often appeared to be catastrophic at the time. (Brown 1985) Fire has played a significant role in the ecosystem of the Mt. Baker-Snoqualmie National Forest. The presence of fire scarred trees and stumps, and of ash layers under the duff of old-growth stands are indicators that fire has been present for hundreds of years.

Before modern fire protection efforts began, fires occurred infrequently but often with high intensity. Lightning was the principal ignition source. These fires interrupted the plant succession patterns; the result is a randomly distributed mosaic of even-aged patches of vegetation. The size of these fires was limited by weather conditions, topographic features, drainage patterns, and natural barriers. Local ecological studies show these stand replacement fires occurred at intervals of 150 years at lower elevations on the south end of the Forest, to 300 to 1,000 years in higher elevations along the Cascade Crest.

Organized fire protection on the Mt. Baker-Snoqualmie National Forest began in the early 1900's with the detection and suppression of lightning fires. During this period, much of the current trail system was built to access the back

country. In the 1940's, an increasing number of roads were built, primarily to access timber. This improved access for fire protection, but also brought more people and activities into the Forest. Human-caused fires increased into the 1960's as use increased faster than did the capability to protect the area from fire. Prevention programs were intensified and more sophisticated fire-fighting equipment was used.

Currently, the Forest maintains six fixed emergency fire lookout stations; in the late 1940's, 53 fixed lookouts were maintained. Improved road systems, supplemented by the use of fire detection aircraft have reduced the need for fixed fire lookouts. In addition, approximately 60 percent of all wildfires are initially reported by the general public. A variety of communication and public media systems are used to inform the public of fire prevention activities, current weather and forest conditions, and forest fire prevention needs.

Since 1960, the number of human-caused fires has remained fairly stable due to more effective prevention efforts. Railroad associated fires have continued to decline due to increased prevention and improved equipment. The ratio of fire starts caused by lightning and caused by man has remained fairly constant since 1960; lightning caused fires are 44-46 percent of the total.

Wildfire

The following table shows a comparison of the total number of fires on the Mt. Baker-Snoqualmie for the period 1970-79 and 1980-89.

Table III-73
Total Fires by Decade

	1970-1979		1980-1989	
Cause	Number of Fires	Acres Burned	Number of Fires	Acres Burned
Lightning	332	246	104	29
Equipment Use	21	413	18	284
Recreation Activities	265	232	252	59
Debris Burning	49	1,200	18	158
Railroad	2	<1	5	<1
TOTAL	669	2,019	397	530

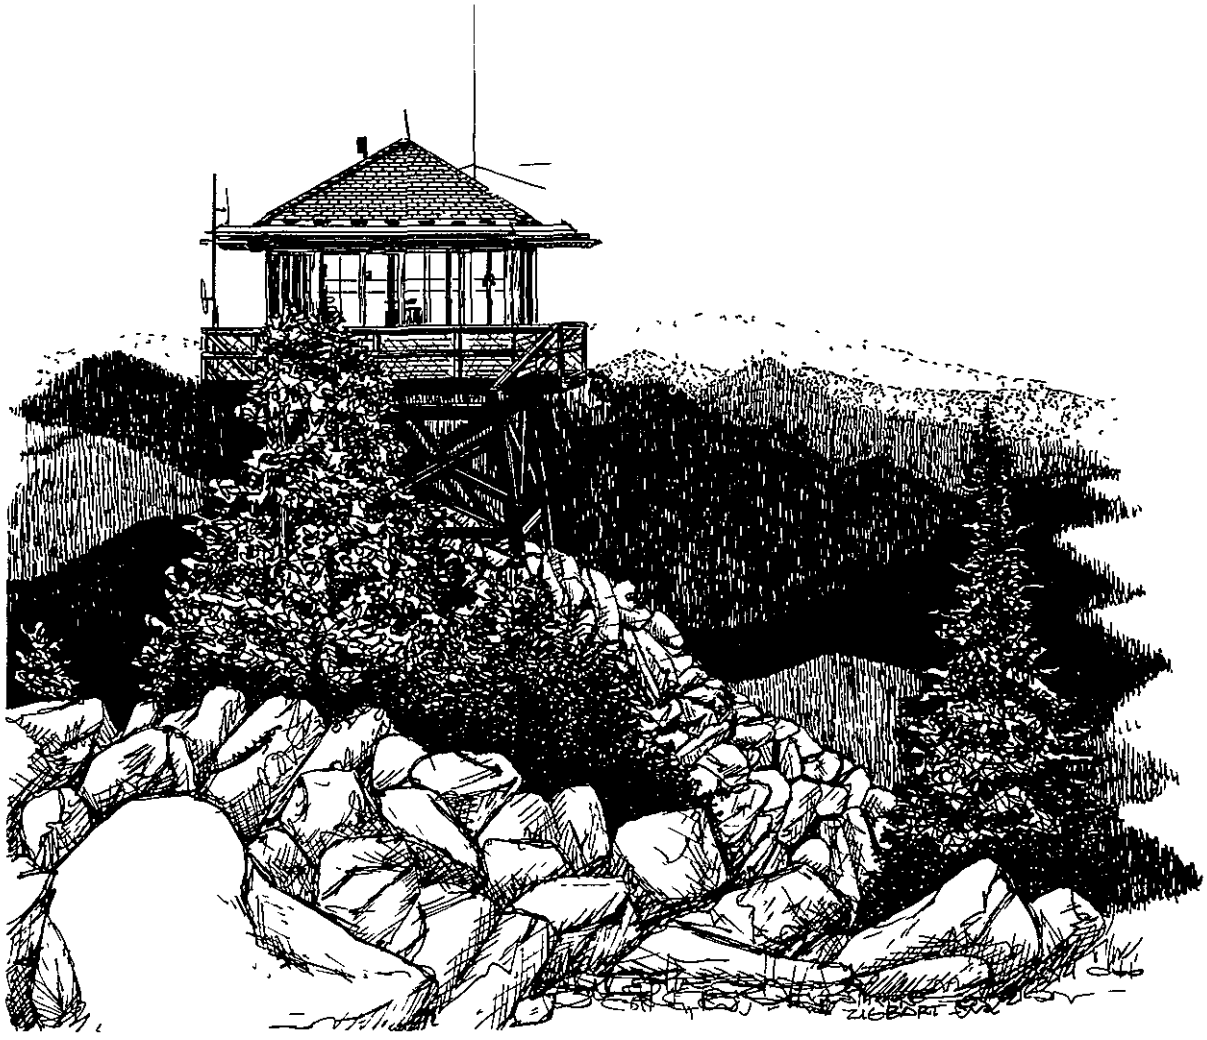
The majority of these fires (97%) were less than 10 acres in size. Most were slow spreading, low intensity fires that did little damage to soil or to living vegetation. The 36 fires over 10 acres in size were often associated with debris disposal activities or logging operations during periods of critical weather, especially east winds or as multiple fire start situations. Three started on private land adjacent to the forest and burned onto National Forest lands. Of the total larger than 10 acres, only 3 were caused by lightning.

A comparison between the 1970 decade and the 1980 decade shows little difference in numbers and burned acres except for lightning and debris burning. Lightning fires are a random event of nature and do not reflect past

management activities. The decline in number of debris burning fires and acreage burned is a direct result of the decline in amount of burning the forest has been doing.

Looking at the past 30 year period, the number of 10 acre and larger fires was about the same for each of the three decades. Large fires have been the exception. In 1967, during a three day period of critical weather and multiple fire starts, a total of 5,277 acres burned, 4010 from a single start. In 1988 a fire that originated in a logging operation on the forest burned a total of 2,600 acres of private and federal lands the majority of which was untreated logging residue. The forest can expect one fire in the 2,500 to 4,000 acre size class once every 15 or 20 years.

The frequency of fire starts and the typical size that has been experienced in the past 30 years is typical of an ecosystem that is not dominated by historic fire. Most ecosystems of the Western Cascades have developed under a regime of very infrequent but large high intensity stand replacement fires, occurring on a return interval of once every 250 to 500 years. It is reasonable to assume that fire protection efforts have not effected the ecosystem diversity of the forest.



Current Protection Programs - Reintroducing Fire Into the Natural Ecosystem

In the early part of this century, most resource agencies adopted the policy that forest and range fires were intolerable and damaging. The high intensity protection programs of the recent past have all but eliminated fire in the natural ecosystem. However, recent ecological studies have re-examined the role of fire in the ecosystem. With the overall objective of reducing fire suppression costs and maintaining or enhancing various forest resources, new programs are gradually being introduced.

In May 1984, the Mt. Baker-Snoqualmie adopted the Forest Service Appropriate Wildfire Suppression Response policy. Three possible strategies are available to the land manager: control the fire, contain it, or confine it. The selected strategy for each fire depends on variables such as land values of the area, the threat to public or private property or resources, the weather, the type of fuels burning, terrain factors, and people and equipment available to fight the fire. The confine strategy will generally be used in wilderness, where natural fire is considered to be an essential part of maintaining the wilderness ecosystem. Confine will also be applied to fires in other high elevation areas where the vegetation is sparse. Little or no resource damage is expected.

At this time, the Alpine Lakes Wilderness is the only wilderness on the Forest with an approved prescribed fire plan. (Refer to Alpine Lakes Wilderness Prescribed Natural Fire Action Plan.) This action plan was implemented in the summer of 1983. Since 1983, there have been seven fires in wilderness (the Mt. Baker-Snoqualmie portion). All spread to less than an acre, and burned themselves out.

The use of fire as a vegetative/habitat management tool may increase. The suppression actions of wildfire may decrease in areas with "near natural" management objectives. Where major investments in improvement and intensive management have been made, quick fire suppression response will continue to be a goal.

Coordination With Other Agencies

The 100 plus miles of boundary common with two National Parks and the 260,000 acres of private land inside the forest boundary have necessitated continued cooperation and coordination of fire protection programs over the years. Various operating agreements exist with the National Park Service and the Department of Natural Resources to facilitate this cooperation. The Forest also maintains close working relationships with the Bureau of Land Management.

In addition, the Mt.Baker-Snoqualmie National Forest has specific operating plans with the Northwest and South Puget Regions of the Washington State Department of Natural Resources; North Cascades and Mt.Rainier National Parks; the Puget Sound Agency of the Bureau of Indian Affairs; and the British Columbia (Canada) Forest Service. These agreements provide for sharing of personnel and equipment for initial attack and support for up to 24 hours without exchange of funds and for extended periods on a reimbursable basis.

The Mt.Baker-Snoqualmie also protects numerous small parcels of Bureau of Land Management lands (totaling approximately 700 acres) within and adjacent to the forest.

Other local operating agreements guide: a joint Forest Service - Department of Natural Resources dispatch office at Enumclaw; an offset protection agreement, where the FS and DNR exchange Initial Attack responsibilities on approximately 20,000 acres of intermingled lands; operations of two Initial Attack Engines, jointly staffed by Forest Service and DNR personnel; and forest dispatching of National Park Service overhead and crews for reinforcement actions outside the local area.

In addition to the suppression coordination efforts between the various wildland protection agencies in the Puget Sound Area, fire training, detection services, fire weather data collection, public use restrictions, and fire prevention activities are all done on an inter-agency coordinated basis.

With the probability of declining budgets and workforce constraints an all agencies there will be an increasing demand for coordination and cooperation between the Mt.Baker-Snoqualmie National Forest and the other wildland fire protection agencies.

MINERALS

Overview

Minerals are fundamental to the Nation's well being; Forest Service policy encourages the exploration for and development of the mineral resources on national forest land. At the same time, mineral exploration, development, and production activities are integrated with the use, conservation, and protection of all other resources.

Mineral commodities are classified by law into three distinct groups: locatable, leasable, and salable. Management of each commodity varies considerably as does the authority of the Forest Service to control the exploration for and development of each commodity.

Locatable minerals are those minerals which, when found in valuable deposits, can be acquired under the General Mining Laws of 1872 (as amended). Examples of locatable minerals occurring on the Mt. Baker-Snoqualmie National Forest include, but are not limited to, copper, gold, molybdenum, tungsten, olivene, chromite, nickel, zinc, silver, lead, and uncommon varieties of limestone, gemstones, and other minerals having unique and special values.

Citizens and those who have declared their intent to become citizens of the U.S. have a statutory right to explore vacant, unwithdrawn public land for these minerals. Upon discovering a valuable deposit, they have a right to locate, mine, and remove the minerals. Forest Service control of these activities is limited to minimizing impacts on surface resources. This is accomplished by reviewing plans of operation to ensure environmental protection standards are met. Protection standards include standards for air, water, cultural resources, threatened and endangered species, and many others. The prompt reclamation or restoration of disturbed lands is accomplished as part of the operating plan process.

Leasable minerals are those mineral commodities which may be acquired under the Mineral Leasing Act of 1920, as amended, the Mineral Leasing Act for Acquired Lands, and the Geothermal Steam Act of 1970. Recent law affecting leasable minerals includes the Federal Onshore Oil and Gas Leasing Reform Act of 1987, and in 36 CFR parts 228 and 261 Regulations, published in the Federal Register in final, March 1990. On the Mt. Baker-Snoqualmie, leasable minerals include coal, oil, gas, and geothermal resources. Also included are all minerals except saleable when occurring on acquired lands. These minerals are subject to exploration and development under leases, permits, or licenses granted by the Secretary of Interior. This authority is administered by the Bureau of Land Management. Forest Service authority for management of these leasable minerals is still oriented toward surface protection. However, its control of prospecting and development activities is considerably stronger in this case than it is for locatable minerals. Table III-74 summarizes Forest Service mineral leasing responsibilities for the public land it administers.

Table III-74
Mineral Disposal and Activity Responsibilities

Commodity	Public Domain Administered by the Forest Service	Acquired Lands Administered by the Forest Service	Preliminary Prospecting Permits 1/
Oil and Gas	BLM requests F.S. consent for leasing & F.S. approves all surface use activities.	BLM requests F.S. consent to lease & F.S. concurrence for permit to operate.	F.S. has authority to issue a permit.
Coal	BLM requests F.S. consent to lease & permit to operate.	BLM requests F.S. consent to lease & permit to operate.	F.S. permit specifically prohibited.
Hardrock Minerals	Locatable = Non-discretionary.	BLM requests F.S. consent to issue a prospecting permit, to lease, & operate.	F.S. has authority to issue a permit.
Geothermal	BLM requests F.S. 2/ consent to lease & to operate.	BLM requests F.S. consent to lease & to operate.	F.S. has authority to issue a permit.

1/ Permits are nonexclusive, do not allow removal of minerals for other than sampling, and do not lead to a preference right lease.
2/ Both public domain and acquired lands categories.

Recommendations concerning the availability of lands for mineral leasing are based on whether development activities could be implemented on National Forests lands and meet the current land management direction.

Processing of mineral use authorizations for federally owned leasable minerals is directed by the policies and procedures set in the June 19, 1984 Interagency Agreement between the Forest Service and the Bureau of Land Management (BLM). In summary, the agreement calls for the Forest Service to participate with the BLM in the formulation of site-specific terms and conditions in the operating plans. The plans must provide appropriate mitigation measures to ensure that adverse impacts on surface resources will not exceed applicable environmental protection standards. Procedures for leasing oil and gas resources and administering the associated activities are addressed in the Federal Onshore Oil and Gas Leasing Reform Act of 1987, published final in the Federal Register, March 1990.

Salable minerals are common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay. In general, these minerals are of widespread occurrence, and are of relatively low unit value. They are generally used for construction materials and for road building purposes. These minerals are disposed of under the authority of the Materials Act of July 31, 1947, as amended by the Act of

July 23, 1955. Disposal of salable minerals from public lands administered by the Forest Service is totally at the discretion of the Forest Service (see regulations in 36 CFR part 228). Management of operations on permit areas is similar to the management of leasable mineral activities.

Geologic Setting

The Mt. Baker-Snoqualmie is located along the west side of the crest of the Cascade Mountains. The core of the Cascades - a young range in geologic time -consist primarily of granitic and metamorphic rocks. The contact zones between these two types of rocks are of considerable interest because these zones are often the geologic environment in which metallic mineral resources occur. There are also several ultrabasic bodies (gabbro and dunite) which are located within the area and are of importance for their mineral resource values.

The flanks and foothills of the Cascades, down to the Puget Sound Lowlands, consist of sedimentary, metasedimentary and volcanic rocks, which may or may not be overlain by recent (in geologic time) alluvium and/or deposits of glacial materials. It is these younger sedimentary rock which are of importance for their potential oil, gas, and coal resources.

There are three inactive volcanoes on or near the Forest: Mt. Baker, Glacier Peak, and Mt. Rainier. All have been volcanically active in Recent (geologic) time. That volcanism was the source of the extensive andesitic flows north of Mt. Rainier, the pumicite and limited volcanic flows around Glacier Peak, and the relatively restricted volcanic flows around Mt. Baker. It is these volcanic centers and the associated fault systems which appear to have the most potential for the occurrence of geothermal related resources.

The Cascade Mountains and the entire Puget Sound area were shaped, to a considerable extent, by both continental and alpine type glaciation. The results of that glacial activity are the large "U" shaped valleys and the abundant glacialfluvial and glaciolacustrine sand, gravel and clay deposits. Those deposits have provided ample supplies of construction materials for the industrial demands and urban expansion of the Puget Sound area.

Locatable Minerals

The Mt. Baker-Snoqualmie National Forest has a long history of mining, dating back to the late 1800's. Numerous mining claims have been located and maintained since that time. Presently, there are approximately 4,000 mining claims properly recorded for the Forest. The majority of these are located in the Middle Fork Snoqualmie, Sunset-Silver Creek, Vesper Peak, Silverton, Sultan, Darrington, Sauk River, Lone Jack and Twin Sisters areas. These claims reflect a continuing interest in the locatable mineral resources of the Forest.

A mineral resource overview has been prepared to assess the present and future potential for the development of locatable mineral resources on the Forest. The overview is based on a literature search. A rating for the potential for the occurrence of mineral resources has been assigned to various areas. It is considered a probabilistic assessment. It indicates, on a relative scale, the odds for successfully finding mineral resources which can be profitably developed. A total of 148,187 acres within the Forest have a moderate to high potential for development of locatable minerals; see Table III-75.

Table III-75
Potential Minerals

Locatable Minerals:	148,187	acres have Moderate to High Potential.
	69,141	acres of these are withdrawn as wilderness.
Energy Minerals:	1,230,478	acres are classified Prospectively Valuable.
	536,848	acres of these are withdrawn as wilderness.

As Table III-75 indicates, the Forest contains potentially significant occurrences of copper*, gold, molybdenum, silver*, lead*, zinc*, chromium*, nickel*, and olivine. (* = Commodities identified as critical or strategic minerals.) Of the metallic minerals, copper and gold appear to have received the most interest in recent years. The copper deposits are not only of interest for their copper values; copper deposits are also often associated with molybdenum, silver, gold and tungsten, which would be produced as by-products should development of the copper occur.

Exploration/development activities have declined during the past few years. This decline is most likely attributed to low market prices and higher costs for resource protection and rehabilitation. Also, availability of land for mineral entry has been affected by withdrawals associated with wilderness designation.

However, interest continues to be expressed, measured by the number of claims located and maintained, by annual assessment work completed, and by the number of notices of intent received. Areas of most interest appear to be the Vesper Peak, Miners Ridge, Carbon River, Church Mountain, Grand Excelsior and Sunset-Silver Creek areas. Interest in the gold deposits of a few other areas is reflected in the number of operating plans filed. Most of this current activity is of a superficial nature.

There are a variety of minerals collected recreationally on the Forest; quartz crystals, garnet, talc or soapstone, olivine, and pyrite appear to be the main

targets of collectors. Of these, the recreationists are most attracted to the garnet occurrences in the Denny Creek, Maloney, Guye Peak, and Vesper Peak areas, where the garnets are not only of good quality but are also often associated with magnetite, epidote, vesuvianite, quartz and calcite crystals. The best known occurrences of quartz crystals is reported to be in the Snoqualmie River drainage. Good agate is reported to be in the Green River drainage and carving grade talc can be found along Marble and Sibley Creeks.

Those collectable minerals of á "locatable" nature are removed from valid mining claims under the authority of the Mining Law of 1872 and an approved operating plan. Removal of more than nominal amounts of the collectable, common variety minerals requires that a permit be issued.

The Forest contains a variety of nonmetallic mineral resources, which may or may not be locatable. Olivine is the only one being commercially produced at the present time. The Twin Sisters massif near Mt. Baker is one of the largest deposits of nearly pure olivine (iron magnesium silicate) in the world. Northwest Olivine has been mining 30,000 tons per year (gross value is $25/ ton or $ 750,000 per year) for several years in the Twin Sisters area. Two other potential producers are attempting to enter the olivine market. Since the resource is virtually inexhaustible, these deposits will meet any foreseeable demand.

The Forest also contains numerous deposits of limestone, some of which are cement grade and may be of a locatable nature. Most deposits are thin, rarely exceeding a thickness of 50 feet; however, some are much larger and may contain reserves of 1,000,000 tons or more. Though the resource is known to exist on the Forest, other limestone sources adequately serve the existing market; consequently, there is presently no limestone production from the Forest.

Clay of glacial origin is found along several major drainages. Samples taken on the South Fork Stillaquamish River have been tested by a major producer and found to have valuable properties for use in the manufacture of certain types of brick. However, there is no present production of clay.

The Forest also has garnet deposits which have potential, but presently there is no indicated interest in developing the resource for commercial purposes.

As on-going mineral activity is relatively minor in scope, locatable mineral resources on the Forest presently play a limited role in the National, Regional, and State-wide social and economic structure. But, the economic and, to some extent, the social characteristics of eastern Snohomish and Whatcom Counties could be significantly affected should the price or demand situation for both precious and base metal commodities change. As new depositional models are formulated and extrapolated to areas having potential, exploration activities may be attracted to these parts of the Forest. The result would be to generate heavy pressures on Forest management within these areas.

Leasable Minerals

Leasable mineral potential has not been assessed in the same manner as have the locatable mineral resources. Portions of the Forest have been classified by the Bureau of Land Management (previously U.S. Geological Survey and Mineral Management Service) as being prospectively valuable for oil, gas, coal, and geothermal resources. Those areas classified as prospectively valuable for

leasable minerals are the areas considered to have at least a "moderate" potential for future development until exploration proves otherwise.

A total of 1,230,478 acres within the Forest are classified as prospectively valuable for development of energy minerals (Table III-77). Only 18,225 acres are classified prospectively valuable for oil and gas resources. A total of 18 oil and gas leasing applications, covering 76,893 acres, have been received by the Forest.

The leasing cycle is in a downturn mode; without some important discovery of oil or gas in the area or a return to the energy shortage situation of the mid-70's, it is expected to stabilize or decline slightly over the next 5 years. Revenue produced from mineral leasing on the Mt. Baker-Snoqualmie National Forest during Fiscal Year 1985 was $52,949, of which $26,475 was returned to the State and counties. This represents rental returns only. Should production begin, royalties would increase this revenue substantially.

Based upon available data, oil and gas resources are not presently known to exist on the Forest in commercial quantities. However, to date, only limited geophysical surveys for oil and gas have been conducted. All of the leasing activity has been concentrated in the White River and Carbon River areas, where Eocene marine and nonmarine sedimentary rocks may underlie younger volcanic rocks. It is doubtful that the area would contain oil, but it does have an unexplored potential for the occurrence of natural gas. From existing information, the potential for the occurrence of petroleum resources on Forest lands appears to be low. Barring any significant discoveries off-Forest, oil and gas activity on the Forest over the short-term is expected to remain relatively minor and will be dominated by speculative leasing actions and exploration activities.

A total of 76 geothermal lease applications have been received; 25 of these are pending (February, 1990). As with oil and gas, geothermal resources are not known to occur on the Forest in commercial quantities. However, the majority of the Forest has been classified "prospectively valuable" for the resource: 1,222,812 acres, which includes areas overlapping acres prospectively valuable for development of other energy minerals. Until deep exploration proves otherwise, the area is considered to have at least a moderate potential for the occurrence of this resource.

According to a recent study (Bloomquist and others 1985), the lands managed by the Forest have 14 identified hot or mineral springs. Of these, none have been identified as having direct utilization potential. The Mt. Baker and Baker Hot Spring sites (T.38N.,R.7,8 and 9E.) are identified as having electrical generation potential. The majority of applications received by the MBS have been filed for areas around Mt. Baker; several applications have also been filed for the Sulphur Creek Hot Springs area, which may be an indication of unexplored potential there. In the near future, any geothermal activities on the Forest are likely to be dominated by exploration until a proven resource is identified. Large scale development in the Mt. Baker area is possible, but not likely within the next twenty years.

The forest presently has no coal leases or pending coal lease applications. However, large portions of the Forest have been classified "prospectively valuable" for coal resources: 107,850 acres, which includes areas overlapping acres prospectively valuable for development of other energy minerals. In

response to changing energy demands, considerable attention has recently been focused on the coal deposits lying just outside the southwest part of the Forest. Should development in this area occur, expansion into the coal on National Forest lands is possible.

There has also been considerable interest in potential production of methane from unmined and unminable coal seams in Washington, which would help to meet the energy demands of the future. Even though this type of development represents a potential future use of the coal, it is unlikely that such development will occur within the next ten to twenty years.

Salable Minerals

The Forest maintains a detailed inventory of rock sources. That inventory is available at Ranger District offices. The dominant market for these mineral materials (sand, gravel, and stone) is the Forest's timber management program. The future demand for these materials will reflect the level of road building and maintenance needed in conjunction with timber harvest activities. Disposal of other types of common variety minerals is insignificant, and presently, the supply appears adequate to meet the anticipated future demand for construction purposes.

The total production of sand, gravel, and stone during the period from 1970 to 1979 was approximately 6,000,000 tons, with a gross value of $11,000,000. Sand and gravel comprises about 10 percent and stone 90 percent of this total. Annual production rates are quite variable, ranging from about 350,000 to 1,350,000 tons. Current production is about 350,000 to 400,000 tons per year. The majority of this is construction materials supporting Forest Service timber management and State highway construction.

In the immediate future, the demand for this resource is expected to lessen in response to reduced road construction activities associated with timber harvest activities. The demand for county and State highway construction is significant locally, but highly variable in the long term.

Supply - Demand Summary

According to U.S. Bureau of Mines data, Washington State ranked 33 out of the 50 states in annual mineral production during 1984. Of the minerals produced in Washington, sand and gravel and industrial minerals far exceeded any of the other commodities. With several gold mining operations coming on line throughout the State, however, production in the future may reflect a change. The Mt. Baker-Snoqualmie's contribution to overall State production was minor.

Except for olivine, locatable mineral activities on the Mt. Baker-Snoqualmie have been depressed during the past few years, due to depressed gold, silver and copper prices and to a shortage of risk capital. However, Bureau of Mines data indicates the demand for mineral resources will continue to increase at an annual rate of at least 1.0 percent to 2.2 percent. As a consequence, locatable mineral related activities (claim staking and maintenance, exploration, development, panning, sluicing, suction dredging and rockhounding) are expected to remain at the current level or possibly increase slightly throughout the next 10 years.

Should exploration activities being conducted throughout Washington State prove positive and new theories concerning mineralized environments be developed and extrapolated to the Mt. Baker-Snoqualmie, mineral activities on this Forest would increase somewhat. Should gold, copper and silver prices return to previous levels, activities related to these three commodities would increase significantly.

Leasing activities are anticipated to decline somewhat over the short-term, but exploration for geothermal, coal, and oil and gas resources in localized areas may increase. Assuming the nationwide demand for energy resources will continue to increase and, considering the political environment around foreign sources of oil, it is highly likely that the demand for domestic sources of oil and alternative sources of energy (coal and geothermal) will increase significantly. The result would be a significant increase in energy mineral exploration activity on the Forest.

While the public's demand for common variety minerals is expected to continue at current levels or possibly increase slightly, the Forest Service demand is expected to decrease slightly. As a consequence, the overall demand for these mineral commodities is expected to decline somewhat over the next ten years.

Land Status

All lands on the Forest are open to prospecting and mining except in certain areas, such as campgrounds or administrative sites which are formally withdrawn from mineral entry; areas where mineral rights are in other than public ownership; or where the mineral estate is outstanding. Presently, the Mt. Baker-Snoqualmie N.F. has 82 areas withdrawn from mineral entry, totaling 14,600 acres. These areas are withdrawn primarily to protect roads, developed recreation sites, and administrative sites.

Mineral withdrawals in designated wilderness are a special category. The Wilderness Act of 1964 authorizes prospecting. However, as of January 1, 1984, or as of the Washington State Wilderness Act of 1984 (July 3, 1984), the minerals in lands designated as wilderness are withdrawn from all forms of appropriation under the mining laws. Valid mining claims perfected prior to

those dates may still be operated. Subject to operating plan requirements, claimants may conduct mining or mining-related activities on valid mining or mill site claims within wilderness, if the claims were perfected as of withdrawal from mineral entry. Forest Service objectives are ensuring that any development project would have as little impact on wilderness resources as possible. No new leases will be issued in wilderness.

The Forest has additional areas which have been withdrawn from mineral entry for the benefit of other agencies (such as FERC, The Geological Survey, etc.), usually to protect reclamation projects, powersites, and transmission corridors. Those withdrawals have not been identified here.

Land status changes (exchanges, disposal, withdrawal) have the potential to affect the availability of mineral resources for future production. The effect of a change in ownership is usually minor, since valuable mineral deposits will generally be developed whether in public or private ownership. However, the effects - both direct and cumulative - of withdrawing lands from mineral entry can be significant.

Review of withdrawals outstanding as of October 21, 1976, is mandated by Section 204 of the Federal Land Management and Policy Act of 1976. That required review is not a part of this planning process, but all existing withdrawals will be reviewed prior to 1991. Recommendation for retention, revocation, or partial revocation will be made based upon an analysis of the resources being protected and of the mineral potential of the area. Where adequate protection is provided by other means or a withdrawal is no longer necessary, it will be revoked or reduced in size. Requests for any new withdrawals will be processed according to Bureau of Land Management regulations and Forest Service guidelines.

Reserved minerals, which involve those situations where the surface estate was conveyed but the mineral estate was reserved to the United States, generally are subject to the location of mining claims and normal mineral leasing procedures.

Outstanding minerals, which involves those situations where the Forest Service acquired the surface estate but not the mineral estate, are not subject to location or leasing under the Federal mining laws. The Forest Service assumes the role of any other surface owner. Based upon past practice, the surface estate will be managed consistent with the principles of the surface management regulations (36 FCR 228).

Access Requirements

Reasonable access is essential to mineral exploration and development. In general, existing forest roads and trails are adequate to satisfy the access requirements for the level of exploration activity conducted during the past 10 years. With several notable exceptions in wilderness, all of the potential mineral areas are served either by existing passable roads or by roads and trails impassable only due to natural deterioration, a result of non-use and lack of maintenance. Otherwise, there are no identifiable major needs for access to any of the inventoried mineral potential areas. Local access needs within areas will be authorized in connection with site-specific activities to be proposed in operating plans.

LAND OWNERSHIP AND LAND USES

As briefly discussed in the introduction to this chapter, 259,545 acres (13%) of the 1,983,774 acres within the boundary of the Mt. Baker-Snoqualmie National Forest are not National Forest land. Most of this intermingled land is located in the southern portions of the Forest, south of Interstate 90.

Principle corporate owners of adjacent and intermingled lands are: Weyerhaeuser Company, Plum Creek Timber Company, Scott Paper Company, and Georgia Pacific Corporation. Much of this land is managed for timber production.

In intermingled or "checkerboard" ownership areas, industrial forest management practices usually result in much faster harvest of old-growth timber on private land. This rate of cutting and the related road construction substantially affects roading, timber harvest, wildlife habitat management, scenery, and recreation on public lands because of the cumulative effects of timber harvest and roading on soil and water quality. It also limits the opportunity to manage public lands for unroaded uses.

Other principle owners are the City of Seattle, in the Cedar River Watershed (see below), and the Washington State Department of Natural Resources.

In addition, there are many existing withdrawals of land, for mineral entry for power sites, electric power withdrawals, water withdrawals, and recreation withdrawals. The Bonneville Power Administration has four energy transmission corridors that cross the Forest, which are managed under agreements signed with the Forest Service. These are discussed in detail below.

Land Ownership Adjustment Program

In the past, the Forest and the large corporate owners of intermingled lands managed their adjacent holdings through mutual access, under cost-share agreements. A number of small land exchanges were made to consolidate ownership, but few large acre exchanges were made.

Since 1975, the number of land exchanges has increased. National policy is to complete land exchanges to consolidate National Forest lands and non-National Forest lands within the exterior boundary of the Forest. Isolated tracts, detached parcels, and projecting narrow strips of National Forest land are examples of lands considered for exchange.

Other considerations in land exchange are the resources on each parcel. The Forest aims to acquire lands that increase the Forest's ability to provide services and produce goods. Lands sought for acquisition should be mostly free of legal and administrative constraints, and should allow a broad range of management options. For example, the program seeks to acquire lands with important fisheries, cultural sites that are candidates for the National Register of Historic Places, habitat for threatened or endangered species, or lands with vegetation that may improve the species and age distribution in an area.

In 1976, under the Alpine Lakes Management Area Act (P.L. 94-357), the Forest Service was directed to acquire private in-holdings in the Wilderness and the Intended Wilderness. Once acquisition of all non-Federal lands within the

Intended Wilderness was completed, those Intended parcels were to be added to the Alpine Lakes Wilderness.

All exchanges in the Intended parcels were completed in 1985 and the 25,977 acres of Intended Wilderness have been added to the Alpine Lakes Wilderness.

There are three land exchange cases in progress on the Forest; under consideration for acquisition are about 8,000 acres of non-federal land. The parcels involved are located throughout the Forest, excluding the White River Ranger District.

Cedar River Watershed Agreement

Seattle draws its water from the South Fork Tolt River and the Cedar River, both of which are partly on National Forest lands. For the Cedar River, a 1962 Cooperative Agreement between the City of Seattle, Forest Service, and private landowners has directed management in the watershed. During the last 20 years, as timber was harvested from National Forest lands within the watershed, the cut-over areas were exchanged for city land within National Forests throughout the State of Washington. Approximately 18,000 acres remain to be exchanged.

The management goals of that Agreement for City-owned lands have recently been modified by the City's Secondary Use Policies. As new findings on wildlife/ wildlife habitat protection needs become known, changes in the management direction for National Forest lands in the watershed are likely to occur as well.

The Forest Service will initiate negotiations on a new Cooperative Agreement between the City of Seattle and the Forest, to reestablish goals and objective for management of the watershed. Until a new agreement is negotiated, the Forest Service will not enter into new land exchanges affecting National Forest lands within the Cedar River watershed. Pending a new agreement, the 1962 Cooperative Agreement remains in effect. When a new agreement is reached, the Forest Plan will be amended to incorporate its goals and direction.

Land Use By Others

The Forest provides lands for a wide variety of special uses by private individuals and public agencies. Such uses are authorized by special use permits, mining laws, and withdrawal authority of other agencies. The most common are those covered by special use permits. Special use permits are grouped into nine categories. Examples of permitted special uses are: electronic sites, telephone lines, roads, reservoirs, pipelines, hydroelectric feasibility studies, powerlines, and organized group events.

There are 590 special use permits (April 1990) on the Mt. Baker-Snoqualmie; they are shown, by category, in Table III-76. Activities involving the greatest area include ski slopes, cooperative easement cost shared roads, powerlines, powerplants, and electronic sites (primarily Jim Creek Electronic Site). These uses produced $ 628,700 in fees in fiscal year 1985. The number of permits and acres under permit change as some permits terminate and new uses are added.

Table III-76
Special Use Permits

Ranger Dist.	Category 1/ 100	200	300	400	500	600	700	800	900	Total
Mt. Baker	21	80	0	9	35	40	12	2	8	99
Darrington	8	6	1	5	1	1	3	4	6	35
Skykomish	18	6	2	8	8	12	2	8	12	76

White River	212	10	0	1	0	2	1	2	70	298
TOTAL	301	32	9	31	52	21	24	22	98	590

1/ Category
100 - Recreation
200 - Agriculture
300 - Community and Public Information
400 - Feasibility
500 - Industry
600 - Energy Generation & Transmission
700 - Transportation
800 - Communications
900 - Water
700 - Transportation
800 - Communications

The demand for electronic and telephone facilities has been increasing each year. Television and movie filming is also a very popular use of the Forest. Because of the proximity to the Seattle-Tacoma metropolitan area, the trend for special uses is maintaining existing levels or a slight increase.

Special uses are periodically inspected to ensure compliance with conditions of the permit and to evaluate the appropriateness of continuing such use. Most permittees are charged fees for the privilege of using National Forest lands.

THE BUILT ENVIRONMENT - ROADS

The Forest road system is a major component of the environment. Roads provide access for all types of recreation and viewing of scenery. One of the popular uses of National Forest land is driving for pleasure. The road system also provides access for the extraction of resources from the land: timber, minerals, etc. Roads allow easy access for fire protection; the old lookout system has almost completely been replaced by aerial surveillance and improved road access. Roads also provide access for many types of fish and wildlife habitat improvement.

Road construction also probably results in the greatest amount of ground disturbance of any forest activity (Wildesen 1982). The impacts of road construction and road use following construction are numerous. Excavation of a road prism removes support for the soil above the cutbanks. Depending on the soil type, slope steepness, and presence of subsurface water, roads across some sideslopes can initiate or accelerate slope failure (Anderson 1971, Swanston and Swanston 1976).

Roads - and to a lesser degree, trails - intercept and change the surface and subsurface drainage patterns. Rainfall on many roads, especially paved roads, becomes instant runoff, as there is no longer any soil to store and slowly release water.

The relationship between forested roads and the occurrence of increased erosion and sedimentation is well documented. Some have concluded that forest roads are the primary initiator of erosion caused by human activities (Sibbons and Salo 1973, Yee and Roelofs 1980). Increased sediment in streams after road construction can be dramatic and long-lasting; the incremental sediment from roads, on a per unit basis, is often many times that from all other land management activities, including log skidding (Yee and Roelofs 1980). In turn, sediment in streams can have a direct and adverse effect on salmonids and their habitat. Roads influence wildlife and their habitat. Effects vary by species, by time of year, and depend on whether roads are open or closed to human use.

For example, the existence of a road may have little impact on species such as deer, elk, and mountain goats; the traffic and associated human activities that occur because the road is open disturbs these species (Geist 1978).

Road management, including year around or seasonal closures, can be used to protect a number of resources. There is the potential to reduce human activity in sensitive wildlife areas (such as bald eagle habitat, or peregrine nesting/foraging territory) and to protect cultural resources from vandalism.

The Forest Road System

The Forest road system includes approximately 2,829 miles of roads. Of these, 2,302 miles are located on National Forest lands within the forest boundary. In addition, the Forest shares in the administration, maintenance, and reconstruction of about 527 miles of roads. Of these, 335 miles occur on private lands within the forest boundary. The Forest has acquired legal rights of access across the private land to reach National Forest land. The other 192 miles are on private, county, or State lands outside the forest boundary. Legal access has been acquired to reach National Forest land.

The road system is divided into three functional classes. Arterial roads form a network of primary travel routes, and usually connect to public highways. Arterial roads are developed for constant, and long-term use. Collector roads serve smaller areas and connect to Forest arterial roads or public highways. They may be operated full-time or intermittently. Local roads connect destinations or facilities, such as recreation areas, trailheads, or timber sales, to collector or arterial roads. Local roads may be developed for either short- or long-term use.

Over half of the 2,829 miles of roads on the Forest system are local roads; about 32 percent are collectors and 17 percent are arterial roads.

Table III-77
Existing Road System (1984) - Miles of Roads

	Within N.F. Bndry		Outside N.F. Bndry	
Functional Class	Roads on NFS Land	Roads on Private Land	Roads on State, Co. & Private Land	TOTAL
Arterial	326	56	105	487
Collector	753	107	52	912
Local	1,223	172	35	1,430
TOTAL	2,302	335	192	2,829

A majority of the existing roads were initially built to access areas planned for timber harvest, as part of a timber sale contract. Other roads, primarily main access, were constructed using appropriated funds to provide access for a broad range of uses. A third category were built primarily for recreation access to campgrounds, trailheads, and other features.

Once constructed, roads are managed for the range of uses planned for the area. Future demands may require construction of additional roads for recreation as well as timber access needs, but most of the demand for additional dispersed recreation access will be met by the roads constructed for timber sales. Reconstruction of some roads (widening, paving, adding shoulders etc.) can better accommodate a mix of users.

The average road density on the Mt. Baker-Snoqualmie, on areas managed intensively for timber production, is currently about four miles of road per square mile, or 3 percent. The density, when spread over most sub-basins is less, due to the presense of lands managed for other than timber.

Currently, some of the system roads are closed to public use; most of these are temporary roads that were constructed to access timber harvest areas. They may be reopened to again access those areas if future management goals so indicate. Others are accessible only by high-clearance vehicles. The table below shows the situation as of June, 1986.

Table III-78
Miles of Road By Accessibility - 1986

Total System Roads	2,829 miles	100 %
Accessible to Passenger Car	1,039	37 %
Accessible Only to High Clearance Vehicles	1,483	52 %
Closed to Public Use	307	11 %

Maintenance

Vegetation Management. Removal of unwanted roadside vegetation is important for safety and visibility and also to protect the road investment. Annually, an average of 300 to 400 miles of roads are "treated". Only a very small amount of herbicides were used. The Forest (and Pacific Northwest Region) are currently under an administrative stay against use of herbicides. Refer to the discussion in the Commercial Timber section of this chapter for more information on the regional programmatic environmental impact statement for Managing Competing and Unwanted Vegetation. Road maintenance has been, and continues to be accomplised by mechanical means.

Road Construction and Maintenance Costs. The following costs have been applied on the Mt. Baker-Snoqualmie National Forest; constant 1982 dollars are shown.

Table III-79
Road Construction and Maintenance Costs

Development and Construction Costs	Costs Per Mile 1982 Dollars
Arterial & Collector	$ 280,000 1/
Local	$ 145,000 1/
Temporary	$ 21,000

Maintenance Costs	Costs Per Mile (1982 $)
Appropriated Funds (cost/mile, arterial-collector/year)	$ 300
Charged to Purchasers (cost/thousand board foot)	$ 50

1/ Includes preconstruction and construction engineering.

THE BUILT ENVIRONMENT - UTILITY CORRIDORS

Four utility corridors cross the Forest under Memorandum of Understanding agreements signed with the Bonneville Power Administration (BPA) in 1974. The major transmission corridor follows the Green River, crossing the Cascade Mountains at Stampede Pass. The other three corridors are located along the Skagit River, through Stevens Pass, and across Snoqualmie Pass. A total of 30.5 miles of utility corridor are located on National Forest land. Table III-80 and Figure III-31 show the acres involved in each corridor and the approximate location of each.

Each corridor contains several powerlines; corridors range in width from 150 to 600 feet; a total of approximately 1500 acres are in utility corridors. The existing utility Corridor Project Plan and Right-of-Way Maintenance Plan guide construction and maintenance activities. Current management of the lands within the corridors is limited, though the corridors do receive some dispersed recreation use, such as cross-country skiing, snowmobiling, and hiking and horse use. Planned activities and management uses, such as growing Christmas trees, are coordinated with the BPA.

Some amount of "vegetation management", or removal of unwanted vegetation, is done each year in the utility corridors. It is necessary to limit the height of trees and shrubs in the corridors so that the vegetation does not interfere with the transmission lines. The Forest Service and Bonneville Power Administration and Puget Sound Power and Light coordinate vegetation management in the corridors. Management plans have been developed for each mile segment of each powerline within the four corridors. Standards are established, detailing how high the brush may reach, etc. Both companies are responsible for the actual work.

Removing brush and trees in the corridors has been accomplished, in the past, by helicopter application of herbicides or by spraying the chemicals from a truck. Stream crossings and water courses have always been "treated" by hand chopping the unwanted vegetation. Since 1984, all removal of brush and trees has been done mechanically or by hand. Refer to the detailed discussion in the Commercial Timber section of this chapter.

Snoqualmie River-Snoqualmie Pass	6.9
TOTAL	30.5

Washington State is currently operating with a surplus of generated power; however, this surplus can be expected to be depleted within the next few years. The continued growth of the Puget Sound area is placing increasing demands on the regional power supply system. The projected demand for

electricity through the year 2002 ranges from an annual growth rate of 0.3 to 2.7 percent (BPA, Forecast of Electric Consumption in the Pacific Northwest, 10/86).

As many of the potential additional power sources are located east of the Cascade Mountains, at Hanford, the need for transmitting energy across the utility corridors through the Cascades will continue. The one remaining cross-Cascade utility corridor lies in the Pyramid Peak-Tacoma Pass area. See Figure III-31, on the next page. Future power lines may also run from Hanford, south to Portland, and then north to Seattle.

Present transmission capacities are adequate to serve the Puget Sound Area through the mid-1990's. Afterwards, higher capacity lines would need to be installed over Stampede or Snoqualmie Pass. BPA is currently evaluating tranmission requirements for serving the Puget Sound Area. Expansion of capacity on Stevens Pass, which serves the north Puget Sound Area, could be needed prior to the year 2000. New technology allows a four-times increase in the capacity of each existing power line, with only a minimal increase in the corridor width.

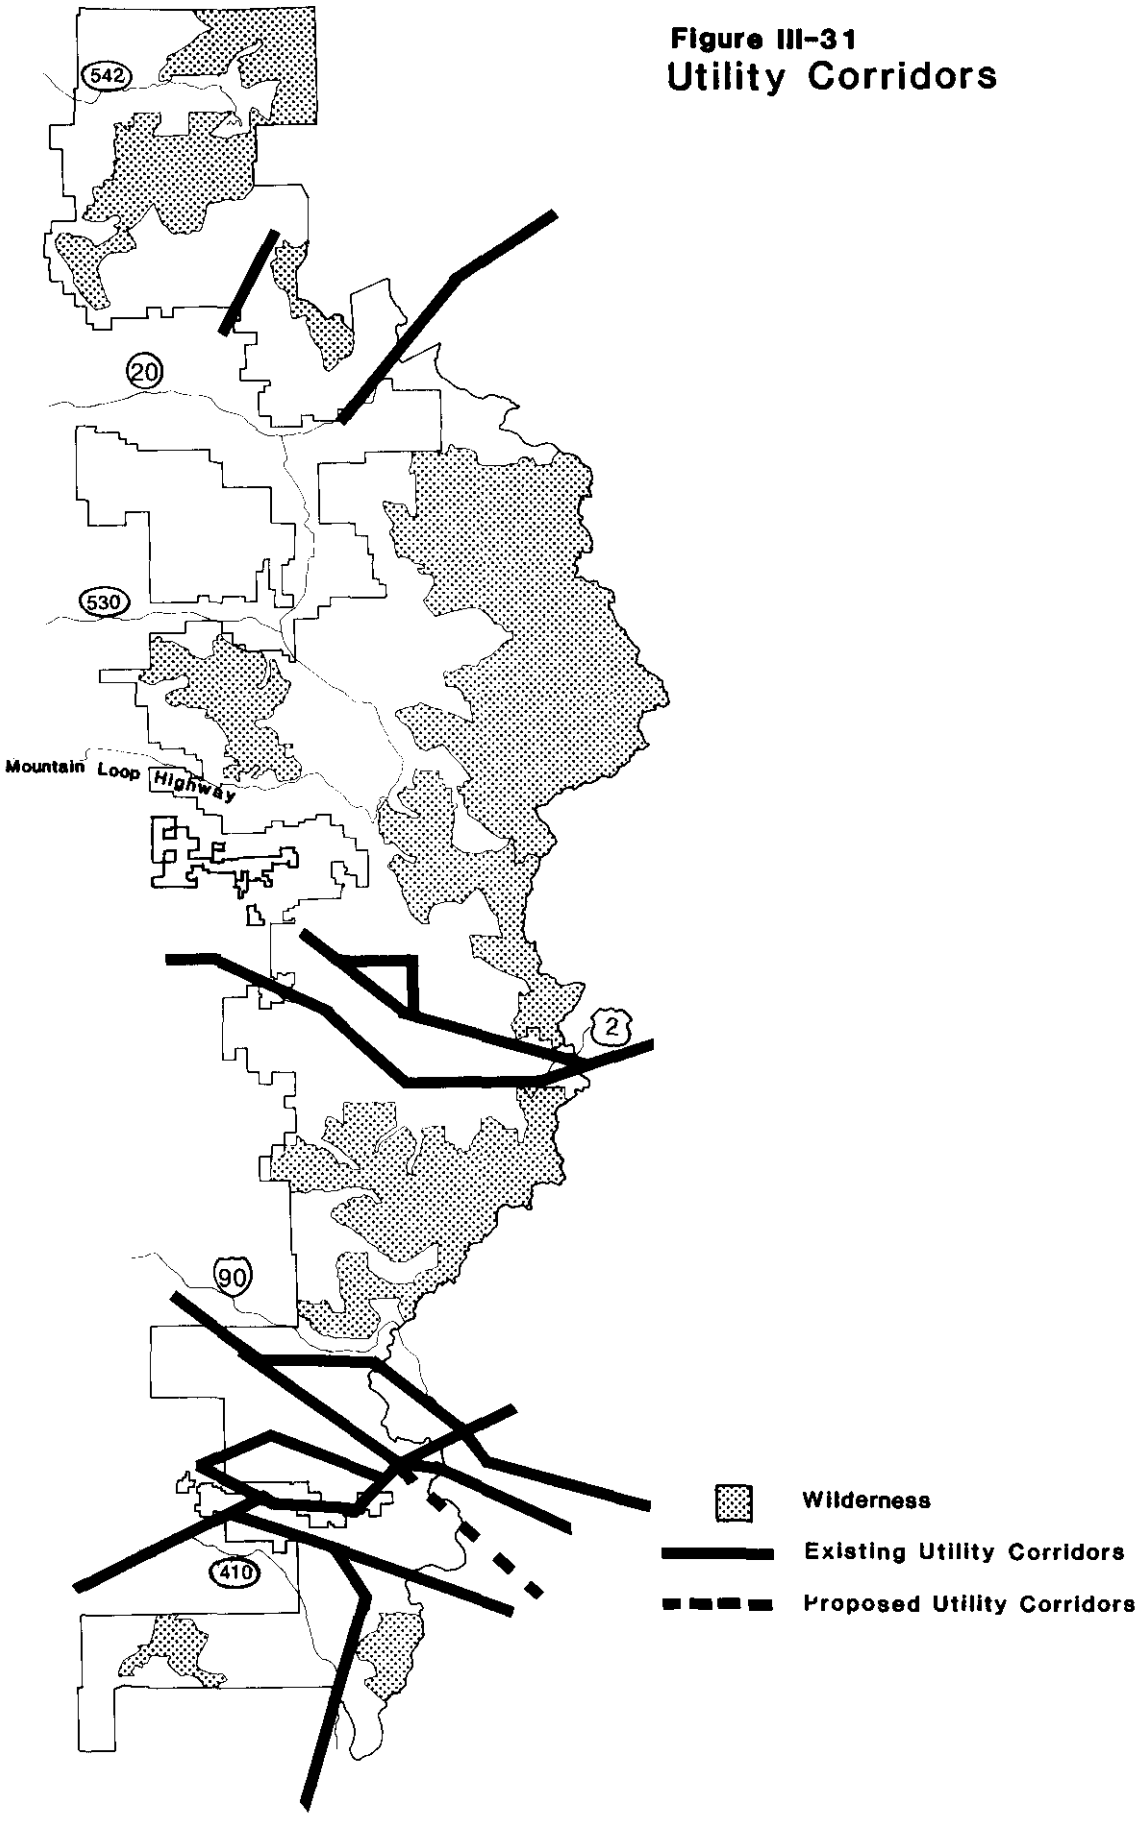
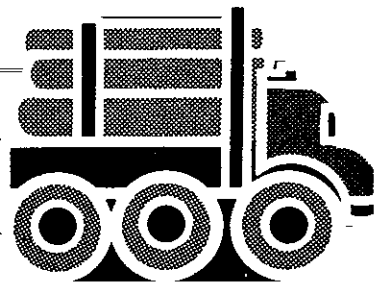
Utility Corridors



Chapter IV



CHANGES BETWEEN DRAFT AND FINAL - CHAPTER IV

Several areas of major change between the draft and final EIS have been discussed in previous chapters; these include developing and displaying two new alternatives. The environmental consequences of implementing Alternatives I and J (Preferred) are included here.

Other major changes in this chapter include:

- The effects of including the hydrologic cumulative effects analysis, completed to develop a procedure to meet the water quality management requirement are reflected in the effects of implementing all alternatives (except NC).

- Based on public comment, additional discussion has been added on the effects of implementing the alternatives on old growth, diversity of vegetation, and plants.

- The discussion of effects on wildlife has been expanded.

- Based on public comment and interest, discussion of the effects of implementing the alternatives on trails has been expanded and separated from the discussions on roads.

CHAPTER IV - ENVIRONMENTAL CONSEQUENCES

A. INTRODUCTION

Environmental consequences are the physical, biological, social, and economic results of an alternative, if implemented. The analysis of these effects provides a scientific basis for comparing the alternatives considered in detail.

This chapter describes the direct, cumulative, and indirect effects of the alternatives. It also describes planned mitigation measures, beyond those listed in Chapter II of this FEIS, and any conflicts between the effects of the alternatives and other organizations' plans and policies.

While Chapter III presents a detailed discussion of the various resources that make up the affected environment, this chapter includes additional discussion of the interrelationships among the resources. Activities or programs that change or impact one component of the environment may have effects on other components as well. The source or basis for these analyses are cited in the text and included in the references section of Chapter V.

The net public benefits from the Mt. Baker-Snoqualmie National Forest are obtained from resources with market and assigned prices, as well as from resources and conditions for which prices cannot be determined. Nonpriced benefits include both quantifiable and qualitative outputs and effects. Both quantifiable and qualitative outputs and effects are crucial for understanding the whole picture of environmental consequences and the net benefits to the public. They are discussed here and in the comparison of the alternatives in Chapter II.

The chapter is arranged by environmental components - soils, water, vegetation, etc. - and the consequences of implementing any of the alternatives are presented resource by resource. The components of the environment are discussed in the same order as presented in Chapter III.

1. Soils
2. Water
3. Vegetative Diversity
4. Old Growth
5. Wildlife
6. Fish
7. Human Community
8. American Indian Religious and Cultural Use
9. Archaeological and Historic Properties
10. Scenery
11. Recreation
12. Trails
13. Wilderness
14. Research Natural Areas
15. Roadless Areas
16. Wild and Scenic Rivers
17. Air
18. Fire
19. Minerals
20. Land Ownership and Use
21. Roads

The interactions between these 21 environmental components and the allocation and program elements of each of the alternatives make discussion of the relative direct, cumulative, and indirect effects of each course of action quite complicated. In order to simplify the discussion, 19 specific allocation and program elements have been identified that may have direct effects on one or more of the 21 environmental components listed above. These 19 allocations and program elements are:

Chapter IV
Introduction

1. Changes in Soils and Water
2. Timber Harvest
3. Old Growth
4. Integrated Pest Management
5. Wildlife Habitat Improvement
6. Fish and Riparian Habitat Improvement
7. American Indian Religious and Cultural Use
8. Archaeological and Historic Properties
9. Scenery
10. Recreation
11. Trails
12. Wilderness
13. Research Natural Areas
14. Wild and Scenic Rivers
15. Air
16. Fire
17. Mining, Energy Development
18. Land Uses
19. Roads

The following discussions of the direct effects of the alternatives on each of the 21 environmental components include only those allocation and program elements having a direct effect on an individual component. Therefore, if one of the above 19 elements does not have a direct effect on an environmental component, it is not addressed.

Likewise, the discussions of indirect effects have been structured to reduce redundancy. Each of the 21 environmental components may have indirect effects on the other environmental components on the above list. Therefore, each discussion of indirect effects will address the indirect effects of the individual environmental component on the components following it on the list. This system of analysis avoids duplication of discussions of indirect effects.

Much of this analysis is based on existing research and professional experience, in addition to computer modeling to determine the estimated outputs for each alternative. Many predictions are based on average values and are at best rough estimates. In some cases, there simply is not enough information available about these interrelationships. An important part of implementing the final Forest Plan will be monitoring the accuracy of these predictions to provide more and better information for future planning. The Monitoring Plan is in the Forest Plan, Chapter 5. Research needs have also been identified (See the Plan document, Chapter 2).

As noted in Chapters II and III, the Forest Service is presently under an administrative stay against the use of herbicides. For planning purposes (and for construction of managed yield tables), it was assumed that herbicides will be available. (See Forest-wide Standards and Guidelines in the Forest Plan.) The use of chemicals for site preparation and release has been a small program in the past. In this chapter, the environmental effects of herbicides will not be discussed. This issue has and will continue to be addressed in separate environmental analyses and NEPA documents at the Regional and Forest levels. Any additional consideration of this issue will be through similar processes at the Regional level, or through Forest environmental analyses tiered to the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation (USDA, 1988).

B. MANAGEMENT ACTIVITIES AND THEIR GENERAL EFFECTS

Some forest management activities broadly affect the environment, such as timber harvest, road construction, and development of areas for recreation etc. The activities of people in the forest can also impact the environment. The section below briefly summarizes forest management activities and their major effects on the environment. On the Mt. Baker-Snoqualmie, changes in vegetation (timber harvest and associated activities) and the construction and maintenance of roads generate a majority of the effects discussed in this chapter.

Cutting Vegetation: This activity requires cutting down and removing trees for their commercial value, and to reduce competition from unwanted species for sunlight and nutrients. Cutting vegetation:

- eliminates the natural condition of areas not previously cut;
- changes species composition by altering the stage of plant succession in the cutover area and in the basin(s) in which the cutting occurs;
- changes age distribution of the vegetation in the cutover area and in the basin(s) in which the cutting occurs;
- alters, for some period of time, the scenery of the area;
- changes amount and arrangement of organic debris such as logs, branches, and twigs;
- kills roots, temporarily reducing resistance to landslides on unstable slopes;
- changes wildlife habitats in the cutover area, and changes the distribution of these habitats in the basin(s) in which the cutting occurs;
- increases growth rate of vegetation on the cutover area;
- alters microclimate by increasing daily temperature fluctuations; and increases surface winds;
- cutting adjacent to streams changes the type and timing of organic debris deposits in stream systems;
- changes the timing and amount of peak flow of streams;
- cutting adjacent to streams increases the temperature of streams and lakes;
- generates revenues locally through returns to the counties, and generates jobs.

Road and Landing Construction: These activities require heavy equipment (tractors, trucks, earth movers) to develop stable surfaces capable of supporting log trucks and log yarding equipment across mountain slopes. The construction, maintenance, and use of roads and landings:

- o permanently displaces, compacts, or buries the topsoil along the road, eliminating or greatly reducing vegetation on the road surface;
- o increases erosion by interrupting and redirecting surface and ground water flow, and exposing the subsoil on cutbanks and fill slopes;
- o increases stream sedimentation and turbidity;
- o may divide wildlife ranges;
- o may block fish passage in streams;
- o provides travel routes for some wildlife species;
- o provides access to resources (timber, recreation opportunities) in remote areas for motorized visitors, loggers, recreationists, and others;
- o increases noise from motors, logging whistles, and people.

Construction of Fish Habitat Structures: This activity involves blasting bedrock, or placing logs, gabions (cobble-filled wire baskets), concrete, or boulders, in stream channels. Fish structures:

- o change stream flow;
- o alter the movement and distribution of stream gravel and sediment;
- o increase the quantity and quality of fish habitat;
- o may introduce fish into streams which originally did not have fish, thus altering the native ecosystem.

Burning Vegetation or Organic Debris: This activity involves broadcast burning in cutover areas to: 1) lower the hazard of wildfire by reducing fuel; 2) reduce competing vegetation to increase sunlight and nutrients for desired species; 3) facilitate tree planting. Burning vegetation:

- o alters the soil by changing the availability of certain nutrients, and resistance to erosion;
- o may alter or destroy soil flora/fauna, reduce long-term site productivity;
- o temporarily alters the scenery of the area;
- o reduces the risk of wildfire and the difficulty of suppressing it;
- o creates smoke in local airsheds;

- alters the microclimate by increasing surface temperatures as long as the black color remains;
- converts long-term nutrient sources (woody debris) into short-term nutrients.

Planting Vegetation: This activity introduces desired species into areas where the vegetation has been cut, or cut and burned. The objective is to enhance economic, ecological, or aesthetic values. Planting vegetation:

- may change species composition, or introduce non-native plant species;
- alters visual characteristics;
- increases soils strength and resistance to erosion by promoting root growth and ground cover;
- may change forage and habitat for some wildlife;
- initiates future timber crops.

Trail Construction: This activity requires light equipment and manual labor to develop stable surfaces (on a much smaller scale than for roads) capable of supporting pedestrians across forested slopes, and, where allowed, off-road vehicles and horses. Trails:

- increase soil erosion by interrupting and redirecting surface water flow;
- by making remote areas accessible to hikers, can increase resource damage from changed use patterns;
- provide travel routes for wildlife.

Construction of Other Recreation Facilities: These activities involve the construction of various buildings, parking lots, shelters, signs and signposts, vault toilets, pavement, etc. to make the use of recreation areas more pleasurable. Recreation facilities:

- attract people to small areas. This results in soil compaction, injury to vegetation, disturbance of wildlife, and increased noise;
- provide safety and comfort for visitors;
- eliminate small areas of wildlife habitat;
- contaminate, or increase the risk of contaminating the soil and streams immediately adjacent to the facilities;
- reduce contamination from human waste and waste water in heavily used areas.

C. EFFECTS THAT DO NOT DIFFER AMONG ALTERNATIVES

Threatened and Endangered Species

Plants

There are no known threatened and endangered plants on the Forest. Standards and Guidelines provide for protection and maintenance of sufficient habitat to meet the recovery objectives for the bald eagle, American peregrine falcon, grizzly bear, and gray wolf. Alternative NC (No Change) will also comply with provisions of the Endangered Species Act of 1973, even though the law is not fully incorporated into the current Timber Management Plans (which are the basis for Alternative NC). To date, impacts on the Potential Yield have been insignificant.

Animals

Under all alternatives, bald eagle, American peregrine falcon, and grizzly bear management is guided by the management goals, habitat objectives, and standards and guidelines in the following T&E recovery plans: (1) Final Pacific States Bald Eagle Recovery Plan; (2) Pacific Coast Recovery Plan for the American Peregrine Falcon; and (3) Grizzly Bear Recovery Plan. Management Standards and Guidelines have been established to assure that Forest management activities will not degrade or compromise T&E species habitat, including the gray wolf. There is currently no recovery plan for the gray wolf.

Bald Eagle. The calculations and management information concerning the bald eagle in the FEIS and PLAN were based on a Recovery Plan objective of protecting one existing and two potential nest sites, each at least 31 acres in size, and protecting known communal roost areas. These areas are Management Requirement areas for the bald eagle, and are protected from timber harvest and other disturbing activities under the Plan. Additional nesting, roosting, and feeding areas will likely be discovered during eagle habitat inventories and other activities. Such sites will also be managed under the bald eagle standards and guidelines.

Management Area 16A of the Forest-wide mitigation addresses the specific restrictions involved with any activity which may have potential adverse impacts on bald eagles and their habitat. Implementation of any of the alternatives will facilitate recovery of the bald eagle.

Grizzly Bear. This species is considered a management indicator species due to its threatened status and occurrence on the Forest. The present Grizzly Bear Recovery Plan does not designate specific minimum habitat requirements for the Forest and for this reason, no MR has been established. Habitat evaluation and population studies are underway, and due for completion in 1991, for the North Cascades Ecosystem. Following this, a determination will be made by the U.S. Fish and Wildlife Service on the feasibility of recovering grizzly bears in this area. Until these evaluation and population studies are completed, proposed major construction and non-construction actions will follow the Section 7 consultation process as developed by the North Cascades Grizzly Bear Working Group and agreed upon by the U.S. Fish and Wildlife Service.

Any grizzly bears occurring on the Forest will be protected. The Forest Plan will be modified if needed to support recovery objectives and management

requirements, should there be a decision to recover the grizzly bear in this ecosystem.

American Peregrine Falcon. As with the grizzly bear, this species is considered a management indicator species due to its Federal status (endangered) and its historical occurrence on the Mt. Baker-Snoqualmie. No MR has been established, as the 1982 Recovery Plan did not identify any recovery habitat on the Forest. This recovery plan is currently being revised. If the revised recovery plan identifies a minimum habitat level for the Forest, the Forest Plan will be modified as needed to support recovery plan objectives and management requirements. In the interim, any occupied sites will be protected as they are discovered.

The Forest-wide Standards and Guidelines for T&E species apply to the American peregrine falcon as there are no specific guidelines for this species. However, in accordance with the Forest management goal and direction to provide habitat to aid in recovery of threatened and endangered species, habitat enhancement opportunities, if identified, will be designed to meet or exceed the requirements of the Pacific Coast Recovery Plan for the American Peregrine Falcon (1982).

