Response: The total acreage within an activity includes roads and landings (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Eighty-five percent of an affected area in a non-compacted and non-puddled condition following timber harvest includes roads and landings. That is, with roads and landings, 15 percent would be a maximum tolerable limit for soil and water impacts resulting from compaction and puddling For skyline yarding systems which comprise over 90 percent of all yarding on the Forest, soil disturbance rarely exceeds five percent of an activity area. However, with ground-based (tractor) yarding of timber, it is sometimes possible to disturb 15 percent or more of an activity area. This mitigation measure is purposefully designed to place impact restraints on the degree of ground disturbance, thereby protecting both site productivity and watershed functioning

232. *COMMENT*: IT IS STATED IN THE FOREST-WIDE GUIDELINES THAT ANY PROPOSED PROJECTS TO ALTER HABITAT OF PLANT SPECIES WILL BE EVALUATED TO DETERMINE IF SENSITIVE SPECIES ARE PRESENT. FIRST, THE TERM "EVALUATED" SHOULD BE BETTER DEFINED AS TO INCLUDE ON THE GROUND INVENTORIES AND REFERRAL TO PROFESSIONAL BOTANISTS FOR MANAGEMENT ADVICE SECONDLY, IT SHOULD BE NOTED THAT LITTLE INFORMATION ON RARE OR SENSITIVE PLANT SPECIES HABITAT HAS BEEN COLLECTED TO DATE WHICH MAKES IT DIFFICULT TO PREDICT THE EFFECTS OF MANAGEMENT ACTIVITIES ON HABITAT.

Response The term "evaluated" has been better defined in the FEIS, Appendix F, and the LRMP, Chapter IV, "Forest-wide Standards and Guidelines." The need for more information on rare or sensitive plant habitat has been addressed in the FEIS, Appendix F, and the LRMP, Chapter II, "Research and Information Needs "

233. *COMMENT*. WITHIN THE LRMP, UNDER FOREST-WIDE STANDARDS AND GUIDELINES, IT APPEARS THAT PRECOMMERCIAL THINNING SHOULD BE INCLUDED AS PART OF 6-1 TIMBER MANAGEMENT (IV-29).

Response. Precommerical thinning was inadvertently omitted during editing processes This has been corrected.

234 *COMMENT*: THE STANDARDS AND GUIDELINES ARE WEAK AND NOT SPECIFIC ENOUGH.

Response: The Forest-wide Standards and Guidelines (LRMP, Chapter IV) are specific to the degree possible without taking away the flexibility needed for individual planning of activity at the project level. Specific management requirements, constraints, and mitigation is developed during the project analysis and recorded in the environmental document and/or implementing instrument (e g , contracts, special use permits, cooperative agreements).

Monitoring

235. *COMMENT*. FOREST SHOULD DEVELOP AN ACTIVE AND ONGOING MONITORING PROGRAM FOR ALL MANAGEMENT ACTIVITIES THAT HAVE AN ENVIRONMENTAL IMPACT. SPECIFIC SUGGESTS FOR IMPROVING THE MONITORING PROGRAM ARE GIVEN.

Response: In response to many suggestions, the Monitoring and Evaluation Program in the Siskiyou National Forest Plan has been changed (LRMP, Appendix D). The Monitoring program is designed to identify acceptable levels of any ground-disturbing activity and provide a basis to measure the effect of this disturbance so that corrective action can be taken if threshold levels are exceeded.

236 *COMMENT*. A NUMBER OF INDIVIDUALS AND AGENCIES EXPRESSED THE DESIRE FOR FOREST-WIDE MONITORING OF FISH HABITATS. MAJOR ITEMS THAT NEED TO BE ADDRESSED INCLUDE DETERMINING THE EFFECTS OF LAND MANAGEMENT ACTIVITIES ON SALMONIDS, AND THE EFFECTIVENESS OF FISH CAPITAL INVESTMENTS IN ENHANCING SALMONID POPULATIONS.

Response· Appendix D of the LRMP describes the proposed fisheries monitoring program. This program was developed from specific concerns raised by individual and agency responses to the DEIS and Draft Plan Monitoring is an essential part of any management program The Region recognizes the importance and has allocated more funds to the Forest fisheries program to accomplish this objective.

237 *COMMENT*: THE DRAFT PLAN AND DEIS DO NOT MAKE CLEAR THE EXTENT OF PAST MONITORING THAT HAS TAKEN PLACE ON THE FOREST WITH REGARDS TO CRITICAL FACTORS AFFECTING THE FISHERIES

Response The *FISH* and *SOIL AND WATER* elements Chapter III of the FEIS now include a brief summary of past fish, soil, and water monitoring that has been done on the Forest

238 *COMMENT* IMPROPER ROAD AND SKID TRAIL CONSTRUCTION AND MAINTENANCE IS PROBABLY THE GREATEST CONTRIBUTOR OF SEDIMENT TO STREAMS. A BETTER SYSTEM OF MONITORING THE ENTIRE ROAD AND SKID TRAIL NETWORK NEEDS TO BE DEVELOPED SO THAT PROBLEMS CAN BE IDENTIFIED AND CORRECTED.

Response Annual maintenance work planning is used as a monitoring tool by road system managers to identify and to fit work needed to correct problems into the maintenance program The level of maintenance is identified in the Road Management Objective for an individual road (See LRMP, Chapter IV, Forest-wide Standard and Guideline 11-5).

239. *COMMENT*. IMPLEMENTATION OF "BEST MANAGEMENT PRACTICES" IS NOT AN ACCEPTABLE SUBSTITUTE FOR WATER QUALITY MONITORING. IT'S NOT CLEAR IN THE DRAFT PLAN HOW SEDIMENT YIELDS AND THEIR IMPACTS WILL BE MONITORED. IN FACT, IT APPEARS NO PROGRAM IS ESTABLISHED AND NO FUNDS WILL BE COMMITTED TO DIRECTLY MONITOR WATER QUALITY STANDARDS SUCH AS TURBIDITY. A WELL-PLANNED AND ADEQUATELY FUNDED MONITORING PROGRAM IS NEEDED

Response· In response to public input, the soil and water monitoring program has been more fully developed and described in Chapter V and Appendix D of the Forest Plan. Water temperature and turbidity monitoring are included as part of the monitoring plan. The on-going project-level soil and water monitoring activity was not displayed in the Forest Plan monitoring summary. Considerable information gathered at the project level can be used to complement the Forest Plan monitoring effort; this is particularly true relative to assessing implementation and effectiveness of Best Management Practices.

240. *COMMENT*: MONITORING OF SNAG LEVELS SHOULD BE INCLUDED IN THE PLAN.

Response: Monitoring of wildlife trees is included in element CW121(d) of the wildlife monitoring plan (LRMP, Chapter V and Appendix D). Details for other monitoring elements, including habitat diversity, are included in these documents.

241. *COMMENT*: THE MONITORING AND EVALUATION PROGRAM IS BIASED, EITHER IN ONE DIRECTION OR ANOTHER. ITEMS NEED TO BE TRACKED FOR BOTH DECREASES AND INCREASES (NOT JUST DECREASES).

Response· The Forest Service Regulations for National Forest System Land and Resource Management Planning (36 CFR 219.12 (k)) describe the goals of monitoring and evaluation. The Forest Service Manual, Section 1920, Land and Resource Management Planning, 1922.7, and the Forest Service Handbook 1909.12, and Land and Resource Management Planning, Chapter 6, stress that the objective of monitoring and evaluation is to determine whether programs and projects are *meeting* direction. In many cases, the monitoring will result in identification of actual levels of outputs or conditions, thus showing the extent that direction is exceeded. In some cases, while it would be of interest to know if objectives are exceeded, the monitoring needed to determine compliance will not supply that information. Collection of such information

would more appropriately be done as research or resource inventory work, and would be subject to the objectives and financing in those areas.

242. *COMMENT*: THE SISKIYOU EIS ERRONEOUSLY SHOWS THAT NO ACRES WILL REMAIN ROADLESS IN TEN YEARS, DEIS II-168. HOWEVER, IT IS ALMOST IMPOSSIBLE TO HARVEST 31,400 ACRES PER YEAR TO DEVELOP ALL THE ROADLESS ACREAGE. THE SISKIYOU SHOULD FOLLOW THE LEAD OF OTHER FORESTS AND SHOULD DISPLAY HOW MANY ACRES WILL REMAIN ROADLESS, IRRESPECTIVE OF THE LAND ALLOCATION.

Response. "Roadless" refers to the inventoried areas identified in Appendix C of the DEIS and FEIS. The observation that it **may** be "impossible to harvest 31,400 acres per year" is accurate However, not all acres must be harvested to change the character of an area from roadless to roaded (or developed). A review of the Ten-Year Timber Sale Action Plan (LRMP, Appendix C) reveals harvest and, more specifically, roading in most areas prescribed for "Roaded Management" during the first decade to a point that will leave many areas (acres) no longer meeting the criteria that created their roadless identity. A display of the acres expected to remain roadless at the end of the first, second, and fifth decades by alternative has been added to Chapter II of the FEIS (Table II-24) and in the Introduction section of Appendix C, FEIS.

243. *COMMENT* IT MAY BE THAT RECREATION USE INCREASES WITH INCREASING TIMBER HARVEST BECAUSE TIMBER HARVEST CREATES JOBS WHICH ATTRACTS PEOPLE TO USE THE FOREST ON THEIR FREE TIME. THESE TRENDS SHOULD BE CAREFULLY MONITORED OVER THE NEXT PLANNING CYCLE.

Response· Monitoring recreation use is included in the LRMP, Appendix D. Access development associated with timber harvest generally increases opportunities for developed recreation, while it generally decreases opportunities for undeveloped recreation such as Primitive and Semi-primitive Non-motorized uses

244. *COMMENT* THE SOIL AND SOIL PRODUCTIVITY MONITORING PROCESS IS WEAK AND NOT SPECIFIC ENOUGH.

Response: Soil (and site) productivity monitoring is currently evolving in the research community. Important to site productivity is the total organic matter, including above ground, surface, and below ground components, provided in several Standards and Guidelines. Monitoring of site productivity will focus on biochemical and physical values of large woody material (LRMP, Chapter V, "Implementation of the Forest Plan"). Monitoring and evaluation of soil conditions will take advantage of the close ties that have been developed with the research communities of Oregon State University and the Pacific Northwest Experiment Station Monitoring projects will be as specific and as current as the scientific community's research. See Appendix D (LRMP) for the monitoring plan pertinent to soils and the soils relationship with water resources.

245. *COMMENT* AN ANNUAL REPORT IS NEEDED FOR THE PUBLIC TO SHOW RESULTS OF MONITORING, INCLUDING THOSE ACTIVITIES THAT EXCEED THE LEVEL OF CONCERN, WHAT ACTIONS WILL BE TAKEN, A COMPARISON OF ALL RESOURCE OUTPUTS AS PROGRAMMED AND ACCOMPLISHED, AND THE FISCAL BUDGET AS PLANNED AND REALIZED.

Response: Table V-1, "Monitoring and Evaluation Program," in the Forest Plan has been changed to clarify that the "frequency" of monitoring means "Reporting Frequency." Most of the actions to be monitored are evaluated annually, an annual report will be available to the public A monitoring element has been

expanded in the Monitoring Plan which will compare actual and planned implementation costs and value which includes monitoring costs (LRMP, Chapter V, Table V-1 and Appendix D)

246. *COMMENT*: THE BUDGET FOR THE FOREST SHOULD CONTAIN ADEQUATE FUNDING TO MONITOR THE ENTIRE ROAD AND SKID TRAIL NETWORK AND ITS STREAM SEDIMENTATION EFFECTS

Response. Appendix D of the LRMP contains monitoring information including estimated annual costs for inclusion in the Forest budget. Stream sedimentation is addressed under the following resource elements in the monitoring plan: fish habitat, water resource, and soil productivity. In addition, project-level monitoring will provide additional and complementary information to Forest Plan monitoring of these elements.

MANAGEMENT REQUIREMENTS

247. *COMMENT*: ESTABLISH AN MMR AND LEGAL REQUIREMENT FOR TIMBER PRODUCTION (EQUAL TO CURRENT PRODUCTION WITHOUT INCLUDING ANY EFFECTS FROM INTENSIVE MANAGEMENT PRACTICES).

Response. There is no requirement or authorization in applicable law or Forest Service policy to establish a Management Requirement (MR) for ASQ The Forest Service is required to constrain timber outputs over time to meet sustained yield principles. The application of an MR for timber outputs could violate sustained yield principles, or could prevent the selection of the alternative which best maximizes net public benefits. The benchmark levels provide a basis for the comparison of tradeoffs for alternatives against the maximum legal potential production of various resources including timber output (FEIS, Appendix B, "Development of Management Requirements").

248 *COMMENT*. MINIMUM MANAGEMENT REQUIREMENTS WERE DONE WITHOUT PUBLIC INVOLVEMENT, INTERDISCIPLINARY ANALYSIS, AND INTEGRATED PLANNING MANDATES OF THE NATIONAL FOREST MANAGEMENT ACT. THE "SENSITIVITY ANALYSIS FOR MINIMUM MANAGEMENT REQUIREMENTS (APPENDIX J) IS A MAJOR STEP TOWARD ALLEVIATING THIS CRITICISM. HOWEVER, IT SHOULD GO FURTHER; SPECIFICALLY, DEMONSTRATE THAT AN EFFICIENT METHOD OF SELECTING MINIMUM MANAGEMENT REQUIREMENTS WAS USED, GIVEN THE OBJECTIVES AND CONSTRAINTS OF THE PREFERRED ALTERNATIVE

Response: The National Forest Management Act (NFMA) set legal guidelines for management of the National Forests The guidelines were interpreted by the Secretary of Agriculture, in cooperation with a Committee of Scientists and with public and professional involvement, to develop regulations Direction from the Chief of the Forest Service and Region 6 resulted in MR's which reflect the requirements of the laws and regulations in NFMA. The MR direction ensures that minimum legal requirements are applied to all alternatives in Forest plans consistently across all National Forests MR's exist for dispersal of created openings, water quality, riparian and wildlife habitat as required by NFMA

The Management Requirements were developed with public involvement. Siskiyou National Forest personnel displayed the preliminary analysis at several public meetings held around the Forest, attempting to involve local people in the development of yield coefficients, planning assumptions, and formulation of alternatives. These meetings are documented in the planning records. The documentation in Appendix B and Appendix J of the DEIS, as well as the discussion in Chapter II, explains how MR's were developed for the Siskiyou These documents provided reviewers with the information needed to comment on the development of the Management Requirements Appendix J has been revised in the FEIS and now

includes some of the information from Appendix B related to the selection of the most efficient methods of meeting the necessary requirements

Designation of MR areas was an interdisciplinary effort. The Interdisciplinary Team has designed the Management Requirements to take advantage of overlaps in resource benefits and minimize tradeoffs to the extent practical This is particularly the case where designated wildlife habitat would preclude timber management These areas are mapped using a priority system which locates them first in dedicated areas (e.g., Wilderness, Wild River), then in areas unsuitable for timber management, then in areas that are potential areas for allocation to Management Areas that would restrict timber management, and finally in area suitable for timber production if the above did not fill the required need. This results in the lowest tradeoffs not only in the Preferred Alternative, but in any alternative formulation considered.

249. *COMMENT* NON-OWL MMR'S SHOULD ONLY INCLUDE THOSE AREAS NEEDED TO MEET MMR'S, AND THAT THE ADDITIONAL ACRES BEING CONSIDERED HERE BE PLACED IN OTHER LESS RESTRICTIVE CATEGORIES.

Response· Management Area 8 (Designated Wildlife Habitat) includes habitat areas for spotted owl, pileated woodpecker, and pine marten (LRMP, Chapter IV, "Management Prescriptions") Management Requirements for all three species are met through an integrated network of habitat areas Appendix J of the FEIS describes the legal foundation and background analysis supporting these Management Requirements.

250 *COMMENT*: THROUGHOUT THE DOCUMENT, THE FOREST SERVICE ASSUMES THAT THE MMR'S WILL INSURE VIABLE POPULATIONS OF OLD-GROWTH DEPENDENT SPECIES. THIS ASSUMPTION IS UNWARRANTED AND, PARTICULARLY IN THE CASE OF THE SPOTTED OWL, IS A MATTER OF CONSIDERABLE CONTROVERSY WITHIN THE SCIENTIFIC COMMUNITY.

Response Although more data remains to be collected, enough information is available to begin to allocate habitat for wildlife species dependent on mature and old-growth forest. Refer to the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines) for details on habitat allocations for spotted owls in the National Forests of Oregon and Washington. For indicator species representing mature and old-growth habitat, habitat networks have been established according to Regional direction (FEIS, Chapter III and IV, "Wildlife", LRMP, Chapter IV, "Management Prescriptions")

251. *COMMENT*: THE MINIMUM MANAGEMENT REQUIREMENT (MMR) FOR MAINTENANCE OF SPECIES FREQUENTING MATURE OR OLD-GROWTH FOREST IS ONLY 20%, WHEREAS 60% WOULD BE REQUIRED TO PROVIDE FOR "HIGHLY VISIBLE POPULATIONS." THE ESTABLISHMENT OF SO LOW AN MMR APPEARS VERY UNWISE

Response: The MR for Primary Cavity Excavators is maintenance of 20 percent habitat capability (The MR's for marten, pileated woodpecker, and northern spotted owl are not described in terms of population percent.) Regional Management Requirements for woodpeckers (primary cavity excavators) are set at 20 percent based on the pioneering work done by Thomas in 1979 (FEIS, "Literature Cited") Thomas points out that populations below 20 percent are considered non-viable; populations between 20 and 39 percent are defined as marginal Thus, Regional Policy is 40 percent (FSM 2630.3 8/87 R-6 Supp 45) Thomas also states that snag habitats maintained at 40-59 percent "will probably maintain viable populations," and that population levels at 60 percent or above "will almost certainly support highly viable populations .." The Siskiyou has maintained a snag policy of 60 percent since 1976, several alternatives in the FEIS, including the Preferred, would reaffirm the 60 percent policy.

252. *COMMENT*: MINIMUM MANAGEMENT REQUIREMENTS FOR OLD-GROWTH DEPENDENT SPECIES ARE BASED ON INADEQUATE DATA.

Response: Preliminary research does indicate dependence of certain wildlife species on mature and old-growth habitats (FEIS, Appendix J). We agree that more research and monitoring is needed. Research needs have been identified (LRMP, Chapter II, "Information Needs") and monitoring efforts of old-growth dependent species will continue during the planning cycle (LRMP, Chapter V and Appendix D) The objective of current Management Requirement allocations is to balance considerations for old-growth dependent species and economic concerns, while maintaining options for managing old-growth ecosystems in the future. Allocations must be made now, based on current knowledge, in some areas of the Siskiyou adequate mature and old-growth habitat will simply not be available at the next revision of the Forest Plan. If more area has been set aside than necessary, habitat can be rededicated to timber management at the beginning of the next planning cycle, if the converse is true, options will already be forgone, i e., cutover areas will not produce mature and old-growth habitat again for many decades

253. *COMMENT*: THE MINIMUM REQUIREMENT STANDARDS ARE FLAWED BECAUSE THEY ARE DIRECTED TOWARDS MAINTAINING WHAT THE USFS CALLS "VIABLE POPULATIONS." THERE IS NO DEFINITION OF WHAT CONSTITUTES A MINIMUM "VIABLE POPULATION" FOR THE MORE THAN 270 SPECIES FOUND IN THE SISKIYOU NATIONAL FOREST. IN FACT, THERE IS NO BIOLOGICAL BASIS TO SUPPORT THE USE OF THE CONCEPT OF MINIMUM VIABLE POPULATIONS IN THIS MANNER.

Response: Although current thinking in the scientific community has been moving away from the concept of indicator species as appropriate measures of habitat capability for entire groups of species, NFMA implementing regulations still require the identification and monitoring of such species. They are thus still identified and provided for in Forest Planning. It is recognized that no single species can be a perfect indicator of habitat for another species. There are many data gaps in our knowledge of habitat requirements, as identified in the Forest Plan (Chapter II, "Information Needs").

The next plan will be founded on better data. In the meantime, only half of the forest is open to timber management During the first decade timber would be harvested on no more than six percent of the Forest under any alternative. Through the Standards and Guidelines, this Forest has tried to accommodate the habitat needs of all wildlife Land allocations and Standards and Guidelines will maintain viable populations of all species inhabiting the Siskiyou The only exceptions will be uncommon species which find scant habitat on the Siskiyou For instance, it would be unrealistic to assume that the Forest could support viable populations of species such as the water pipit (which finds only marginal habitat on the Siskiyou), or occasional visitors such as Clark's nutcracker.

RESEARCH

254. *COMMENT*: A COMPREHENSIVE AND COMPLETE INVENTORY OF THE PLANTS AND ANIMALS OF OUR NATIONAL FORESTS SHOULD BE COMPILED SO THAT OUR UNDERSTANDING OF THEIR COMPLEX INTERRELATIONSHIPS CAN ASSIST US IN OUR STEWARDSHIP OF THE WILDERNESS.

Response: The long-range goal is to have a complete inventory of the Siskiyou's plants and animals and their habitat, and a better understanding of how the entire ecosystem functions (LRMP, Chapter IV, "(Forest Management Goals," and Chapter II, "Information Needs") The Forest Service is committed to learning as much about sensitive plants and their role in ecosystems as is possible. In 1988, a botanist was hired to oversee the sensitive plant program on the Rogue River and Siskiyou National Forests. Also, inventory and

monitoring of sensitive plants is an important part of implementing the Forest Plan Specific inventories are identified in the "Threatened, Endangered, and Sensitive Wildlife and Plant Capital Investment" Schedule in the LRMP, Appendix B. Also, ongoing monitoring is identified in Chapter V and Appendix D of the LRMP.

255. *COMMENT*: BUILDINGS CAN BE MADE OF EARTHQUAKE-PROOF, MOLDED MATERIALS, ESPECIALLY SHOPS AND SMALLER DWELLINGS. RESEARCH MONIES SHOULD BE SET ASIDE FROM ALL TIMBER COMPANIES AND WOODS OPERATIONS IN 1988 AND BEYOND FOR THIS TYPE OF RESEARCH CONSTRUCTION.

    WE SHOULD NOT BE "LOCKING UP" OUR FOREST, BUT SHOULD BE SPENDING MORE MONEY ON RESEARCH TO FIND MORE USES FOR WOOD AND WOOD FIBER TO REPLACE DEPLETED RESOURCES LIKE COAL, STEEL, AND PETROLEUM. TREES ARE OUR ONLY RENEWABLE RESOURCE

Response: Both private and government agencies are conducting basic research into wood technology and forest management Two examples of such agencies are the Pacific Northwest Experiment Station, and the Wood Products Laboratory in Wisconsin The Siskiyou National Forest, on occasion, cooperates with research organizations. Based on public input, this research need is now identified in "Information Needs" in Chapter II of the Forest Plan.

256. *COMMENT*: CONDUCT MORE BASIC RESEARCH ON THE IMPACTS OF TURNING THE OLD-GROWTH FORESTS OF THE PACIFIC NORTHWEST INTO TREE FARM PLANTATIONS.

Response: "Better understanding the importance of old-growth ecosystems" is identified as among "Regional Needs" in the Forest Plan (Chapter II, "Information Needs").

257. *COMMENT*: ESTABLISH AND FUND LONG-TERM RESEARCH PROGRAMS EMPHASIZING NON-TIMBER PRODUCTION ISSUES.

Response: The Pacific Northwest Experiment Station is responsible for doing basic forest management research Basic research is beyond the scope of the Siskiyou National Forest mission. However, the LRMP (Chapter V, "Implementation") provides a Monitoring and Evaluation Program for all Forest activities Some of the non-timber resources that will be monitored include smolt production, sensitive plants, Roosevelt Elk populations, osprey, and recreation (LRMP, Chapter V and Appendix D). A number of research needs for non-timber-production issues are identified in "Information Needs" in the LRMP (Chapter II).

MANAGEMENT OF THE FOREST

258 *COMMENT*: MANAGEMENT PLANS MUST LOOK CENTURIES INTO THE FUTURE. INCREASING POPULATIONS OF FUTURE GENERATIONS WILL HAVE NEEDS REQUIRING THE INCREASE OF PRODUCTIVITY AND OUTPUT OVER TIME. NATURAL RESOURCES CANNOT BE MANAGED OR EXPLOITED JUST TO SATISFY THE NEEDS OR DESIRES OF THE PRESENT GENERATION OR OF LOCAL INTERESTS.

Response: Yes, management plans must look to the future, and demands for goods and services provided by the Forest will increase with time A 150-year time span (or "planning horizon") is used to display effects of alternatives and the nondeclining flow of timber. Re-examination of the LRMP will occur at least every 10 to 15 years to ensure changing conditions and demands can be incorporated into the analysis (LRMP, Chapter I).

259. *COMMENT*. THE FOREST, UNDER YOUR MANAGEMENT, IS NOT A "RENEWABLE RESOURCE." ONCE ROADED AND LOGGED, THE FOREST PRIMEVAL IS GONE, HUMANLY SPEAKING, FOREVER AND THOUGH MUCH OF IT COULD HEAL (IF YOU COULD FIND IT IN YOURSELVES TO LET IT BE FOR A FEW HUNDRED YEARS), THERE IS NO WAY - IF YOU CONTINUE YOUR PRESENT COURSE - THAT YOU WILL EVER BE ABLE TO RECREATE THE FISHER, SPOTTED OWL, WILD FISH RUNS, AND PORT-ORFORD-CEDAR, TO NAME A FEW CREATURES YOUR PRESENT MANAGEMENT DIRECTION HAS PUT IN JEOPARDY.

Response: We have endeavored to create a choice of alternatives in the FEIS that will preserve viable populations of all native and desirable non-native plants and animals. For instance, we have incorporated Standards and Guidelines listed in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines), and taken actions to insure that minimum requirements for insuring viable populations and habitat are met. Most land management options available today will still be available at the end of this planning period It would not be possible, or wise, to make land allocation decisions now which would forever govern future actions

OTHER PLANNING COMMENTS

260. *COMMENT*· A FOREST PLAN REVISION AND AMENDMENT PROCESS SHOULD BE DEVELOPED TO GUIDE THE AMENDMENT AND REVISION PROCESS.

Response: Forest Service Regulations, National Forest System Land and Resource Management Planning (36 CFR 219.10 (f),(g)), provide for Amendments and Revisions under certain situations. This process is described in Chapter V of the Forest Plan ("Amendment and Revision").

261. *COMMENT*· A DEFINITION OF "SIGNIFICANT" SHOULD BE DEVELOPED TO GUIDE THE AMENDMENT AND REVISION PROCESS

Response. In determining "significance," factors are described in the Forest Service Handbook, 1909.12, Land and Resource Management Planning. The Handbook lists those factors that are to be used when determining whether a proposed change to a forest plan is significant or not. These include (1) timing; (2) location and size; (3) goals, objectives, and outputs, and (4) Management Prescriptions. More description of these factors is available from the Forest Supervisor's Office. The process for change is generally described in the Forest Plan, Chapter II, "Amendment and Revision."

262. *COMMENT*: A CLEAR DISCUSSION OF THE FOREST'S ABILITY TO IMPLEMENT THE PLAN AT EXPECTED LEVELS SHOULD BE INCLUDED IN THE EVENT OF FUTURE BUDGET REDUCTIONS, THE SISKIYOU PLAN SHOULD CLEARLY INDICATE WHAT PRIORITIES WILL BE ESTABLISHED (WITH CRITERIA FOR SAME) AND WHAT ACTIVITIES WILL BE CURTAILED.

Response· Implementation of the Forest Plan is discussed in the LRMP, Chapter V, while Appendix D of the LRMP contains monitoring information associated with Plan implementation. Budget information is provided in Appendix B of the LRMP for Fiscal Year 1991

Amendments to the Forest Plan may be triggered by changes in funding received as opposed to funding requested through the budgeting process The amounts received could be more than, the same as, or less than the amounts requested For instance, the Fiscal Year 1991 budget request identifies and prioritizes activities at both 30 percent reduction and 10 percent increase levels Major program areas identified at the reduced funding level include facilities, timber, and lands.

263. *COMMENT*: AT A MINIMUM, MONITORING SHOULD INCLUDE: NUTRIENT LOSS, EFFECTS FROM BURNING, COMPACTION, EROSION LOSS AND DISPLACEMENT, AND REDUCTION IN SOIL PRODUCTIVITY THE PLAN SHOULD DESIGNATE WHO IS RESPONSIBLE FOR MONITORING AND ENFORCEMENT AND WHAT COURSE OF ACTION THE FOREST SERVICE WILL TAKE TO PROTECT AGAINST LOSSES.

Response: Monitoring of soil productivity has been added to the Monitoring Plan (LRMP, Appendix D)

264. *COMMENT*: UNLESS SCIENTIFICALLY JUSTIFIED AND WITH FULL PUBLIC PARTICIPATION, NO NEW CONSTRAINTS SHOULD BE APPLIED IN THE INTERIM TO EXISTING PLANS IN CONTEMPLATION OF THE NEW PLAN

Response: The Forest is currently managed through direction provided within the Chetco-Grayback, Rogue-Illinois, Rogue, and Mt. Butler-Dry Creek Land Management Plans, portions of the Powers and Illinois Valley District Multiple Use Plans, the Timber Management Plan, and other sources, including the Forest Service Manual, Regional Guide, and numerous environmental documents, laws, regulations, and Executive Orders.

The Forest Plan supersedes or incorporates all previous land and resource management plans prepared for the Siskiyou National Forest (FEIS, Chapter I, "National, Regional, and Forest Planning"). Upon implementation of the Forest Plan, Forest management activities will be brought into compliance with the Forest Plan. Until implementation, the Forest continues to be managed through the existing plans as provided for in NFMA.

265 *COMMENT*: A FINAL PLAN SHOULD NOT BE ADOPTED UNTIL THE CUMULATIVE EFFECTS OF ALL DRAFT, REVISED DRAFT, AND SUPPLEMENTAL NATIONAL FOREST PLANS ARE KNOWN BY THE PUBLIC MOREOVER, PLANS DRAFTED BEFORE THE FINAL EIS FOR THE SPOTTED OWL, FINAL EIS FOR VEGETATION MANAGEMENT AND THE MMR POLICY PAPER, SUCH AS THE SISKIYOU, MUST TAKE A "HARD LOOK" AT THE EFFECTS OF EACH OF THESE AGENCY POLICY DOCUMENTS BEFORE A FINAL FOREST PLAN IS TO BE SERIOUSLY ADOPTED.

Response: The FEIS's for the spotted owl and vegetation management have been released. The Forest is consistent with this direction as well as that for Management Requirements. See the FEIS, Chapter I, "National, Regional, and Forest Planning" for information on the relationship between the Forest Plan and other pertinent documents

266. *COMMENT*: THE LENGTHY APPEALS PROCESS ALLOWS ENVIRONMENTALISTS TO TIE UP TIMBER SALES. THERE SHOULD BE A SHORTER APPEAL PROCESS.

Response: Recent changes (February 1989) have been made to the appeals process; however, these are not addressed as part of the planning efforts for the Siskiyou National Forest LRMP. Revising the appeals process is not within the scope of the FEIS for the Forest Plan.

267. *COMMENT*: THE NATIONAL FORESTS IN THE KLAMATH-SISKIYOU REGION OF CALIFORNIA AND OREGON SHOULD COOPERATE AND PRODUCE A REGIONAL PLAN FOR PROTECTING THE INTEGRITY OF THE VIEW, ITS BIOLOGICAL FUNCTION AND RECREATIONAL AMENITIES FOR THE LONG TERM THEN, AND ONLY THEN, WILL WE BE ABLE TO DETERMINE WHAT LEVEL OF LOGGING CAN BE SUSTAINED.

Response: NFMA requires each National Forest to prepare a Forest Plan and for each Forest Service Region to prepare a Regional Guide. See the LRMP, Chapter I, "Relationship of the Forest Plan to Other Documents" for more information Cooperation and coordination between adjacent Forests and Regions is on-going.

268. *COMMENT*: AN EXPLICIT STRATEGY IS NEEDED FOR BETTER INTEGRATING RECENT AND FUTURE RESEARCH KNOWLEDGE INTO FOREST PLANNING, OPERATIONAL GUIDELINES, AND ON-THE-GROUND IMPLEMENTATION AND MONITORING.

Response: The Forest Service, through its network of Experiment Stations and contacts with the academic community, strives to keep abreast of substantive research applicable to its management activities. Additionally, Forest Service employees are involved in training sessions, conferences, seminars, workshops and other situations where information is exchanged that is intended to provide employees with current knowledge in their various resource disciplines and specialties (LRMP, Chapter II, "Information Needs")

269. *COMMENT*: THE PUBLIC COMMENT SYSTEM TO INSURE PUBLIC INFLUENCE ON THE PLAN IS DESIGNED TO FAVOR THE TIMBER INDUSTRY. NATIONAL OPINION POLLS GENERALLY SHOW THAT THE PUBLIC FAVORS GREATLY INCREASED PROTECTION FOR OLD GROWTH AND ROADLESS AREAS. YET THIS IS NOT ADDRESSED IN THE PLAN. RESULTS OF BOTH NATIONAL AND STATE OPINION POLLS BY REPUTABLE ORGANIZATIONS SHOULD BE USED AS A MAJOR PART OF THE PUBLIC PARTICIPATION PROCESS.

Response: The public comment process is designed to insure that all responses from all people who responded to the Draft Forest Plan will be read, considered and recorded. Public opinion polls, while read by Forest managers, were not incorporated into the planning process. While opinions may definitely play a role in forming policy and aiding in decision making, the responsibility for management of National Forests resides with the Agency and professionals retained by the public to manage these public lands. NEPA procedures must insure that environmental information made available to the public and decisionmaker is measured against standards of quality and accuracy of scientific analysis. It is with this requirement that a systematic, interdisciplinary approach be used to insure the integrated use of the sciences and environmental design arts in planning provide as reasonable and non-opinionated analysis as possible.

For information relative to public participation and comments to the DEIS and Proposed Forest Plan, see the FEIS, Summary, "Public Response to the DEIS," "Changes Between DEIS and FEIS," and "Issues, Concerns and Opportunities."

RESOURCE PROTECTION

ROADLESS AREAS

270 *COMMENT*: MORE ROADLESS AREA SHOULD BE PROTECTED. NO LOGGING, MINING, HUNTING, LIVESTOCK GRAZING, OFF-ROAD VEHICLES, AIRCRAFT, INTERNAL COMBUSTION ENGINES, ROAD CONSTRUCTION, OR DEVELOPMENT OF ANY KIND SHOULD BE PERMITTED WITHIN EXISTING ROADLESS AREAS

Response: The FEIS contains a wide range of alternatives concerning the inventoried roadless areas on the Siskiyou. These alternatives range from little development of the roadless areas to nearly full development. Alternatives M, E, and G provide for maximum protection of the remaining roadless areas through management as "Backcountry Recreation" (see FEIS, Chapter II). Based on public input to the DEIS and consideration of need for this type of recreation opportunity over the next decade, this issue was seriously considered in developing Alternative S Standards and Guidelines (LRMP, Chapter IV) provide for restraints on nonconforming uses in Backcountry Recreation areas. No logging or road construction is programmed for the area Mining and hunting would continue much as it has in the past. Some areas have historic ORV use; the demand for this kind of recreation was considered in providing for both motorized and non-motorized recreation opportunities.

271. *COMMENT* ALLOW ROADS INTO THE NORTH KALMIOPSIS ROADLESS AREA ONLY IF IT IS WORTH THE HARVEST THAT WILL BE GAINED AND/OR WORTH IT TO KEEP WILDERNESS BUG-FREE, ETC.

Response· Benefits to the public must occur before a decision is made to construct a road The determination of whether the costs and impacts are acceptable is made in the site-specific project analysis stages, which is done based on NEPA and the Standards and Guidelines found in the Forest Plan (LRMP, Chapter IV). The Forest Plan FEIS established that portions of this inventoried roadless area should be placed in allocations which permit timber harvest and other activity.

272. *COMMENT*: FISH HABITAT STRUCTURES ARE INCONSISTENT WITH WILDERNESS MANAGEMENT GOALS, AND CANNOT BE ALLOWED IN WILDERNESS OR RESEARCH NATURAL AREAS.

Response: The Standards and Guidelines for Wilderness have been changed (LRMP, Chapter IV). Fish habitat structures will not be planned in designated Wilderness or RNA's.

273. *COMMENT*: ALL PRIMITIVE ROADS NOT ACTIVELY IN USE FOR MINING CLAIMS IN THE SOUTH KALMIOPSIS SHOULD BE CLOSED AND REVEGETATED.

Response· It is the intent of the Forest Service to either eliminate or minimize any adverse impacts on all areas of the Forest resulting from previous or current commercial operations. Primitive roads that can be closed will be barricaded to exclude any travel. In most cases, natural revegetation processes will be allowed to take place; however, if needed for erosion prevention reasons, revegetation and other restoration treatments may be implemented.

274. *COMMENT*: OPEN UP SOME OF THE WILDERNESS TO THE PUBLIC SO WE AND OUR CHILDREN CAN SEE THE BEAUTY THAT IS HIDDEN WITHIN THESE BOUNDARIES, AND MAKE AVAILABLE AREAS FOR CAMPING, PICNICKING, RECREATION, AND HIKING

Response: Designated Wilderness is open for use by the public. Trail systems designed to provide opportunities are routinely planned and constructed in Wildernesses. All alternatives provide for increased trail construction ranging 86 miles (Alternative S) to 24 miles (current direction) Table II-4, FEIS, displays all trails planned for construction in the Wildernesses over the course of the Plan. Motorized access and the construction of developed campsites are precluded by the Wilderness Act, but camping, picnicking, and hiking are part of the Primitive and Semi-primitive recreation experience for which Wilderness is valued

275. *COMMENT*: THE WILDERNESS SHOULD BE RESPONSIBLY DEVELOPED TO PROVIDE TIMBER HARVEST, PROTECT WILDLIFE, AND PROVIDE A SAFE ENVIRONMENT FOR FAMILIES TO ENJOY OUR STATE

Response. Wildernesses were designated by Congress An Act of Congress would be required to remove them from Wilderness or develop them in any way other than for their designated purposes. Wilderness management is limited to those activities that would not degrade the area's character (See LRMP, Chapter IV, "Standards and Guidelines") Timber harvest and other activities that require significant ground disturbance are precluded by law.

276. *COMMENT*. THE FOREST SERVICE DOES NOT MENTION HOW INCREASED VISITATION WILL AFFECT WILDERNESS MANAGEMENT INCREASING RECREATION VISITOR DAYS WITHOUT A CONCOMITANT CHANGE IN FOREST SERVICE MANAGEMENT, SUCH AS AN INCREASE IN THE ACREAGE DEVOTED TO WILDERNESS, MAY VIOLATE 36 CFR 293.2, BECAUSE THE WILDERNESS RESOURCES THAT ARE PRESENTLY AVAILABLE MAY NOT BE ABLE TO SUSTAIN ALL OF THEIR WILDERNESS CHARACTER WITH THE ANTICIPATED INCREASE IN VISITATION.

Response: Wilderness use on the Forest is low, and recreationists are encouraged to visit these areas The levels of use projected may or may not occur (see FEIS, Chapter III, "Wilderness"). It is important to understand that they are projections made for planning purposes.

Wildernesses are managed under the "Limits of Acceptable Change" concept (LRMP, Appendix A). Under this concept, the effects of recreation use within the Wildernesses are monitored on a more or less constant basis. If impacts reach unacceptable levels, the Forest will ask visitors to utilize other areas of the Wilderness, restrict use, or close an area to use so that sufficient time is allowed for recovery. The Forest has estimated "carrying capacities" for each of the Wilderness Recreation Opportunity Classes (refer to the Wilderness Rating System described in Chapter IV, FEIS). These are estimates of the amount of visitor use the Wilderness can sustain and still provide Primitive or Semi-Primitive Wilderness recreation experiences. As use approaches these levels, the Forest has the option to institute a permit system or some other means of limiting recreation use. In all cases, the Wilderness resource is primary; recreation is merely an activity that may occur provided the character of the Wilderness is not degraded.

277. *COMMENT*: THE PROPOSED EXTENSION OF ROADS INTO THE KALMIOPSIS WILDERNESS FOR THE PURPOSE OF LOGGING OPERATIONS IS UNACCEPTABLE.

Response: The Wilderness Act of 1964 and later legislation designating Wilderness preclude logging and associated roading in Wilderness. No roads are proposed in any Wildernesses.

278. *COMMENT*: THE DESIGNATION OF CUSTODIAL (ROADLESS) MANAGEMENT AREAS VIOLATES THE WILDERNESS ACT OF 1964 AND THE OREGON AND WASHINGTON STATE WILDERNESS ACTS. THE SISKIYOU DOES NOT HAVE THE AUTHORITY TO CREATE WILDERNESS THROUGH ADMINISTRATIVE FIAT.

Response: Public comments to the DEIS strongly noted that the objectives and prescriptions of the Custodial (Roadless) Management Area closely approximated that for Wilderness. The original intent of this allocation was to provide a recreation opportunity somewhere between that found in the Wilderness and those provides under General Forest As a result, the area was renamed to Backcountry Recreation and the objectives better clarified The Backcountry Recreation (Management Area 6) prescription was rewritten to represent an area where motorized and non-motorized recreation could occur in a largely

unroaded environment, but without the constraints of Wilderness. While no timber harvest is programmed in these areas, mineral access and other activities are not heavily constrained.

The Oregon and California Wilderness Acts of 1984 provided release/sufficiency language which precluded these areas from consideration as Wilderness for the planning period (next 10 to 15 years). Recognizing this law and the potential of these areas, a full range of alternatives was explored during the analysis to examine the other issues of roaded and unroaded management with and without harvesting activities (FEIS, Chapter IV and Appendix C) A discussion and comparison of alternatives is documented in Chapter II of the FEIS The comparisons are based on the environmental effects displayed in Chapter IV.

279. *COMMENT.* THE 10-YEAR PLAN PRESCRIBES ENTRY INTO APPROXIMATELY 85 PER CENT OF WHAT IS NOW ROADLESS AREA THIS MUST NOT OCCUR UNTIL AFTER A BETTER INVENTORY OF POTENTIAL LOSSES HAS BEEN PRESENTED.

Response. An inventory of these areas was completed and identifies the fact that these areas have numerous attributes with many opportunites for various uses These attributes were considered and trade-offs discussed in the FEIS and Appendix C of the FEIS In the development and analysis of the alternatives, the attributes of all areas of the Forest in various combinations and amounts to meet the demands were considered, and identified in the Summary of the Analysis of the Management Situation, Chapter II of the Forest Plan, and in Appendix B of the FEIS

The impacts or environmental consequences of each alternative are discussed and displayed in Chapter IV of the FEIS Chapter II of the Forest Plan also compares the identified demands with the ability of the Forest Plan to meet those demands

280 *COMMENT*: THE ACREAGES ALLOCATED TO ROADLESS MANAGEMENT SHOULD BE LISTED FOR EACH ALTERNATIVE MENTIONED IN THE FINAL DOCUMENT.

Response: These figures have been displayed in the FEIS, Chapter II (Table II-2, "Acreages in Management Areas by Alternative"). These are generally summarized by combining Management Areas 1 through 9 which have no programmed harvest and roading Appendix C provides the same information, but specific for each inventoried roadless area. In addition, the inventoried roadless area remaining unroaded in blocks greater than 5,000 acres, or smaller areas contiguous to Wilderness, is provided in Chapter II (Table II-24) and Appendix C of the FEIS. These tables provide a summary of the acres remaining unroaded on the Forest at the end of the first, second, and fifth decades

281. *COMMENT.* THE CABIN AND GENERAL AREA OF THE BIG JUMBO MINE ON JOSEPHINE CREEK SHOULD BE DESIGNATED AS SPECIAL INTEREST AND PROTECTED FROM FURTHER DESTRUCTION THIS OLD MINING CABIN HAS LOCAL HISTORICAL SIGNIFICANCE AS DOES THE AREA

Response As the LRMP indicates (Appendix B), a cultural resource survey and evaluation of the historic mining areas on the Illinois Valley Ranger District have been scheduled. The Big Jumbo Mine (or "Cutler Mine") and its vicinity will be covered by this project Until that evaluation is completed, historic sites will continue to be evaluated on a case-by-case basis All significant cultural resources will be protected from disturbance

282. *COMMENT:* THERE IS A QUESTION WHETHER PUBLIC INTEREST IN THE SOUTH KALMIOPSIS PORTION IS IN FACT ONLY "MODERATE" AS STATED IN THE TABLE ON PAGE 6 IN THE DEIS, APPENDIX C. THERE IS ALSO DOUBT WHETHER PUBLIC PREFERENCE FOR NONWILDERNESS FOR THE SOUTHERN AREA WAS MOSTLY UNANIMOUS IN RARE II.