Gray Wolf. The gray wolf, like the peregrine and grizzly bear, is considered a management indicator species due to its endangered Federal status and documented occurrences on the Forest. As of yet, it is not clear whether wolf sightings on the Forest represent breeding individuals or packs, only transient or dispersing individuals, or other non-breeding animals (e.g. released captive-bred wolves). There is at present no recovery plan for the gray wolf, so no minimum habitat levels have been identified.

The effects of the alternatives on gray wolf are not known but are thought be similar to effects on grizzly bear habitat. The factors most likely to affect suitability of the Forest for gray wolves are prey population abundance, and remote areas where human activities and road traffic are at low levels. The Forest-Wide Standards and Guidelines for T&E species apply to the gray wolf. There are no specific standards and guidelines for gray wolf. Should a recovery plan for the area be developed, the Forest Plan will be modified to support recovery objectives and incorporate management requirements.

Any identified habitat protection or enhancement opportunities will be designed to meet the requirements of a gray wolf recovery plan, if developed. This is in accordance with the Forest management goals and direction to provide habitat to aid in recovery of T&E species.

Other Sensitive Species. Six Region 6 Forest Service Sensitive animal species which occur on the Forest are candidates for federal listing. Category 2 candidate species are the bull trout, the marbled murrelet, Townsend's big-eared bat, the California wolverine, and the North American lynx. The Northern spotted owl is proposed for Federal listing. Two sensitive plant species, suspected but not known to occur on the Forest, are Category 2 candidates for federal listing. They are Calamagrostis crassiglumis and Castilleja cryptantha. The common loon, also a sensitive species, is not a candidate for Federal listing.

It is Forest Service policy to protect the habitat of sensitive species from adverse modification or destruction, as well as to protect individual organisms

from harm or harassment as appropriate (FSM 2670.3). All Forest Service projects, programs, and activities are reviewed for possible effects on threatened, endangered, and sensitive species. Forestwide management direction was designed to protect sensitive species' and their habitats, and calls for the development of species management guides for all sensitive species. These guides will determine viable population levels of each species and appropriate management to maintain viable populations. Should any of these species be added to the Federal Threatened and Endangered Species List, they would then be managed according to the provisions of the Endangered Species Act.

In addition, no action will be taken under any alternative which would lead to the classification of any sensitive species as threatened or endangered. Sensitive plant surveys are required during any project design stage.

Summary

No adverse direct, indirect, or cumulative effects are expected to occur, due to management activities in any alternative, for T&E&S species. Identified bald eagle roost areas and nesting sites are protected as Management Requirement Areas. No timber harvest or other disturbing activities will be allowed in these areas. Direct effects on the present habitat condition of these species are expected to occur to varying degrees depending on the alternative. However, no alternative will decrease T&E habitat requirements below recovery plan levels. Any management activity which may result in adverse effects on a T&E species would require consultation with the U.S.D.I. Fish and Wildlife Service.

Forest-wide management direction, as well as specific management area direction, was designed to protect T&E habitats and/or facilitate recovery. To summarize, no action will be taken under any alternative which would adversely affect the recovery of any threatened or endangered species, and to the extent possible, management will facilitate recovery.

Timber Harvest Activities. In the first decade timber harvest activities in all alternatives would occur primarily in old growth stands; harvest would occur utilizing primarily even-aged silviculture systems (clearcutting). The effects of timber harvest activities include reduction of habitat, temporal displacement, change in numbers and composition of species, and increased interaction with humans.

Special Habitats. All alternatives contain provisions, through land allocations and forestwide standards and guidelines, for special wildlife habitats not represented by indicator species. These special habitats are discussed in Chapter III, Wildlife.

Habitat Improvements. All alternatives provide for wildlife habitat improvements through implementation of the Forest's Comprehensive Fish and Wildlife Plan (Sikes Act--Public Law 93-452) and K-V (Knutson-Vandenberg Act) projects.

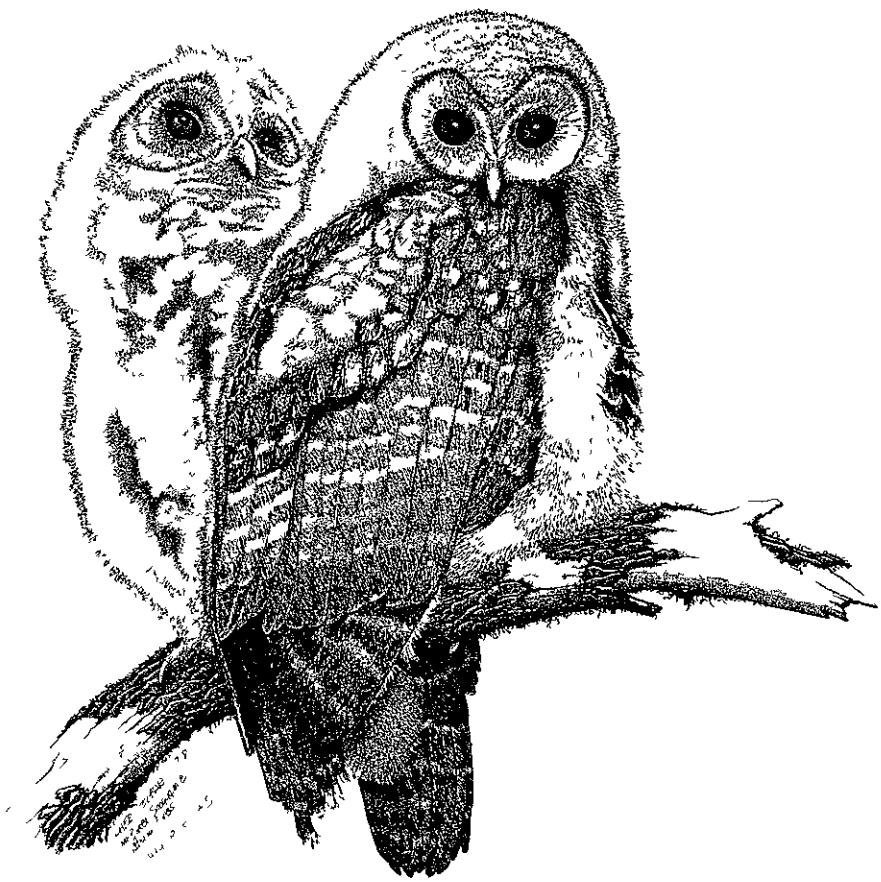
Overall. Regardless of the alternative considered, the ecosystem will continue to change through time. None of the alternatives are designed to return the Forest ecosystems to those of any previous time in history.

American Indian Cemeteries

In all alternatives, American Indian cemeteries have high protection from any development.

Civil Rights

Various Civil Rights, Affirmative Action, and Equal Opportunity Acts require that Forest Service hiring, supervisory, and contracting practices be conducted in a manner conducive to meeting established Regional and Nationwide goals in these areas. These practices will be maintained in all alternatives. In all alternatives, positive steps will be taken to ensure that facilities, sites, and activities will not be denied to any individual on account of race, color, creed, sex, marital status, age, handicap, or national origin.



D. EFFECTS THAT VARY BY ALTERNATIVE

SOILS AND WATER

Soils - The Direct Effects of Each Alternative

General

As a nonrenewable resource, soils can be affected by activities which cause soil erosion, soil compaction and changes in nutrient cycling. Road construction, timber harvest, mining, and residue management activities cause the greatest effect. Activities such as trail construction, recreation facility construction, fish habitat projects, etc. have a relatively minor impact.

Landslides, slump earthflows, and debris torrents are common mass erosion events west of the Cascades, and are very commonly and widely distributed on the Mt. Baker-Snoqualmie. In many cases, debris torrents and/or landslides are the result of natural events (floods, rain-on-snow storms) and management activities (Doyle 1985 unpublished). The rate of occurrence of debris torrents is closely related to timber harvest and the density and condition of forested roads (Swanson and Dryness 1975).

Changes in water velocity, volume, and/or direction cause changes in soil. Erosion, both surface and mass wasting, adversely affects soils by reducing soil productivity from the loss of topsoil and total amount of soil, and the resulting reduction of water storage capacity and total rooting capacity. This can be quite significant where soils are inherently erosive or unstable.

Timber harvest causes changes to soils which result from disturbance, root decay, compaction, and changes in nutrient cycling. Disturbance is caused by logs coming into contact with the ground during yarding, operation of tractors during construction of landings and spur roads, and by removal or piling of residue material.

The amount of soil erosion from disturbance, by alternative, is somewhat measurable. (See Table IV-1.) Other direct effects are harder to measure. In general, effects are greater in alternatives with a high number of acres assigned to timber management and roading.

Direct Effects of Timber Harvest on Soils

After trees are cut, root decay reduces the structural strength of the soil. Soils are most susceptible 3-15 years after harvest, after most original roots have deteriorated but before new roots have developed to the point of furnishing adequate root strength (Ziemer 1981). This is most important on unstable soils.

Past practices show that soil compaction is only a concern with tractor harvest; cable systems have not contributed to significant compaction except on landings and spur roads. As only a small percent of the Mt. Baker-Snoqualmie is tractor logged, the total effect of soil compaction caused by tractor harvest is minor.

Timber harvest causes changes in the nutrient cycling process within soils. These nutrient relationships are complex and highly interrelated. However, past management practices show that where erosion control practices and correct silvicultural and logging systems are used, soil productivity can be maintained and in some cases, improved over the long-term (by improving soil moisture and the soil nutrient budget.)

The table below, based on available data (Snyder 1981), shows erosion relative to timber harvest in the first decade. Background erosion is a result of past harvested areas and existing roads. New erosion results from first decade timber harvest, road construction, and road reconstruction.

Table IV-1
Erosion Relative to Timber Harvest During First Decade

Alternative	Background Tons/Year	New Tons/Year	Total
NC	83,253	79,567	162,820
A (No Action)	61,549	41,342	102,891
I	58,207	38,467	96,674
B (RPA)	57,663	38,043	95,706
H	55,263	36,058	91,321
J (Preferred)	53,789	34,738	88,527
C	41,539	25,919	67,458
G-Modified	42,109	24,737	66,846

Thinning and release programs can have both adverse and favorable impacts on soil nutrients.

Burning causes physical and chemical changes in the soil. The magnitude of these changes depends upon: intensity and duration of the fire, thickness of the duff, and the moisture content of the soil and duff.

Chemical changes occur as the soil pH, phosphorus, exchangeable potassium, calcium, and magnesium increase immediately after burning. Nitrogen is lost by volatilization. However, nitrogen fixation, both symbiotic and non-symbiotic, is more active following fires and in some ecosystems nitrogen fixation may restore the lost nitrogen to the soil (USDA 1979). Soil properties subject to physical changes include texture, structure, organic matter, and duff removal which can lead to erosion. In the northwest, Dyrness and Youngberg (1957) reported that only severely burned soils were significantly changed in particle size distribution, soil structure, and organic matter.

Some studies indicate that these changes in soil do not have long lasting effects. Comparing paired burned and unburned soil plots from areas burned 25 years ago (in the western Cascades of Oregon and Washington), Kraemer and Hermann (1979) found there were no statistically significant differences in the properties of the soils. This suggests that broadcast burning does not have a lasting effect on chemical and physical properties of soils.

The extent and duration of impacts to soil physical and chemical properties is directly related to fire intensity. Boyer (1980) determined that threshold values for duff and surface nitrogen were 15% bare ground on soils with a very high surface erosion hazard and a 50% reduction of total nitrogen in the surface two inches. On the MBS these conditions are normally obtained under a severe wildfire or intense broadcast burn. Most broadcast burning on this Forest is done under conditions that leaves the duff uncharred at the duff-soil interface. At this burn intensity any physical or chemical changes are too small to be measurable.

However, assuming that some changes will occur, the area affected by these changes will be proportional to the total acres burned. Based on Standards and Guidelines and ecological factors, an estimated 10 percent of final harvest acres will be broadcast burned during the first years of the initial decade of implementing the Forest Plan. (See Table IV-2.) During this period more residue will be 1) removed as commercial products; 2) retained for site productivity and habitat needs; and 3) located in higher elevations, all of which will reduce the intensity, if not the need to burn. By the end of the first decade, the proportion of final harvest acres that will be broadcast burned will be reduced to approximately five percent of the area. This ratio should continue into future decades.

Table IV-2
Acres of Final Timber Harvest, Broadcast Burned Per Year

Alternative	Total Acres Final Harvest, 1990	Ac. Broadcast Burned, 1990	Ac. Broadcast Burned, 1997
NC	4,240	424	212
A (No Action)	4,068	407	203
I	3,260	326	163
B (RPA)	3,221	322	161
H	3,042	304	152
J (Preferred)	2,865	287	143
C	1,873	187	94
G-Modified	2,291	229	115

Direct Effects of Archaeological and Historic Properties on Soils

Excavation of an archaeological site will have small-scale, localized effects on soils of the area: soils are physically removed. The greatest amount of site excavation is likely to occur in Alternatives NC, A, I, and B; in these alternatives, more acres of timber will be harvested, and it is through such ground-disturbing activities that most sites are found and possibly excavated. In Alternatives H and J (Preferred), moderate amounts of excavation will occur.

Direct Effects of Recreation on Soils

The activities of developed and dispersed recreationists can destroy ground vegetation and cause soil compaction. Compaction is a progressive process over

time, and depends upon the number of people on an area. The effects occur in all alternatives and vary only slightly. Effects are localized and occur only on a very small percentage of the Forest, but they can be intense where they do occur.

The development and operation of ski areas impacts soils in those areas. All alternatives have opportunities for future expansion of existing areas. Alternative I would allow expansion to occur outside of the existing permit area of Crystal Mountain. If development occurs, effects will include soil erosion during lift construction and slope grooming, compaction from concentrations of people during the summer, and some effects to soils from salt applied to snow during spring grooming. The displacement of topsoil can be significant in these high-elevation areas, because the inherent fertility is low and the exposed subsoil is even less fertile than the original topsoil.

Direct Effects of Mining and Energy Development on Soils

The potential for mining development is somewhat dependent upon the level of restrictions, and the number of acres allocated to management areas that preclude development.

Mineral exploration involves borings, diggings, and access trails and roads. These produce localized but severe impacts to soils. Soils are displaced, compacted, and eroded. Extraction of minerals would have a severe impact on soils, the extent of which depends upon the size and type of mine. Soils may be taken out of production or removed entirely, depending on the type of operation.

Geothermal, gas, and oil exploration and/or development would have similar effects. Oil spillage would cause detrimental chemical changes to soils. Any required pipelines would disturb soils during installation.

Direct Effects of Roads on Soils

Construction of roads has a number of effects on soils. During construction, soils are severely compacted, displaced, and sometimes eroded; soil productivity on the sites is sharply reduced or destroyed. Construction on steep slopes causes a potential loss of soil stability. Roads also intercept and change the surface and subsurface drainage patterns. Soil erosion can occur when water flows are directed and concentrated on soils with no vegetation.

The effects depend upon a number of factors. In locations where soils are stable, and good construction and maintenance are accomplished, the impacts to soils are much less than where the reverse occurs.

Where soils and bedrock are inherently unstable, excavation of a road prism removes toe support for the soil above the cutbank, which increases the potential for slope failure. This "cut" material is usually added as "fill" on the slope just below the road. It adds weight to the slope, and the re-worked fill material is also inherently less stable than the natural underlying soil. The fill material itself has failure potential and it also increases the failure potential of the underlying natural soil (from the weight of the fill plus the the additional weight of the water it will adsorb.)

Road construction will take between 40 and 133 acres of land out of production per year in the first decade. As shown in Table IV-3, Alternative NC removes the most acres from production, Alternative G-Modified the least, with the others in between. Estimates of soils that are lost as a result of road impacts are more difficult to quantify, as soil is lost from both surface erosion and slide events. The method used to develop the data shown in Table IV-3 is fully described in a document on file at the Forest Supervisor's Office (Snyder 1981)

It must be fully understood that the numbers generated by this method are, at best, only an approximation of the true numbers. Due to uncertainties involved, it is not possible to accurately predict actual amounts of erosion which can be expected to occur in a planning area in a given time period (Ellson 1981). However, the numbers have value as an index, and the relative differences are valid. A brief description of the process used follows:

Sediment is that part of erosion that reaches water. Therefore, to estimate sediment it is first necessary to estimate erosion. The procedure for estimating erosion was divided into two phases, one for mass movements (slides) and one for surface erosion. Total erosion is the summation of these two sources.

Mass Movements: Three sample areas representing a cross section of soil and topographic factors on the Forest were evaluated on aerial photos using stereo photo techniques. The total area was 75,000 acres.

All slides of 1/4 acre or larger were recorded. Slides were recorded as to size, soil type, whether they occurred in timbered areas, clearcuts, or along roads and whether or not they entered water.

In managed areas only the past 20 years were considered. This was divided by 20 to determine a yearly average.

All slides were treated as debris avalanches. Area was measured on photo and average depth of two feet was estimated to provide volume. Volume estimates were converted to tons.

A natural slide background rate was taken as 0.1 ft/year (estimate).

The increased total slide area in clearcuts over comparable soil types in timbered areas was taken to mean that this additional area is that which was involved in slide movement as result of timber harvest.

Surface Erosion: Surface erosion estimates were based on 10 surface erosion collector plots which have operated for one year.

Actual surface erosion expected is based on average of disturbance from different harvest methods and roads.

Sediment was estimated from "stiff" diagrams and using aerial photos to estimate landslide amounts entering water.

The values for erosion and sediment as developed through this procedure are valid for comparison purposes only. They show the relative differences

that would be caused by various management activities on the primary soil and topographic types.

The figures in Table IV-3 include surface erosion and sloughing that occurs on cutbanks and fill slopes. This occurs most frequently during the first year after construction. During the next five years, the erosion rate steadily declines and then it tends to level out.

Table IV-3
Road Impacts to Soils

Alternative	Acres Removed From Production	Background Sediment Tons/Yr	Road Construction Sediment Tons/Yr
NC	133	33,314	6,030
A (No Action)	94	14,994	3,251
I	86	17,780	2,936
B (RPA)	81	14,905	3,095
H	71	14,964	3,086
J (Preferred)	67	14,896	2,916
C	52	12,832	2,432
G-Modified	40	14,299	1,983

Road management activities, or lack thereof, can also affect soils. Keeping the road drainage systems clear can prevent water diversion and soil erosion.

Soils - The Cumulative Effects of the Alternatives

The cumulative effects to soils are those additive actions to soils in place or over an area which change their productivity over time. They are caused by the multiple application of one or more types of effects.

Cumulative impacts to soils occur over an area, as each additional unit of timber harvested contributes to the total amount of soil that is disturbed and subjected to detrimental impacts. New harvesting adds to the impacts of past cutting on both public and private lands within the Forest boundary. In addition, sequential events occur in place that cause cumulative soil impacts. Soils are impacted by yarding during logging. Fuel reduction and site preparation activities, such as residue removal and broadcast burning, cause additional impacts. Soils are subjected to further impacts when intermediate harvest or the next clearcut harvest occurs on the location.

The amount of impact can be expected to be in proportion to the acres harvested by each alternative with Alternatives NC, A, I, and B impacting soils the most.

Much of the transportation system for public and private lands within the Forest boundary is in place and has removed soil from production. The addition of new roads has a cumulative effect on the total area of soil taken out of production. Also, the erosion and sloughing that occurs along cut and fill slopes has a detrimental cumulative effect, both to the on-site soils and those

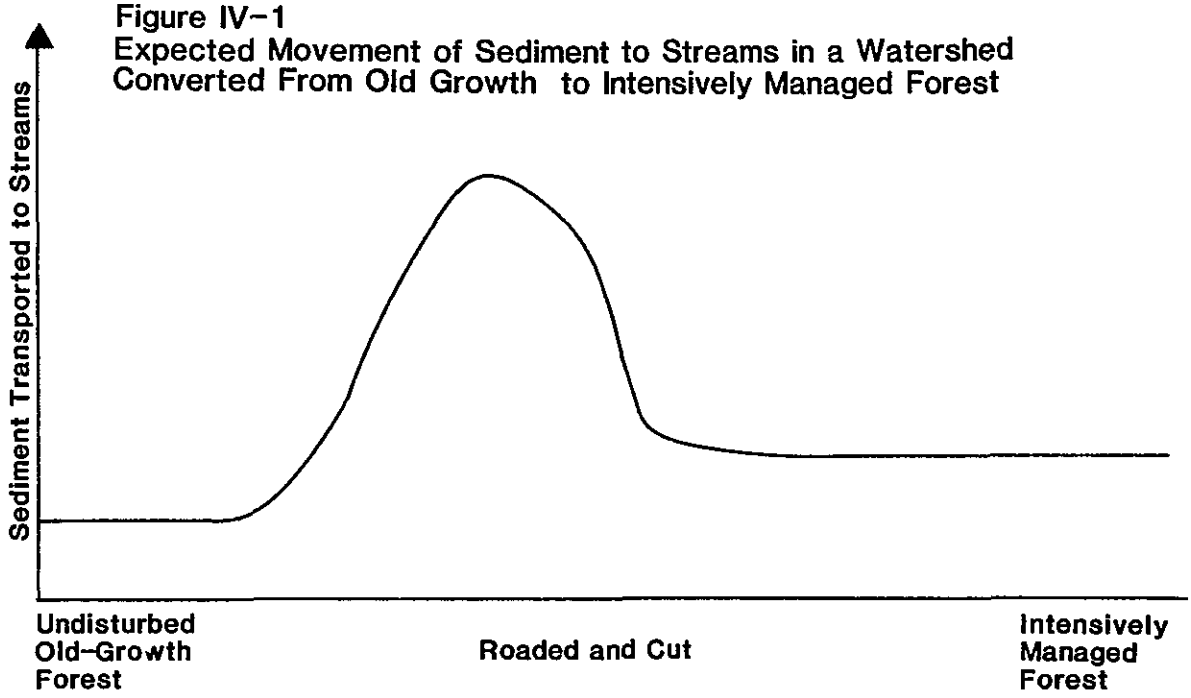
downslope. The alternative that constructs the most roads will have the most effect. Alternative NC constructs far more roads than any of the other alternatives at 28 miles a year. Alternatives A, and I will construct 18.8 and 17.1 miles per year, respectively, during the first decade. Alternatives C and G-Modified construct the least, 10.3 and 8.1 miles, respectively; the other alternatives fall between these.

Soils - The Indirect Effects on Other Resources

Water

Changes in soil which promote surface erosion and/or mass wasting can strongly affect water quality, specifically sedimentation. (See Figure IV-1) There will be an increase in turbidity as a result of soil disturbance.

Figure IV-1
Expected Movement of Sediment to Streams in a Watershed
Converted From Old Growth to Intensively Managed Forest



Increased sedimentation in any of the watersheds may result from surface erosion or mass wasting. The significance depends upon the volume and type of sediment, and whether the water is taken directly from a stream or from an impoundment; sedimentation has less effect if water is taken from an impoundment, which acts as a settling basin. Impoundments in the Cedar River and Tolt River Watersheds are the most effective because soils there are dominated by sands and gravels which rapidly settle to the bottom. The Green River watershed, and more so the Sultan, contain soils that have a higher percentage of silts and clays which remain in suspension for long periods. For those watersheds where water is taken directly from a stream, the amount and type of sediment which enters the stream will have a direct effect on the quality of the water taken out.

Changes in the soil that decrease water storage capacity affect water runoff. The most significant occurrence of this change is when an area once occupied by soil is replaced by a road. Rainfall (which is seasonally heavy on the Forest) on a road becomes instant runoff, as there is no longer any soil to store and slowly release water. Alternatives with the most new road construction include NC, A, I, and B. Of lesser significance, surface erosion and/or mass wasting events reduce the depth of soil, reducing storage capacity and allowing runoff to occur sooner. Soil compaction, which occurs in small areas, reduces the rate of water entry and therefore increases the rate of runoff. This effect is vastly overshadowed by the effect of large areas of vegetation removal.

The literature applicable to the west slopes of the Cascades suggests that clearcutting can increase water yields by decreasing interception and transpiration, thus making more water available for run-off. There is the potential to cause peak water flows to occur sooner after heavy rain events and there may be higher peak flows. In addition, activities associated with timber harvest often cause water to be concentrated and misdirected onto areas where flow did not previously occur (Dyrness 1965, Froehlick and Bergland 1976, Cline and others 1977, Harr and Krygier 1972, Harr 1976a 1976b 1979, Stan and others 1979, Haris 1973, Johnson and Beschta 1980, Krygier 1971, Power 1974, Rothacher 1971 and 1973, Hess 1981).

There are no significant indirect effects on flood plains and wetlands as a result of changes in the soils from implementing any of the alternatives.

Vegetative Diversity

Implementation of alternatives will cause changes in soils that indirectly affect vegetation. The most pronounced change is the displacement of soil where land is removed from production, such as during excavation for new roads. On all roads other than temporary spurs, the soil is permanently removed and does not support any vegetation. The amount of land removed ranges from 94 acres per year (first decade) in Alternatives A and NC to 40 acres per year in Alternative G-Modified.

Temporary roads remove soil from production for several years. Often, disturbed areas are scarified, seeded, and replanted. This partially restores soil production, although soils do not provide the same level and quality of vegetation that they did prior to the disturbance.

Soil compaction affects vegetation by restricting root development and movement of air and water through the soil; growth is slower and less vigorous.

Fire, either prescribed (such as broadcast burning) or wildfire, causes changes in soils that indirectly affect vegetation. Fire can accelerate plant succession, cause retrogression, or act as the removal agent to perpetuate a vegetative cycle (Boyer and Dell 1980). Past management practices have shown that changes in soils, by burning, that affect vegetation have more effect on brush and understory vegetation than timber. An example is the common establishment of fireweed after burning.

Old Growth

See previous discussion of the Indirect Effects of Soils on Vegetative Diversity.

Wildlife

Changes in wildlife habitats due to changes in soil are limited to those changes that may affect cover, forage, calving areas, and/or travel routes.

Most significant are changes in soils due to road construction, where the original soil is removed or changed so that it is totally non-supportive of any type of cover or forage. The extent of these effects are assessed in the Direct Effects of Roads on Wildlife section later in this chapter.

Soil disturbance and compaction in clearcuts may change the habitat by altering both forage and cover. The extent of these effects are assessed in the Direct Effects of Timber Harvest on Wildlife section later in this chapter.

Fish

Changes in soil which increase surface erosion and/or mass wasting can have a major effect on fish spawning and rearing, when this material reaches stream channels and is deposited as sediment. The extent to which fisheries will be affected depends upon the type and size of the disturbance and the susceptibility of a particular soil to be involved in a mass wasting event. Activities associated with Alternatives NC and A will generate the most sediment; the sediment index is estimated to be 125,000 tons per year during the first decade for Alternative NC, and 102,900 tons per year for Alternative A. Alternative G-Modified has the least, with an index of 66,800 tons per year. (See the Direct Effects of Roads on Water, Table IV-6, for more detail.)

Human Community

Changes in soils as a result of implementing alternatives can impact the human community. A significant effect occurs when an activity causes an impact to soils resulting in a mass wasting event (a slump or slide) or road-fill washouts. Typically, slide material enters a stream, is transported during a flooding event, and is deposited onto property. This type of event has occurred in the past and there is risk of future occurrence. The alternatives that cause the most soil disturbance (NC, A, I, and B) have the greatest potential for causing this type of occurrence.

Changes in soils as a result of implementing alternatives are not likely to affect the economy.

American Indian Religious and Cultural Use

Changes in soil as a result of implementing any of the alternatives would not affect American Indian Religious and Cultural Use, but might reflect other significant effects (for example, road construction).

Archeological and Historic Properties

Soil disturbance resulting from implementing any of the alternatives would have significant effects on archeological properties and less impact on historical properties, which for the most part consist of standing structures. Effects would be most widespread in Alternatives NC and A, least in Alternatives C and G-Modified. Effects would be high in Alternatives B, H, I, and J (Preferred).

Scenery

Changes in soils as a result of implementing alternatives will have a significant effect on scenery.

The most visible change in scenery occurs where raw soils are exposed. Scenery is also strongly affected where the soil colors contrast with the colors of vegetation. Mass wasting events strongly affect scenery due to the unnatural color and shape of irregular gashes on hillsides. Those alternatives with the highest harvest levels (NC, A, I and B) will have the largest area of exposed soils. Alternatives C and G-Modified will have the lowest amount of exposed soils.

Recreation

Changes in soils as a result of implementing alternatives will have only minor effects on developed recreation.

Changes in soils as a result of implementing alternatives will cause some minor changes to dispersed recreation. When unprotected and subject to use by vehicles (especially ORV's) during wet conditions soils change to deep mud. This affects the quality of the ORV experience.

Trails

Changes in soils as a result of implementing alternatives have little effect on trails. Some weakening of soil strength adjacent to trails could result in small landslides causing trail damage. These changes will occur on trails passing through wet soil areas when repeated traffic (especially horse) convert the soil to mud.

Wilderness

Changes in soils, as a result of implementing the alternatives, will have an effect on the naturalness of wilderness. The alternatives that favor the primitive end of the WROS will result in less soil disturbance, thus will be more natural in appearance and in ecosystem development. Alternatives C, G-Modified, and H have the least human use within wilderness (Decade 1); Alternatives I, A, and J (Preferred) will have the most.

Research Natural Areas

No effects from changes in soils on Research Natural Areas are anticipated.

Roadless Areas

No effects from changes in soils on Roadless Areas are anticipated.

Wild and Scenic Rivers

No effects from changes in soils on Wild and Scenic Rivers are anticipated.

Air

There will be no measurable changes in air quality caused by changes in soils as a result of implementing alternatives of this plan. Changes will be limited to increased particulate concentrations caused by wind blown dust for disturbed soils or vehicular traffic. These events are limited in extent and are of short duration. There will be no measurable effect on noise as a result in changes in soils brought about by the alternatives.

Fire

Changes in soil properties and characteristics as a result of implementation of alternatives will have some effect on fire protection. Exposed mineral soils that result from alternative implementation can create a barrier which may restrict wildfire spread. Alternatives NC and A will have the greatest amount of exposed soils while C and G-Modified will have the least amount of exposed soil to effect fire spread. Chemical and/or physical changes in soils can result in vegetative communities that may be different from those previously present on the site. This change in vegetation may present different fire spread characteristics, i.e. more flamable annual vegetation than somewhat resistant native perennials.

Minerals

Changes in soils as a result of implementing alternatives will have no effect on minerals.

Land Ownership and Use

Changes in soils as a result of implementing alternatives will have no effect on land ownership and use.

Roads

Changes in soils as a result of implementing alternatives will have no effects on roads.

Mitigation Measures for Soils

Potential impacts to 95,500 acres of highly unstable soils have been eliminated by removing these lands from the tentatively suitable land base; no timber harvest or road construction is permitted.

The primary method of mitigating damage to soils from timber harvest activities is to ensure that the anticipated level of disturbance is within the limits of the soil to absorb. This was ensured by using a cumulative effects process that set a cap on the amount of harvest that could occur regardless of the alternative. Other mitigation includes fully suspending logs to restrict ground contact of highly sensitive soils, and limiting the size of timber harvest units on unstable soils. Soil disturbance is mitigated by such measures as scarification of compacted areas, revegetation, and proper channeling of water. These measures, when properly done, have been quite effective. The long-term effects of vegetative removal will need to be monitored to determine if adverse effects are occurring.

Techniques such as "soil ripping" followed by revegetation may be applied in heavily compacted areas (such as a landing). While this does not completely return soil to its pre-compacted condition, past experience has shown that it is effective in restoring soil productivity.

Erosion on ski areas can be effectively mitigated by controlling runoff, using contour ditching and revegetation of slopes. When surface soil is removed during slope grooming, mitigation measures include stockpiling and saving the surface soil while the grooming is taking place, then respreading the original surface soil. These measures have been used in the past with good success.

The potential for impacts to soils from broadcast burning can be mitigated by using prescriptions resulting in lower intensity and duration, thus ensuring that the lower portion of the duff layer remains intact. This prevents significant adverse changes in physical and/or chemical properties of the soil.

The use of "light handed" suppression techniques that minimize the amount of surface disturbance from fireline construction and post fire restoration activities will minimize surface erosion associated with fire suppression activities.

There are two types of mitigation for road construction. The most effective mitigation is the use of practices that prevent soil damage from occurring. The second type of mitigation is the use of practices that reduce or reverse damage that has already occurred.

Conflicts Between The Effects of the Alternatives and Others' Plans and Policies for Soils

There are no anticipated conflicts between the plans and policies of others and the effects of the alternatives on soils.

Water - The Direct Effects of Each Alternative

General

The environmental effects - direct, cumulative, and indirect - of one or more Forest management activities on water quality and quantity must be examined on a watershed basis. There are 66 watersheds on the Mt. Baker-Snoqualmie; these

are hydrographic watersheds, not the municipal watersheds discussed in Chapter III.

Direct Effects of Timber Harvest on Water

Removing vegetation affects water in several different ways. The interrelationships of timber harvest, the hydrologic process, and the kinds of impacts that are incurred, are briefly discussed in Chapter III.

Regeneration timber harvesting can have the following effects on water:

o Total annual water flows are increased following extensive timber removal.

Completely clearcutting small watersheds can increase annual yields by 50 cm (Fredriksen and Harr 1979). In larger watersheds, where only a small percentage of the total area is cutover at one time, water yield increases would be considerably less. Increases in water yields as a result of sustained yield harvesting in the larger watersheds (such as the Cedar River) may be almost undetectable (Heilman 1979). Harr (1983) developed a regression equation for use in estimating potential increases in annual water yield, which can be expected from clearcutting in western Oregon and Washington based on research results in experimental watersheds. Initial on-site increase of up to 20 inches are predicted, though they completely disappear in about 27 years. The equation predicts smaller annual water yield increase when annual precipitation is less.

Harr estimated that sustained increases in water yield from most large watersheds in western Oregon and Washington subject to sustained forest management are, at best, three to six percent more than flows from an undisturbed forest. Kattelmann et al. (1983) estimated similar maximum potential increases in Sierra Nevada watersheds if minimum standards for all applicable laws were followed. However, they concluded that the typical increase in a large watershed drops to approximately one percent when constraints are imposed to meet other resource demands. A similar scenario is expected in Region Six National Forests due to multiple use considerations. Flow increases on these forests have already been realized due to past harvesting, so there is little or no potential for increasing yields in most large watersheds.

This is especially true on the Mt. Baker-Snoqualmie, as timber harvest levels of the past (over 300 million board feet annually) have dropped. (Refer to Chapter III.) Other factors which further minimize potentials to affect changes in streamflow are high natural variability, lack of flow measurement accuracy (within five percent, at best, so potential changes are less than what is measurable in large watersheds), and the fact that most of the flow increases occur when they are least needed or useable - during spring runoff on the eastside, and during fall storms on the westside.

o Effects of harvesting timber on groundwater recharge and aquifers are similar to effects on streamflow, except for timing differences; eg., aquifer responses are typically slower and flucuate less than streamflow.

The above-mentioned research findings indicate timber harvesting, as will be practiced under any selected forest plan alternative, is expected to

have a negligible, unmeasurable effect on downstream aquifers. There is no realistic potential to modify timber harvesting to measurably increase downstream water supplies. This assumes management practices are conducted in a manner which reasonably maintains water infiltration characteristics, as is typical of current practices on National Forest System lands. Best Management Practices (see Appendix I and Plan Standards and Guidelines) will ensure adequate infiltration characteristics are maintained. Only if extensive, contiguous areas were compacted would infiltration be expected to be reduced so as to adversely affect downstream aquifers. This is not expected to be significant because tractor logging, from which most compaction normally occurs, is very limited on the Mt. Baker-Snoqualmie.

- Water yields will not be noticeably different from one alternative to another or from the present situation.

- Openings in the forest canopy tend to accumulate more snow than adjacent forested areas.

- There is some evidence that clearcutting in the transient snow zone can add water to high flows that cause flooding. Although intensive forest management may not cause catastrophic flooding or channel erosion, it might add enough water during naturally high critical flows to increase level of flooding or channel erosion. It might be that a particular situation may cause high flows that would not result in catastrophic flooding, but when additional water attributable to harvest activities is added, the result could be catastrophic.

- The water chemistry of some streams and lakes is affected by timber harvesting activities.

- Management of the vegetation within riparian areas is very critical. Retention of vegetation that will provide the shading and large organic debris recruitment is important within riparian areas. In some streams, loss of vegetation will affect stream temperatures.

Figure IV-1 (page IV-7) shows the expected movement of sediment to streams in a watershed converted from an undisturbed old-growth forest to an intensively managed forest. (Refer to Table IV-6 for the actual amount of sediment, by alternative, produced by various management activities, plus natural background sediment.)

Implementation of any of the alternatives will have minor effects on wetlands, based on the Forest-wide Standards and Guidelines and the Standards and Guidelines for riparian areas (MA 13). These measures minimize the risk of disturbance. While all alternatives will have a relatively low risk of creating disturbance in wetlands, the alternatives that prescribe the most ground-disturbing activities (NC, A, I, and B) create the most risk. Any areas that are disturbed will be rehabilitated.

Table IV-4 shows the condition of the Forest's Class II and III watersheds (or Allocation Zones; refer to Chapter III, page III-14 and III-109). The ratings - A for acceptable condition and U for unacceptable condition - are based on the hydrologic cumulative effects analysis, completed to develop a method to meet water quality and riparian MR's. This is documented in detail in Appendix

H, FEIS; the process is summarized in this section, pages IV-30 to 32 and discussed in Chapter IV, Fish, pages IV-91 and IV-92.

In all alternatives, to meet management requirements, the acres available for final timber harvest are limited, by Decade, in the watersheds listed. This will allow those in an unacceptable condition to recover and improve to an acceptable condition; it will also prevent those watershed currently in an acceptable condition from becoming degraded. Refer to Appendix H, and Forest Plan, Chapter 4, Forest-wide Standards and Guidelines for Water and Riparian Areas.

There is one watershed on the Forest (rated unacceptable) that, and due to the seriousness of the damage, will receive no timber harvest activities for the first two decades of the Plan, in all alternatives except NC (which does not meet MR's). That watershed is Deer Creek, on the Mt. Baker Ranger District.

Chemicals used for vegetative control can create water toxicity. Chemical entry into streams is mainly through direct application to stream surfaces or through drift from nearby treatment units. Standards and Guidelines (Appendix D and the Forest Plan) provide specific direction for any application of chemicals near water. The use of any herbicides will follow the direction established in the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation (USDA 1988b). Norris (1978) found that leaching of chemicals through the soil profile is the process most feared by the general public, but is the least likely to occur. Chemicals used in forestry are relatively immobile in soil.

Fire causes rapid mineralization and mobilization of nutrient elements that enter the soil solution and eventually the stream through leaching and overland flow. Both wildfire and prescribed fire can affect water by causing an increase in sedimentation and causing changes in water chemistry (Stednick and others 1982); researchers do not believe that these chemical changes cause long-term degradation. Data to support quantitative fire impacts on water is not available, but it can be assumed that impacts to water will be in proportion to the total acres burned.

Direct Effects of Wildlife on Water

Management of municipal watersheds with controlled access, such as the Cedar, Green, and Tolt River watersheds, can be affected by changes in elk, deer, and mountain goat populations or management activities. Increased populations of these animals would be expected because of a greater use of available habitat, allowed by minimal harassment and limited vehicular traffic in the closed watershed. There is ongoing research into the effects of increased animal populations on domestic water supplies.

An effect of minor significance occurs with the installation of fish habitat structures which cause sedimentation, and once installed, change water velocity, which may affect channel erosion, causing sedimentation.

Direct Effects of Archaeological and Historic Properties on Water

Excavation of archaeological sites may result in short-term, small scale changes in water quality and clarity. If excavation occurs along a stream bank, the sediment load of the stream will be increased for a short period and accelerated erosion along the cut bank may occur. These effects would be most pronounced in Alternatives NC, A, and I, least pronounced in Alternatives C and G-Modified.

Direct Effects of Recreation on Water

Lift construction and slope grooming at ski areas, and recreation use in campgrounds can create disturbed areas which can cause small amounts of sediment. Dispersed recreation use affects water through placement of human wastes in or near water, and through introduction of pollutants from pets (such as dogs introducing giardia).

The amount of maintenance in recreation areas can have an effect on water quality, sanitation, and aesthetics. Low levels of maintenance in moderately to heavily used areas may result in health, aesthetic, and water quality problems.

Riparian and wetland areas, as discussed in Chapter III, are particularly susceptible to impacts from recreation facilities (Bull and Skovlin 1981). However, in all alternatives, the amount of habitat lost through campground expansion or other site development will be quite small. Alternatives I and G-Modified propose no new construction. In the other alternatives, some new recreation construction will remove a minimal amount of habitat, while at the same time, some less-efficient sites will be phased out and allowed to return to a natural condition.

Direct Effects of Trails on Water

Trail construction and management will have a very minor effect on water due to the very small amount of land, Forest-wide, affected by trails.

Direct Effects of Mining, Energy Development on Water

Mining will impact the water resource only if areas are explored or developed for minerals. Mining activities can affect both surface and subsurface water resources by changes in surface runoff. There may also be effects on sediment yield, erosion, water chemistry, stream channel characteristics and stability, aquifer recharge, and ground water quality. The degree or amount of effect depends upon the commodity involved, equipment used, and location of the operation.

The primary impact from mining is chemical pollution (Down and Stocks 1977); severe water toxicity can occur. In addition, geothermal, gas, and oil operations may require pipelines that disturb soils during installation.

Considering the regulatory controls available for water resources, it is assumed that the impacts caused by mining will not be significant under any alternatives, nor vary significantly by alternative. It can be assumed that effects will be less under Alternatives C and G-Modified, followed by J (Preferred), H, and I, where more area is withdrawn from mineral entry or

managed under "highly" restrictive management strategies. (Refer to the Minerals section of this chapter.)

In all alternatives in Decade 1, there is no expected production of energy minerals, and only slight variations from current production of non-energy minerals.

The alternatives that, through assignment of acres to management areas, allow the greatest development of small hydroelectric projects should have the greatest potential impact on the water resource. Table IV-5 shows the effect of the alternative land allocations on 109 potential FERC projects.

Table IV-5
Development of Potential Small Hydroelectric Projects, By Alternative

Status	NC	A	I	B (RPA)	H	J (Pref)	C	G (Mod)
	number of projects							
Allowed by Allocation	1/	68	80	76	68	64	45	53
Precluded by Allocation	1/	4	5	3	7	16	14	14
Questionable 2/	1/	37	24	30	34	29	50	42

1/ Alternative NC is similar to Alternative A.
2/ Project may be precluded either by allocation or project design.

Access roads, pipelines, and powerhouse construction for hydroelectric projects may disturb soil, resulting in sediment in the streams; if soils are unstable, mass movement into the stream is a possibility.

Small hydro projects also reduce water flow rates, as water is diverted into the pipeline. During flood periods, the diversion structure acts as a barrier which alters velocity. This can change rates and locations of sediment deposition, and may create stream bank erosion. Also, water on which flow and velocity has been reduced is likely to increase in temperature. Full mitigation is legally required for any adverse impacts on fish and wildlife resources.

Direct Effects of Roads on Water

Forest roads cause stream sedimentation. In addition to stream sedimentation from mass soil wasting from roads, surface erosion from road surfaces, cut and fill slopes, and drainage ditches also contribute sediment to streams. Road construction can also impede or change surface and subsurface runoff patterns.

Implementation of alternatives would contribute sediment as shown in Table IV-6. Heavy truck traffic on roads plus mass soil movements (landslides) cause most of the road-related sediment, rather than the road construction itself.

Table IV-6
Sediment Produced From Various Sources
Thousand Tons Per Year During First Decade

Alternative	Harvest	New Roads	Old Roads	Background 1/	Total
NC (No Change)	47.5	3.8	18.6	55.1	125
A (No Action)	38.1	3.2	14.9	46.5	103
I	35.5	3.0	14.8	43.2	97
B (RPA)	35.0	3.1	14.9	42.8	96
H	33.0	3.1	14.9	40.3	91
J (Preferred)	31.8	2.9	14.8	39.8	89
C	23.5	2.4	12.8	28.7	67
G-Modified	22.7	2.0	14.2	27.8	67

1/ From acres of previously disturbed ground plus natural sedimentation. It varies due to different amounts of rehabilitation work done on existing roads among the various alternatives.

Cederholm and Salo (1979) found on the Clearwater River that when the roaded portion of a sub-basin area exceeds 2-3% the accumulations of sediment in streambeds became significant. While it is recognized that the conditions on the Mt Baker-Snoqualmie are somewhat different, it does form a basis of comparison, lacking better data. The average road density on this Forest, and the actual acres intensively managed for timber production, is about four miles per square mile, or three percent. The density, when taken over most sub-basins is less due to the presence of other management areas such as SOHA's. As a subdrainage normally has some unsuitable or nonforest land, and is not 100% managed for timber, the percent of a drainage that is roaded will vary. In many places, it will be somewhat less than three percent density. Of course there is much more to the issue than just density. On the Mt. Baker-Snoqualmie, where slopes are steep and unstable, location, construction, and maintenance are of major importance. In order to approach a three percent density without significant impact, roads must be located to avoid unstable soils, be constructed using Best Management Practices, and be fully maintained to prevent landslide failures and drainage failures. Assuming that this will occur, roads will contribute a sediment level less than critical even in alternatives with high levels of road construction (NC, A, I, and B) (long-term studies such as Cedarholm and Salo 1979).

Implementing the alternatives in the large, municipal watersheds will have the following effects regarding road construction:

Cedar River. All alternatives will permit road construction, reconstruction, and maintenance to occur as necessary.

Green River. All alternatives will permit road construction, reconstruction, and maintenance to occur as necessary.

Sultan River. Alternative C prohibits new road or trail construction except for special administration or access of other ownership. All other alternatives will permit road construction, reconstruction, and maintenance to occur as necessary.

Other Municipal. Alternative C prohibits new road construction except for accessing other ownership. All other alternatives will permit road construction, reconstruction, and maintenance to occur as necessary.

Major stream sedimentation impacts can still occur from mass erosion after sedimentation from surface erosion has dropped to a low level and a road is considered relatively stable (Megahan and Kidd 1972). Extensive road systems often convert large amounts of subsurface water to ditch flow, causing a more rapid, severe runoff event (Hess, 1981). Mitigation measures, proper construction, and timely maintenance can help negate these effects.

Water - The Cumulative Effects of the Alternatives

Table IV-7 shows major management activities that can cause cumulative effects. Some exert more influence than others. Management activities on public and private lands can affect the 66 watersheds both outside and within National Forest boundaries. Due to resource limitations and data constraints, this cumulative effects assessment will only address the major causes of effects. One or two minor causes may not affect water quality and/or quantity, but a host of minor causes plus the presence of one or two major causes could result in major cumulative effects.

Table IV-7
Management Activities (On and Off Forest) Potentially Causing Adverse Cumulative Effects on Watersheds (Riparian Areas, Floodplains, and Wetlands)

Management Activity	.....Degree of Effect..... Major	Minor
Timber Regeneration Harvesting	X

Geothermal, Gas, Oil	X	
Land Use Grant		X
Special Uses	X	
Insect and Disease Control		X
	X	

In most cases, there is little or no data, and little or no professional knowledge or information on the cumulative effects to water values from such activities as trail construction and operation and other forms of dispersed recreation. These activities generally encompass small areas and may or may not be within riparian areas, floodplains, or wetlands. If these minor causes are combined with other events (major causes plus natural causes), the cumulative effects to water quality and quantity would likely be the same as those that will be described. Only the intensity or degree of effect could be different.

Most of the major cumulative effects to water quality/quality are direct in nature. Forest management activities may occur on a short or long-term basis. The potential adverse cumulative impacts and their extent are dependent upon what impacts occur, and how, where, and when they occur.

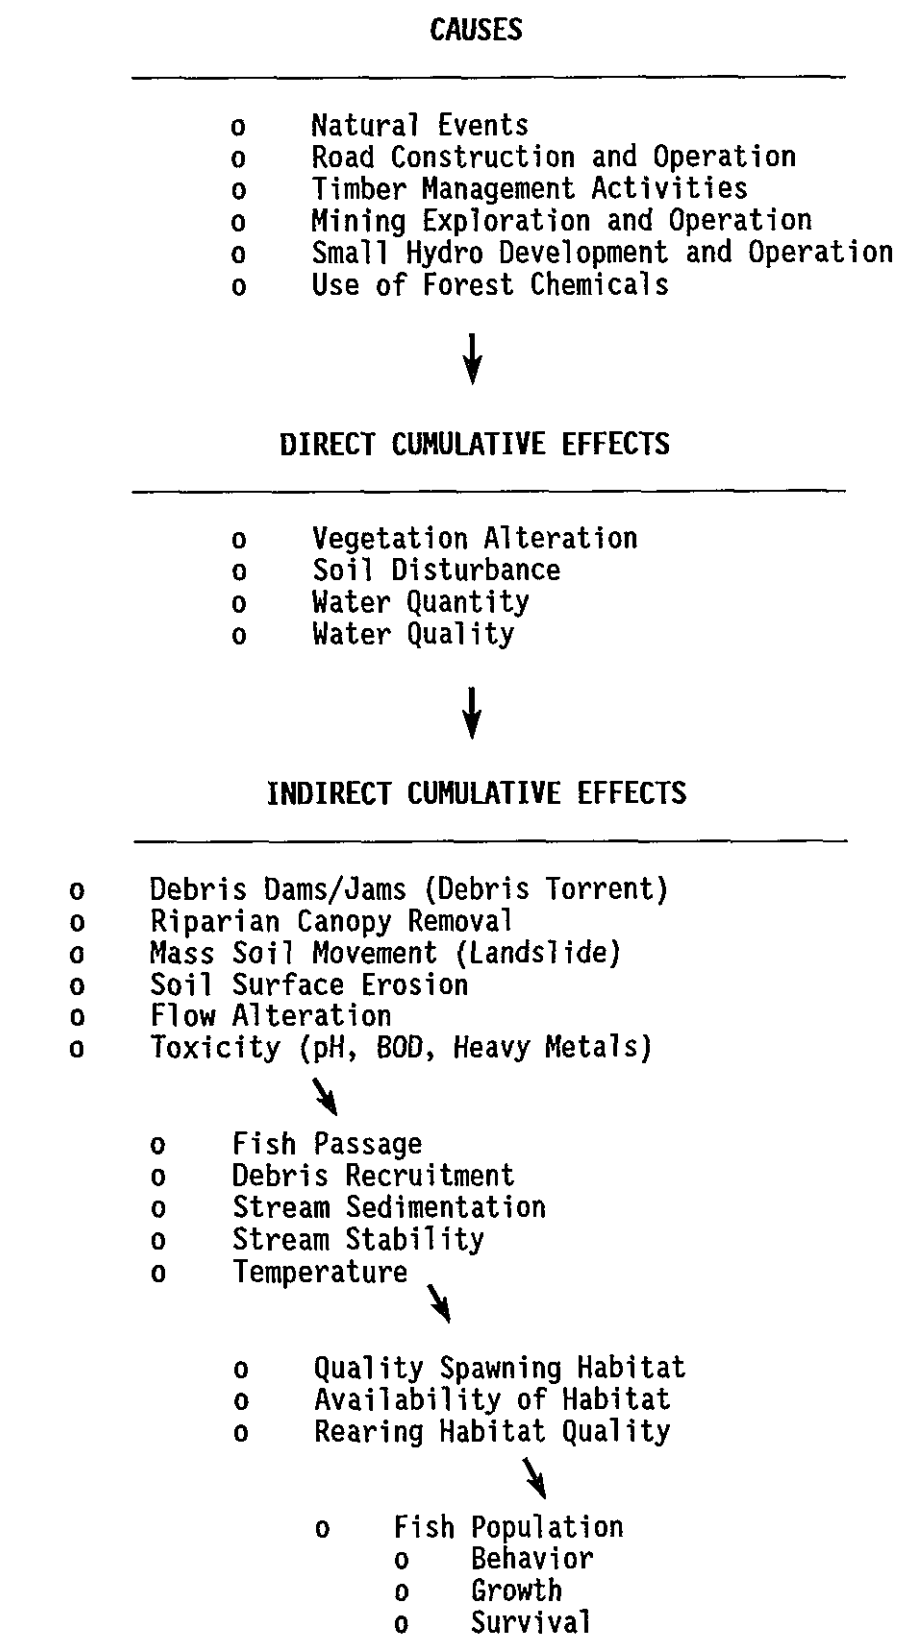
The impacts caused by management activities and the interrelationships of these are complex, as shown in Figure IV-2. This figure is a model depicting what and how activities have the potential to create major adverse cumulative effects on water quality and quantity and directly or indirectly affect the primary beneficial use of this water, the various anadromous and resident fish populations of the Forest. Activities that potentially have adverse cumulative effects include timber management activities (timber harvesting, site preparation, reforestation, intermediate harvest, and fertilization), road construction and management, mineral exploration and extraction, special uses and grants (small hydro, administrative sites), and use of chemicals on the Forest. Natural events are also shown as a potential cause of cumulative effects.

Process for Assessing Cumulative Effects

The major contributor to cumulative effects is timber harvest and associated activities. Past activities have resulted in severely deteriorated watersheds on 18 of the allocation zones and significant deterioration on many others. This deterioration was determined by evaluating the factors of stream channel stability, streambank stability, pool/riffle ratio, and amount and mobility of large woody debris.

None of the alternatives will have a further negative impact on watersheds. This is because the Forest assessed cumulative effects by developing a process that was used to evaluate the condition of each allocation zone (AZ) and then establish a harvest constraint level based on this condition and the AZ's capability to absorb and recover from timber harvest generated impacts. This harvest constraint level applies equally to all alternatives. It establishes, for watershed protection purposes, the maximum harvest level that can occur on each AZ for each decade. The harvest rate on each AZ is different and was determined by evaluating the physical and past management factors which are unique to that AZ. The background and the process are discussed in greater detail in Appendix H.

Figure IV-2
Effects of Management Activities on Soils, Water, Fisheries



Water - The Indirect Effects on Other Resources

Vegetative Diversity

Changes in water as a result of implementing any of the alternatives can have indirect effects on vegetation and timber. Several management activities can cause the water table to rise or fall, either of which will affect vegetation. One common change, resulting from a rising water table, is that red alder will become established in an area that was previously dominated by conifers.

Changing waterlevels can have a major effect on wetlands, causing them to dry up and change to other vegetation or habitats, or flooding and killing wetland vegetation. Flood waters can deposit sediment and bury vegetation; if silt is deposited, vegetation in the short-term will be destroyed, but in the long-term, vegetative growth could improve. High water flows can also undercut banks, resulting in local soil slides which destroy the vegetation on the areas affected. Saturated soils may result in mass wasting, which in turn causes vegetative destruction. These effects can be quite significant in local areas.

The risk of these changes occurring would be greatest in those alternatives that have the greatest harvest levels, NC, A, I and B. Alternatives C and G-Modified would have the lowest level of risk due to the lower levels of acres harvested over time.

Old Growth

The effects would be the same as those described above in Vegetative Diversity.

Wildlife

Implementation of the alternatives will not cause many changes in water which would affect elk, deer, and mountain goats. One change in water that could have an effect is increased snow pack accumulation from clearcuts, which could cause changes in migration routes and habitat usage. Indirect effects on the northern spotted owl, pileated woodpecker, pine marten, primary cavity excavators, or their habitats from changes in water are not likely.

Conditions which cause the water table to rise could significantly affect burrowing animals. Also, changes in water table level would change the vegetation on the site and could affect the types of mammals present. For example, if an area were to become swampy, it might become favorable habitat for beaver.

Changes in water that could affect reptiles and amphibians are changes in flow, temperature, and water table, and increased sedimentation. Either a rise or lowering of the water table would cause changes in soil wetness and vegetation composition. Risk of these changes occurring would be highest in Alternatives NC, A, I and B, and lowest in Alternatives C and G-Modified. Alternatives H and J (Preferred) would fall between these two groups.

Fish

Changes in water quantity and quality can cause significant effects on fish and fish habitat; the most significant effects are related to lowflow conditions (impacts on availability of rearing and spawning habitat) and highflow

conditions, e.g. flood or peak flow events (impacts of bedload and sediment deposition on spawning and rearing habitat). Alternatives NC and A would have the highest risk, while C and G-Modified would have the lowest.

Any on-Forest or off-Forest management activity that singly or in combination with other water use activities impact the quality and/or quantity of the Forest's aquatic systems will have a negative impact on the fish or fish habitat resources. This is discussed in detail in Appendix H.

The effects of municipal watershed management on fish vary by alternative, depending upon the amount of timber harvest, road construction and road use. The effects to fish and fish habitat within the large watersheds (Cedar, Green, and Sultan Rivers) are tied primarily to the level of roading and timber harvest. Provisions for fish habitat restoration in all alternatives will mitigate some effects. The greatest effect will occur in Alternatives NC, A, I and B. In Alternative C, the Sultan River and other small municipal watersheds would be closed to timber harvest activities; there would be the least effect to water.

Human Community

Changes in water as a result of implementing alternatives can cause changes in land use. A significant effect occurs when an activity causes a mass wasting event and this material enters streams. During high water it is transported downstream (sometimes as a debris torrent) and occasionally deposited onto property causing damage to land and/or buildings.

Changes in water as the result of implementing the alternatives could have an effect on prime forest and farm land adjacent to rivers and their tributaries. Flooding could change the land by sediment deposition or erosion.

Changes in water that cause changes in fish production can cause indirect changes in that sector of the economy. Fish production would not fall below the MR level for fish production (the current level) for any alternative. The highest risk of this occurring would be in alternatives with high harvest levels, NC, A, I and B. Alternatives C and G-Modified will have the lowest risk due to the lower harvest levels.

American Indian Religious and Cultural Use

Changes in water as a result of implementing alternatives may affect the values of inventoried American Indian religious and cultural use sites and areas. Purity of environment is an important value in spirit and legend sites; degradation of the water quality or quantity will impact the value of these sites for religious and cultural practices. These changes would be most pronounced in Alternatives NC, A, B, and I, and least in Alternatives C and G-Modified. Changes in fish populations resulting from changes in water can also affect the ability of the Forest to contribute to Treaty obligations. (See the discussion of Fish resources later in this chapter.)

Archaeological and Historic Properties

There are no measurable effects.

Scenery

Changes in water as a result of implementing alternatives would have only localized affects on scenery, such as bank erosion, landslides, or channel changes initiated by high water flows.

Recreation

Changes in water as a result of implementing alternatives could have minor, localized effects on developed recreation. Changes may include local degradation of drinking water in developed sites from chemical contamination or sedimentation. More likely to be significant on a local basis is erosive destruction caused by high water flows, associated with storm events.

Watershed restoration and improvement projects will vegetate eroded areas and stabilize areas of high erosion. There will likely be short-term impacts from traffic, dust, and noise during construction, but in the long run, these projects would improve the recreation setting by improving water quality of adjacent streams.

Changes in water that would affect dispersed recreation (motorized) are high water flows, associated with storm events, that causes road closures due to landslides and washouts. This is a minor problem Forest-wide, but locally can occur with any alternative. Unroaded dispersed recreation could be indirectly affected by increased water flows and/or misdirected water that causes trail erosion, muddy trail conditions, and trail closures due to landslides and washouts. This also can occur locally with any alternative.

Trails

There may be local indirect effects on trails. Increased water velocity and misdirected water can cause erosion and trail washout. Any impact is likely to occur in any alternative, but would be very minor Forest-wide.

Wilderness

There is no measurable effect.

Research Natural Areas

There is no measurable effect.

Roadless Areas

There is no measurable effect.

Wild and Scenic Rivers

Any management activities affecting water quality or quantity could have an adverse effect on Wild and Scenic River designation.

Air

There is no measurable effect.

Fire

There is no measurable effect.

Minerals

There is no measurable effect.

Land Ownership and Use

There is no measurable effect.

Roads

Changes in water as a result of implementing alternatives may affect roads. A road that is adjacent to a river can be removed by that river during flooding. However, in the more commodity-oriented Alternatives (NC, A, I and B) the risk would increase as more roads are constructed.

Mitigation Measures for Water

Mitigation measures that are applicable to all alternatives (Forest-wide Standards and Guidelines) and mitigation measures appropriate for each management area are discussed in Chapter II. There are some state-of-the-art, but expensive and sophisticated, watershed restoration techniques that will be occasionally used. These may include stabilizing landslide areas, installing check dams in steep drainage areas, and permanent and temporary water barring of road prisms. These activities are effective, but expensive techniques. They will be used on a case-by-case basis at the project level as determined by District personnel. A seriously damaged area will likely be repaired, regardless of watershed class, provided that repair is necessary to protect resource values, and funds are available.

Guides, steps, and recommendations to minimize the impacts of road construction on streams are available (Yee and Roelofs 1980, Sidle 1980, Amaranthus and others 1985). In addition, proper maintenance has been identified as an essential part of minimizing erosion and sedimentation from road surfaces (Sidle 1980, Lantz 1971).

Measures to control waste and drainage water from mines, and measures to impound mill tailings will be required, as will the installation of waterbars, culverts, and fords to prevent erosion of roadbeds and stream crossings. Except when required for mining purposes, avoidance of channels and floodplains of live streams will be required. If avoidance is impossible, appropriate reclamation will be required.

Proper control of chemicals and organic pollutants will be done in accordance with The Final Environmental Impact Statement for Managing Competing and Unwanted Vegetation, December 1988, and the Mediated Agreement.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Water

The City of Seattle

The Cedar River Watershed is managed under a 1962 Agreement between the Forest Service and the City of Seattle. The agreement provides for timber harvest on a sustained yield basis within the watershed. As National Forest lands have been cut, they have been exchanged to the City for City lands located elsewhere. On August 7, 1988, the Seattle City Council adopted Ordinance 114632, which embodies the new Secondary Use Policies for the Cedar River Watershed. The City will set aside approximately 50% of its lands in a reserve precluding timber harvest. They will prepare a long-range timber harvest plan for second-growth lands outside that reserve. In addition, the policies call for acquiring 4,000 - 6,000 acres of old-growth forest that are currently NFS lands, to be maintained as old-growth habitat. This ordinance may, in the future, cause the 1962 Agreement to be amended.

Under Alternative J (Preferred) this agreement would be renegotiated and, until a new agreement was developed, no new exchanges affecting national forest lands in the watershed would occur. Alternatives NC, A, I and H would continue with the 1962 agreement and lands would be harvested and exchanged. In Alternative B, all national forest lands would be retained and old growth stands kept. All national forest lands would be exchanged except for old growth stands in Alternatives C and G-Modified.

City of Tacoma

The Requirements for Protection of Water Supply in the Green River Watershed states that the policy of the City of Tacoma is to limit access to the Green River Municipal Watershed Area to persons who either live within its confines, or are employed in the area. Outdoor recreation is not considered a compatible use, and is not approved within the borders of the Green River Watershed on city lands. National Forest lands are open to recreation use, but access is limited to entrance from Stampede Pass at the east end of the watershed.

Alternatives B and I prohibit recreation use on National Forest lands except those authorized to participate in controlled hunts, and use of the Pacific Crest trail. All other alternatives provide for controlled recreation use on National Forest lands.

City of Everett

The objective of the Sultan River Basin Resource Management Plan is to provide a common framework to guide the desired activities of a variety of government agencies, having jurisdiction and interests in the basin, in a way which will allow maximum utilization of resources while preserving and maintaining the highest levels of water quality. The plan identifies a need for a management agreement (in the form of a memorandum of understanding). It also contains general management guidelines for the management of the timber resource in the basin.

Alternative C (closed watershed) conflicts with this plan. Alternatives B and I modify the current objective of consolidating National Forest land by maintaining ownership of isolated parcels of land within the watershed.

VEGETATIVE DIVERSITY

Diversity can not be described or tracked as a single number or index. In its broadest sense, diversity is the variety of life. To describe present and planned diversity on the Forest, we must have a manageable way to describe the variety of plant and animal species and biological processes. The elements of diversity include the viability, distribution and abundance of wildlife and plant populations; structure and composition of managed Forests; the role of agents such as fire and insects; long-term productivity; and the fragmentation of scarce community types.

The following section addresses the effects of alternatives on diversity of vegetation species and communities. A subsequent section addresses effects on wildlife diversity. See also the Soils and Fire section for effects on these elements of diversity.

Vegetative Diversity - The Direct Effects of Each Alternative

General

Management of vegetation for the production of goods and services, and natural succession results in constant changes in the abundance and distribution of plants and animals on the Forest (Odum 1971). Maintenance of biological diversity of vegetation is essential to the long-term goals of the Forest. The diversity of plant communities on the Forest has changed from historic times to current conditions, and all alternatives will have additional effects. Plant community diversity is affected both by the amount and kinds of habitats on the Forest, and by the amount and distribution of successional stages. As discussed in Chapter III, diversity elements include:

(1) viability, distribution, and abundance of plant populations; this includes maintaining viable populations of all threatened, endangered and sensitive plant species and not eliminating any species from an area;

(2) structure and composition of forest communities, including diversity of tree species, and numbers of horizontal layers of vegetation at the ground, shrub, understory tree and overstory tree levels, and;

(3) maintenance of longterm productivity, including maintenance of soil productivity, dead and down trees, and a duff layer; and

(4) fragmentation and reduction of scarce or fragile community types, such as old-growth, riparian communities, vegetation communities in cliff, cave and talus areas, and hardwood communities.

Regardless of the alternative considered, the ecosystem will continue to change. None of the alternatives are designed to return the Forest ecosystems to those of any previous time in history.

In the absence of fire or timber harvest, most plant communities will change toward "climax conditions", represented by species of vegetation that are able to survive and reproduce continually. Timber harvesting, fire, and other disturbances stop the successional trend, and move it back to an earlier stage.

All of the alternatives except Alternative NC are designed to meet legal requirements (36 CFR 219.27) for the preservation and enhancement of diversity of plant and animal communities to the extent practicable. Management requirements (Appendix H), management area category assignment, and Standards and Guidelines in Chapter 4 of the Forest Plan are tools for achieving legally mandated and socially desirable levels of protection of all species of plants and animals, while providing needed outputs of goods and services to the nation. (Refer to Chapter II, Table II-9(a-o) for the outputs of goods and services for all alternatives.)

Nearly all of the activities performed in managing the National Forest cause changes in the vegetation on the Forest. Some of these activities occur so infrequently, are so localized in nature, or affect such a small acreage that in the first decade, the effects are considered to be minor.

Direct Effects of Timber Harvest on Vegetative Diversity

Direct Effects Common to Alternatives. Timber harvest and the related timber management activities of site preparation, reforestation, stocking level control, fertilization, and intermediate harvest all affect vegetation. These activities have the greatest single effect on vegetation of any of the management activities conducted on the Forest.

Acres harvested in Decade 1 are a direct indicator of the magnitude of the effects of timber harvest on vegetation, by alternative. These effects include the cutting and removal from the forest of all trees that are of a merchantable size. Material that is not merchantable is either left on the ground as is, rearranged (chipping etc.), or relocated to a central area for disposal later, either as useable residue, cutting for fuelwood, or burning. Harvesting trees also affects the other vegetation in the harvest area; it is frequently damaged or destroyed during the removal of merchantable material. Some species of shrubs, forbs, and grasses cannot tolerate direct sunlight following removal of the overstory vegetation; these species will be replaced by more sun-tolerant plants.

During the first decade, timber harvest activities in all alternatives will occur in old growth stands varying from 100% of the acres harvested in Alternative NC for a high to 59% of the acreage harvested in Alternative A for a low; harvest will basically be accomplished utilizing even-aged silvicultural systems. Under all alternatives, total acres of remaining old growth will decline as a result of timber harvest. Acres harvested in old growth stands, by alternative, are shown in Table IV-8, below.

Each microsite that is cut will respond to changes in light, heat, and nutrients available, and each may respond with a different mix of grasses and forbs adapted to that site. When reforested, either by planting or natural regeneration, the seedlings introduced to the site overtop these grasses and forbs, thus changing the light, heat, and nutrient relationship. The plant successional sequence will then begin again. On suitable lands, this continues, over time, until the stand is harvested again, and the cycle begins again.

Table IV-8
Summary of Acres Harvested in Old Growth Stands (mature large) in the 1st Decade, by Alternative

Alternative	Total Acres Harvested 1st Decade	Old Growth 1/ Acres Harvested 1st Decade	% of Acres Harvested that Are Old Growth
NC (No Change)	42,000	42,400	100%
A (No Action)	40,684	23,841	59%
I	32,599	22,750	70%
B (RPA)	32,207	22,098	69%
H	30,416	20,673	68%
J (Preferred)	28,654	18,879	66%
C	18,734	11,548	63%
G-Modified	22,906	14,201	62%

1/ Old Growth based on mature large material only.

Following harvest and prior to reforestation, the cutover site will be prepared for planting or seeding, removing undesirable vegetation which would compete with the young tree seedlings and/or logging residue. The amount of site preparation is highly dependent on specific site needs and could vary substantially within an individual harvest unit. Site preparation methods may include broadcast burning as well as mechanical, manual, and chemical methods in accordance with the Final Environmental Impact Statement for Managing Competing and Unwanted Vegetation, December 1988, and the Mediated Agreement. Fewer acres will be broadcast burned over time. (Refer to the Direct Effects of Each Alternative on Soils.) Generally, less site preparation is done in the Pacific silver fir zone, as importance is placed on protecting seedlings already established prior to the timber harvest activities.

All harvested acres will be reforested through either natural or artificial means. If seedlings are planted, reforestation is generally done within 1 to 2 years after harvest; a three-year period is allowed in the timber yield tables, in case of poor seed years. If the area is to be naturally regenerated, reforestation occurs within four years, with a seven-year period allowed in the yield tables. All alternatives reforest at least 70% of the harvested areas artificially.

Where artificial reforestation is employed, species other than those planted will occur in the stands, both from seedlings remaining after harvesting and from natural seed sources. Most artificial reforestation activities match the species to the site, and in favor of those species which have the greatest growth and economic potential, usually Douglas fir, Pacific silver fir, noble fir, western hemlock, western red cedar and white pine. In some instances, an introduced species will be used; noble fir will be planted on specific sites on the Darrington and Mt. Baker Ranger Districts.

Stocking level control - pre-commercial thinning, release, etc. - will be practiced on some lands to increase the growth rates and/or control species

composition. Stocking level control is normally accomplished manually with the use of chainsaws. Chemicals, prescribed fire, or mechanical methods may also be used where practical. Excess trees may be of the same species or of lower value species than the crop trees. Normally coniferous trees are preferred over hardwood species, ie., alder, cottonwood, etc., because of their historically higher values.

By removing competing trees, the growth rate of the remaining "crop trees" will increase. Board foot gains from pre-commercial thinning vary by site anywhere from +6 to +66 percent (Reukema and Bruce 1977). This increase in growth rate allows the production of larger sized trees in a shorter period of time that are less susceptible to bark beetle infestation. Stocking level control maintains plants found in early successional stages for a longer period of time.

Because the diversity of managed forest stands is somewhat lower than the natural diversity of forest stands, one way to compare management alternatives is to compare the total number of acres on the Forest which will be subject to timber harvest. These acres allocated to management areas with some level of timber harvest are compared below.

Alternatives do not vary widely in the number of old-growth acres remaining at the end of the first decade, although a difference is clear over the longer term (e.g. five decades). The difference among alternatives at the end of the first decade lies more in the degree of fragmentation of old growth blocks, the distribution of old growth, and the acreage remaining at lower elevations. (See Old Growth, this chapter)

No federally-listed threatened or endangered vegetative plant species have been found to date on the Forest; sensitive plants which are known to occur or suspected to occur are discussed in Chapter III. Where these are found, policy requires that activities be modified to protect them, as needed to maintain viable populations. Refer to Chapter III, Vegetation, for information on individual species, and to the Forest Wide Standards and Guidelines in the Forest Plan. Because there is a lack of information on the habitat requirements of sensitive plant species, and inadequate information on their distributions and occurrence, the more ground-disturbing activities which occur, the more the risk of inadvertently having a detrimental impact on a listed species.

Alternatives. There are 1,723,500 acres on the Forest; 1,301,000 of which are forested. The potential for changing overall diversity of plant communities is based on the number of suitable acres in each alternative. Table IV-9, Acres Subject to Timber Harvest, By Alternative, displays forested acres subject and not subject to vegetative manipulation.

A review of the table indicates that Alternatives NC and A have the highest potential for changing the overall diversity of plant communities on the Forest. While Alternatives I, B, H and J (Preferred) have a moderate potential for change. Alternative C and G-Modified have the lowest potential of all to cause changes in overall diversity of plant communities.

Table IV-9
Acres Subject to Timber Harvest, By Alternative

Total Forested Acres = 1,301,100

Alternative	Forested Acres Available for Timber Harvest	Forested Acres Not Harvested
NC (No Change)	579,800 acres (45%)	721,300 acres (55%)
A (No Action)	412,508 acres (32%)	888,592 acres (68%)
I	386,512 acres (30%)	914,588 acres (70%)
B (RPA)	380,448 acres (29%)	920,652 acres (71%)
H	358,754 acres (28%)	944,346 acres (72%)
J (Preferred)	346,411 acres (27%)	954,689 acres (73%)
C	256,206 acres (20%)	1,044,894 acres (80%)
G-Modified	247,091 acres (19%)	1,054,009 acres (81%)

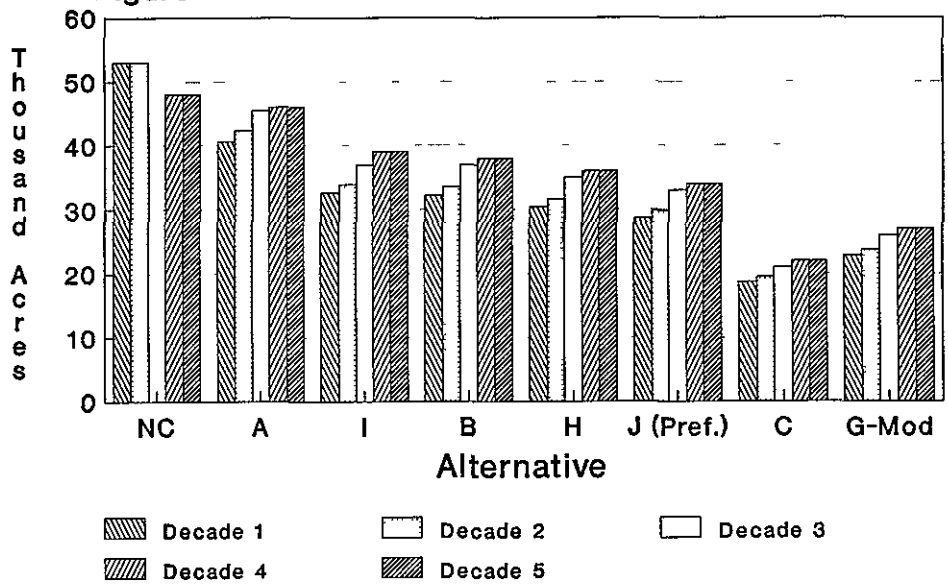
The potential for change varies from a high of 579,500 acres (45%) subject to harvest in NC to a low of 247,091 acres (19%) subject to harvest in Alternative G-Modified. Conversely Alternative G-Modified has the most acres 1,054,009 (81%) where no vegetative manipulation (harvest) will occur and Alternative NC will have the least number of forested acres 721,300 (55%).

Changes in plant communities are directly affected by the number of acres harvested and/or treated by some type of silvicultural practice. These types of treatments can take many different forms, but can be described as regeneration, reforestation and silvicultural treatments.

Regeneration harvest entails the removal of the existing stand of trees. This results in a change in plants from older larger ones to smaller younger ones. The more acres that are harvested, the greater the change. Alternatives NC and A have the greatest number of acres regenerated in the first decade and over the first five decades. Alternative I, B, H and J (Preferred) produce a mid level of timber harvest in the first decade varying from 3,260 acres per year in Alternative I to 2,865 acres per year in Alternative J (Preferred). These same alternatives fall in the same grouping over the first five decades. Alternatives C and G-Modified have the lowest number of acres regenerated in the first decade, 1,873 acres per year and 2,291 acres per year respectively and over the first five decades. A summary of acres final harvest can be found in Figure IV-3, Acres of Final Harvest.

With varying levels of harvest there will be varying degrees of risk of inadvertent loss of individual plant species, and of loss of distribution of sensitive or uncommon plant communities, such as alder riparian vegetation and lower elevation old-growth. There will be a high risk of loss in Alternative NC and A, a moderate risk of loss in Alternatives B, I, H, and J (Preferred) and a low risk in C and G-Modified.

Figure IV-3 Acres of Final Harvest



For Alternatives A, B, I, H, J (Preferred), C and G-Modified, management requirements would prevent losses of minimum levels of vegetation types and age classes. Riparian standards and guidelines would provide a fairly high level of protection to these areas. MR areas for mature and old-growth forest types (spotted owl, pine marten, and pileated woodpecker MR's) will maintain a network of old-growth set-asides, ranging from 160 acres to 2200 acres in size, over the Forest. Riparian MR requirements would maintain mature and old-growth riparian vegetation areas which would provide connections among other MR areas.

In Alternative NC, management requirements for prevention of serious environmental impacts are not applicable to this alternative. It can be inferred from this that there be significantly more risk of loss of individual plant species (including sensitive plant species) or communities, particularly those related to lower elevation old-growth forest types and riparian areas, than other alternatives. With this, there will be some loss of distribution over the Forest of older, coniferous and older riparian forest stands and undisturbed plant communities of all types. Forest-wide Standards and Guidelines would not be in-place to limit timber harvesting in riparian areas and to maintain long-term productivity of managed sites.

The level of regeneration harvest also determines the number of acres to be reforested in each alternative. Again NC and A will have the highest level of reforestation, Alternatives I, B, H, and J (Preferred) will have moderate level and C and G-Modified will have the lowest. Two types of regeneration will occur: artificial and natural. Better than 70% will be reforested using artificial means in all alternatives. Alternative NC will use artifiical methods 100% of the time. Alternatives I, B, H, J (Preferred) and G-Modified

will range from 72% (A) to 76% (B), and Alternative C will use artifiical methods 70% of the time. A summary of reforestation can be found in Table IV-10, Acres of Silvicultural Treatments, By Alternative, Decade 1.

Table IV-10
Acres of Silvicultural Treatment, By Alternative, Decade 1

Alternative	Treatment			
	....Reforestation.....		.....Thinning.....	
	Natural	Artificial	Precommercial	Commercial 1/
NC (No Change)	0	4,360	3,000	200
A (No Action)	1154	2,914	1,141	200
I	862	2,398	996	200
B (RPA)	772	2,449	989	200
H	835	2,207	1,005	200
J (Preferred)	781	2,084	996	200
C	569	1,304	615	123
G-Modified	607	1,684	873	175

Acreage receiving silvicultural treatment, precommercial and commercial thinning varies by alternative. Alternative NC has the highest level of precommercial thinning of all alternatives, 3000 acres per year followed by Alternatives A, H, I, J (Preferred), B, G-Modified and C, respectively. Alternative C has the lowest level of 615 acres per year, an 80% reduction from Alternative NC. Commercial thinning remains constant in Alternatives NC, A, B, I, H and J (Preferred) at approximately 200 acres per year. Alternatives G-Modified and C have fewer acres commercial thinned, 175 acres per year in G-Modified and 123 acres per year in C.

The reduction of older successional stages is proportional to the harvest of acres containing mature large sawtimber (old-growth.) Each of the alternatives have different acreages of old-growth available for harvest and enter them at different rates. By the end of the first decade, a pattern of old-growth harvest begins to emerge with Alternative NC having the most acres harvested 42,400 acres. Alternatives I, A, H, and J (Preferred) harvest from between 22,750 acres to 18,879 acres of old-growth. The lowest levels of old-growth harvest occur in Alternatives C and G-Modified where 11,548 acres and 14,201 acres are harvested, respectively. (See Table IV-8.)

This pattern continues through the fifth decade where almost all acres meeting the old growth definition will be harvested and converted to younger successional stages on suitable lands. The number of acres still meeting the old growth definition on suitable lands varies from 7,824 acres in Alternative G-Modified to a high of 33,134 acres in Alternative C. This does not represent the total old-growth remaining as more acres meeting the old growth definition are allocated to non timber prescriptions. When this is taken into account the number of acres of latter successional stages (old growth) remaining varies from 573,427 acres in Alternative C to a low of 431,538 acres in Alternative

NC. (See Table IV-11 for future information on old growth remaining through the first five decades.)

Table IV-11
Remaining Old Growth and Mature Acres by Alternative
on Total Acres and Suitable Acres

Alt		Decade	1	2	3	4	5

T = Total Acres mature large, 240 years of age or older.
S = Total acres mature large, 240+ yrs. on lands suitable for timber harvest.
*NC Based on Potential Yield Statement 1985 Final Harvest.
Alt. A-J Based on FORPLAN acres by age class.

Direct Effects of Integrated Pest Management (IPM) on Vegetative Diversity

Insect, disease, and animal damage control activities are minor programs on the Forest, and are usually performed on very localized areas. The control activities that do have an affect on vegetation, such as dwarf mistletoe control, are generally accomplished through timber harvest activities.

In some activities, such as recreation development, trail construction, wildlife habitat improvement, etc., the opportunity exists to introduce foreign vegetative species. The introduction of new species is generally short-lived, as the native natural plant species will out-compete them. However, there are

instances where, on a local basis, foreign species have thrived (tanzy ragwort is an example) and outcompete native species. In some cases, these species need to be controlled, under a noxious weed treatment plan.

Direct Effects of Wildlife Habitat Improvement on Vegetative Diversity

Habitat improvement is directed primarily toward deer, elk, and mountain goat. Its effect on vegetation primarily includes scheduling and locating timber harvest activities to achieve an optimum mix of forage, hiding, thermal, and optimal cover on winter range. This optimum mix results in mature timber stands on 37-45 percent of the winter range at all times, to provide optimal cover. These stands of trees are larger than would normally occur on areas managed for timber production. The optimal cover stands also have small natural openings where low-growing browse species of vegetation occur.

Projects to improve deer, elk, and especially mountain goat habitat may involve burning areas to provide more forage in the early plant successional stages. Other options include seeding, planting, and fertilizing grasses and shrubs, as well as timber harvest to improve forage and cover arrangement.

Alternatives NC and A have no assigned winter range improvement areas, although some habitat improvement would be done in compatible management areas in all alternatives. Refer to Chapter II, Table II-8, which shows the acres allocated to MA's 14 (Deer and Elk Winter Range, Improvement) and 15B (Mountain Goat, Habitat Improvement). Alternative B includes 106,632 acres and Alternative C includes 39,057 acres of assigned habitat improvement for deer, elk, and mountain goat. All other alternatives assign habitat improvement acres to deer and elk only: Alternative I, 106,632 acres; Alternative H, 34,239 acres; Alternative G-Modified, 26,622 acres; and Alternative J (Preferred), 33,587 acres.

Direct Effects of Fish and Riparian Habitat Improvement on Vegetative Diversity

Fish habitat improvements and associated maintenance activities, conducted along and within stream courses throughout the Forest, amount to small acreage. It is estimated that about 50 small (one acre or less) impoundments and about ten to twenty miles of streamsides will have some vegetative manipulation conducted on them over the next ten-year period. Seeding for deer, elk, and other species along streams may provide more shade, reduce stream temperatures, and increase streambank stability. Changing vegetation near streams (through prescribed fire or other methods) may affect fish habitat.

Direct Effects of Archaeological and Historic Properties on Vegetative Diversity

Protection of, and mitigation for cultural resources involves minimal manipulation of vegetation. Protection of an archaeological site or historic structure through avoidance may result in retention of vegetation, with current plant species remaining and natural processes continuing. This can include commercial timber species, otherwise suitable for timber harvest. Excavation of an archaeological site will result in removal of vegetation over a small, localized area. Usually the scale of disturbance is so low, that the effect is short-term.

Direct Effects of American Indian Religious and Cultural Use on Vegetative Diversity

Management of American Indian religious and cultural use sites have little effect on vegetation. The consultation process with affected tribes, prior to any proposed project, may result in deferring or relocating the activity, or mitigation measures to lessen the effect on the site. Experience to date has shown this has little effect on vegetation.

Direct Effects of Scenery on Vegetative Diversity

The only effects of scenic viewsheds on vegetation and timber from implementation of any of the alternatives is the reduction of management activities on suitable lands assigned to scenic viewshed. Activities will be extended over time, 200 years in foreground areas and 100 years in middleground areas, to meet visual objectives of an alternative. This will result in a retention and eventual mixing of plant species and successional stages in these areas. These changes, combined with forested areas which are excluded from harvest because of unsuitability, will result in a landscape which has all successional stages represented. Table IV-12 shows acres assigned to scenic viewsheds, by alternative.

Acres managed for foreground will retain a diversity of tree species and age classes; timber is managed at about 65 percent of full yield. In acres managed for middleground, timber harvest yield will be about 86 percent of full yield.

Table IV-12
Scenic Corridors - Thousand Acres

Alternatives	Foreground	Middleground
NC (No Change) 1/	NA	NA
A (No Action)	3.3	0.0
I	29.2	0.0
B (RPA)	4.0	0.0
H	24.6	81.5
J (Preferred)	23.4	85.8
C	65.7	57.5
G-Modified	9.5	0.0

1/ The TM Plan upon which Alternative No Change is based was developed in 1963. It was not an integrated resource plan, and consequently did not address all resource uses and outputs. The missing information cannot be reasonably estimated, since acres of retention and partial retention were not determined in the TM Plan.

Direct Effects of Recreation on Vegetative Diversity

Recreational improvements on the Forest such as campsites, picnic areas and trailheads currently occupy about 1855 acres or about 0.1 percent of the

Forest. Ski areas occupy about 6,335 acres or about 0.4 percent of the Forest. Some vegetation is more resistant to trampling than others, thus, as the more sensitive plants are eliminated, the mixture of vegetation will change over time within developed recreation sites.

The recreational activities and facilities on a developed site require space that would otherwise be occupied by vegetation. Consequently, establishing a developed recreation site results in the loss of a significant portion of the vegetation in that area.

Alternatives with the largest developed recreation site programs would have the most effect on vegetation on the actual site - a very small amount Forest-wide. Briefly, Alternative I proposes the largest program, followed by Alternatives C, H, J (Preferred), and A (NC would be similar to A). Alternatives B and G-Modified decrease emphasis on new developed site opportunities. The effects of ski area development on vegetation would be the same in all alternatives except Alternative I which allows expansion of Cystal Mountain beyond current permit boundaries. (Refer to the Direct Effects of Each Alternative on Recreation section of this chapter for more detailed information.)

The effects of dispersed recreation on vegetation are minor Forest-wide but can be measurable at localized high use sites. Dispersed campsite users may carve on trees, remove branches, and cut down standing trees. Campsite establishment and expansion in dispersed areas can result in denuded sites; depending on use level, vegetation may not return or the original species may be replaced by more hardy species. Social trails can proliferate from user campsites. Damage is more pronounced and slower to recover at higher elevations, where soils are shallower, and the growing season is shorter. The effects will be most noticeable in alternatives that assign the fewest acres to nonmotorized dispersed recreation: Alternatives A (NC is similar to A), B, and I. Alternatives G-Modified, C, and J (Preferred) provide the largest acreage of nonmotorized dispersed recreation.

Total RVD's for alternatives will be positively correlated with the likelihood of recreational uses affecting vegetation and possibly affecting threatened, endangered and sensitive plants. Alternatives I, A, B and H have the highest levels of RVD's.

Direct Effects of Trails on Vegetative Diversity

Development of trails, trail maintenance, and trail use may cause changes in or complete removal of vegetation, though the effects are much smaller in scope and size than those involved with construction of roads. Trail construction removes approximately one-half acre of vegetation per mile. Alternatives I,and G-Modified would construct 350 miles of new trails in the first decade; Alternative J (Preferred) constructs 220 miles; Alternative C, 178; Alternative H, 155 miles; Alternatives NC and A, 140 miles each; and Alternative B, 102 miles.

Direct Effects of Wilderness on Vegetative Diversity

Natural changes in the diversity of plants may have indirect, localized effects within wilderness. Any effects would be the same in all alternatives.

Direct Effects of Wild and Scenic Rivers on Vegetative Diversity

The recommendation for Wild and Scenic River designation for specific rivers affects the amount of timber harvested on any suitable lands within river corridors. Until Congressional action, the "outstanding remarkable" values of the eligible rivers must be protected. After designation, timber activities will be allowed in Scenic and Recreation classifications.

The degree of visual resource protection offered in the viewsheds adjacent to the rivers becomes the means to evaluate acceptable levels of timber activity. As a result of longer average rotations needed to meet the goal of these allocations, activities will be extended over time. This will result in a retention and eventual mixing of plant species and successional stages in these areas. These changes, combined with forested inclusions of unsuitable timber land, will result in a landscape which has all successional stages represented. Classification would add to the natural diversity of vegetation in river corridors, as larger, older trees are retained.

Alternatives NC, B, and I have no rivers recommended for designation. Alternative H recommends the North Fork of the Nooksack, the North and South Forks of the Skykomish, the Tye River, and the Middle Fork of the Snoqualmie as suitable for designation. These five rivers total 23,616 acres of National Forest land, encompassing one quarter mile on either side of each river. Alternatives C and G-Modified recommend 47 rivers as suitable for designation. Alternative C recommends 606 miles (193,920 acres) and G-Modified recommends 796 miles (254,720 acres). Alternative J (Preferred) recommends 452 miles on 30 rivers or 144,640 acres.

Direct Effects of Mining, Energy Development on Vegetative Diversity

Mineral and energy extraction can potentially change or completely remove vegetation through clearing for physical developments associated with these activities. Most exploration activities are currently conducted from the existing road system and have little or no affect on vegetation. Mineral extraction is extremely speculative. Due to current demand for minerals and the high costs associated with development, no mineral production is anticipated in any of the alternatives in the next decade. In the event that some development does occur, the Forest-wide mitigation measures state that an environmental analysis must be conducted to determine the stipulations needed to protect other resources. Efforts will be made to reclaim all sites. To date, little vegetative manipulation has taken place on mining claims on the Forest.

Geothermal, oil, and gas development have the potential for changing vegetative diversity, but no activity is predicted in the first decade.

Direct Effects of Land Uses on Vegetative Diversity

Land use grants and land exchanges are administrative activities that may have a direct effect on vegetation. The granting of a special-use permit may result in destruction of vegetation, such as clearing for a structure, but the acreage involved is generally small. Approximately one percent of the Forest is currently under special-use permit and this figure is not expected to change in any of the alternatives.

Land exchanges may result in changes in vegetation conditions on lands moving out of federal ownership. Changes will vary depending on the location and the new owner. It can be anticipated that most land exchanges will result in harvesting of timber and young stands on the area; in addition, private landowners are not required to meet Forest Service policy on endangered, threatened or sensitive plant species. Sizes of openings will also tend to be larger on private ownerships.

There are about 1500 acres in utility corridors, 0.09 percent of the Forest. The land occupied by the corridor is removed from production of commercial vegetation, though there is some production of Christmas trees. Diversity is affected as the vegetative characteristics are altered (through maintenance to remove unwanted vegetation) during the lifetime of the corridor. Vegetation maintenance would not vary by alternative. (Refer to Chapter III for a description of the maintenance program.) No construction of new corridors is anticipated during the first decade.

Direct Effects of Roads on Vegetative Diversity

Road construction activities are included in all alternatives and have direct effects on vegetation. Effects include removal of the land from vegetative production, plus subsequent management (removal, pruning, etc.) of the vegetation along the road corridor. An average of five acres of land is cleared for each mile of road constructed (a Forest-wide average). Table IV-13 shows the acres of vegetation removed in each alternative by road construction activities.

Table IV-13
Vegetation Removed By Road Construction - Acres

Alternatives	Decade 1	Decade 2	Decade 3
NC (No Change)	1400	1200	700
A (No Action)	940	850	540
I	855	760	465
B (RPA)	805	720	445
H	705	615	420
J (Preferred)	670	590	395
C	515	455	270
G-Modified	405	385	285

Land taken out of production ranges from 1400 acres in Decade 1 in Alternative NC, to 405 acres in G-Modified, with the other alternatives falling in between.

Road construction is greatest in Alternative NC. By the end of Decade 3, when all planned road construction is completed, about 3,330 acres of currently vegetated land will be roaded (0.2%). Alternative G-Modified, with the fewest miles of new road construction would affect approximately 1,075 acres of vegetation over the next three decades. Not reflected in Table IV-13 are the miles of existing roads that would be closed and revegetated: about 300 miles

in Alternative C, 20 miles in H, 65 miles in G-Mod., and 25 miles in J (Preferred).

In addition to arterial and collector road construction, temporary roads would be built to facilitate timber harvest activities. (Refer to Table IV-48 in the Roads section later in this chapter for the miles of local roads by alternative.) These roads are located primarily in timber harvest units; following harvest, the roads would be closed and the area revegetated.

Vegetative Diversity - The Cumulative Effects of the Alternatives

No quantitative analysis was completed to determine the cumulative effects of the alternatives on plants and plant communities. The Forest instead chose major indicators of diversity and developed quantitative and qualitative representations of these indicators. These include:

Protection of Riparian Areas
Habitat for mature and old-growth wildlife indicator species
Acres of old-growth
Dead and Defective Tree Habitat
Maintenance of Long-term productivity
Maintenance of all vegetative communities
Protection of fragile and uncommon habitat types
Maintenance of viable populations of all threatened, endangered, and sensitive plant and animal species.
Acres of Forest under timber management and acres in natural condition.
Maintenance of viable populations of mature and old-growth wildlife indicator species

These indicators have been addressed in the previous Soils and Direct Effects on Vegetative Diversity sections, and in the following Old Growth, Wildlife, Fish, and Fire sections. They are likely to be inadequate to describe biological diversity in total because current knowledge concerning all components necessary for maintenance of diversity is inadequate. There is mounting evidence that retaining all the pieces of the ecosystem is essential for long-term production of goods and services, as well as to life itself. All of the alternatives, except NC, are designed to provide legally mandated levels of diversity; therefore no significant, cumulative effects are predicted. Because of the uncertainty as to the requirements for maintaining all elements of diversity, the risk level of an alternative is likely to be related to the amount of lands on the Forest allocated to human uses and consumptive production.

Vegetative Diversity - The Indirect Effects on Other Resources

Discussions of indirect effects on the environment are complex and difficult to separate out; discussions within the Soils, Old Growth, Wildlife, Fish, Wilderness, and Fire sections of this chapter also address indirect effects relating to biological diversity.

Old Growth

See Direct Effects of Timber Harvest on Vegetative Diversity.

Wildlife

Changes in vegetation will have long-term effects on the habitats of many species. In areas of the Forest managed for timber production, the numbers of those animals that prefer a late successional or old-growth habitat will decline due to the decrease in this habitat over time.

Also affected are deer, elk, and mountain goat habitats. Major effects will be the changes that will occur in the cover/forage relationship, and the amount and quality of thermal cover. Clearcut harvest generally improves the quality and quantity of forage by creating openings in forest stands and initiating plant succession. Preferred forage is increased, but the area no longer provides thermal or hiding cover that may be essential. The effects would be magnified if large openings occur within winter range. Harvest may also impact migration routes (Harper 1969, Reynolds 1966, Swanson 1970), and remove habitat. Alternative NC and A would have the greatest change in vegetation while Alternative C and G-Modified have the least change in vegetative condition. The remainder of the alternatives fall in between. (See the Direct Effects of Timber Harvest on Wildlife, later in this chapter; also refer to Chapter III, Wildlife for additional discussion.

Fish

Changes in vegetation have the potential to severely affect anadromous or resident fish. However, in all alternatives, management requirements and mitigation measures will provide for maintaining at the MR level or improving current levels of habitat capability.

Human Community

There is no measurable effect.

American Indian Religious and Cultural Use

Changes in diversity of vegetation in any of the alternatives are not expected to have significant adverse effects on American Indian Treaty rights. (See the discussions of the Direct Effects of Timber Harvest on Wildlife and on Fish later in this chapter.)

There are effects on American Indian Religious and Cultural Use from changes in vegetation and timber. The effects of timber harvest on vegetation can be disturbing to religious use of spirit sites. The logged area has lost its purity, at least temporarily, and the purity and isolation of surrounding areas is reduced.

Cutting of cedar, particularly old-growth cedar, is perceived as irreparable destruction. All alternatives result in a substantial loss of cedar within the inventoried acres over five decades. Only Alternatives C and G-Modified will protect, over time, fifty percent of the cedar areas. Over the Forest, as a whole, Alternatives NC, A, I, and B will result in the most extensive removal of old growth cedar. Alternatives H and J (Preferred) will result in intermediate levels of removal.

Timber harvest will have localized effects on those ceremonial plants growing in the area. Clearcutting does increase the abundance of those seral species

used for ceremonial purposes; however, the religious suitability of seral species when gathered in clearcuts is diminished or destroyed. Alternative C protects, from timber harvest, the largest percentage of inventoried ceremonial plant areas, followed by Alternatives G-Modified, J (Preferred), and H. Alternatives NC, A, B and I allow the most harvesting in these flora areas.

Some changes in the diversity of plant communities may enhance cultural uses, such as gathering of foods and materials, or berry picking. These are normally enriched as old-growth successional stages are converted to younger stages through timber harvest. However, existing evidence indicates demand for such enhancement is limited or non-existent.

Archaeological and Historic Properties

Ground disturbance associated with vegetative manipulation has the potential to affect archaeological and historical properties. The more extensive the ground disturbance, the greater the effect on these properties. However, through the Forest-wide Standards and Guidelines and in compliance with law, cultural resource inventories implemented as a result of proposed timber sale projects have resulted in most of the findings on the Forest. To date, funding for cultural resource inventories has come mostly from timber sale funds. These compliance activities will produce archaeological and historical information for public interpretation.

Timber harvest is most extensive in Alternatives NC, A, I, and B. This will result in the greatest effects. Although fewer sites will be left undisturbed and in their original condition, more information may be available for interpretation. Impacts may also be sustained in areas managed for timber production in Alternatives H and J (Preferred). Alternatives C and G-Modified will result in the least amount of ground disturbance and the fewest number of losses.

Scenery

Changes in vegetation will have an appreciable effect on scenery in all alternatives as a result of vegetation manipulation. There will be both short- and long-term effects that will vary by alternative. The effects will be most visible on those lands with a timber management emphasis, as opposed to those that are managed primarily for other emphasis, but which still permit timber harvest. (Refer to the Direct Effects of Timber Harvest on Scenery, later in this chapter.)

Recreation

People staying at developed sites may find their daytime dispersed recreation precluded or altered by nearby timber harvest. The presence of, and intensity of trucks hauling logs by a campground will create noise and a potential safety hazard which may reduce the quality of the recreational experience. This may be offset by increased access. Consequently, alternatives that provide for a high level of timber harvest (NC, A, B, I, H) will indirectly affect and ultimately reduce dispersed recreation for developed site users. This will be true for most family summer camping experiences. However, this may not be the case for off-road vehicle use and for fall hunting, as these users are less affected by timber harvest activities (Clark and Stankey 1979). These impacts are minor in all alternatives.

Fall hunters seeking deer, elk, birds, and bear drive the road system hoping to spot quarry. The more numerous the cutting units (with resulting openings and food sources) the more likely they are of success. Alternatives that harvest higher amounts of timber (NC, A, B, I, and H) will increase the satisfaction of these groups.

The more extensive the timber harvest the greater the shift toward the roaded modified and roaded natural ROS classes.

Trails

Vegetative manipulation and associated timber management practices will affect trails primarily by changing the character of the recreational setting. Some trail users will be displaced during and for a period of time after the harvest activity (Anderson and Brown 1984, Clark and Stankey 1979). During the actual harvest or post-harvest site preparation activities, the trail prism is likely to be made impassable by felled timber; portions of the trail prism may actually be destroyed during yarding or other associated ground disturbing activities. This will require temporary closures, relocations, or reconstruction of effected trail segments.

Alternatives NC, A, B, and I would have the greatest effect on trails through timber harvest in Decade 1. The least impact would result from Alternatives C and G-Modified. The other alternatives impact a moderate amount of acreage in the first decade.

Wilderness

Effects are insignificant in all alternatives.

Research Natural Areas

No effects are expected from changes in vegetative plant diversity to Research Natural Areas. Timber harvest would preclude future designation of Perry Creek (200 acres) in Alternative B.

Roadless Areas

No effects.

Wild and Scenic Rivers

The more unique ecological value the more apt that the river will be considered for formal designation.

Air

The indirect effects on air quality caused by changes in vegetation are minimal. Living vegetation, through photosynthesis, converts carbon monoxide to carbon dioxide, a process important in maintaining life on earth. Vegetation manipulating practices included in this plan result in removing vegetation and replacing it with the same, or other vegetation. There is conflicting research evidence on what the effects on the photosynthetic process are when older forests are replaced by younger vegetation. Standards and

Guidelines ensure that the lands will be revegetated soon after vegetation is removed. Any alternative that includes management practices that converts lands containing living vegetation to other uses will have an impact on the rate of carbon monoxide/carbon dioxide exchange. All alternatives contain a limited amount of such conversion but the effects on local, regional or global scale are not measurable. All alternatives would have the same effect over time.

Fire

Modification to vegetation affects fire in a number of ways. Removal often changes the micro climate from a moist shaded condition to a more exposed drier situation which can increase intensity and rate of spread of fire. Likewise, most vegetation manipulation activities result in residue left on the area in the form of dead branches, stems, etc. These also contribute to fire intensity and spread. Standards and Guidelines, especially those that emphasize vegetation utilization or removal from the site tend to mitigate this situation. Though all alternatives include some vegetation modification and will affect fire potential, the low frequencies of fire starts from natural and accidental causes make the differences minimal in comparing alternatives.

Minerals

Threatened and Endangered plant species are protected by the Endangered Species Act. Mineral related activities that have the potential to impact these species or critical habitat would not be approved. This will be the same for all alternatives.

Land Ownership and Use

There are no measurable effects.

Roads

Changes in vegetation will have some minor effects on roads in all alternatives. Vegetation adjacent to roads will encroach on roads over time requiring control actions. Encroaching vegetation decreases sight distances as it grows taller on shoulders and cut/fill slopes. Control is needed when safety hazards result.

Vegetative management activities such as tree cutting, moving the logs to the landings adjacent to roads, and loading the logs on trucks causes damage to road cut and fill slopes, road surfacing, and drainage structures. The damage generally consists of displacement of soil and surfacing, culvert ends being crushed, and displacement of erosion control vegetation.

Snow plowing of roads will be needed to access some sites for planting in the spring. Access for reforestation activities may also require that some roads be built and maintained for use for one to two years after the timber sale harvest activities are completed. Alternatives NC, A, B, and I contain the greatest impacts in this area.

Mitigation Measures for Vegetative Diversity

To reduce the probability of introducing non-desirable foreign or off-site species of vegetation, additional mitigation measures may be employed. Where cut and fill slopes are treated for bank stabilization, a specific prescription will be developed identifying objectives, maintenance plans, and expected results, both short and long-term. In most cases, grasses and fertilizer are applied, providing for quick growth of the ground cover. This initial cover generally gives way to natural, on-site species of vegetation over time. To prevent long-term or unwanted weed species from being introduced, certified seed (known species of a given purity) will be requested. Similar processes will be followed for the implementation of other, similar activities (USDA 1979), including any type of erosion control measures on trails, transportation corridors, mineral exploration and extraction, and ski slopes as well as range, fisheries, or wildlife enhancement activities.

Other precautions will also be taken. A site specific evaluation and prescription will be made by a qualified professional (USDA 1985). Further, a literature review and/or research should validate that introduction of a specific species to a new environment will grow and flourish and reach the end objective for which it was introduced.

Mineral operating plans will include revegetation of sites.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Vegetation, Timber

An evaluation of the plans and policies of others indicates some potential conflicts between the effects of the alternatives on vegetative diversity and those plans.

County plans are generally compatible with National Forest management; however, as lands adjacent to the Forest are developed or managed for timber production, Forest Service management is affected. Wildlife species dependent on old-growth timber can be adversely affected. This would be most evident in Alternatives NC, A, B, and I which produce higher timber yields.

Skagit County, Eastern Planning District has a policy that recreational uses and areas should be encouraged in appropriate Forest areas, provided they do not conflict with or become burdensome to commercial timber operations. Alternatives C and G-Modified allocate a significant portion of the tentatively suitable forest lands to recreational uses.

Whatcom County Comprehensive Plan policy for forested lands is that timber should be regarded as the preferred use of these lands. Alternative C and G-Modified allocate significant portions of forested lands to non-timber uses.

Safety Standards for Logging Operations, State of Washington requires that "danger trees" be felled for safety. Often standing dead trees, and defective standing green trees which would be desirable to leave to meet dead and defective tree requirements, and to maintain long-term ecosystem productivity, conflict with this safety concern. All alternatives, except NC, include the retention of dead and standing green trees for wildlife habitat. Under all alternatives, timber harvest units will have to be planned so that dead and defective tree requirements can be met, while providing for worker safety.

Clumping of these retention snags and trees, choice of logging system, harvest unit design, and selection of safe trees to leave are all means to mitigate this conflict. The larger the amount of timber harvest in an alternative, the more frequently this conflict may arise. Also, concentrated of timber harvest in a smaller amount of suitable acres is likely to increase the risk of not meeting dead and defective tree requirements in those areas. Conversely, areas which do not have timber harvest will likely retain their often high, natural dead and defective tree levels.

Master Plan for Mt. Rainier National Park proposes that lands along the west and north boundaries have a primary objective of preservation. All alternatives, except C, permit some timber harvest activities adjacent to the Park boundary.

OLD GROWTH

Old Growth - The Direct Effects of Each Alternative

General

Issues of old-growth are very complex and occur on local, regional, and national levels. (Refer to Chapters II and III, for differing definitions and values of old growth.) Of concern are the amount and distribution of the stands remaining, questions about the possibility of replacing old growth in the future, and the long period of time it would take to grow replacement old growth. The amounts and distribution of natural, old-growth forest stands are the issues addressed in this section. (Refer to related discussions in this chapter on Soils, Vegetative Diversity, Wildlife, Fish, and Fire.)

There are 232,500 acres of mature and old-growth forest found within wilderness areas on the Forest and another 134,400 acres outside of wilderness which are unsuited for timber management. None of these areas will be altered by timber harvest under any alternative, although they may be affected by other activities, such as recreational use. In all of the alternatives other than Alternative NC, the total percentage of the Forest available for timber harvest varies from 19 percent to 32 percent. All of the alternatives would have 431,538 or more acres of old-growth remaining after the fifth decade.

This sets a framework for a discussion of the effects of alternatives on old-growth. There is a moderate difference in total remaining acres of old-growth on the Forest, but alternatives do vary in the amount of acreage which is assigned to management area categories other than wilderness and MR areas which will maintain older forest areas unharvested. They will harvest suitable timber areas at different rates. They will also produce different results in the way the remaining old-growth will be distributed over the Forest: the amount of low-elevation old-growth retained and the degree of fragmentation of remaining old-growth outside of reserved areas.

Direct Effects of Timber Harvest on Old Growth

Alternative NC places the highest number of acres of old-growth acres within management areas suitable for timber harvest, 232,509 acres. Alternatives A, B, and I have the next highest levels, 163,169; 157,826; and 157,660 acres, respectively. Alternatives H and J (Preferred) have moderate levels of old-growth in the suitable-for-timber harvest category, 145,778 and 140,817, respectively. Alternative G-Modified places the lowest number of old-growth acres in management categories which include timber harvest: 80,692 acres.

Table IV-11 in the Vegetative Diversity section, Figure IV-4, and Figure IV-5 show the amount of remaining old growth, both total and on lands suitable for timber harvest, for each alternative, in the first five decades. Under all alternatives, the amount of old-growth will decrease. The alternatives are not greatly different in the total amount of old-growth remaining through the first decade. Differences are more apparent starting with the second decade.

Alternative NC will result in the largest decrease in old-growth acres. It does not provide the network of MR old-growth areas. Old-growth will be both decreased and less well-distributed under this alternative than under any other. Remaining old-growth outside of reserved areas will become highly

Figure IV-4 Total Old Growth Remaining

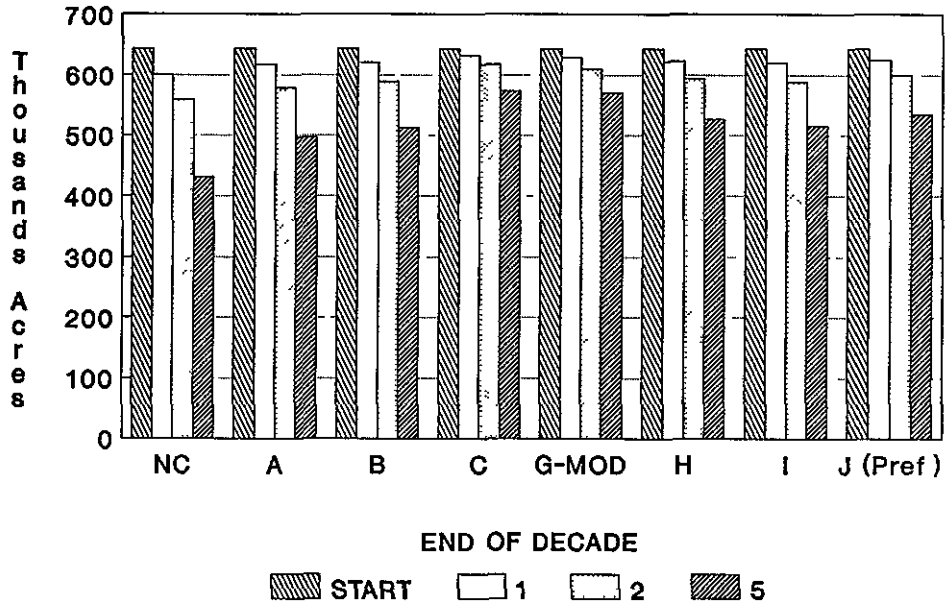

Figure IV-5 Old Growth Remaining (Suitable Acres)

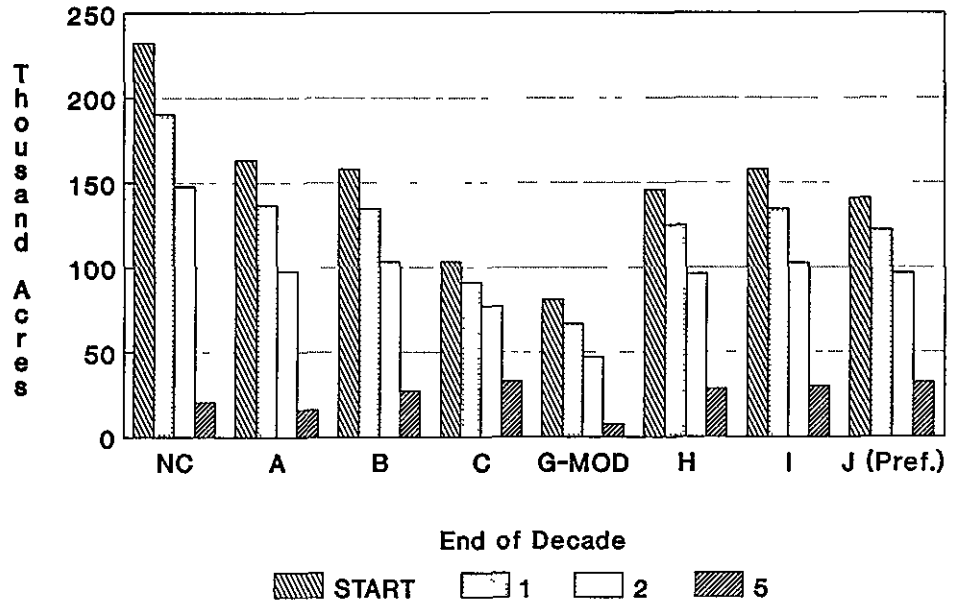

fragmented over time. Alternative NC has the highest rate of cutting old-growth in the early decades. With the highest number of old-growth acres categorized as suitable to start, it has the largest number of suitable old-growth acres remaining at the end of five decades. However, it has the lowest total amount of old-growth remaining of the range of alternatives.

Alternative A has the second-lowest amount of old-growth remaining. Because Management Requirements are included in this and the remaining alternatives, a network of MR spotted owl, pileated woodpecker, and marten areas, and mountain goat MR areas will remain untouched by timber harvest. This provides an amount and distribution of old-growth which is designed to maintain viable populations of old-growth dependent species. Riparian management areas will maintain corridors of mostly older forest between MR areas.

Alternatives B, H and I have similar amounts of remaining old-growth in the first and fifth decades and similar rates of harvesting. They are intermediate to other alternatives in both aspects.

Alternatives C, G-Modified , then J (Preferred) provide for the most retention of old-growth over time. In the first decade, C and G-Modified maintain more old-growth than J (Preferred). These three alternatives have the lowest rates of harvesting old-growth.

Alternative C and G-Modified concentrate old growth timber harvesting on 20% and 19%, respectively, of the Forest. This will allow the maintenance of more large, contiguous old-growth areas, but will highly fragment the areas where harvesting does occur. These alternatives will maintain the highest amount of ecologically effective old-growth, i.e. larger blocks of old growth. Alternatives A, H, I, and J (Preferred) allow timber harvest on 29%-32% of the Forest (See Table IV-8 in the Vegetative Diversity section), with amounts of fragmentation and maintaining old-growth blocks intermediate to those of Alternative NC and Alternatives C and G-Modified.

Alternatives also differ in the amount of old-growth which will be harvested at higher and lower elevations. Table IV-14 shows the number of acres that will be harvested above and below the 3000' elevation (in the Western Hemlock, Silver Fir, and Mountain Hemlock types), under the alternatives. Under all alternatives, most of these acres are old-growth acres and stands past maturity, with large-diameter trees. Table IV-15 displays the modeled amounts of final harvest of mature, large trees (over 21 inches in diameter; average diameter 32"), compared to the harvesting of mature, small trees (less than 21 inches in diameter).

Table IV-14. Mature, Large-sized Acres Harvested by Elevation Zones (In Thousands of Acres)

		Alternatives						
First Decade Timber Harvest								
Elevation	NC	A	I	B	H	J(Pref)	C	G-Mod
+3000 ft	N/A	7.9	9.0	8.8	8.1	7.2	5.2	5.1
-3000 ft	N/A	16.0	13.8	13.3	12.5	11.7	6.3	9.1
Five-decade Timber Harvest								
+3000 ft	N/A	43.3	48.0	47.1	42.1	36.1	23.3	23.1
-3000 ft	N/A	101.6	79.4	86.6	75.3	72.3	46.5	49.7

Table IV-15. Percentages of Timber Harvest Acres By Size and Age Class

	Alternatives							
	NC	A	I	B	H	J(Pref)	C	G-Mod
Mat. Lg. 1/	100	59	70	69	68	66	61	62
Mature Small 2/	0	12	14	14	14	14	13	14
Immature/Mature Small & Poles 3/	0	19	12	12	15	17	21	19
Hardwoods (all sizes)	0	5	3	3	3	3	3	5
Mature Lg/Sm Inaccessible	0	5	1	2	0	0	2	0

1/ Mature large stands are over 21" dbh; the average size is 26" in dbh with an average age of 246 years. Most of these acres are old growth.

2/ Mature small stands are less than 21" dbh; average size is 20" in dbh with an average age of 145 years. Most of these acres are old growth, at higher elevations.

3/ Immature/Mature Small-Pole stands are less than 21" dbh and can be old growth, mature, or younger; average size is 18" in dbh with an average age of 93 years. Most of these stands are mature or old growth.

Direct Effects of Integrated Pest Management (IPM) on Old Growth

Pest control or the lack thereof will affect the condition of old growth stands in any alternative. Major insect and/or disease epidemics have been centered in these stands in the past. It can be anticipated that this will occur again therefore, control activities may be needed to protect these stands as well as adjacent managed stands.

Alternatives C and G-Modified, with the most acres of old growth, will have the greatest risk of major epidemic and application of control measures. Conversely, the alternatives with the fewest acres of old growth, NC and A, will have the lowest risk of epidemics and control activities. However, control measures may be used in these low risk alternatives due to the value and investment of the managed stands.

Control activities will be conducted in accordance with Integrated Pest Management Guidelines, Forest Standard and Guidelines, and Management Objectives for each area.

Direct Effects of Mining, Energy Development on Old Growth

Mineral and energy extraction can potentially change or completely remove vegetation old growth through clearing for physical developments associated with these activities. Mineral extraction is extremely speculative. Due to current demand for minerals and the high costs associated with development, no mineral production is anticipated in any of the alternatives in the next decade. In the event that some development does occur, the Forest-wide mitigation measures state that an environmental analysis must be conducted to determine the stipulations needed to protect other resources. Efforts will be made to reclaim all sites. To date, little vegetative manipulation has taken place on mining claims on the Forest.

Direct Effects of Land Uses on Old Growth

Land use grants and land exchanges are administrative activities that may have a direct effect on old growth. The granting of a special use permit may result in destruction of old growth, such as clearing for a structure, but the acreage involved is generally small.

Land exchanges usually result in changes in vegetation conditions. Changes will vary depending on location and the objectives of the new owner. It can be anticipated that most land exchanges will result in harvesting of timber and young stands on the area; in addition, private landowners are not required to meet Forest Service policy on endangered, threatened or sensitive plant species. Sizes of openings will also tend to be larger on private ownerships.

It is anticipated that land use grants, land exchanges and special uses will be the same level in all alternatives.

Direct Effects of Roads on Old Growth

Road construction activities are included in all alternatives and have direct effects on old growth acres. Effects include removal of lands that can be classified as old growth. An average of five acres of land is cleared for each mile of road constructed.

The alternatives that harvest the greatest number of acres of old growth will also build the largest number of roads in and through old growth stands. It can be expected that Alternatives NC and A will have the largest number of roads built in old growth stands. Alternatives C and G-Modified will have the least number of road miles built in old growth stands with the remainder of the alternatives falling in-between.

Old Growth - The Cumulative Effects of the Alternatives

The cumulative effects of the alternatives on old growth are tied to the level of management activity. Timber harvest and road construction, both on and off the Forest, are the major activities that affect old growth. Land allocations, e.g. semi-primitive nonmotorized, nonmotorized recreation, mountain goat habitat, scenic viewsheds, etc., may preclude or lessen activity.

Alternatives such as C or G-Modified, which have high levels of acreage assigned to non-harvest prescriptions, will maintain the largest acreages of old growth and harvest the fewest acres. Alternatives such as NC and A have the fewest acres set aside and the largest number of old growth acres harvested, thus resulting in the fewest acres of old growth maintained through time.

Inventory data for old-growth are not available for private lands within and adjacent to the Forest. However, most of the large private, industrial land owners have indicated they intend to harvest nearly all of their old-growth within the next decade. Old-growth stands also occur in the Mt. Rainier and North Cascades National Parks, adjacent to the Forest. This old-growth will remain essentially as it is today, barring natural catastrophic effects.

The State of Washington Department of Natural Resources (DNR) manages 1.4 million acres of commercial forest land in western Washington. As of 1983, approximately 74,000 acres (5%) was considered to be old-growth (Washington State DNR 1983). Approximately 11,000 old-growth acres are not scheduled for harvest during the first decade of the DNR's Forest Land Management Program. A State Task Force, appointed by the Governor, is currently evaluating the issue of managing for some spotted owl habitat areas on DNR lands.

Old Growth - The Indirect Effects on Other Resources

Wildlife

Changes in old growth have long-term effects on the habitats of many species. In areas of the Forest managed for timber production, the numbers of animals that prefer a late successional or old growth habitat will decline due to the decrease in this habitat over time.

Also affected are deer, elk and mountain goat habitats. Major effects will be the changes that occur in the cover/forage relations and the quantity and quality of thermal cover. The alternatives that maintain large stands of old growth, C and G-Modified, provide more hiding and thermal cover. Alternatives that have higher harvest levels of old growth stands, such as NC, A and B, produce more forage.

Fish

Changes in old growth have the potential to severely affect anadromous or resident fish with the highest risks coming in Alternative NC and A, where the most old growth acres are harvested over the 50 year period. Alternative C and G-Modified have the lowest risk with the other alternatives falling in between. However, in all alternatives, management requirements and mitigation measures will provide for maintaining at the MR level or improving current levels of habitat capability.

Human Community

There are no measurable indirect effects of Old growth On the Human Community in any of the alternatives.

American Indian Religious and Cultural Use

Changes in old growth vegetation in any of the alternatives are not expected to have significant adverse effects on American Indian Treaty rights. (See the discussions of the Direct Effects of Timber Harvest on Wildlife and on Fish later in this chapter.)

There are effects on American Indian Religious and Cultural uses from changes in old growth. The effects of loss of old growth can be disturbing to religious use of spirit sites. The logged area has lost its purity, at least temporarily, and the purity and isolation of surrounding areas is reduced.

Cutting of cedar, particularly old growth cedar, is perceived as irreparable destruction. All alternatives result in a substantial loss of cedar within the inventoried acres over five decades. Only Alternatives C and G-Modified will protect, over time, fifty percent of the cedar areas. Over the forest as a whole, Alternatives NC, A, I and B will result in the most extensive removal of old growth cedar. Alternatives H and J (Preferred) will result in intermediate levels of removal.

Some changes in the number of acres in old growth plant communities may enhance cultural uses, such as gathering of foods and materials, or berry picking. These are normally enriched as old growth successional stages are converted to younger stages through timber harvest. However, existing evidence indicated demand for such enhancement is limited or non-existent.

Archaeological and Historic Properties

The maintenance of old growth stands will result in less properties being disturbed due to inactivity on the acres. It will also result in less sites being found because activities scheduled in old growth stands often result in their discovery.

Scenery

Changes in old growth will have an appreciable effect on scenery in all alternatives as a result of vegetation manipulation. There will be both short- and long-term effects that will vary by alternative. The effects will be most visible on those lands with a timber management emphasis, as opposed to those that are managed primarily for other emphasis, but which still permit timber

harvest. (Table IV-8 in the Vegetative Diversity section shows the acres of harvest per decade.) (Also refer to the Direct Effects of Timber Harvest on Scenery later in this chapter.)

Recreation

The maintenance or loss of old growth will affect those people who want to visit this type of vegetative stand. Alternatives C and G-Modified will provide the most acres while NC and A will provide the least.

Trails

There is no measurable effect.

Wilderness

Indirect effects are insignificant in all alternatives.

Research Natural Areas

No effects are expected from changes in Old Growth to Research Natural Areas. Timber harvest will preclude future designation of Perry Creek (200 acres) in Alternative B.

Roadless Areas

There are no know indirect effect on Roadless Areas from changes in Old Growth in any alternative.

Wild and Scenic Rivers

The more unique its ecological value, including old growth value, the more likely it is that a river will be formally designated as wild and/or scenic. Alternatives C and G-Modified retain the highest number of acres in an old growth condition; Alternatives NC and A have the fewest acres.

Air

The indirect effects on air quality caused by changes in old growth are minimal. Living vegetation, through photosynthesis, converts carbon monoxide to carbon dioxide, a process important in maintaining life on earth. Vegetation manipulating practices included in this plan result in removing old growth and replacing it with the same, or other vegetation. There is conflicting research evidence on what the effects on the photosynthetic process are when older forests are replaced by younger vegetation. Standards and Guidelines insure that the lands will be revegetated soon after vegetation is removed. Any alternative that includes management practices that convert lands containing living vegetation to other uses will have an impact on the rate of carbon monoxide/carbon dioxide exchange. All alternatives contain a limited amount of such conversion but the effects on local, regional or global scale are not measurable. All alternatives over time would have the same effect.

Fire

Modification to old growth vegetation affects fire in a number of ways. Removal often changes the micro climate from a moist shaded condition to a more exposed drier situation which can increase the intensity and rate of spread of fire. Likewise, most vegetation manipulation activities result in residue left on the area in the form of dead branches, stems, etc. These also contribute to fire intensity and spread. Standards and Guidelines, especially those that emphasize utilization, or removal from the site, tend to mitigate this situation. Though all alternatives include some modification of old growth and this will affect fire potential, the low frequencies of fire starts from natural and accidental causes make the differences minimal in comparing alternatives. All alternatives will have the same effect over time.

Minerals

There are no measurable indirect effects.

Land Ownership and Use

There are no measurable indirect effects.

Roads

There are no measurable indirect effects.

Mitigation Measures For Old Growth

All of the alternatives except Alternative NC are designed to meet legal requirements (36 CFR 219.27) for the preservation and enhancement of diversity of plant and animal communities to the extent practicable. A network of Management Requirement areas for old growth and mature species are distributed over the Forest under all alternatives except Alternative No Change. Wildlife management indicator species for these areas are the spotted owl, the pine marten, and the pileated woodpecker. This network consists of spotted owl areas (2,200 acres in size), pileated woodpecker areas (300 acres in size) and pine marten areas (160 acres in size). Information on these requirements can be found in Appendix I. In addition, riparian Standards and Guidelines will maintain mature and old growth stands in many areas adjacent to streams, which will provide corridors of older, connecting habitat between MR areas.

In addition, many more acres of old growth are maintained in wilderness areas and forested lands that are unsuitable for timber production. These acres are fixed for all alternatives. Additional acres are set aside via the designation of acres in which timber harvest is precluded. This varies with each alternative.

Conflicts Between Effect of the Alternatives and Others' Plans and Policies for Old Growth.

There are several plans in conflict with alternatives emphasizing timber harvest, thus indirectly affecting old growth habitat.

City of Seattle

The Cedar River Watershed is managed under a 1962 Agreement between the Forest Service and the City of Seattle. The agreement provides for timber harvest on a sustained yield basis (see Glossary) within the watershed. As National Forest lands have been cut, they have been exchanged to the City for City lands located elsewhere. On August 7, 1988, the Seattle City Council adopted Ordinance 114632, which embodies the new Secondary Use Policies for the Cedar River Watershed. The City will set aside approximately 50% of its lands in a reserve precluding timber harvest. They will prepare a long-range timber harvest plan for second-growth lands outside that reserve. In addition, the policies call for acquiring 4,000 - 6,000 acres of old-growth forest that are currently NFS lands, to be maintained as old-growth habitat. This ordinance may, in the future, cause the 1962 Agreement to be amended.

Under the Alternative J (Preferred) this agreement would be renegotiated and, until a new agreement was developed, no new exchanges affecting national forest lands in the watershed would occur. In addition, a SOHA (Management Area II) will be allocated within the watershed. Alternative G-Modified would result in more SOHA's and MR acres within the Cedar River Watershed. Alternative C would stipulate land exchange with two SOHA's intact; the City of Seattle would be required to maintain the SOHA's. Alternatives NC, A, I and H would continue with the 1962 Agreement, and all old growth acres would be harvested.

The State of Washington

Strategies for Washington's Wildlife (WDG 1982) contains a comprehensive strategy for the management of Washington's wildlife, game, and fisheries resources until 1995. It emphasizes habitat protection and improvement. Washington Department of Wildlife Program Plans gives population and animal harvest objectives for wildlife in 1989, lists key elements needed to meet these objectives, and shows the priorities for activity within the plan.

Strategies for Washington's Wildlife (WDG 1982) could be in conflict with Forest alternatives that emphasize timber harvest NC, A, B, and I, because of the land classification, harvest levels, and resulting loss of old growth. The same is true for the Wildlife Program Plans, Washington Department of Game.

Possible conflicts also exist with the Statewide Comprehensive Plan for Fish and Wildlife on the National Forests in the State of Washington. The primary goal of this Plan is to maintain and enhance existing fish and wildlife populations. Heavy timber harvest alternatives (NC, A, B, I) can result in unacceptable reduction in old growth habitat and thus reduction in old-growth dependent species.

WILDLIFE

The management objective for wildlife resources is to provide habitat capable of indefinitely supporting all native and desirable nonnative wildlife species. All alternatives, except the No Change Alternative, are designed to meet legal requirements (36 CFR 219.27) for the preservation and enhancement of diversity of plant and animal communities. The No Change Alternative does not fully incorporate the following provisions of NFMA:

36 CFR 219.19(a)(1),(2) and 219.27(a)(6) - Requires that wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species,

36 CFR 219.26, .27(a)(5), .27(g) - Requires that diversity of animal communities be provided and maintained.

Wildlife - The Direct Effects of Each Alternative

General

Land allocations affect wildlife populations. Alternatives that allocate relatively large amounts of land for preservation of specific wildlife resources result in the best long-term protection. Alternatives that allocate the most land to categories other than General Forest, especially those allocations with no timber harvest or with lengthened rotations of timber harvest, also result in the best protection of species requiring older forest successional stages. In areas of the Forest managed for timber production, the numbers of those animals that prefer a late successional or old-growth habitat will decline due to the decrease in this habitat over time.

In the absence of fire or timber harvest, most plant communities (and thereby animal communities) will change toward "climax conditions", represented by species of vegetation that are able to survive and reproduce continually. Timber harvesting, fire, and other disturbances basically reverse the successional trend, moving succession back to an earlier stage.

Management requirements (Appendix I), management area category assignment, and standards and guidelines are tools for achieving legally mandated and socially desirable levels of protection of all species of plants and animals, while providing needed outputs of goods and services to the nation. Refer to Table 2-7a for the outputs of goods and services for all alternatives.