Response: See the FEIS, Appendix C ("Table C-4 Key to Attribute Ratings") for the definitions of high, moderate, low, and none or negligible public interest pertaining to roadless areas Public preference data provided in the FEIS for RARE II, Appendix U, indicates 5,008 respondents (63 percent) favoring non-Wilderness status for the South Kalmiopsis area. With Forest Planning continuing since the RARE II decision in 1979, public interest relative to the South Kalmiopsis area (as separate from the Illinois River corridor) has been moderate, at best. Additionally, the input has remained more development oriented or "leave as is" (i.e , allow mining, motorized use, some timber harvest) than otherwise. See the FEIS, Appendix C, "South Kalmiopsis No 6709," for a complete discussion of that roadless area

283. *COMMENT.* DEVELOPMENT OF ROADLESS AREAS IS A CONCERN BECAUSE OF DEVELOPMENT AND USE OF NEW ROAD SYSTEMS VEHICLE USE OF ROADS REDUCES HABITAT EFFECTIVENESS FOR DEER AND ELK AND DIMINISHES THE QUALITY OF THE HUNTING EXPERIENCE FOR THOSE PREFERRING TO HUNT IN AREAS OF SOLITUDE.

Response: For the FEIS, Standards and Guidelines have been revised. Vehicle entry will either be limited or closed in areas where there is conflict with deer, elk, and other sensitive species. Much of the area will not be developed due to lands allocated to Backcountry Recreation and similar Management Areas which have no programmed harvest Some of the Backcountry Recreation areas may or may not be closed to motorized use, decisions will be made as part of site specific analyses, or as part of the scheduled Forest-wide deer and elk management plan (LRMP, Chapter IV, "Forest-wide Standards and Guidelines")

284. *COMMENT* THERE IS A PRESSING NEED FOR A REALISTIC DEFINITION OF "ROADLESS" WHEN IT COMES TO DEFINITION OF LAND AND DESIGNATION FOR WILDERNESS AND "ROADLESS." AREAS WITH IMPROVED GRAVEL ROADS HAVE BEEN DESIGNATED WILDERNESS BY BUREAUCRATIC FIAT BY MERELY GATING THE ROAD IN QUESTION, THEN IMAGINING IT NO LONGER EXISTS THE CLASSIFICATION OF "ROADLESS AREAS" MUST BE MADE CONSISTENT WITH FS POLICY OF CLASSING ANY PRIMITIVE TRAVELWAY (OVER 40 INCHES WIDE) AS A ROAD, AND NOT DISREGARDING THEM OUT OF CONVENIENCE JUST BECAUSE THEY ARE CLOSED. "ROADLESS AREAS" SHOULD BE EVALUATED SOLELY ON WHETHER ANY ROADS, PRIMITIVE OR OTHERWISE, EXIST.

Response: Roadless areas are characterized as areas 5,000 acres or larger, or contiguous to Wilderness, that are "essentially unroaded " Roadless evaluations were done during the RARE and RARE II planning in the 1970's. That inventory has been modified over time and updated during the Forest Planning process. Adjustments in the inventoried roadless areas for nonconforming uses, such as roads and harvest units, have occurred twice (the latest being the 1988 update) since the original RARE II inventory. Further addition unroaded areas is not anticipated as no other area meets the current criteria. Complete descriptions of all roadless areas are located in the FEIS, Appendix C

SOILS/WATER QUALITY/FISHERIES

Soil

285 *COMMENT.* HOW WILL LARGE WOODY DEBRIS BE MANAGED TO HELP PROTECT THE LONG TERM PRODUCTIVITY OF THE SOIL?

Response: The Forest has an increased awareness of the value of organic residues, as a result, emphasis has been placed on retention of large and small woody material following timber harvest. This is reflected in the Forest Plan by reservation of large woody material at levels compatible with the needs of the site. Research currently indicates this level may be on the order of 5 to 20 pieces, each of 40 cubic feet or more, per acre. Other woody materials will also be preserved by short duration site preparation burns made in the spring and by reservation of wildlife trees (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Current evidence suggests that small woody material and needles are most important for mitigating against soil fertility loss. Soil productivity will be monitored to insure long-term Forest productivity (LRMP, Chapter V and Appendix D).

286 *COMMENT* DISPERSION OF LOGGING ACTIVITY NEEDS TO BE CLEARLY ADDRESSED IN STANDARDS AND GUIDELINES. WHAT SPECIFICS OF THE STANDARDS AND GUIDELINES WILL BE USED TO SEE THAT LAWS PROTECTING SOIL AND WATER WILL BE MET?

Response. Dispersion of timber harvesting is addressed in a number of ways. The FORPLAN model uses timber harvest dispersion constraints in projecting outputs (FEIS, Appendix B). Forest-wide, not more than 20 percent of each Planning Basin is scheduled for harvest activities per decade. The Preferred Alternative was modeled using slightly more restrictive Planning Basin constraints which will be monitored as part of overall cumulative watershed effects (LRMP, Chapter V and Appendix D).

At the project level, dispersion constraints are addressed in Forest-wide Standards and Guidelines by limiting harvesting in smaller watersheds (500-2500 acres) to 20 percent of the area in a single decade (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Riparian Management Prescriptions limit harvest entry to 11 percent of the Riparian acreage within each Planning Basin per decade.

A number of Forest-wide Standards and Guidelines (LRMP, Chapter IV) describe practices that are directed toward meeting laws and regulations. Among them are 7-2, Soil Compaction and Puddling; 7-3, Rehabilitation of Roads; 7-4, Soil Erosion; and 7-9, Soil and Water Resource Improvements. Standard and Guideline 7-2 has been revised to include roads and landings in the affected area Also 7-5 through 7-15 address soil and water protection. The Monitoring Plan of the LRMP is designed to ensure that Standards and Guidelines are carried out. The Best Management Practices Appendix (LRMP, Appendix F) and General Water Quality Best Management Practices (Pacific Northwest Region, 1988), describe methods used to protect soil and water

287. *COMMENT*: A SLOPE STABILITY OR LANDSLIDE PROPENSITY MAP SHOULD BE INCLUDED TO FULLY DESCRIBE THIS PROCESS AND ITS IMPACT ON EACH LAND USE ALTERNATIVE.

Response· Detailed maps showing landslide potential are outside the scope of this Forest Plan, but are prepared either during area geologic inventories or in site-specific project-level planning. Potential for mass movement is evaluated before timber harvest, road building, or other vegetation or land disturbing activity (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Forest management activities, such as timber harvest and road construction, are not normally done in terrain with high potential for landslides or with active landslides. Additionally, the Forest has been initially screened for areas suitable for timber production Large areas of land unsuitable for management activities has been withdrawn from the land base Sediment tables in the FEIS (Chapter IV, "Soil and Water") include estimates of increased sedimentation from landslides for each alternative. Landslide mapping for activity monitoring and cumulative effects analysis is scheduled for most of the Planning Basins during the next four or five years

288 *COMMENT*· FOREST SOILS MUST BE TREATED AS GEOLOGIC MATERIAL AND AGRONOMIC MANAGEMENT PRACTICES GENERALLY ARE NOT APPROPRIATE IN A FOREST SETTING THE

DOCUMENT UNDER REVIEW TENDS TO LOOK AT SOILS AS BEING MUCH MORE COMPLEX AS TO DISTRIBUTION AND ATTRIBUTES THAN IS WARRANTED WHEN THEY ARE VIEWED THROUGH A PEDOLOGISTS EYES.

Response: As described in Chapter III of the FEIS, soil (as a product of climate, parent material, topography, plants, and time) is much more than a geologic material. Some soil chemical and physical properties closely reflect the parent rock, but the biochemical, climatic, and physical weathering processes tend to dominate. Experience in managing these soils suggests the soils are complex. It is important to understand how soils behave under a variety of management practices that may affect nutrient status and cycles, water transmission rates and plant growth. Forestry, while less intensive than agronomy, strives to avoid detrimental impacts and to maintain productivity as discussed in Chapters III and IV of the FEIS

289. *COMMENT*: THE PLAN DOES NOT ADEQUATELY RESTRICT TIMBER HARVESTING IN LANDS IDENTIFIED AS HIGH EROSION HAZARD. THE PLAN WILL NEED TO EXCLUDE ALL SOIL-DISTURBING ACTIVITIES FROM HIGHLY FRAGILE AREAS (AS REQUIRED BY NFMA).

Response: Lands with high potential for erosion and mass wasting have been classified as unsuitable for timber production where these are "lands where the technology is not available to prevent irreversible resource damage." As a result, they are not included in "tentatively suitable land for timber production" (FEIS, Appendix B).

Roads and timber harvest are not planned on unstable slopes or where soil erosion (loss of cohesion) and mass wasting would be excessively increased if the effects of these actions cannot be mitigated (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). It is recognized that any land or vegetative disturbance will likely cause some change and potential increase in erosion. However, what is tolerable will be evaluated against water quality standards and likelihood of an irreversible loss of the soil resource This evaluation by specialists and public disclosure of the potential impacts are accomplished within project-level analyses and accompanying environmental documents. All proposed timber harvest units and roads are located and designed with direct involvement of engineering geologists, hydrologists, engineers, and soil scientists to minimize impacts on any resources

Sedimentation

290. *COMMENT*: MINIMIZE SEDIMENTATION AND EROSION BY REDUCING DISTURBANCES, I.E. ROADBUILDING, LOGGING AND MINING. SEDIMENTATION AND ITS EFFECTS ON FISHERIES (SUCH AS CHINOOK SALMON) HAS NOT BEEN ADEQUATELY ADDRESSED. THE MEASURES TO REDUCE SEDIMENTATION NEED TO BE DESCRIBED. MORE RESEARCH AND MONITORING NEEDS TO BE CONDUCTED TO DETERMINE THE ACTUAL EFFECTS.

Response: Sedimentation and erosion will be minimized through land allocations, watershed improvement activities, and Standards and Guidelines and associated Best Management Practices (BMP's). Project-level analysis and implementation will evaluate the need and provide appropriate levels of mitigation to prevent or minimize potential sediment impacts. In addition under the Preferred Alternative S, approximately 50 percent of the total Forest would be managed with no programmed timber harvest and associated roadbuilding. (See discussions in FEIS, Chapter II and IV.)

Standards and Guidelines have been designed to protect soil, water and fisheries. Experience on the Siskiyou National Forest shows that by incorporating Standards and Guidelines (LRMP, Chapter IV) and BMP's (LRMP, Appendix F), water quality and fisheries are protected. BMP's for all resource management activities are implemented on the Forest to prevent nonpoint source pollution. Appendix F describes the

process for implementing BMP's on the Forest General Best Management Practices for the Pacific Northwest Region are described in General Water Quality Best Management Practices, Pacific Northwest Region, 11/88 The Forest-wide Standards and Guidelines (LRMP, Chapter IV) provide further guidelines and criteria for minimizing sediment production.

Sediment, coarse or fine, affects salmonid fishes when excessive amounts enter streams and rivers The early intergravel life stages of chinook salmon have been identified as being especially vulnerable to impacts from both fine and coarse sediments (FEIS, Chapter III, "Fish, Bedload Sediment"). The dynamics of coarse sediment transport in streams are extremely complex and are still being evaluated by scientists The Preferred Alternative S shows a decrease in sediment from levels under current management (FEIS, Chapter IV, "Fish" and "Soil and Water"). Riparian areas in basins that are used most extensively by chinook salmon have special allocations and prescriptions under the Preferred Alternative (FEIS, Chapters III and IV) These will minimize or reduce the potential risks of adverse impacts from increased sediments (in comparison to current conditions)

A wealth of information is available as to sediment and fish interrelationships However, additional research is necessary to fully specify how excessive sediments adversely affect salmonids, particularly within a given stream system This research need is identified in "Information Needs" (LRMP, Chapter II) Monitoring plans for water quality and fish habitat have been improved to incorporate many suggestions by the public (LRMP, Chapter V, and Appendix D). Recognizing that excess sediment above the natural variation can affect salmonid habitat capability, Forest management practices will be designed to prevent or minimize adverse impacts.

291 *COMMENT*. HOW DO YOU SELECT THE ROAD BUILDING AND LOGGING METHODS TO CONSIDER FOR EACH TYPE OF GROUND? WHAT TYPE OF ENVIRONMENTAL ASSESSMENT IS DONE PRIOR TO ROAD CONSTRUCTION? EROSION RESULTING FROM POOR ROAD LOCATION AND CONSTRUCTION IS ONE OF THE BIGGEST THREATS TO OUR RIVERS AND STREAMS

Response: All road proposals are evaluated by an interdisciplinary team during the environmental analysis to assure that erosion, mass wasting, and stream sedimentation are avoided or minimized (LRMP, Appendix F and Chapter IV, "Forest-wide Standards and Guidelines"). Engineers, hydrologists, foresters, soil scientists, geologists, and biologists who are trained to identify and understand erosion and mass wasting processes perform these evaluations. Specific mitigation measures and BMP's are designed for each project by the interdisciplinary team

Following the project analysis and public involvement phase, and before any construction, a "plan-in-hand" field review of the proposed road is made to identify and eliminate potential problems During construction, project administration and reviews continue which occasionally find items needing correction. After the road is in place, maintenance inspections, annual maintenance work, and reconstruction, if necessary, occurs. The post-construction phase also includes resource and facility monitoring and surveillance All actions contribute to the reducing actual and potential impacts of the road system on the soil and water resources.

292 *COMMENT* WHAT FACTORS WERE CONSIDERED IN THE DEVELOPMENT OF THE SEDIMENT YIELD MODEL? THE SEDIMENT YIELD MODEL APPEARS TO UNDERESTIMATE: (1) CUMULATIVE LOADING TO STREAM CHANNELS, AND (2) LONG-TERM INCREASES IN LANDSLIDE OCCURRENCE ON ROADED AND SECOND-GROWTH FOREST SLOPES AND DOWNSTREAM RIPARIAN AREAS.

Response: The sediment yield model was developed to include both natural and resource management-related surface, channel, and mass erosion The values generated by the sediment yield

model are an index of sediment production, and are not absolute amounts. They provide a basis for comparing trends between alternatives and estimating effects. Appendix B of the FEIS contains a more detailed description of how the sediment yield model was developed.

The graphs in Figures IV-1 to IV-12 of the FEIS (Chapter IV) show the average index of sediment yield per decade for the next five decades. The analysis of potential risk to beneficial uses took into account the long-term sediment yield for each alternative. The estimate of risk is based on the current condition of water quality and beneficial uses On a Forest-wide basis (FEIS, Table II-43), Alternative S is expected to have a negligible effect on current levels of water quality and the beneficial uses of water over the next five decades No decline in current fish habitat capability is expected for the Preferred Alternative.

Considering that two major floods (the 1964 flood being rated as a 100-year runoff event) occurred during the 1956 to 1976 period used for the aerial photograph inventory of natural and management-related landslides. Sediment yield due to mass erosion (landslides), therefore, is probably slightly over-estimated rather than under-estimated in the sediment yield model. In this same time frame, harvest and road construction activities were considerably different. From the late 1970's to present, major changes and shifts in logging systems, road locations, design, and construction practices, and input to all phases of an activity by a wide range of disciplines has greatly reduced the actual and potential erosion, slope failure, and stream channel impacts. The model attempts to build in the new practices (evidence indicates success), however measurements of this effort are still occurring.

293. *COMMENT* THE RELATIONSHIP BETWEEN STREAM SHADING AND SEDIMENTATION WAS NOT ANALYZED IN A HOLISTIC MANNER. THERE IS INCREASING EVIDENCE THAT ONE MAJOR EFFECT OF INCREASED SEDIMENT YIELDS IS CHANNEL WIDENING, LATERAL SHIFTING, AND THE DESTRUCTION OF RIPARIAN VEGETATION.

Response: Since the sediment yield index value for the activities proposed under Alternative S is projected to be 12 percent less than for Alternative A (Current Direction), no overall-increased channel widening, lateral shifting, and loss of riparian vegetation and stream shading is expected as a result of resource management activities on Forest-administered lands. The Riparian Prescriptions are expected to be the main variable controlling the amount of stream shading following timber harvest. Catastrophic flooding, if and when it occurs, has the greatest potential to result in the loss riparian vegetation The 1964 flood resulted in a substantial loss of riparian vegetation and major channel changes in many watersheds on the Forest. An example is the East Fork Illinois River, where stream temperatures increased several degrees Fahrenheit following the 1964 flood

However, observations of practices within the last decade do not support the hypothesis that major channel changes are occurring. The trend appears to be just the opposite, i.e., that many of the streams adversely impacted in the 1950's through mid-1970's are in a state of recovery. Nearly all channels subjected to the more current prescribed activities remain in a healthy and productive condition; adverse changes are not anticipated. In the 1980's, there has been no long-term (sustained) or major water quality problem encountered The worst cases are those associated with isolated landslides, some natural and others man-caused; even these have not been significant relative to magnitude or duration.

294 *COMMENT*. IS THERE ANY DIFFERENCE BETWEEN RIPARIAN PRESCRIPTIONS B, C, AND THE MINIMUM LEVEL IN TERMS OF REDUCING SEDIMENTATION TO STREAMS?

Response. The major difference between Riparian Prescriptions B, C, and Minimum Level in terms of sediment delivery to streams is primarily a matter of risk reduction because of varying degrees of vegetation removal (FEIS, Chapter III, "Fish"). Sediment delivery differences are not likely measurable as

the risk difference is negligible; all Prescriptions maintain a strong vegetative cover for erosion and healthy root mass for slope stability.

295. *COMMENT*: ERRONEOUS ASSUMPTIONS THAT STREAM POWER IS SUFFICIENT TO TRANSPORT SEDIMENT OUT OF MOST FOREST STREAMS (I.E. VIRTUALLY INSTANTANEOUSLY) LEAD TO GROSS UNDER-ESTIMATION OF SEDIMENTATION IMPACTS ON FISH HABITAT.

Response: Stream power on the Forest is not assumed to be sufficient to instantaneously transport sediment out of stream systems. Rather, based on the experience of Forest watershed and fish scientists, stream power in a combination of average winters and larger storm events has been sufficient to transport sediment downstream, yet maintain quality fish habitat. Forest personnel are well aware of the critical nature of lower gradient stream reaches, and the sensitivity of these to changes in sediment and water yield fluxes. The amount of sedimentation to streams is minimized by implementing Best Management Practices and Standards and Guidelines to protect water quality during all resource management activities (LRMP, Appendix F and Chapter IV). The monitoring program for fish, soil, and water outlined in Chapter V and Appendix D of the Forest Plan is designed to monitor water quality and fish habitat trends, as well as the projections made in the FEIS

296. *COMMENT*. THE RELATIONSHIP BETWEEN "AVERAGE" SEDIMENT YIELD AND INSTANTANEOUS PEAK SEDIMENT LOADING TO INDIVIDUAL STREAMS IS NOT EVALUATED PEAK SEDIMENT LOADS MAY EXERT AS SEVERE IMPACTS AS CHRONIC SEDIMENT LOADS.

Response· The estimated "average" and "peak" decade sediment yield indices shown in Figures IV-1 to IV-12 (FEIS, Chapter IV) was considered as part of the analysis of potential risk to beneficial uses Also considered were land allocations, beneficial uses of water, watershed condition, and past, present and future (anticipated) levels of management activity on National Forest lands and other ownerships.

297. *COMMENT*· A LIST NEEDS TO BE DEVELOPED THAT INCLUDES ALL AREAS THAT ARE SUBJECT TO EROSION OR ARE ALREADY ERODED. THE LIST SHOULD IDENTIFY THE LOCATION, NATURE OF THE PROBLEM, CAUSE, ESTIMATED REPAIR COSTS, AND COULD BE USED TO BUDGET AND SCHEDULE THE REPAIR AND MAINTENANCE OF THE SITES

The Forest maintains a Watershed Improvement Needs Inventory. The inventory contains a list of areas where watershed restoration work is needed. Annual programming identifies new areas requiring treatment, priorities projects, and schedules projects for accomplishment. In addition, the on-going Sale Area Improvement plans include projects identified for fish and watershed improvement or enhancement during project assessments. In extraordinary cases, such as the severely burned areas needing emergency treatment following the 1987 wildfires, special funding is requested if erosion threatens onsite and downstream soil and water resources, beneficial uses of the water, and facilities

298 *COMMENT* ARE NATURAL SEDIMENT GENERATION RATES KNOWN FOR THE FOREST, OR SPECIFIC PLANNING BASINS, SUCH THAT ALTERNATIVES COULD BE COMPARED TO THESE RATES AS WELL AS THAT OF THE CURRENT DIRECTION (A)? THIS COULD BE IMPORTANT IF SEDIMENT GENERATION IS CURRENTLY VERY HIGH RELATIVE TO NATURAL RATES IN THE REGION. IF KNOWN, THIS SHOULD BE INCLUDED IN THE FEIS

Response The natural rates (index values) of sediment yield have been provided for each Planning Basin (Chapter IV, FEIS) They are included along with sedimentation from existing roads as part of the

background sediment production of 623,000 tons/year for the Forest. This background value is an index, and represents an estimate of the amount of sediment yield from the Forest assuming no further timber harvest or road construction. It provides a basis for comparing trends between alternatives and estimating effects. Figures IV-1 to IV-12 in the FEIS show the mean (five decades) and peak decade percentage increase in accelerated sediment for each Planning Basin, by alternative. The percentages are calculated based on the background sediment yield index value for each Planning Basin, and are an index of the relative increase in sediment production over natural conditions.

Stream and River Protection

299 *COMMENT*: MANY STREAMS AND RIVERS ON THE FOREST NEED MORE PROTECTION.

Response. Responding to concerns expressed by individuals, groups, and agencies regarding values of streams and rivers, the Preferred Alternative S was developed to give more protection to fish, soil, and water quality Many suggestions made by the public were incorporated in the design of the Preferred Alternative. Under Alternative S, the total Forest area which would be managed under Management Areas 1-9 (with no programmed timber harvest) is higher than under the DEIS Preferred Alternative K (FEIS, Chapter II, "Alternative Descriptions"). Timber harvest dispersion constraints would be adjusted to include effects of adjacent landowners and the 1987 fires. Seven of the high fish-value basins would be managed under the more restrictive Riparian Prescription C, compared to one in Alternative K. Increased area would be managed as Supplemental Resource (FEIS, Chapter II, "Preferred Alternative") Standards and Guidelines and Monitoring Plans for water quality, soil protection and fish habitat have been improved to include public input (LRMP, Chapter IV, "Forest-wide Standards and Guidelines," and Appendix D). The Best Management Practices have been described in more detail to show how water quality, soil and fisheries are protected through the Forest Service's processes, procedures, activity location, design, construction, and maintenance practices, and monitoring and surveillance actions (LRMP, Appendix F).

300. *COMMENT*. PROTECTION OF WATER QUALITY THROUGH MMR'S AND STREAMSIDE MANAGEMENT UNITS (SMU's) GO FAR BEYOND THE OREGON FOREST PRACTICES ACT REQUIREMENTS. THE SISKIYOU STAFF SHOULD EXAMINE WHETHER SUCH LARGE BUFFERS ARE NEEDED FOR THE CLASS III STREAMS, IN PARTICULAR.

Response: The Forest Practices Act was not developed for application to lands with a multiple-use mandate. Neither the Forest Service Memoranda of Understanding with the States of Oregon and California or the definition of Best Management Practices prevents the Forest Service from prescribing land treatment which is more restrictive than the Forest Practices Act or minimum requirements for the protection of water quality. The specific BMP's selected by the Forest Service may be more restrictive where the objective is to improve water quality or minimize risk. Basic to the Memoranda of Understanding, the Forest Service has agreed to meet or *exceed* (emphasis added) those requirements imposed by the Forest Practices Act. In keeping with the principles and guidelines contained in the NFMA and implementing regulations, to provide greater protection for a multitude of benefits other than just achieving water quality standards is well within the Agency's mission to best manage public lands for all.

The Riparian Area prescriptions for Class III streams subject to management (termed Streamside Management Units, or SMU's) have been established as a result of recent project activity, SMU inventory, and monitoring. Monitoring will continue during implementation of the Forest Plan to better define the actual SMU widths, degree of harvest (basal area removal), and streamside vegetative cover within the Riparian area (LRMP, Chapter V, "Monitoring and Evaluation Program"). Field measurements will be evaluated against the management objectives for the Riparian ecosystem to determine whether they have been achieved or not. If the objectives have been met, the data will then be used to adjust or modify the

modeling assumptions and Standards and Guidelines (LRMP, Chapter IV). SMU width, effective canopy cover (stream shade), basal area removed, and other land, fish, and water parameters will be specifically tracked

301. *COMMENT.* CONSTRUCTION OF ROADS AND BRIDGES WHICH CROSS RIPARIAN ZONES SHOULD BE ACCOMPLISHED IN A WAY THAT WILL NOT HARM FISHERIES, WATER QUALITY OR STREAM CHARACTER. BIOLOGISTS NEED TO BE DIRECTLY INVOLVED TO INSURE PROTECTION OF INDIGENOUS SPECIES

Response: Biologists have for some time determined the periods in which construction can be permitted in fish-bearing streams Several specialists, such as geologists, hydrologists, and biologists provide input into the location, design, construction, and maintenance of stream-crossing structures during project planning and where existing structures pose problems. To minimize potential adverse impacts, inspectors at the site can shut down a project in which the work activity causes unacceptable turbidity in the stream or improperly changes the character of the stream These actions are supported by Riparian Management Area Standards and Guidelines MA11-3, MA11-6, and MA11-9, and supported by Forest-wide Standards and Guidelines 7-10 and 11-2 (LRMP, Chapter IV, "Management Prescriptions").

302. *COMMENT*: THE PRACTICE OF INTENSE MANAGEMENT FOR A SHORT DISTANCE THAT MIGHT CROSS THROUGH A CLEAR CUT UNIT IS A VERY NARROW APPROACH TO STREAM MANAGEMENT INCLUDE THE TOTAL STREAM IN POLICIES. THE FOREST SERVICE, IN CONJUNCTION WITH THE FISH AND GAME DEPARTMENT, SHOULD TARGET PROBLEM AREAS THAT ARE DETRIMENTAL TO A HEALTHY AQUATIC COMMUNITY

Response. Under the Preferred Alternative, management of Forest streams is designed to maintain or enhance aquatic habitats (FEIS, Chapter II, "Preferred Alternative"). Specific management of streams that are adjacent to harvest areas follow guidelines set forth in the Standards and Guidelines (LRMP, Chapter IV). Basin-wide Riparian Prescriptions B and C consider net impacts to the entire basin Streamside Management Unit Prescriptions (SMU'S) that are written for every harvest unit and other activity near Class 1, 2, 3, and 4 streams take into account the possible effects on stream habitats, including on-site, upstream and throughout the system below, that could occur. Prescriptions are designed to minimize effects not only in areas immediately adjacent to the harvest unit, but both down and upstream as well

Throughout the planning process, the Siskiyou National Forest has worked with the public and the Oregon Department of Fish and Wildlife biologists to help identify key stream areas that are important for salmonids. As a result of this process, we have included nearly all of the more productive salmonid fish sites in specially-designated areas under the Preferred Alternative (FEIS, Chapter II, "Preferred Alternative") In locations where there have been problems associated with past activities, these streams have management designations that are anticipated to improve current conditions. In more critical situations or where water quality problems are more pronounced, the Environmental Protection Agency and State Department of Environmental Quality have aided in interpretation and analysis of effects, and suggested measures to mitigate potential impacts.

303 *COMMENT* FROM THE MAP, ONLY ABOUT 100 FEET OF PROTECTION APPEARS TO HAVE BEEN GIVEN TO SOME AREAS, E G , THE WEST BANK OF THE NORTH FORK SMITH RIVER AS A SUPPLEMENTAL RESOURCE AREA A WIDER AREA OF PROTECTION SEEMS MORE APPROPRIATE.

Response· The Supplemental Resource area along the west bank of the North Fork Smith River may appear narrow on the map, but actually extends for approximately 1/8 mile (660 feet) from the water's edge,

as do other areas managed as Supplement Resource Areas (LRMP, Chapter IV, "Management Prescriptions"). Larger Class I and II streams and rivers, if they do not have other special Management Area allocations, are provided protection through the Riparian Prescription. The width of protection in these cases extends on the average 150-feet horizontal distance from the stream bank.

304. *COMMENT*: THE FOREST SERVICE MAY NOT BE ABLE TO MEET STATE WATER QUALITY STANDARDS. OF PARTICULAR CONCERN WAS THE STATE'S ANTIDEGRADATION POLICY FOR HIGH QUALITY WATERS. MANY OF THE RIVERS IN THE FOREST ARE HIGH QUALITY WATERS THE FEIS SHOULD ADDRESS IN DETAIL COMPLIANCE WITH THE STATE'S ANTIDEGRADATION POLICY. FOR WILD AND SCENIC RIVERS, THE ANTIDEGRADATION POLICY OF THE WATER QUALITY STANDARDS REGULATIONS EXPLICITLY PROHIBITS ANY LOWERING OF WATER (40 CFR SECTION 130.12).

Response. Standard and Guideline 7-14 in Chapter IV of the Forest Plan requires compliance with State requirements in accordance with the Clean Water Act for protection of waters of the State of Oregon and California through planning, application, and monitoring of Best Management Practices (BMP's) This includes compliance with the requirements of the State's Anti-degradation policy. The process for implementing Best Management Practices (BMPs) contained in Appendix F of the Forest Plan and the General BMP's listed and described in *General Water Quality Best Management Practices*, Pacific Northwest Region, 11/88, are designed to maintain water quality and the associated beneficial uses of the water. The water quality and fish habitat monitoring program described in Chapter V and Appendix D of the Forest Plan will be used to evaluate both the implementation and effectiveness of the BMP's, as well as compliance with State requirements in accordance with the Clean Water Act.

Proposed activities that cannot be appropriately mitigated to meet the established water quality standards will have to be either reanalyzed with new recommendations, deferred, or dropped from consideration Active projects, if they are not meeting either requirements imposed by the BMP's or as measured against the water quality standard(s), will likewise be halted or corrected

Wild and Scenic Rivers

305 *COMMENT*: THE NORTH FORK SMITH, CHETCO AND ELK RIVERS SHOULD/SHOULD NOT MERIT MORE PROTECTION AND BE DESIGNATED AS WILD AND SCENIC RIVERS.

Response: The Omnibus Oregon Wild and Scenic Act of 1988 was passed by Congress and signed by the President The Act includes designation of the Elk, Chetco and North Fork Smith Rivers.

306. *COMMENT*: DETAILED SUITABILITY STUDIES SHOULD BE CONDUCTED FOR ALL ELIGIBLE RIVER SEGMENTS. THOSE ALREADY IDENTIFIED IN THE PLAN AND THOSE WHICH MAY BE IDENTIFIED THROUGH ANALYSIS OF SUCH OTHER STUDIES AND INVENTORIES AS THE PACIFIC NORTHWEST RIVERS INVENTORY.

Response: The DEIS did provide an evaluation (Appendix E) of the "suitability" of the rivers inventoried in the National Park Service's Northwest Rivers Study. As a result of changes in criteria and public input into the DEIS, several other rivers not included in the rivers study were also examined for "eligibility" during the summer of 1988. A summary of this evaluation is discussed in the FEIS, Chapter III, "Wild and Scenic Rivers " The study is in the Planning Records, Forest Supervisor's Office. Of the potential rivers, Elk River was determined to be eligible and received an interim classification.

307. *COMMENT*. THE CORRIDOR OF THE ILLINOIS RIVER SHOULD BE LEFT ALONE, BUT THE RIVER SHOULD NOT BE DESIGNATED AS A WILD RIVER. THE ILLINOIS RIVER HAS ALMOST NO WATER IN IT DURING THE SUMMER MONTHS, PROBABLY DUE TO CLEAR CUTTING LARGE AREAS OF THE DRAINAGE WATER IMPOUNDMENT PROJECTS WOULD DO MORE FOR OUR AREA THAN THE PRESENT DESIGNATION ALLOWS. IT COULD KEEP THE WATER LEVELS UP FOR FISH, RAFTS, IRRIGATION, AND MAYBE A FEW BOATS AND PEOPLE ON THE LAKES THAT WOULD THEN EXIST.

Response· The Illinois River was designated by Congress as Wild and Scenic in 1984. The implementation of the LRMP will have no effect on the designation or classification.

The Forest has recognized that the Wild section of the Illinois River is perhaps the most pristine in the western United States (FEIS, Chapter III, "Wild & Scenic Rivers"), and for that reason the river is unique. There are virtually no human caused intrusions to the river corridor from Pine Flat to Nancy Creek The focus of management is to retain the undisturbed character of the lands within and adjacent to the Wild section of the Illinois, including the area outside of the Wilderness between Silver and Nancy Creeks (LRMP, Chapter IV, "Management Prescriptions").

Low water in the summer months is attributed to the lack of rainfall and to private landowners in the Illinois Valley who draw water off the River for irrigation and domestic purposes. Impoundment of any section of a designated river, Wild, Scenic, or Recreation, is prohibited by law (Wild and Scenic Rivers Act, 1984). However, the Forest, State, and other Federal agencies recognize several potential reservoir sites in principal tributaries of the Illinois River above Illinois Valley. If developed, these reservoirs could substantially benefit fishery, wildlife, recreation, and other uses affected by the severe dewatered conditions experienced downstream in both the Illinois Valley and River.

Water Quality/Quantity

308 *COMMENT*: DOMESTIC WATER RESOURCES MUST BE IDENTIFIED AND PROTECTED, E G , CITY OF BROOKINGS.

Response: The Forest goal identified in Chapter IV of the Forest Plan is to meet or exceed State and Federal requirements which provide protection to the water resources on the Forest Table III-9 in the FEIS identifies the key municipal water supplies on the Forest The numerous individual domestic water uses are taken into account through the the Forest's stream classifications and during project planning The stream classification system is briefly described in Chapter III ("Soil and Water") of the FEIS. Each Ranger District is familiar with local domestic water use, and can work with County agencies to identify downstream users in case of an emergency.

Under Alternative S, the current level of water quality and beneficial uses will be maintained or improved. The process for implementing Best Management Practices (described in Appendix F, and the Monitoring Plan in Chapter V and Appendix D of the Forest Plan) will ensure protection of domestic water supplies, including the City of Brookings and Harbor water supply taken from the lower reach of Chetco River.

309. *COMMENT*: THERE ARE SEVERAL MUNICIPAL WATERSHEDS IN THE SISKIYOU NATIONAL FOREST. ARE THESE UNFILTERED SURFACE WATER SUPPLIES? UNDER AN EPA PROPOSED RULE AS REQUIRED BY THE 1986 AMENDMENTS TO THE SAFE DRINKING WATER ACT, AN AGREEMENT MUST BE REACHED WITH THE FOREST SERVICE THAT WOULD ALLOW THE MUNICIPALITIES TO HAVE WATERSHED CONTROL IN ORDER FOR THEM TO CONTINUE TO USE THESE SOURCES WITHOUT FILTRATION.

Response: The municipal supply watersheds listed in Table III-9 of the *Soil and Water* element of the FEIS are either filtered or are indirect gravel-filtered water supplies drawn from stream alluvium. The season of use is also shown in the table. Intakes for the Brookings, Powers, and Cave Junction water supplies are downstream from the Forest boundary. The winter supply for Powers, however, comes from sources other than the National Forest

310. *COMMENT*: THE PROCESS FOR MANAGING FOREST ACTIVITIES IS NOT SUFFICIENTLY EXPLAINED TO ASSURE THAT ADVERSE ENVIRONMENTAL EFFECTS, PARTICULARLY TO WATER QUALITY, WILL BE PREVENTED. MORE FULLY DESCRIBE THE MANAGEMENT PROCESS OF THE SISKIYOU NATIONAL FOREST.

Response: In response to public input, Appendix F has been added to the Forest Plan to describe the process to be used for implementing Best Management Practices (BMPs) for all resource management activities on the Forest. The BMPs are designed to maintain the downstream beneficial uses of the water. Each General BMP is described in *General Water Quality Best Management Practices*, Pacific Northwest Region (1988). Each General BMP consists of a title, objectives, explanation, implementation and responsibility, and monitoring. The Siskiyou National Forest BMP's are evaluated for their Forest-wide effectiveness which covers a narrowed range of conditions and practices The ability to implement, effectiveness, and more specific monitoring for each BMP is most appropriately identified at the project level.

311. *COMMENT*: BEST MANAGEMENT PRACTICES MUST BE PART OF THE FOREST PLAN FAILING TO INCLUDE THESE DIRECTIONS WOULD BE A VIOLATION OF NFMA AND NEPA.

Response: A new appendix has been added to the Forest Plan to describe Best Management Practices (LRMP, Appendix F) in addition to the reference to and application of the existing set of Standards and Guidelines (LRMP, Chapter IV).

312. *COMMENT*: THE PLAN SHOULD SPECIFY AT WHAT STEP IN THE PROCESS THE BMP'S FOR INDIVIDUAL TIMBER SALE UNITS WILL BE IDENTIFIED AND SPECIFIED. IT HAS BEEN STAFF EXPERIENCE THAT THIS NEEDS TO OCCUR IN THE PROJECT LEVEL ENVIRONMENTAL ASSESSMENTS TO HELP ENSURE ADEQUATE FIELD IMPLEMENTATION.

Response: Appendix F (Best Management Practices) of the Forest Plan and General Water Quality Best Management Practices (Pacific Northwest Region, 11/88) describe the process for project-level implementation of BMP's.

313 *COMMENT*: THE DEIS RECOGNIZES APPROVED BEST MANAGEMENT PRACTICES AS A MEANS TO ACHIEVE AND MAINTAIN WATER QUALITY GOALS. THE PLAN SHOULD ALSO RECOGNIZE THAT THE STATE OF CALIFORNIA AND FEDERAL WATER QUALITY STANDARDS ARE THE NORTH COAST BOARD'S BASIN PLAN WATER QUALITY OBJECTIVES AND WASTE DISCHARGE PROHIBITIONS.

Response: The State of California's Porter-Cologne Water Quality Control Act and North Coast Board's Basin Plan are now referenced in Chapter IV ("Forest-wide Standards and Guidelines") and Appendix F (Best Management Practices) of the Forest Plan.

314 *COMMENT* NEEDED INFORMATION IS LACKING IN THE DEIS ON BASELINE WATER QUALITY CONDITIONS FOR INDIVIDUAL STREAMS AND THE EFFECTS OF PLANNED FOREST ACTIVITIES ON THOSE STREAMS

Response: Tables III-12 and III-21 of the FEIS show the baseline water quality conditions related to the beneficial uses of water for each Planning Basin. The potential risk of planned Forest activities on the current level of water quality and beneficial uses for each Planning Basin and alternative is described under "Soil and Water" and "Fish" in Chapter IV of the FEIS.

315. *COMMENT*: THE DEIS RECOGNIZES THAT THE FOREST LANDS PROVIDE A MAJORITY OF WATER FOR DOWNSTREAM USERS, BUT FAILS TO MENTION THAT MINIMUM STREAMFLOWS HAVE BEEN ESTABLISHED ON MANY STREAMS IN THE AREA. ALL AREAS WITH MINIMUM STREAMFLOWS SHOULD BE PROTECTED. ANY FOREST ACTIVITY THAT WOULD PRODUCE ADVERSE EFFECTS TO THE WATERSHED SHOULD BE AVOIDED AND OR MITIGATED.

Response: Chapter III ("Soil and Water") of the FEIS states that minimum streamflows have been established in the State of Oregon Water Resources Department's Rogue River and South Coast Basin Study/Plans. The Forest has been a cooperator in the evaluation and selection of the numerous streams on or affected by National Forest System lands. The Standards and Guidelines and Best Management Practices are designed to ensure that the beneficial uses of water on the Forest are protected

316 *COMMENT*: HARVESTING TIMBER COULD REDUCE WATER YIELD IN PROPORTION TO THE AMOUNT OF TIMBER HARVESTED

Response The Environmental Effects Unchanged by Alternatives, Chapter IV of the FEIS, describes why there is normally a small increase in water yield expected following timber harvest. The additional water produced by timber harvest is very small, and declines with time as the harvested areas reforest. Research is not as clear as to specifics of long-term water yield changes resulting from timber harvest, or whether 20 to 100-year-old conifer trees transpire more water than slower growing mature trees.

The dispersion of timber harvest across the Planning Basins should help to ensure that timber harvest is not concentrated in any watershed, thereby reducing the potential for any measurable changes in low or peak flows. Table II-5 indicates that no significant difference occurs in water yield changes between alternatives, and especially when compared to the current situation represented in Alternative A.

317. *COMMENT*: THE PLAN DOES NOT ACCOUNT FOR THE EFFECTS OF POSSIBLE INCREASES IN WINTER PEAK FLOWS AND DECREASES IN SUMMER LOW FLOWS ON STREAM HABITAT, FISH PRODUCTION, AND DOWNSTREAM RIPARIAN LANDS.

Response The section of Chapter IV of the FEIS, Environmental Effects Unchanged by Alternatives, describes why there is no expected increase in winter peak flows or decrease in summer flows for the resource management activities proposed under the Preferred Alternative.

318 *COMMENT*: NO DISCUSSION ON GROUNDWATER WAS FOUND IN THE DEIS. SINCE THIS IS AN IMPORTANT RESOURCE IN THE AREA, THE FOREST SERVICE SHOULD INFORM THE WATER RESOURCES DEPARTMENT OF ANY POTENTIAL GROUNDWATER PROBLEMS ENCOUNTERED

Response: A brief discussion of groundwater has been included under the "Soil and Water" section of Chapter III of the FEIS. Research on effects of Forest Management on water quality does not indicate

ground water problems are likely to result. Further, except for extremely localized problems of developing water sources for National Forest System purposes, few people or other agencies have addressed the subject as either a concern or problem. Little input exists to suggest that further discussion is necessary

319. *COMMENT*: CLEARCUTTING DESTROYS THE LITTLE AQUIFERS THAT LET THE RAIN SEEP INTO SUBTERRANEAN AQUIFERS. THIS RESULTS IN HEAVIER RUNOFF WHEN IT RAINS WITH A HIGHER RATE OF FLOODING IN THE WINTER.

Response: The Standards and Guidelines for Soil and Water described in Chapter IV of the Forest Plan and the General Best Management Practices (Pacific Northwest Region, 11/88) are designed to ensure that the hydrologic function of the watershed is maintained. Protecting soil cover and structure will maintain the high natural infiltration rates of forest soils on the Forest. Peak winter flows are not expected to be increased as a result of the resource management activities proposed under Alternative S. The scenario, as described, is not supported by research, administrative studies, or hydrologic principals. Only where the hydrologic cycle and soil functioning has been severely damaged would such events occur.

320. *COMMENT*: THE HYDROPOWER RESOURCES ON THE FOREST SHOULD BE DISCUSSED IN THE WATER RESOURCES SECTION. THE EXISTING POWER CLAIMS ON THE FOREST SHOULD BE LISTED AS WELL AS THE CONDITIONS UNDER WHICH DEVELOPMENT COULD OCCUR. AS PART OF THAT SECTION, THE HYDROPOWER RULES AND BASIN PROGRAM HYDRO RESTRICTIONS NEED TO BE ADDRESSED.