Direct Effects of Timber Harvest on Wildlife

Table IV-16 shows the acres of old-growth and mature acres remaining in each decade, by alternative. Old growth habitat is reduced in all alternatives. According to Hall and others (1986b), regeneration harvest of old growth in Western Washington can be expected to displace or eliminate most of the 77 species that use a typical stand as primary breeding habitat, while gaining 28 new species in the grass-forb condition. Most of the displaced species will not return until plant succession on the unit reaches the large saw timber stand condition. Displacement or elimination of wildlife species would be the greatest in Alternatives NC, then A, followed by Alternatives I and B.

1/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs Habitat capability was calculated using the same models as used for other alternatives.

2/ For purposes of comparison, habitat capability for spotted owls was determined using the same model as used for other alternatives. However, direction in Alternative A is to manage for 84 sotted owl management areas of 1,000 acres in size and does not meet FSEIS requirements.

3/ Population numbers would be similar to those shown in Alternative A for Decade 1. Populations would be expected to decline at a rate faster than Alternative A because no specific provision is made in Alt. NC to maintain viable populations.

By the second decade, the loss of habitat which has already occurred and which will occur in the first decade is reflected in the population estimates for these species. The values are estimates of maximum habitat potential in each alternative. In Alternative NC, population numbers would be expected to be similar to Alternative A for the first decade, and then decline at a faster rate, because no specific provision is made in Alternative NC to maintain viable populations.

All alternatives, except Alternative NC, designate the same number and size of pileated woodpecker and pine marten habitats, to meet the MR's. All but NC and A have the SEIS network of spotted owl habitat areas. Differing amounts of additional habitat capability would derive from old growth and mature habitat habitat suitable for these species that is assigned to other compatible

management areas, such as wilderness and semi-primitive nonmotorized and suitable habitat in areas available for timber harvest, but which have not yet been harvested. For the first decade, population estimates for Alternative NC are expected to be similar to Alternative A; thereafter, they would decline at a faster rate, as no specific provisions are made to maintain viable wildlife populations in this alternative.

Alternatives provide for dead and defective tree habitat at the 20 percent (MR), 40 percent or 60 percent population levels on lands managed for timber production (Table IV-18). Areas not subject to timber harvest will generally maintain high levels of this habitat. These areas will support a varying number of primary cavity excavators, usually greater than what suitable timber lands will support.

Table IV-18

Percent of Potential Populations
of
Primary Cavity Excavators on Suitable Lands

NC	A	I	B	H	J	C	G-Modified
1/	40%	20%	20%	40%	40%	60%	20%

1/ Estimated to be similar to Alt. A for the first decade. No provisions made for cavity excavators

The viability of snags left in timber harvest areas varies. When timber stands are clearcut, snags and green trees designated for wildlife retention may be cut for safety reasons, or knocked over in the process of yarding logs. Older unmanaged stands, which usually containing many large snags, will be replaced with younger, intensively managed stands. Snags retained in clearcut units of the previous stands remain standing for 10 to 20 years, on the average, and then fall and become down logs. The young stands which have grown up around them will not produce large snags until decades later. To provide for "recruitment" of new snags during this interim period, green trees must be left at the time the stands are harvested, to become snags in later years. Timber yield tables have been adjusted to account for the decreased timber production as a result of leaving some trees unharvested.

Timber harvesting will have long-term effects on deer, elk, and mountain goat habitats. Major effects will be the changes that will occur in the cover/forage relationship, and the amount and quality of thermal cover.

Major effects on deer, elk and mountain goats will be brought about through changes in the abundances of forage and cover, and their proportions to one another, and particularly in the amount and quality of thermal cover. Clearcut harvest generally improves the quality and quantity of forage by creating openings in forest stands and initiating plant succession. Preferred forage is

increased, but the area no longer provides thermal or hiding cover that may be essential. The effects would be magnified if large openings occur within winter range. Harvest may also impact migration routes (Harper 1969, Reynolds 1966, Swanson 1970), and remove habitat. (Refer to Chapter III, Wildlife for additional discussion.)

Alternatives provide for significantly different levels of foraging habitat for deer and elk; provisions for optimal thermal cover for these species are generally reciprocal, that is, lower where open forage availability is higher.

All alternatives reduce thermal cover in winter range for big game species. Winter deer and elk habitat capabilities under the alternatives are shown in Table IV-19. These habitat capability numbers include the increases due to forage enhancement of timber harvest units in winter range. The amounts of winter range enhancement differ from one alternative to the next and are discussed in the subsequent section on Effects of Habitat Improvements. Increases in forage production in the first decade offset the decline in thermal cover, resulting in increased habitat capability (higher populations) for deer and elk. By the second decade, due to decreasing thermal cover, habitat capability returns to near-present levels (slightly below in some alternatives and slightly above in others. By the fifth decade, habitat capability increases, in Alternatives J, A, B, H and I, decreasing slightly in Alternatives C and G. However, the model used is primarily a forage-based model, and may overestimate the longterm capability for alternatives with high timber harvest and underestimate it for those with low timber harvest levels. See Appendix B for a discussion of the deer and elk winter range calculations.

Summer deer and elk habitat capabilities are shown in Table IV-20. In all alternatives, summer deer and elk habitat capability remains roughly at constant levels under all alternatives. These levels are higher than winter range habitat capability levels. Winter capability is probably a better predictor of the sustainable level of actual animal populations, since winter range is limiting to most populations of deer and elk on the Forest and off-Forest also. Few off-Forest winter range areas provide, or will continue to provide, adequate levels of optimal thermal cover for wintering deer and elk.

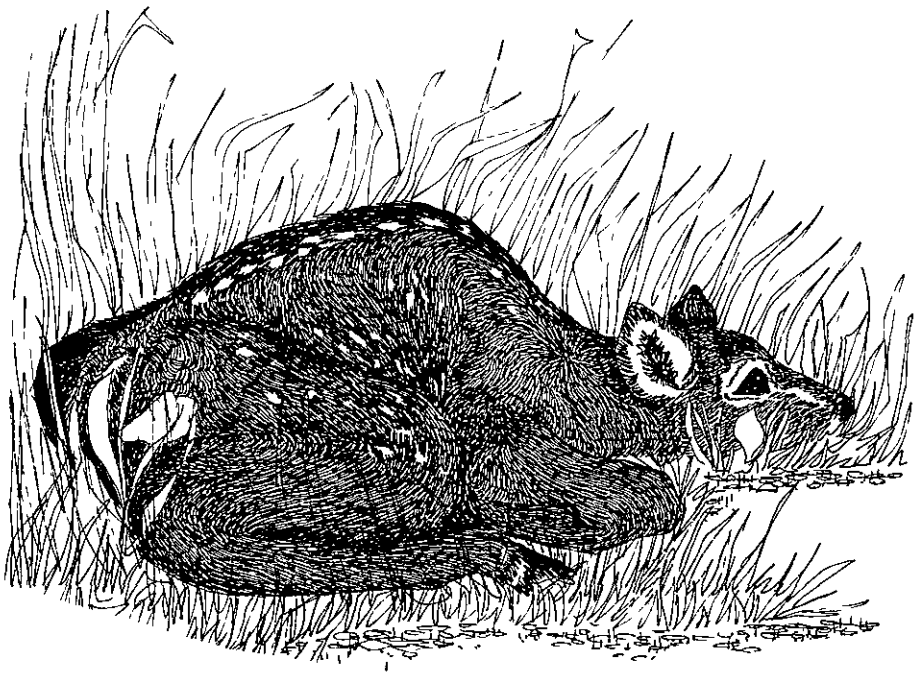

Table IV-19

Deer and Elk Winter Range Habitat Capability By Alternative

1/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. Populations would be expected to decline at a rate faster than Alternative A

Mountain goat habitat capability decreases in all alternatives (Table IV-21) due to the removal of thermal cover by timber harvest, although this decrease is much greater in Alternative A. This is a major limiting factor to the goat population. Although the areas of thermal cover that receive timber harvest are improved in terms of forage, this improvement can not replace the loss of thermal cover. Current populations numbers appear to be considerably lower than the current habitat capability. Disease; parasites; disturbance from vehicles on roads; human recreational activities; and over-harvesting, legally and illegally, all may be factors in keeping goat populations lower than they might be.

Table IV-21

Mountain Goat Habitat Capability

Alt	Start	1	2	3	4	5
NC	1/	-	-	-	-	-
A	1450	1430	1400	1380	1350	1330

G-Mod	1450	1450	1450	1450	1450	1450

1/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs. Populations would be expected to decline at a rate faster than Alternative A

Timber harvest also affects recreational uses of wildlife. Many wildlife species avoid areas of human activities. Forest users hunting, viewing and photographing wildlife may find their recreation precluded or altered at specific sites by nearby timber harvest. The presence of, and intensity of trucks hauling logs by a campground will create noise and a potential safety hazard which may reduce the quality of the recreational experience. However, these users can enjoy increased access, where that enhances or facilitates their activity. Alternatives that provide for a high level of timber harvest will affect these dispersed recreation opportunities the most. Fall hunting is less likely to be affected by timber harvest activities (Clark and Stankey 1979). These impacts are minor in all alternatives.

Some hunters seeking deer, elk, birds, and bear drive the road system hoping to spot quarry. The more numerous the cutting units (with resulting openings and food sources) the more likely they are of success. Alternatives that harvest higher amounts of timber will increase the success of these Forest users.

Direct Effects of Wildlife Habitat Improvement on Wildlife

Wildlife habitat improvement projects vary by the habitats to be enhanced. These projects are both structural and nonstructural in nature, and include, but are not limited to, creation of snags, osprey and loon nesting platforms, roost and nest boxes, burning, planting and seeding for forage production, and timber harvest to create optimum dispersion of habitat components.

Deer and elk winter range habitat in assigned and compatible management areas will be considered for timber harvest (thus improving forage) where it would benefit winter range habitat conditions. In addition, small units located adjacent to thermal cover, would be designed. Harvest would be limited to a maximum of approximately 6 percent per decade. The optimal ratio of forage, thermal/hiding cover, and optimal thermal cover is discussed in the Forest Plan, Management Prescription for Management Area 14, 15. Habitat improvement may be considered in the additional areas, depending on the standards and guidelines for those areas.

Table IV-22 shows the totals for acres assigned to habitat improvement in each alternative and additional acres in compatible MAC's which include winter range considerations in their standards and guidelines and which may be considered for habitat improvement when timber is harvested. These additional acres are lands of inventoried deer and elk winter range that are assigned to management areas compatible with habitat improvement. This table also show the actual number of acres on which timber is harvested in these MAC's managed for winter range in the first, second and fifth decades. These areas would be considered for forage enhancement.

Direct Effects of Recreation on Wildlife

Most of the effects on wildlife populations and habitat by recreational use and facilities are not major, but vary somewhat among uses and alternatives.

However, site-specific impacts, due to developed recreation sites, trail construction and use, or dispersed activities, such as ORV use or hunting, will have adverse effects on localized wildlife communities. Many wildlife species avoid areas of human activities.

Associated with developed recreation site maintenance in all alternatives is the removal of "hazard" trees, which are often large snags. This results in a reduction of habitat for species using old-growth forest or snags. Snag removal reduces cavity excavator density and diversity (Zarnowitz 1982).

Existing campgrounds are generally located within the low-elevation riparian areas that are also used by many species throughout the year, and by deer and elk as winter range. Any construction or reconstruction of developed sites physically removes some forage and cover; use of surrounding habitat may be affected by new or increased vehicular traffic.

Ski area expansion, in all alternatives except I, should have minor effects on big game habitat. Alternative I allows expansion of Crystal Mountain to the maximum skiable area and may affect mountain goats by removal of habitat and increased disturbance.

Table IV-22
Acres of Deer and Elk Winter Range In Management Areas Which Benefit Habitat and Acres of Forage Enhancement Per Decade, By Alternative

	Alternatives						
	NC 1/	A	I	B	H	J (Pref)	C	G-Mod
Deer & Elk Winter Range (WR) MAC acres	NA	0	106,632	158,824	34,239	33,587	39,057	26,623
Additional Acres In Compatible MAC's[2]	NA	113,098	118,038	94,647	222,487	245,960	241,706	85,943
Total Acres Managed for Deer/elk WR	NA	113,098	224,670	253,471	256,726	279,547	280,763	112,566
Timber Harvest WR Acres Available For Forage Enhancement[3]								
First Decade	NA	2,634	10,081	13,338	10,966	9,576	7,723	4,706
Second Decade	NA	1,548	6,903	8,566	7,308	7,378	8,615	8,088
Fifth Decade	NA	5,843	23,046	32,813	26,379	21,321	20,134	19,499

1/ The timber management plan upon which the No Change Alternative is based was developed in 1963. The plan was not anintegrated resource plan, and consequently did not address all resource uses and outputs. The information in this table was developed using the management *areas assigned in alternatives. No MA's are assigned in Alternative NC and the above* information cannot be reasonably estimated.

2/ Acres Suitable for Improvement are those deer and elk winter range or mountain goat habitat areas located in management areas that are compatible with habitat improvement, e.g. scenic, roaded natural dispersed recreation, etc.

3/ The total acres available for forage enhancement in a decade are the acres of Deer and Elk Winter Range MAC on which timber is harvested plus the acres of compatible MACs on which timber is harvested.

Alternatives NC, A, B, and I will create the highest level of conflict between wildlife and recreationists because of their emphasis on roaded modified and roaded natural recreation settings. These alternatives also provide moderate to high ORV use, and have the highest amount of road construction. The potential for disturbance is high, as these alternative provide more access and easier access to previously unroaded areas.

Although Alternative B emphasizes an increase in big-game numbers, the amount of road building, and high acreage in RN and RM creates a situation of potential conflict with wildlife.

Effects of Alternative J (Preferred) would be intermediate to those of A and C. Operation and expansion of developed recreation sites can result in change or loss of habitat, displacement or harassment of wildlife, change in wildlife species composition, and increased potential for conflicts between humans and wildlife (Thomas and others 1979a). In all alternatives, effects would be minor and very site specific. In the first decade, only limited construction occurs; any new construction to meet future demand would likely be extensions of existing sites.

The effects of dispersed recreation on wildlife are likely to be significant, since this Forest has a very high recreation use level. These effects are mainly associated with human disturbance and vehicular traffic. Effects can be great if dispersed activity occurs in or near specialized habitat or summer and winter ranges (Geist 1978, Lyon and others, 1985). The effects may also be significant in critical habitats for threatened and endangered species, and species which are sensitive to human disturbance or which do not mix well with humans (e.g. grizzly bear). The continuous use of roads and trails has a greater effect on deer, elk, and mountain goat than does the construction of such facilities.

Alternative C will likely produce the lowest level of conflict between dispersed recreationists and wildlife, because of the high levels of primitive and semi-primitive nonmotorized recreation, strict wilderness management, road closures, and low level of ORV use. Except for ORV use in the Kelly Butte area, Alternative G-Modified would be similar.

Direct Effects of Trails on Wildlife

The effects of trails on wildlife are significant in that trails are the primary access for humans into animal habitats. Trail access increases the exposure of wildlife to hunting and harassment.

Development of trails, trail maintenance, and trail use may cause changes or complete removal of vegetation, though the effects are much smaller in scope and size than those involved with construction of roads. Trail construction removes approximately one-half acre of vegetation per mile. Alternatives I and G-Modified would construct 350 miles of new trails in the first decade; Alternatives J (Preferred), 220 miles; Alternative H, 90 miles; Alternative A, 70 miles; Alternative B, 50 miles; and Alternative C, 90 miles.

Direct Effects of Fire on Wildlife

Direct interactions between fire and wildlife populations vary widely. While some evidence of vertebrate mortality has been reported, the most commonly held opinion is that vertebrates are rarely killed in fires. Instances of mortality are usually negligible, in terms of the population. Fire may set back the successional stage of the vegetation, making it suitable for a different set of wildlife species than were in the area previous to the fire. The immediate post-fire environment presents terrestrial wildlife with a sudden and drastic modification of habitat structure and local microclimates. Vegetation growth and change following fire make for a dynamic system of successional change, favoring different species through time.

Spot-fires can increase the incidence of dead and defective trees, which may enhance the habitat for those species which use or require cavities for nesting or decaying trees for feeding.

Interactions of fire with invertebrate populations may be short-term or long-term. Population levels may decrease because the individuals or their eggs are killed, or their food supply or shelter are diminished. In some cases, populations of invertebrates are attracted to heat, smoke or damaged trees, and actually increase following fire.

Direct Effects of Mining, Energy Development on Wildlife

Mining activity has had minor effects in the past and is not expected to increase noticeably in the future. The effects that mineral related activities have on wildlife include, but are not limited to, the disturbance of migration, mating, and birthing habits and habitats.

The impacts of any mining activity will generally be disturbance from vehicles and humans, rather than substantial loss of habitat. Alternatives that restrict the fewest acres from mineral exploration, B and I, potentially would affect deer, elk, and mountain goats the most. Alternatives with the most acres allocated to deer and elk winter range and goat MR will be less likely to have any effect on the species from energy or geothermal exploration and development. These include Alternatives B, C, H, J (Preferred) and G-Modified.

The consequences of energy and geothermal activities on old-growth and mature wildlife habitat will likely be minimal, as change or loss of habitat and human interactions are generally very localized. Impacts may be significant if mining activity occurs near, or removes nest sites. Alternatives with the most road access, such as NC, A, H, B, and I, are more likely to encourage these developments.

Areas allocated to Northern spotted owl, pileated woodpecker, or pine marten can be withdrawn from mineral entry. Mineral exploration is most likely in those alternatives that place the fewest acres in restrictive categories and have the most road access: NC, A, I, H, and B. Alternatives G-Modified and C place the most acres in restrictive allocations. Alternative J (Preferred) is intermediate.

Extraction of sand and gravel has historically occurred in habitat favored by small wildlife species, including riparian zones and talus slopes. The potential exists for habitat loss in these areas in all alternatives, especially Alternatives B and I, which have the fewest acres in prescriptions that restrict mineral exploration. Effects would likely be site specific. As discussed above, alternatives that provide the most road access are more likely to encourage energy and geothermal activities.

Mining activities, small hydropower projects, and other activities which alter or remove vegetation and bring in or increase human disturbance may adversely affect wildlife needs. Wildlife habitats may be modified and species distribution influenced. During mining activities, wildlife may be exposed to toxic substances used or uncovered in the mining process. Vehicle uses and human movements produce noise and other disturbance which may affect reproduction, feeding, migration, or other activities of wildlife.

Reclamation of such sites may replace forage and draw some wildlife back to these areas.

Direct Effects of Land Uses on Wildlife

Land exchanges may result in changes in vegetation conditions. The effects of Timber Harvest are discussed above.

Development of utility and transportation corridors has the same potential to affect various animals as does road construction (see below). Maintenance of existing utility corridors in a low grass and shrub vegetative stage precludes use of the area as thermal cover for deer and elk, but keeps the land available for intensive forage use.

A proposal exists for one new utility corridor to be located between Pyramid Peak and Tacoma Pass. Alternative G-Modified precludes this development; it is not expected that this facility would be built in the first decade in any other alternative.

Direct Effects of Roads on Wildlife

For all species, the consequences of road construction and use include: reduction of habitat, increased human interaction, temporal displacement of wildlife, and changes in numbers and species composition. Effects from collector and arterial roads to wildlife are more substantial, as they generally remain open permanently; local roads are often closed and rehabilitated or abandoned after timber harvest. Proposed new road locations may need to be altered in order to protect specific species.

Alternatives with the most lands remaining unroaded and the fewest concentrated human activities will be of the highest benefit to species which use large habitat areas and avoid human activities. Roads needed for access to timber harvest areas allow the public greater access to wildlife habitat. Although roads provide travelways for many species, roads which remain open may result in increased road mortality, disturbance of wildlife, causing them to avoid habitat areas near roads, and increased legal and illegal hunting mortality.

Direct effects of road construction include the removal of snags within 100 to 200 feet of roads, reducing snag habitat; creation of additional brushy habitat for species such as the pine marten; loss of other types of habitat; and increased interaction with humans. In Alternatives NC, A, B, H, I, where higher miles of new roads would be constructed, the effects of this activity will be the greatest. Alternatives C and G-Modified, combining permanent road closures and a low amount of road construction, will have the least potential effects.

The suitability of vegetative cover for wildlife is modified by the amount of roads open to and traveled by the public. The effectiveness of wildlife hiding cover is reduced by an increase in roads. Specific roads can be closed to protect wildlife travel corridors, hiding cover, or seasonally-used habitats. Permanently closed roads can be seeded to provide additional forage. Deer and elk use of otherwise suitable habitat is reduced adjacent to open primary and secondary roads (Brown 1985). New road construction results in the direct loss of habitat. Trails accessible to motorized vehicles can have the same effects.

Human activities, including vehicles on roads, displace wildlife from one area to another, moving them into territories of other individuals and increasing competition of space and forage (Brown 1985). Increased access has a short-term detrimental effect on some species, which adjust to human traffic, such as songbirds and squirrels. Other species, such as elk, bear, and cougar are likely to continue to avoid areas of human use.

Deer and elk avoid areas of human use (Lyon 1985). When roads are open and traveled, deer and elk densities are reduced. Animals remaining within the area expend more energy avoiding the intrusion and this can affect survival and reproduction. When a particular type of habitat is in short supply, reductions in quality are more detrimental.

Roads affect small mammals by removing cover which allows them to become prey to predators.

Any changes in the road system are not likely to cause significant changes in the Northern spotted owl, pileated woodpecker, pine marten, primary cavity excavators, or their habitats. Management prescriptions contained in the Forest Plan restrict new road location and construction in these areas.

Road construction is greatest in Alternative NC. By the end of Decade 3, when all planned arterial and collector road construction is completed, about 3,330 acres of currently vegetated land will be roaded (0.2% of the Forest). Alternative G-Modified, with the fewest miles of new road construction would affect approximately 1,075 acres of vegetation over the next three decades. Not reflected in Table IV-13 in the Vegetative Diversity section are the proposed miles of existing roads that would be closed and revegetated: about 300 miles in Alternative C, 65 miles in G-Modified, 20 miles in H, and 25 miles in J (Preferred).

In addition to arterial and collector road construction, temporary roads would be built to facilitate timber harvest activities. (Refer to Table IV-48 in the Roads section later in this chapter for the miles of local roads, by alternative.) These roads are located primarily in timber harvest units; following harvest, the roads would be closed and the area revegetated.

Wildlife - The Cumulative Effects of the Alternatives

The cumulative effects of the alternatives on wildlife are generally tied to the level of timber harvest and road construction both on and off the Forest.

With the exception of the National Parks, adjacent landowners are not required to retain old growth to provide habitat for old-growth dependant species. Much of the old growth in these ownerships has already been harvested and the rest is expected to be harvested in the near future. Viewed in this light, Alternatives B, H, I, NC, A have potentially the greatest cumulative effects, as there is substantial habitat modification involved. The modifications result in the loss of old-growth habitat over a large area and over a long period of time. As trees take approximately 200 years to grow to an overmature stage, mitigation is often not possible, although, some harvest methods may provide these "old-growth" characteristics in less time. Alternative J (Preferred) would have a moderate cumulative effect, and Alternatives C and

G-Modified the least amount of cumulative effects, when considering all factors discussed above.

Management of adjacent lands also effects the snag and downed log habitat. Much of the adjacent lands are managed more intensively than the National Forest, many have already been harvested and are largely devoid of snags. Slash disposal practices vary with ownership, so that some lands also lack downed logs. National Forest lands are the only lands where policy requires the retention of snags or management of viable levels of cavity excavators.

The cumulative effects of timber harvesting and forage enhancement activities on deer, elk and mountain goat habitat and populations are shown in Table II-9k of Chapter II. Summer populations rise slightly, while winter habitat and populations show an initial increase, decrease for a period of time, and then increase in the fifth decade.

Deer and elk often occupy ranges which include Forest lands in one season (typically summer) and off-Forest lands in other seasons. Population levels are determined by habitat conditions both on and off the Forest. Habitat conditions vary with different landowners. Except for the National Parks, adjacent lands have generally been heavily cut over and/or affected by growing urban/suburban development close to the Forest boundary in the last fifteen years. These lands lack optimal thermal cover for winter range. The distribution of cover and forage areas is poor on these lands because openings tend to be large.

On summer range this is not likely to be limiting, but high-quality winter habitat is becoming increasingly scarce off of the Forest. This increases the significance of the Forest's winter habitat.

There could be desirable cumulative effects on elk, deer and mountain goats resulting from management of a controlled watershed, where decreased significant human disturbance and reduction in vehicular traffic will result in almost total use of available habitat by the animals.

Wildlife - The Indirect Effects on Other Resources

Fish

Enhancement of riparian areas for wildlife may have a benefit for fish by providing future large woody debris and shading. Alternatives C, G-Modified and J (Preferred) would provide the highest levels of enhancement. Alternatives B, H and I would provide a moderate level, while Alternative A would provide the lowest level of habitat improvement. Alternative NC contains no habitat improvement.

Human Community

There is no measurable effect.

American Indian Religious and Cultural Uses

Wildlife habitat improvement has the potential to reduce the purity and wildness of the natural environment surrounding spirit quest sites. Winter range closures may temporarily restrict motorized access to spirit quest sites. Alternative B has 178,982 acres of allocated deer and elk winter range and goat habitat improvement; Alternative C, 42,097 acres; and Alternative H 34,239 acres. Alternatives NC, A, I, and G-Modified will have no assigned goat habitat improvement.

Archaeologic and Historic Properties

There is no measurable effect.

Scenery

There is no measurable effect.

Recreation

Changes in populations of deer, elk, and mountain goat can affect hunting, and indirectly influence local economies. Alternatives A, B, and I provide the most Wildlife and Fish User Days, followed by Alternatives Hand J. Alternatives C and G-Modified provide the fewest user days.

Wildlife habitat improvements and maintenance can affect the recreation experience by increasing the number of animals available for consumptive and non-consumptive uses. This effect is most important for users who enter the Forest to view or hunt wildlife.

Seasonal closures to recreational use (especially ORV's) may occur in areas managed for calving, fawning, and deer and elk winter range and goat habitat.

The effects of bald eagle habitat management on developed sites will not vary by alternative. In all cases developed site use will be modified to accommodate the eagles. For example, the Money Creek campground contains a number of large snags used by eagles for staging before flying off to roost at night. The snags will be retained and the campground will be closed in early fall, when the windy weather starts. In the long-term, Money Creek campground will be closed; the eagle staging area will be protected and all snags will be retained.

In other cases, if a nest is established early in the year, near or in a developed site, public use of the site will be curtailed until the young have fledged, usually in mid-August. These effects will be evaluated in the environmental analysis process conducted when nesting habitat management plans are established.

Trails

Wildlife should have no significant effects on trails. Indirectly, however the location of these improvements may be affected by the presence of, or the needs of, a particular species of bird or mammal. For example, the location of a bald eagle or northern spotted owl nest may affect the location of a trail.

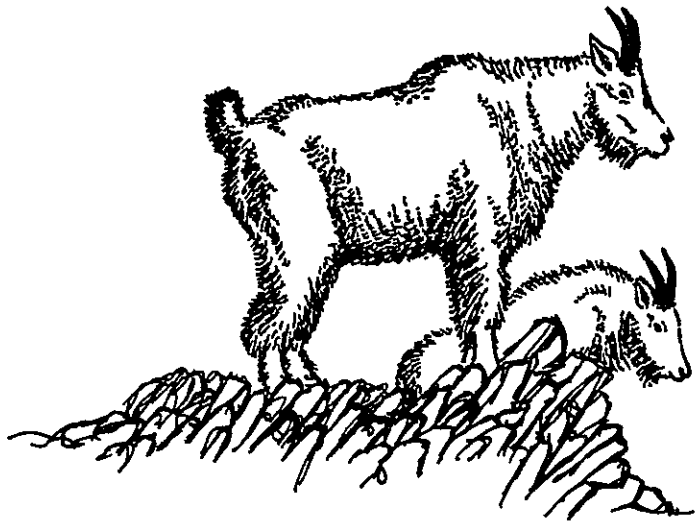
(See Direct Effects of Trails on Wildlife for more information on miles of trail by alternative.)

Wilderness

There is no measurable effect.

Research Natural Areas

There is no measurable effect.



Roadless Areas

There is no measurable effect.

Wild and Scenic Rivers

There is no measurable effect.

Air

There is no measurable effect.

Fire

There is no measurable effect.

Minerals

There is no measurable effect.

Land Ownership and Use

Wildlife should have no significant direct effects on utility corridors. Indirectly, however the location of these improvements may be affected by the presence of, or the needs of, a particular species of bird or mammal. For example, the location of a bald eagle or northern spotted owl nest may affect the location of a corridor. The potential utility corridor between Pyramid peak and Tacoma Pass will have to avoid SOHA's; this is the same in all alternatives.

Roads

Wildlife habitat management and improvement is expected to have an insignificant effect on the road system. However, wildlife management (in cooperation with the Washington State Department of Wildlife) may result in seasonal road closures during hunting and calving seasons. Additional closures may become necessary during other seasons in order to reduce animal harassment. The greatest effects would be seen in Alternatives NC, A, I, and B; the least, in Alternatives C and G-Modified.

Mitigation Measures for Wildlife

Most research on mitigation practices has been related to primary effects. Cumulative and secondary effects are more difficult to mitigate than are

primary effects since they usually affect wider geographic areas. Their impacts are more diffuse, and are therefore more difficult to define, and regulatory controls for wildlife are lacking or inconsistent among local jurisdictions. These three factors make it difficult for any one agency to fully protect wildlife resources at the local level (Comer 1984).

Mitigation and best management practices for fish and wildlife, described in the Forest-wide Standards and Guidelines and outlined in the last section of this chapter, are adequate to assure viable populations under any of the alternatives proposed, except Alternative NC, which makes no specific provisions to maintain viable populations.

The standard for open-road density for elk, deer, and mountain goat MR's is an average of two miles/square mile. The land manager has the option of restricting that to less than two miles if a conflicting situation might jeopardize a local viable population.

A timber harvest scheduling standard exists for the harvest intensity of the deer and elk winter range, and mountain goat habitat management areas. This standard should assure adequate acreage of optimum thermal cover on winter range, as well as optimum quality of thermal cover by providing an average of 160 to 200 year old trees (200 in mountain goat habitat).

Opportunities to protect specialized habitats, are provided for in the Forest-wide Standards and Guidelines, and specific management area prescriptions.

There are several specific measures that habitat managers can apply to maintain or improve bald eagle habitat. Nests are protected with a minimum quarter-mile radius buffer; the Forest-wide Standards and Guidelines and management area 16A prescription include other specific measures designed to protect known perching and roosting sites. There are other measures (some of which have not been proven but seem reasonable to institute in specific areas) for providing wintering birds with supplemental food, maintaining seclusion, and altering the shape, size and number of trees in use areas (Steenhof, 1978). Enhancing natural spawning populations of chum, Coho, and Chinook salmon in areas receiving bald eagle winter use would be an indirect benefit to eagles.

A study was initiated in 1985 to determine the effects of recreational activity on feeding and roosting eagles; it is a cooperative effort between the Forest Service and the U.S. Fish and Wildlife Service. If a substantial impact is found, mitigation measures will be developed to reduce these effects. Other human use next to winter use areas may be restricted by seasonal closures of roads, trails, or campgrounds. Signing critical habitat areas to discourage human activity may also be a suitable mitigation measure (Stalmaster, 1980).

Timber in potential or used habitat, may be topped, girdled, or partly limbed to maintain desired characteristics for perching, roosting or perhaps even nest trees (Stalmaster and others 1985).

Forest management practiced under all alternatives is compatible with maintaining and providing the eagle habitat. Regardless of the level of planned activity, the eagle will receive protection because of its threatened status.

In general, the Forest-wide Standards and Guidelines and Management Prescriptions provide adequate protection for selected forest management indicator species and their habitats at the MR level, except in Alternative NC (No Change), as discussed above. These habitats include: snags and dead and down woody debris habitats; riparian raptor nest sites; deer, elk and mountain goats ranges; and threatened and endangered species habitats.

Management Requirements for maintaining viable populations establish the least amount of mature and old growth forest to be retained. This is necessary to avoid losing species dependent on mature and old-growth forest. Old growth habitat lost to timber harvesting cannot be mitigated. If new silvicultural methods are established to harvest timber while providing for "old growth" characteristics at an earlier stand age these methods may be implemented as mitigation.

Mitigation for loss of snag habitat involves the retention of snags and future snags at various population levels between 20 and 80 percent biological potential of primary cavity excavators on lands suitable for timber production (except in Alternative NC). Nest boxes and the drilling of nest holes in trees replace habitat for some cavity-nesters. Down and woody material mitigation includes retention of slash piles and large woody debris throughout harvest units.

To assure habitat requirements are maintained for amphibians and reptiles as well as other ground-dwelling mammals and birds, it is desirable to specify a density of logs left per cutover acre; an example is 4 merchantable logs per acre in decomposition classes 1, 2, and 3, each having a volume of 40 cubic feet. See page 183 of Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington (Brown 1985).

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Wildlife

The Cedar River Watershed

The Cedar River Watershed is managed under a 1962 agreement between the Forest Service and the City of Seattle. The agreement provides for timber harvest on a sustained yield basis (see Glossary) within the watershed. As National Forest lands have been harvested, they have been exchanged to the City for City lands located outside the watershed. On August 7, 1989, the Seattle City Council adopted Ordinance 114632, which embodies the new Secondary Use Policies for the Cedar River Watershed. The City has set aside approximately 50 percent of its lands in a reserve precluding timber harvest. It will also prepare a long-range timber harvest plan for second-growth lands located outside the reserve. In addition, the policies call for acquiring 4,000-6,000 acres of old-growth forest, that are currently a part of the national forest, to be maintained as old-growth habitat. This ordinance may, in the future, cause the 1962 agreement to be amended. Under Alternative J (Preferred), this agreement would be renegotiated and, until a new agreement was developed, no new land exchanges would occur. In addition, a SOHA (Management Area 11) would be allocated within the watershed. Alternative G-Modified would result in more SOHA's and MR acres within the Cedar River Watershed. Alternative C would stipulate land exchange with two SOHA's intact; the City of Seattle would also be required to maintain the SOHA's.

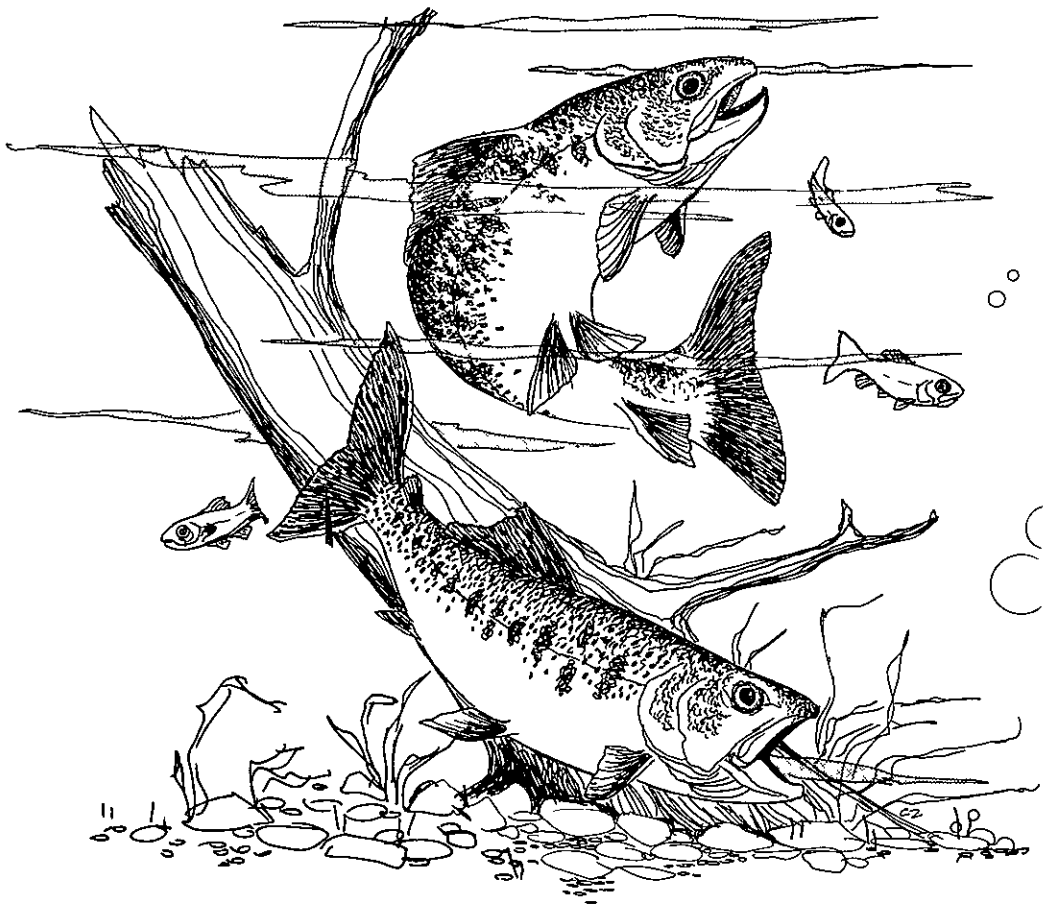
Other Plans

There are several plans in conflict with alternatives emphasizing timber harvest, thus indirectly affecting old-growth habitat and and dependent species.

Strategies for Washington's Wildlife (WDG 1982) could be in conflict with Forest alternatives that emphasize timber harvest because of land classification, harvest levels, and resulting loss of habitat. The same is true for the Wildlife Program Plans, Washington Department of Game.

Possible conflicts exist with the Statewide Comprehensive Plan for Fish and Wildlife on the National Forests in the State of Washington. The primary goal of this plan is to maintain and enhance existing fish and wildlife populations. Heavy timber harvest alternatives (NC, A, B, and I) could result in unacceptable reduction in old-growth habitat and thus reduction in old-growth dependent species.

Strategies for Washington's Wildlife (WDG 1982) contains a comprehensive strategy for the management of Washington's wildlife, game, and fisheries resources until 1995. It emphasizes habitat protection and improvement. Washington Department of Wildlife Program Plans gives population and animal harvest objectives for wildlife in 1989, lists key elements needed to meet these objectives, and shows the priorities for activity within the plan.



FISH

Fish - The Direct Effects of Each Alternative

General

The fish production capability of Forest fish habitats is directly dependent upon the protection and maintenance of riparian zone integrity, in-channel stability, stream bank stability, and desirable levels of pools and large organic debris in stream systems. Impacts upon these resources affect forest habitat capability to rear juvenile anadromous salmonids to the smolt stage and resident salmonids through the juvenile and adult stages. Furthermore, the anadromous salmonid life cycle involves both on- and-off-Forest habitats; from headwater streams to estuaries and the ocean. Any weak link within the cycle can have major influences upon a given fish population. Excess harvesting of fish, poor ocean food conditions, competition from hatchery stocks, and off-Forest land and water activities are potential impact factors beyond the Forest's control.

Management of salmonid fish habitat interacts significantly with nearly all other Forest resource management. By protecting, maintaining, or improving salmonid habitat capability and production, fish habitat objectives complement water quality goals and the desires of recreational, treaty, and non-treaty commercial fishing interests. Increasing numbers of the public enjoy fishing and the aesthetic values associated with fishing. But protecting, maintaining, and/or improving fish habitat can directly interfere or interact with the maximization of timber production capability, developed recreation plans, as well as road development plans and other special uses of the Forest aquatic systems. The ability of the Forest to rear resident trout and juvenile anadromous salmonids is directly related to how well both the aquatic and terrestrial habitat is managed.

The major effect of all alternatives on fish is a change in habitat condition. Viable populations of fish are maintained on the Forest in all alternatives; the amount of fish habitat capability to support and maintain fish populations above the viability level does vary by alternative. Viable populations of fish are defined as the current or existing levels of fish production across the Forest. The variation in alternatives is primarily a response to effects of forest management activities on key, in-channel and upslope conditions within stream systems, plus the emphasis on fish habitat restoration/improvement capital investment activities.

In general, alternatives displaying the least acres of final timber and associated road construction would protect and maintain fish and fish habitat values the most. Alternatives J (Preferred), C and G-Modified would afford the most protection, while alternatives NC, A, I, and B the least.

Direct Effects of Timber Harvest on Fish

Timber harvest and the associated road construction are the major management activities that affect the Forest's fish populations and their habitats. Based on Forest documentation and experience, the more acres of timber harvesting and the more miles of arterial and collector road construction, greater is the risk for adverse effects on fish habitat. Fish habitat components (in-channel stability, streambank stability, pool condition, and the presence and abundance

of large organic debris) are impacted by mass soil movement, surface soil erosion, and peak flow events that are triggered or influenced by harvest units and constructed roads.

In alternatives NC, A, I and B more acres are harvested and a high amount of roads are constructed, thus producing the highest annual sediment production for Decades 1 and 2. In addition, alternatives A, B and I show the highest levels of sediment and erosion relative to timber harvest and road construction during the first decade. (see Tables IV-1 and IV-3 in the Soils and Water section of this chapter.) The risk for adverse effects on fish and fish habitat is high in these alternatives.

Fish habitats face lesser risk of being impacted in alternatives with lower numbers of acres harvested and miles of road constructed, resulting in lesser amounts of sediment production (Alternatives H, J (Preferred), C, and G-Modified). Alternatives C and G-Modified generate the lowest levels of sediment due to management-caused erosion, while alternatives H and J (Preferred) generate moderate amounts of sediment from erosion relative to these activities.

Direct Effects of Wildlife Habitat Improvement on Fish.

Wildlife management emphasis areas generally affect fish and fish habitat in beneficial ways. Management Areas 11 (old growth habitat) and 12 (mature & old growth habitat) prohibit timber harvest and limit road and trail construction. Management Area 15 (Mt. Goat MR) prohibits timber harvest and road construction. The ecosystems in these areas are maintained and protected. This is beneficial to fish and fish habitat values. In addition, Management Area 14 (deer and elk winter range) contains a large number of acres located in the Forest's riparian areas. The Standards and Guidelines for managing deer and elk winter range in these riparian areas benefit fish and fish habitats.

Direct Effects of Fish and Riparian Habitat Improvement on Fish

Fish and fish habitat is one of the four riparian area-dependent resources. (See Management Area 13, Chapter II, FEIS.) In addition to the Forest-wide Standards and Guidelines for riparian protection, alternatives with high investment levels in MA 13 (Watershed, Wildlife, and Fisheries Emphasis in Riparian Areas) will best protect, maintain, and/or improve fish habitat. Alternatives J (Preferred), C, and G-Modified have high levels of capital investment for anadromous and resident fish habitat restoration and/or improvement. Alternatives B, H, and I provide high levels of investment for enhancement for anadromous fish only. Alternative A provides the management requirement level (MA 13A) for anadromous fish habitat restoration. Alternative NC has no provisions for fish habitat improvements.

Direct Effects of American Indian Religious and Cultural Use on Fish.

When religious and cultural use areas fall within riparian and wetland areas, fish and fish habitat will benefit. Alternative C would provide the most protection followed by G-Modified, J (Preferred), and H. Alternatives NC, A, B, and I would afford the least protection.

Direct Effects of Recreation on Fish.

The developed recreation intensities 3A (public sector sites), 3C (winter sports resorts), and 3D (private sector sites) have the potential to impact fish and fish habitat. These direct effects are usually very site specific; recreation impacts include alteration or modification of one or more of the key in-channel habitat components during construction or operation of a recreational site or facility, and the alteration of the natural characteristics of the riparian area. In addition, because they are located near aquatic systems, these developed recreational facilities may increase the potential for additional human harassment of some fish populations during critical life-cycle stages and increase the potential for human disturbance of fish habitat. Alternatives I, H, and J (Preferred) place high emphasis on developed recreation and would have higher potentials to affect fish and fish habitat. Alternative A would have the least effect, while alternatives B, C, and G-Modified would have moderate effects.

Direct Effects of Research Natural Areas on Fish.

Alternatives displaying the most acres designated as research natural areas would tend to increase the protection and maintenance of fish and fish habitat. Alternatives C, H, J (Preferred) and G-Modified would afford the most protection, while alternatives NC, A, I and B, the least protection provided by RNA's.

Direct Effects of Wild and Scenic Rivers on Fish.

One of the values qualifying for recommending a river for Wild and Scenic River designation is its fishery resource values. Alternatives displaying the greatest number of recommended wild and scenic rivers would afford the best protection and maintenance of the existing natural riparian area and fish habitats. Alternatives C and G-Modified afford the most protection (47 Rivers); Alternatives J (Preferred) (30 rivers) and A (15 rivers) afford the next level of protection; Alternative H with 5 rivers, and Alternatives B and I (0 rivers) afford the least protection.

Direct Effects of Air on Fish

The direct effect of air polluting chemicals and particulates resulting from the implementation of any of the alternatives would be minimal. A more likely impact is the indirect impact to habitat caused by changes in water quality. These impacts are described in a previous section of this chapter: Soil and Water. The impacts to water quality from the very low levels of chemical pollutants and suspended particulates is negligible and is the same for all alternatives.

The most likely sources of air quality related impacts on fish habitat are from outside of the Forest, and are not a function of the alternatives. The Federal Clean Air Act requires that proper consideration be given to fish and water impacts during the review process for new air pollution sources. The Standards and Guidelines reinforce this process.

Direct Effects of Roads on Fish

See previous discussion of Timber Harvest on Fish.

Fish - The Cumulative Effects of the Alternatives

On-and off-Forest management activities can cause cumulative effects on fish and fish habitat within the hydrologic boundary of a Forest watershed. One or more of the same types of management activities (e.g. more than one timber harvesting operation) and/or two or more different management activities (e.g. timber harvesting operation and a small hydro operation) within the same watershed, over time, are potential causes of cumulative effects to salmonid populations and their habitat. Any of these effects may be beneficial, adverse, or neutral in impacting fish and fish habitat.

Figure IV-2 in the Soil and Water section of this chapter displays major Forest management activities that can cause or trigger watershed and fish habitat cumulative effects. On this Forest, the major causes are timber harvesting and associated road building activities. Changes in the upslope conditions due to these management activities plus natural conditions lead to the transport of large amounts of water, sediment, and organic debris into stream channels. The major effects of this are changes in the stream channel and fish habitat conditions, including shifts in stream channel stability, changes in streambank stability, changes in pool/riffle complexity, and changes in the presence and abundance of large woody debris. These changes can occur in both the upper watershed area (first and second order channels) and in the lower watershed areas (third and fourth order channels). All of the third and fourth order channels are fish bearing channels; many of the Forest's second order channels also contain fish.

The past, present, and potential effects of the Forest's timber harvesting and road construction activities on the Forest's ability to protect and maintain a high level of fish habitat capability was assessed by the Forest through a hydrologic cumulative effects analysis process.

In this process, each Forest watershed was examined by a Interdisciplinary Team (composed of a fishery biologist, watershed specialist, geologist, forester, and engineer) to determine the present condition of four in-channel and fish habitat features. These were (1) stream channel stability (2) streambank stability (3) pool condition (4) presence or absence of large woody debris. These teams determined the overall channel and habitat conditions as acceptable or unacceptable by examining these four features. This was done by evaluating past harvesting and road construction records and by analyzing past stream channel conditions from stream survey data and aerial photos. Additional support information such as the soil resource inventory, landslide inventory, and flooding history files were also used. After the condition of a watershed was determined, (See Table IV-4), these teams derived a timber harvest level or activity that could be applied in that watershed over a 10 year period to either maintain or upgrade the watershed's condition. The results of this procedure are used to meet water quality and riparian MR's. The process and the resulting watershed assessments are covered in detail in Appendix H.

The Forest developed this process to address water quality and fish habitat cumulative effects because the existing processes and models were not applicable to or did not fit with the natural processes found in the watersheds on the Forest. For example, sediment models and recovery models used by other Forests in the Region were evaluated for use, but were found to be

inappropriate or inadequate for use on the Mt. Baker-Snoqualmie National Forest. None of these models incorporated how climatic factors, such as peak flow events, and upslope factors, such as mass wasting events, influence or affect in-channel factors, such as channel and bank stability, pool condition, and the supply of large woody debris, over space and time. Because of this, the Forest developed the process described in Appendix H.

Alternatives having a greater amount of acres harvested and roads constructed over the next four decades would have a higher potential for contributing to adverse fish and fish habitat cumulative effects (Alternatives NC, A, B, and I). These cumulative effects would include decreasing stream channel and streambank stability, loss of or lack of pools in providing habitat or channel structure, and the loss of, or displacement of, large woody debris from the channel. In addition, harvesting and/or road building in the riparian area reduces the recruitment of large wood into the channel network over time.

Alternatives C, G-Modified, and J (Preferred) would have less potential for cumulative effects because of the reduced acres harvested and roads constructed.

Fish - The Indirect Effects on Other Resources

Wildlife

Improvement of salmon spawning habitat should increase population levels and provide additional food for bald eagles and other fish and/or carrion eaters.

Human Community

Alternatives B, C, I, G-Modified, J (Preferred), and H, which provide for high levels of anadromous fish enhancement, will result in increased outputs for the Puget Sound fishery, and benefits to that sector of the economy.

American Indian Religious and Cultural Use

Fisheries habitat improvement structures can directly affect the natural and wild character of the streams. High levels of investment in fisheries habitat improvement in Alternatives A, H, J (Preferred), I, and B may conflict with spirit questing in some cases. This is less likely in Alternatives C and G-Modified due to restrictions on access and fewer potential habitat improvement locations. In sensitive areas, use of hand tools and proper timing of such construction can limit negative effects to religious use. However, habitat improvements will assure viable populations of fish needed to secure Treaty rights. Fish available to harvest would be most limited in Alternatives NC and A.

Archaeological and Historic Properties

There are no known indirect effects on Archaeological and Historic Properties from changes in fish and fish habitat in any of the alternatives.

Scenery

There are no known indirect effects on scenery from changes in fish and fish habitat in any of the alternatives.

Recreation

Changes in fish habitat improvements and maintenance can affect the recreation experience for all types of users by altering the number of fish available for viewing or catching. Effects from most alternatives are expected to be modest. In some cases, fish habitat improvements can be constructed in association with visitor interpretive facilities that explain the structures to the public. This type of facility would then increase the quality of the recreation experience for the forest visitor.

Trails

There are no known indirect effects on Trails from changes in Fish and fish habitat in any of the alternatives.

Wilderness

There are no known indirect effects on Wilderness from changes in Fish and fish habitat in any of the alternatives.

Research Natural Areas

There are no known indirect effects on Research Natural Areas from changes in Fish and fish habitat in any of the alternatives.

Roadless Areas

There are no known indirect effects on Roadless Areas from changes in Fish and fish habitat in any of the alternatives.

Wild and Scenic Rivers

The indirect effects are minor and not measurable.

Air

There are no known indirect effects on Air from changes in Fish and fish habitat in any of the alternatives.

Fire

There are no known indirect effects on Fire from changes in Fish and fish habitat in any of the alternatives.

Minerals

There is no measurable indirect effect on Minerals.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Fish and fish habitat in any of the alternatives.

Roads

Fish habitat improvements and maintenance will have little effect on the road system except where these activities take place upstream from road drainage structures. During periods of high flow, some of these fish habitat improvements, such as small logs and other devices used to form pools, could be expected to wash out, move downstream, and block culvert and bridge openings. The result would be damage to the road and an increase in sedimentation in nearby streams. Alternatives B and I propose the largest number of fish habitat improvements upstream from roads and will have the greatest potential for affecting the road system.

Fish projects may include the replacement and/or removal of culverts.

Mitigation Measures for Fish

Mitigation measures for fish and fish habitat include all mitigation measures for water, as discussed in an earlier section of this chapter. In addition, there are other mitigation measures applied specifically to fish and fish habitat. Management requirements in the Forest-wide Standards and Guidelines include: water quality and fish passage requirements for various levels of fish habitat capability; high water-temperature concerns; large organic (woody) debris recruitment; bed load movement; stream channel and bank stability; other water quality parameters (ph, dissolved oxygen, heavy metals); and adequate flows. (Refer to the mitigation measures applicable to each Management Area, in Chapter II.)

Habitat work in upper channels would include installation of log-check dams and/or rock dams as energy dissipaters and sediment collectors. Streambank areas will be planted and seeded to help stabilize eroded sections. The overall mitigation strategy in these upper channel areas of watersheds is to maintain and increase sufficient amounts of structural components to provide channel and bank stability. Examples of this strategy can be found in portions of the Deer Creek watershed, and in Canyon Creek, a major sub-basin in the North Fork Nooksack River. In both of these watersheds, the Forest has begun to implement multi-year watershed rehabilitation-improvement plans to correct and mitigate upper channel areas impacted by a combination of natural events and past management practices.

Habitat channel work in lower channel areas would include installation of large structures (wood, native rock, or concrete) in the channels to restore or improve spawning and/or rearing habitat quality and quantity to re-create pools, or to improve pool quality increase stream channel and bank stability by deflecting or diverting stream-flow away from unstable, eroding bank sections. Examples of these structures providing high quality spawning, rearing, and adult rearing habitat can be found in the following watersheds: Canyon Creek & portions of the N.F. Nooksack River tributaries, S.F. Stillaguamish River tributaries, N.F. Skykomish River, Beckler River, Foss River, Miller River, Upper Green River, Greenwater River, Huckleberry Creek and the West Fork of the White River. Structures have been installed in these systems over the past nine years, and evidence and documentation demonstrates that these structures are effective in providing high quality habitat for salmon and trout juveniles and adults.

Other habitat work in lower channel areas can include improving or enhancing off-channel juvenile salmon and trout habitat by constructing either rearing channels or rearing ponds. These sites are designed to provide protected areas where fish can imprint, rear, or seek sanctuary from high flow or flood conditions in main channels. Examples of successful off-channel or pond construction include sites within the N.F. Nooksack River, the Suiattle and Sauk Rivers, S.F. Stillaguamish River, and in Huckleberry Creek.

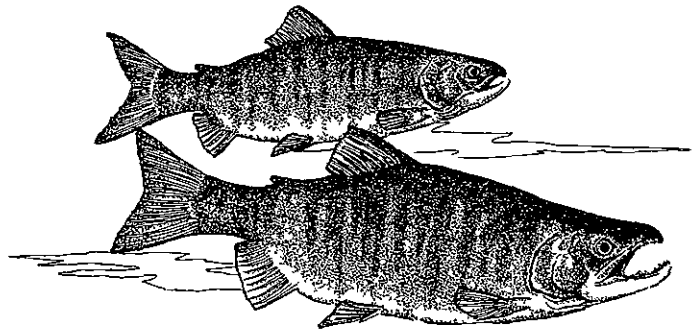
Where important fish habitat has been lost or displaced, additional mitigation will be required. This may involve restoring passage to previously accessible habitat, or restoring past spawning areas capable of producing fish. Other measures could include rehabilitating lost or reduced fish-rearing areas. These are covered in detail in the various fish-riparian management area prescriptions, found in Chapter II and Appendix D of the FEIS, and in the Forest Plan document.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Fish

The State of Washington Department of Fisheries and Department of Wildlife both have in place, or in the development stage, management plans or programs for managing the anadromous and resident fish populations in the State. The Wildlife Department's Strategies for Washington's Wildlife (1982) contains a comprehensive program for habitat protection and improvement of the State's fishery resource values. This program details population and harvest objectives for game fish populations in 1989, and lists and prioritizes key elements needed to complete these objectives.

The Department of Fisheries is finalizing salmon management strategies by major river basins in the State. The river basins that will emphasize natural over artificial production of salmon including the following Puget Sound basin rivers: Skagit River and all its tributaries, the Stillaguamish River Basin, and the Snohomish River Basin. In order to achieve such an emphasis of natural production of salmon, a comprehensive program of habitat protection, restoration, and improvement will be required.

Alternative NC does not meet the MR level for anadromous fish. Both these alternatives would conflict with State Management plans. All other alternatives make significant investments in habitat protection, restoration, and improvement, resulting in higher populations of anadromous fish consistent with these state plans.



HUMAN COMMUNITY

Human Community - The Direct Effects of Each Alternative

General

The economic impacts, estimated using the Implan IO model and 1982 coefficients (see Appendix B, Chapter IV, Human Community), expressed by changes in area employment and income that would result from the implementation of alternative management plans, are shown in the Table IV-23. Alternative A (No Action) approximates the existing condition. For comparison, the jobs and income supported by average annual Forest outputs for two earlier periods are also shown. Alternative A in the first decade would support 1000-1300 fewer jobs than the 1977-88 or the 1985-88 periods. Alternative NC (No Change) would support 200-500 fewer jobs.

Table IV-23
Employment and Income, By Alternative

Outputs/Effects	Unit of Measure	NC 1/ (No Chg.)	A (No Act.)	I	B (RPA)	H	J (Pref)	C	G-Mod.
Jobs Supported by the Alts. Decade 1	Thousands of Jobs Per Year	30.1	29 3	29 1	29.1	28.9	28 8	28.0	28.4
For Comparison:		30.6 Thousand Jobs Supported by 1985-88 Average Forest Outputs							
For Comparison:		30.3 Thousand Jobs Supported by 1977-88 Average Forest Outputs							
Income Based On Projected Outputs for Alts. Decade 1	Mil.1982$ Per Year	559	537	532	531	526	522	501	512
For Comparison:		572 - Income Based on 1985-88 Average Forest Outputs							
For Comparison:		565 - Income Based on 1977-88 Average Forest Outputs							

1/ The Timber Management Plan upon which the No Change Alternative is based was developed in 1963. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs Alternative NC was not modeled in FORPLAN; information in this table was calculated outside of FORPLAN.

The economies of the five-county area of influence are among the most important in the State of Washington. The area is highly urbanized, the economies are diversified, and they constitute a large portion of the statewide economy. For these reasons, the Mt. Baker-Snoqualmie's contribution to the overall area economy is relatively small. Both directly and indirectly, the Forest generates only about three percent of the area's total employment, and just two percent of the area's total income (1982 data).

The effects, therefore, in either employment or income generated from the implementation of any of the alternatives will, at most, only decrease the total area employment and/or income by about 0.2 percent.

Even though the potential economic impacts in the form of employment and income, as shown in Table IV-23, reveal that alternatives which produce commodity based outputs will tend to have more positive impacts on the area's economy, it must be kept in mind that the input-output model used to derive figures is an accounting device. No attempt has been made in the above table, to value non-market attributes (such as those emphasized in Alternatives such as C and G-Modified) or to determine where employment gains or losses will occur.

Land allocation and resource management decisions affect people and communities in a variety of ways and through a variety of channels. An economic impact analysis can only reveal the "best" alternative if the goals of individuals, communities, or special groups are closely specified. Moreover, the conclusions drawn from the economic impacts are bound by the assumptions of the input-output models. Although these assumptions in general do not reduce the usefulness of the analysis, it is important to remember that the model and its outputs should not be applied mechanically.

As shown in Chapter II, Table II-9n, the dollars returned to the counties vary by alternative. The payments to counties in the first decade will be at levels experienced in the middle 1980's. In later decades they rise, as both ASQ levels and real prices increase.

Alternative A will vary the least from the current situation, being just slightly under a 10-year average of about $6.1 million in payments to the five counties. Alternative C will contribute the least - only $2,600,000 per year, or about $3.3 million less than Alternative A. This would affect King and Pierce Counties less than Whatcom, Snohomish, and Skagit Counties (the former have larger, more diverse economies and less National Forest land.) Alternative G-Modified will return about $3,800,000 per year to the counties. Both Alternatives H and J (Preferred) will return about $1 million less than Alternative A, while the others will return about $500,000 less that A. Alternative NC (No Change) would contribute almost 60 percent more than A.

The alternatives will have a direct effect on minorities and women through job opportunities, primarily jobs generated in the five-county area by Forest outputs (timber, recreation, fish, etc.) and expenditures.

Forest Service policies encourage employment and contracting opportunities for all. These policies will continue under any alternative, but the number of agency contracts will vary. Compared to the present, more contracts would probably be available under Alternatives NC and A. All others, especially C and G-Modified, would provide fewer contracts.

In the first decade, there will likely be no effects in any alternative on urban quality.

As the Puget Sound area is the largest, most diverse, and most urbanized in the Pacific Northwest, the effects of implementing any alternative are somewhat muted. Those groups and individuals who work in forest products, who live very near or within the Forest boundary, or who recreate in the Mt. Baker-Snoqualmie National Forest may be affected. Thousands of others in the greater Puget Sound region will not be impacted, one way or the other, by any alternative.

The spread of knowledge, technology, and new values has shifted the metropolitan part of the Puget Sound area away from an economy based on resource extraction to one based more on diversified manufacturing, trade, finance, tourism, and government. This same shift is now beginning to take place in the more rural portions of the area. The shift from resource extraction to services tends to place increasing emphasis on public goods such as developed and undeveloped recreation resources, clean air and water, and preservation of scenery (Bradshaw and Blakely 1979). This will not vary by alternative.

In the future, in all alternatives, the decline of the traditional rural community is expected to continue, though overall population will increase. The changing local population composition, including greater numbers of people over age 65, a diverse regional economic base, and growth of regional industrial areas is likely to change the occupational patterns and value structures of many smaller towns.

As this occurs, traditional lifestyles in the smaller rural communities will be more and more challenged by new, more urban values and lifestyles. The Forest can expect to see increasing demands for recreation-oriented outputs and increasing challenge to ground and vegetation disturbing management activities. The rate of change can be expected to be faster in towns closer to the metropolitan area, including Sedro Woolley, North Bend, and Enumclaw. Those towns further away, such as Darrington, will experience this change more slowly.

The diversity and quality of the developed and dispersed recreation program will have a noticeable impact on the quality of life enjoyed in communities in the Puget Sound basin. The Mt. Baker-Snoqualmie National Forest provides a recreation ground for the major population concentrations of both Washington and British Columbia. The Forest is the major supplier of several recreational opportunities, including alpine skiing and primitive and semi-primitive non-motorized uses. Outdoor activity is a vital part of the area's reputation and quality of life.

No effects specific to consumers, civil rights, minority groups, and women are expected from changes in the recreation program.

Direct Effects of Recreation on the Human Community

The size of recreation programs can have a real impact on the economy of small communities adjacent to National Forests. Communities like Glacier and Marblemount might qualify as recreation-dependent communities because their economies are largely based on tourism associated with federal lands.

Heavy use caused by the success of sites such as ski areas or lakeside resorts may generate special problems. These include large areas needed for parking, heavy traffic flow, law enforcement problems, and impacts on local communities. In short, these developed recreation areas create communities of several thousand people often without the benefits of needed community support services.

Ski areas, in particular, may have significant effects on the local economy. A service industry catering to skiers typically occurs on private lands leading to ski areas. As local logging becomes less significant, small rural

communities typically tend to depend more heavily on recreation for support. Consequently, developed sites can significantly affect local economies.

Developed site camping, by its nature, requires some specialized equipment, including campers, trailers, and tents. The manufacture, sale, and services of these products is a significant industry, employing many people in the area.

Motorized vehicle use can affect local economies indirectly through the sale of motorized vehicles and equipment, restaurants and motel use, and purchase of ORV permits. It can affect the state economy through license fees, gas taxes, and sno-park permits. It supports small business income and employment.

Alternatives that encourage high levels of recreation activity, either dispersed or developed, will result in the largest contribution to this segment of local and regional economies. Alternatives C and G-Modified would encourage the most dispersed unroaded recreation activity. Alternatives A, I and B emphasize dispersed roaded recreation, with less emphasis on unroaded dispersed recreation. Alternative I also encourages high levels of developed recreation. Alternative NC would be similar to A. Alternative G-Modified offers one area of ORV emphasis (Kelly Butte), but unroaded dispersed recreation is emphasized elsewhere. Alternative H would provide moderate developed and dispersed recreation. Alternative J (Preferred) would provide high levels of developed recreation opportunities and would emphasize unroaded recreation a little more and roaded recreation a little less than Alternative H.

Direct Effects of Wild and Scenic Rivers on the Human Community

Wild and Scenic Rivers contribute many amenity values. Alternative G-Modified has the largest allocation with 796 miles. Alternative A protects 287 miles. Alternative C recommends 606 miles, while Alternative H recommends 154 miles. No miles are recommended in Alternatives NC, B, and I. The Preferred Alternative J (Preferred) recommends 452 miles.

Direct Effects of Mining, Energy Development on the Human Community

The economic effects of minerals are unquantified because the timing of their development and the quantities that will be extracted are highly speculative. The Forest does have mineral resources, which if developed, could contribute significantly to the local economy - and less significantly to the regional and national economies. This contribution would be in the form of rental fees, royalty fees, salaries of employees, etc. However, future development will depend on outside influences, and, therefore, these effects will probably not vary appreciably by alternative. It can be assumed, however, that as the acres assigned to "highly" restrictive management areas increase, the potential for minerals to contribute to the economy decreases.