Response: Hydropower resources are discussed under the "Energy" and "Improvements" sections of Chapter III of the FEIS. A discussion of hydropower sites is included in the Current Demands, Wants, and Desires subpart of "Energy" in Chapter III A listing of the individual sites might serve a special interest or need for the commentor, but would not add substance to the FEIS. A listing of sites could be provided upon request The number of operating hydropower facilities and demand for additional sites is quite limited

The criteria or conditions for hydropower development are described in the Standards and Guidelines, Chapter IV of the Forest Plan. Site-specific criteria or conditions would be developed as part of the environmental analysis for a specific proposal Evaluation of specific proposals would include an analysis of whether the proposed project would be in compliance with the Water Resources Department's administrative rules for hydropower development (OAR 690-74).

Water Temperature

321. *COMMENT*: STREAM TEMPERATURE/CANOPY COVER OBJECTIVES SHOULD BE IMPLEMENTED BUT NOT BY A FIXED MINIMUM BUFFER WIDTH AND MINIMUM BASAL AREAS

The stream temperature goal contained in the Standards and Guidelines for Management Area 11 - Riparian (Chapter IV, Forest Plan) is to at least maintain current water temperatures in all Planning Basins. The width of the SMU specified in the Standards and Guidelines is a guide. The actual width may vary depending on resource protection needs identified at the project level by an interdisciplinary team The basal area specified in the Standards and Guidelines is the amount estimated to be necessary to meet effective canopy or stream shading requirements. It also helps ensure that enough conifers are retained in the riparian zone to provide a potential long-term source of large woody material for the stream and wildlife habitat needs.

322. *COMMENT*: PORTIONS OF ALL NINE MAJOR RIVERS HAVE HIGH SUMMER WATER TEMPERATURES. THE SMOLT REARING CAPABILITY IN 18 OF THE 19 PLANNING BASINS HAS BEEN REDUCED FROM 5 PERCENT TO 20 PERCENT BECAUSE OF TEMPERATURE PROBLEMS. HOW WILL MANAGEMENT ACTIVITIES UNDER THE PREFERRED ALTERNATIVE RESPOND TO WATER TEMPERATURES IN THESE BASINS?

Response: In the Preferred Alternative, seven of the 19 Forest Planning Basins would be managed with Riparian Prescription C designed to reduce summer water temperatures up to two degrees Fahrenheit over time (the next three decades). The remaining basins will be managed to maintain existing summer water temperatures as a minimum. The Riparian widths are expressed as a minimum area of consideration. On-site conditions may in certain cases show that wider areas are necessary to maintain or enhance fish habitat capability and water quality (FEIS, Chapter IV, "Management Prescriptions, Management Area 11 - Riparian"). Likewise, site conditions may indicate that the 100- or 150-foot widths are in excess of the riparian needs.

Certain Forest streams are given additional protection through allocations to Supplemental Resource which further maintain or enhance their high water quality and fish habitat values. In addition to the Riparian and Supplemental Resource areas and prescriptions, other stream protection aspects also apply. Some of the more significant of these include: (1) Allocation to Management Areas 1-9 which have no programmed timber harvest (FEIS, Chapter II, "Alternative Descriptions, Alternative S"); (2) Standards and Guidelines which are either directly or indirectly complementary to soil, water and fish habitat values; (3) Basin timber harvest constraints beyond MR levels (LRMP, Chapter IV); and, (4) Application of Best Management Practices (LRMP, Appendix F).

323. *COMMENT*: IN THE DEIS, ALTERNATIVE K ASSIGNS PRESCRIPTION B TO THE EAST FORK ILLINOIS RIVER BASIN RIPARIAN AREAS. THIS PRESCRIPTION WILL CAUSE A SIGNIFICANT INCREASE IN THE BASIN'S STREAM TEMPERATURES AND NEGATIVELY IMPACT THE BASIN'S FISH HABITAT AND POPULATIONS. ASSIGN THE MINIMUM LEVEL PRESCRIPTION WHICH RETAINS EXISTING STREAM SHADING TO THIS BASIN

Response: The purpose of Riparian Prescription B when applied to Stream Management Units (SMU's) at the project level is to, as a minimum, maintain existing summer water temperatures (LRMP, Chapter IV, "Management Prescriptions"). Only about 60 percent of the National Forest lands in the East Fork of Illinois River Basin are tentatively suitable for timber production. Much of the East Fork Basin would be managed as Wilderness, Designated Wildlife Habitat, or Backcountry Recreation Management Areas which have no programmed timber harvest in Alternatives G, K, M and S.

Cumulative Effects

324. *COMMENT*. CUMULATIVE EFFECTS OF SEDIMENTATION ON FISH HABITAT FROM PRIVATE LANDS (AGRICULTURAL, INDUSTRY AND RESIDENTIAL) OUTSIDE THE FOREST BOUNDARIES ARE NOT ADDRESSED. ALSO, STREAMS LYING PARTIALLY OUTSIDE NATIONAL FOREST BOUNDARIES MAY SUFFER FROM ON-FOREST ACTIVITIES BECAUSE THEY HAVE BEEN EXCLUDED FROM IMPACT ANALYSIS. A CUMULATIVE EFFECTS ANALYSIS MUST BE DONE FOR EACH PLANNING BASIN

Response: Chapter IV ("Fish") of the FEIS addresses the potential risk for on- and off-Forest cumulative effects as well as those of roading and harvest of private and Forest lands in multiple-ownership watersheds for each Planning Basin. The discussion under "Soil and Water" of Chapter IV (FEIS)

summarizes the potential risk for cumulative effects by alternative. Site-specific planning may require a cumulative effects analysis (LRMP, "Forest-wide Standards and Guidelines").

The harvest dispersion constraints for each Planning Basin were developed by analyzing past, current, and future management activities, multiple ownerships, geologic hazard, recovery potential, beneficial uses, and watershed and channel conditions. The past and projected level of harvest and roading on other lands in multiple-ownership watersheds was analyzed. The assumptions used to develop the harvest dispersion constraints are described in more detail in Appendix B of the FEIS. The monitoring program in Chapter V and Appendix D of the Forest Plan is designed provide the information need to verify the effectiveness of the harvest dispersion constraints for each Planning Basin, and the second level of harvest dispersion for Watershed Analysis Areas (LRMP, Forest-wide Standard and Guidelines). National Forest activities are not anticipated to affect the opportunity for other landowners to manage their lands in multiple-ownership watersheds, or result in adverse cumulative effects on and off-Forest.

325. *COMMENT*: THE POTENTIAL CUMULATIVE EFFECTS OF CONCENTRATING TOO MUCH HARVESTING IN ANY ONE WATERSHED IS A CONCERN. A RISK ANALYSIS OF THE CUMULATIVE IMPACTS INCLUDING THE EFFECTS AND PROBABILITIES OF MAJOR EROSION-TRIGGERING STORM EVENTS IS SUGGESTED.

Response Dispersing timber harvest activities over space and time is one fundamental method used in reducing the potential for cumulative impacts on soil, water, and fisheries. Timber harvest is limited to no more than 20 percent of each Planning Basin as a Management Requirement applicable to all alternatives except Alternative NC (FEIS, Appendix J, "Water Quality Management Requirements").

In addition, the Preferred Alternative S is designed using timber harvest dispersion constraints specific to conditions of each Planning Basin Factors in developing these included analysis of past, current, and future management activities; multiple ownerships; geologic hazard; recovery potential; beneficial uses; and watershed and channel conditions. The past and projected level of harvest and roading on other lands in multiple-ownership watersheds was analyzed (FEIS, Appendix B).

Table II-3 (Special Area Assignments) of the FEIS identifies the harvest dispersion constraint for each of the 19 Planning Basins. They were developed to prevent concentrating too much timber harvest in any one Planning Basin during a decade. The harvest dispersion constraint is applied to the total area of Management Areas 10-14 within each Planning Basin The process for developing the harvest dispersion constraints is described in Appendix B of the FEIS.

The second level of harvest dispersion is for smaller watersheds (Watershed Analysis Areas) of about 500 to 2,500 acres in area Standard and Guideline 7-15 in Chapter IV of the Forest Plan describes the requirements for project-level cumulative effects assessments for the Watershed Analysis Areas. A more detailed analysis must be done if timber harvest is proposed for more than 20 percent of a Watershed Analysis Area.

The analysis of the potential risk to the beneficial uses of water described in "Fish" (FEIS, Chapter IV) took into account the probability of cumulative effects resulting from resource management activities and major erosion-triggering storms

326. *COMMENT*: THE SISKIYOU NATIONAL FOREST DEIS AND FOREST PLAN FAIL TO ADDRESS CUMULATIVE EFFECTS CREATED BY SEPARATELY MANAGED RIPARIAN AREAS.

Response: Appendix B of the FEIS briefly describes the stream temperature modeling done for the Forest Plan. Riparian Prescriptions B and C were developed as a result of modeling stream temperatures in seven

Planning Basins. The analysis modeled both the removal of riparian shading within each Planning Basin, as well as regrowth of riparian vegetation in areas harvested in the past.

The goal of both Riparian Prescriptions is to at least maintain the stream temperature in all Planning Basins. The monitoring plan in Chapter V and Appendix D of the Forest Plan describes the monitoring to be done to verify the effectiveness of the Riparian Prescriptions and validate the assumptions made in the cumulative effects analysis. No cumulative effect on stream temperature created by separately managed riparian areas is expected

327. *COMMENT:* THE PLAN FAILS TO MENTION WHAT CUMULATIVE IMPACTS ARE UNACCEPTABLE THE MONITORING PROGRAM FOR CUMULATIVE IMPACTS IS INADEQUATE

Response: Chapter IV of the FEIS ("Fish") has been expanded to address the potential risk for on- and off-Forest cumulative effects, as well as those of roading and harvest of private and National Forest lands in multiple-ownership watersheds for each Planning Basin. The Monitoring Plan for fish, soil and water (LRMP, Chapter V and Appendix D) has also been expanded The Monitoring Plan is designed to ensure that Standards and Guidelines are met (LRMP, Chapter IV, "Forest-wide Standards and Guidelines").

Fish Habitat

328. *COMMENT.* MORE SHOULD BE DONE TO PROTECT FISHERIES. RIPARIAN ZONES SHOULD BE WIDER (1/4-1/2 MILE) TO PROTECT FISH AND WILDLIFE WITH NO LOGGING ALLOWED.

Response: In response to public input from individuals and agencies, the Preferred Alternative is specifically designed to manage Riparian areas for the benefit of salmonid fish habitats Seven out of 18 basins will have Riparian Prescription C designed to reduce temperatures and more fully protect the integrity of riparian areas. All seven are important salmonid producing basins (LRMP, Chapter IV, "Management Prescriptions"). Supplemental Resource areas have been designated along streams that have a high potential for adverse watershed impacts within the inner gorge and contain high-valued fish habitat. A combination special Management Areas with constrained or no programmed harvest border nearly all important salmonid producing streams; these land allocations include Partial Retention and Retention Visual, Designated Wildlife Habitat, Special Wildlife Site, Botanical, Wilderness, and Backcountry Recreation among others. For the most part, each of these special allocations extends at least 1/8 mile away from the streams.

The width of Riparian area and the amount of timber removed from those zones is determined during the environmental analysis process for individual timber sales. The Standards and Guidelines specify the minimum width of consideration and the maximum amount of shade canopy removed.

329 *COMMENT:* FISH HABITAT IMPROVEMENT PROJECTS SHOULD NOT BE USED AS MITIGATION FOR DAMAGE RESULTING FROM POOR MANAGEMENT. THE EFFECTIVENESS, BENEFITS AND COSTS OF ENHANCEMENT NEEDS TO BE ANALYZED.

Response: Fish enhancement is *not* designed simply to mitigate "poor" management. None of the alternatives will degrade salmonid habitat capability below the conditions prior to implementing the Forest Plan (FEIS, Chapter II, "Fish"). The Forest goal is to maintain or enhance water quality and fish habitat (LRMP, Chapter IV, "Forest Goals") The Preferred Alternative S was carefully designed to maintain and, in many areas, enhance water quality and fish habitat (FEIS, Chapter II, "Preferred Alternative").

Mitigation is a key element in the design of any alternative as described in the "Introduction" to Chapter IV, FEIS. Mitigation under the Preferred Alternative S includes managing land under restrictive Management Areas which have no programmed timber harvest, such as Supplemental Resource areas along important fish-producing streams. It includes the application of more stringent Riparian management direction -- seven of the most important salmonid basins on the Forest will have Riparian Prescription C (LRMP, Chapter IV, "Management Prescriptions"). Streamside Management Unit (SMU) prescriptions that are part of the environmental analysis for each timber sale or other activity are specified on-site, and are intended to minimize impacts to streams (LRMP, Chapter IV, "Forest-wide Standards and Guidelines")

Capital investments are planned to improve fish habitat. In some cases, they are planned to rectify old problems created by past activities such as closing roads to reduce sediment from erosion, replacing culverts with bridges to allow upstream passage, or stabilization of erosive slopes. In most cases, capital investments for fish improvement projects are designed to enhance existing habitat conditions or to create even more productive sites. An example of this work includes riparian planting to promote stabilization of naturally-occurring landslide areas or increase shade canopy to lower stream temperatures.

Actual benefits and costs associated with fisheries enhancement techniques are extremely variable considering individual stream and Planning Basin differences such as existing salmonid habitat of streams, geology, access, ability to perform work, etc Fish enhancement projects have been proven successful on the Forest An "Inventory of Fish Project Work" (1988; Planning Records) evaluated over 900 instream structures which had been installed from 1985-1987. Eighty-one percent of these are in place and meeting original design objectives

330 *COMMENT*: THE CAPITAL INVESTMENTS DISCUSSING SALMONID CAPABILITY IMPROVEMENTS NEED TO BE SPECIFICALLY DEFINED.

Response: Fish habitat capabilities have been enhanced through capital investment projects on nearly all the Planning Basins. The majority of instream fish habitat enhancement work involves rearing pool development or adding cover to existing pool areas to benefit juvenile anadromous or resident salmonids See the FEIS, Chapter III, and the LRMP, Appendix B (Table B-3) for more information regarding fisheries capital investments and activities.

331. *COMMENT*: FISH HABITAT IMPROVEMENT PROJECTS SHOULD BE PROHIBITED (OR HELD TO A MINIMUM) IN WILDERNESS AREAS.

Response. In response to public concern about structures in Wilderness, this has been changed in the Forest Plan (LRMP, Chapter IV, "Management Prescriptions"). No capital investments are planned for streams in Wilderness.

332. *COMMENT*: THE FOREST SERVICE SHOULD EXPLAIN FURTHER THE CRITERIA FOR INCLUDING OR EXCLUDING AREAS FROM THE SUPPLEMENTAL RESOURCE ALLOCATION.

Response: An explanation of criteria used in considering managing lands as Supplemental Resource Management Areas has been expanded in the FEIS, Chapter IV, "Fish." Factors influencing the choice of these areas were water quality, salmonid rearing capability, soil and geologic risk (i e., potential risk to soil and water elements), and associated values in this environment (notably thermal cover for wildlife, outstanding scenery or unique features, and higher valued recreation sites and trails). The Supplemental Resource area designation provides important protection of fish habitat in inner gorge areas (FEIS, Chapter II, Management Area 7).

333 *COMMENT*. ALLOWABLE ACTIVITIES WITHIN SUPPLEMENTAL RESOURCE AREAS NEED TO BE DESIGNED TO PROTECT FISHERIES.

Response: The primary consideration within Supplemental Resource areas is to manage the sensitive inner gorge environment for the protection and enhancement of fish and wildlife habitats Activities within the inner gorge areas would be designed by an interdisciplinary team through the NEPA process. Management Goals, Desired Future Condition, and Standards and Guidelines for Supplemental Resource areas are explained in LRMP IV, Management Area 7,Supplemental Resources

334 *COMMENT*: A MAJOR HABITAT REHABILITATION PROGRAM SHOULD BEGIN IMMEDIATELY TO OPTIMIZE THE NATURAL PRODUCTION CAPABILITIES OF THE CHETCO BASIN. IT WOULD BE ONE OF THE BEST INVESTMENTS FOR LONG-TERM BENEFITS.

Response: Fish habitat and mitigation is an important and very active part of the Siskiyou Forest resource program In cooperation with the Oregon Department of Fish and Wildlife, the Forest completed a "Chetco River Basin Anadromous Salmonid Habitat Overview." This document outlines fish population status, habitat description and limiting factors, habitat improvement objectives and opportunities, and habitat improvement priorities. Major salmonid habitat enhancement work in the Chetco River basin was initiated in 1987 by the Forest

335. *COMMENT*: FISHERIES DESERVE SPECIFIC FISHERIES MANAGEMENT PLANS.

Response· The concern for development of long-range management plans is shared by Forest personnel A Fisheries Management Plan is currently being developed on the Forest. Reinventory of the existing habitat and fish populations using the Hankin and Reeves method is occurring (LRMP, Appendix D) The inventory procedure will allow the Forest to better quantify changes in habitat condition and fish populations over time.

The new "Rise to the Future" Fisheries Program represents National emphasis on strengthening the fisheries program (LRMP, Chapter II, "Resource Summaries"). Forests in Region 6, including the Siskiyou, are currently in the process of developing long-term fisheries program management plans in cooperation with the State, other Federal agencies, sportsman's clubs and the public. Forest plan development offers guidance for development of Fisheries Management Plans.

336. *COMMENT*: ESTABLISH EXPERIMENTAL SECTIONS ON IMPORTANT SPAWNING RIVERS TO ENCOURAGE THE DEVELOPMENT OF KNOWLEDGE CONCERNING THIS RESOURCE.

Response· Fisheries research on the Forest is conducted by the Pacific Northwest Experimental Station. In coordination with Siskiyou National Forest and Oregon Department of Fish and Wildlife personnel, they are currently working in the Elk River basin, an important system for anadromous salmonids. An intensive fish habitat and population study is being conducted by Siskiyou personnel in Sucker Creek, a tributary of the South Fork Coquille River, to monitor the effects of habitat enhancement projects Much of the monitoring planned will be coordinated with the research scientists (LRMP, Appendix D). Further research needs are identified in the Forest Plan (LRMP, Chapter II, "Information Needs").

337. *COMMENT* PRESENTLY FISH ARE TREATED ONLY AS A COMMODITY IN THE PLAN, WITH NO INHERENT LONG-TERM BIOLOGICAL OR CULTURAL VALUE BEYOND THE SHORT-TERM ECONOMIC BENEFITS THEY CREATE.

Response The importance of salmonid fish for their long-term biological and cultural values is recognized. As stated in the Plan (FEIS, Chapter III, "Fish"), demand relates not only to harvest, but also to the values of maintaining wild stock genetics, viewing fish, or just knowing that fish exist and thrive in the local streams Increasing numbers of people enjoy observing adult salmon or steelhead moving upstream over low falls or spawning on shallow river and stream riffles.

338. *COMMENT.* THE ECONOMIC POTENTIAL OF PRODUCTIVE SALMON AND STEELHEAD STREAMS NEEDS TO BE ANALYZED.

Response: The economic values of sport fishing are important for local and tourist-based economies in southwest Oregon. We recognize that a large percentage of the adult salmonids which are caught by sport fishermen in this area are produced on Forest lands (FEIS, Chapter III, "Fish"). Economic analyses of predicted changes in fish output pounds and WFUD'S for individual planning basins are taken into consideration in the allocation of the riparian prescriptions and design of the timber harvest dispersion constraints (FEIS, Chapter IV, "Fish"). More detailed economic analysis is needed for the large fish-producing basins such as the Rogue River, as identified in the Forest Plan as future work (LRMP, Chapter II, "Information Needs")

339. *COMMENT.* IF ROAD MILES ARE UNDERESTIMATED, CAN WE ASSUME THE IMPACTS ON WATER QUALITY AND FISHERIES ARE ALSO UNDERESTIMATED?

Response· No. Potential impacts to salmonid fish and other beneficial uses from proposed management activities (including roads) are discussed in the FEIS (Chapter IV, "Fish") The analysis took into account the anticipated level of timber harvest and road construction, and the associated sediment yield index value for the next five decades. Using this period as an average levels out the large natural variability expected as a result of floods and low flow periods In addition, this provides a more accurate analysis considering the variation in actual harvest and road construction (the primary Forest elements affecting the degree of impact for any one period). Other indirect effects such as off-shore catch, shifts in short-term climatic patterns and ocean currents, etc, also effect short-term changes in fishery outputs which may mask impacts attributed to water quality changes

Project environmental analyses will further evaluate the effect of proposed timber harvest and road construction on water quality and salmonid fish habitat from both a local and basin context. Any under- or overestimates of scheduled and actual activity, including recent past and reasonable future plans, can best be evaluated when spatial and timing resolution is more defined.

340. *COMMENT*· LRMP FAILED TO MENTION IMPACTS FROM GOLD DREDGING ON SALMONID PRODUCTION.

Response: From a Forest-wide perspective, dredging and other mining activities are very localized and have only limited impact on the fishery resource based on recent past and present experience. Forest Service regulations require mineral development on Forest lands be covered with an approved operating plan. A major goal of operating plans is compliance with Federal and State water quality regulations Plans also specify such things as time of operations, methods of operation, equipment use, riparian area and fish habitat protection methods, etc. Operations are reviewed by Forest Service personnel to assess compliance with approved operation plans Standards and Guidelines in the Forest Plan give emphasis to addressing risk of surface disturbance and water quality impacts in developing plans of operation (LRMP, Chapter IV, "Forest-wide Standards and Guidelines").

Working closely with miners the Forest Service can normally assure that mineral operations are conducted to protect water quality and fish habitat. Guidance for acceptable mineral development techniques can be found in Water Quality Best Management Practices, Pacific Northwest Experiment Station, November, 1988.

341. *COMMENT*: THE NEED FOR ADULT FISH TO NEGOTIATE THE SEVERE WATER TEMPERATURE CONDITIONS FOUND IN THE ROGUE DURING SUMMER, AND THE LIMITED AREA UTILIZED FOR SPAWNING AND REARING HABITAT NEEDS TO BE ADDRESSED. THIS SUMMER RACE DESERVES SPECIAL PROTECTION. THE PLAN SHOULD IDENTIFY SUMMER STEELHEAD SPAWNING AND REARING HABITAT AND PROPOSE STRATEGIES FOR PROTECTION AND ENHANCEMENT OF THE HABITAT.

Response: In natural situations, temperatures (and, to a lesser degree, spawning and rearing habitat) are influenced by riparian areas, geology, and climate. Siskiyou streams have natural high water temperature problems (FEIS, Chapter III). In particular, these problems are severe in the upper Illinois River basin outside of the Forest boundary due primarily to off-Forest water withdrawals. This has significant impacts on downstream areas in the Rogue River used by summer steelhead and early-run fall chinook

The portions of the Rogue and its major tributaries (Illinois basin, including Silver and Indigo Creeks) within the Forest boundary lie within complementary land allocations such as Wilderness, Wild River, Scenic/Recreational River, and Supplemental Resource Management Areas. These designations combine to protect streamside areas, and will therefore protect or enhance stream habitats not only for summer steelhead, but other important salmonid species as well Outside of these special areas, all Riparian areas are to be managed with Prescription B or C designed to maintain or improve stream temperatures.

The Forest Service uses a stream classification system based on beneficial uses of water. Under this system, some intermittent streams can be elevated to Class I because they are used by spawning summer run steelhead Class I and II streams receive the highest level of protection (Refer to FEIS Chapter III, Soil and Water).

342. *COMMENT*: EFFORTS SHOULD CONTINUE AND/OR BEGIN TOWARDS MAINTAINING NATIVE FISH POPULATIONS SUCH AS CUTTHROAT TROUT AND ANADROMOUS SPECIES.

Response: Management of fish habitat and native fish species on Forest Service administered lands is a shared responsibility between the Forest Service, Oregon Department of Fish and Wildlife, and California Department of Fish and Game. Some of the best native fish habitat in Oregon is found within the Siskiyou National Forest. There is strong support for maintaining capability for native salmonid species. In response to public input, Alternative S was developed to increase protection of soil, water, and fisheries. Water quality and fish habitat will be maintained at or enhanced above present capability in each of the 19 Planning Basins in the Preferred Alternative (FEIS, Chapter IV, "Fish").

343 *COMMENT*: SOME INDIVIDUALS SUGGESTED THAT INTERMITTENT STREAMS WITH ANADROMOUS FISH SPAWNING USE SHOULD BE ELEVATED IN STATURE AND THAT TIMBER HARVESTING AND ROAD CONSTRUCTION BE EXCLUDED

Response: The Forest uses a stream classification system based on the beneficial uses of water (FEIS, Chapter III, "Soil and Water"). Some intermittent streams have been elevated to Class I status because they are used by spawning salmonid fish. All streams, whether intermittent or not, are managed to maintain or enhance water quality

344 *COMMENT.* THE WHITE STURGEON DESERVES MORE ATTENTION IN THE PLAN. DATA COLLECTION AND OTHER RESEARCH IS NEEDED AND A MANAGEMENT STRATEGY SHOULD BE DEVELOPED. THE WHITE STURGEON'S RARITY IS A CAUSE FOR CONCERN.

Response: The Oregon Department of Fish and Wildlife regulates fish harvest. The Forest Service manages habitat. The sturgeon is present in the Rogue River to Grants Pass (Savage Rapids Dam). More information is needed on this species. The Oregon Department of Fish and Wildlife is developing a basin fisheries management plan for the Rogue River system which will address the habitat needs and harvest concerns of the sturgeon. The Forest will cooperatively input to this plan. Our goal in Forest management is to maintain or enhance fish habitat capability and maintain the native species component Normally the protection and capital investments for salmonids should also benefit other game fish (FEIS, Chapter II, Management Area 11 - Riparian, and Chapters III and IV, "Fish"). These are principally oriented to the water quality concerns.

OLD GROWTH

Harvest of Old Growth

345. *COMMENT*: CONVERT OLD-GROWTH FORESTS TO SECOND GROWTH AS QUICKLY AS POSSIBLE TO MAXIMIZE NET WOOD PRODUCTION.

Response: Some of the Siskiyou National Forest old-growth inventory is unsuitable for timber management according to the criteria described in the FEIS, Appendix B, "Inventory Data and Information Collection--Suitability Analysis." The allocation of land to Management Areas in the Forest Planning process results in some old-growth forests being suitable but unavailable for harvest conversion Some of these allocations are necessary to comply with the requirements of laws and regulations; others are selected to maximize the net public benefits available from the resources of the Siskiyou National Forest. Old-growth stands located on unavailable or unsuitable lands are not planned for conversion in this Forest Plan.

Of the remaining Management Areas, all except General Forest have constraints on old-growth harvest to protect, maintain, or enhance the featured resource values. However, environmental and economic limits must be applied to the General Forest Management Area to meet legal and policy requirements, and the objectives of the Forest Plan. Size and duration of created openings, and dispersion of openings are principle environmental constraints on the rate of old-growth harvest. Nondeclining yield is the principle economic limitation on the rate of old-growth conversion. These constraints and their effects are discussed in the FEIS, Chapter II, "Management Requirements," and FEIS, Appendix B, "Constraints and Management Requirements."

The combined effects of land suitability, land allocations, and management constraints described above determine the extent and rate of old-growth harvest in the Forest Plan

346. *COMMENT*· THE SISKIYOU NATIONAL FOREST SHOULD BE ACCELERATING THE HARVEST OF OLD GROWTH TO MAKE ROOM FOR NEW GROWTH AND TO FORESTALL ANY PRESSURE ON THE HARVEST OF IMMATURE TREES NOW IN RE-GROWTH ON LANDS OTHER THAN ON NATIONAL FOREST LANDS. THE FOREST SERVICE SHOULD OUTLINE A MAJOR DEPARTURE TIMBER CUT POLICY FROM ITS PRESENT EVENFLOW POLICY OF ANNUAL TIMBER SUPPLY (WITHOUT IT EXCEEDING THE LONG-TERM SUSTAINED YIELD CAPACITY OF A FOREST).

Response: The Siskiyou National Forest is a deficit inventory forest which means the old-growth trees available for harvest must be metered out for 70-80 years before the young growth on the Forest is ready

for harvest If the harvest of old growth is accelerated now, then future harvest levels must decline until the younger stands are ready for harvest This option of departing from the non-declining flow policy is evaluated in the departure alternatives (B, A-Departure) of the FEIS

347 *COMMENT.* THE SISKIYOU NATIONAL FOREST CONTAINS 443,000 ACRES OF OLD-GROWTH TIMBER OF WHICH 138,000 ACRES ARE LOCATED WITHIN THE WILDERNESS AREAS THE REMAINING 305,000 ACRES OF OLD GROWTH ON YOUR FOREST ARE CURRENTLY BEING HARVESTED AT A RATE THAT WOULD TAKE 48 YEARS TO CONSUME. THESE ACRES SHOULD BE GROWING FIBER OF PRIME YOUNG TREES, NOT STAGNANT OLD GROWTH.

Response: The rate of harvest of the remaining old growth is of concern. Let's assume for a moment that the remaining old growth would be harvested at a faster rate...say all in 10 years Most professional forest managers would object because of the jeopardy to other forest values that such a rate of harvest would mean. Professional forest managers are concerned about water quality, wildlife, and a host of other forest values After the remaining old growth was harvested, the second growth would not have had sufficient time to grow to a merchantable size. The result would be a scarcity of timber the other 38 years. The rate of harvest is carefully planned and metered out to provide for forest values such as recreation, fisheries, and wildlife. Timber supply and community stability are also a serious part of planning the harvest rates

348. *COMMENT*: THE AMOUNT OF OLD GROWTH TO BE SOLD (EXCEPT AFTER A FIRE) SHOULD BE SUFFICIENT TO REGAIN AND CONTINUE STABILITY OF LOCAL LOG-DEPENDENT COMMUNITIES AND THE MARKET'S CRYING NEED

Response· The Forest only has influence on the amount of timber sold from the Forest, not on the amount of timber harvested. Cycles in the wood products industry have been a greater influence in community stability. The Forest has considered the cumulative effects assessment of timber supply and effects on community stability (FEIS, Chapter II, III)

349. *COMMENT*: REGARDING OLD-GROWTH TIMBER IN MULTIPLE USE AND/OR HARVEST AREAS THE OLD GROWTH SHOULD BE SYSTEMATICALLY HARVESTED AS PART OF THE TIMBER MANAGEMENT PLAN

Response: Mature and old-growth stands residing in Management Areas 1-9 are not available for timber harvest. Stands residing in Management Areas 10-14 will be harvested in accordance with Standards and Guidelines for the individual Management Areas.

350 *COMMENT*· OLD-GROWTH TREES IN WILDERNESS AREAS SHOULD BE SELECTIVELY CUT AND REPLANTED ON A SMALL SCALE SO THE OVER-RIPE TREES ARE USED BUT THE GROWING AND STRONG TREES REMAIN.

Response. The Wilderness Act prohibits any timber harvest in Wilderness

351. *COMMENT*: BEFORE MORE OLD GROWTH IS CUT, THE EXISTING AREAS SHOULD BE ACCURATELY MAPPED AND THEIR FULL RANGE OF NON-TIMBER VALUES EVALUATED THE FINAL PLAN SHOULD INCLUDE A GOOD MAP INDICATING THE LOCATIONS OF THOSE GROVES OF OLD GROWTH WHICH WOULD BE MAINTAINED BY THE PREFERRED ALTERNATIVE. THE VOLUME AND LOCATION OF OLD-GROWTH TIMBER AS IT RELATES TO TIMBER SALES IN THE FUTURE SHOULD BE IDENTIFIED AS WELL.

Response Management Areas 1 through 9 prohibit or severely restrict timber harvest (LRMP, Chapter IV, "Management Prescriptions"). A comparison of maps depicting Forest age classes (FEIS, Chapter III, "Vegetation") and Alternative S (map packet) will give a rough estimate of the location of protected mature and old-growth stands Almost all timber harvest programmed for the next decade will come from mature and old-growth stands located in Management Areas 10 through 14. The 10-Year Action Plan (LRMP, Appendix C) gives general locations and approximate volumes for sale activities in the first decade For more detail, a visit to the Planning section at the Supervisor's Office in Grants Pass is needed.

All land management activities, including timber sales, receive a site specific environmental analysis, and all non-timber values are evaluated are evaluated at that time Land allocation changes are recommended through this site specific analysis when not appropriate for timber management or other resources

352. *COMMENT:* ARE THE OLD-GROWTH ACRES ACCURATE TO 1985-1986 FIGURES? COMBINING OLD-GROWTH AND MATURE ACRES IS CONFUSING AND MISLEADING, AS A MATURE FOREST IS NOT OLD GROWTH, AND USE WAS NOT CONSISTENT THROUGHOUT THE DRAFT. TIMBER 160 YEARS OF AGE IS NOT OLD GROWTH. HOW MUCH OLD GROWTH WAS LOST IN THE 1987 FIRES?

Response: The DEIS contained various inconsistencies in the use of the terms "mature" and "old-growth"; this was not intentional. For analysis purposes, our data base does not differentiate between mature and old-growth forest We estimate that prior to the 1987 fires, the Siskiyou contained 443,000 acres of mature and old-growth forest; all is considered old-growth except for approximately 50,000 acres of mature Approximately 25,000 acres of mature and old-growth forest was lost in the fires. We have endeavored to make sure that references to mature and old-growth forest are straightforward and non-confusing in the FEIS.

In this Forest Plan, the data on acres of mature and old-growth forest is from the 1979 timber inventory updated for areas sold for timber harvest through 1984 A comprehensive resource inventory will be initiated on the Siskiyou in 1990 Data collected on mature and old-growth forest will enable us to refine our data base and help us to better manage this important component of the Siskiyou ecosystem.

The average age of stands in the old-growth category has been established at 160 years from the inventory statistics. Dominant trees in old-growth stands typically range from 200 to 300 years old, with individual trees occasionally reaching 400 years or more Our definition of old growth generally follows the Regional Guide (USDA-Forest Service 1984). See the description of Designated Wildlife Habitat (LRMP, Chapter IV, "Management Prescriptions") for a more detailed description. Our definition of old growth will probably be revised as result of the new resource inventory. Our old-growth stands are generally a mixture of ages and layers; most stands are not entirely comprised of large conifers.

353 *COMMENT:* HOW WILL YOU ADDRESS THE IMPORTANCE OF OLD GROWTH ECOSYSTEMS? PROTECT MUCH LARGER AMOUNTS OF OLD GROWTH ECOSYSTEMS AND FULLY PROTECT THE OLD GROWTH HABITAT AROUND ALL KNOWN PAIRS OF SPOTTED OWLS. FULLY PROTECT ALL REMAINING, OLD, LARGE REDWOODS WITHIN CHETCO RANGER DISTRICT. DO A COMPLETE INVENTORY OF THE SISKIYOU'S OLD GROWTH FORESTS AND PERFORM MORE BASIC RESEARCH ON THE IMPACTS OF TURNING THE OLD GROWTH FORESTS INTO TREE FARM PLANTATIONS.

Response: Alternatives considered in the FEIS included a range of "Old Growth and Mature Reserved and Unsuitable" acres, from 153,000 in the No Change Alternative to 289,600 acres in Alternative M The preferred Alternative S will retain approximately 181,000 acres of mature and old growth, reserved and unsuitable (FEIS, Table II-5, "Monster Matrix").

The importance of old-growth is stressed in many places in the documents. Allocations for Designated Habitat, Supplemental Resource, Backcountry Recreation and other sites (LRMP, Chapter IV, "Management Prescriptions") attest to the value put on old growth. "Biological Diversity" has also been added as a topic in the FEIS and as a monitoring element in the LRMP (Chapter V and Appendix D), this further underscores the importance placed on old-growth.

All nest sites and important roost sites of spotted owls will be protected (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"), however, extensive old-growth stands surrounding non-SOHA sites will not be preserved over the long-term. A significant number of old-growth redwood groves will be protected under the Preferred Alternative S; see Appendix F (FEIS) for a detailed discussion of Redwood Groves. A comprehensive resource inventory set to begin in 1990 will provide updated data on the amount of old growth on the Siskiyou. The Forest Service will continue to conduct research on mature and old-growth ecosystems.

354. *COMMENT.* OLD-GROWTH FOREST VALUES ARE NOT ADEQUATELY ADDRESSED IN THE FOREST PLAN. FLORA AND FAUNA DEPENDING ON THIS TYPE OF HABITAT ARE REDUCED PROPORTIONATELY. THE SPOTTED OWL IS JUST ONE OF OVER A HUNDRED RECOGNIZED SPECIES. THE BIG OLD TREES AND THE LIVING THINGS THAT NEED THEM COMBINE TO MAKE A LIFE FORM THAT SHOULD HAVE THE RIGHT TO EXIST FOR ITS OWN SAKE, IN ADDITION TO ITS VALUE TO HUMANS. WE ENJOY A TREMENDOUS BOTANICAL DIVERSITY THAT TESTIFIES TO THIS BELIEF. A LIST OF THE OLD-GROWTH DEPENDENT SPECIES OF THE SISKIYOU FOREST COULD REINFORCE TO READERS THE BROAD PURPOSES THESE AREAS FULFILL. SIMILARLY, A LIST OF CAVITY-DEPENDENT SPECIES WOULD BE HELPFUL

Response: Old-growth forests are addressed more fully in the FEIS Tables in Chapter II depict the amount harvested per decade and percent seral stages present at selected decades A more in-depth discussion of forest diversity has been developed for the FEIS as well. In Chapter III of the FEIS ("Wildlife") there is discussion of the number of wildlife species which use mature and old-growth forest habitat. NFMA provides important direction to the Forest Service: "Fish and wildlife habitat shall be managed to maintain viable populations of existing native and non-native species in the planning area" (36 CFR 219.19). All wildlife species are important, and the Forest Service is obligated to manage for all species.

Through land allocations, and Standards and Guidelines (LRMP, Chapter IV), the Forest's fish, wildlife, and plant resources will be maintained. No species will be reduced below viable population levels, and habitat for many species will be enhanced.

Although lists of old-growth and snag-dependent species would provide more detailed information, because of limited space we did not display these lists in the FEIS In the Wildlife section of Chapter III of the FEIS, we mention the estimated numbers of species in the two categories. Contact the Supervisor's Office in Grants Pass for a list of species and their habitats.

355 *COMMENT:* MANAGEMENT OF OLD-GROWTH TIMBER AS A RENEWABLE RESOURCE IS INAPPROPRIATE. ONLY SECOND GROWTH IS ECONOMICALLY RENEWABLE. OVERMATURE AND DECADENT OLD-GROWTH FORESTS DO HAVE HIGHER LOSSES OF MERCHANTABLE MATERIAL, BUT THOSE LOSSES ARE ACCEPTABLE GIVEN THE QUALITY OF LUMBER GENERATED AND STORED IN THESE FORESTS OLD GROWTH IS TOO PRICELESS TO DESTROY JUST TO HARVEST TIMBER WHOSE STUMP PRICE DOESN'T PAY FOR THE EXPENSES OF ROAD BUILDING AND "MANAGEMENT."

Response: Of the 443,000 acres of mature and old-growth forest that currently exist on the Siskiyou, approximately 391,800 will remain at the end of the first planning decade During this period, research is

planned to validate and refine proposed silvicultural techniques so that old-growth forest habitat may be available in perpetuity.

There have been many generations of "old growth" on the Siskiyou National Forest Each generation has its peculiar characteristics depending on the weather cycles and existing stand composition when it was conceived The present generation originated during the "Little Ice Age," a period of much cooler weather than we are presently experiencing While it is true that new generations will not be the same, they will be better adapted to the changing climate Death and disturbance such as fire are nature's way of bringing on a new generation for changing conditions. While the species may not be in the same proportions, the habitat created will be similar in structure and still appropriate for the animals that depend on it Old growth and its character have been repeatedly "renewed" by nature and can still be allowed to develop. In fact, all "old-growth" stands will in time be replaced They will succumb to succession (death) or be "destroyed" by fire.

356 *COMMENT:* WHAT WOULD AN OLD GROWTH CHARACTER STAND LOOK LIKE? HOW MANY TREES PER ACRE, HOW BIG IN DIAMETER, HOW OLD? HOW CAN AN OLD GROWTH ECOSYSTEM BE CREATED IN 250 YEARS ON EVEN THE BEST OF SITES? HOW MANY ACRES ON ROTATION WILL BE ABLE TO SUSTAIN GROWTH FOR THE 250 YEARS PLANNED? WHAT IS THE GROWTH OF THE TIMBER ON THESE SITES CURRENTLY? HAVE ANY OF THE TREES BEEN BORED TO DETERMINE GROWTH, MATURATION AND FUNCTION OF THE FOREST AS AN ECOSYSTEM? WE WOULD SUGGEST AN UNEVEN-AGED APPROACH TO HARVESTING ON A LIMITED NUMBER OF SITES, PREFERABLY THOSE ON SITE I, II, OR III GROUND.

Response Not all lands on the Siskiyou National Forest are managed on the same rotation. Some Management Areas, like Research Natural Areas, Botanical, Special Interest, Wilderness, and several other categories, are managed to maintain longer rotations essentially determined by natural ecosystem processes Other areas are specifically managed for wildlife species that require later successional stages to maintain viable populations Then there are lands (less than half of the Forest) that are managed for a variety of uses including timber products. The likelihood of old-growth conditions being "reached" and having a certain portion of the Forest in late successional stages is almost certain. Moreover, Standards and Guidelines (LRMP, Chapter IV) regarding timber management include guides for leaving much of the old-growth character and diversity intact.

Uneven-age management is just one tool that could be used to maintain habitat diversity. Class I and II Riparian areas (those areas along the larger streams and rivers) offer a "managed old growth" opportunity, most stands that have been harvested in these areas still maintain old-growth characteristics. Obtaining reliable information on the application of uneven-aged management under local conditions is identified as a "Forest Need" (LRMP, Chapter II) Thus, even-aged stands managed for timber will have elements of habitat commonly found in the later seral stages of succession

Because the character of old growth is dependent on the ecosystem, there is no one definition of old growth that could be universally applied across the Northwest. Just as old growth in the redwoods (a fire dependent system) differs from "old growth" in the chaparral (also a fire dependent system), old growth in the Siskiyou National Forest differs from old-growth found on the Willamette National Forest. Siskiyou managers have used thousands of plots to determine the character of the older stands in late seral stages. We have found and used many plots over 200 years old. Some stands are as old as 425 years, and we have found individual trees as old as 600 years. Our definitions are based on conditions within the forest and reflect the natural potential of our sites.

Site quality is not related to the longevity of a stand For example, some of the older stands in existence (4,000 year old bristlecone pine in the Southwestern United States) are very low in productivity, yet the redwoods (some stands are also very old) occur on some of the most productive sites in the world On

the Siskiyou, some of the oldest conifers are not "old growth" by the definition, but are classic in terms of their own characteristics The serpentinite-peridotite soils produce a sparse, open forest which is atypical to the surrounding lush, densely forested environment. The difference is not in the climate, aspect, or elevation, but simply due to the soil chemical imbalance The ability to provide "old growth" is dependent on understanding the relationships between ecosystem processes, the environment, and species physiological requirements Our direction is to continue to monitor activities, analyze the result of our management activities, and learn from our own analysis, and that of the research community.

357 *COMMENT.* IT IS NOT CLEAR WHETHER THE ACREAGES OF OLD GROWTH PROPOSED FOR PRESERVATION ARE SUFFICIENT OR THAT THEY WILL BE PRESERVED THE FINAL EIS SHOULD CONTAIN AN ELABORATION OF ADVERSE EFFECTS FOR EXAMPLE, HOW MUCH VIRGIN OLD GROWTH WILL BE LOST BY EACH ALTERNATIVE THE FINAL DOCUMENT SHOULD CLEARLY STATE HOW MUCH WILDLIFE NEEDS TO BE PRESERVED AND CLEARLY DESCRIBE HOW MUCH WILL BE PRESERVED, WHERE AND HOW.

Response: Quantitative and qualitative resource outputs for the alternatives considered can be found in Chapter II of the FEIS. Tables II-5 ("Monster Matrix") through II-7 ("Incremental Change Comparison of Planning Problem Response by Alternative"), display the estimated mature, old-growth and wildlife habitat for easy comparison More detailed discussion of the environmental impacts on old-growth and wildlife habitats are found in Chapter IV, "Environmental Consequences," of the FEIS.