Direct Effects of Roads on the Human Community

The effects of road construction would have little if any measurable effect on the economy of any community within the Puget Sound area. Local jobs may be affected; this would vary by alternative. During the first decade, Alternative NC will construct the most miles each year: 28.6 miles. Alternative A would construct 18.8 miles per year in the first decade. In Alternative C, 10.3

miles would be built per year, and Alternative G-Modified would construct the fewest roads, 8.1 miles.

Human Community - The Cumulative Effects of the Alternatives

There are only minor measurable cumulative effects, primarily in terms of the employment and income changes discussed above.

Human Community - The Indirect Effects on Other Resources

AMERICAN INDIAN RELIGIOUS AND CULTURAL USE

American Indian Religious and Cultural Use - The Direct Effects of Each Alternative

General

There are five categories of sites, as mapped and described in the 1981 Forest Inventory (Blukis Onat and Hollenbeck 1981): spirit quest sites, legend sites, cedar areas, ceremonial flora areas, and archaeological sites and cemeteries. Archaeological sites and cemeteries are addressed under Archaeological and Historical Properties, the next section of this chapter.

Table IV-24, below, shows the percent of inventoried use areas, by type of site, that will receive moderate to high protection in each alternative. Cemeteries will receive 100 percent protection in all alternatives; they are not discussed below.

High protection areas include lands where no timber harvest or road construction will occur and where expected frequency of human contact is low. Such lands include wilderness (except the transition class), research natural areas, old growth and mature wildlife habitat areas, and primitive recreation areas. Moderate protection areas include lands where no timber harvest or road construction will occur but where human encounters are more likely: semi-primitive nonmotorized recreation, wilderness (transition areas), threatened and endangered species habitat, and municipal watersheds where no timber harvest occurs.

Table IV-24
Inventoried American Indian Religious and Cultural Use Areas
Receiving High to Moderate Protection - Percent

Type of Site	NC (No Cng)	A (No Ac)	I	B (RPA)	H	J (Pref)	C	G (Mod)
Spirit Quest	NA 1/	40%	46%	50%	56%	59%	66%	65%
Legend Site	NA	18	32	44	51	57	68	65
Cedar Areas	NA	23	29	33	35	35	50	54
Ceremonial Flora	NA	52	57	63	70	71	82	81

1/ The TM Plan upon which Alternative NC (No Change) is based was developed in 1963. It was not an integrated resource plan and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated because the data was developed by overlaying inventoried use sites and areas with MA's; MA's were not assigned in Alternative NC.

Alternatives C and G-Modified allocate the most acres to some level of protection for American Indian religious and cultural uses. Alternatives NC, A, I and B allocate the least acres to protection.

While approximately 447,500 acres (excluding cemeteries) were identified as sites and areas important for religious and cultural practices, the 1981 Inventory stressed that religious and cultural significance was not limited to the identified areas. In other words, additional areas, yet to be specifically identified, may contain the environmental conditions suitable for religious practices and use. In the following discussion, the effects of the alternatives on lands inventoried as use sites and areas will be supplemented by estimates of the effects of the alternatives on the forested lands with environmental characteristics deemed important by local tribes.

These characteristics include unmodified streams, old-growth forest, cedar, ceremonial plants, and, for some practitioners, the additional qualities of isolation, privacy, and purity of the environment. Wilderness and unroaded areas come the closest to approaching most of these qualities.

Direct Effects of Timber Harvest on American Indian Religious and Cultural Use

Changes in diversity of vegetation in any of the alternatives are not expected to have significant effects on American Indian treaty rights. (See preceding discussions in the Wildlife and Fish sections of this chapter.)

There may be effects on American Indian religious and cultural uses from timber harvest. Consultation with Indian tribes about the effects of proposed activities would continue under any alternative. This consultation identifies where conflicts may exist. In some cases, modification of a proposed project will occur to the degree requested; in other cases, it will not be possible. In those situations, the environmental setting will be changed to the point that value as a religious or cultural use area will be reduced or lost. Such situations will be most common in Alternatives NC and A and least common in C and G-Modified.

The effects of timber harvest can be disturbing to religious use of spirit sites. Logging and ground disturbance provide conspicuous evidence of secular or commercial activities. The logged area has lost its purity, and the purity and isolation of surrounding areas is reduced. Cutting of cedar and old growth forest is perceived as irreparable destruction. Other forestry practices (site preparation, reforestation) contribute to further loss of the natural conditions of the environment.

Cedar is used for a variety of purposes and is an important component of the environmental setting for religious practices and uses. Old-growth cedar is used for canoes and longhouses. Not just old-growth cedar is important; when cedar is of "saw log" size (or about 17" DBH), its bark is most suitable for gathering and use in baskets and other items. Cedar of a variety of age classes from old-growth to saw-log size is more valuable than cedar of smaller sizes.

Through the consultation process, it appears that the importance of isolation, privacy, and purity in cedar gathering areas is somewhat less than that required for spirit quest sites, but may still be important. The following

discussion is limited to a description of direct effects on abundance and availability of cedar, and its permanency in the forest ecosystem.

Timber harvest has had and will continue to have the most direct effects on old growth cedar. Timber harvest will result in reduction of the availability of cedar of various ages for American Indian religious and cultural use.

All alternatives result in a substantial loss of cedar within the inventoried acres over five decades. Only Alternatives C and G-Modified will protect, over time, over 50 percent of the cedar areas. Over the Forest, as a whole, Alternatives NC, A, I, and B will result in the most extensive removal of old growth cedar. Alternatives H and J (Preferred) will result in slightly less removal. In cut-over areas, clearcuts will be frequent in the lower elevation forest zones where cedar grows. In intensively managed areas (with short rotations), cedar will be scarce. Forest-Wide Standards and Guidelines (see the Forest Plan) do provide for the replanting of cedar where it has historically occurred.

Alternatives G-Modified and C provide for retention of old growth at lower elevations and for the longer rotations approaching those necessary for cedar to reach maturity.

Over 75 species of medicinal and ceremonial plants have been identified in the Inventory (Blukis Onat and Hollenbeck 1981). Rights to gather some of these plants are provided for by both the American Indian Religious Freedom Act and Treaties of Point Elliot and Medicine Creek. Like cedar, the extent to which isolation, privacy, and purity are necessary may be less than for spirit quest sites, but undisturbed areas are preferred.

Timber harvest will have localized effects on those ceremonial plants growing in the area. Ceremonial shrubs and herbs can be physically destroyed during timber harvest or subsequent forestry practices (site preparation and reforestation). Trampling from pedestrian or vehicular use may also damage areas. The severity of effects to the setting will vary according to the type of plant and its intended use.

Clearcutting does increase the abundance of seral species used for ceremonial purposes: alder, vine maple, big huckleberry, bear grass, thimbleberry, blackberry, foxglove, blackcap, salmonberry, fireweed, and yarrow (Henderson, personal communication). However, the religious suitability of seral species when gathered in clearcuts is variable. For instance, huckleberries gathered from a clearcut may be acceptable, but vine maple must be gathered from locations which retain ritual purity (Snyder 1981).

Alternative C protects, from timber harvest, the largest percentage of inventoried ceremonial plant areas, followed by Alternatives G-Modified, J (Preferred), H, B and I. Alternatives NC and A allow the most harvesting in these flora areas.

Outside the inventoried areas, Alternatives NC, A, B, I, H, and J (Preferred) will result in reduced abundance of those plants dependent on habitats found only in old growth or mixed aged stands. These alternatives will result in increased abundance of seral species inhabiting clearcuts. In Alternatives C and G-Modified, ceremonial flora will be left undisturbed in most areas.

Changes in the diversity of plant communities may increase opportunities for cultural uses such as berry picking or the gathering of other foods and materials. These are normally enriched as old growth successional stages are converted to younger stages through timber harvest. These opportunities reverse the order described for protection, that is, Alternatives A and NC would offer the most opportunities, and C and G-Modified the least. However, existing evidence does not indicate that such increases are desired for traditional American Indian uses.

Fire suppression results in some localized damage of ceremonial flora, but this is overshadowed by long term protection of large areas where ceremonial plants grow. Indian use of fire is documented in the early historic period; the abundance of certain species was maintained through use of fire (Norton 1979).

Direct Effects of Archaeological and Historic Properties on American Indian Religious and Cultural Use

None of the alternatives would have significant effects arising from cultural resource management activities. Cultural resource inventory and protection can, in some instances, infringe on the privacy, isolation, and purity of the environment, and may disturb archaeological sites which American Indians would prefer to leave untouched. Such effects are most likely to result from archaeological excavation. Archaeological excavation will be most frequent under Alternatives NC, A, I and B, as a result of high levels of development activity. Hence the greatest chances of disturbance will occur under these alternatives. Archaeological disturbance will be relatively small-scale compared to the effects of the development activities.

Direct Effects of Recreation on American Indian Religious and Cultural Use

Because of the loss of privacy and isolation, use sites or areas located close to existing campgrounds have probably already lost their value. It is likely that expansion of existing recreation sites would, therefore, not affect American Indian sites further.

New recreation construction could destroy cultural resource sites or be used to protect sites. The builders of historic and prehistoric sites used criteria for locating their activities similar to those used by modern-day recreation planners, so sites often occur on the same location. Developed recreation acres, and hence potential for conflict, would be greatest in Alternative J (Preferred), and least in Alternative A, but are similar and relatively small in all alternatives.

The presence of dispersed recreationists intrudes on the privacy of a religious use site, and can be disturbing to the practitioners. The presence of others may also threaten the resting place for ceremonial articles left in the forest with the intention that they will be undisturbed by humans (Kent 1981).

In Alternatives NC, A, I, and B, and, to a lesser extent, Alternatives H and J (Preferred), it is expected that there will be increased competition between recreationists and Native American religious practitioners in wilderness areas. In these alternatives, there will be fewer opportunities for dispersed primitive and semi-primitive recreation outside of wilderness. Recreationists desiring these experiences will likely shift to wilderness.

At the other end of the spectrum, more opportunities for dispersed recreation in a primitive or semi-primitive setting will be present in Alternatives C and G-Modified. It is expected that opportunities for use, and the possibility of competing uses, would be much like it is today.

The effects of motorized dispersed recreation are damaging because of both the intensity (loud noises) and the extensive nature (over large distances) of the recreation. Alternatives NC and A, and to a lesser extent I, will result in greater capacity for motorized recreation and greater potential for disturbances to religious users. Alternatives B, H and J (Preferred) provide for moderate amounts of motorized recreation. Alternative C will provide the greatest protection to sites from motorized recreation; it provides the fewest acres in SPM and closes about 300 miles of roads. Alternative G-Modified, with its emphasis on primitive recreation, protection of low-elevation old growth, and closure of 65 miles of roads, will also provide high protection to inventoried sites and areas.

Recreation will have localized effects on those ceremonial plants growing in collecting areas. Trampling from pedestrian or vehicular use may damage areas. Consumptive uses (picking berries, wildflowers, pine cones, mushrooms, ornamental boughs, etc.) will compete with American Indian uses. The severity of effects to the setting will vary according to the type of plant and its intended use. Effects are likely to be greatest in the Alternatives with the most substantial allocations to dispersed recreation (NC, A, C and G) and least in Alternatives I and B. Alternatives H and J (Preferred) are intermediate in their effects.

Direct Effects of Trails on American Indian Religious and Cultural Use

Trail construction and maintenance will result in the limited removal of plants within and along the trail corridor. Trail construction and maintenance may reduce the purity, privacy, and isolation of some sites. Trail use results in an increase in potential encounters with others. Trails, however, also provide access to unroaded and unlogged areas of the forest.

Direct Effects of Wild and Scenic Rivers on American Indian Religious and Cultural Use

Recommending rivers for inclusion in the National Wild and Scenic River System may attract more recreationists and increase the disturbance to religious users along these rivers. Miles recommended by alternative are: Alternative G-Modified, 796 miles; Alternative C, 605 miles; Alternative J (Preferred), 452 miles; Alternative A, 287 miles; and Alternative H, 154 miles. Alternative B, NC and I recommend no rivers for designation.

On the other hand, some management activities that may be detrimental to religious and cultural uses would be reduced or eliminated (timber harvest and water diversions are examples) on those rivers recommended for designation.

Direct Effects of Mining, Energy Development on American Indian Religious and Cultural Use

The ground disturbance associated with mining results in loss of ritual purity in sensitive areas and in surrounding areas. The sights and sounds of mining can impact religious uses occurring within the vicinity.

The greatest potential disturbances to spirit and legend sites will occur in Alternatives NC, A, I and B, which allocate the fewest acres to prescriptions that restrict mineral activity. In Alternatives C and G-Modified, there will be the fewest conflicts, as more acres are restrictive to mineral development.

Mineral development can result in the localized removal of cedar and ceremonial plants, and reduction in the area of old growth and mixed-aged stands. The potential for reduction is highest in Alternatives NC, A, I and B and is lowest in C and G-Modified.

Any effects from other mineral related activities would be evaluated at the time mineral activity is proposed.

Small hydropower development can result in loss of the ritual purity of streams both up and down stream. The presence of power generating equipment and any changes in the physical properties of the water (rate of flow, turbidity, etc.) are damaging. Even if the water undergoes no observable physical changes, some practitioners believe that it will have lost its spiritual purity after passing through a generating facility. This development may occur in any alternative, but is most likely in alternatives that provide the most access and the Forest recommended Wild and Scenic Rivers: Alternatives A (NC would be similar to A), I, B, and H.

Direct Effects of Land Uses on American Indian Religious and Cultural Use

Land adjustments can result in the transfer of sites out of federal ownership. The new property owner may choose to deny access to newly acquired lands, as the American Indian Religious Freedom Act does not apply to private landowners. However, religious and cultural use sites will generally not be exchanged (see the prescription for Management Area 7 in the Forest Plan). The exceptions occur in municipal watersheds, where all alternatives except B would exchange some National Forest lands.

Utility corridors can disrupt the purity and isolation of religious use areas. Alternative G-Modified designates no new utility corridors; the remaining alternatives designate one new corridor.

Direct Effects of Roads on American Indian Religious and Cultural Use

Roads can disturb the qualities of isolation and privacy of sensitive areas. Roads can be a visual intrusion from a distance and a conduit of secular activity (traffic, noise, mechanized equipment, etc.). Roads also make lands more accessible to other Forest users, whose presence may intrude upon the privacy of a religious activity.

Road construction can result in the removal of cedar and the bisecting of old growth cedar stands. Alternatives C and G-Modified provide for the fewest roads and the greatest long-term abundance of cedar.

Alternatives A (NC is similar), I and B provide for the most road construction, reduced isolation of sites, and increased possibility of disturbance to sites. Alternatives H and J (Preferred) provide for moderate levels of road construction. Alternatives C and G-Modified would result in far fewer roads, with disturbances more at a level like that of the present. Alternatives C and

G-Modified also close miles of existing roads, which could increase solitude and privacy in some instances.

Construction permanently destroys all vegetation within the road prism. Alternatives A (NC is similar), I and B will construct the most miles of new roads, increasing the chance of ceremonial plant loss.

American Indian Religious and Cultural Use - The Cumulative Effects of the Alternatives

Traditional religion is a significant component of the social and community structure of Puget Sound tribes. The religion teaches good and correct character and behavior, contributing to the smooth operation of personal and group relationships. Further, proper religious practice ensures success in life. Those who are successful become role models and authority figures within the community. Loss of religious use areas can therefore destroy personal sense of worth and interfere with interpersonal relations and tribal leadership.

As a result of the development of state and private lands, the demand for suitable National Forest lands will increase. Cumulative effects from implementing the alternatives will occur in American Indian religious and cultural sites and areas located in virgin stands of trees on suitable lands. Besides wilderness, these areas hold the greatest amount of ritual purity and isolation. Timber harvest, road construction, mining, small hydropower development, and other major ground disturbing activities may damage both the resources and their setting. Spirit quest and legend sites will be most impacted.

Short rotations are insufficient to allow the growth of large-diameter, mature cedar trees. Timber harvest will result in reduction of the availability of cedar of various ages for American Indian religious use. While cedar will be present, the numbers and the average age of trees will be smaller. Standards and Guidelines for western red cedar will, upon Plan implementation, encourage regeneration of cedar where it has occurred in the past; however, rotation length will not allow trees to grow to large diameters.

Cumulative effects to ceremonial flora areas will be localized in extent, for the most part. None of the known ceremonial plants are threatened or endangered. While patterns of local availability, abundance, and accessibility will change, their overall presence on the forest will remain similar to the current situation. However, these changes may have more serious harmful effects to specific tribes, depending on their use of protected areas.

Alternatives NC, A, I and B will have the most serious effects on the availability of old growth cedar and ceremonial plants, and on the undisturbed natural setting required for spirit questing and other religious activities. These effects will occur in intensively managed areas in all alternatives. The greatest degree of protection of the resources and their setting, important in the practice of American Indian religion, will be provided in Alternatives C and G-Modified, while Alternatives H and J (Preferred) will provide a moderate level of protection.

Thirty-four percent of the identified American Indian religious and cultural use areas are located within wilderness. As such, they will be protected, in

perpetuity, from timber harvest, road construction, and those forest activities which have the most severe effects on the sites and areas themselves. Wilderness also protects, to some degree, isolation, purity, and privacy of the environmental setting. These religious use areas, however, will be subject to recreation uses which have the potential to reduce the isolation, privacy, and purity of the setting, and to disturb some American Indian religious and cultural activities.

Since many religious and cultural uses are dependent on the availability of old growth timber, readers are referred to the discussion of effects on Vegetative Diversity and Old Growth earlier in this chapter for further information.

American Indian Religious and Cultural Use - The Indirect Effects on Other Resources

Archaeological and Historic Properties

Changes in some cultural properties are of great interest to the American Indian community. There is extreme concern for the protection of archaeological sites, as they are part of the tribal heritage. Mitigation through excavation of archaeological sites may be encouraged by tribes in some cases, and discouraged in others. While American Indians do not want to see any archaeological sites damaged, they may also view excavation itself as a disturbance to sacred ground. When excavation may affect sites of interest to Indians, tribes will be notified of the planned activity. Opportunities for excavation may be foregone as a result of the resulting consultation.

In alternatives with high timber production (NC, A, I and B), there will be more frequent archaeological data recovery and greater involvement of the American Indian community. Data recovery will be less frequent in Alternatives C and G-Modified.

Scenery

There is no measurable effect.

Recreation

Protection for American Indian religious sites and areas may restrict or modify construction of developed recreation sites in those areas, as determined in project-level environmental analyses. The effects will not vary appreciably by alternative.

Trails

American Indian inventoried site management can affect trails when sites are in need of protection from destructive influences of visitors attracted by trails. Archaeological sites and American Indian religious and cultural use areas can attract collectors or vandals who may remove or destroy valuable property. Protection measures may require deterrence of trail users from passing into or near such sites for all or some portion of the year. The effects on trails in all alternatives is considered to be slight.

Wilderness

Increased American Indian religious use has the potential to compete with wilderness recreation use. Such competition can be expected in Alternatives NC, A, I and B, as opportunities to achieve privacy and isolation will occur primarily in wilderness. Fewer conflicts would be expected in the other alternatives. Effects on recreation activities are not expected to vary appreciably between alternatives.

Research Natural Areas

There is no measurable effect.

Roadless Areas

There is no measurable effect.

Wild and Scenic Rivers

Increased American Indian religious use has the potential to compete with recreation use of potential wild and scenic rivers, once designated. Such competition is expected to be the greatest in Alternatives NC, A, I and B, as use is focused on remaining areas with low or no development. Restrictions or alterations of recreation use may be developed on a case-by-case basis.

Air

There is no measurable effect.

Fire

There is no measurable effect.

Minerals

There is no measurable effect.

Land Ownership and Use

Avoidance of religious use areas in utility corridors might require the re-location of lines or the employment of non-standard construction techniques. The effects in all alternatives, except G-Modified, are slight and similar. Alternative G-Modified designates no new utility corridors.

Roads

Since the type of religious and cultural use sites varies widely, the degree and type of effects would also be expected to vary. The effects on roads could range from none, to seasonal closures, to precluding new road construction. Alternatives NC, A, I and B would have the greatest effects, by increasing pressure to close roads or preclude construction.

Mitigation Measures for American Indian Religious and Cultural Use

Recommendations in the Inventory of Native American Religious Use were consistent in stating that all categories of sites (spirit quest, legendary, ceremonial flora areas, cedar gathering areas, and cemeteries) be protected. Protection requires the maintenance of the site in a pure, private and isolated state - in other words, undeveloped.

It will not be possible to maintain all sites in an undeveloped state upon implementation of any Plan alternative. Alternative effects can be assessed by consulting Table IV-24, which shows the acreage of inventoried sites receiving high or moderate protection.

In cases where religious and cultural use sites are allocated in developed Management Areas, consultation with the affected tribes shall be undertaken to identify means of avoiding or mitigating the effects. Generally, these will mean reducing or minimizing the area, ground, or vegetation disturbance and separating them to the extent possible from Indian practitioners who may be present. Separation may be spatial or temporal, depending on the specific use of the area.

Closure of roads can be used to limit access of these routes to religious sites. This would reduce those disturbances which detract from the isolation, privacy, and purity of the sensitive area.

Seasonal trail closures might be used to protect sensitive areas from heavy recreation use. Use of hand tools in trail construction or fish and wildlife improvement projects will reduce the noise associated with these construction projects.

Various activities can be scheduled so as not to coincide with the season during which most of the religious activity occurs. However, there is evidence that some religious activity occurs throughout the year (Haeberlin and Gunther 1930).

Silvicultural practices can be modified to accommodate the long-term needs of American Indians for cedar. Extended rotations (a minimum of 250 years) could be employed in prime sites for cedar growth. This would allow the growth of mature cedar trees and other ceremonial plants which thrive in that habitat type. A Forest-Wide Standard and Guideline has been established to assure the regeneration of cedar where it has historically occurred.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for American Indian Religious/Cultural Uses

No municipal, county, or state-level plans address American Indian religious and cultural use. The Bonneville Power Administration's Northwest Rivers Assessment may address such use but that study is not available at this time. The 15 American Indian tribes with which the Forest actively consults have expressed their views in person and in writing, but there are no known plans which address this issue.

ARCHAEOLOGICAL AND HISTORIC PROPERTIES

Archaeological and Historic Properties - The Direct Effects of Each Alternative

General

There is a wide range of archaeological and historic property on the Forest, as discussed in Chapter III. Included in the following discussion are the environmental effects on: 1) archaeological sites, 2) historic buildings and structural remains, and 3) linear cultural features, including trails, wagon roads, railroads, and historic districts (for example, the Stevens Pass Historic District).

Archaeological sites derive their significance from the data they contain. Potential negative effects on these sites include physical loss of artifacts and disturbance of sites which destroys the context of artifacts in the soil profile. This loss of stratigraphy, or the sequence of cultural and natural soil horizons, can mean loss of much of the scientific value.

Buildings, structures and many linear features derive their significance from their associations with important persons or events, or from their aesthetic value. Conditions which break the association, for example the removal of the work of a master builder, and conditions which change the aesthetics, can damage or destroy the significance of the building or feature.

Linear cultural features may consist of structures such as roads, or collections of buildings, structures, features and archaeological sites, connected by roads or trails. Negative effects can include the physical severance of the connecting link, the introduction of incompatible developments, and the full range of effects that may also impact archaeological sites, buildings and structures.

The alternatives do not differ significantly in management direction, which is governed by Sec. 106 of the National Historic Preservation Act of 1966. But in the management activities proposed in each alternative (especially timber harvest and road construction), there is a varying risk of impact and effect on archaeological and historic properties.

Direct Effects of Timber Harvest on Archaeological and Historic Properties

Ground disturbance associated with vegetation manipulation has the potential to affect archaeological and historic properties. The more extensive the ground disturbance, the greater the effect on these properties. However, such activities also provide the greatest opportunity to discover and interpret new sites. Through current standards and management practices, and in compliance with law, cultural resource inventories implemented as a result of proposed timber sale projects have resulted in most of the findings on the Forest. To date, funding for cultural resource inventories has come mostly from timber sale funds.

Considerable ground disturbance occurs in localized areas, such as landings, where heavy equipment runs repeatedly over a limited area of ground. Development of skid trails, ground scarification, yarding, and machine piling can result in displacement and crushing of archaeological materials (Bryant and others 1982, Gallagher 1977, Wildesen 1982). Impacts of different magnitudes

result from the use of different logging systems. Removal of vegetative ground cover and subsequent soil loosening and soil moisture changes can result in damage to archaeological sites and their contexts (Butzer 1982, Dancey 1969). The effects may be mitigated by recovering data before disturbance occurs, or by altering the extent, timing or method of vegetation removal.

Timber harvest can usually be designed to avoid historic buildings located within a timber sale area, but may change the association or aesthetics. In some cases it is impractical to avoid structures. In these cases, the surface disturbance caused by logging and associated activities can result in complete removal or irreversible damage to historic structures. Such adverse effects may be partially mitigated by documentation of structures to the standards of the Historic American Building Survey (HABS). Timber harvest can also result in the destruction of associated historic features and landscape modifications which provide important historic or aesthetic context for the structures themselves (Gallagher 1977).

The body of scientific knowledge will be increased, as funding for documentation and inventory of any buildings or structural remains is provided by the timber sale; the costs of timber harvest will also increase.

Timber harvest is most extensive in Alternatives NC and A. This will result in the greatest potential impacts. Fewer sites will be left undisturbed and in their original condition. Impacts may also be sustained in areas managed for timber production in all other alternatives. Alternatives C and G-Modified will result in the least amount of ground disturbance and the fewest losses. Alternatives I, B, H and J (Preferred) have intermediate levels of impact.

Timber harvest can severely affect linear cultural features. Use of heavy equipment, construction and use of landings, construction and use of spur roads, tree falling, ground scarification, and machine piling can destroy the original tread or grade of an historic route (Gallagher 1977). Potential effects, by alternative, follow the same pattern discussed above. Due to their extensive nature, mitigation of effects to linear cultural features is difficult to achieve. Partial mitigation (directional felling, restriction on the number of crossings, etc.) increases the costs of timber harvest as does documentation of the features. The greatest number of undisturbed linear cultural features will be retained in Alternatives C and G-Modified. As with other types of archaeological and historic property, the remaining alternatives have intermediate levels of impact.

Associated timber management activities, such as site preparation and reforestation, can have additional effects on archaeological sites. The impacts will be greatest in the alternative where site preparation is most extensive: Alternative NC. Alternatives A, I, B, H, and J (Preferred) have moderate impacts, and Alternatives C and G-Modified will have the fewest impacts. The mitigation of these impacts will add to the cost of these forestry practices.

Direct Effects of Fish and Riparian Habitat Improvement on Archaeological and Historic Properties

Ground disturbing fisheries habitat construction may have a direct effect on archaeological sites located adjacent to streams. Habitat improvement can result in the removal of vegetation and increase the visibility of historic

sites and structures. This can expose them to accelerated natural weathering and make them more visible to visitors. These impacts are most likely to occur in Alternatives A, I, B, H and J (Preferred).

Direct Effects of Recreation on Archaeological and Historic Properties

Because prehistoric humans were attracted to the same localities that modern recreationists find desirable, recreation developments and activities have a high probability of affecting archaeological and historic properties. Dispersed recreation causes much less damage than recreation developments and motorized recreation.

Recreation use can have direct effects; archaeological remains often attract collectors or "pot-hunters" who remove artifacts and destroy their context (Hedlund and others 1978, Wildesen 1982). Purposeful vandalism can also result in loss of a site's integrity. Inadvertent loss can be caused by heavy use from campers, hikers, stock animals, off-road vehicles, or bikes.

Alternatives that provide the most access, by road or trail, to areas likely to contain historic properties have the greatest potential for damage. Most cultural resource sites known to exist are located in areas that already have a well-established travelway development of both roads and trails (Madonna Moss, personal communication).

Alternatives A (NC would be similar) and I provides the greatest amount of roaded recreation. Alternatives B, H, J (Preferred) and G-Modified also provide moderate acres of semi-primitive motorized recreation (primarily for trail bikes) and roaded, natural-appearing recreation. Alternative G-Modified provides the lowest roaded recreation acres. Alternative C has no semi-primitive motorized recreation, but does have more acres of roaded, natural-appearing recreation than Alternative G-Modified.

Alternative J (Preferred) has the highest level of trail construction/reconstruction and Alternatives A and B the least. Alternatives I and G-Modified have high trail construction/reconstruction miles. Alternatives H and C have intermediate levels.

While potential effects cannot be quantified, Alternatives A (NC would be similar) and J (Preferred) are more likely to result in recreation impacts to archaeological sites. Alternatives C and G-Modified propose substantial miles of new trails, but have the fewest miles of road construction and resulting roaded recreation; recreation effects from C and G-Modified will likely be minimal.

Direct Effects of Trails on Archaeological and Historic Properties

Trail construction can result in greater accessibility and visibility of historic buildings and structures. By facilitating visitor use, the property becomes vulnerable to the effects of human use. Increased access can also have the effect of enhancing the recreation experience of the interested and sensitive visitor.

Alternatives G-Modified, I and J (Preferred) will construct the most miles of trails, followed by Alternatives C, H and A (NC would be similar to A). If trail construction is executed in a manner consistent with historic values,

these alternatives will provide the greatest opportunity for maintenance and interpretation of linear cultural features.

Off-road vehicle (ORV) use can cause significant resource damage through soil disturbance, artifact collection and vandalism. These effects will be greatest in Alternative I and least in Alternative C. Moderate to low impacts would result from the other alternatives.

Direct Effects of Research Natural Areas on Archaeological and Historic Properties

RNA designation generally discourages the retention of structures, including historic structures. They may be removed or allowed to deteriorate naturally. Opportunities for archaeological research are foregone. These effects will be greatest in Alternatives H, J (Preferred), C and G-Modified, and least in Alternatives NC, A and I. Because RNAs are frequently areas with little prior human use, these effects are expected to be limited in any alternative.

Direct Effects of Mining, Energy Development on Archaeological and Historic Properties

Mineral related activities affect cultural resources during exploration, development and extraction of minerals, when surface disturbing activities take place. These activities may provide opportunities to identify previously unknown cultural properties at some sites, while resulting in the damage to or destruction of historic values at other localities. The degree of effect varies by the commodity that is explored, developed, or mined. The type of mining operation, the degree of environmental alteration required, and the location of the development also are key factors.

Alternatives NC, A, I and B have the fewest acres in a highly restrictive category for mineral entry; implementation of these alternatives will most likely result in loss of the greatest number of historic sites. Partial mitigation will result in documentation of some of these sites, but many will not be retained in place. There will be fewer conflicts between historic preservation and mineral development in Alternatives C and G-Modified. More historic mining sites will be retained under these alternatives.

Alternatives NC, A, I and B also have the fewest restrictions on all types of energy development, resulting in a higher potential loss of historic structures.

In all alternatives, all lands not withdrawn from mineral entry will remain subject to exploration and development under mining and mineral leasing laws. For leasable minerals, all costs of site protection and salvage are borne by the operator; if at all possible, the resource is protected. If the impacts of mining cannot be satisfactorily mitigated, surface occupancy of the area is restricted.

Small hydropower developments can result in severe, localized damage. While stream locations are sensitive areas, many of the streams chosen for FERC licensing are smaller, lower-order streams with a steep gradients. These smaller streams have less potential for containing archaeological sites. The Alternatives that provide the most access and development (NC, A, I and B) will provide the most opportunities for small hydro development, hence the highest

likelihood of adverse effect. Alternatives C and G-Modified have the lowest likelihood of adverse effect.

Direct Effects of Land Uses on Archaeological and Historic Properties

Land adjustments can result in transfer of archaeological sites, historic buildings and structures, and linear features out of federal ownership. If sites are detected prior to land exchange, data from the sites can be recovered and can contribute to understanding of our cultural heritage. Transfer of unknown archaeological sites can result in their ultimate destruction by the new landowner's activities. On the other hand, valuable properties can also be acquired for federal protection.

Municipal watershed management can result in a variety of effects to cultural and historic properties as a result of policies toward land exchange. The probability of archaeological sites occurring within watersheds is relatively high, due to the tendency for sites to be located along streams and waterways. Closing watersheds to public use reduces the number of visitors to the area and the potential of vandalism to sites. It also reduces the possibility that sites will be investigated by scientific or educational organizations.

From the perspective of municipal watershed management, historic buildings and properties can be a nuisance, because they are potential sources of contamination, and they attract visitors. In watersheds closed to public use, historic buildings are more inaccessible to the public and less prone to vandalism.

Retention of National Forest land in the Cedar and Sultan River watersheds will result in the greatest chance of long-term protection (Alternative B). Where lands are managed for timber production, there will be more sites identified, and more impacts (Alternatives NC, A, I, H and J (Preferred)). Where old growth habitat is afforded protection, as in Alternative C, there should be fewer disturbances to archaeological sites. However, old growth maintenance will be at local discretion. Alternatives A, I, H, J (Preferred), G-Modified and, to a lesser extent, C would allow recreation use, resulting in a greater chance of human impacts on archaeological sites.

Alternative G-Modified precludes the construction of an additional utility corridor between Pyramid and Tacoma Pass. In all other alternatives, the potential exists for historic or cultural sites to be impacted by utility corridor construction.

Direct Effects of Roads on Archaeological and Historic Properties

Road construction probably results in the greatest amount of ground disturbance of any forest activity (Wildesen 1982). Areas selected for roads often follow the route of least topographic resistance and some locations, like relatively level benches or terraces above stream channels, have a high potential for archaeological and historic properties. Because of this potential for the co-occurrence of roads and sites and the magnitude of disturbance, it is expected that road construction has the greatest potential to damage sites. Site deposits may be damaged through physical loss of remains and/or mixing of site stratigraphy (Butzer 1982).

However, road construction also has the effect of providing the opportunity to identify previously undiscovered sites. This can provide opportunities for interpretation and an improved understanding of site distribution patterns.

Alternatives A (NC would be similar), I, and B will result in the greatest amount of road construction in the first decade, followed by Alternatives H and J (Preferred). The frequency of site discovery and mitigation of potential impacts will be greatest in these alternatives. Fewer sites will be left undisturbed. The greatest number of archaeological sites will likely be damaged through road construction in these alternatives. Similar impacts would be sustained on those areas developed in Alternatives C and G-Modified, but the number of cases would be smaller.

Archaeological and Historic Properties - The Cumulative Effects of the Alternatives

The cumulative effects of landscape modifications and private land developments have already destroyed much of the archaeological and historic record in Western Washington (Carter 1978). In all alternatives, but especially Alternative A (NC would be similar), as additional components of the network are destroyed, the information contained in these properties is destroyed.

Figure IV-3 in the Vegetative Diversity section earlier in this chapter shows the acres of timber harvest by alternative over the first five decades of the Plan. The acres harvested are much higher in Alternatives NC and A than in the rest of the alternatives. The cumulative effects of implementing these alternatives would be much greater. Acres harvested are high in Alternatives I, B and H (but less than NC or A), intermediate in J (Preferred), and lowest in C and G-Modified.

Cultural and historic properties contain information of a type that cannot be duplicated in any other form. For this reason, their loss is irreversible. The value of information contained in such sites is difficult to measure. These sites make up a finite resource which is becoming increasingly scarce. Their educational and public value can only increase with time. As discussed in Chapter III, the academic community, American Indians and the public at large is becoming more aware of the exceptional value of the cultural and historic properties located on National Forest land; many sites located within the Forest have escaped human caused disturbance, and they represent some of the most pristine examples of archaeological sites in the region. Their research value in reconstruction of prehistoric and historic lifeways is recognized (Blukis Onat 1980, Carter 1978), and there will likely be an increased demand for protection, preservation and study of these properties.

Cumulative effects on sites can be mitigated through scientific data recovery. Alternatives NC and A will result in the greatest number of sites discovered and from which data could be scientifically recovered. This could result in greater knowledge of the nature and distribution of sites in the Forest and the human behavior they represent. This knowledge may come at the price of site loss through development, increased vandalism, and evaluation itself. Alternatives NC and A will also result in the greatest number of sites damaged through ground disturbance.

In Alternatives C and G-Modified, there will be greater <u>in situ</u> (in place) preservation of sites, with less opportunity to find sites, record and study

them. If Alternative C or G-Modified were implemented, the sites themselves would be preserved for the future, but there will be fewer opportunities to understand and interpret the resource.

Cumulative effects on linear cultural features are unavoidable due to the extensive nature of these properties and their location along optimal travel routes. On-going management activities of many types (road construction and timber harvest having the most severe effects) will gradually reduce the integrity of these features and their associated information and interpretive values.

The extent and severity of effects on linear features will be greatest under Alternatives NC and A, less under Alternatives I, B, H and J (Preferred), and least under Alternatives C and G-Modified.

Archaeological and Historic Properties - The Indirect Effects on Other Resources

Scenery

Cultural properties often greatly enhance the natural forest setting. They provide the visitor with a tangible experience of the landscape as it may have looked in the past; they evoke a sense of history and stimulate questions as to how people adapted to the environment in the years gone by. Their loss can detract from the scenic quality of the forest environment.

In Alternatives NC, A, I and B, and in areas managed for timber production in the other alternatives, many of the historic structures and linear features will be permanently removed from the scenic landscape. The greatest number of undisturbed historic properties will remain in Alternatives C and G-Modified.

Recreation

Protection of cultural resource sites may reduce the number and size of developed sites. This can be offset by interpretation of the resource, which creates additional, if somewhat different, recreation opportunities. Opportunities for interpretation, arising from recreation development, will be greatest in Alternative J (Preferred), and least in Alternatives NC and A, but in any case, will be relatively similar from alternative to alternative.

The protection and mitigation of cultural resources may result in the restriction of dispersed use in some areas, if use would result in destruction or compromise of the cultural resource. The significance of this restriction depends on the location and the size of the area involved in protecting a cultural resource site. However, most sites are relatively small (under an acre), and total restrictions would be minor in any alternative.

Trails

Trails can be designed in such a way as to avoid or minimize damage to historic properties. Trail construction and maintenance can be used to restore and preserve some historic properties. Trail work can also make an area accessible to the public for cultural use and interpretation. These effects and opportunities will exist in proportion to the miles of trail constructed in each alternative.

Wilderness

Cultural resources are a unique and nonrenewable part of the wilderness resource and are recognized in the Wilderness Act. However, there is direction that the "untrammeled" character of the environment be preserved, and above-ground historic structures may be removed or left to deteriorate through natural processes. The effects are subjective. Depending on the observer, some would argue that the loss of historic structures detracts from the wilderness experience, while others feel that their elimination enhances that experience.

Where wilderness is most accessible (Alternatives NC, A, I, J (Preferred) and G-Modified), there will be more conflicts between those who would like to see historic structures and features preserved, and those who would like them removed. These conflicts can also be expected in those wilderness areas made accessible in other alternatives.

In any case, implementation of any of the alternatives will have a limited effect on cultural resources in wilderness, which achieves its character from an apparent absence of human modification. Removal or retention decisions will be made on a case-by-case basis with input from affected users, and will not differ significantly between alternatives.

Research Natural Areas

There is no measurable effect.

Roadless Areas

There is no measurable effect.

Wild and Scenic Rivers

Existing and recommended wild and scenic rivers and their tributaries contain numerous prehistoric and historic properties. Alterations and disturbances to these resources are very likely on the intermingled state and private lands. These losses affect the integrity of the network of historic properties which are located along the river. Those alternatives which designate the most miles of river (G-Modified and C) offer the most opportunities to coordinate state and private land management with federal protection efforts. Those alternatives which designate the fewest miles of river A, NC and I offer the fewest opportunities to coordinate management, and hence the highest likelihood of loss of archaeological and historic properties. Alternative J (Preferred) designates an intermediate mileage, with corresponding effects.

Air

There is no measurable effect.

Fire

There is no measurable effect.

Minerals

If obvious or suspected cultural resources are discovered during a mining operation, the operator must cease his activity and notify the Forest Service immediately. Protection or mitigation activities are undertaken. For leasable mineral activities all cost of protection and salvage are borne by the operator and, if at all possible, the resource is protected. For locatable mineral activities where a valid mining claim is involved, a plan of operation must be approved following compliance with Section 106 of the National Historic Preservation Act. This is true even where data recovery or adequate mitigation of cultural resource values is not possible.

Because of the relatively small size of most archaeological and historic properties, and because many activities to develop locatable minerals must be allowed even if cultural resources are present, the alternatives are not expected to differ appreciably in the impacts of cultural resource management on minerals and energy. Cultural resource mitigation activities for leasable minerals may increase the cost of mineral extraction, but not in a manner that differs predictably by alternative.

Land Ownership and Use

Protection of cultural resources may result in the deletion of lands from exchange programs. Decisions on deletion will be made on a case-by-case basis, incorporating the consultation procedures of 36-CFR-800.

Location of a cultural resource in an existing or proposed utility corridor, may require that facilities be redesigned, or that mitigation activities be undertaken, with consequent increases in construction costs. Effects will be similar in all alternatives except G-Modified, which proposes no new utility corridors.

Roads

Protection of cultural resource sites may affect road location and/or methods of construction, requiring re-routing or non-standard construction methods. These effects are expected to be similar for each alternative, with the potential for encountering sites increasing as miles of road construction increases. Alternatives NC, A, I and B would have a high probability of occurrence. Alternatives H and J (Preferred) would have a moderate probability of occurrence, with C and G-Modified having the least probability.

Mitigation Measures for Archaeological and Historic Properties

All ground disturbing activities, and building alterations, will include a professionally-supervised project-level inventory and evaluation, in compliance with the National Historic Preservation Act of 1966 (as amended 1980), and the Forest-Wide Standards and Guidelines. Protection or mitigation may be appropriate, depending on the cultural resource and activity. Inventory, evaluation and the development of protection and mitigation measures will be undertaken in consultation with the State Historic Preservation Officer and the Advisory Council on Historic Preservation, as required by 36 CFR 800.

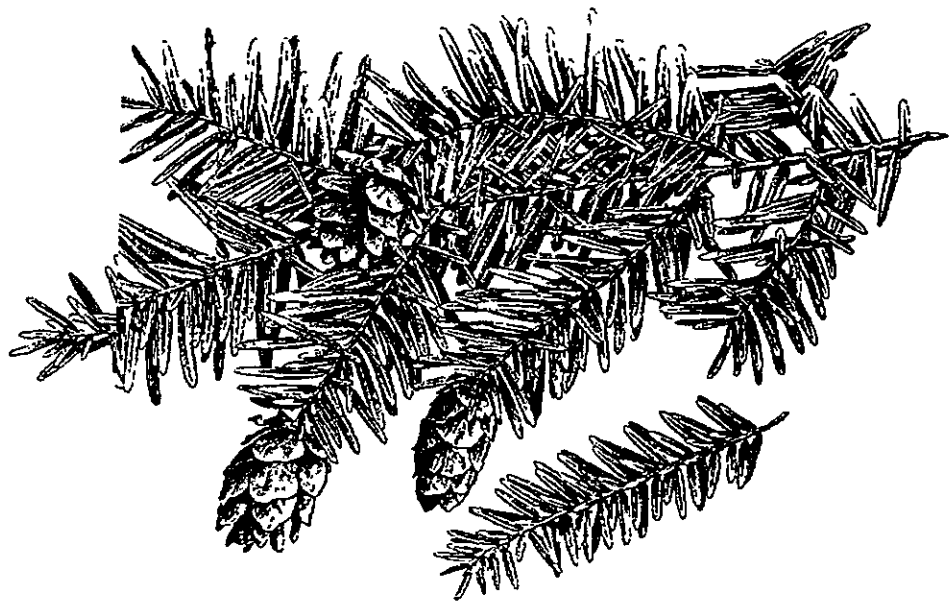
When any project may affect a cultural resource eligible for the National Register of Historic Places, the consultation will consider protection of the

resource or mitigation of the effects. In many cases, adverse effects to cultural and historic properties can be avoided through project re-design. Mitigation may be achieved through project implementation using special restrictions or advanced technology. Mitigation can also take the form of scientific investigations of the cultural or historic property. In the case of historic structures, it may also be possible to adaptively reuse buildings or relocate them to places where they can be reused. Effects to linear cultural features can be partially mitigated by such techniques as directional felling of trees away from the feature and limitations on the number of crossings across the feature. Typical measures are cited in 36 CFR 800, but others may be developed during consultation.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Archaeological and Historic Properties

In general, the City and County Preservation programs share the same goals as the cultural resource program of the Forest Service. However, in many cases, the preservation community prefers in situ preservation of archaeological sites or historic buildings through avoidance or restoration/rehabilitation rather than mitigation through data recovery or documentation.

The Washington State Office of Archaeology and Historic Preservation (OAHP) has issued a State Heritage Plan I (1986). The Forest's cultural resource plan, in all alternatives, is compatible with the Plan; coordination with the State will be continued.



SCENERY

Scenery - The Direct Effects of Each Alternative

General

Scenic quality can be significantly affected by forest management practices and land development. The recreating public has expectations of a natural forest setting. These expectations have been inventoried through the Visual Management System (VMS). The forest plan alternatives have been formulated to show a range of forest management schemes, and therefore vary in their incorporation of VMS recommendations. In some management areas, higher visual quality standards are recommended, and in others, visual quality standards are reduced. A comparison of the alternatives showing gross acres that maintain a high degree of visual quality is shown in Table IV-25 (for all management areas) and in Table IV-26 (for scenic corridors). For a site specific comparison of alternatives refer to Tables IV-27 and IV-28, which show (1) the existing visual condition of each drainage, (2) the condition that would result from the visual management system, and (3) the condition that would result from each alternative.

A Forest-wide measurement of how the various alternatives affect scenery can be made by comparing acres assigned to the various Visual Quality Objectives. Table IV-25, below, shows this relationship. All acres in wilderness (721,716 acres) are assigned to preservation in all alternatives.

Table IV-25
Acres Assigned to Management Areas With a Visual Quality Objective of Partial Retention, Retention, or Preservation

Thousands of Acres

NC 1/	A	I	B(RPA)	H	J (Pref)	C	G-Mod.
NA	1,187	1,243	1,296	1,322	1,372	1,514	1,365

1/ The TM Plan upon which Alternative NC is based was developed in 1963; it was not an integrated resource plan. This information cannot be reasonably estimated as the original plan was based on yield tables and resource information that do not reflect the standards in NFMA or the latest scientific techniques and information.

The Forest-wide acres in Table IV-25 do not indicate how the more scenic portions of the Forest or the more heavily traveled corridors are affected by the alternatives. Table IV-26, below, indicates the acres assigned to scenic corridors (Management Areas 2A Scenic Viewshed, Foreground and 2B Scenic Viewshed, Middleground) for each alternative.

Table IV-26
Acres Assigned to Scenic Corridors
Thousands of Acres

	NC (No Change)	A (No Action)	I	B (RPA)	H	J (Pref)	C	G-Mod
2A Foreground	NA 1/	3.3	29.2	4.0	24.6	23.4	65.7	9.5
2B Middleground	NA	0	0	0	81.6	95.8	57.5	0

1/ As stated in the footnote above, this information cannot be reasonably estimated for Alternative NC.

In the preceding table, alternatives C, H, and J (Preferred), all have acres assigned to Scenic Viewshed, Middleground. Although Alternative C protects all of the inventoried viewsheds, it appears that less middleground is protected than in Alternatives H or J (Preferred). In Alternative C, some inventoried middleground will be managed for Primitive/Semi-primitive Nonmotorized Recreation, thus the acres are assigned to other management areas (1A,1B). *These MA's will provide a higher level of scenic protection than 2B.*

Direct Effects of Timber Harvest on Scenery

Timber harvest and associated access roads and landings can have a very significant effect on scenic quality in western Cascade landscapes. The most obvious impact is likely to occur on landscapes with steep, visible slopes having a solid texture of forest canopy. Clearcuts leave a very distinct contrast between forest and bare ground that can be a focal draw to an observer. The impact of timber harvest varies widely, depending on shape and scale of units, texture of edges, partial retention of established stand, and the amount of area in a disturbed state at one time.

The effects of timber harvest will occur primarily in the following management areas: 2A Scenic Viewshed, Foreground (Retention - alterations will not be evident); 2B Scenic Viewshed, Middleground (Partial Retention - alterations will remain subordinate); 14 Deer and Elk Winter Range (Partial Retention to Modification - varies from subordinate to dominant, based on the viewshed); 17 Timber Management Emphasis (Modification to Maximum Modification - alterations will be dominant); and in the MA 20-23 Municipal Watershed strategies that permit timber harvest (Maximum Modification - alterations will be dominant).

For management prescriptions where timber harvest is dominant, there will be long-term changes in what constitutes the "characteristic landscape". A mosaic of various sized timber stands will evolve, and within 15 to 20 years of each entry, units will introduce significant contrast in form, texture, and color.

For management prescriptions where timber harvest is subordinant, there will be a subtle evolution of the forest over time.

The most noticeable short-term effects of timber harvest are the highly visible contrasts between continuous textured mature timber stands and newly cutover

lands. The visual appearance of recently cutover lands with slash, stumps, and areas of exposed soil, is quite striking until cutover lands have "greened up" with grasses, shrubs, forbs, and young stands of trees. These effects can often be mitigated through unit design and long range planning.

Additional timber management activities occurring after harvest, such as site preparation, reforestation, and pre-commercial thinning, are secondary in their effect on scenery since the dominant activity (timber harvest) has already altered the landscape.

In all alternatives, the scenic appearance of lands adjacent to or intermingled with private timber lands will be dominated by the contrasting shapes and lines created by harvesting along property boundaries. In these situations, scenery can at best be "rehabilitated" to a Modification or Maximum Modification level.

The timber management plan upon which Alternative NC is based was not amended for the Alpine Lakes Management Plan or the Skagit Wild and Scenic River Management Plan. In all other alternatives there are three constants: (1) Stevens Pass (US 2) viewshed; (2) Snoqualmie Pass (I-90) viewshed; and (3) the Skagit Wild and Scenic River system. They will be managed as prescribed in these respective plans, and analysis is not repeated in the comments for each alternative that follows.

Alternative A (No Action) has conflicting targets for resource outputs. It is impossible to sustain the Visual Management System's inventoried visual quality levels with an emphasis on timber management at low elevations. These lands include many scenic roadsides. While there is a serious effort to meet Visual Quality Objectives, it will not always be possible with this management emphasis, and the cumulative effect will be significant, even in highly scenic areas. The impact is currently most apparent on steep middleground slopes below 4000 feet elevation, where management activities significantly alter the natural landscape. This will continue, and timber harvest will become increasingly apparent in foreground areas. The foreground of Mather Memorial Parkway is the only allocated scenic viewshed in Alternative A. In this alternative, there are 844,352 acres in management areas where timber harvest will not be evident (Retention or Preservation). Visual quality will gradually be reduced on all areas of the Forest with road access.

Alternative NC will have effects on scenery which are greater than Alternative A due to the greater amount of roading and harvest. Mather Memorial Parkway is designated as a scenic viewshed in Alternative NC.

Alternative B has high levels of timber harvest and road construction, with a majority of the tentatively suitable land available for timber management. In addition, only existing unroaded acres not suitable for timber management will remain roadless. Of the forest highway corridors, only the foreground of the Mather Memorial Parkway will be managed as a scenic area. In Alternative B, there are 1,011,566 acres in management areas where timber harvest will not be evident (Retention or Preservation). Visual quality will deteriorate over time for almost all of the lands accessible by road. Scenic enjoyment of the Forest will be significantly decreased.

Alternative C has low levels of timber harvest and road construction with the least acres of suitable lands managed for timber production. Nearly all existing unroaded areas will remain roadless and most primary and secondary

corridors will be managed as scenic viewsheds. In Alternative C, there are 1,366,248 acres in management areas where timber harvest will not be evident (Retention or Preservation). Visual quality will be retained in unroaded areas and retained or improved over time in the scenic corridors.

Alternative G-Modified would have lower levels of timber harvest. While scenic "corridors" are not specifically assigned, the foreground of several corridors would be protected, including the upper end of Mt. Baker Highway, portions of the Cascade River and North Fork of the Cascade, portions of the Mountain Loop Highway, the Upper Sauk, the lower Sultan, and the Mather Memorial Parkway. In addition, areas with old growth or wild and scenic rivers would be managed to retain their scenic quality. Middleground areas are not included; they would be managed at a modification level. In Alternative G-Modified, there are 1,308,216 acres in management areas where timber harvest will not be evident (Retention or Preservation). Scenic quality would be reduced moderately in several significant viewsheds, but would remain high in unroaded areas.

Alternative H has a moderate level of timber harvest, with 60 percent of the tentatively suitable acres available for timber harvest. However, foreground and middleground seen areas of heavily traveled highway corridors are managed for scenic quality. These include Mather Memorial Parkway, and the Mountain Loop, Mt. Baker, Baker Lake, and North Cascades Highways. There are five rivers recommended for wild and scenic designation. In Alternative H, there are 1,140,536 acres in management areas where timber harvest will not be evident (Retention or Preservation).

Alternative I maintains foreground corridors on the major highways, but does not include middlegrounds. In Alternative I, there are 931,908 acres in management areas where timber harvest will not be evident (Retention or Preservation). Over the long term, management would result in dominant timber harvesting in most currently scenic viewsheds.

Alternative J (Preferred) manages for a high level of scenic quality. Scenic corridors include the Mt. Baker Scenic Byway, Baker Lake Highway, North Cascades Highway, Cascade River Road, Mountain Loop Scenic Byway (proposed), North Fork Sauk Road, Whitechuck River Road, Crystal Mountain Road, and Suntop Road. The Mather Memorial Parkway and Heather Meadows have no programmed harvest. The Carbon River Road is designated as Roaded Natural. There are 30 rivers recommended for Wild and Scenic designation. In Alternative J (Preferred), there are 1,167,398 acres in management areas where timber harvest will not be evident (Retention or Preservation).

The above narrative summarized highlights of each alternative. The following two tables focus on the individual viewsheds of the Forest. Table IV-27 shows, by alternative, the visual condition of each viewshed - natural appearing, slightly altered, moderately altered, or heavily altered - at the end of the first decade. Table IV-28 shows the same information at the end of Decade 5. The analysis is based on recommended visual quality levels associated with each allocation and gives an average rating for the viewshed.

Table IV-27

EVC = Existing Visual Condition. NOTE: many of the acres currently in a heavily altered condition will remain that way for several decades

VMS = Visual Management System. The expected visual condition if attempts to achieve the inventoried visual quality objectives were implemented.

N = Naturally Appearing: Area appears untouched by man; changes are not visually evident. Corresponds to a visual quality objective of retention.

S = Slightly Altered: Changes may be noticed by the average visitor but do not attract attention. Natural appearance dominates. Corresponds to a visual quality objective of partial retention.

M = Moderately Altered: Changes are easily noticed by the average visitor and may attract attention. Disturbances are apparent. Corresponds to a visual quality objective of modification.

H = Heavily Altered: Changes are strong and obvious to the average visitor. Changes dominate the landscape but may resemble natural patterns when viewed from a distance of 3 to 5 miles. Disturbances are major. Corresponds to a visual quality objective of maximum modification.

(+) and (-) = These symbols indicate, by alternative, the change in a viewshed's condition from the level listed in the Existing Visual Condition. Example: Corral Pass is currently Moderately Altered. At the end of Decade 1, it will be Heavily Altered in Alternative A (a drop (-) of one level), in Alternative C, the condition has changed to Slightly Altered (an increase (+) of one level). If there is no (+) or (-), the condition is unchanged

Table IV-28

EVC = Existing Visual Condition. NOTE: many of the acres currently in a heavily altered condition will remain that way for several decades

VMS = Visual Management System. The expected visual condition if attempts to achieve the inventoried visual quality objectives were implemented.

N = Naturally Appearing: Area appears untouched by man; changes are not visually evident. Corresponds to a visual quality objective of retention.

S = Slightly Altered: Changes may be noticed by the average visitor but do not attract attention. Natural appearance dominates. Corresponds to a visual quality objective of partial retention.

M = Moderately Altered: Changes are easily noticed by the average visitor and may attract attention. Disturbances are apparent. Corresponds to a visual quality objective of modification.

H = Heavily Altered: Changes are strong and obvious to the average visitor. Changes dominate the landscape but may resemble natural patterns when viewed from a distance of 3 to 5 miles. Disturbances are major. Corresponds to a visual quality objective of maximum modification.

(+) and (-) = These symbols indicate, by alternative, the change in a viewshed's condition from the level listed in the Existing Visual Condition. Example: Corral Pass is currently Moderately Altered. At the end of Decade 5, it will be Heavily Altered in Alternative A (a drop of one level (-)); in Alternative C, the condition has changed to Naturally Appearing (an increase (++) of two levels). If there is no (+) or (-), the condition is unchanged.

Direct Effects of Recreation on Scenery

Developed recreation sites, such as campgrounds and picnic areas, generally occur on flat terrain, and their effect on scenery is limited to their immediate environment. Alternative A's (NC would be similar) emphasis would allow low future expansion of developed recreation sites. Alternatives C and H allow for moderate expansion of developed sites. Alternatives B and G-Modified have the lowest emphasis on developed recreation; some existing sites may be closed, and the effects on visual resources from developed recreation would be the lowest of all alternatives.

Developed ski areas can have a significant effect on scenery. Removal of vegetation for ski runs can have an effect similar to a clearcut if the forest canopy has a solid texture. All alternatives allow expansion of ski areas within current permit boundaries. Ski area development will allow the removal, modification, or addition of vegetation; the shaping of slopes; and the addition or modification of structures, but will be guided by Visual Quality Objectives.

Nonmotorized dispersed recreation will have an imperceptible impact on scenic qualities under any alternative. The effect of motorized recreation would also be very minor, due to the lack of opportunities for this type of recreation on the Forest.

Direct Effects of Wild and Scenic Rivers on Scenery

Another measure of the effects of the alternatives on scenery is the number of Wild and Scenic River recommendations that are included in a particular alternative. Table IV-29, on the following page, shows the number and lengths of rivers that would be recommended for Wild and Scenic River designation.

Table IV-29
Wild and Scenic Rivers Recommended for Designation
Number of Segments/Miles Inside the National Forest Boundary

Alternative	No. Segments	Miles
NC (No Change) 1/	0	0
A (No Action)	15	287
I	0	0
B (RPA)	0	0
H	5	154
J (Preferred)	30	452
C	47	606
G-Modified	47	796

1/ The TM Plan (developed in 1963), upon which the No Change Alternative is based was not an integrated resource plan. Not all resource uses and outputs were addressed. The missing data in this table cannot be reasonably estimated; refer to footnote in previous table.

Direct Effects of Air on Scenery

The clarity with which an individual is able to view scenic vistas is affected by the concentrations of aerosals and suspended particulates between the viewer and the scene. Prescribed burning is the variable included in the alternatives that will contribute to increased particulate concentrations. Alternatives vary in their effects on the ability to view scenery proportionally to the amount of prescribed burning being done. The relationships in Table IV-41 reflect this ranking as it is based on the expected particulate emissions associated with each alternative.

Direct Effects of Fire on Scenery

From a landscape perspective, historic wildfire occurrence contributes to diversity in the vegetative mosaic. In the foreground, periodic low intensity fire is responsible for an open appearance with little understory, or limited buildup of down material on the ground. Over time, prescribed burning can assume the same appearance as wildfire. Most of the impacts of fire are subtle and only noticeable to the trained eye. A more visible impact of fire is the appearance of areas immediately after a fire or prescribed burn. Fire may remove portions of the ground cover, kill or scorch understory vegetation, leave blackened debris, or expose mineral soil, all of which interfere with the appearance of the natural setting. The duration of these impacts is determined by the time it takes for vegetation to re-establish, the species involved, soil moisture levels, intensity of burn, and other variables.

The expected acres burned from wildfire is essentially the same under all alternatives; thus, similar effects could be expected in all alternatives. Prescribed burning may be used in all alternatives. The effects of the alternatives will be determined by the extent to which this practice is applied. The ranking of the alternatives based on air quality impacts (displayed in Table IV-41 in the Air section later in this chapter) can be used to compare the way each alternative affects scenery. (This table is based on the amount of burning expected under each alternative.)

Direct Effects of Mining, Energy Development on Scenery

Some level of mineral exploration and development may be expected but the magnitude of its effect on scenery is speculative since specific projects and their locations are unknown. If a large scale mineral development was to occur, land forms as well as vegetation could be altered; effects would last through the life of the project and the time needed for rehabilitation. Mineral exploration consistent with regulations would be allowed in all alternatives, but is subject to visual resource mitigation measures to minimize impacts. The level of restriction on mineral development is tied to the acres assigned in various management areas, which vary by alternative.

Since mineral operations involve a range of activities, the degree to which they affect scenery is strongly affected by the type and location of activity being conducted. Even though some areas would be managed primarily to protect recreational and visual resources, they may be affected by mining claimants, leases, or permittees exercising their statutory or exclusive right to explore, mine or remove minerals from public lands. In approving mining related activities within these areas, scenery will be protected to the extent practicable. However, in some cases, mitigation may be the only option.

To date, however, the effects mining has had on visual resources has been relatively minor and localized, and they would not increase appreciably under any of the alternatives. It can be assumed that the effects would vary slightly by alternative. As with the other resources, these effects would lessen as the area withdrawn or managed under "highly" restrictive management strategies increases.

Direct Effects of Land Uses on Scenery

Land exchange can have a significant effect on scenery, through the acquisition or disposition of sensitive landscapes. Exchanged landscapes may be unnaturally altered in the future, a result of another owner's management practices. If acquired lands are cut over, scenery may not appear as natural as surrounding areas and management practices may not be able to alleviate this effect for several decades. In either event, the future management of exchanged parcels will likely be different than under its current management. The immediate effect of land exchange may not be noticeable.

Generally, land withdrawals tend to leave scenery unaltered by limiting the kind of management activity that can take place on a particular piece of ground, but they do not ensure the preservation of scenery in an unaltered state.

Direct Effects of Roads on Scenery

Roads are the primary method used to access the National Forest. Roads across steep side slopes require cuts and fills that create unnatural straight lines across the landscape when screening vegetation is removed. These exposed slopes often create a permanent visual scar. Effects will be the greatest in those alternatives with the most miles of new road construction: NC, A, B, I, and H.

The forms of many utility structures are geometric, forceful, and large. They often contrast with and visually dominate the landscape. Right-of-way clearings, access roads, storage yards, and other utility support facilities alter the landscape. Requests for the use of National Forest lands for utilities will continue; however, specific projects and locations are not known. The introduction of utility structures is governed by the Visual Quality Objectives associated with each management area. Alternatives which do not emphasize high scenic quality in roaded areas (NC, A, B, I, and G-Modified) have the greatest potential impact.

Design techniques are available that lessen, but do not eliminate the effects of utility corridors. The one potential new corridor (Pyramid Peak-Tacoma Pass area) would be located entirely in checkerboard ownership. The visual condition of this landscape has been heavily altered by timber harvest. A proposal for a new power transmission line between Pyramid Peak and Tacoma Pass would be permitted in all alternatives except Alternative G-Modified. The need for this potential utility corridor is not anticipated in the next decade.

Scenery - The Cumulative Effects of the Alternatives

While the impact of one project may not seem significant, when carried out over time, the cumulative effects of continuous practices or additional activities

proposed by an alternative may change the character of the scenic setting by intensifying disturbance or healing through revegetation. Because much of our landscape is steep and readily viewed, it has low visual absorbtion capability. Recovery occurs in stages. In the middleground restablishment of a conifer stand after clearcutting takes about 15-20 years to eliminate soil color contrast. The contrasting height remains much longer but is more subtle. In the foreground, the age of the forest, composition of understory species, and remains of harvest activities, are much more noticeable. Timber harvesting in scenic viewsheds is planned at a rate that allows retention of a mature forest character. Alternatives and management allocations emphasizing commodity production (alternatives NC, A, I, B) will, in the long-term, result in a lower visual quality level and a more altered landscape than the non-market emphasis alternatives. Table IV-28 predicts the long term visual quality levels that would result under each alternative by viewshed.

Scenery - The Indirect Effects on Other Resources

General

The extended rotations planned to retain mature forest character results in reduced timber harvest levels in allocated viewsheds. Mitigation measures proposed to meet visual quality objectives may increase costs for planning and implementing projects.

Recreation

Alternatives which maintain or enhance visual quality along scenic highways (C, H, J (Preferred)) may gradually increase demand for driving for pleasure. These alternatives offer many opportunities for a Roaded Natural experience. Alternatives A, NC, B, and I would offer few or no Roaded Natural opportunities; they would be replaced by Roaded Modified. As more of the Forest is converted from an unroaded to a roaded condition (Alternatives NC, A, B, and I), access increases; however, the associated scenic quality will decline because the landscape will be more altered.