Refer to the map of Alternative S (Preferred) accompanying the FEIS There is no timber harvest programmed for Management Areas 1-9. Compare the Alternative S map to the mature and old-growth forest map in the "Vegetation" section of Chapter III of the FEIS. This will show which areas of mature or old-growth Forest are protected, and their distribution. Regional direction has been followed for installing a habitat network for spotted owls (for details see the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide - Spotted Owl Guidelines). A network of habitat areas for pileated woodpeckers and pine martens has also been established. The composite network for all three species will maintain sufficient habitat for all species which use mature and old-growth forest.

358 *COMMENT·* THE FOLLOWING CONSEQUENCES ARE SUGGESTED IF OLD-GROWTH FORESTS IN THE SISKIYOU'S ARE REPLACED BY INTENSIVELY MANAGED, SHORT ROTATION, EVEN-AGED PLANTATIONS: A. SPECIES DIVERSITY WILL BE REDUCED B THE FUTURE'S RESERVOIR OF GENETIC MATERIAL FURNISHED BY OLD GROWTH FOREST WILL BE LOST; THERE WILL BE A LOSS OF GENE POOL DIVERSITY.

Response. In the FEIS (Chapter IV, "Environmental Consequences," especially the "Vegetation" section), there are several discussions that estimate the consequences of implementing each alternative on old-growth forests Some of these estimates for a particular alternative do not disagree with the above comment. The FEIS displays the range of alternatives considered that would protect various amounts of old-growth forests on the Siskiyou The preferred Alternative S allocates approximately 43 percent (465,000 acres) of the Forest to nonconsumptive management that has lesser direct impacts on vegetation.

Some old-growth stands on the Siskiyou will be replaced by intensively managed, shorter rotation, even-aged stands as a result of timber harvest The Organic Act and Multiple-Use Sustained-Yield Act mandates the harvest of timber on National Forests. Conversely, NFMA mandates that old-growth habitat be maintained Old-growth forests will be far from liquidated on the Siskiyou Old-growth habitats will remain under several land allocations including· Wilderness, Research Natural Area, Designated Wildlife Habitat, Special Wildlife Sites, Botanical, Backcountry Recreation, Wild and Scenic/Recreation River corridors, Riparian, Retention Visual, and Supplemental Resource These areas will serve as reservoirs for genetic diversity and provide for species associated with old-growth ecosystems.

359. *COMMENT* STUDY THE GENETIC VALUE OF THE OLD-GROWTH SURVIVOR TREES

Response: We feel that the oldest trees provide a source of genetic material that links us with past climates and adaption pressures. As it is wise to use historic information to shape the future, it is wise to retain these individuals as a source of seed and pollen to help shape future forests The plan provides for distributing old-growth stands throughout the forest. Many of these areas are along riparian corridors where the oldest trees reside. Other areas are distributed to provide habitat for species dependent on the later seral stages.

There are a number of studies now in progress (administered by the Research Stations of the Forest Service) studying the values of the older components of the forest. The National Forest System, to which the Siskiyou National Forest belongs, is not authorized to carry out research, but does cooperate with the projects of the Research Stations.

360 *COMMENT*: THE OLD GROWTH INVENTORY OFFERED IN THE PLAN IS A POSITIVE FIRST STEP BUT IS NOT SUFFICIENTLY INFORMATIVE WHERE ARE THE TRUE OLD-GROWTH STANDS, I E. FROM 500 TO 650 YEARS OLD?

Response: There are no stands on the Siskiyou from 500 to 650 years old. Individual trees occasionally attain that age, but stands do not. Fire frequency prevents stands from reaching that advanced age. Maximum stand age on the Siskiyou is seldom past 300 years

361. *COMMENT*: POCKETS OF REAL OLD GROWTH (200-YEARS AND UP) SHOULD BE INCLUDED IN ALL FOREST MANAGEMENT PLANS AS CORE AREAS FOR REPLENISHMENT OF ALL KINDS OF PLANT, FUNGAL, AND ANIMAL FORMS TO REBUILD FOREST HABITAT.

Response: The age of a stand is only one criterion for its inclusion as old growth. The number of tree species, the structure of the canopy and the forest floor, including the size and distribution of live and dead trees, are much more important than the age of the stand. The Siskiyou supports stands over three hundred years old that do not meet the accepted definition of old growth, as well as stands less than two hundred years old that do have old-growth character.

Some species require early seral stages for optimum habitat, while others require the later seral stages. Providing a diversity of habitat is a major aim of the plan. The Siskiyou Forest Plan (LRMP) does provide old growth distributed throughout the forest in all management categories.

362. *COMMENT:* MA8. THE DESIRED FUTURE CONDITION SHOULD BE BROKEN DOWN BY SPECIES, AS EACH USES DIFFERING COMPONENTS FOR MATURE AND OLD GROWTH, AND SOME DO NOT OVERLAP.

Response· There are differences between species; habitat requirements are spelled out in the Standards and Guidelines for Management Area 8 (LRMP, Chapter IV, "Management Prescriptions"). Areas for all three species also have similarities. For instance, spotted owl areas also must serve as habitat for pileated woodpeckers and pine marten (plus all the other species which use mature and old-growth forest).

363. *COMMENT*· PROTECT MORE OF THE OLD-GROWTH HABITAT ON THE INDIGO CREEK AND SILVER CREEK WATERSHED. LEAVE SUBSTANTIAL MATURE AND OLD GROWTH ALONG THE ELK, CHETCO, AND NORTH FORK OF THE SMITH RIVERS.

Response: More old-growth habitat has been protected from timber harvest in the preferred Alternative S (FEIS). Indigo and Silver Creek watersheds, in particular, have greater amounts of old growth contained in several large Management Area allocations with no programmed harvest, and on areas that are classified unsuitable for timber production. The Elk and North Fork Smith Rivers are included in the National Wild and Scenic River System. Naturally occurring old growth will be reserved within the classified Wild corridors and several overlapping Management Areas which also have no programmed harvest (primarily Designated Wildlife Habitat).

364. *COMMENT*. WHY WAS OLD GROWTH NOT SET ASIDE AS RECREATIONAL POTENTIAL BY ITSELF? HAVE ANY OLD-GROWTH STANDS, THE CATHEDRAL TYPE, BEEN SET ASIDE NEAR EASILY ACCESSIBLE ROADS OR TRAILS FOR RECREATIONAL PURPOSES?

Response: Five "cathedral" old-growth sites are listed as potential Botanical areas in the FEIS. All five sites are selected in the Preferred Alternative S. Most of the sites have very good recreational potential See FEIS Appendix F for more details Other land allocations such as Designated Wildlife Habitat and Supplemental Resource contain "cathedral" old-growth stands, but in the planning documents we have not taken credit for that aspect of their character.

365. *COMMENT*: I HARVEST WILD MUSHROOMS AND COLLECT AND MAKE WINE FROM WILD ORGANIC BERRIES. ANY MANAGEMENT OF THESE AREAS MEANS DESTRUCTION OF IRREPLACEABLE HABITAT. OLD-GROWTH STANDS SUPPORT MANY SPECIES OF CANTHARELLIS MUSHROOMS AND THIS IS THEIR ONLY HABITAT SECOND-GROWTH FORESTS ARE NOT ABLE TO SUPPORT THEIR MYCORRHIZAL ASSOCIATION.

Response: The Forest Service helps the people manage the land for many purposes. Management plans for medicinal, decorative, and edible plant species have been and are being developed. Habitat information on various plant species is continually being gathered and analyzed by the Forest's ecologists and botanists; this information is integrated into Forest activities and management.

Most berries are in the *Rubus* genus of the rose family and require early seral conditions to produce abundant crops and seem to prefer mineral soil. Mushrooms occur in later stages of succession where organic material has been incorporated into the soil surface layers. Old-growth stands are not the only habitat for mushrooms, and they are replaceable. Today's old-growth stands represent about the twentieth cycle of old growth since the recession of the last ice advance. The Forest Service plans to provide for old growth and a diversity of species for all purposes, including berries and mushrooms.

366. *COMMENT*· THE REGIONAL GUIDE HAS ESTABLISHED A REFINED DEFINITION OF OLD GROWTH FOR VARIOUS PLANT COMMUNITIES. DID THE SISKIYOU USE THE REFINED DEFINITIONS WHEN MAPPING OLD GROWTH?

Response: The Siskiyou's old-growth was mapped during a 1979 timber inventory. We were not able to use the "refined definitions." However, the Siskiyou's old-growth forest does contain the general characteristics associated with these stands (USDA Forest Service 1984b)· well into mature and over-mature stage, multi-layered canopy and trees of several age classes, standing dead trees and down materials, and insignificant evidence of human activities.

367. *COMMENT*· AT ONE TIME THIS ENTIRE AREA WAS OLD-GROWTH TIMBER, AND ALL BIRDS AND ANIMALS LIVED IN OLD GROWTH NOW THAT WE HAVE CUT MUCH OF THE OLD GROWTH, WE STILL HAVE THE SAME BIRDS AND ANIMAL SPECIES. THEY HAVE SIMPLY ADAPTED TO THE

CHANGE. NO MORE OLD-GROWTH FOREST SHOULD BE RESERVED FOR SPOTTED OWLS AND OTHER ENDANGERED SPECIES.

Response Except for introduced species like the opossum, wildlife species inhabiting the Siskiyou National Forest have lived here for centuries. Populations of these indigenous species have fluctuated considerably over time Forest fires, windstorms, and floods brought habitat change at periodic intervals, but these changes never occurred systematically over very large areas; populations of the species we have today were never reduced below viable levels by natural events.

Individual species do not adapt (in a short-term sense) to changes; their populations fluctuate in response to environmental changes. In large measure, wildlife species are creatures of instinct; their brains are programmed to accept certain habitat types and conditions Of course there is always some variability in behavior among individuals of a species, whether it be at the local or range level. However, the most important point is that wildlife species cannot simply "adapt" to a new habitat type; their instincts will not let them.

Instinctive behavior plays a larger role in the daily lives of the more primitive animals (such as amphibians) than with the more advanced (mammmals). The instincts of some species in the same group (such as birds) allow them to take advantage of a variety of habitats; other species are more restrictive in their requirements. For example, Oregon juncos utilize a variety of habitats, from openings to old growth On the other hand, the northern subspecies of the spotted owl is instinctively tied to mature and old-growth forest. Spotted owls are creatures of habit and cannot simply adapt to loss of their habitat.

As a society we are bringing systematic change to our forest lands. If sufficient amounts of habitat are not reserved for species that need mature and old-growth forest, then these species will eventually disappear. The Forest Service has developed Management Requirements to ensure that fish and wildlife habitat shall be managed to maintain viable populations of existing native and non-native species on the Siskiyou as required by NFMA (36 CFR 219.19).

368. *COMMENT*: TIMBER HARVEST IN OLD GROWTH (AS WELL AS IN MATURE FOREST) SHOULD BE REDUCED, BECAUSE 76 OF THE FOREST'S 250 WILDLIFE SPECIES UTILIZE SNAG HABITAT.

Response: A large number of the Siskiyou's wildlife species need snag habitat. That is why the Forest has stated, "Habitat capability for woodpeckers (indicators for cavity nesting species) should be continually maintained throughout the Forest at not less than 60 percent of maximum," (LRMP, Chapter IV) We also state, "The Siskiyou Wildlife Tree (Snag) Policy and Guidelines and District supplements should be followed for all project activities." In areas where timber is not harvested (about half of the Forest), snag habitat will be retained at existing levels, or approximately 100 percent of woodpecker needs. Given these levels of snag management, viable populations of cavity nesters will be maintained indefinitely on the Siskiyou.

Regional Management Requirements for woodpeckers are 20 percent of maximum, the Siskiyou is well above that level. Cavity nesters will remain a functioning component of the Siskiyou ecosystem.

Once the Plan is implemented, the Siskiyou will monitor snag levels in areas where timber is harvested to ensure that management direction is being met

369 *COMMENT*· ALTERNATIVE K DOES NOT ADEQUATELY PROTECT HABITAT FOR SENSITIVE SPECIES. NO DECREASE SHOULD BE CONTEMPLATED IN NUMBERS OF SENSITIVE AND INDICATOR SPECIES.

Response. The Forest Service is mandated by law to manage for multiple use, which includes harvest of timber. Protecting habitat for many sensitive and indicator species often requires restricting or precluding timber harvest activities The plan protects habitat to maintain viable populations of all species,

including sensitive and indicator species. The final Preferred Alternative S preserves significantly more habitat for sensitive species than did the DEIS Preferred Alternative K.

WILDLIFE

Habitat

370. *COMMENT:* FOREST FRAGMENTATION NEEDS TO BE CONSIDERED AND EFFECTS ON PROTECTION OF WILDLIFE AND SPECIES DIVERSITY. USE CORRIDORS, NO-CUT BUFFERS, AND OTHER CONNECTING HABITAT.

Response. Designated Wildlife Habitat areas are part of an interconnected network meeting Management Requirements. The areas are spaced close enough to provide for exchange of animals and their genes (FEIS, Appendix J)

The wildlife habitat issue highlights spotted owls, pileated woodpeckers, and pine marten because they are indicator species. Habitat provided for these three species also serves other species dependent on mature and old-growth forest. Habitat areas for these indicator species and their associated species are well distributed Special Wildlife Sites such as meadows, springs, and swamps are interspersed throughout the Forest

In addition, riparian corridors provide diversity along perennial streams. A number of important fish-producing streams (such as Lobster and Indigo Creeks) are designated as Supplemental Resource (1/8 mile corridor on either side of the waterway). The Elk, Rogue, Illinois, Chetco, and North Fork Smith Rivers are designated as Wild and Scenic Rivers. These land allocations ensure that corridors of unlogged or lightly managed stands with good wildlife habitat characteristics will occur at a variety of locations on the Forest.

Timber harvest activities will provide for interspersion of various seral stages and increased edge, which will increase habitat diversity. Maintenance of biological diversity is a cornerstone of the Forest Plan Preferred Alternative S.

371. *COMMENT*: SETTING ASIDE SCATTERED PARCELS OF OLD GROWTH FOR WILDLIFE PROTECTION, IN A PATTERN AS IF SCATTERED BY A GIANT SALTSHAKER, IS A FLAWED CONCEPT. ONE LARGE BLOCK SOMEWHERE WOULD BE MORE PRODUCTIVE IN THE LONG RUN.

Response: The Siskiyou's strategy is a combination of large blocks (Wildernesses) and smaller parcels arranged in a network that allows relatively free dispersal of individuals (FEIS, Chapter III, "Wildlife").

372. *COMMENT.* REMOVING MORE TIMBER WILL MAKE FOR BETTER WILDLIFE HABITAT

Response. For some species of wildlife this is true. But the Siskiyou harbors over 250 wildlife species, and their habitat requirements are very diverse (FEIS, Chapter III, "Wildlife"). Some will not do better if more timber is removed. Alternatives vary in their ability to provide habitat for various species of wildlife (FEIS, Chapter II, "Wildlife"). The Preferred Alternative was developed to achieve a balance of varied habitat types and stages to insure viable populations of existing native and non-native species are maintained on the Forest (FEIS, Chapter II, "Alternative S").

373 *COMMENT*. EXCESSIVE LOGGING ACTIVITY AS PROPOSED IN ALTERNATIVE K DESTROYS FISH AND WILDLIFE HABITATS WHICH THE FOREST SERVICE THEN MUST SPEND HUGE SUMS OF MONEY ON REHABILITATING.

Response: Timber harvest increases quality of habitat for some species of wildlife and decreases quality of habitat for other species Wildlife habitat areas have been designated to provide habitat for viable populations of species whose habitat will decrease with timber harvest. Riparian management is designed to protect fish habitat by reducing sediment input and reducing or maintaining stream temperatures. With proper planning, implementation, maintenance, and monitoring of activities using the set of Management Area prescriptions and Standards and Guidelines available for the alternatives, little effort in rehabilitating any resource should be required.

374 *COMMENT*· DEAD STANDING TREES SHOULD BE LEFT UPRIGHT (WHERE SAFETY CONSIDERATION PERMITS) TO PROVIDE NESTING SITES FOR CAVITY DWELLERS AND TO PROVIDE SLOWLY RECYCLED BIOMASS TO THE SOIL.

Response: Dead standing and downed trees are being left as habitat for wildlife. The existing Siskiyou National Forest Wildlife Tree (Snag) Guidelines require that snags and down logs be left for wildlife. The LRMP (Chapter IV, "Forest-wide Standards and Guidelines") contains specific Standards and Guidelines for retention of large woody material

375. *COMMENT*: WHILE MUCH ATTENTION HAS BEEN PAID TO SNAG RETENTION, IT IS NOT APPARENT FROM THE PLAN WHETHER THIS POLICY WILL PERMIT CAVITY NESTING SPECIES TO MAINTAIN THEIR CURRENT POPULATIONS GIVEN AN INCREASINGLY MONOCULTURAL, SHORT-ROTATION FOREST.

Response· It is assumed that habitat capability for woodpeckers will be maintained at not less than 60 percent of potential population levels. This will be accomplished by following the Siskiyou Wildlife Tree (Snag) Guidelines, as detailed in the Forest-wide Standard and Guidelines (LRMP, Chapter IV). These guidelines were designed with the best information available on cavity-nesting species and their habitat requirements. The snag guidelines may be revised as new research data becomes available.

376. *COMMENT*: NO METHODS ARE DISPLAYED FOR PROTECTING DEAD AND DOWN WOODY HABITATS FROM ACTIVITIES SUCH AS FIREWOOD CUTTING AND PRESCRIBED BURNING DURING SITE PREPARATION. INCLUDE STRONGER PROVISIONS FOR FUNDING TO INSURE TIMBER SALES WILL BE MONITORED AND ADEQUATE RETENTION OF SNAGS, WILDLIFE TREES, AND DOWNED WOODY MATERIALS IS OCCURRING. HABITAT SHOULD BE PROTECTED REGARDLESS OF COST TO TIMBER HARVEST.

Response· Forest-wide Standards and Guidelines prohibit the use of designated wildlife trees for firewood. Protective measures are applied on a site-specific basis. The Siskiyou does not lose many wildlife trees to firewood cutting because of steep terrain making access very difficult

Standards and Guidelines have been revised and strengthened (see Chapter IV of the Forest Plan). Refer also to the Siskiyou Wildlife Tree (Snag) Guidelines for further explanation (copy available at any Siskiyou National Forest Office). A falldown in timber yield (less than one percent) has been applied to the timber yield tables to account for trees left for wildlife (see Appendix B, FEIS). Protection of wildlife trees from prescribed burning is desirable; this issue is addressed in individual analyses done for specific timber sale areas

Timber sales will be monitored to insure that we are meeting our Standards and Guidelines (LRMP, Chapter V). The Standards and Guidelines have been revised and strengthened (LRMP, Chapter IV).

377. *COMMENT*: THERE SHOULD BE COOPERATIVE ROAD CLOSURES IN THE NATIONAL FOREST DURING VARIOUS BIG GAME SEASONS AND IN AREAS WHERE BIG GAME BREED AND WINTER.

Response: The Siskiyou National Forest will develop a Deer and Elk Management Plan within three years after the implementation of the Forest Plan (LRMP, Chapter V, "Project Planning"). Road closures are a key issue, and will be addressed in that plan.

378. *COMMENT*: TO A LARGE EXTENT, THIS DOCUMENT SHOULD BE A RECOVERY PLAN FOR A DECLINING SPECIES. THE PROTECTION OF "LARGE BLOCKS" OF HABITAT AND "STRONGHOLDS" OF POPULATION ARE TRADITIONAL MANAGEMENT TACTICS. WHY WEREN'T THE "LARGE BLOCKS" AND "STRONGHOLDS" OF HABITAT AND POPULATION IDENTIFIED AND RETAINED AS MANAGEMENT TOOLS IN AT LEAST A FEW ALTERNATIVES?

Response: Through land allocations, and Standards and Guidelines, the Forest's fish and wildlife resources will be maintained. No species will be reduced below viable population levels, and habitat for many species will be enhanced.

In all alternatives, habitat is protected in Wildernesses (LRMP, Chapter IV, "Management Prescriptions"). In several alternatives (including M, E and G), "large blocks" of habitat are protected outside of Wildernesses (FEIS, Chapter II, "Wildlife").

379. *COMMENT*. SPECIES INDICATIVE OF TRIBUTARY STREAMS AND WET MEADOWS SHOULD BE ADDED TO TABLES IN THE FINAL DOCUMENT.

Response: We chose not to use indicator species for these habitats. Tributary streams, wet meadows, and their endemic plants are protected under Management Area 9, Special Wildlife Sites, and Management Area 11, Riparian areas (LRMP, Chapter IV, "Forest Management Direction"). The Management goals for these areas include, in part, the protection of the unique plants and animals In addition, these species are protected in Wilderness, Research Natural Areas, and Botanical areas

380. *COMMENT*: COMMODITY PRODUCTS, HARVEST AND SILVICULTURAL TECHNIQUES ARE COVERED IN GREAT DETAIL. FISH AND WILDLIFE, ON THE OTHER HAND, HAVE FEW QUANTIFIABLE OBJECTIVES OTHER THAN REFERENCES TO MAINTAINING MINIMUM POPULATION VIABILITY. IF FISH AND WILDLIFE RESOURCES ARE TO BE GIVEN EQUAL CONSIDERATION AS REQUIRED BY LAW, THEY MUST BE TREATED WITH THE SAME DEGREE OF MANAGEMENT SPECIFICITY AS TIMBER.

Response: We have provided management specificity in the form of Standards and Guidelines. Assessments of habitat capability have been made for indicator species, but in most cases populations can only be estimated grossly Taken as a whole, the natural histories of 250+ wildlife species are amazingly complex. We have just begun to understand their relationships to one another and the land Research needs have been identified (LRMP, Chapter IV), habitat inventories have been planned (LRMP, Appendix B), and a comprehensive resource inventory of the Forest will begin in 1990. We expect to be able to make better-informed decisions when the Forest Plan is next revised; we also firmly believe that all species on the Siskiyou today will still be with us at the next revision of the Forest Plan. We have based our land management decisions on the best information available.