Alterations of the landscape may change use patterns of recreational activities simply because the "setting" has been altered. For example, the use of a trail may be displaced to another trail when a clearcut is harvested nearby; the management activity has altered the setting and the experience level, causing the use to be displaced to another area. The resulting ROS class would be the best measure of this change.

If primitive or semiprimitive recreation opportunities are desired, a naturally appearing landscape is required. These settings also best contribute to the conservation of natural biological diversity.

Trails

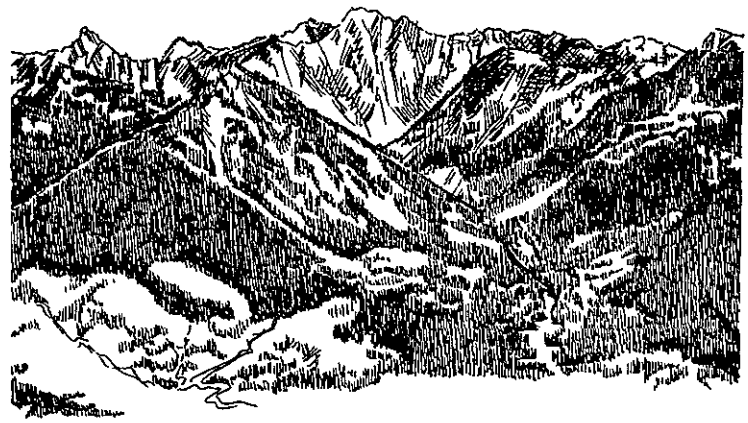
There are no measurable effects.

Wilderness

There are no measurable effects.

Research Natural Areas

There are no measurable effects.



Roadless Areas

There are no measurable effects.

Wild and Scenic Rivers

There are no measurable effects.

Air

There are no measurable effects.

Fire

There are no measurable effects.

Minerals

Mitigation measures may increase operation costs and may make some potential mineral sources uneconomic to develop. This will be the same for all alternatives.

Land Ownership and Use

There are no measurable effects.

Roads

Mitigation measures may influence road or utility facilities location and design. This will be greatest in Alternatives H, J (Preferred) and C; moderate in Alternative I; and lowest in Alternatives NC, A, B and G-Modified based on number of acres in scenic viewshed.

Mitigation Measures for Scenery

The effects of most management activities can be mitigated through design. The minimum standard for the Forest is Maximum Modification. Mitigation measures applicable to each management area are discussed in Chapter II. Design and selection of construction materials to blend with the natural landscape can mitigate impacts and are guided by the Standards and Guidelines.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Scenery

National Park Service policy is to preserve landscapes in as near natural conditions as possible. Alternatives emphasizing commodity production on lands adjacent to North Cascades and Mt. Rainier National Parks would result in obvious visual contrasts.

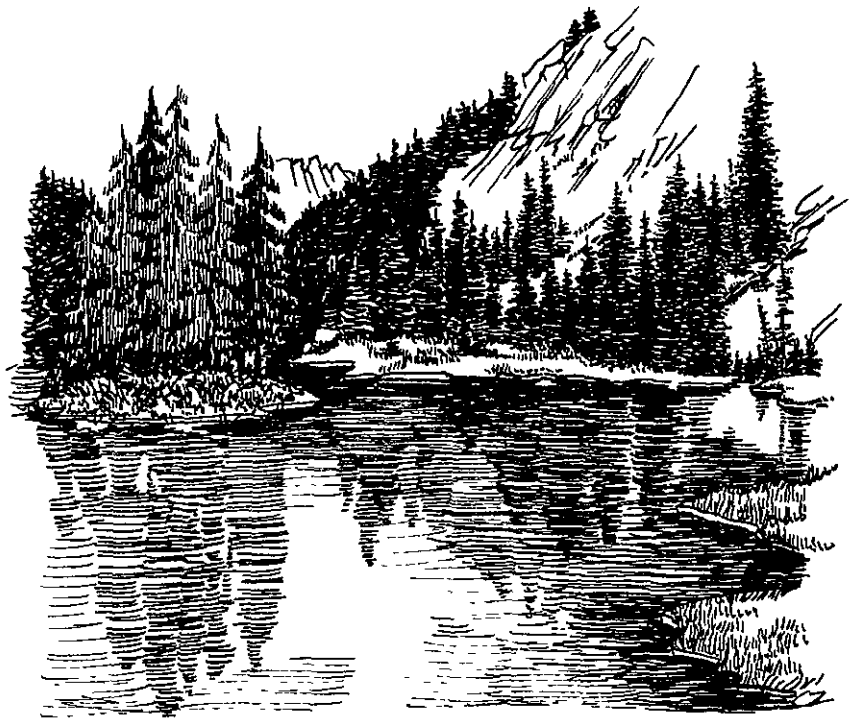
All alternatives would protect scenic quality along the foreground of the Mather Memorial Parkway leading into Mt. Rainier National Park; in addition,

Alternatives C, H, and J (Preferred) would maintain scenic quality in the middleground of this corridor.

The viewshed of the North Cascades Highway (Hwy 20) accessing the North Cascades National Park is predominately a middleground corridor. Scenery would be managed under a scenic corridor allocation in Alternatives C, H, and J (Preferred), and largely protected through semi-primitive or old growth allocations in Alternative G-Modified. In Alternatives NC, A, B, and I, scenic quality will be reduced.

The Cascade River Road is designated as a Scenic Viewshed in Alternatives C and J (Preferred).

No other specific inconsistencies or incompatibilities were identified in the review of other federal agencies', state and local governments', and Indian tribes policies' or plans.



RECREATION

Recreation - The Direct Effects of Each Alternative

General

Developed Recreation. The alternatives presented in this FEIS all have the potential to directly or indirectly affect the recreation associated with developed sites. Opportunities for developed site recreation (campgrounds and day-use) would remain about the same in all alternatives. Current developed site capacity is more than sufficient to meet projected demand in the near future. In all alternatives, emphasis will be on the maintenance and operation of existing sites in a cost efficient manner. Rehabilitation and expansion of deteriorated existing sites would occur before new facilities are constructed.

Although the number of developed recreation sites would not decrease under any alternative, the number of sites which would eventually be in a modified setting would vary by alternative. The differences relate to the amount of roading and vegetative manipulation which would occur on lands surrounding the sites. Timber management activities have a high potential to alter the recreation setting and the experiences offered at these sites. Timber harvest and other management activities tend to give the forest a cultured look as opposed to a natural setting. These activities reduce the primitive and remote feeling for many recreationists. On the other hand, the harvest of diseased or dangerous trees in campgrounds through timber sales improves safety at the site. Alternatives A, B, and I have the greatest effect on developed site settings. This information is displayed in the following table, Table IV-30.

Table IV-30
Developed Sites in a Modified Setting

Alternative	Trailheads	Campgrounds	Picnic Sites	Total	%
A (No Action)	2	11	3	16	21%
I	3	10	3	16	21%
B (RPA	3	8	1	12	16%
H	1	4	1	6	8%
J (Preferred)	1	1	0	2	3%
C	0	2	0	2	3%
G-Modified	0	8	1	9	12%

The developed recreation setting, particularly the social component, and developed recreation opportunities are directly affected by recreation visitor use. As recreation use of a site increases, the social setting changes along with the experience available to the users. Some people are not concerned with the changes, others are displaced and seek other less crowded areas on the Forest or in other sites off of the Forest. Crowding results in increased social interaction and conflicts, noise, dust and congestion, law enforcement problems, and increased demands on the sanitation and water systems.

Alternatives B and G-Modified have a decreased emphasis on new developed site construction and would offer fewer sites for public use. Even though in these alternatives, no new developed sites are constructed, there will be more than enough capacity to meet current demand. Social setting changes in these alternatives will occur sooner than in the other alternatives.

Alternatives that reduce the number of developed site opportunities will divert some use into roaded dispersed areas. Individuals who traditionally utilize the smaller more remote, non-fee campgrounds will gradually lose that camping opportunity and will most likely turn to motorized dispersed camping (Mitchell, 1989).

Alternatives NC, A, C, I, H, and J (Preferred) will increase the future developed site capacity, which could affect adjacent lands suitable for dispersed nonmotorized recreation. Adding new sites or upgrading existing sites to accommodate more use can change the number of encounters experienced in adjacent undeveloped areas. An increased number of dispersed campsites can result in less solitude. In addition, as more people visit an area, the type of experience that is available will change (Mitchell, 1989).

The amount of land available for dispersed recreation would not be substantially altered by the implementation of any alternative program for developed sites.

Dispersed Recreation. Management activities, especially timber harvest and road construction, can directly and indirectly affect dispersed recreation settings and change the nature of recreational experiences. When MA's prescribing timber harvest and road construction are applied to areas currently providing dispersed unroaded opportunities, those areas will change to dispersed, roaded types of recreation. The change is usually irreversible; the opportunity to provide unroaded dispersed recreation would be lost in those areas.

This shift from dispersed unroaded to roaded is the most severe of the effects of the alternatives on the recreational setting, as the Mt. Baker-Snoqualmie already cannot meet the demand for unroaded dispersed recreation. As use exceeds the practical capacity in an area, the user's experience becomes more like that of a roaded natural area, in terms of social and physical impacts.

A reduction in solitude and loss of primitive opportunities is the result of this reduction in the unroaded dispersed component of the recreation spectrum.

Alternatives C, and G-Modified emphasize unroaded recreation and would provide the greatest amount of Semi-Primitive Nonmotorized recreation.

Alternatives B and I retain the fewest acres in a roadless condition and provide the greatest road access potential. The majority of the roadless area acres suitable for harvest would be roaded and the timber harvested. Those recreationists who utilized unroaded dispersed areas for hiking, climbing, hunting, and fishing will find a declining number of acres of land available. Both the number of opportunities and the quality of those remaining opportunities would be reduced. Those recreationists relying on roaded settings would benefit from more opportunities under these alternatives. Access would be improved in these alternatives, making it more convienent for some segments of the public to use these areas.

Table IV-31, below, and Figure IV-6 on the following page, show the effects of implementing the various alternatives on the recreational opportunity spectrum. The ROS acres would be achieved by the end of the fourth decade of Plan implementation, but not sooner. As the land allocations for each alternative are implemented, the recreation setting will gradually change, resulting in the acres shown below by the end of Decade 4.

Table IV-31
ROS Acres Available, By Alternative - Fourth Decade

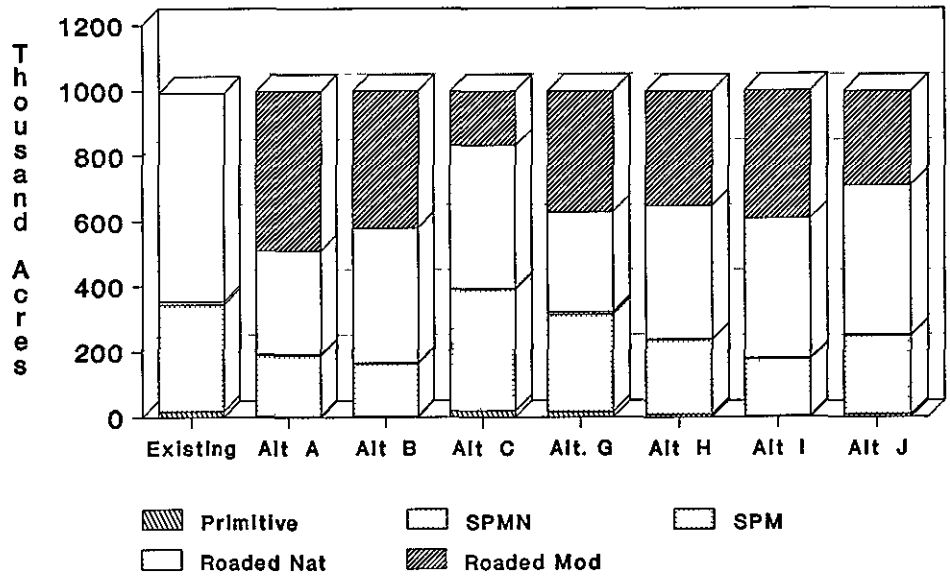
Alternative	Nonmotorized		Motorized		
	Primitive	SPNM	SPM	RN	RM
Existing	16,700	326,500	9,700	------638,600------	
NC (No Change)1/	.....Similar to A.....				
A (No Action)	3,700	184,700	2,600	317,600	489,800
I	3,400	170,700	4,400	429,500	391,100
B (RPA)	3,100	158,400	3,100	415,400	418,600
H	7,800	227,400	1,800	410,700	349,200
J (Pref)	8,000	238,800	3,300	458,900	289,300
C	19,400	371,700	700	439,300	167,200
G-Modified	15,000	297,200	8,300	308,000	369,000

1/ The No Change Alternative does not include ROS as management direction. However, it offers a mix of acres and uses similar to those in Alternative A.

The activities of people participating in recreation activities in the Semi-Primitive Nonmotorized zone can cause much change in this setting. The effects of use vary by numbers and activity (hiking, horse, etc.). Impacts to dispersed campsites include the establishment of additional sites; trampling of vegetation (leaving the site denuded and/or revegetated with more resistant[6] plant species); new or additional tree damage; and root exposure from horse use or intensive foot traffic. Even light use produces substantial unnatural change in these areas (Frissell and Duncan 1965, Merriam and others 1973).

Semi-Primitive Motorized recreation opportunities are very limited on the Forest, due to climatic and topographic constraints. The Mt. Baker-Snoqualmie cannot even meet current demand for this use. All alternatives will further reduce the acres in this ROS class, as they are converted to Roaded Natural and Roaded Modified conditions. This trend will cause increased potential conflicts between motorized and nonmotorized use, particularly in the unroaded areas. For some people, ORV use is a disruption of their recreation experience; they feel it creates noise, dust, and impacts to soils, vegetation,

Figure IV-6 ROS Acres Reached by Decade Four



Existing situation combines RN & RM; all alternatives have very few SPM acres

and wildlife. Others feel the recreation setting should be able to accommodate more ORV use and that the impacts are not significant.

Projections indicate that the overall future demand for dispersed roaded recreation can be met in all alternatives. Recreation opportunities associated with roads in Roaded Modified and Roaded Natural ROS settings would be plentiful. These include hunting, driving for pleasure, ORV use of roads, dispersed camping, and fishing.

The alternatives offer different mixes of recreation opportunities in a roaded setting. Alternatives NC, A, B and I have the highest miles of new road construction and provide the most roaded recreation opportunities. Alternatives H and J (Preferred) develop moderate amounts of new roads, while Alternative C and G-Modified have low new road mileage.

Alternatives C and G-Modified would be the most restrictive to future roaded dispersed recreation. About 300 miles of arterial and collector roads will be closed in Alternative C, to create more Primitive and Semi-Primitive Nonmotorized recreation opportunities. Alternative G closes 65 miles of roads, producing similar results. Both Alternatives C and G-Modified continue to produce more than enough dispersed roaded recreation opportunities to meet anticipated future demand for approximately forty years.

Direct Effects of Timber Harvest on Recreation

The most direct effect of timber harvesting on the recreation setting is the shift in acres from a Semi-Primitive Nonmotorized setting to the roaded ROS classes. This process is generally irreversible. Timber management activities reduce the natural appearance of the setting. These activities reduce the wild, primitive, and remote feeling for many recreationists and change their overall experience. The presence of roads encourages motorized use in these areas, reducing solitude and freedom from the sights and sounds of human activity. Although the roads could be closed to motorized use, their presence would change the natural, unmodified quality of the SPNM setting. The opportunity to provide for unroaded dispersed recreation would be lost in those areas. This will be the most pronounced in Alternatives NC, A, B, I and H. Only Alternative C offers an increase in number of acres and opportunities in the unroaded ROS classes.

On the other hand, timber sale activities may be designed to improve trailheads and trail locations, achieve vegetative diversity, and provide openings for viewing scenic panoramas.

Those alternatives which assign the most acres to timber harvest will result in the greatest effects on the trail system and trailheads, as harvest areas and access roads cause the relocation or reconstruction of trails. Temporary trail bypasses may be necessary during harvest activities unless the permanent trail is to be relocated outside of the harvest area. Alternatives A (20%), B (18%), and I (14%) will have the greatest percent of trails within timber management areas. Alternatives C and J (Preferred) will have five percent of their total trail mileage in intensive timber management allocations. Trails in these areas could be heavily impacted by harvest activity.

Some timber management activities and new access would increase the availability of areas for snowmobiling, cross-country skiing, mountain biking, and ORV/ATV use. This would be the greatest in alternatives A, NC, B, and I.

Developed site users may find their daytime use of surrounding dispersed recreation areas precluded or altered by nearby timber harvesting. The presence of, and intensity of trucks hauling logs by a campground will create noise and a potential safety hazard. This may be offset by increased ease of access. Consequently, alternatives that provide for a high level of timber harvest, such as Alternatives NC, A, B, I and H, will indirectly affect and ultimately reduce dispersed recreation opportunities for developed site users. This will be true for most summer camping experiences. However, this may not be the case for off-road vehicle use and for fall hunting, as these users are less affected by timber harvest activities (Clark and Stankey 1979).

Direct Effects of Wildlife Habitat Improvement on Recreation

Seasonal closures of roaded areas to recreational use (ORV's) may occur in areas managed for elk calving, for deer and elk winter range, or for mountain goat habitat. User restrictions or closures for wildlife purposes would influence where visitors go to participate in recreation activities or the quality of their experience.

Direct Effects of Archaeological and Historic Properties on Recreation

Protection of cultural resource sites may require redesign of proposed recreation sites, or alter the use of existing sites. Protection may include interpretation of the cultural resource, which will create new recreation opportunities. Effects will be similar in nature and extent in all alternatives, and will be evaluated through compliance with 36 CFR 800 and the environmental analysis process on a project-level basis.

Direct Effects of Trails on Recreation

Trail construction increases the opportunities for public use of many areas of the National Forest. Because many recreationists utilize a developed site for an overnight base and spend the day on hikes into the backcountry and wilderness, alternatives that result in increased construction and maintenance of the trail system would increase the opportunities and quality of experiences for these individuals. In the next decade, all alternatives would construct additional miles of trails, ranging from a low of 102 miles in Alternative B, to a high of 350 in Alternative G-Modified and C. (See Table IV-32.)

Table IV-32
Trail Construction and Reconstruction - Miles in Decades 1 & 2

	NC 1/	A (No Act.)	I	B (RPA)	H	J (Pref)	C	G (Mod)
Construction	Sim							
Wilderness	to	10	10	18	43	20	43	10
Non-Wilderness	A	130	340	84	135	200	135	340
Reconstruction (Decade 1)	"	120	236	140	240	493	160	236

1/ Similar to Alternative A.

Expanded trail construction and reconstruction can relieve heavy use trails by providing alternative travel opportunities and providing specialized trails for use by horses, motorized vehicles, and others.

Direct Effects of Fire on Recreation

The low frequency of wildfires on this Forest pose little threat to the safety of the recreating public or the facilities provided for their use. All alternative have the same potential for wildfire, and therefore, the same effects. The Standards and Guidelines provide direction for the use of prescribed burning in and around recreation sites. This will mitigate the differences between any alternatives for prescribed burning.

Direct Effects of Mining, Energy Development on Recreation

Oil, gas, and geothermal potential on the Forest in the vicinity of developed sites is extremely limited. The environmental analysis process will consider

these situations on a case-by-case basis. No development is anticipated in the first decade.

The most significant effect from oil, gas, and geothermal lease development on nonmotorized recreation would be the development of any long-term road access necessary to extract minerals. Road development would result in a change in the ROS class in the immediate area. Alternatives NC, A, B, and I will provide for greatest increased road access to the National Forest, which would make the development of oil, gas, and geothermal leases easier. Alternatives H and J (Preferred) provide for moderate access; Alternatives C and G-Modified with low road construction would tend to discourage this activity. The energy market will tend to be more of a driving force than planned land allocations.

Access roads built for mineral exploration and extraction can provide motorized use opportunities. They can also create safety problems between motorized users and mineral extraction vehicles during the period of extraction. Mineral and energy extraction could increase the acres of Roaded Natural on the Forest, thus providing more motorized recreation opportunities. However, given the kinds and amounts of mineral deposits on the Forest, the effects resulting from variations in minerals management of the different alternatives is expected to be slight.

Those areas being managed as unroaded will not be withdrawn from mineral entry. They will remain subject to exploration, mining claim location, leasing, permitting and development activities, and they will remain subject to the associated environmental effects. Since reasonable access for mining purposes on valid mining claims is a statutory right, mineral activities may result in roading of areas which are managed primarily for unroaded recreation. The activities could degrade the visual quality and recreation experience by introducing the sights and sounds of man to such an extent that the ROS class may be changed from Semi-Primitive to Roaded Natural. Displacement of users could be expected. Effects resulting from mineral activities conducted within these areas would include the improved access to remote areas which were previously inaccessible (due to lack of roads or poor road conditions).

Direct Effects of Land Uses on Recreation

Some land use grants and utility corridors provide opportunities for ORV use, in the powerline easements. (ORV use often occurs under the powerlines within the cleared right-of-way). These easements offer one of the most attractive locations for ORV and ATV use on the Forest. Only one potential utility corridor exists on the Forest, crossing the Cascades between Pyramid Peak and Tacoma Pass. This corridor would not be constructed in the first decade. Only Alternative G would preclude construction of this corridor. Construction in other alternatives would be contingent on meeting direction contained in the Management Prescriptions.

The public will use the utility corridors, particularly the high-voltage line right-of-ways for cross-country skiing and snowmobiling, and for summer ORV use.

Structures, such as powerlines would generally not be compatible with Primitive and Semi-primitive recreation opportunities. They would be compatible with

roaded recreation opportunities depending on the location and design of the structures.

Direct Effects of Roads on Recreation

The alternatives will affect dispersed recreation to the extent that they construct new roads and maintain existing ones. During the first decade, Alternative NC will construct the most miles each year at 28 miles; Alternative A is the next highest at 18.8, and Alternative G-Modified, the least at 8.7. The other alternatives fall between.

The primary effect of alternatives with more extensive road construction will be to modify the overall recreational setting. A shift will take place from Semi-Primitive Nonmotorized and Motorized ROS classes to Roaded Natural and Roaded Modified. A loss of more primitive settings will result in displacement of users into remaining roadless areas, wilderness, or adjacent National Parks.

Besides the decrease in the acres of roadless lands, the remaining roadless acres will be more accessible due to the number and proximity of adjacent roads. These effects will be most noticeable in alternatives with high road mileage and high development of the roadless areas. Alternatives NC, A, B, I. Alternatives C and G-Modified have the most acres dedicated to a roadless status (and also proposed road closures to expand primitive and semi-primitive dispersed areas), so fewer acres will be affected by the existence of adjacent roads in these alternatives.

The road system is used by many ORV enthusiasts, much as they would use an ORV park like Evans Creek. Thus, ORV recreationists would be better served by alternatives that construct more roads (Clark and others 1984).

A road network also enhances other dispersed recreation opportunities by providing motorized access for hunting; for the collection of such forest products as firewood, berries, and Christmas trees; or for dispersed camping and hiking.

Road maintenance requirements will vary in proportion to total visitor use and the miles of new roads constructed.

Some developed recreation sites, such as ski areas, can become so successful that they outgrow their local support systems. For example, a highway that can carry 2,000 skiers per day to a ski area may become dangerous when traffic levels reach 5,000 skiers per day. The potential for this exists at Crystal Mountain and Mt. Baker Ski Areas.

Recreation - The Cumulative Effects of the Alternatives

The Mt. Baker-Snoqualmie National Forest has a broad diversity of recreation settings and opportunities with recreation occurring in almost all areas of the Forest at some time of the year. Because of the proximity of the Forest to the large populations in the Puget Sound area, recreation is a major Forest program. The quality of the setting is an extremely valuable amenity, and the maintenance of a variety of settings is very important to the public. The recreation setting is easily managed and has not been, for the most part, subject to permanent degradation. However, major changes due to a combination of factors, including road construction, alteration of vegetation, construction

of facilities and the effects of fire, insects, and disease in forested areas, can produce long term impacts requiring up to 100 years to repair. The scope of these effects includes all lands in the Forest.

Cumulative effects on the recreation setting can be on the basis of change in visual qualities of an area, both foreground and background, the feeling of remoteness or wildness of the area, the natural-appearing qualities of the area, and the social conditions. The social conditions include the presence or absence of other people, the interaction or conflicts between users, and the type of facilities and developments provided for users.

On the Mt. Baker-Snoqualmie, the cumulative effects of the alternatives on recreation would primarily be reflected in the development of areas currently offering unroaded dispersed recreation opportunities. Those alternatives which assign the roadless areas to timber harvest and roading could be expected to gradually reduce opportunities for recreation in an unroaded setting. The Forest is the primary supplier for unroaded recreation in the Puget Sound Basin; use is already above the capacity expected in a Semi-Primitive ROS setting. Any reduction of unroaded dispersed recreation area would only further worsen this situation and contribute to a regional decline in the availability of this form of recreation. The alternatives which emphasize development of the Forest resources and have the greatest acres assigned to intensive management allocations are A, NC, B, and I. These alternatives may substantially alter the environment, present a risk of long term modification of the recreation setting, and may have cumulative impacts. Alternatives H and J (Preferred) present a moderate risk of long term modification of the recreation setting and may also have cumulative effects. In Alternatives C and G-Modified, the lower acreages in intensive management present the least potential for cumulative effects on the recreation setting.

There are few apparent cumulative effects on developed recreation. A possible cumulative effect for developed sites could occur if funding is not available to maintain these facilities to a standard service level. If forced to operate at below standard levels, effects would be continued soil erosion, degradation of facilities, closure of already degraded sites, loss of vegetation, and water quality problems.

Recreation - The Indirect Effects on Other Resources

Trails

See previous discussion of the Direct Effects of Trails on Recreation.

Wilderness

Developed recreation sites often serve as a base for trips of one or more days into wilderness. Consequently, wilderness may receive a greater number of visits because of a nearby developed recreation site. The possible effects of this are that the quality of the recreation experience for the developed site user could be improved, and some areas in wilderness may be significantly over-used.

Semi-primitive nonmotorized areas are able to absorb higher levels of impact than is allowed in wilderness. Some uses of wilderness can be shifted to non-wilderness, taking some of the pressure off wilderness. This becomes

increasingly important as wilderness near the conditions described by the Limits of Acceptable Change.

Alternatives A, NC, B, I, and H reduce the semi-primitive nonmotorized area appreciably. This will reduce the opportunity for these areas to absorb non-wilderness activities. With few areas allocated to unroaded status, pressure will increase to use wilderness and the remaining semi-primitive nonmotorized areas.

Research Natural Areas

As has been the case for many years at the established Lake Twenty-two RNA, the potential Green Mountain and Perry Creek RNAs have highly-used trails and popular destination points within their boundaries. This use is allowed by the management area prescriptions so long as the objectives for that RNA can be met. While this is currently the case, possible future changes that could affect recreation include:

1. If recreational use becomes so great that the RNA objectives are being compromised, closure, or a permit system to enter, would need to be implemented to prevent damage.

2. Trail condition will likely deteriorate, as the trail system will be managed only to the level needed for research access, not for public use.

These changes would apply to the established Lake Twenty-two RNA in all alternatives, and to the Green Mountain and Perry Creek potential RNAs in Alternatives C, G-Modified, H, and J (Preferred).

Roadless Areas

There are no known indirect effects on Roadless areas from changes in Recreation in any of the alternatives.

Wild and Scenic Rivers

No indirect effects from changes in Recreation to Wild and Scenic Rivers from implementing alternatives are anticipated.

Air

No indirect effects from changes in Recreation to Air from implementing alternatives are anticipated.

Fire

Special protection needs of developed recreation sites have created isolated enclaves requiring more intensive fire protection programs than are required for the areas surrounding them. To insure that protection goals for these special areas are met, it has been necessary to design protection strategies that over protect some of the area surrounding these sites. The Alternatives (A, B and I) which include the highest level of recreation facility development have the highest protection needs. Since this is a very small part of the total fire protection program on this forest, the variation between alternatives does not reflect differences in total protection investments.

Since a majority of human caused fires on the Forest are associated with recreation use, it could be assumed that alternatives which result in the greatest recreation use in the summer will have the greatest number of fires to suppress. Past trends in human caused fire frequency have shown little relationship to recreation use. In fact, recreation related fire occurrence has been somewhat constant over the past 30 years (Annual Fire Reports for the MBS), while recreation use has increased significantly. Fire protection needs associated with recreation use are assumed to be equal under all alternatives.

Minerals

If potential developed sites are withdrawn from mineral entry, any mineral values they contain will be unavailable for human use.

Recreation sites will bring many people into an area who would not otherwise be there. If mineral extraction is located near a developed recreation site, there could be conflicts between the miner and the recreation visitors.

Alternative G-Modified would manage for small developed recreation sites, spread throughout the National Forest, increasing the likelihood of mining/recreation conflicts (although mineral development potential has been low on the Forest). Alternatives B and I provide for high levels of ORV use. Alternatives C and G-Modified would have low levels of motorized use and thus less opportunities for conflict.

Land Ownership and Use

No indirect effects from changes in Recreation to Land Ownership and Use from implementing alternatives are anticipated.

Roads

Roads require maintenance if they are to remain open. However, increased use will also increase the need for maintenance on roads and trails.

The indirect effect of dispersed recreation on roads will vary among alternatives. Those alternatives with high levels of motorized dispersed use and low level of nonmotorized dispersed use will require more roads be kept open for public use than those alternatives which have the reverse relationship. (See Table IV-33.)

Changes in the density and location of roads on the periphery of the semi-primitive areas can increase the number of vehicles accessing these areas.

Facilities

Developed recreation services and facilities, and services permitted on National Forest land but administered by the private sector can have similar but additional effects. Private sector developments include lodges, resorts, ski areas, organization camps, summer homes, and other similarly developed sites. In addition to those effects resulting from attracting and concentrating recreationists, these sites tend to occupy large tracts of land and can affect trails by disruption of travel routes. Private sector recreation development can cause trails to be displaced and relocated.

Table IV-33
Recreation Use Relative To Roads, During Decade 1

Alternative	Unroaded Recreation Use (M) RVD's 1st Decade	Roaded Recreation Use (M) RVD's 1st Decade	Miles New Road 1st Decade
NC (No Change)	.....Similar to A.....		288
A (No Action)	201	1,854 to 2,266	188
I	208	"	171
B (RPA)	200	"	161
H	205	"	141
J (Preferred)	208	"	134
C	222	"	103
G-Modified	218	"	81

Mitigation Measures for Recreation

Numerous mitigation measures would be applied to lands capable of providing Semi-primitive or Roaded Natural recreation opportunities, but not allocated to Semi-primitive or Roaded Natural management areas. These mitigation measures would reduce the impacts of other management activities upon scenic quality, wildlife habitat, and recreation opportunities. These measures would include varying the size and location of harvest units to blend with the landscape, properly locating range improvements, providing adequate cover/forage ratios for big game, leaving sufficient standing dead trees for nesting/roosting habitat, and providing informational signing for users. These measures, however, would not reduce the loss of Semi-primitve or Roaded Natural recreation opportunities. Thus, the only mitigation measure that would prevent the loss of these settings would be allocation to Semi-primitive or Roaded Natural Dispersed Recreation.

Potential conflicts between users would be mitigated by working with the affected user groups. Visitor control measures such as signs, permits, and restrictions would be used where necessary. In some situations, separation of activities may be required, but would be used as a last resort.

Expansion of existing sites or construction of new sites would be programmed where necessary to meet demand for developed recreation opportunities.

Conflicts Between Effects of Alternatives and Other's Plans and Policies for Recreation

National Forest developed sites are used as a base for users of the two National Parks adjacent to the Mt. Baker-Snoqualmie. In some cases, they are a base for a significant amount of National Park use. National Park Service management plans assume this will continue. Most alternatives maintain or increase developed site capacity, but closure of some campgrounds that serve as base camps for use of National Parks may reduce use, or increase pressure on sites within the National Park, thus conflicting with National Parks Service plans. Also, the shift in ROS classes toward the developed end of the spectrum may result in an

increasing displacement of recreationists into National Parks and into other National Forest wilderness areas.

Several communities adjacent to the National Forest are engaged in recreational promotions to increase tourism and to stimulate local economies. Some of these plans are dependent on National Forest developed sites as an attraction to visitors. For example, communities may provide food and lodging for skiers to a ski area located on National Forest land. The same community may promote summer camping, day use, rafting, and pack trips to provide year-round economic activity. All alternatives except G-Modified reduce small developed site opportunities while concentrating management efforts and funds on larger sites that could compete with private sites located off of National Forest land. Some developed sites (campgrounds and day-use sites) may be closed in all alternatives, which could conflict with the plans of these communities. Alternative G-Modified would reduce or prevent the expansion of resorts and thus may be contrary to these community plans.

Some developed sites, especially resorts and ski areas, can develop large traffic volumes for short periods of time. The necessary expensive road maintenance to handle these traffic volumes may not be part of the state or county plans for management of these roads. The opposite may also be true in situations where the local agencies may plan on a road standard higher than that desired for dispersed recreation management of an area, thus leading to overuse of the area.

TRAILS

Trails - The Direct Effects of Each Alternative

General

Use of the Forest trail system is one of the largest dispersed recreation uses on the Forest. Trails are located in roaded and unroaded settings; over 42 percent of the current inventory (1,384 miles) is located in wilderness.

Varying miles of trails are constructed and reconstructed in the alternatives to meet the objectives of each alternative. The estimated miles of construction and reconstruction are shown, by alternative, in Table IV-33a.

Table IV-33a
Trail Construction and Reconstruction Miles - Decades 1 & 2

	NC (No Chg.)	A (No Act.)	I	B (RPA)	H	J (Pref)	C	G(Mod)
Construction	1/							
Wilderness	1/	10	10	18	43	20	43	10
Non-Wilderness	1/	130	340	84	135	200	135	340
Reconstruction	1/	120	236	140	240	493	160	236

1/ Similar to Alternative A.

Direct Effects of Timber Harvest on Trails

Trails in management areas which allow timber harvest are subject to relocation and other impacts associated with roading and timber harvest. Effects on trails include segmentation, where the trail is crossed several times in a short stretch by roads. The net effect is a loss of total trail mileage. Clearcuts along and across trails change the character of the recreation setting; they can open distant views, or create unnatural openings. The setting will generally appear heavily modified when viewed in the foreground from the trail.

Direct Effects of Recreation on Trails

Motorized trail use occurs in all alternatives. However, in some management areas, motorized trail use is prohibited, including: 1A (Primitive Dispersed Recreation), 1B (Semi-Primitive Dispersed Recreation), 4 (Mt. Baker National Recreation Area - allows winter motorized use), 5C (Potential Wild River), 10 (Wilderness), 11 (core acreage of SOHA's), and 18 (RNA). In addition, ORV use may be restricted in the following management areas: 7 (American Indian Religious and Cultural Use Areas); 8 (Special Areas); and 11, 12, 14, and 15 (Wildlife MR's and habitat improvement areas).

It is anticipated that additional miles of trail could be closed to prevent resource damage and to minimize user conflicts. Examples of closures could include seasonal closures on deer and elk winter range; closures to reduce user conflicts between hikers, horse use, and trailbikes; closures on all trails leading to wilderness; and closures around Spotted Owl Habitat Areas.

Alternative C and G-Modified are the most restrictive towards trailed ORV use. The allocation to Semi-Primitive Motorized Dispersed Recreation in Alternative I is very misleading. While a large number of acres are allocated, most of these acres will remain in a SPNM ROS setting; SPM ROS in this alternative equals 4,400 acres. It is on these acres that non-roaded motorized use will occur. Alternative G-Modified contains the largest assignment to Semi-Primitive Motorized Dispersed Recreation, with concentrated ORV use in the Kelly Butte Area; but over much of the rest of the Forest, use is restricted.

Alternatives H and J (Preferred) restrict trailed ORV use on any trail leading to wilderness or terminating on a hiker-only trail. Alternatives A (NC is similar) and I retain the most trailed ORV opportunities. The other alternatives fall in the moderate range.

Direct Effects of Roads on Trails

Construction of additional roads may result in a loss of trail miles as new roads are added to the system. New roads generally replace trails as main access routes into areas when commodity production is undertaken. This will be most noticeable in alternatives NC, A, I, and B where the largest number of suitable acres are found. Alternative C and G-Modified, which have the fewest number of suitable acres, will have the lowest number of new roads built and will have the lowest impact on the trail system in the managed forest.

Trails - The Cumulative Effects of the Alternatives

Activities that destroy trails by obliteration or bi-section without relocation or replacement mitigation measures have the greatest cumulative effect on trails. System trail mileage on the Mt. Baker-Snoqualmie National Forest has decreased over the years to the current inventory level of 1,384 miles. The decrease in mileage is mostly a result of road development and lack of funding for trail maintenance and construction. The cumulative loss of trail mileage is inversely proportional to the cumulative gain of road mileage (USDA Forest Service Trail and Road Inventory Reports).

The greatest cumulative effect from road construction and subsequent trail displacement is the elimination of trailed recreation opportunities. Where areas have been roaded extensively, trail users seek other unroaded areas where trails exist to hike (Anderson and Brown 1984, Clark and Stankey 1979). Development of hiker trails in heavily roaded areas is relegated to a much lower priority in Forest management, due to user preference for trails in unroaded areas that offer a higher degree of solitude. The roaded areas on the Forest are generally at the lower elevations, which provide users a longer season of use, compared to the shorter use season at higher elevations. Demand exists for lower elevation trails to provide user opportunities when higher trails are snow-covered. This preference has been expressed during public input phases of several planning efforts - 1977 Trail Plan, Skagit Wild and Scenic River Plan, 1981 Alpine Lakes Plan, and in response to the FEIS of this

Forest Plan. Public comments on trails and their management were one of the major issues identified by respondents to the Draft Plan.

An additional cumulative effect of trail loss or relocation through replacement by roads is the concentration of users on fewer and fewer trail miles. This is compounded by increased trail use, as each year, recreationists seek new and more challenging hiking experiences (Schreyer and others 1984). This situation may conflict with management attempts to limit a trail user's encounters with other trail users and maintain a defined recreation experience on a particular trail. Overcrowding of trails results in secondary impacts to trails such as litter, sanitation, and trail tread deterioration (USDA Forest Service 1986).

Trails - The Indirect Effects on Other Resources

Wilderness

Some roads would be closed in Alternatives C and G-Modified to increase Primitive and Semi-primitive Nonmotorized opportunities. This would help minimize impacts on wilderness by lengthening wilderness access trails. Several alternatives greatly increase the non-wilderness trail mileage; allowing alternative recreation opportunities and alternate use areas to wilderness areas. Alternatives G-Modified and I build 350 miles of new trails, 340 outside of wilderness, and 10 within. These alternatives reconstruct 236 miles of existing trail in Decade 1.

Alternative J (Preferred) takes a different approach, building 220 miles of new trails (200 non-wilderness and 20 wilderness), and reconstructing 493 miles of existing trail. The focus in this alternative is on reconstruction of existing trails, while Alternatives I and G-Modified focus on new trail construction.

Mitigation Measures for Trails

Many of the potential impacts caused to soils by trails are mitigated by location of trails on stable, well drained soils, and construction and maintenance that includes good drainage and surfacing.

For a complete discussion of mitigation for trails, refer to Chapter II and to the Forest-wide and individual management area Standards and Guidelines (Appendix D and the Forest Plan Document).

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Trails

National Park Service plans and programs indicate considerable concern regarding external threats to the parks. Trails constructed and maintained within National Forest land that provide and encourage access into National Park areas that are particularly sensitive to user impacts could be considered incompatible with National Park plans.

This concern will be greatest in Alternatives C, G-Modified, and J (Preferred) where major portions of the roadless areas remain undeveloped and trail construction adjacent to Mt. Rainier National Park and some portions of North Cascades National Park could be greatest.

National Forests have historically provided the majority of trails in the west, especially the larger trail segments in natural environments. If a large number of trails are replaced by roads, combined with low new construction, displacement of trail users from National Forests to National Parks could occur. Alternatives A, (NC is similar), B, and I, would have the greatest potential for this displacement.

The Sixth Edition of the State Comprehensive Outdoor Recreation Plan identifies several state districts, coincident with this Forest, that have shortages of trails in semi-primitive motorized and semi-primitive nonmotorized categories. Alternatives that maintain large roadless acreage and expand the trail system in roadless areas would be compatible. Alternatives C, J (Preferred), and G-Modified would provide the greatest SPNM and P acreage and would allow construction of the most trails within these allocations.

WILDERNESS

Wilderness - The Direct Effects of Each Alternative

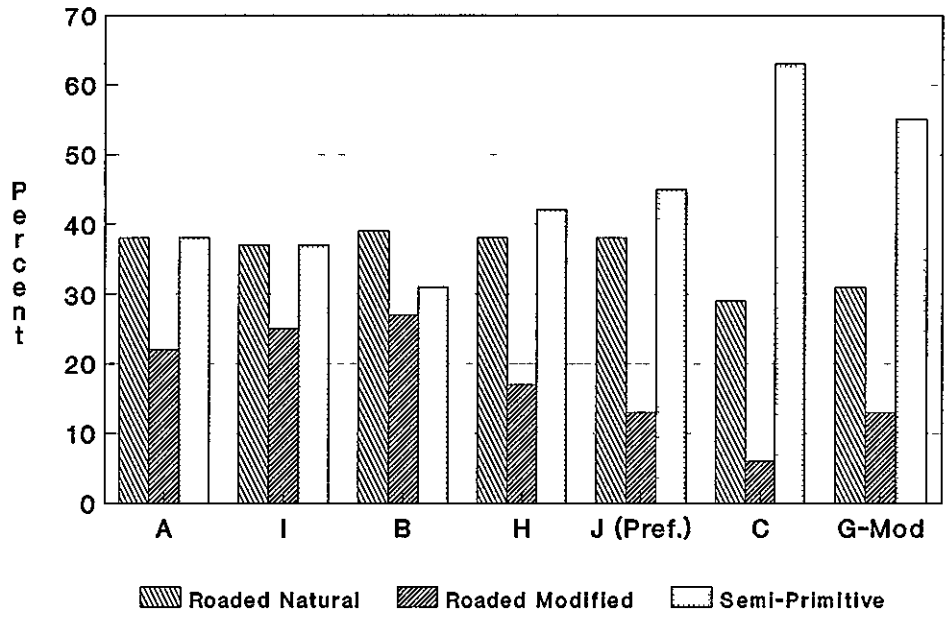
General

The eight wilderness areas on the Mt. Baker-Snoqualmie National Forest are described in Chapter III. The amount of wilderness acres will remain constant in all alternatives at 721,718 acres. While the physical size and physical attributes of the wilderness will remain unchanged by the alternatives, several factors will affect the social setting or experiences the wilderness visitor can expect. Impacts to the wilderness resource will vary through the range of alternatives.

One foremost principle of wilderness management is that "the management of wilderness must be viewed in relationship to the management of adjacent lands" (Hendee, Stankey, and Lucas, 1978). The greater the intensity of resource management activities adjacent to the wilderness and the greater the ease of access, the greater the effects upon wilderness resources. Management activities in areas adjacent to the wilderness that may be seen or heard by recreationists will affect the quality of wilderness experiences. Proposed activities adjacent to the wilderness are evaluated at the site-specific project level and appropriate measures are taken to mitigate potential effects.

Figure IV-7, which follows, indicates the relationship of unroaded and roaded recreation settings of the lands adjacent to the wilderness areas. Alternatives C and G-Modified have the least external effect on the wilderness, while Alternatives A, B and I have the greatest effect due to potential adjacent management activities.

Figure IV-7 Percent of Lands Adjacent to Wilderness
Allocated to Roaded and Unroaded Management



Another agent affecting wilderness is the alternative prescriptions with varying degrees of use and management in the wilderness. These will vary based on the number of acres assigned to each prescription within each wilderness area. Management activities proposed within any alternative will be implemented using the LAC standards under each prescription.

Those alternatives which assign more acres to the Transition WROS class than are assigned in Alternative A will generally provide for increased wilderness use by allowing more people per acre on average. (See Table IV-34.)

Table IV-34
Wilderness Recreation Opportunity Spectrum
Acres 1/ - All Decades

Alt.	Transition	Trailed	General Trailless	Dedicated Trailless	Special Management
NC (No Chg)2/	.....Similar to Alternative A.....				
A (No Action)	12,067	44,356	585,326	80,000	0
I	21,878	49,628	643,495	0	6,715
B (RPA)	14,402	39,686	543,881	121,409	2,238
H	7,982	46,734	437,931	219,292	9,777
J (Pref.)	15,078	49,015	457,000	191,606	9,017
G-Modified	7,644	52,669	444,688	207,930	8,785
C	7,032	45,700	272,679	383,992	9,313

1/ Acres depicted are from R-2 Map and may not agree with other wilderness acres in this document.
2/ The TM Plan upon which Alternative NC is based was developed in 1963. It was not an integrated resource plan and consequently did not address all resource uses and outputs.

Increases in average numbers of people per acre in a wilderness area will result in some degradation of naturalness and loss of opportunities for at least a degree of solitude. Several alternatives reduce the amount of Transition WROS (C, G-Modified, and H) from the existing situation, either by road closures which lengthen the access, or by changing the limit of acceptable change an area. The wilderness in these alternatives will offer a more natural setting with fewer opportunities for social interaction.

Another important indicator of the WROS's effect on wilderness is the amount of Dedicated Trailless allocated in any alternative. Alternative C, with a large amount of this class will be the least affected by human use since this is the most pristine of the wilderness allocations, allowing the least amount of change to the ecosystem. Alternatives G-Modified, J (Pref.), and H offer a moderate amount of Dedicated Trailless, while Alternatives B, I and A allocate the least to this class. Alternative I allocates no acreage to this WROS class and thus would be the alternative resulting in the most change within the wilderness. Alternative NC (No Change) would be similar to A.

Another way to view the effects of implementing alternatives on wilderness is to examine the wilderness capacity which results from the allocation of acres portrayed in Table IV-35. This table shows essentially the same effects discussed above, only the effects are expressed in terms of recreational visitor days.

Implementation of Alternative I would allow use far in excess of the levels that current Forest Service policy allows, and thus, would necessitate a change in agency wilderness policy.

Table IV-35
Wilderness Capacity - RVD's

Alt.	Transition	Trail	General Trailless	Dedicated Trailless	Special Management	Total
NC (No Chg) 1/	.....Similar to Alternative A.....					
A (No Action)	181,005	166,335	146,331	6,240	2/	499,911
I	328,170	186,105	160,873	0	2/	675,148
B (RPA)	216,030	149,197	135,970	9,469	2/	510,666
H	119,730	175,252	109,482	17,104	2/	421,568
J (Pref.)	226,170	183,806	114,250	14,945	2/	539,171
G-Modified	114,660	1975083	111,172	16,218	2/	439,558
C	105,480	171,375	68,169	29,951	2/	374,975

1/ The TM Plan upon which Alternative NC is based was developed in 1963. It was not an integrated resource plan and consequently did not address all resource uses and outputs.
2/ To be determined.

Estimating a carrying capacity for wilderness has a somewhat limited value in describing effects of alternatives. The coefficients used to produce these estimates are included in Appendix B. Total use is a measure somewhat related to wilderness condition for management purposes. Mode of travel, spacial and temporal aspects of use, and visitor behavior are often more significant (Washburne 1982).

Direct Impacts of Recreation on Wilderness

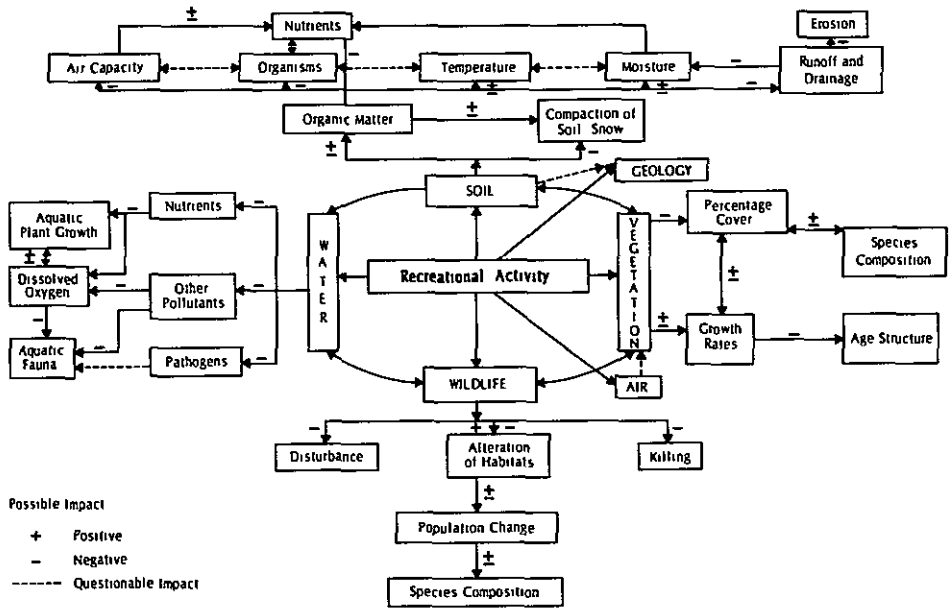
Almost all human activities disturb natural ecosystems. Although the specific impacts associated with recreational activities differ to some extent, they all potentially can affect soil, vegetation, wildlife and water. These affects and their relationships are laid out in the following chart.

Impacts to soils start with the destruction of surface organic matter and the compaction of soil or snow. Each of these changes alters basic soil characteristics related to aeration, temperature, moisture, nutrition, and the organisms that live in the soil. These changes, which adversely affect the ability of the soil to support plant life, are most visible in the barren, compacted soils of campsites. Compaction reduces water infiltration rates,

increases runoff, and increases erosion. Erosional impacts are most severe on trails.

Most of the changes in soil condition inhibit the establishment of new plants and adversely affect the growth of existing vegetation. Existing plants are injured or killed by the trampling of feet and horse hooves. Plant cover, growth rates, and reproductive capacities are all diminished. For trees, in particular, this alters the age structure of the population. On many campsites, for example, tree populations consist entirely of middle-aged and older trees; reproduction is totally lacking. Even these older trees are often scarred by ax marks, saw cuts, and nails. Understory vegetation varies greatly in its ability to tolerate recreational impact. Since more tolerant species are more likely to survive on recreation sites, changes in species composition shift toward these more tolerant species. An ability to grow close to the ground is one important survival mechanism that partially explains the reduced height of most vegetation on recreation sites.

Figure IV-8
Ecological Impacts of Wilderness Recreation



Although the indirect effects of soil impacts on vegetation are obvious, they are also reversible. Loss of vegetation cover exacerbates such impacts as loss of organic matter and increased erosion. It is also related to wildlife impacts, especially through the alteration of habitats. For large mammals the most serious impacts of recreation are direct, either outright killing or

unintentional disturbance and harassment. Disturbance can reduce reproduction (as when a disturbed bird leaves her nest), lead to migration to more remote areas, or result in adaptation (as when bears rely on garbage dumps for food). Smaller animals are more affected by habitat alterations. For example, soil impacts, such as loss of organic matter, remove a home and food source for many insects; vegetation impacts, such as a chopped-down tree snag, eliminate homes of cavity nesting birds. Many of these animals have important effects on soils and vegetation from there roles as decomposers and grazers and their place in the nutrient and energy cycles. Altered population structures, distribution and abundance will therefore, have an impact on soil, vegetation, and water.

Direct Effects of Trails on Wilderness

Of all the management activities, wilderness is affected most by changes in the trail system. While the trails themselves have only a minor effect on wilderness, the indirect effect of human visitation in the wilderness is the primary impact. Indirect impacts include loss of vegetation at new campsites, new social trails, and potential increases in encounters at or between campsites. (See the previous discussion on the Direct Effects of Recreation on Wilderness.)

Trail construction and/or reconstruction can influence or interfere with wilderness management depending on where and to what standard the trails are constructed or reconstructed. Experience has shown that when a new trail is constructed, the use significantly increases and environmental damage is increased. When an old trail is reconstructed to the same standard, the use will not significantly increase (example: Melakwa Lake, Alpine Lakes Wilderness). Thus, construction of a new trail is more detrimental to wilderness than reconstruction of an existing trail.

The majority of new trail construction in all alternatives occurs outside of wilderness. Alternatives A, NC, C, I, and G-Modified construct the fewest miles of new wilderness trails; Alternatives B, H, and J (Preferred) construct the most.

Alternatives G-Modified, I, and J (Preferred), construct the greatest miles of trail outside of wilderness which could have the advantage of dispersing use and increasing opportunities in locations other than the wilderness. Alternatives A, B and I have the greatest mileage of trail located within management areas emphasizing timber management. This may make these trails less desirable than trails in more primitive locations.

Alternatives A, B, H, and C provide for the least non-wilderness trail construction. Thus, these alternatives offer the fewest alternate recreation opportunities.

Direct Effects of Roadless Areas on Wilderness

Although not measurable, roadless areas provide alternatives for the wilderness user and reduce the effects of people using a wilderness area. Alternatives which develop the roadless areas are also likely to increase recreation use of wilderness, as dispersed recreationists will seek opportunities that are no longer available outside of wilderness. More importantly, development of roadless areas adjacent to wilderness also increases access to wilderness. Alternatives B and I would have the greatest potential effect on wilderness by

eliminating alternative sites for primitive or semi-primitive nonmotorized recreation. Alternatives C and G Modified would retain the greatest percent of unroaded area.

Direct Effects of Air on Wilderness

All alternatives contain some management practices which generate air pollution. Some are within the wilderness, some adjacent to them. The most likely source of pollution is particulates and smoke from prescribed burning and wildfire suppression activity. The effects on wilderness vegetation, soils, fish and wildlife, and visibility are discussed elsewhere in this chapter. Standards and Guidelines establish procedures which will ensure that the impacts are acceptable.

The most likely air quality related impacts on wilderness are from sources outside of the Forest. These would be the same for all alternatives as they are not a function of the alternatives. The Federal Clean Air Act requires that proper consideration be given to wilderness values and impacts during the permit review processes for new air pollution sources. The Standards and Guidelines reinforce this process.

Direct Effects of Fire on Wilderness

There have been historic occurrences of fire in the wilderness for hundreds of years. The existing vegetative pattern is a product of periodic, high intensity, but infrequent fires. Standards and Guidelines for wilderness management are designed to allow these natural processes to continue to the extent that they are compatible with other activities within and adjacent to the wilderness.

Direct Effects of Mining, Energy Development on Wilderness

The 1964 Wilderness Act specifies that no new claims may be located in wilderness after December 31, 1983. Wilderness areas are subject to valid existing rights perfected prior to withdrawal. These areas may be impacted by mining related activities conducted under such rights. The effects on wilderness values of solitude, pristine nature and unmodified environment could be severe. If production results, the landscape modification needed for production facilities, as well as the facilities themselves, will remain highly visible for the life of the project. None of the alternatives will have an affect on the number, type or location of activities conducted under valid existing rights. Valid existing rights, however, will be determined before approving any such activity. If those rights exist, activities will be controlled, but not precluded, to ensure no undue degradation of the wilderness characteristics of the area occurs.

Development of valid claims in wilderness is largely a matter of mineral markets and other factors independent of these alternatives. Each operating plan, including appropriate planned access and support facilities, will be dealt with on a case-by-case basis through the environmental analysis process.

The effects that mining would have on existing wilderness areas would not vary by alternative.

The potential for energy and geothermal activity in wilderness is limited on this Forest and has been restricted by Congress in recent years. Implementation of any of the alternatives will have an insignificant effect on energy and geothermal development. The major impacts will result from the development of favorable markets and Congressional activity.

Direct Effects of Land Uses on Wilderness

Generally, the only special use allowed in wilderness are outfitter guides. In all alternatives, these permits will continue to be allowed and the resulting environmental and social impacts will vary depending on actual numbers of permits issued.

Land ownership patterns within and adjacent to wilderness can be an important factor in preserving wilderness values. Acquisition by the Forest Service of private property located adjacent to wilderness will generally lessen the potential of negative impacts on wilderness. The acres involved in all alternatives are minimal.

Direct Effects of Roads on Wilderness

Road construction outside of wilderness can have a substantial effect on the wilderness resource. Building roads to the edge of a wilderness can dramatically affect the amount and character of wilderness use by making access easier and changing the WROS zoning (for example by changing a trailed overnight area into a transition day-use area). Experience has shown that new road construction adjacent to wilderness often encourages increased use of nearby focal points, especially lakes, and also encourages the establishment of unplanned substandard user-built trails.

Alternatives NC, A, I, H could have the greatest impacts in terms of easier access to, and thus greater impacts on wilderness. Some of these impacts can be minimized through the environmental analysis process for individual projects and the establishment of suitable road management objectives for new roads.

Alternatives C and G-Modified would construct the least roads and would create the fewest road-related impacts.

Experience has shown that if a road is closed for a good distance from the wilderness boundary, an "over used" area will not only experience less use but will revegetate and regenerate itself. (An example is Snoqualmie Lake in the Alpine Lakes Wilderness Area.) Alternatives that propose road closures are C (approximately 300 miles), G-Modified (about 65 miles), H (about 20 miles), and J (Preferred) (25 miles).

Wilderness - The Cumulative Effects of the Alternatives

Long-term timber harvest and related road construction in adjacent areas will have the greatest effect on the wilderness resource. The cumulative effects of each alternative are directly related to the amount of road access, timber harvest and development adjacent to wilderness areas. Harvest and road construction results in easier access and can attract more visitors to the wilderness setting. The greater the number of visitors to wilderness, the greater the impact on the social and environmental features of wilderness.

Under all alternatives, long-term increases in demand for wilderness settings would result in higher use levels in wilderness. Managerial controls would be required to minimize environmental impacts and to protect primitive opportunities offered in wilderness areas.

One long-term effect of providing fewer opportunities for wilderness recreation would be the displacement of users into the National Parks or other lesser used areas.

Wilderness - The Indirect Effects on Other Resources

Vegetative Diversity

Designated wilderness contributes to the conservation of diversity because these areas are protected against most forms of development. Wilderness can withstand large scale natural disturbances and is capable of sustaining populations of certain wildlife species with large home ranges (Wilcove, 1988). Under all alternatives, the wildernesses would continue to contribute to the conservation of diversity.

All alternatives would provide habitat for sensitive plant species.

Wildlife

All alternatives would provide for maintaining animals and fish indigenous to the wilderness and would provide protection for populations of threatened and endangered species and their habitats.

Fish

All alternatives would provide for maintaining fish indigenous to the wilderness and would provide protection for populations of threatened and endangered species and their habitats.

Research Natural Areas

There are no known indirect effects on Research Natural Areas from changes in Wilderness in any of the alternatives.

Roadless Areas

There are no known indirect effects on Roadless Areas from changes in Wilderness in any of the alternatives.

Wild and Scenic Rivers

There are no known indirect effects on Wild and Scenic Rivers from changes in Wilderness in any of the alternatives.

Air

There are no known indirect effects on Air from changes in Wilderness in any of the alternatives.

Fire

There are no known indirect effects on Fire from changes in Wilderness in any of the alternatives.

Minerals

There are no known indirect effects on Minerals from changes in wilderness in any of the alternatives.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Wilderness in any of the alternatives.

Roads

There are no known indirect effects on Roads from changes in Wilderness in any of the alternatives.

Mitigation Measures for Wilderness

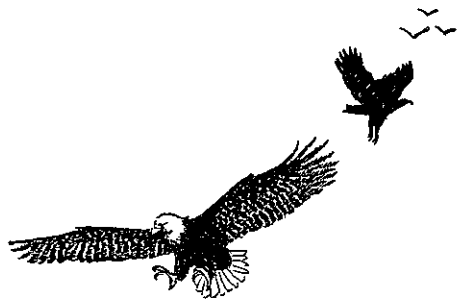
Potential effects of visitor use would be mitigated by keeping the type and amount of use within limits of acceptable change by utilizing visitor information and education and by implementing indirect and direct visitor management techniques where necessary.

New trail construction would generally be confined to relocation of trails not currently in the proper location. This would reduce adverse effects to soils, water, vegetation and wildlife. Trails not needed to meet wilderness objectives would be allowed to brush in or returned to as near a natural condition as possible.

Potential effects of management activities outside of wilderness could be mitigated by constructing lower standard roads or by closing roads to public use at the end of a project.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Wilderness

The Forest Service wilderness philosophy, which remains unchanged by any alternative, may occasionally conflict with the plans and philosophy of fisheries management enhancement of the Washington State Department of Wildlife. Conflicts with the Environmental Protection Agency and the U.S. Geological Survey may also arise occasionally regarding water sample collection and mineral surveys.



RESEARCH NATURAL AREAS

Research Natural Areas - The Direct Effects of Each Alternative

General

Research Natural Areas are representative ecosystems where natural processes dominate. Designating the new areas as RNA's would augment the baseline ecological data presently provided by the Pacific Northwest Region RNA program. By designating the proposed areas to RNA status, ecosystems not currently represented in the existing program would become represented. In alternatives where the potential RNA's are allocated to other uses, the opportunity for research and establishment of baseline data on plant communities available through the RNA program could be lost. Designation to RNA or Botanical Area status would preclude use for timber management or mining exploration and development. All of the alternatives would recommend proposed RNA's be withdrawn from entry under the Mining Laws.

The three currently established RNA's described in Chapter III would be maintained in all alternatives.

Five candidate RNA's have been identified by the Regional Research Natural Area Committee. Four are totally or partially located within wilderness. Alternatives C, G-Modified, H, and J (Preferred) would recommend designation of four new Research Natural Areas plus an addition to the existing North Fork Nooksack area. Alternatives NC, A, B, and I would recommend no new RNA's. (See Table IV-36.)

Designation would occur after the Record of Decision for the Forest Plan is released, and after an establishment report is prepared and approved by the Chief of the Forest Service.

Table IV-36
Potential Research Natural Areas Recommended By Alternatives

Area	Alternatives							
	NC (No Chg)	A (No Ac)	I	B (RPA)	H	J (Pref)	C	G (Mod)
N. F. Nooksack Addition 1/					x	x	x	x
Lily Lake 1/					x	x	x	x
Perry Creek					x	x	x	x
Green Mountain 2/					x	x	x	x
Chowder Ridge 1/					x	x	x	x

1/ Within wilderness.
2/ 80% within wilderness.

Perry Creek and a portion of the Green Mountain area (296 acres) are located totally outside of wilderness. Alternative A allocates the non-wilderness acres of Green Mountain to management area 1E (General Dispersed Recreation); minimal change would occur under this allocation. Alternative A allocates 13% of Perry Creek to management area 17 (Timber Management) and the remainder to General Dispersed Recreation.

In Alternative B, all of the non-wilderness portion of Green Mountain and most of Perry Creek are allocated to Management Area 1B. The goal of this management area is to provide dispersed recreation in a semi-primitive nonmotorized setting.

Alternative I allocates the non-wilderness portion of Green Mountain to management area 19 (Mountain Hemlock), and 85% of Perry Creek is allocated to management area 1C (Semi-Primitive Motorized). The potential for change or adverse impacts to the non-wilderness portions of the potential RNA's is the greatest in Alternative I.

Research Natural Areas - The Cumulative Effects of the Alternatives

Nonrecommendation of a candidate RNA reduces the land base available for the study of undisturbed ecological processes. Reductions would be greatest under Alternatives NC, A, B, and I and least under Alternatives C, H, G-Modified and J (Preferred). Nonrecommendation of a candidate RNA also may reduce biological diversity by not providing protection for populations of rare plants. RNA designation will result in curtailment of commodity resource activities for those sites established. The cumulative effects of designation also result in preservation of natural genetic diversity in commercially valuable conifer species.

Research Natural Areas - The Indirect Effects on Other Alternatives

Vegetative Diversity

RNA's serve as important reservoirs of biological diversity (Wilcove, 1988).

Allocation of these areas to something other than RNA's or Botanical Areas could slightly increase the timber volumes the Forest. This would be the greatest in alternatives NC, A, B, and I as there are no NRA's proposed in these alternatives.

Wildlife

RNA's also serve as important reservoirs of biological diversity (Wilcove, 1988). Designating RNA's maintains current wildlife habitat helps sustain population levels of wildlife using these areas. Alternatives H, J(Preferred), C, and G-Modified would provide for more diversity because of the number of NRA's proposed in each.

Roadless Areas

There are no known indirect effects on Roadless Areas from changes in Research Natural Areas in any of the alternatives.

Wild and Scenic Rivers

There are no known indirect effects on Wild and Scenic Rivers from changes in Research Natural Areas in any of the alternatives.

Air

There are no known indirect effects on Air from changes in Research Natural Areas in any of the alternatives.

Fire

There are no known indirect effects on Fire from changes in Research Natural Areas in any of the alternatives.

Minerals

Research Natural Areas are withdrawn from mineral entry; this would be most evident in Alternatives H, J(Preferred), C, and G-Modified. Allocation of these areas to something other than RNA's or Botanical Areas could slightly increase minerals accessibility on the Forest. This would occur in Alternatives NC, A, I, and B.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Research Natural Areas in any of the alternatives.

Roads

Designation of an RNA precludes future roading and utility corridors. Existing trails may remain, and new trails must conform to the objectives of the RNA. These effects would be the same in all alternatives.

Mitigation Measures for Research Natural Areas

Refer to the Standards and Guidelines for Management Area 18, Research Natural Area (Chapter IV, Forest Plan).

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Research Natural Areas

There are none.

ROADLESS AREAS

Roadless Areas - The Direct Effects of Each Alternative

General

The environmental consequences of the alternatives on roadless areas are summarized below. For a detailed and site-specific analysis of environmental effects see Appendix C of the FEIS.

Direct Effects of Timber Harvest on Roadless Areas

All of the alternatives call for some degree of timber management in roadless areas. The undeveloped character of those areas scheduled for entry would be altered as road construction and timber harvesting occurs.

The following table, Table IV-37, shows the amount of the roadless areas that would be developed or remain undeveloped in the various alternatives by decade. Alternatives A and I retain the fewest roadless acres as undeveloped, 73 percent and 78 percent, respectively, of the total 402,930 acres. Alternative C retains 96 percent as undeveloped, and Alternative G-Modified retains 93 percent. Alternative J (Preferred) retains 86 percent of the area in an undeveloped character by the end of the fifth decade.

No alternative develops more than approximately one-third of the total roadless acres due to the large amount of land unsuitable for timber harvest found in these areas.

Table IV-37

Acres of Roadless Areas Remaining at End of Decades 1, 2, and 5, by Alternative

Alternative	Acres Remaining End of Decade 1	2	5	Percent Remaining
A	361,665	329,773	293,305	73%
B	371,619	347,041	317,728	79%
C	397,854	393,564	387,257	96%
G	392,421	383,715	375,470	93%
H	377,058	354,602	328,498	82%
I	370,878	344,998	313,914	78%
J	382,587	365,565	344,730	86%

Direct Effects of Trails on Roadless Areas

Trails will be constructed and reconstructed within the roadless areas in all alternatives, but will have only minor effects. Some vegetation will be lost by the development of new trail corridors.

Improved access is another result of trail development. Those alternatives which construct a large number of trails in roadless areas, such as Alternatives G-Modified, I, and J (Preferred), will provide greater access to roadless areas and an increase in dispersed recreation capacity. There will be an attendant loss of solitude in these areas.

Direct Effects of Wilderness on Roadless Areas

Though additional wilderness is not recommended in this plan, areas left roadless would maintain their wilderness character for future consideration. All alternatives would foreclose these options to varying degrees. The wilderness characteristics of those roadless areas allocated to development would be largely foregone, primarily because the imprint of human activity would be noticeable. These imprints could consist of logging slash, skid trails, log landings, roads or any combination of these factors. Trail systems which currently provide access for recreational enjoyment into some of these areas would be disrupted. Alternatives B and I would have the greatest number of acres developed; Alternatives C and G-Modified would protect the most acres for future wilderness consideration.

Table IV-38 shows how the roadless areas are allocated, by management area, in each alternative. Total acres vary by alternative due to R2-map rounding. (Refer to Chapter II for descriptions of the management areas.)

Direct Effects of Mining, Energy Development on Roadless Areas

Roadless areas are not withdrawn from mineral entry; exploration and development is permitted under current mineral laws. During development and operation, the roadless characteristics will be changed. Such changes will be mitigated to the extent possible, based upon a site specific operating plan.

Those alternatives with the greatest amount of roading and development within the roadless areas allow the easiest access for mineral exploration and development. Such development would lead to a reduction in roadless character, solitude, and opportunities for primitive recreation. Alternatives A, I, B, and H have the greatest potential to effect the roadless character due to mineral entry. Alternatives C, G-Modified, and J (Preferred) the least.

Roadless Areas - The Cumulative Effects of the Alternatives

Each time a roadless area is developed, there is a cumulative impact, in that development contributes to an overall reduction in roadless acres from either a local, regional or national perspective. It not only affects unroaded areas per se (in terms of the amount of semiprimitive environment available) but also affects wilderness on the Forest, and roadless areas/wilderness off the Forest. This results in a shift in current or future use to alternate areas.

Long term timber harvest, road construction, and commodity development will reduce the roadless area resource. The effect of each alternative is directly

Table IV-38

Management Area Allocations of Roadless Area by Alternatives

Management Area	Alt. A	Alt. I	Alt. B	Alt. H	Alt. J (Pref)	Alt. C	Alt. G Mod

related to the amount of development, with Alternatives NC, A, B, and I having the most development. Alternatives C and G-Modified retain the most acreage in roadless status.

Roadless Areas - The Indirect Effects on Other Resources

Vegetative Diversity

Roadless areas contribute to the conservation of diversity because these areas generally receive lower levels of development; can generally withstand large scale natural disturbances and are generally capable of sustaining populations of certain wildlife species with large home ranges. As these areas are entered for development, diversity changes. Alternatives C, G-Modified, and J (Preferred) best contribute to the conservation of natural diversity. Alternatives B and I cause the greatest potential impact on natural diversity.

American Indian Religious and Cultural Use

Roadless areas are often important to American Indian religious and cultural use and the development of currently roadless lands will result in fewer sites and areas available for these practices. Alternatives C and G-Modified have the most acres remaining in a roadless condition, followed by Alternative J (Preferred). Alternatives NC, A, B, I, and H develop more acres of roadless lands.

Recreation

Research has shown that recreationists will substitute one environmental setting for another if their expectations can no longer be met (ORRRC, 1962; O'Leary, 1974; Bryan, 1982). As the roadless areas on the Forest are developed, recreational uses formally occurring in roadless areas would be displaced to the Forest's wilderness areas. This displacement of recreation use may result in conflicts among the various visitors deriving different expectations and satisfactions from the same environmental setting. For example, those visitors who visit the wilderness to experience solitude, isolation, and freedom from the sights and sounds of other recreationists would not experience such qualities because of increased contacts with other visitors, many of whom may not consider these values important (Lime, 1971; Stankey, 1971). This could have serious effects on the wilderness resource since capacity has almost been reached for the wilderness areas on the Forest.

The depletion of roadless areas over time could also result in the displacement of roadless recreation use to other undeveloped Forest lands, such as areas allocated to provide old growth habitat. This shift in recreation use would affect old growth dependent species such as pine marten and spotted owls through harassment and loss of solitude. Changes in wildlife species and number would be dependent upon the amount and location of timber harvest and roading activities.

Wild and Scenic Rivers

There are no known indirect effects on wild and scenic rivers from changes in roadless areas in any of the alternatives.

Air

There are no known indirect effects on air from changes in roadless areas in any of the alternatives.

Fire

There are no known indirect effects on fire from changes in roadless areas in any of the alternatives.

Minerals

There are no known indirect effects on minerals from changes in roadless areas in any of the alternatives.

Land Ownership and Use

There are no known indirect effects on wild and scenic rivers from changes in roadless areas in any of the alternatives.

Roads

Road miles will not increase in those alternatives (C and G-Modified) that have a large acreage of roadless areas allocated to non-development in management areas 1A, 1B, 1C, 8, 10, 11, 12, 15A, 16, 18, and parts of 27.

Mitigation Measures for Roadless Areas

Numerous mitigation measures can be applied to reduce changes in the soil, water, and wildlife habitat characteristics of roadless areas allocated to development. These measures are described in the various other resource sections of this chapter. Such mitigation measures cannot eliminate or avoid the alteration of the natural integrity and basic character of the roadless area.

The allocation of roadless areas to Semi-Primitive and Primitive Dispersed Recreation management is a mitigation measure designed to offset the overall reduction of roadless areas on the Forest and to preserve some undeveloped roadless area for future consideration as wilderness.

Several measures can be applied to minimize impacts where Roadless Area size has been reduced:

1. Road closures along the periphery of such areas reduce the sights and sounds of people and help maintain a Semi-Primitive setting within the roadless area.

2. Existing trails may be restored or relocated within the developed portions of roadless areas.

3. Smaller undeveloped areas may be retained to protect important natural features.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Roadless Areas

There are none.

WILD AND SCENIC RIVERS

Wild and Scenic Rivers - The Direct Effects of Each Alternative

General

Skagit Wild and Scenic River. The Skagit River system, which is currently the only component of the National Wild and Scenic River System on the Forest, will be managed in accordance with the Skagit River Management Plan (Vol. II, 1984). Management plans for the river system will not be affected through the range of alternatives.

Land allocations on the periphery of the wild and scenic river corridor, however, have a potentially significant impact on wild and scenic river attributes. Depending on the land allocations within the alternatives, the potential for adverse effects varies greatly. The allocations can affect the quality of the recreation experiences (Clark, 1984). Timber harvest and related road construction are the management activities within any one of the alternatives that would have the greatest effect on the quality of the river experience. The degree of visual protection offered in the viewsheds adjacent to the rivers becomes the means to evaluate acceptable levels of activities in the various management areas. Resource activities are mitigated through the use of Standards and Guidelines applicable to the visual resource.

Recommended Wild and Scenic Rivers. There were 795.9 miles of rivers and streams in 47 segments studied for possible inclusion in the National Wild and Scenic River System. The direct effect of implementing any one of the alternatives will be a decision to recommend or not recommend designation of a river for inclusion in the National System. If a river is recommended, then management will be oriented toward protecting the features of the river system which would be important under the National Wild and Scenic River Act; no activities would be allowed which could preclude future designation. Management will protect all eligible rivers until Congress acts on the Forest's recommendation.

The Forest Service has no authority to control development of private lands along eligible rivers. Thus, extensive development of the shoreline could downgrade the classification of a river segment prior to Congressional action.

Table IV-39 shows the rivers recommended for designation in each alternative. Eligible river segments crossing the Mt. Baker-Snoqualmie National Forest vary by alternative. For a more detailed discussion, see the FEIS, Appendix E. The number of rivers and streams found suitable for inclusion in an alternative varies from none in Alternatives NC, B and I to 47 in Alternatives C and G-Modified. Alternative A contains 15 rivers and Alternative J (Preferred) has 30 suitable rivers.

Table IV-40 indicates the percent of each potential Wild and Scenic River Corridor assigned to a management area in which no development (timber harvest or roads) would occur for each alternative. In other words, Table IV-40 shows the level of protection a river will receive even if not formally designated as a wild and/or scenic. For example, in Alternative H, Diobsud Creek is not a Designated River, but is still afforded 99% protection from future development by it's management area assignment. Under Alternative I, 90% of Diobsud Creek would be assigned to MA's restricting development.

Table IV-39
Wild and Scenic Rivers Recommended For Designation

Alternatives	No. of Rivers	Total Miles Recommended
NC	0	0
A (No Action)	15	287
I	0	0
B (RPA)	0	0
H	5	154
J (Preferred)	30	452
C	47	606
G-Modified	47	796

(Refer to Appendix E for further discussion on the effects of implementing any of the alternatives on potential Wild and Scenic Rivers.)

Direct Effects of Wilderness on Wild and Scenic Rivers

Within wilderness, water developments may be sanctioned only by the President (Sec. 4 (9)(4) of the Wilderness Act). Such authorization would be exceptionally rare; it has never been exercised in the past. Wild and Scenic River designation within wilderness would prohibit dam construction and other water development projects.

Direct Effects of Mining, Energy Development on Wild and Scenic Rivers

Because mining and exploration often involve the use of heavy equipment, the removal of vegetation, the excavation and washing of gravel deposits, and the diversion of water, such activities would have the potential to significantly impact the outstanding values of a river. Wild and Scenic Rivers are not automatically withdrawn from mineral entry.

Wild and Scenic Rivers - The Cumulative Effects of the Alternatives

All eligible rivers are protected from degradation of their outstandingly remarkable values, thus there will be no adverse cumulative effects. For rivers not found eligible, the cumulative effects of management activities may change the values and characteristics necessary for wild and scenic river classification and preclude such designation at any future date.

After Congressional action, the greatest cumulative effects would occur in Alternatives NC, B and I, which recommend no rivers for designation. Any dams built on rivers within the Forest can, over time, result in reduced opportunities for dispersed recreation associated with free-flowing rivers (such as fishing and rafting). Additional effects of hydroelectric development on anadromous fisheries include reductions in regional fish production, when portions of a river may become unavailable for spawning and rearing.

1/ Calculated on non-wilderness Forest Service ownership only.

No cumulative effects would occur, at least within National Forest boundaries, in Alternatives C and G-Modified.

Wild and Scenic Rivers - The Indirect Effects on Other Resources

Air

There are no known indirect effects on Air from changes in Wild and Scenic Rivers in any of the alternatives.

Fire

There are no known indirect effects on Fire from changes in Wild and Scenic Rivers in any of the alternatives.

Minerals

The allocation of Wild and Scenic Rivers in any alternative could cause restrictions in mineral exploration and/or development if the river corridor were to be withdrawn from mineral entry.

Land Ownership and Use

Those rivers recommended to Congress for designation in an alternative would retain their free-flowing character; any developments affecting future classification would be delayed until Congressional consideration.

The potential for hydroelectric energy would be limited. Values associated with the natural free-flowing characteristics of the stream would be favored. For example, existing scenic values, white water recreation, and anadromous fishery values would be retained or enhanced. Such activities as timber harvest and management of deer and elk habitat would have to be conducted in a manner consistent with meeting Wild and Scenic River objectives. These objectives vary by classification. For example, a Wild classification retains the most natural river environments, while a Recreational classification allows for more development. Maintaining wild and scenic eligibility for these rivers will have a slight indirect effect on vegetation, as timber harvest activities are modified. This would be most evident in alternatives G-Modified, C, and J (Preferred).

Those rivers not found eligible are available for hydroelectric development. Such development could have the effect of eliminating their free-flowing character. Other attributes such as fisheries and water quality could be adversely affected by dams. Recreation activities, such as rafting and kayaking, normally associated with moving water, might be reduced or eliminated. *This would be most likely in Alternatives NC, I, and B.*

Roads

There are no known indirect effects on Roads from changes in Wild and Scenic Rivers in any of the alternatives.

Mitigation Measures for Wild and Scenic Rivers

The values and characteristics important for classification of rivers as wild and/or scenic will be protected until Congressional action. Management activities which would adversely affect these values and characteristics would be deferred.

Little opportunity exists for mitigating activities which affect the free-flowing character of those rivers not chosen. If a project is developed which affects streamflow, a project environmental assessment would be written. The mitigating effects, such as fish ladders, etc., would be addressed in the project environmental assessment.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Potential Wild and Scenic Rivers

Regional and state energy plans may address energy potentials from rivers recommended for Wild and Scenic River classification.

The analysis and classification of Wild and Scenic Rivers requires coordination with state, county, and other administrative jurisdictions and ownerships through which these rivers flow.

AIR

Air - The Direct Effects of Each Alternative

General

Air quality over the National Forest is affected by a combination of the gaseous and particulate emissions generated by management practices and activities within the Forest and from urban and industrial sources outside of the Forest. The extent air quality over the Forest will be effected varies with the mix of management practices applied under the different alternatives and the rate of urban and industrial development adjacent to the Forest.

Procedures outlined in the Federal Clean Air Act insure federal land manager involvement in developing emissions control requirements for new or modified point sources having the potential to impact air quality related values of the Forest. The 1988 emissions inventory from the Puget Sound Air Pollution Control Agency indicates that point sources contribute considerably less pollutants than do area sources. The largest area sources are transportation and residential heating. Slash burning is a small contributor to the inventoried emissions within the agency's jurisdiction. Area sources of pollutant generation are included in all activities presented, though most impacts are not measurable due to low frequency, duration, or scope of application.

Of the regulated pollutants identified in the Federal Clean Air Act, only Total Suspended Particulates (TSP) are generated in any measurable quantity by the management practices included in the plan. Effects of the alternatives relative to TSP generation are presented in Table IV-41 by the sources of emissions. Of the chemical pollutants, carbon monoxide and NOx emissions are the greatest but are very low. Generation of these pollutants are evaluated by comparison with other sources.

The primary Forest sources of gaseous and particulate emissions are from wildfires and the prescribed burning activities included in all alternatives. Human health impacts of the pollutants emitted from prescribed burning activities have been addressed in the Vegetation Management EIS and Record of Decision approved by the Regional Forester, Nov., 1988. Wildfire effects are expected to be about the same.

Impacts of pollutants, mainly suspended particulates, on visibility is another important air quality impact. Suspended particulates in the 0.3 to one micron diameter range are the principle source of visibility impairment. Sandberg and Martin (1985) report that as much as 80% of the particulate mass in wood smoke is less than one micron in diameter. EPA data indicates that concentrations as low as two micrograms per cubic meter of air produce a perceptible reduction in clarity as seen by the human eye. Fine particulates tend to be transported long distances and remain suspended for long periods of time under light and variable wind conditions. Table IV-41 displays the level of TSP generated by each of the various management practices under each alternative.

Table IV-41
Generation of Total Suspended Particulates (TSP)
Expected Average Production by Source and Alternative
Expressed in Tons Per Year

Sources	Emission Factor	Alternatives NC	A	I	B	H	J Pref	C	G Mod
Broadcast Burning	30# / Ton	127	122	98	97	91	86	69	56

Burning Const. Debris	36# / Ton	105	105	94	90	80	77	51	55
Campfires	36# / Cd	78	78	78	78	78	78	78	78
Firewood Burning	28# / Cd	135	135	135	135	135	135	135	135
Total TSP Produced (Tons)		902	900	822	962	786	767	710	646

Note: An Emission Factor is the rate of particulate emission per ton of fuel consumed. It varies due to differences in combustion efficiency. These factors are not well defined for many of the activities. The Pacific Northwest Forest and Range Experiment Station has developed factors for broadcast burning and pile burning (Hardy 1988). Firewood burning factors are from work by Duncan and others in 1979. Emission factors for other activities are best estimates based on known relationships and characteristics.

The Washington State Implementation Plan required by the Federal Clean Air Act includes strategies to reduce the amount of TSP generated by prescribed burning activities on the National Forests by 35% by the year 1990. The base line for calculating improvement was the average of the 1976-1979 period. For the Puget Sound area, this amounted to 155,900 tons of suspended particulates per year. (Final EIS of Pacific Northwest Regional Guide - Table 4-8.) Of that total, 57,000 tons were attributable to the prescribed burning programs of the Mt. Baker-Snoqualmie Forest. Table IV-41 data shows that all alternatives clearly meet this goal.

TSP emission levels are expected to decline slightly over the first decade then level off as the amount of prescribed burning activities stabilizes. By the end of the fifth decade of plan implementation, emissions from prescribed burning of logging residue will be near zero for all alternatives, while wildfire and other prescribed burning activity emissions will remain near current levels.

Pollutants in the form of carbon monoxide and other gaseous emissions are produced at varying levels under each of the alternatives. The scattered

locations of most of the sources and the low emission rates prevent concentrated buildup of these pollutants. Isolated areas where measurable concentrations may accumulate are possible, but they are expected to be well below any level of concern for human health or biological impacts. The highest concentrations are expected to occur along the major highway corridors through the Forest such as Interstate 90. Since no actual monitoring data is known to exist for this section of I-90, a comparison to data measured on I-5 is presented. (It should be noted, the volume of I-90 traffic is no more than 10% of the volume of I-5 in the metropolitan Seattle.)

The Puget Sound Pollution Control Agency monitors carbon monoxide emissions along Interstate 5 at Northgate, just north of Seattle. Monitoring data indicates that on three days in 1988, the eight-hour average exceeded nine ppm, which is the state and national standard for carbon monoxide. The highest eight-hour value recorded in 1988 at the Northgate site was 11 ppm. One hour averages were well below the national standard of 35 ppm. The highest one-hour concentration value measured was 15 ppm. This is a worst case comparison as the Northgate site also has many other sources of carbon monoxide that are not present along the portion of I-90 that crosses the Forest. Carbon monoxide emissions associated with the various alternatives and use of the Forest are expected to be no higher than 0.1 of those measured in the urban setting, well below any known threshold of human health or biological impact. Other gaseous pollutants associated with Forest use or activities are expected to have similar levels.

State and local control strategies, such as auto emission checks and elimination of led from fuels, are expected to keep concentrations well within state and federal standards.

Noise. Noise on the Forest occurs at various intensities and is transient in nature. It is generated to some extent by management activities, vehicles, aircraft, users, and even natural events.

There is little objective data available relative to the noise levels currently experienced on the Forest. Since there are no new activities or management practices proposed in any of the alternatives, there will be no new sources of noise within the Forest. Shifts in frequency, location and duration of noise emitting activities will occur within the range of alternatives.

Noise generated by automobile use, aircraft and human activity will likely be similar in all alternatives except Alternatives C and G-Modified where noise levels on the forest are expected to be lower than current levels. Noise generated by heavy equipment operations associated with timber harvest, log transport and road construction will likely be the greatest in those alternatives with the highest levels of timber harvest activity and road construction.

Direct Effects of Timber Harvest on Air

Management practices associated with road construction, site preparation, and disease control include prescribed burning. The Standards and Guidelines for these activities will insure that impacts are acceptable. Alternatives (NC, A, I and B) have the highest levels of harvest activity and road construction would have the greatest impact on air and noise.

Direct Effects of Mining, Energy Development on Air

The interaction between minerals extraction and air quality is not unique to the Mt. Baker-Snoqualmie National Forest. As with all surface disturbances, exploration, mining, milling and benefaction activities can result in increased particulate levels in the immediate area. In addition gaseous emissions in the form of carbon monoxide, hydrocarbons, sulfur dioxide, and nitrogen oxides are emitted from internal combustion engines used in the various phases of mining operations. Similarly, the equipment typically used in mining operations does produce localized noise levels that may be heard for some distance from the actual operation itself. Federal and state regulations ensure these impacts are minimized. This would be the same throughout all of the alternatives.

Complying with the regulations increases capitalization costs, development costs and operating costs. As a consequence, overall production cost is higher, and interest in mineral development may be decreased. Because operators must comply with federal and state air quality and noise abatement requirements, the effects that mineral related activities have on air would vary only slightly by alternative. It can be assumed, however, that the effects would lessen slightly as the area managed by "highly" restrictive management strategies increases.

Direct Effects of Roads on Air

There is a short term increase in noise and particulate levels associated with road construction. These drop off after construction and are limited to vehicle use and wind. These events are limited in extent and of short duration. Surfacing and maintenance standards minimize the generation of particulates from road use. These effects would be greatest in Alternatives NC, A, I and B; moderate in Alternatives H and J (Preferred); and lowest in Alternatives C and G-Modified

Air - The Cumulative Effects of the Alternatives

Cumulative effects on air are apparent by changes in visibility and in concentrations of particulates and gaseous emissions monitored in and adjacent to the Forest. Of the regulated pollutants, total suspended particulates (TSP) generated by prescribed burning activities will be the most likely to accumulate over time. These will be of short duration as normal weather patterns tend to dissipate any extensive buildup. The contribution of management practices to any measurable change in average annual concentration of TSP will be negligible.

As discussed above, TSP generation is expected to decline over time for all alternatives.

Air - The Indirect Effects on Other Resources

Fire

The management emphasis in all alternatives is to encourage the utilization of harvest residue for firewood. This will affect air quality through an increase in TSP and gaseous emissions associated with home heating. This will be felt heaviest in the urban areas during cold, winter months when air dispersion conditions are poor or limited. Due to the abundance of firewood from other

sources and the limited contribution that the National Forest makes to the total supply, variation in availability between alternatives will not effect the amount of firewood consumed and emissions generated.

Minerals

There are no known indirect effects on Minerals from changes in Air in any of the alternatives.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Air in any of the alternatives.

Roads

There are no known indirect effects on Roads from changes in Air in any of the alternatives.

Mitigation Measures for Air

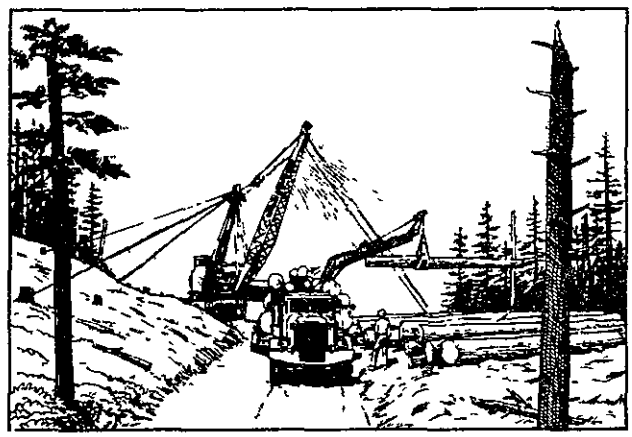
Prescribed burning on National Forest land is accomplished within the guidelines of the Washington State Smoke Management Plan, a part of the State Implementation Plan required by the Federal Clean Air Act. This plan is administered by the Washington State Department of Natual Resources. The potential for smoke from a prescribed burn to dissipate along the direction of plume travel and the number of projects proposed for an area are evaluated before approval is granted to burn. Though some prescribed burning is done throughout the year, most occurs in the spring, before July 1, or in the fall, after October 1. This concentrates the impact on visibility to periods when the fewest visitors are likely to be in the Forest or when weather (cloudy conditions) is likely to preclude good visibility anyway.

Roads may receive dust abatement (water or other) treatments to control dust during summer months.

(Also, refer to mitigating measures applicable Forest-wide and to each management area in Chapter II.)

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Air.

There are none.



Chapter IV
Fire

FIRE

Fire - The Direct Effects of Each Alternative

General

There is a theoretical relationship between the intensity of management activities, public use of the Forest, and the number of human-caused forest fires. However, on the Mt. Baker-Snoqualmie, based on the past thirty years of record, this relationship does not hold true. There does not appear to be any direct correlation between the number of forest visitors and the number of recreation related fires in a given year. The annual fire frequency appears to be more dependent on the weather severity during the fire season than on the number of summertime recreation visitors. Likewise, the number of industrial related fires also appears to be more a function of weather than of the level of timber harvest activity.

Based on (1) the historic relationships between fire frequency and human activity levels, (2) the direction in the Forest-wide Standards and Guidelines, and (3) the ranges of timber harvest and summertime recreation use included in the alternatives, there are no differences anticipated in fire frequency between the various alternatives presented in this plan.

Lightning fire frequency has shown a downward trend over the past thirty years but this is felt to be due to natural climatological factors rather than management activities. The frequency of these naturally occurring fires will remain at past historic levels under all alternatives.

All protection planning is accomplished using the National Fire Management Analysis System model and is based on the frequency and intensity of fire occurrence experienced in the 1970 decade. This is felt to be representative of what will occur in the first decade of plan implementation. If anything, it may be a liberal estimate based on what has occurred in the 1980 decade, though significant variation is expected between decades due to weather patterns and lightning occurrence.

Wildfire intensity is directly related to the volume of dead woody fuel available on the ground. Under normal conditions present on the Forest, weather influences will keep the intensity of fires occurring in naturally generated fuels (dead woody material) low, allowing easy containment. Though the volume of natural fuel falling to the forest floor is high, depth accumulation is slow due to the rapid rates of decomposition in the forests of western Washington, especially at the lower elevations. The various management practices associated with alternatives will not alter this fact. Therefore, there will be no measurable differences in potential fire intensity in natural fuels between alternatives presented in this plan.

Fire Protection Standards. Each management area has its own unique fire protection needs to ensure that the goals and outputs for the area are achieved. Since each management area may be broken into several parcels and scattered across the Forest, it is not practical to have a different protection standard for each area. For ease of implementation, Management Areas with similar basic protection goals have been combined into Fire Protection Groups. Table IV-42 displays how the various Management Areas are combined into Fire Protection Groups.

Table IV-42
Crosswalk of Management Areas to Fire Protection Groups

Fire Protection Group	Applicable Management Areas
Group A	2A-B, 3A-D, 7, 8, 11, 12, 16A, 23, 25A, 25B
Group B	4, 10A-E
Group C	1A-D
Group D	5, 6, 13
Group E (1)	14, 15, 17, 19, 21
Group E (2)	17, 21, 22
Group E (3)	17, 21

Note: Management Areas 18, 20 and 27 have their own unique protection requirements or are covered by other plans.

It is not economically practical to plan to eliminate fire completely from a Management Area, therefore each Fire Protection Group has an expected fire loss and maximum fire size for the first decade of the plan. These values have been determined from historic occurrences and the goals and Standards and Guidelines for each area. The expected burned acreage and maximum fire sizes for each Fire Protection Group are displayed in Table IV-43.

Direct Effects of Timber Harvest on Fire

Activities which involve cutting of live vegetation such as timber harvest, commercial and precommercial thinning, and clearing for roads, trails, buildings and other facilities, accelerate the accumulation of dead woody debris. These increased loadings can increase fire intensity. Alternatives which include the largest amounts of the above-mentioned activities will impact the protection program the most. However, differences of up to 1,000 acres between alternatives on a forest the size of the Mt. Baker-Snoqualmie, which has a relatively low fire incidence, will not influence the size of the protection organization needed. Standards and Guidelines are designed to mitigate the impacts of this debris on fire protection needs.

Direct Effects of Roads on Fire

In addition to woody material created during road construction, road and trail systems tend to provide increased access and improve opportunities for easier control of wildfires. On the opposite side, they also tend to increase the potential to spread forest visitor use over a larger area which can complicate prevention activities and suppression response. The low incidence of fire starts on the Forest and the relatively small increases in additional miles of

Table IV-43

Footnote *- 10 ac when threatening private land or areas with tighter control objectives.

**- Maximum fire size is variable. See Standards and Guidelines

roads and trails makes the differences in fire protection needs between alternatives insignificant.

The presence of scenic corridors in some alternatives does create increased protection needs and limits suppression options. Fire occurrence is very low in these areas and differences in total protection program needs is insignificant.

Fire - The Cumulative Effects of the Alternatives

The discussion of the Direct Effects of Each Alternative on Fire describes the minimal impact expected to occur on fire protection programs. The only activity that is expected to be cumulative in any form is the increase in acreage where harvest and silvicultural activities have created modified fuel bed conditions in terms of fuel loading and dryness. Since the acreages involved are significantly lower than historic levels, the cumulative effects of the alternatives will be an improvement over what has historically occurred. In this respect fire protection needs in future decades will be lower than in past decades.

Fire - The Indirect Effects on Other Resources

Minerals

There are no known indirect effects on Minerals from changes in Fire in any of the alternatives.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Fire in any of the alternatives.

Roads

There are no known indirect effects on Roads from changes in Fire in any of the alternatives.

Mitigation Measures for Fire

Seasonal closures of specific areas, operational shutdowns, and restrictions on public activities will be used to reduce the risk of fire starts during periods of extreme fire weather. This will be the same in all of the alternatives. (Refer to Forest-wide mitigation measures in Chapter II and to the Fire Prevention Plan in the Forest Plan document.)

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Fire

There are none.

MINERALS

Minerals- The Direct Effects of Each Alternative

General

The manner in which lands are to be managed under each alternative will have an effect on the availability of those lands for mineral entry; it will also have an effect on the cost of conducting exploration, development, and reclamation activities. Under the various alternatives, certain lands are recommended for withdrawal from mining activity. Not only might implementation of the Forest Plan preclude future exploration and development in areas recommended for withdrawal, but management prescriptions may affect exploration for mineral resources in some areas. Alternatives C, G-Modified, H and J (Preferred) will have the most restrictions on mineral entry. While alternatives B, I, A, and NC will have the least amount of restrictions to mineral activity.

In most cases, the value of mineral resources is not well quantified, and therefore, it is difficult to quantify the effects on minerals from each alternative. The consequences are best shown by analyzing how acre assignments to management areas (MA's) may limit the availability of lands for minerals exploration and development or constrain proposed mineral activities.

Demand for access to National Forest System lands for the purpose of mineral exploration and development is expected to continue to increase over the long term. This will not change as a result of implementing any of the alternatives. Operating plans will continue to be submitted for approval and the regulations under which those operating plans are processed will not change as a result of implementing any of the alternatives. Mineral commodities, deposit locations, and deposit characteristics will not vary by alternative, and the demand for mineral commodities is expected to increase regardless of the alternative selected. As described in Chapter III, minerals are classified as locatable, leasable, or salable, and the laws by which each type is governed will not change by alternative. Those lands that are not withdrawn from mineral entry will remain subject to exploration and development under the mining and mineral leasing laws.

The management areas have been grouped by restrictive categories, Table IV-44. MA's requiring complete withdrawal of lands from mineral entry (such as Developed Recreation sites and Wilderness) are the most restrictive because withdrawals usually preclude mineral entry. The only mineral activities allowed in these areas will be those conducted on mining claims, leases, or permits having valid existing rights established prior to the date of withdrawal. Prospecting, leases, and mineral permits may be allowed in some circumstances.

The next group, which is considered to be "highly restrictive" towards minerals, include special management area categories such as Scenic Viewsheds and Old Growth Habitat Areas. Special provisions will be required to ensure management objectives are met. These provisions may increase costs and/or operating season restrictions. Alternatives J (Preferred), H and C will have the most acres in these categories.

The least restrictive management areas are those which include timber harvest and roading in their management prescriptions: 1D, 1F, 17, 19, 24, and 27.

In all categories except withdrawal, mineral activity is not restricted beyond reasonable precautions for environmental protection and compliance with management objectives.
The public has a right to explore for leasable minerals and to produce both leasable and salable minerals from public lands if they hold a valid lease or permit. Specific leasing decisions will be made when proposals to lease are received. When claimants have a right to mine or produce minerals, they are also guaranteed reasonable access for mining purposes. The same rights apply to withdrawn areas if valid rights were perfected prior to the withdrawal.

The effect that the highly restrictive management strategies will have on mineral resources cannot be accurately quantified in terms of tons at a certain grade or in dollars. However, Figures IV-9 through IV-14 and Tables IV-45 and IV-46 show the relatively restrictive effect that implementing the various alternatives would have.

Table IV-44 lists MA's by restrictive category and describes each category's restrictions. The overall effect on mineral activity for each alternative is summarized in Table IV-45. Less than one percent of the Forest area is prescribed to be withdrawn in addition to existing withdrawals for wilderness. Fifty-eight percent remains open for mineral entry. Of the area available for mineral entry, a range from 13% in Alternative A, to 68% in Alternative C have highly restrictive management area prescriptions. Only 33% of the available Forest in Alternative B is available for mineral entry, while the numbers are 40% and 49% in Alternatives I and J (Preferred), respectively.

The overall effect can be further described by comparing the percentage of acres of potential mineral resource development (for locatable and energy minerals) that would be either withdrawn or highly restrictive to mineral activity by the MA prescriptions under each alternative.

In all alternatives, except Alternative G-Modified, the management area prescribes withdrawals on 42 acres identified as having a high potential for locatable mineral resources. In Alternative G-Modified, there are 232 acres withdrawn. These withdrawal areas do not include any area classified as a "known" geothermal mineral energy resource in any alternative.

Common variety minerals, by contrast, occur throughout the Forest, and it appears that none of the alternatives will significantly affect the availability of that resource.

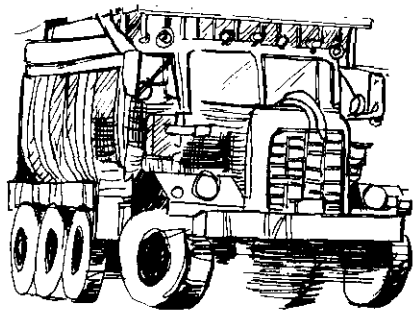

Table IV-44
Management Areas By Restrictive Categories 1/

Withdrawal

3 - All developed recreation sites
4 - Mt. Baker National Recreation Area (Geothermal withdrawal)
5C - Wild portion of Potential Wild and Scenic Rivers
8 - Special Areas
10 - Wilderness
16 - T & E Species
18 - Research Natural Area
20 - Cedar River Municipal Watershed
21 - Green River Municipal Watershed
26 - Administrative Areas
27 - Alpine Lakes Special Areas

Highly Restrictive

1A-C- Dispersed Recreation
4 - Mt. Baker National Recreation Area (locatable and saleable minerals)
5A-B- Recreation and Scenic segments of Potential Wild and Scenic Rivers
6 - Skagit Wild and Scenic River
7 - American Indian Religious and Cultural Uses
11 - Old Growth Habitat Emphasis (MR)
12 - Mature and Old Growth Wildlife Habitat (MR)
13A-D- Riparian and Fish Habitat Emphasis
14A - Deer and Elk Winter Range Habitat (MR)
15A - Mt. Goat Habitat (MR)
22 - Sultan River Municipal Watershed
23 - Other Municipal Watersheds
25 - Special Use Sites (Utilities and Electronic Sites)

Moderately Restrictive

1E - General Dispersed Recreation
2 - Scenic Viewshed
27 - Alpine Lakes Scenic
27 - Alpine Lakes Dispersed Recreation

Low Restrictions

1D - Roaded Natural Dispersed Recreation
1F - Mt. Baker Recreation Area
17A-F- Timber Management Emphasis
19 - Mt. Hemlock Zone
24 - Minimum Management Emphasis
27 - Alpine Lakes General Forest

1/ Refer to Chapter II for brief descriptions of the management areas.

Figure IV-9

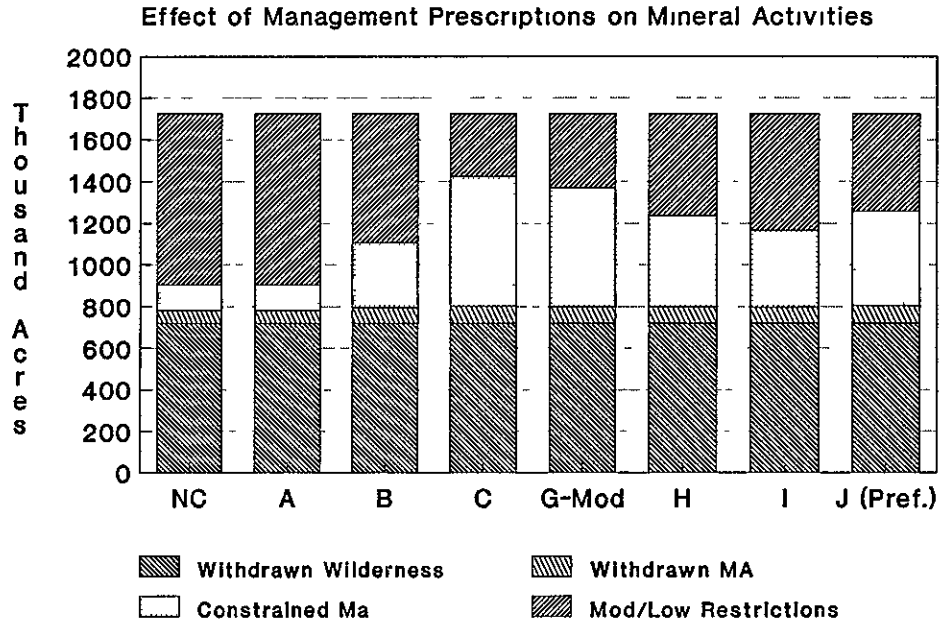

Table IV-45
Acres And Percentages Of The Forest Withdrawn Or Highly Restricted

Alternative	Area Other Than Wilderness Where MA Prescriptions Specify Withdrawal	Area Highly Restricted By MA Prescriptions 1/	% of Forest available for mineral entry - in Highly Restricted MA Prescriptions Category
NC (No Chg) 2/	Similar to A	Similar to A	Similar to A
A (No Action)	58,708 acres	124,429 acres	13%
I	75,162 acres	370,267 acres	40%
B (RPA)	74,231 acres	310,692 acres	33%
H	79,638 acres	437,423 acres	47%
J (Preferred)	83,797 acres	453,558 acres	49%
C	79,638 acres	624,468 acres	68%
G-Modified	78,3708 acres	569,603 acres	62%

1/ Includes Mt. Baker National Recreation Area (8,743 acres), which is withdrawn from geothermal entry.
2/ No actual acres can be estimated for Alternative NC, as management areas were not assigned in that alternative.

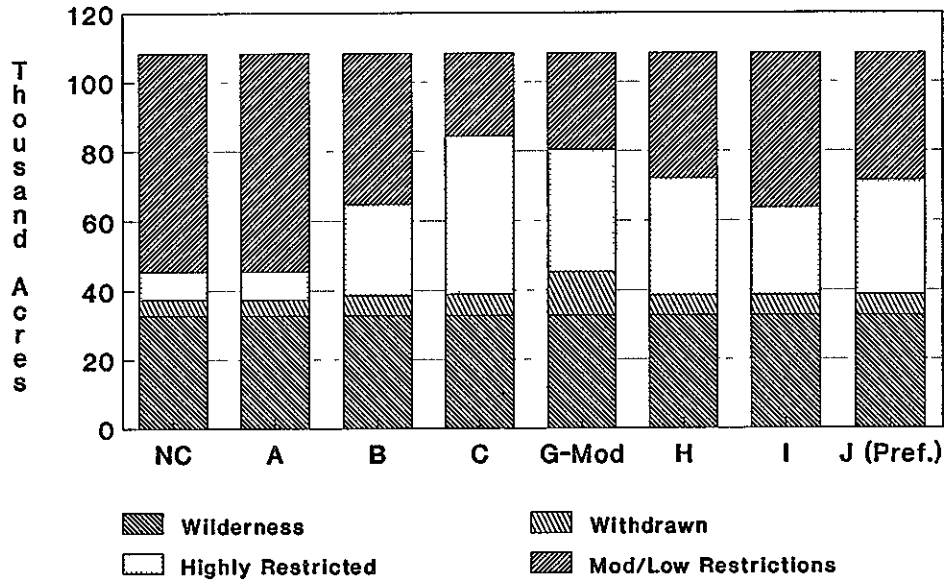

Figure IV-14 Consequences in Areas "Prospectively Valuable" for Geothermal Resources

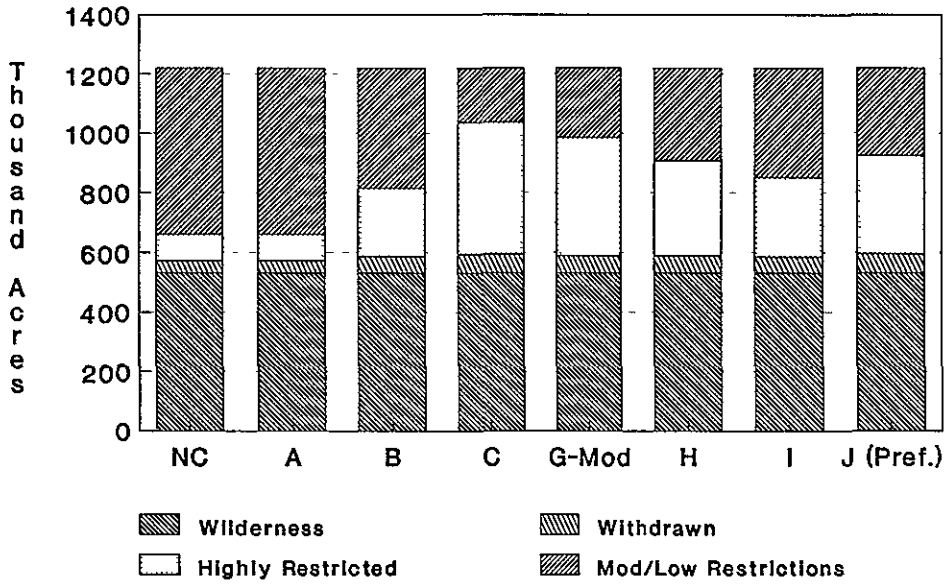

Direct Effects of Wilderness on Minerals

In all alternatives, the acres of wilderness (721,718 or 42 percent of the Forest) have already been withdrawn. The only mineral operations allowed within these areas will be those authorized by valid existing rights perfected prior to the area's withdrawal as wilderness. The quantified effect of wilderness withdrawals has not been determined.

Direct Effects of Research Natural Areas on Minerals

The potential for major direct effects on minerals can occur in these areas. Because of the potential conflict with sensitive plants and unique plant communities, this allocation imposes high restrictions relative to access and development. If protection could not be assured during mining, the need for withdrawal will be considered through an environmental analysis of specific operating plans.

Existing RNA's are withdrawn from mineral entry. Impact on the non-wilderness potential areas will vary by alternative and by area depending on mineral potential. Alternatives H, J (Preferred), C, and G-Modified will be the only ones to have any additional effects. The same number of Research Natural Areas are proposed in each of these four alternatives.

1/ Mineral resources grouped to eliminate overlaps between resource areas

Direct Effects of Wild and Scenic Rivers on Minerals

Allocations to or designations of Wild, Scenic, or Recreation Rivers could have a significant direct effect on mineral activities due to high or withdrawn access restrictions. Allocations to Wild River will generally result in the withdrawal of land from mineral activities within 1/4 mile either side of the river. In some cases, withdrawal may be recommended in Scenic Segments. Protection of visual resources on lands adjacent to the 1/4 mile corridor (i.e. within the viewshed) may impact mineral activities on a much larger area due to public demand for protection of those areas. Development of reservoirs and powerlines, and other types of intensive use, are generally not permitted on Wild and Scenic Rivers. Removal of sand and gravel will usually be prohibited. Alternatives G-Modified, C and J (Preferred) will have the greatest effects while Alternatives NC, I, and B will have no effects at all. There will be some effects in Alternatives A and H, but they will be minimal due to the few rivers and/or miles recommended.

Direct Effects of Roads on Minerals

In general, the relationship between the Forest's road system and mineral resources is a positive effect. Common variety mineral resources provide the materials from which roads are constructed and maintained, whereas the road system provides access for mineral exploration, development and production activities. On the Forest, the dominant market for construction materials is in support of the timber management program. Future demand will continue to reflect the level of road building and maintenance needed for timber harvesting activities. It appears that the need for new roads will not be influenced significantly by mineral-related activities unless on-going and future exploration leads to larger scale development.

Minerals - The Cumulative Effects of the Alternatives

Even though an area has a high or moderate potential for the occurrence of mineral resources, it is of little value if the area is withdrawn for mineral exploration and development or highly restricted by management area prescription.

The cumulative effects of the existing withdrawals and any new withdrawals resulting from the Forest Plan, are increased by those withdrawals made when a new application for a power project is received. Not only is the site automatically withdrawn from mineral entry when the application is received, but it remains withdrawn; there is presently no mechanism for revocation. Since it is not known where, when, or what type of hydroelectric project might be applied for in a given area, it is not possible to quantify the anticipated impact that future proposals of this nature will have on minerals availability.

Minerals - The Indirect Effects on Other Resources

Trails

Mining activities could influence the location of proposed new trails. Existing facilities would be protected through mining operation plans. Alternatives that have the largest number of trails (I, G-Modified, and J (Preferred)), will have the greatest risk of conflict.

Land Ownership and Use

There are no known indirect effects on Land Ownership and Use from changes in Minerals in any of the alternatives.

Roads

In general, existing Forest roads and trails on the Mt. Baker-Snoqualmie National Forest have been adequate to satisfy the access requirements for the level of exploration activity conducted during the past 10 years. Whether the system remains adequate will depend on the results of recent and future exploration. In most cases, when access is needed for mineral-related activities, it can be developed so that it is compatible with the Forest Service road system. However, the holder of a valid mining claim has a statutory right of appropriate access to the claim. The claimant's road needs may not always be compatible with planned or existing systems. In such cases, the incompatibility will be mitigated to a reasonable extent through an approved plan of operation, while recognizing the rights of the mining claimant. This is constant through all of the alternatives.

Mineral exploration and extraction, and geothermal exploration can result in damage and/or obliteration of existing roads if sites are adjacent to or within roadways. If a significant ore body were discovered, a large increase in use of the affected road system would result. The actual amount of development is beyond the control of any alternative, as existing mining laws and regulations take precedence. However, the alternatives vary in their degree of restrictions, and the alternatives that have the most highly restrictive acres would be the least favorable to development. Alternatives C, G-Modified, H, and J (Preferred) will have the most restrictions on mineral entry and development, while Alternatives B, I, A, and NC will have the fewest restrictions.

Mitigation Measures for Minerals

Under all alternatives, threatened and endangered plant and wildlife species would be protected to the extent required by law, as would flood plains and wet lands. Potential damage to archaeological and/or historic sites would require mitigation or avoidance by the prospector or miner. Protection of surface and subsurface waters from contamination would be required, as would maintenance of air quality. For each mining development, a Plan of Operation would be prepared and submitted to the Forest Service for approval. The Plan of Operation would incorporate these requirements and others as needed, as well as identify how each requirement would be met. All mitigation costs would be borne by the proponent.

Proposals for mineral exploration and development are negotiated on a case-by-case basis. When a proposal is received, the Forest Service can work with a proponent and other agencies to minimize or mitigate adverse impacts on those resources requiring some degree of protection. Only reasonable restrictions to mining can be legally imposed on areas not withdrawn.

Examples of possible mineral activities might include proposals to test drill for ore in wilderness, wild and scenic rivers, or semi-primitive nonmotorized dispersed recreation areas. If roads were needed to transport the drilling

equipment and a site needed to be leveled and cleared in order to operate, the integrity of these areas could be compromised. To mitigate these impacts, the operator may be required to build roads with costlier standards or in less-than-optimum locations, or drilling equipment and personnel may need to be flown in. Hence, the economic viability of an operation may be reduced.

Another example might be a proposal to test drill in a Research Natural Area, Botanical Area, or Special Area. Sensitive plants are known to inhabit such ares. In order to protect the plants, the operator may be required to slant drill from an off-site location.

Other mitigation could be required if valuable deposits were found in a dedicated wildlife habitat area. The proposal might threaten to drive the animals from the site and make it unusable. To mitigate this impact the proposal could be scaled down. In addition, restrictions would be placed on operations during the mating, birthing, and rearing seasons for the species.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Minerals

Mining and minerals are important to county, state and national plans at all levels of the economy. The effects of implementing any alternative many conflict with their objectives and federal mining laws. The U.S. Mining Laws Act of 1872 predates all other laws that govern Forest Service activity. Because of this, frequent conflicts arise between administration of mining and other resources such as visuals, wilderness, water, sensitive wildlife and plants, and recreation.

ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL

General

Table IV-47 shows the net energy balance calculated for each Forest Plan alternative. The net Forest resource energy balance is the difference between the energy produced and the energy expended in utilizing a resource or service. The Methods for Evaluating Energy Effect of Forest Management Alternatives, Volume 1, written by Gideon Schwartzbart and Patrick L. Schmidtz was used as a reference for energy formula formats and coefficients.

Energy considerations for each resource activity include the following:

	Energy Consumption
Water:	Construction and maintenance of hydroelectric facilities.
Timber:	Extraction, transport, processing, road construction and maintenance.
Recreation:	Recreation transportation, campground and resort construction and maintenance.
Wildlife:	Not considered.
Range:	Not considered.
Minerals:	Not considered.
Fire Management:	Prevention and suppression.
	Energy Yield
Water:	Energy production at existing sites only.
Timber:	Savings over other construction material, heating value.
Recreation:	None
Wildlife:	Harvest of game.

Due to the minor amount of minerals development and the minor nature of the range program, these were not considered in the energy balance calculations. The potential geothermal and potential hydroelectric power development were not quantified. These sources will probably add to the long-term energy output of the Forest in any alternative selected.

Table IV-47
Net Energy Balance For All Resource Activities
Figures in billions of British Thermal Units (BTU's)

Alternative	1986	2000	2030
NC	11,998	11,707	11,471
A (No Action)	11,980	11,542	11,116
I	12,259	11,971	11,509
B	12,286	14,975	11,520
H	12,416	12,149	12,250

G-Modified	12,790	12,603	12,352

LAND OWNERSHIP AND USE

Land Ownership and Uses -The Direct Effects of Each Alternative

None of the alternatives propose adding or deleting land uses from the current situation; however, all alternatives will affect future adjustments in the land base. All alternatives maintain approximately the same total number of National Forest acres, but consolidate ownership into different configurations to reduce operation and maintenance costs, respond to issues, or continue current plans.

Land Ownership and - Use The Cumulative Effects of the Alternatives

There are none.

Land Ownership and Use - The Indirect Effects on Other Resources

Roads

There are no known indirect effects on Roads from changes in Land Ownership and Use in any of the alternatives.

Mitigation Measures for Land Ownership and Use

During land exchanges, title to rights-of-ways needed to access other National Forest land will be held. (Refer to the discussion of mitigation measures, Chapter II.)

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Land Ownership and Uses

There are none.

ROADS

Roads - The Direct Effects of Each Alternative

General

Roads, in particular new construction and reconstruction, have significant effects on nearly all of the environmental components discussed in this chapter. A multitude of direct, indirect, and cumulative effects on various resources are associated with roads.

The effects of the alternatives on roads is linked directly with the level of timber harvest. Alternatives (NC, A, I, and B) with the highest amounts of timber harvest construct the most miles of new roads.

Construction of new arterial and collector roads occurs in all alternatives and will take place primarily in the roadless areas released by the Washington Wilderness Act of 1984. Alternatives with high timber harvest levels will build up to 28 miles of arterials and collectors in Decade 1. Alternatives with low timber harvest levels build as few as six miles of these roads. The estimated miles of arterial, collector, and local road construction and reconstruction under each alternative are shown in Table IV-48 and Figure IV-15.

Table IV-48
Road Construction and Reconstruction

	Decade 1		Decade 1	Decade 5
	..... Construction.....		..Reconstruction...	Construction
Alternative	Arterial/ Collector (miles/year)	Local (miles/year)	Local (miles/year)	Local 1/ (miles/year)
NC (No Change)	8.2	20.4	72.0	6.1
A (No Action)	1.4	17.4	55.8	10.8
I	1.8	15.3	47.7	9.3
B (RPA)	1.5	14.6	47.1	8.9
H	0.6	13.5	43.1	8.4
J (Preferred)	0.8	12.6	40.1	7.9
C	0.7	9.6	24.7	5.4
G-Modified	0.6	7.5	32.8	5.7

1/ All new arterials and collector road construction will be completed prior to Decade 5.

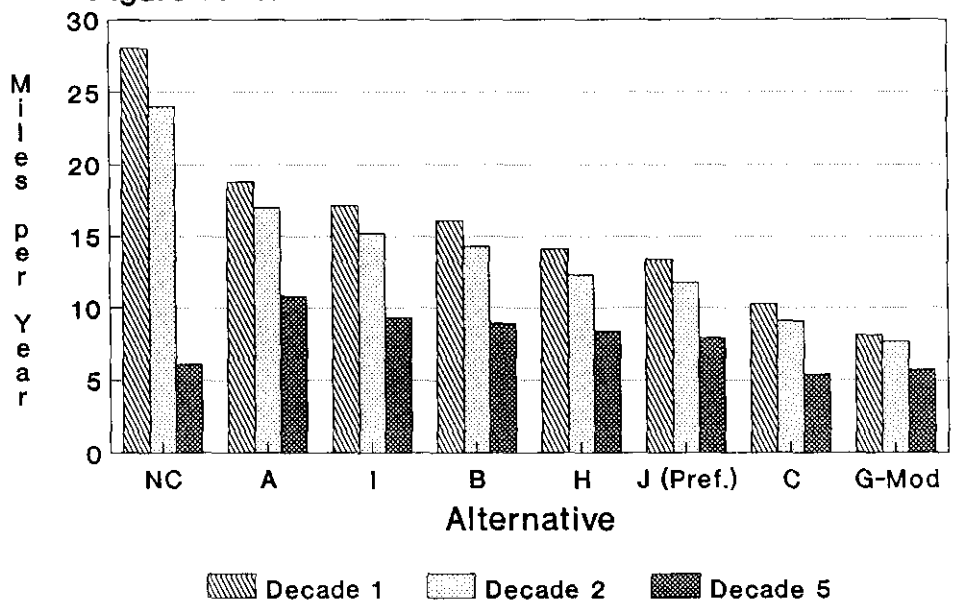
All alternatives purpose local road construction that is proportional to timber harvest activity. For the first decade, local road construction ranges from a total of 75 miles in Alternative G-Modified to 204 miles in Alternative NC.

Reconstruction of local roads for timber management will consist principally of the reopening of temporary roads, replacing sections destroyed by fill failure or slides, and minor improvements to drainage and surfacing. Miles of local

road reconstruction in the first decade vary from 247 miles in Alternative C to 720 miles in Alternative NC.

Road management of the local roads will be consistent across the Forest within a given management area. Therefore, overall differences in road management between the alternatives is a function of the acres assigned to each management area. Many of these roads will be designed to make them unattractive for use by passenger cars.

Figure IV-15 Average Annual Road Construction



The construction of a road over the Cascade Crest in the vicinity of Naches Pass could occur in Alternatives NC, A, I, B, H, and J (Preferred).

Direct Effects of Trails on Roads

Construction of additional new trails may result in a need for additional signing, trailheads, and parking areas adjacent to roads. It may also require the construction and maintenance of short access roads to these new facilities. These effects will vary with the amount of new trail construction in each alternative. Increased use of both the existing trail system and new trails to be constructed could result in higher levels of use of the roads accessing the trails.

Trail maintenance would have little effect on roads except in those situations where reduction of trail funding would cause some trails to deteriorate to a point where they would be unusable. When this happens, the signing needs and road access needs for trail use will also be less.

Direct Effects of Mining, Energy Development on Roads

The construction, operation, and maintenance of small hydroelectric facilities may require the construction of both permanent and temporary roads by the developers for access. These effects vary by alternative, based on the number of FERC projects which could be developed under the management area assignments of that alternative. For these estimates, see the section on Water earlier in this chapter.

Roads - The Cumulative Effects of the Alternatives

In general, the effects of management activities increase as the road mileage increases and as the intensity of each management activity increases. In addition to the total miles of road, the cumulative effects that would vary by alternative include changes in levels of road use by timber purchasers and recreationists; maintenance standards (smoothness and type of road surface); miles of roads closed for game management, economic, and recreation needs; and miles of roads reconstructed.

Roads - The Indirect Effects on Other Resources

Refer to the previous Chapter IV discussions of Soils and Water, Vegetative Diversity, Old Growth, Wildlife, Fish, American Indian Religious and Cultural Use, Archaeological and Historic Properties, Scenery, Recreation, Wilderness, Research Natural Areas, Roadless Areas, Wild and Scenic Rivers, Air, Fire, and Minerals and Landownership for additional information.

Trails

Road construction historically has had the greatest effect on trails primarily by replacement. Roads have tended to replace trails, rather than be built as additions to the transportation network because (1) roads often have the same destination as trails and (2) the most favorable locations for proper road grade and alignment have followed the same routes as trails. This trend has been most pronounced in the lower elevation commercial forest land, where roads have served predominately as the means to remove harvested timber from the Forest. In these lower elevations of the Forest, the primary road system has been built, and most of the once-existing trails have long been obliterated or bisected to the point that they receive little or no use.

The actual effect of any alternative on trail system mileage will be a function of (1) the miles of trail needing relocation due to new road construction; (2) miles of trail reconstructed; and 3) miles of trail maintained or abandoned.

Although it cannot be predetermined how many actual miles of trails would be replaced and relocated by road development in any of the alternatives an idea of impacts can be assessed by reviewing the of miles of the trail system located in areas were timber management would occur.

Alternative A would have a high risk of trail loss as there 166 miles of the trail system in timber management allocations where severe impacts to these trails may be expected.

Obliteration, bisection, relocation, and reduction of recreational experience will be higher in Alternative NC than in Alternative A due to its higher degree of roading.

In Alternative I, high levels of road construction in the roadless areas would result in a high number of trail miles obliterated, severely impacted, or bisected. As large areas of the unroaded lands become roaded, there would be fewer practical locations for relocation of affected trails. Lands allocated to timber management contain 158 miles of system trail in this alternative, resulting in a high level of impact to the system. Roads constructed close to the wilderness would tend to attract trail users, make access easier, and (as has happened in the past) encourage creation of multiple user-made trails. While loss of trail mileage would be somewhat mitigated by trail relocation, the loss of wilderness values (naturalness and solitude) would be accelerated (Hendee and others, 1978). Motorized trail use would decline, and motorized ORV use on closed roads would increase.

Alternatives B would be similar in effects to Alternative I. Alternative B has the greatest risk of change to the trail system, with 191 miles of trail within timber management allocations.

In Alternative G-Modified roads do not replace trails. This alternative has 100 miles of trails within timber management areas, but these trails will be protected in this alternative.

In Alternative J (Preferred) trails may be bisected or relocated, but the total mileage on the Forest will not be decreased. Only 74 miles of trail occurs within timber allocations in this alternative.

Alternative C causes the least impact to the existing trail system with only 57 miles of trail in timber allocations.

Signing will be needed to inform users of trail relocations. Additional roads bisecting trails will make the trail more attractive to motorized off-road users. With an increase in ORV use, trail width, and tread erosion will increase unless major reconstruction measures are taken.

In general, opportunities for off-road motorized use of trails would decline as the miles of road constructed increases. Segments of trail remaining will tend to be in the "most difficult" category and would not be suitable for motorized use. Conversely, those alternatives which would construct the most road will, in general, provide the greatest opportunities for "snow trails" for cross-country skiing and snowmobiling.

Mitigation Measures for Roads

The potential for adverse impacts can be reduced by minimizing road widths, minimizing total road miles, and using good locations. Much of the severe soil impact of mass wasting can be prevented by locating roads where soils and bedrock are stable. Where it is necessary to cross unstable soils, use of specialized structures such as binwalls and lightweight sawdust fills will help mitigate effects. The potential for erosion and mass wasting on fill slopes is reduced by end hauling excavation waste when constructing on steep slopes. Experience with these methods has shown them to be effective.

Cuts and fills are stabilized by grass seeding and/or brush plantings. The potential damage incurred by disrupting the natural surface and subsurface drainage patterns on the slope is mitigated by constructing the road with drainage dips and/or culverts and cross drains. At some stream crossings where there is a high potential for culvert blockage and subsequent road washout, impacts are mitigated by installing specialized overflow type structures.

Maintenance can mitigate potential impacts by cleaning ditches, opening up culverts, and repairing portions of the road before damaging failures occur.

To mitigate the effects on the environment of an expanded road system, selected road closures would be implemented, and trails would be relocated or reconstructed to meet the objective of no cumulative lose of trail mileage.

Some roads are closed to meet resource management objectives. Closures are used to discourage or eliminate all use by motorized vehicles over 40 inches in width. Road closures may eliminate traffic altogether where resource sensitivity is of particular concern. The purposes for closures include providing for water quality, erosion control, public safety, reduction of road user conflicts, reduction of maintenance costs, legal mandates, managing recreation opportunities, and protection/management of wildlife and wildlife habitat. Road closures can result in reduced disturbance to big game and to help meet the demand for quality hunting experiences. Closures may be permanent or periodic. Road closures are authorized in the Code of Federal Regulations, Title 36, part 261.

Permanent road closures would occur in Alternatives C (about 300 miles), G-Modified (about 65 miles), and H (about 20 miles), with the roadbeds being allowed to revert to a natural condition.

Other mitigation measures are discussed in Chapter II.

Conflicts Between the Effects of the Alternatives and Others' Plans and Policies for Roads

The City of Seattle and the Forest Service currently have an agreement whereby the Forest has not acquired public access rights over private road systems that access public land in the Cedar River watershed. Alternative B will pursue acquisition of public rights on roads leading to these public lands.

Some counties have approved subdivision plats and developments on private lands adjacent to National Forest System roads. Although the Forest has a responsibility to provide access to individual landowners whose properties are entirely surrounded by NFS lands, the Forest has no responsibility to provide access to subdivisions and developments. Counties are responsible for overseeing such access. If the counties continue to approve such subdivisions, additional conflicts over road responsibilities will develop.

E. RELATIONSHIP BETWEEN SHORT-TERM USES OF MAN'S ENVIRONMENT AND MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

The relationship between short-term uses of the environment and the maintenance and/or enhancement of long-term productivity is complex. Short-term uses refer to those that would occur within the life of this plan, generally 10 years or less, but a maximum of 15 years. Long-term productivity refers to the capability of the land and water to produce a continuous supply of resources and values for future generations. Soil and water are the primary factors of productivity and represent the measurement of the relationship between short-term use and long-term productivity.

Some short-term uses can be detrimental to long-term productivity, particularly if effective mitigation measures are not implemented. Surface mining can leave an area with greatly diminished productivity for growing vegetation if the top soil is removed and not replaced. This adverse effect can be mitigated effectively by requiring stock piling and spreading of topsoil. Introduction of sediments into a stream on a continuous basis could adversely effect the future long-term productivity of that stream for production of fish. This potential adverse effect can be effectively mitigated by elimination of sediment sources or trapping sediment before it reaches the stream by maintaining vegetation along stream banks.

Some short-term uses also have the potential to increase long-term productivity. Harvest of old-growth timber stands and establishment of young faster growing stands increases the long-term productivity of the land to produce wood fiber. The current productivity of the Mt. Baker-Snoqualmie National Forest in terms of net timber growth is approximately 34 cubic feet per acre per year (1976 Timber Inventory). Harvest of these old growth stands can increases average annual growth on the Forest up to 90 cubic feet per acre per year.

The Multiple-Use Sustained-Yield (MUSY) Act of 1960, one of the principal laws relating to the Forest Service activities, requires the management of the various resources in such a manner that the productivity of the land will not be impaired. This law along with Forest Service Policy that was in effect prior to the MUSY Act have provided the basic frame work for development of management activities that are centered around maintaining the long-term productivity of the National Forests.

Many of the mitigation measures described in detail in Chapter II, Mitigation Incorporated in Alternatives, are designed specifically to maintain or enhance long-term productivity as short-term uses (projects) are designed and implemented.

In all resource ares, long-term productivity of soil and water will be maintained or enhanced as a result of implementing the alternatives.

Implementation of the Forest Plan, which accompanies this FEIS, includes a monitoring plan. This monitoring plan will provide the data necessary to determine if the prescribed mitigation measures are effective in maintaining long-term productivity.

F. IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

An "irreversible commitment of resources" results from decisions to use or modify resources or environmental components of the Forest that cannot be renewed, or are renewable only over long periods of time. Examples are: old growth, soil productivity, minerals, cultural resources, scenery, and roadless areas. Once these resources are used or modified, they are irreversibly lost.

Soil productivity can be irreversibly lost or reduced by dedicated uses of the land. Examples of these uses would be arterial and collector roads, administrative sites, and developed recreation sites. Soil erosion, as a result of management activities, is an irretrievable loss because once the soil particles are removed from the site and deposited into a stream or river, they are no longer available. Accelerated erosion rates can reduce soil productivity and also reduce the water-holding capacity of the soil.

Removal of mineral or energy resources is an irreversible commitment of resources. The removal and utilization of rock resources for road construction would be an example of a common use on the Forest.

Reductions in habitat capability for old-growth-dependent species due to timber harvesting involve an irreversible and irretrievable commitment of resources.

The development of roadless areas would mean an irreversible loss of the characteristics which qualify these areas for Wildernesses or Roadless Areas. Development could also mean an irreversible loss of natural scenery and, in some cases, old-growth habitat.

Archaeological resources may be damaged by ground-disturbing activities; Irreversible information loss can result. Even when mitigation occurs prior to the activity, future study with more advanced techniques is precluded.

For American Indian religious use, land development removes the spiritual influence on the environment; this irreversibly removes the opportunity to conduct religious activities.

An "irretrievable commitment of resources" refers to a resource that is lost because of land use decisions or designations and/or scheduling decisions. These are opportunities foregone for the period of time that the resource cannot be used. Timber stands in management areas where timber harvest is not permitted represent an irretrievable loss of growth increases that could be made if the stands were being actively managed for timber production. Although the lost growth is irretrievable, the decision is not irreversible, since the stands could be managed at a later date in the future.

G. PROBABLE ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

Implementation of Alternative J (Preferred) will result in some adverse environmental effects that cannot be avoided. The identification of an "adverse effect" is somewhat subjective, depending upon an individual's point of view. There are some effects considered to be adverse, by general agreement. The following effects are associated with implementation of Alternative J (Preferred). Although many of these effects can be reduced through the use of mitigation measures, they cannot be completely eliminated.

Timber harvest and associated road construction will result in adverse effects on scenery, water quality, soils, American Indian religious and cultural use areas, and dispersed recreation use in a non-motorized environmental setting.

Harvest of old-growth timber stands will reduce the amount of habitat available for old-growth dependent species and reduce their populations.

Ground-disturbing management activities and facilities management will probably result in inadvertent destruction or displacement of archeological and historical resources. Even when mitigation occurs, future study and interpretation are precluded.

Any mineral extraction activities that occur will result in destruction of vegetation, production of sediments, and effects on scenery.

Development and use of recreation facilities will result in compaction of soil, loss of vegetation, water pollution, dislocation of wildlife and disturbance of their habitat, noise and dust production in small areas, and localized air pollution from campfire smoke and vehicle exhaust.

Air quality will be degraded on a localized and short-term basis from prescribed fire and activities that generate dust from unpaved roads.

Any of the proposed small hydroelectric projects that reach the construction stage will result in adverse impacts on soil, water, and vegetation to some degree. These would generally be on a localized area. Construction techniques and mitigation measures can minimize most impacts and limit them to the construction effects on the visual resource. Some projects will also have long-term impacts on wildlife, American Indian religious and cultural use (see below), and recreation.

Development, especially timber harvest and hydroelectric projects, will create features and habitats out-of-keeping with traditional Indian religious use, and will reduce the availability of some plant materials, such as cedar.

H. ENVIRONMENTAL CONDITIONS UNCHANGED BY ALTERNATIVES

Some environmental conditions and resource uses are essentially unchanged by any of the alternatives. These are resources which are often protected by law and are managed consistently in all alternatives. They include:

The wilderness acres are unchanged in any of the alternatives (refer to Chapter II, Alternatives Considered but Eliminated for Detailed Study). The acres assigned to each wilderness ROS class vary between alternatives, but total wilderness acreage does not.

Management of the Skagit Wild and Scenic River is unchanged across all alternatives. The existing management plan for this river system (which is incorporated into this Forest Plan) will provide the same set of environmental conditions in each alternative (refer to Chapter II, Alternatives Considered but Eliminated from Detailed Study).

The basic land allocations established through implementation of the Alpine Lakes Area Land Management Plan (1981) are the same in all alternatives (refer to Chapter II, Alternatives Considered But Eliminated from Detailed Study).

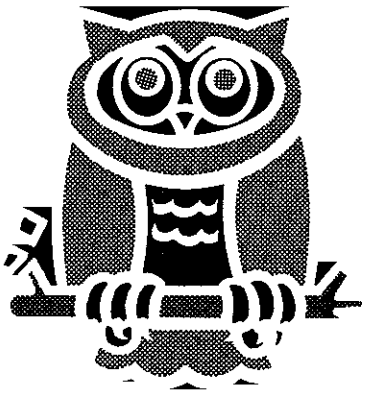
The Mt. Baker National Recreation Area, size and management, is unchanged in any of the alternatives.

Management of the North Fork Nooksack, Lake Twenty-two, and Long Creek Research Natural Areas will remain the same in all alternatives. Although the alternatives recommend different numbers of new research natural areas for designation, the existing ones remain unchanged.

None of the alternatives result in any environmental consequences on prime farmlands, prime rangelands, or prime forestlands. None of these prime lands would be converted to other uses as a result of the implementation of any of the alternatives.

None of the alternatives results in any change in Indian Treaty Rights.

List of Preparers



LIST OF PREPARERS

Interdisciplinary team participants in the preparation of this Draft Environmental Impact Statement include: the Forest Management Team, consisting of the Forest Supervisor, District Rangers, and Forest Staff Officers; the Forest Planning Team; and other members of the IDT who provided analysis and support.

Forest Management Team

The primary role of this group was to help identify major Forest Issues, Concerns, and Opportunities (ICO's); develop Forest-wide Standards and Guidelines; develop alternative management schemes, and assist the Regional Forester in identifying a preferred alternative.

J. D. MACWILLIAMS	Forest Supervisor - B.S. Forest Management, Oregon State College, 1960 - 31 years experience with the USDA Forest Service.
BERNARD WEINGARDT	Deputy Forest Supervisor - B.S. Forest Management Science, Colorado State University, 1973 - 18 years experience with USDA Forest Service.
RUDY EDWARDS	North Bend District Ranger - B.S. Biology, Jackson State University, 1969; M.S. Soil Science, Tuskegee Institute, 1975, - 2 years experience with the Peace Corps in Swaziland 16 years experience with the USDA Forest Service.
PHYLLIS GREEN	Skykomish District Ranger - B.S. Forest Management, Oregon State University, 1974; M.B.A. Oregon State University, 1975 - 14 years experience with USDA Forest Service.
FRED HARNISCH	Darrington District Ranger - B.S. Forest Management, Purdue, University, 1963 - 27 years experienc with the USDA Forest Service.
LARRY HUDSON	Mt. Baker District Ranger - B.S. Forest Science, Colorado State University, 1971 - 19 years experience with USDA Forest Service.
TED LEWIS	White River District Ranger - B.S. Forest Management, Pennsylvania State University, 1960 - 30 years experience with USDA Forest Service.
*MIKE COOLEY	Recreation, Cultural, and Visual Resources Staff Officer - B.S. Forest Management, Oregon State University, 1966 - 26 years experience with USDA Forest Service.
RONALD DeHART	Public Affairs Officer - B.A. Communications, University of Minnesota, 1974 - 15 years experience, USDA Forest Service.
RICHARD DEARSLEY	Soils, Range, Water, Fish & Wildlife Staff Officer - B.S. Forest Management, Michigan State University, 1957 - 30 years with USDA Forest Service, 3 years with Environmental Protection Agency.

ROBERT DUNBLAZIER Planning Staff Officer - B.S. Forest Management, University of Michigan, 1963; M.L.A., University of Michigan, 1971 - 17 years experience with USDA Forest Service.

BOYD LEONARD Administrative Officer - B.A. Accounting, Eastern Washington State, 1961 - 28 years experience USDA Forest Service.

BRUCE MATEER Timber Staff Officer - B.S. Forest Management, University of Michigan, 1960; M.F. University of Michigan, 1963 - 31 years experience with USDA Forest Service.

SAMUEL NAGEL Lands and Minerals Staff Officer - B.S. Forest Management, Iowa State University, 1958 - 33 years experience with USDA Forest Service

WALT WEAVER Forest Engineer - B.S. Civil Engineering, Iowa State University, 1961 - 27 years experience with USDA Forest Service.

Past Management Team Members

*JOSEPH ASTLEFORD, Deputy Forest Supervisor - B.S. Forestry, Pennsylvania State University, 1959 - 30 years experience with USDA Forest Service.

*LYLE E. JACK Planning Staff Officer - B.S. Forestry, Iowa State College, 1955 - 35 years experience with USDA Forest Service. (Retired)

*ARNOLD MASONER, Administrative Officer - Attended Fresno State, Business Major - 26 years experience with USDA Forest Service.

Forest Planning Team

The primary role of this group was to develop a proposed Forest Land Management Plan, along with a Draft Environmental Impact Statement. The Team developed a computer model of the Forest to help in assessing the effects of implementing each alternative.

*DON CULVER Interdisciplinary Planning Team Leader - A.A.S. Forestry, Paul Smith's College, 1952; B.S. Forest Management, University of Maine, 1957 - 34 years experience with USDA Forest Service. (Retired)

ROBERTA B. ESTES Geographer, Cartographic Technician - A.A.S. Forestry Technology, Green River Community College, 1983; B.A. Geography, University of Washington, 1990 - 12 years experience with USDA Forest Service.

CHRISTOPHER S. HANSEN Economist - B.A. Political Science, University of Colorado, 1968; M.A. Political Science/Economics, University of Colorado, 1969; PhD. Natural Resources/Economics, University of Michigan, 1977 - 13 years experience with USDA Forest Service.

PAULA JAMES Cartographic Technician - Attended Oregon Institute of Technology - 18 years experience with USDA Forest Service.

JAMIA MURRAY	Social Scientist, Writer-Editor - B.A. Political Science, University of Washington, 1976 - 15 years experience with USDA Forest Service.
DAVID REDMAN	Geographer, Recreation Planner - B.A. Geography, University of Washington, 1970; graduate study in Forestry and Geography, University of Washington, 1973 - 17 years experience with USDA Forest Service, 4 years private business.
MICHAEL T. WILSON	Forester, Resource Planning Specialist - B.S. Forest Management, University of Wisconsin, Stevens Point, 1974 - 4 years experience with USDA Bureau of Indian Affairs, 12 years experience with USDA Forest Service.
FRANK VELLA	Operations Research Analyst - B.S. Forest and Range Management, Colorado State University, 1982; M.S. Economics, Colorado State University, 1986 - 6 years experience with USDA Forest Service.
WILLIAM WAGSTAFF	Computer Analyst - B.A. Psychology, Pennsylvania State University, 1970; B.S. Forest Management, University of Washington, 1980 - 10 years experience with USDA Forest Service.
CHERI ZIEBART	Visual Information Specialist - Attended Montana State University, 1968-71 Graphic Design; Art Instructor and Substitute Teacher, Baker Mont Public School System - 4 years, 15 years experience with USDA Forest Service.

Past Planning Team Members

*PAUL FRANKENSTEIN	Recreation and Wilderness Specialist - B.S. Forest Management, University Michigan, 1949 - 33 years experience with USDA Forest Service. (Retired)
*DEBORAH GAY	Wildlife Biologist - B.S. Wildlife Management, Humboldt State University, 1976 - 8 years experience with USDA Forest Service, 2 years Plant Protection Service, 1/2 year National Park Service.
RICHARD KANG	Computer Programmer, Analyst - B.S. Forest Planning, University of Washington, 1980; graduate study in Public Administration and Forest Planning, University of Washington, 1982 - 10 years experience with USDA Forest Service.
*JAMES SCHMIDT	Economist - B.S. Economics, University of Santa Clara, 1972; M.F. Forest Management, Oregon State University, 1977; graduate study in Resource Economics, University of California, Riverside, 1973-74 - 13 years experience with USDA Forest Service.
*ROCKY SPENCER	Wildlife Biologist - A.A. Forest Science, Lower Columbia College, 1974; B.S. Wildlife Science/Ecology, Western Washington University, 1978 - 1 1/2 years experience with USDA Forest Service, 8 years experience with Washington Department of Game.

*DEWEY TATE — Data Manager - A.A. Forest Management, Wenatchee Community College, 1972; B.S. Forest Management, University Washington, 1976 - 17 years experience with USDA Forest Service.

*ROBERT E. TAYLOR — Forester, Resource Planner - B.S. Forest Management, University of Idaho, 1950 - 36 years experience with USDA Service. (Retired)

ID Team, Providing Substantial Contributions

The primary role of this group was development and analysis of inventory data, development of alternatives, analysis of effects, and contribution to preparation of the documents.

*JAMES BARTELME — Forester, Timber Budgeting and Analysis, W.O. - B.S. Forest Management, Washington State University, 1970 - 20 years experience with USDA Forest Service.

LEE BOECKSTIEGEL — Silviculturist - B.A. Forestry, University of Missouri, 1955; M.A. Forest Resources, University of Idaho, 1982 - 35 years with USDA Forest Service.

JAMES BRAIN — Assistant Fire Staff Officer - B.S. Forest Management, University of Washington, 1963 - 27 years experience with USDA Forest Service.

*WILLIAM BUTLER — Darrington District Ranger - B.S. Forestry, University of California, 1959 - 28 years experience with USDA Forest Service. (Retired)

LARRY DONOVAN — Resource Assistant - B.S. Forest Management, University of Minnesota, 1972 - 17 years experience wit the USDA Forest Service.

JAMES DOYLE — Fisheries Biologist - A.A.S. Professional Forestry, Paul Smith's College, 1965; B.S. Wildlife Management, Utah State University, 1967, graduate study Fisheries/related aquatic sciences American University and University of Washington - 3 years Research Zoologist, Defense Nuclear Agency, 14 years experience with USDA Forest Service.

GERALD E. HAZEN — Logging System Specialist, Timber Sale Planner - B.S. Forest Management, University of Montana, 1962 - 29 years of experience with USDA Forest Service.

CAROLYN HOLBROOK — Landscape Architect - B.L.A. Virginia Polytechnic Institute and State Unversity, 1976 - 13 years experience with USDA Service, 8 months USDI Bureau of Land Management.

SANDRA KNIGHT — Wildlife Biologist - B.A. Psychology, Washington University, St. Louis, Missouri, 1972; M.S., Wildlife Biology, Utah State University, 1978 - 11 years of experience with USDA Forest Service, 4 years experience wildlife research, Utah State University and USDI Fish and Wildlife Service.

GEORGE LARSEN	Civil Engineer - B.S. Civil Engineering, University of Washington, 1961; M.S. Civl Engineering, University of Washington, 1974; Professional Engineer Registered in Washington since 1965 - 26 yrs experience USDA Forest Service.
*DAN MESCHTER	Mining Engineer - B.A. Geology, Darmouth College, 1950; graduate study Geology, Washington University, Missouri - 11 years experience with USDA Forest Service, 20 years experience with U.S. Geological Survey, Atomic Energy Commission, Bureau of Land Management, and Private Industry. (Retired)
JAMES MCDONALD	Archaeologist - B.A. Archaeology, Yale University, 1973; M.A. Archaeological Resource Management, University of Arizona, 1975 - 13 years experience with USDA Forest Service.
*MADONNA MOSS	Archaeologist - B.A. Anthropolgy, William and Mary, 1976; M.A. Anthropolgy, University of California at Santa Barbara, 1982; PhD. Anthropology, University of California at Santa Barbara, 1989 - 7 years experience with USDA Forest Service.
*SID NERDAHL	Engineering Staff Officer - B.S. Agricultural Engineering, North Dakota State University, 1959 - 27 years experience with USDA Forest Service. (Retired)
DALE POTTER	Recreation Planner - Graduate, New York State Ranger School, 1962; B.S. Forest Management, University of Idaho, 1968; M.S. Outdoor Recreation, University of Washington, 1970; PhD. Candidate Outdoor Recreation, Wildlife Management, and Research Methods, University of Washington, 1974 - 26 years experience with USDA Forest Service.
JONI SASICH	Forester, Special Uses and Minerals - B.S. Soil Science, Montana State University, 1981 - 10 years of experience with the USDA Forest Service, 2 years experience as a consultant with the Montana Department of Natural Resources.
PATRICIA SERAFINI	Assistant Lands and Minerals Staff Officer - B.S. Forest Resources, University of Washington, 1982 - 10 years experience with the USDA Forest Service.
JOHN SIMMONS	Geologist,Area Mining Engineer - B.S. Geology, Western Washington State University, 1973; graduate study Geology Western Washington State University, 1974; Additional study Geology and Mining at the Colorado School of Mines, Mackay School of Mines, and University of Nevada, Reno - 7 years experience USDA Forest Service, 6 years experience with Bureau of Land Management.
*BERNARD A. SMITH	Mt. Baker District Ranger - B.S. Biological Sciences, California Polytechnic, 1967; M.S. Forestry, Utah State University, 1969 - 16 years experience USDA Forest Service.

ROBERT SNYDER	Soils Scientist - B.S. Soil Science, Washington State University, 1964 - 26 years experience with USDA Forest Service.
KEN WHITE	Trails, Winter Sports Specialist - Attended Oregon State University, Forest Management - 33 years exerience with USDA Forest Service.
*ALAN WOLFSON	Marketing Specialist - A.A. Political Science, Kendall College, 1967; B.S. Forest Management, Utah State University, 1970; M.F. Forest Ecology, Oregon State University, 1971; Graduate, Washington Agriculture and Forestry Education Foundation Rural Leadership Program, 1984 - 16 years with USDA Forest Service.

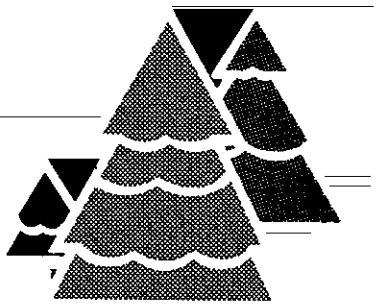
Glossary



Abbreviations Used In The Documents

AASQ - Average Allowable Sale Quantity

AMS - Analysis of the Management Situation

AQRV - Air Quality Related Value

ASQ - Annual Allowable Sale Quantity

BD - Brush Disposal

BLM - Bureau of Land Management

BMP - Best Management Practices

BSS - Base Sale Schedule

CEQ - Council on Environmental Quality

CF - Cubic Foot

CFL - Commercial Forest Land

CFR - Code of Federal Regulations

CMAI - Culmination of Mean Annual Increment

DBH - Diameter at Breast Height

DEIS - Draft Environmental Impact Statement

DNR - Department of Natural Resources, Washington State

DOE - Department of Ecology, Washington State

EIS - Environmental Impact Statement

EPA - Environmental Protection Agency

EVC - Existing Visual Condition

FEIS - Final Environmental Impact Statement

FERC - Federal Energy Regulatory Commission

FS - Forest Service

FSH - Forest Service Handbook

FSM - Forest Service Manual

FVC - Future Visual Condition

FWS - Fish and Wildlife Service, U.S. Department of the Interior

ICO - Issues, Concerns, Opportunities

ICOR - Interagency Committee for Outdoor Recreation, Washington State

IDT - Interdisciplinary Planning Team

KV - Knutsen-Vandenberg Fund

LAC - Limits of Acceptable Change

LTSYC - Long-Term Sustained Yield Capacity

MAI - Mean Annual Increment

MBNRA - Mt. Baker National Recreation Area

MBS - Mt. Baker-Snoqualmie National Forest

MIS - Management Indicator Species

MBF - Thousand Board Feet

MMBF - Million Board Feet

MCF - Thousand Cubic Feet

MMCF - Million Cubic Feet

MR - Management Requirement

MSF - Mt. Baker-Snoqualmie National Forest

NDY - Non Declining Yield

NEPA - National Environmental Policy Act

NF - National Forest

NFMA - National Forest Management Act

NFS - National Forest System

NPB - Net Public Benefit

PAOT - Persons-At-One-Time

PSD - Prevention of Significant Deterioration

OFM - Office of Financial Management, Washington State

ORV - Off-Road Vehicle

PCT - Precommercial Thin

PNV - Present Net Value

PNW - Pacific Northwest Region, USDA Forest Service

PNW - Present Net Worth

RARE II - Roadless Area Review and Evaluation

RIM - Recreation Information Management

RM - Roaded Modified

RN - Roaded Natural

RNA - Research Natural Area

ROS - Recreation Opportunity Spectrum

RPA - Forest and Rangeland Renewable Resources Planning Act

RVD - Recreation Visitor Day

SCORP - State Comprehensive Outdoor Recreation Plan

SEIS - Draft Supplemental to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide - Spotted Owl Guidelines, 1986

SMU - Streamside Management Unit

SOHA - Spotted Owl Habitat Area

SPM - Semi-Primitive Motorized

SPNM - Semi-Primitive Nonmotorized

TSPQ - Timber Sale Program Quantity

TRI - Total Resource Inventory

TSE - Timber Stand Examination

TSI - Timber Stand Improvement

USDA - United States Department of Agriculture

USDI - United States Department of Interior

USFWS - United States Fish and Wildlife Service

VAC - Visual Absorbtion Capacity

VQL - Visual Quality Level

VQO - Visual Quality Objective

WFUD - Wildlife Fish User Day

WMU - Wetland Management Unit

WROS - Wilderness Recreation Opportunity Spectrum

Acquired Lands - Lands added to the National Forest system by purchase, transfer, or donation under authority of the Weeks Law or related acts. Also, lands obtained by the Forest Service by exchange for other acquired lands.

Acre Equivalent - Used to adjust actual acres of habitat improvement or improvement structures to reflect overall habitat benefits derived. It reflects the zone of influence of the habitat improvement for the target species. For example, a single water development for upland game birds has an acre equivalent of 160, whereas a single water structure for big game has a value of 640 because it has a larger zone of influence for the more mobile big game animals.

Acre-foot - A measure of water or sediment volume, equal to the amount which would cover an area of one acre to a depth of one foot (i.e., 43,560 cubic feet or 325,851 gallons).

Activity - Actions, measures, or treatments that are undertaken that directly or indirectly produce, enhance, or maintain forest and rangeland outputs or achieve administrative or environmental quality objectives An activity can generate multiple outputs Forest Service activity definitions, codes, and units of measure are contained in the Management Information Handbook (FSM 1309.11).

Administrative Unit - An area under the administration of one line officer, such as a District Ranger, Forest Supervisor, or Regional Forester.

Air Quality Related Value (AQRV) - Any physical, chemical, or biological component of an ecosystem that can be affected by changes in air pollutant levels. As an example: visual range as measured from a vista may be shortened by the presence of fine particulates in the air. Similarly a threatened or endangered plant species may be sensitive to sulphur dioxide levels.

Airshed - A geographical area that, because of topography, meteorology, and/or climate, shares the same air.

Age Class - An interval, usually 10 to 20 years, into which the age ranges of vegetation are divided for classification or use.

Allocation Zone - Geographic subdivisions of the Forest delineated for the purpose of controlling land allocations, so the FORPLAN Model could select only from a set of spacially feasible land allocations and harvest schedules. In addition, outputs and costs portrayed by zones would be more meaningful than portrayed by Forest-wide analysis areas.

Allowable Sale Quantity (ASQ) - The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the plan This quantity is usually expressed on an annual basis as the "Average Annual Allowable Sale Quantity." For timber resource planning purposes, the allowable sale quantity applies to each decade over the planning horizon and includes only chargeable volume Consistent with the definition of timber production, fuelwood and other non-industrial wood shall not be included in the allowable sale quantity.

Alternative - One of several policies, plans, or projects proposed for decision making.

Amenity - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. Amenity value is typically used in land use planning to describe those resource properties for which market values (or proxy values) are not or cannot be established (such as clean air and water, scenic quality, etc.).

Anadromous Fish - Those species of fish that mature in the sea and migrate into streams to spawn. Salmon, steelhead, and shad are examples.

Analysis Area - A grouping of homogeneous land areas, formed from the land and resource inventory data comprising the data base. Similarities are in terms of common capabilities to produce resources and susceptibility to impacts. Analysis areas need not be contiguous areas of land.

Analysis of the Management Situation (AMS) - A determination of the ability of the planning area to supply goods and services in response to society's demand for those goods and services.

Animal Unit Month (AUM) - The amount of forage required by one mature (1,000 lb) cow or the equivalent for 1 month, based on an average of 26 lbs. of dry forage per day.

Aquatic Ecosystems - Stream channels, lakes, marshes or ponds, and the plant and animal communities they support.

Aquifer - An underground geological formation or structure that contains water in sufficient quantity to supply needs for water development.

Arterial Roads - See "Road, Arterial."

Average Annual Allowable Sale Quantity (AAASQ) - See "Allowable Sale Quantity."

Background - The viable terrain beyond the foreground and middleground where individual trees are not visible, but are blended into the total fabric of the stand. Includes the view beyond 3-5 miles from the observer and as far as the eye can see. (See "Foreground" and "Middleground.")

Basal Area - The area of the cross-section of a tree stem near the base, generally at breast height and inclusive of bark.

Base Sale Schedule (BSS) - A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than the long-term sustained yield capacity. This definition expresses the principle of non-declining flow.

Bedload - The sediment that moves by sliding, rolling, or bounding on or very near the streambed; sediment moved mainly by tractive or gravitational forces or both but at velocities less than the surrounding flow.

Benchmark - 1) The analytical basis from which the alternatives were developed. The use of assessed land capability as a basis from which to estimate the effects of alternative patterns of management on the land 2) Reference points that define the bounds within which feasible management alternatives can be developed. Benchmarks may be defined by resource output or economic measures

Benefit/Cost Ratio - The ratio obtained by dividing the anticipated benefits of a project by its anticipated costs (or realized benefits by realized costs) to obtain a measure of expected (or realized) benefits per unit of cost--a common exercise in cost-benefit analysis which gives a measure of economic efficiency.

Best Management Practices (BMP's) - A practice or combination of practices that is determined by a State (or designated area-wide planning agency) after problem assessment, examination of alternative practices, and appropriate public participation, to be the most effective, practicable (including technological, economic, and institutional considerations) means of preventing or reducing the amount of pollution generated by nonpoint sources to a level compatible with water quality goals (Federal Register, Volume 40, No. 230 dated 11/28/75).

Big Game - Those species of large mammals normally managed for sport hunting. Big Game Summer Range - A range, usually at higher elevation, used by deer and elk during the summer Summer ranges are usually much more extensive than winter ranges.

Big Game Winter Range - A range, usually at lower elevation, used by migratory deer and elk during the winter months; usually more clearly defined and smaller than summer ranges.

Biological Growth Potential - The average net growth attainable in a fully stocked natural forest stand

Biological Potential - The maximum production of a selected organism that can be attained under optimum management.

Biomass - The total quantity at a given time of living organisms of one or more species per unit of space (species biomass), or of all the species in a biotic community.

Board Foot - The amount of timber equivalent to a piece of wood one foot square and one inch thick, being the unit in board foot measure.

Board Foot/Cubic Foot Ratio - A ratio expressing the number of board feet in a cubic foot of timber. Varies with tree species, diameter, height, and form factors.

Broadcast Burn - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard or as a silvicultural treatment, or both.

Browse - Twigs, leaves, and young shoots of trees and shrubs on which animals feed, in particular, those shrubs which are used by big game animals for food.

Brush - A growth of shrubs or small trees, usually of a type undesirable to livestock or timber management.

Brush Disposal (BD) - A term commonly used to refer to disposal of slash. See "Slash," "Broadcast Burn," and "Residue Utilization."

Bureau of Land Management (BLM) - An agency within the Department of the Interior, with land management responsibility for the Public Domain lands.

Canopy - The more-or-less continuous cover of branches and foliage formed collectively by the crown of adjacent trees and other woody growth.

Capability - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at given levels of management intensity Capability depends upon current conditions and site conditions such as climate, slope, landform, soils, and geology, as well as on the application of management practices, such as silviculture or protection from fire, insects, and disease

Capital Investment - An input that increases the value of natural or manmade resources (assets) needed to maintain or increase the flow of outputs in the future Benefits resulting from capital investments are normally recouped in excess of 1 year

Carrying Capacity - 1) The number of organisms of a given species and quality that can survive in, without causing deterioration of, a given ecosystem through the least favorable environmental conditions that occur within a stated interval of time 2) In recreation management, the level of recreational use that a site can provide without deterioration of the quality of the recreation experience of the resource.

Cavity Excavators - The hollow excavated in trees by birds or other natural phenomena; used for roosting and reproduction by many birds and mammals.

Cedar - Areas that have been sources of various cedar products, or are at least identified as significant stands of cedar Cedar is used in everything from smokehouse construction to spirit dancer costumes to basketry and other utilitarian items. Of all forest products it may be the most significant to the Indians of today, although it cannot survive without a total appropriate environment, most of which was used by the Indians in the past

Cemetaries & Archaeological Sites - Villages, camps, and burial areas (not in most instances known to be cemetaries) Other sites are ethnographically and/or historically known cemetaries Some are maintained and still used, others are not

Ceremonial Flora - Locations known to contain certain plants that have ritual or healing properties. Some areas so designated are large and may contain several such plant species, others are small and may possess only a few. Often areas containing specific flora are considered as ceremonially, ritually, and/or religiously powerful.

Channel or Stream Scour - Erosion of the channel bottom caused by high flows of water, loss of channel stability, or debris torrents.

Chargeable Volume - All volume that is included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on Regional utilization standards.

CHUNK Study - An economic-efficiency study of the developed campgrounds on the Forest, completed in 1984. Refer to Chapter III, DEIS, Recreation.

Class I Stream - Perennial or intermittent streams (or segments thereof) that have one or more of the following characteristics: provide a direct source of water for domestic use; are used by large numbers of fish for spawning, rearing, and/or migration; and/or are major contributors to the quantity of water in a Class I stream. See "SMU."

Class II Stream - Perennial or intermittent streams (or segments thereof) that have one or more of the following characteristics: are used by moderate though significant numbers of fish for spawning, rearing and/or migration, and/or flow enough water to be moderate or not clearly identifiable contributors to the quantity of water in a Class I stream, or are major contributors to a Class II stream. See "SMU."

Class III Stream - All other perennial streams or segments thereof not meeting higher class criteria. See "SMU."

Deeply Incised - A stream channel with perennial stream flow, steep deep streambanks, and unstable sideslopes that can generate slumps and slides resulting in debris torrents. Class III channels incised more than 10 feet and having one or more unstable soil types qualifies as a deeply incised Class III stream. On this Forest, 70% of the Class III streams are deeply incised; they represent 66% of the total Forest stream miles.

Lightly Incised - Class III channels incised less than 10 feet, and in some cases, possessing unstable soil types, qualifies as a lightly incised Class III stream. For this Forest, 30% of the Class III streams are lightly incised; this represents 27% of the total Forest stream miles.

Class IV Stream - All other intermittent streams not meeting higher class criteria. See "SMU."

Clearcutting - A silvicultural system in which all trees on an area are harvested in one cut for the purpose of regenerating a new, even-aged stand. The area harvested may be a patch, strip, or stand large enough to be mapped or recorded as a separate class in planning for sustained yield

Climax - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

Climax Species - Those species that dominate a climax stand in either numbers per unit area or biomass.

Code of Federal Regulations (CFR) - A codification of the general and permanent rules published in the Federal Register by the Executive departments and agencies of the Federal Government.

Collector Roads - See "Road, Collector."

Commercial Forest Land (CFL) - See "Timber Resource Land Suitability Classification."

Commercial Thinning - Any type of tree thinning that produces merchantable material at least equal in value to the direct costs of harvesting.

Commodity - A transportable resource product with commercial value; all resource products that are articles of commerce.

Compaction - The packing together of soil particles by forces exerted at the soil surface, resulting in increased soil density.

Concern - A point, matter, or question raised by management and/or the public that must be addressed in the planning process.

Concession - A commercial public service enterprise which operates on National Forest land under a "Special Use Permit" for the purpose of providing goods and services to the public.

Condition Class - A descriptive grouping into 10 classes of the existing forest vegetation based on age, tree size, maturity, species mix, and accessibility by road. Condition class is an important component of the Forest Model structure. See "Forest Model" and Appendix B.

Congressionally Classified and Designated Areas - Areas that require congressional enactment for their establishment, such as National Wilderness Areas, National Wild and Scenic Rivers, and National Recreation Areas.

Connecting Habitat - Areas which serve as travel corridors or habitat connections, provide for the dispersal and interaction of indicator species, and avoid the isolation of habitat into geographic islands. These areas provide species access across and/or along drainages and elevation gradients (ridgeline to valley floor). Connecting habitat can be provided in several ways:

1. Utilize natural land forms, such as riparian areas along creek drainages, or the areas adjacent to avalanche chutes, where possible.

2. Maintain areas in blocks of land that generally are one or more logical harvest units in size. This will provide the option of rotating the designation of connecting habitat to adjacent areas, as the adjacent harvested areas mature or develop the desired habitat structure.

Constraint - A confinement or restriction on the range of permissible choices.

Consumptive Use - A use of resources that permanently reduces the supply, such as mining. (See also Non-consumptive Use.)

Core Area - (As related to a Spotted Owl Habitat Area) An area encompassing at least 300 contiguous acres of old growth suitable for nesting and reproduction. Centering on a reproductive site or a site of concentrated pair use where such information is available. See "Spotted Owl Habitat Area "

Corridor - A linear strip of land identified for the present or future location of transportation or utility rights-of-way within its boundaries.

Costs:

1. **Direct cost** - a cost that directly contributes to the production of the primary outputs of an activity, project, or program.

2. **Economic cost** - total fixed and variable costs for inputs, including costs incurred by other public parties and, if appropriate, opportunity costs and cost savings.

3. **Fixed cost** - a cost that is committed for the time horizon of planning or the decision being considered. Fixed costs include fixed ownership requirements, fixed protection, short-term maintenance, and long-term planning and inventory costs.

4. **Investment cost** - a cost of creating or enhancing capital assets, *including costs of administrative or common-use transport facilities and* resource management investments.

5. **Joint cost** - a cost contributing to the production of more than one type of output.

6. **Non-Forest Service cost** - a cost of investment and operating activities *paid by cooperators or other non-Forest Service agencies which are part* of Forest Service management programs, or which contribute to the outputs included in the analysis.

7. **Opportunity cost** - the value of a resource's foregone net benefits in its most economically efficient alternative use.

8. ***Unit cost or cost per unit*** - *total cost of production divided by the* number of units produced.

Cost Efficiency - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values, but are achieved at specified levels in the least costly manner. Cost *efficiency is usually measured using present net value, although use of* benefit-cost ratios and rates-of-return may be appropriate.

Cost Share - A term referring to investment sharing provided under Public Law 88-657 (16 U.S.C 535) whereby forest development roads may be financed cooperatively with public or private agencies or persons. Investment sharing may be accomplished in several ways. Road right-of-way construction and use agreements (referred to as cost share agreements) are a common method used in this Forest where there are large areas of intermingled landownership.

Council on Environmental Quality (CEQ) - An advisory council to the President established by the National Environmental Policy Act of 1969. Reviews federal programs for their effect on the environment, conducts environmental studies, and advises the President on environmental matters. (Abstracted from NEPA.)

Cover/forage Ratio - The mixture of cover and forage areas on a unit of land, expressed as a ratio.

Created Openings - Openings in the forest created by the silvicultural practices of: shelterwood regeneration cutting at the final harvest; clearcutting; seed tree cutting; or group selection cutting.

Crop Tree - Any tree forming or selected to form, a component of the final crop. Generally a tree selected in a young stand or plantation for carrying through to maturity.

Crown Height - In a standing tree, the vertical distance from ground level to the base of the crown, measured either to the lowest live branch whorl, or to the lowest live branch (excluding shoots arising spontaneously from buds on the stem of a woody plant), or to a point halfway in-between.

Cubic Foot - A unit of quantity for lumber or timber equal to a cube 1x1x1 foot.

Cull Material - Timber which does not meet the specified utilization standards (usually in a timber sale contract) for size and percent of sound wood. See "Utilization Standards."

Culmination of Mean Annual Increment (CMAI) - The age at which the average annual growth is greatest for a stand of trees. Mean annual increment is expressed in cubic feet measure and is based on expected growth according to the management intensities and utilization standards assumed in accordance with 36 CFR 219.16(a)(2)(i) and (ii) Culmination of mean annual increment includes regeneration harvest (cutting) yields and any additional yields from planned intermediate harvests (cuttings).

Cultural Resource - The physical evidence of our Nation's heritage. Included are: archaeological sites; historic buildings, structures, and districts; and localities with social significance to the human community. In the plan, they are classified as archaeological and historical properties, and American Indian religious and cultural use areas

Cumulative Effects or Impacts - The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. (40 CFR 1508.7 - these regulations use effects and impacts synonymously.)

DBH (d.b.h.) - Diameter at breast height, measured at 4 feet 6 inches from the ground.

Debris Slide - A shallow landslide of soil, rock, and organic material that occurs on steep slopes.

Debris Torrent - A large debris slide that is charged with water and confined to a steep stream channel. Debris torrents may travel several thousand feet

Decision Space - Decision space defines the outer limits past which it is not physically, biologically, or economically possible to produce a feasible combination of Forest goals and services, and land allocations.

Demand - The amount of an output that users are willing to take at a specified price, time period, and condition of sale

Departure - A sale schedule that deviates from the principle of non-declining flow by exhibiting a planned decrease in the sale schedule at any time during the planning horizon. A departure can be characterized as a temporary increase, usually in the beginning decade(s) of the planning horizon, over the base sale schedule that would otherwise be established, without impairing the future attainment of the long-term sustained yield capacity.

Developed Recreation - Recreation that requires facilities that, in turn, result in concentrated use of an area. Examples of recreation areas are campgrounds and ski areas, facilities in these areas might include roads, parking lots, picnic tables, toilets, drinking water, ski lifts, and buildings. See "Recreation Development Scale (Level)."

Dispersed Recreation - A general term referring to recreation use outside a developed recreation site, such as scenic driving, hiking, fishing, cross-country skiing, horseback riding, snow mobiling, hunting, backpacking, and recreation in primitive environments.

Diversity - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. See also "Edge," "Horizontal Diversity," and "Vertical Diversity."

Douglas-fir Type - An association of tree species in which Douglas-fir is recognized as one of the principal seral species.

Draft Environmental Impact Statement (DEIS) - The draft statement of environmental effects which is required for major federal actions under Section 102 of the National Environmental Policy Act, and released to the public and other agencies for comment and review.

Duff - Organic matter in various stages of decomposition on the floor of the forest.

Early Forest Succession - The early stage or condition of a plant community that occurs during its development from bare ground to climax.

Economic Efficiency - The usefulness of inputs (costs) to produce outputs (benefits) and effects when all costs and benefits that can be identified and valued are included in the computations. Economic efficiency is usually measured using present net value, though use of benefit-cost ratios and rates-of-return may sometimes be appropriate.

Economic Impacts:

1. **Direct economic impact** - effects caused directly by forest product harvest or processing or by forest uses.

2. ***Indirect economic impact*** - *effects that occur when supporting* industries sell goods or services to directly affected industries.

3. **Induced economic impact** - effects that occur when employees or owners of directly or indirectly affected industries spend their income within the economy.

Ecosystem - An interacting system of organisms considered together with their environment; for example, marsh, watershed, and lake ecosystems.

Edge - An interfacial area where plant communities meet or where successional stages or vegetative conditions within plant communities come together. See also "Diversity," "Edge Contrast" and "Horizontal Diversity."

Edge Contrast - A qualitative measure of the difference in structure of two adjacent vegetated areas; for example, "low," "medium," or "high" edge contrast.

Effects - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and occur later in time and/or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air, water, and/or other natural systems, including ecosystems.

> Effects and impacts as used in this statement/plan are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial (40 CFR 1508.8).

Electronic Sites - Areas designated for the operation of equipment which transmits and receives radio signals (excluding television aerials and antennas) for individual pickup of programming, and passive reflectors

Endangered Species - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified by the Secretary of the Interior as endangered in accordance with the Endangered Species Act of 1973, as amended.

Ending Inventory Constraint - The standing volume left in the inventory at the end of the planning horizon. The constraint insures that there is enough standing inventory at the end of the planning horizon to perpetuate long-term sustained yield capacity harvest levels on a nondeclining flow basis.

Environmental Analysis - A process associated with the preparation of an environmental assessment or environmental impact statement. An analysis of alternative actions and their predictable short- and long-term environmental effects, including physical, biological, social, and economic.

Environmental Assessment - A concise public document, providing sufficient evidence and analysis for determining whether to prepare an environmental impact statement or a finding of no significant impact.

Environmental Impact Statement (EIS) - A statement of the environmental effects of a proposed action and alternatives to it Required for major federal actions under Section 102 of the National Environmental Policy Act (NEPA), and released to the public and other agencies for comment and review. A formal document that must follow the requirements of NEPA, the Council on Environmental Quality (CEQ) guidelines, and directives of the agency responsible for the project proposal. See DEIS and FEIS

Environmental Protection Agency (EPA) - An agency of the Executive Branch of the Federal Government which has the responsibility for environmental matters of national concern.

Erosion - 1) The wearing away of the land surface by running water, wind, ice, or other geologic agents, including such processes as gravitation creep; or 2) detachment and movement of soil or rock fragments by water, wind, ice, or gravity.

Even-Aged Management - The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together. Managed even-aged forests are characterized by a distribution of stands of varying ages (tree sizes) throughout the forest area. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands. (36 CFR 219.3)

Even-aged Stands - Stands in which all trees are of about the same age. (A spread of 10 to 20 years is generally considered one age class.) Cutting methods producing even-aged stands are clearcut, shelterwood, or seed tree systems.

Existing Visual Condition (EVC) - The "Existing Visual Condition" of the Forest was prepared in 1979. See "Visual Condition."

Final Environmental Impact Statement (FEIS) - The final version of the statement of environmental effects required for major federal actions under section 102 of the National Environmental Policy Act. A revision of the draft environmental impact statement to include public and agency responses to the draft.

Final Harvest - Synonomous with "regeneration cutting" (harvest) in the clearcutting silvicultural system.

Fisheries Habitats - Streams, lakes, and reservoirs that support fish populations.

Floodplain - The lowland and relatively flat areas adjoining inland and coastal waters including, at a minimum, those areas subject to a 1-percent or greater chance of flooding in any given year (100-year recurrence).

Flood Proof - Using special measures during road construction to insure that flood occurrences will not cause road damage.

Forage - All browse and nonwoody plants that are available to livestock or game animals and used for grazing or harvested for feeding.

Forb - Any herb other than grass.

Foreground - A term used in visual management to describe the portions of a view between the observer and up to 1/4 to 1/2 mile distant. The stand of trees immediately adjacent to a high-value scenic area, recreation facility, or forest highway. See "Background," "Middleground."

Forest or Forest Land - 1) Forest is used in the text as a proper noun to substitute for Mt. Baker-Snoqualmie National Forest. 2) See "Timber Resource Land Suitability Classification."

Forest Model - An idealized (simplified) representation of the real life Forest system, developed from a set of simplifying assumptions. The "Forest Model" serves as a format to structure Forest management resource data, i.e. yields (activities and outputs) over time, acres, and management constraints. The "Forest Model" developed by the interdisciplinary team was incorporated into the computer program model FORPLAN for use in this planning effort. See "FORPLAN." See Appendix B for more detail.

Forest Service Handbook (FSH) - For Forest Service use, directives that provide detailed instructions on how to proceed with a specialized phase of a program or activity

Forest Service Manual (FSM) - A system of manuals which provides direction for Forest Service activities.

Forest Types - A classification of forest land based upon the tree species presently forming a plurality of basal area stocking in live trees

FORPLAN - Acronym for Forest Planning Model. A linear programming system used for developing and analyzing forest planning activities. Can be used to simulate management practices while at the same time optimizing for any given desired objective. As a manageable representation of reality, it can be used to manipulate information and look at alternative approaches to management, calculating tradeoffs and opportunity costs. See "Forest Model." See Appendix B for more detail.

Fuel Management - The practice of planning and executing the treatment or control of living or dead vegetative material in accordance with fire management direction

Fuel Treatment - The rearrangement or disposal of natural or activity fuels (generated by management activity, such as slash left from logging) to reduce fire hazard. Fuels are defined as both living and dead vegetative materials consumable by fire.

Fuels - Combustible wildland vegetative materials. While usually applied to above ground living and dead surface vegetation, this definition also includes roots and organic soils such as peat

Game Species - Any species of wildlife or fish for which seasons and bag limits have been prescribed and which are normally harvested by hunters, trappers, and fishermen under state or federal laws, codes, and regulations.

Genetic Integrity - Refers to a normal, healthy genetic pool within a biological population to provide for long-term maintenance and survival of the species. Of specific concern in management direction is the prevention of loss of genetic variance and the avoidance of inbreeding. See the Draft SEIS, Spotted Owl Guidelines for more detail.

Genetic Seedlings - Tree seedlings from a genetically superior seed source. The seeds are collected from trees displaying exceptional form and raised in nurseries before outplanting. The seedlings usually have faster growth rates than naturally regenerated seedlings.

Geothermal - Of or pertaining to the internal heat of the earth.

Glaciolacustrine - Soil materials transported by glaciers and deposited by glacial meltwater in glacier lakes.

Goal - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms with no specific completion date. Goal statements form the principal basis from which objectives are developed.

Goods:

1. **Nonmarket good** - an output that is not normally exchanged for money in a market. Usually no market has evolved because ownership of the good is not clear, exclusive use is not possible under current laws, or it is not possible to consistently define good.

2. **Public good** - an output for which it is impractical to impose a charge, either because it must be supplied to all if it is supplied to one or *because the costs of collection and control exceed likely revenue.*

Goods and Services - The various outputs, including on-site uses, produced from forest and rangeland resources.

Grass/forb - An early forest successional stage where grasses and forbs are the dominate vegetation.

Group Selection Cutting - Removal of tree groups ranging in size from a fraction of an acre up to about 2 acres. Area cut is smaller than the minimum feasible under even-aged management for a single stand.

Growing Season - That part of the year when temperature and moisture are favorable for vegetation growth.

Growing Stock Trees - Live trees, meeting specified standards of quality or vigor, that are included in growth and yield projections to arrive at the allowable sale quantity.

Guideline - An indication or outline of policy or conduct that is not a mandatory requirement (as opposed to a standard, which is mandatory).

Habitat - The place where a plant or animal naturally or normally lives and grows.

Habitat Capability - The estimated ability of an area, given existing or predicted habitat conditions, to support a wildlife, fish or plant population. Measured in tems of potential population numbers.

Habitat Diversity - The distribution and abundance of different plant and animal communities and species with a specific area.

Hardwood - A broad-leaved flowering tree.

Harvest Cutting Method - A combination of interrelated actions whereby forests are tended, harvested, and replaced. The combination of management practices used to manipulate the vegetation results in forests of distinctive form and character. Harvest cutting methods are classified as even-aged and uneven-aged. See "Silvicultural System "

Harvest Dispersion (factor) - The dispersion of cutting units over the land base in order to meet clearcut size limitations, or other resource constraints. An example of a harvest dispersion constraint is. no more than 25 percent of an analysis area may be harvested in one decade

Headwaters - The upper tributaries of a river.

Herbaceous - An adjective describing seed-producing plants that do not develop persistent woody tissue, but die down to ground level at the end of the growing season.

Hiding Cover - Any vegetation used by wildlife for security or to escape from danger. For example, hiding cover is capable of hiding 90 percent of an adult deer or elk from the view of a human at a distance of 200 feet or less.

Historic Site - Site associated with the history, tradition, or cultural heritage of national, state, or local interest, and of enough significance to merit preservation or restoration.

Horizontal Diversity - The distribution and abundance of plant and animal communities or successional stages across an area of land; the greater the number of communities, the higher the degree of horizontal diversity (or richness). This concept is similar but not identical to "even-aged management." Application of even-aged management, for example, can be designed to accomplish horizontal diversity objectives. See also "Vertical Diversity."

Hydrology - The scientific study of the properties, distribution, and effects of water in the atmosphere, on the earth's surface, and in soil and rocks.

ID Team - See Interdisciplinary Team

Impacts - See Effects.

IMPLAN - A computer-based system used by the Forest Service for constructing nonsurvey input/output models to measure economic input. The system includes a data base for all countries in the U.S. and a set of computer programs to retrieve data and perform the computational tasks for input/output analysis.

Indicator Species - Species identified in a planning process that are used to monitor the effects of planned management activities on viable populations of wildlife and fish including those that are socially or economically important. See Management Indicator Species.

Instream Flows - A prescribed level (or levels) of streamflow, usually expressed as a stipulation in a permit authorizing a dam or water diversion, for the purpose of meeting National Forest System management objectives.

Integrated Pest Management - A process for selecting strategies to regulate forest pests, in which all aspects of a pest-host system are studied and weighed. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable. (36 CFR 219.3)

Intensive Forest Management - A high investment level of timber management that envisions initial harvest, regeneration with genetically improved stock, control of competing vegetation, fill-in planting, precommercial thinning as needed for stocking control, one or more commercial thinnings, and final harvest.

Interdisciplinary Approach - Using individuals representing two or more areas of knowledge and skills focusing on the same tasks, problem, or subject.

Interdisciplinary Team (ID Team) - A group of individuals with different training assembled to solve a problem or perform a task The team is assembled out of recognition that no one scientific discipline is sufficiently broad to adequately assess the situation.

Intermediate Cutting - Any removal of trees from a regular crop or stand between the time of its formation and the harvest cutting (final harvest). Generally includes cleaning, thinning, liberation, and improvement cuttings, increment fellings, and sometimes even salvage and sanitation cutting.

Intermingled Ownerships - Lands within the National Forest boundaries or surrounded by National Forest lands owned by private interests or other government agencies. Because of early land grants, these lands frequently are in a checkerboard ownership pattern.

Intermittent Stream - A stream that runs water in most months, but does not run water during the dry season during most years.

Irretrievable - Applies to losses of production, harvest, or use of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

Irreversible - Applies primarily to the use of non-renewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods. Irreversible also includes loss of future options.

Issue - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process.

J-8 - A map code used on this Forest to designate unsuitable forest land not managed for timber production because there is no reasonable assurance that these lands can be adequately restocked within 5 years after harvest. This is based on existing technology and knowledge as reflected in current research and experience. See "Timber Resource Land Suitability Classification, 3.(d)."

Knutsen-Vandenberg Fund (KV) - Authorization to withhold a portion of timber sale receipt funds for reforestation of harvested areas, rehabilitation of streams and habitat affected by timber sales, etc.

Lacustrine - Refers to material deposited in lake water and later exposed either by lowering of the water level or by the elevation of the land.

Land Allocation - The assignment of a particular land area(s) to a specific "Management Area."

Landing - Any place where round timber is assembled for further transport, commonly with a change of method.

Landownership Classification Groups - All National Forest land and land in other ownerships within the Forest boundary will be classified in one of five landownership classification groups. This classification system identifies opportunities to acquire, retain, exchange, or relinquish lands to facilitate administration of the Forest (FSM 1920.42, 1982 or as revised).

Group I - Lands where Congress has either directly or indirectly instructed the Forest Service to retain ownership and acquire non-Federal lands for a designated purpose.

Group II - Retain National Forest ownership and acquire private land as the opportunity and/or need occurs.

Group III - Lands are available for land adjustment and usually will provide most of the land considered in exchange projects.

Group IV - Lands normally made available to acquire private lands in Groups I, II, or III.

Group V - More intensive study and planning are necessary before landownership decisions are made.

Lands Not Appropriate for Timber Production - Includes lands that: 1) are proposed for resource uses that preclude timber production, such as Wilderness; 2) have other management objectives that limit timber production to the point where management requirements set forth in CFR 219.27 cannot be met; or 3) or are not cost efficient over the planning horzon in meeting forest objectives including timber production.

Lands Not Suited (Unsuitable) for Timber Production - Includes lands that: 1) are not forest land as defined in CFR 219 3; 2) are likely, given current technology, to suffer irreversible resource damage to soils productivity, or watershed condition; 3) cannot be adequately restocked as provided in 36 CFR 219.27; or, 4) have been withdrawn from timber production by an Act of Congress, the Secretary of Agriculture, or the Chief of the Forest Service. In addition, Forest lands other than those that have been identified as not suited for timber production shall be reviewed and assessed prior to formulation of alternatives to determine the costs and benefits of a range of management intensities for timber production.

Legendary - Locations that may have, or may have had, spiritual significance. They appear also to be areas which are significant to the cosmology of the Indian groups in the project area. They are significant in mythology having to do with the origin and development of the area and of the people of that area.

Limits of Acceptable Change (LAC) - Maximum limit of human-caused change allowed in wilderness. Each WROS Class has a set of limits which presupposes that certain areas of wilderness (trails) will be allowed to receive higher levels of use than other areas (trailless), and thus will receive more change or resource impact. LAC's are not a management objective, but a maximum limit. See "Wilderness Recreation Opportunity Spectrum."

Local Roads - See "Road, Local."

Logging Systems - See "Yarding."

Tractor - Use of tracked or rubber-tired vehicle to skid logs to a central loading point. This method is typically used on dry, gently sloping ground; it is infrequently used on this Forest.

Highlead - A cable system operated from a tower or spar-tree, which drags logs to a central loading site. One end of a log may be lifted off the ground for short distances. Used most often in moderately steep terrain over relatively short distances.

Skyline - The log yarding cable is attached between a tower or spar-tree and an elevated point in the distance. Logs are transported partially or completely suspended above the ground with a movable carriage on the cable. Used in steep or unstable terrain with minimal impacts on the land, this method can reach for long distances.

Helicopter - Use of helicopter to lift logs from a logging site to a nearby central loading point. Most economical on relatively remote and difficult to reach sites. Avoids road building where roading is inappropriate because of steep terrain, unstable soils, visual consideration, etc.

Long-Term Sustained-Yield Capacity (LTSYC) - *The highest uniform wood yield* from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives.

Macropore Space - Space in soil composed of larger pore spaces. See "Pore space," "Porosity," and "Soil."

Management Area - *An area or non-contiguous areas of the Forest assigned to a* specific management strategy (the management strategy then becomes the management prescription for the area(s)).

Management Concern - An issue, problem, or condition which constrains the range of management practices identified by the Forest Service in the planning process.

Management Direction - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them.

Management Emphasis - The major resource uses, outputs, and activities emphasized in a management area.

Management Indicator Species (MIS) - A species selected because its welfare is presumed to be an indicator of the welfare of other species using the same habitat. A species whose condition can be used to assess the impacts of management actions on a particular area. See "Indicator Species."

Management Intensity - A management practice or combination of management practices and associated costs designed to obtain different levels of goods and services.

Management Practice - A specific activity, measure, course of action, or treatment.

Management Prescription - Management practices and intensity selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives.

Management Requirement (MR) - Minimum standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, soil and water diversity, to be met in accomplishing National Forest System goals and objectives.

Management Strategy - A specific set of management practices appropriate for application to Forest lands or resources. The management strategy should define the management goals or objectives, resource priorities, and intensities to be considered. See "Management Area" and "Management Prescription."

Marginal Component - The portion of the regulated commercial Forest land on which it is presently not feasible (economically or technologically) to manage for timber crops because of soil constraints, difficulties in establishing tree regeneration or excessive development costs.

Market Resources - Products derived from renewable and nonrenewable resources that have a well-established market value for example, forage, timber, water, and minerals.

Market Value - The unit price of an output normally exchanged in a market after at least one stage of production. Market value is expressed in terms of prices as evidenced by market transactions

Mass Movement - A general term for any of the variety of processes by which large masses of earth material are moved downslope by gravitational forces - either slowly or quickly.

Mass Wasting - All landslide events, the detachment and movement of soil or surface mantle material. Landslides may fall in a single mass or single event, moving downslope to cause debris slides and avalanches, or they may detach and move slowly downslope over a period of years.

Maximum Modification - See "Visual Quality Objectives."

May (or Can) - Verb used in the Management Prescriptions, Proposed Forest Plan. Action is optional.

MBF - One thousand board feet Lumber or timber measurement term.

MCF - One thousand cubic feet. Lumber or timber measurement term.

Mean Annual Increment (MAI) - The total increment up to a given age divided by that age.

Mesotrophic - Habitats, particularly soil and water, of moderate nutrient capacity.

Middleground - The visible terrain beyond the foreground where individual trees are still visible, but do not stand out distinctly from the stand. See "Foreground" and "Background."

Mineral Entry - The filing of a mining claim upon public domain or related land to obtain the right to any minerals it may contain.

Mineral Soil - A soil consisting predominantly of, and having its properties determined predominantly by, mineral matter. It usually contains less than 20% organic matter but may sometimes contain an organic surface layer up to 30 centimeters thick. Mineral soil is the soil where surface erosion of individual soil particles can take place, not the loose unconsolidated organic surface layer.

Mineral Withdrawal - The exclusion of mining locations and mineral development work on areas required for administrative sites by the Forest Service and other areas highly valued by the public.

Minerals -

1. **Common** - mineral deposits which do not possess distinct, special economic value, such as common varieties of sand, stone, gravel, pumice, pumicite and cinders. They may have value for use in trade, manufacture, science, or in the mechanical or ornamental arts.

2. **Leasable** - federally owned minerals which are disposed of under the Mineral Leasing Act of 1920, as amended. These include coal, oil, gas, phosphate, sodium, potassium, oil shale, and in some states sulphur and geothermal steam.

3. **Locatable** - federally owned minerals which can be located and patented under the 1892 Mining Law, as amended. In general, the locatable minerals are those hardrock minerals which are mined and processed for the recovery of metals. They also may include certain nonmetallic minerals and uncommon varieties of mineral materials, such as valuable and distinctive deposits of limestone or silica.

4. **Valuable Deposit** - where minerals have been found and the evidence is of such a character that a person of ordinary prudence would be justified in further expenditure of his labor and means with a reasonable prospect of success in developing a valuable mine.

Minimum Streamflows - A specified level of flow through a channel that must be maintained by the users of streams for biological, physical, or other purposes.

Minimum Viable Population - The low end of the viable population range.

Mining Claim - A portion of the public lands which a miner, for mining purposes, takes and holds in accordance with mining laws.

Mining Claim, Perfection - All steps legally required to give a secured party an interest in subject property have been met. One cannot perfect a mining claim without actual discovery of minerals in place. Perfection occurs when a discovery of a "valuable" mineral deposit has been made within the boundaries of a mining claim which has been located on public lands in conformance with State and Federal statutes. Once the claim has been perfected, the claim has the effect of a grant by the US of the right of present and exclusive possession and the claimant may receive patent. Discovery normally precedes location, but (US v. Carlile 67 I.D 417,420 (1960)) discovery may follow location and give validity to a previously located claim as of the time the discovery was made. When such occurs, the claim has been perfected.

Mining Claim, Validity - Synonymous with perfection when exclusive rights against the government are concerned. For a claimant to establish exclusive rights against the government, the claim must be located on public lands in conformance with State and Federal statutes and a discovery of a valuable mineral deposit must have been made within the boundaries of the claim.

Mitigation - Avoiding or minimizing impacts by limiting the degree or magnitude of the action and its implementation; rectifying the impact by repairing, rehabilitating, or restoring the effected environment; reducing or eliminating the impact by preservation and maintenance operations during the life of the action.

MMBF - Million board feet. Lumber or timber measurement term.

MMCF - Million cubic feet. Lumber or timber measurement term.

Model - See "Forest Model."

Modification - See "Visual Quality Objectives."

Monitoring - A process to collect significant data from defined sources to identify departures or deviations from expected plan outputs.

Multiple Use - The management of all the various renewable surface resources of the National Forest System so that they are utilized in the combination that will best meet the needs of the American people; making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions; that some lands will be used for less than all of the resources; and harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land, with consideration being given to the relative values of the various resources, and not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output.

Municipal Supply Watershed - A watershed that provides water for human consumption, where Forest Service management could have a significant effect upon the quality of water at the intake point, and that provides water used by a community, or any other public water system that regularly serves at least 25 individuals at least 60 days out of the year or that provides at least 15 service connections. In addition to cities, this includes campgrounds, residential developments, and restaurants.

Must (or Shall) - A verb used in the Management Prescriptions, in the Proposed Forest Plan. Action is mandatory.

National Environmental Policy Act (NEPA) of 1969 - An act to declare a National policy which will encourage productive and enjoyable harmony between humankind and the environment, to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of humanity, to enrich the understanding of the ecological systems and natural resources important to the Nation, and to establish a Council on Environmental Quality. (The Principal Laws Relating to Forest Service Activities, Agriculture Handbook No. 453, USDA, Forest Service, 359 pp.)

National Forest Management Act (NFMA) of 1976 - A law passed as an amendment to the Forest and Rangeland Renewable Resources Planning Act, requiring the preparation of Regional Guides and Forest Plans and the preparation of regulations to guide that development.

National Forest System (NFS) Land - Federal lands that have been designated by Executive order or statute as National Forests, National Grasslands, or Purchase Units, and other lands under the administration of the Forest Service, including Experimental Areas and Bankhead-Jones Title III lands.

Natural Forest - The Forest that would occur on the planning area if natural processes were allowed to function without man's influence.

Natural Regeneration - Reforestation of a site by natual seeding from the surrounding trees. May or may not be preceded by site preparation.

Net Public Benefits - An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs), whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of units of the National Forest System is consistent with the principles of multiple use and sustained yield.

Net Receipts - Net receipts are the total cash receipts received by the Forest Service less budget costs.

Nitrogen-Fixing (Nitrogen Fixation) - Conversion of free nitrogen into combined forms useful in nutrient cycles and other functions in the biosphere.

Noncash Benefits - These are benefits or values that people derive from the good or service being provided, but where there is no market in which to exchange that good or service for cash, i.e. the person benefitting does not pay any of the actual value received.

Nonchargeable Volume - All volume that is not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity (FSH 2409.13)

Non-consumptive Use - That use of a resource that does not reduce its supply, for example, non-consumptive uses of water include hydroelectric power generation, boating, swimming, and fishing.

Non-declining Flow - Where the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than the long-term sustained yield capacity.

Non-forest Land - Lands that never have had or that are incapable of having 10 percent or more of the area occupied by forest trees; or lands previously having such cover and currently developed for nonforest use.

Nongame - Species of animals not managed for sport hunting.

Non-market - Products derived from National Forest resources that do not have a well-established market value for example, recreation, wilderness, wildlife.
Not Appropriate Land - See 36 CFR 219 4 and FSH 2409.13-23. See "Timber Resource Land Suitability Classification, Unsuitable."

No-Trace Camping - A concept of recreation use in wilderness which encourages the recreation user to leave "No-Trace" of a visit to aid in protection of the wilderness resource.

Not Suited Lands - See 36 CFR 219.14. See "Timber Resource Land Suitability Classification, Unsuitable."

Objective - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals.

Off-Road Vehicle (ORV) - Any motorized vehicle designed for or capable of cross-country travel on or immediately over land, water, sand, snow, ice, marsh, swampland, or other natural terrain. The term excludes any registered motorboat, any military, fire, emergency, or law enforcement vehicle when used for emergency purposes, and any vehicle whose use is expressly authorized by the respective agency head under a permit, lease, license, or contract. (Executive Order 11644)

Old-Growth Stand - Any stand of trees 10 acres or greater generally containing the following characteristics: 1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage; 2) stands will usually contain a multi-layered canopy and trees of several age classes; 3) standing dead trees and down material are present; and 4) evidence of human activity may be present, but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand

Opportunity Cost - The dollar-quantifiable net loss resulting from a less efficient course of action