381. *COMMENT*: PROTECT FISH AND WILDLIFE HABITAT; DO THE BEST POSSIBLE JOB OF MANAGING FOR ALL SPECIES, FROM COUGARS AND DEER, TO BUTTERFLIES AND RATTLESNAKES TOO MUCH EMPHASIS HAS BEEN PLACED ON DEER AND ELK AT THE EXPENSE OF OTHER LESS SHOWY CREATURES. THE POPULATIONS OF SOME SPECIES ARE GOING TO BE REDUCED FROM PRESENT LEVELS; THE FOREST SERVICE NEEDS TO KNOW MORE ABOUT THE NEEDS OF INDIVIDUAL SPECIES BEFORE CONTINUING TO MANAGE THE FOREST FOR RESOURCES WHICH FOSTER CHANGE, MOST NOTABLY MANAGEMENT FOR TIMBER PRODUCTION.

Response. It is true that some species will diminish in numbers as more of the Forest is brought under management for timber production. However, NFMA provides important direction to the Forest Service: "Fish and wildlife habitat shall be managed to maintain viable populations of existing native and non-native species in the planning area" (36 CFR 219.19). All wildlife species are important to the Siskiyou; we are obligated to manage for all species. Through land allocations, standards, and guidelines, the Forest's fish and wildlife resources will be maintained. No species will be reduced below viable levels, and habitat for some species will be enhanced.

We considered all available information and established Management Requirements for various species, such as the pileated woodpecker The Forest cannot wait until all the information is in; it never will be. At this time we are taking stock of existing knowledge and options, and establishing allocations and Standards and Guidelines to govern our activities during the interval before the next revision of the Forest Plan. However, if new information becomes available in the interim which could have a significant impact on existing management policies and procedures, the Forest has the option to amend or revise the Plan In the case of the spotted owl, we expect a wealth of information to become available in the next five years from a large variety of research projects. This new information could result in modification of the Standards and Guidelines set in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines).

382 *COMMENT*: THE PRESENTATION OF "THE OPTIMUM" HABITAT MIX FOR WILDLIFE SEEMS INAPPROPRIATE SINCE THERE IS NO CONSENSUS ON WHAT "OPTIMUM" MEANS. A DEER ADVOCATE WOULD HARDLY CALL A MIX OPTIMUM WHICH REDUCED DEER POPULATIONS TO ROUGHLY 55% OF PRESENT LEVELS. THE CALCULUS OF WHAT CONSTITUTES "OPTIMUM" PRESUMABLY IS WHAT ALTERNATIVE SELECTION IS ALL ABOUT

Response: The "optimum habitat mix" described in Chapter III of the DEIS was not meant to be a "consensus " On the Siskiyou, the term "wildlife" encompasses over 250 species; their habitat needs vary from openings to old growth. Because any single management action benefits SOME wildlife, but not all, the optimum habitat mix was devised as a tool to help the public weigh their thoughts on the adequacy of each alternative. The optimum mix was meant to be myopic in its vision; coordination needs with other resources were intentionally not considered. Because the optimum habitat mix was intended for use as a discussion tool by respondents to the Draft EIS and Forest Plan, it is not included in the final documents.

383. *COMMENT*: AN OLD GROWTH-DEPENDENT SPECIES WHICH HAS RECEIVED VIRTUALLY NO ATTENTION FROM THE FOREST SERVICE IS THE MARBLED MURRELET KNOWLEDGE OF NESTING HABITS AND LOCATIONS FOR THIS SEA BIRD IS SCANTY, BUT ALL PRESENT EVIDENCE INDICATES THAT IT NESTS IN OLD-GROWTH TREES WITHIN 20 MILES FROM THE OCEAN. CLEARLY, THERE IS RELATIVELY LITTLE REMAINING OF THIS ONCE-ABUNDANT HABITAT THUS, THE MARBLED MURRELET IS PROBABLY HEADED TOWARD EXTINCTION THE SISKIYOU NATIONAL FOREST IS, IN ALL LIKELIHOOD, PROVIDING NESTING SITES FOR THIS SPECIES CONCERTED EFFORTS SHOULD BE MADE TO LOCATE THE BIRD DURING NESTING SEASON BEFORE THEIR NESTING TREES ARE INADVERTENTLY CUT.

Response The Forest Service conducted an inventory for marbled murrelets during the spring and summer of 1988 (murrelets were found at six locations on the Chetco Ranger District) No nests were founds. An extensive survey for marbled murrelets will be conducted on the Siskiyou National Forest during 1989. In the future, work will be conducted to quantify habitat requirements, and delineate suitable habitat, and analyze present habitat capabilities. It is very possible that habitat needs for murrelets are being met by protection of river-associated mature and old-growth forests through other land allocations Mature and old-growth forest habitat along rivers is maintained under several land allocations, including Wild River, Wilderness, Supplemental Resource, Scenic/Recreation River, and Designated Wildlife Habitat. The Forest Plan does not designate old-growth forest along rivers specifically as murrelet habitat, and such designation under a Plan revision would not be likely unless additional habitat was required beyond that which is already protected Additional allocations could be proposed in the future if necessary to sustain a viable population of murrelets.

Sensitive, Threatened and Endangered Species (Animals)

384 *COMMENT*: AREAS OF KNOWN HABITAT OF SUCH SENSITIVE SPECIES AS SPOTTED OWLS AND GOSHAWKS SHOULD BE PARTICULARLY PRECLUDED FROM ANY PLANS FOR LOGGING.

Response: The Forest Service assumes that land allocations installed for Management Indicator Species representing mature and old-growth forest (spotted owl, pileated woodpecker, pine marten) will maintain a viable population of goshawks

A significant portion of the habitat presently suitable for goshawks, spotted owls, and other species which utilize mature and old-growth forest will be harvested as the Forest brings additional acres under rotation. However, enough habitat will remain to ensure that viable populations of all species will be maintained over the long term. As for spotted owls not within Management Area 8, all known nest sites and heavily used roost areas will be protected (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). In the case of goshawks and other raptors, active nest and roost sites will be protected (LRMP, Chapter IV)

385 *COMMENT*: PURCHASE INHOLDINGS AND SURROUNDING AREAS FOR ENDANGERED SPECIES HABITATS.

Response: No inholdings have been identified which have an effect on habitat for designated endangered species. This situation will continue to be monitored If necessary, key tracts could be purchased or acquired through land exchange.

386. *COMMENT*: ONE BIRD ALREADY ON THE ENDANGERED SPECIES LIST IS THE BALD EAGLE. A KNOWN NESTING TERRITORY FOR THIS BIRD EXISTS ON THE FOREST, YET THE PLAN OFFERS DISTURBINGLY LITTLE INFORMATION ON HOW THE FOREST SERVICE PLANS TO INSURE THE SURVIVAL OF THIS GREAT BIRD. A SITE-SPECIFIC BALD EAGLE MANAGEMENT PLAN SHOULD BE PREPARED FOR THE ACTIVE PAIR AND MANAGEMENT DIRECTION SHOULD INCLUDE IMPROVING SEARCHES FOR EXISTING WINTER HABITAT.

Response: Management direction for bald eagle habitat is contained in the Forest-wide Standards and Guidelines in Chapter IV of the Forest Plan. A site-specific management plan for bald eagles will be written within two years of Forest Plan publication. That plan will be tiered to the Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986) Interim management of eagle habitat will require informal consultation with the Fish and Wildlife Service any time a project proposal involves site disturbance which

might affect bald eagles. Such consultation will ensure that survivability of the species on the Siskiyou National Forest is not jeopardized.

The Siskiyou National Forest participates in the annual winter bald eagle count, in cooperation with ODFW and the National Wildlife Federation Although there is no systematic winter inventory for eagles, sightings by district personnel in pursuit of other field duties are recorded (and verified, when possible). These observations will be used in preparation of the Forest bald eagle management plan

387. *COMMENT*: THE TREATMENT OF BALD EAGLES AND OSPREY IS NOT CONSISTENT BETWEEN THE DEIS AND LRMP.

Response: In the Preferred Alternative, 53,000 acres of prime habitat out of 58,000 acres available are protected. Not all of the Forest's old growth is bald eagle and osprey habitat The Rogue River corridor contains the best bald eagle habitat (FEIS, Chapter II, "Comparisons of the Alternatives Considered in Detail").

388 *COMMENT*. PEREGRINE FALCONS WERE NOT DISCUSSED DESPITE THE FACT THAT FALCONS HAVE BEEN OBSERVED ON THE FOREST. ALTHOUGH SUSPECTED EYRIE LOCATIONS ARE ALREADY PROTECTED BY WILDERNESS AND WILD RIVER DESIGNATIONS, NOT MENTIONING THE PRESENCE OF THE BIRDS OR THE IMPORTANCE OF MAINTAINING CLIFF HABITATS IS AN OVERSIGHT.

LONG-TERM MONITORING OF ACTIVE BREEDING PAIRS IS NEEDED TO DETERMINE THEIR PRIMARY USE AREAS, AND HISTORICAL AND POTENTIAL EYRIES. ADDITIONAL MANAGEMENT DIRECTION TO PROMOTE CONSERVATION OF THE PEREGRINE IS NEEDED, INCLUDING CONSTRUCTION OF HACKSITES FOR REARING PARENTLESS YOUNG

Response· At the time the draft plan was written, we knew of no peregrines falcons on the Forest; we were beginning to formulate plans for potential hack sites. In the summer of 1987 the first active nest was discovered; in 1988 two more active sites were found The planning documents have been rewritten to reflect this new information. A peregrine falcon habitat inventory and management plan is required in the Forest-wide Standards and Guidelines (LRMP, Chapter IV). Reintroduction/hacking will be considered.

Peregrine habitat and monitoring of breeding pairs will be addressed as part of scheduled management plans (LRMP, Chapter IV, "Forest-wide Standards and Guidelines" and "Special Wildlife Sites - Management Area 9," and Chapter V, "Monitoring").

389. *COMMENT*. THE CONSTRAINTS WHICH ARE SUPPOSED TO ENSURE THE VIABILITY OF ALL WILDLIFE SPECIES HAVE NOT BEEN TESTED OR VALIDATED A MONITORING PROGRAM BASED ON MAINTAINING SPECIES' VIABILITY AT MINIMUM LEVELS IN INADEQUATE.

Response: The best available data was used to produce Standards and Guidelines for indicator species and others (LRMP, Chapter IV). Current and planned research, and monitoring for Forest plans will help validate the assumptions (LRMP, Chapter II, "Information Needs," and Chapter V, "Monitoring, and Appendix D).

390 *COMMENT*: THE PLAN MAKES REFERENCE IN SEVERAL SECTIONS TO THE NEED FOR MORE INFORMATION ON ENVIRONMENTAL REQUIREMENTS FOR SENSITIVE SPECIES. IT IS TO BE HOPED THAT THE FOREST SERVICE WILL GIVE HIGH PRIORITY TO THE GATHERING OF SUCH

INFORMATION AND TO ONGOING MODIFICATION OF THE PLAN AS THE NEED FOR CHANGE BECOMES EVIDENT

Response. More information is certainly needed on habitat for sensitive species, both plant and animal, as identified in "Information Needs" (LRMP, Chapter II). Considerable data is presently being collected on spotted owls. Good progress has been made on some of our sensitive plants; draft Species Management Guides have been prepared for *Bensoniella Oregana* and a few other species Wildlife and fish biologists and the Zone Botanist (shared between the Rogue River and Siskiyou National Forests) will be spending a significant portion of their time gathering information about sensitive species and recommending appropriate management The Forest is scheduled to host a regional meeting on sensitive plants in the spring of 1989. Information needs have been programmed into our budgeting process (LRMP, Appendix B, "Threatened, Endangered and Sensitive Wildlife and Plant Capital Investments"). Further information needs are also identified in the Forest Plan (Chapter II, "Information Needs"). If necessary, the Forest Plan will be modified (LRMP, Chapter V, "Monitoring and Evaluation" and "Amendment and Revision")

391 *COMMENT*. ONLY A FEW RESEARCH NATURAL AREAS AND BOTANICAL AREAS ARE PROPOSED IN THE DEIS ALL OF THE PLANTS IN TABLE F-2 SHOULD BE MANAGEMENT INDICATOR SPECIES, INSTEAD OF JUST THE FEW IN TABLE F-6 (APPENDIX F).

Response: Four potential RNA's (proposed by the PNW Research Station) are listed in the FEIS, along with 27 Botanical areas All RNA's are recommended in the Preferred Alternative S. Nineteen Botanical areas are recommended (all or in part).

If all plant species in Table F-2 (FEIS, Appendix F) were used as Management Indicator Species, there would be not point in having Management Indicator Species. Specific Management Indicator Species were selected because their population changes are believed to indicate the effects of management activities. These Management Indicator Species represent other species with similar habitat requirements Over 250 wildlife species inhabit the Forest, and at least 1400 plants. It is not feasible to monitor all species.

Spotted Owls

392. *COMMENT*: A 70 PERCENT REDUCTION IN SPOTTED OWL PAIRS OVER 50 YEARS DOES NOT SEEM RESPONSIBLE OTHER REDUCTIONS OF INDICATOR SPECIES LISTED IN THE PLAN ARE LIKEWISE UNDESIRABLE.

Response: Habitat capability calculations for spotted owl have been revised for the FEIS. Spotted owls are expected to experience a predicted population decline of a little less than 40 percent by the fifth decade. The population decline for the first decade is less than 10 percent. They same general trend will apply to the pileated woodpecker and pine marten. Options will be available at the beginning of the next planning cycle to protect more mature and old-growth forest, especially if research in progress shows that this is necessary to maintain viable populations of dependant wildlife. The Forest endeavored to create a Preferred Alternative S which would insure that wildlife habitat shall be managed to maintain viable populations of all existing native and desirable non-native species.

393 *COMMENT* RESEARCH DONE TO DATE ON SPOTTED OWLS AND THEIR HABITAT IS INCONCLUSIVE. NO HABITAT SHOULD BE SET ASIDE UNTIL FURTHER RESEARCH SHOWS CONCLUSIVELY THAT IT IS ACTUALLY NECESSARY, NO MORE LAND SHOULD BE SET ASIDE FOR THE SPOTTED OWLS, BECAUSE WITH EXISTING WILDERNESS, RESEARCH NATURAL AREAS, WILD RIVER, AND STREAM BUFFER STRIPS THERE ARE OLD GROWTH STANDS OVER THE ENTIRE SISKIYOU FOREST THAT WILL NEVER BE CUT, (OTHER PEOPLE BELIEVE) NO

MORE HABITAT SHOULD BE CUT UNTIL FURTHER RESEARCH CONCLUSIVELY DETERMINES HOW MUCH IS NEEDED TO MAINTAIN A VIABLE POPULATION

(MANY PEOPLE THOUGHT THAT) A SPECIFIC AMOUNT OF HABITAT SHOULD BE ALLOCATED TO SPOTTED OWLS; (OTHERS THOUGHT) NO HABITAT SHOULD BE SET ASIDE FOR SPOTTED OWLS SOME PEOPLE EXPRESSED A PREFERENCE FOR A SPECIFIC AMOUNT OF HABITAT PER DESIGNATED HABITAT AREA. A FEW PEOPLE EXPRESSED THE SAME CONCERNS ABOUT PILEATED WOODPECKER AND PINE MARTEN.

Response· The spotted owl has received considerable attention for the last 15 years. Much research has been conducted into the owl's habitat requirements, including home range size, juvenile dispersal, need for mature/old-growth forest, and food requirements. A number of radio telemetry studies on spotted owls are currently in progress; the knowledge base on spotted owls is constantly expanding. Extensive monitoring programs are being conducted to determine the effects of forest management over time As new information becomes available, adjustments may be made to management plans A mandatory evaluation of current planning for spotted owl habitat will occur five years after approval of the Spotted Owl Supplement to the Regional Guide (USDA Forest Service 1988b); Appendices C and D contain further information on Regional research needs and plans In addition, a comprehensive resource inventory will be initiated on the Siskiyou in 1989. Data collected on mature and old growth forest will enable us to do a better job of managing these important habitat types

Research is also being conducted into the habitat needs of pileated woodpecker and pine marten, although not at the same intensity as for spotted owls. The Siskiyou feels that based on current knowledge, allocations must be made now for indicator species representing mature and old-growth forest habitat. In some areas of the Siskiyou, adequate mature and old-growth habitat will simply not be available at the next revision of the Forest Plan. If more area has been set aside than necessary, habitat can be rededicated to timber management at the beginning of the next planning cycle; if the converse is true, options will already be forgone - cutover areas will not produce mature and old-growth habitat again for many decades.

The Forest Service is committed to maintaining viable populations of all wildlife species, including spotted owls. Standards and Guidelines detailed in Chapter IV of the Forest Plan insure a viable population of spotted owls will be maintained on the Siskiyou during the current 10- to 15-year planning period. The Siskiyou's habitat network for spotted owls conforms to the Standards and Guidelines contained in the Spotted Owl Supplement to the Regional Guide (USDA Forest Service 1988b). Forest and Regional Standards and guidelines conform to direction in the National Forest Management Act (NFMA)

The Siskiyou Forest Plan will meet the direction established by NFMA: *Fish and wildlife habitat shall be managed to maintain viable populations of existing native and non-native species in the planning area For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure its continued existence is well distributed in the planning area. In order to insure that viable populations will be maintained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area (219 19)*

394. *COMMENT*: CATCH OWLS AND MOVE THEM TO NEW TERRITORY

Response: Assuming that "owls" means spotted owls, this technique has been suggested from time to time by people in and outside of the Forest Service. Owls could be caught, and they could be moved The problem is there is no habitat to move the owls to All suitable habitat is occupied by other owls If the habitat base spotted owls depend on is reduced, the owl population is correspondingly reduced

395. *COMMENT*: FORGET ABOUT THOSE SPOTTED OWLS AS THEY ARE A MIGRATORY BIRD SO CAN TAKE BETTER CARE OF THEMSELVES THAN WE HUMANS CAN.

Response: Spotted owls are not migratory; they spend the entire year in the same general area At some locations owls may spend the breeding season at higher elevations, and the non-breeding season at lower elevations.

396. *COMMENT*. THERE IS NO CONCLUSIVE SCIENTIFIC EVIDENCE THAT SPOTTED OWLS ARE THREATENED OR ENDANGERED. THE BIT OF RESEARCH THAT HAS BEEN COMPLETED ASSUMES SPOTTED OWLS ARE OLD-GROWTH DEPENDENT AND FAILS TO SEARCH FOR OWLS LIVING AND SURVIVING IN SECOND-GROWTH TIMBER

Response: Spotted owls are not listed by the USDI Fish and Wildlife Service as threatened and endangered. They are classified as "sensitive" by the Forest Service Spotted owls are currently being intensively studied, much has been learned about their habits and habitat Spotted owls are dependent on mature/old-growth forest Spotted owls are occasionally found in non-typical habitat. Juvenile birds sometimes disperse to non-typical habitat, this does not mean that they can successfully live there long-term. A few nesting pairs have been found in what some have termed "second growth " On closer examination, it is apparent that these stands have the habitat character required by the owls for successful nesting. Smaller diameter trees may predominate in these stands, but these are areas that have not been clearcut in the past. In other words, the stand has natural character; for instance, large woody material is present in natural amounts (on the ground) Prey animals are present in sufficient numbers to sustain the owls. These stands also include at least some larger trees suitable as nest sites For more information, see the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines, USDA Forest Service, 1988b).

397 *COMMENT*: THE NORTHERN SPOTTED OWL IS NOW LISTED AS THREATENED IN OREGON AND IT MIGHT BE ASSUMED THAT IT WILL RECEIVE A FEDERAL LISTING AS ENDANGERED OR THREATENED BEFORE LONG IN THESE CIRCUMSTANCES, ANY DELIBERATE, HUMAN-INDUCED DROP IN THE SPOTTED OWL POPULATION OF THE FOREST IS UNACCEPTABLE

Response: The spotted owl is listed by the Oregon Department of Fish and Wildlife as a Threatened species; however, this does not have the same legal status as would listing as threatened or endangered by the USDI Fish and Wildlife Service under the provisions of the Endangered Species Act.

Region Six of the Forest Service has published a Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines, USDA Forest Service, 1988b) dealing with the spotted owl issue. The Forest Service goal is to preserve enough habitat to maintain a viable population of spotted owls through time (at least through the planning horizon of 150 years). The word "viable" is not a synonym for "maximum"; as old-growth stands continue to be harvested, less habitat will be available for spotted owls, and their population will drop. But the National Forests of the Pacific Coast will always preserve enough old-growth forest to maintain a viable population of spotted owls If new data becomes available that shows spotted owls need significantly more (or fewer) acres of old growth per pair than is currently allocated, then the Regional Guide and Forest Plan will be revised to reflect the new data A great deal of research is being conducted on spotted owls by federal and state agencies, and universities At present, well over 100 northern spotted owls are fitted with radio transmitters throughout the Pacific Northwest; data generated from radio telemetry and other types of studies will help fill in our knowledge gaps about their habitat requirements.

398 *COMMENT*: PRESERVE THE HABITAT OF THE NORTHWEST SPOTTED OWL (2000 TO 3000 ACRES AROUND EACH NESTING TREE) AND CONTINUE TO MONITOR AND RESEARCH ALL KNOWN PAIRS IN ORDER TO PREVENT LOCAL EXTINCTION OF OUR NORTHERN SPOTTED OWL

AN INTERAGENCY AGREEMENT SIGNED ON DECEMBER 1, 1987, BY THE DIRECTOR OF THE FWS AND THE CHIEF OF THE FOREST SERVICE COMMITS THE FOREST SERVICE TO ENSURE THE CONTINUED EXISTENCE OF A WELL-DISTRIBUTED NORTHERN SPOTTED OWL POPULATION THROUGHOUT ITS NATIONAL FOREST RANGE.

Response. A new interagency agreement between the USDA Forest Service and USDI Bureau of Land Management, National Park Service, and Fish and Wildlife Service was signed in August 1988. It focuses on the fact that all four agencies are integral to the success of maintaining a viable spotted owl population

At a minimum, the Forest will meet the Standards and Guidelines described in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines, USDA Forest Service, 1988b). This means that on the Siskiyou, at a minimum, each Spotted Owl Habitat Area (SOHA) will consist of 1,000 acres of suitable habitat. The SOHA network (plus randomly sampled areas) will be intensively monitored for at least five years.

399 *COMMENT*. MODIFY THE ALTERNATIVES TO INCREASE THE NUMBERS OF SPOTTED OWL PAIRS OVER FIVE DECADES.

Response: Table II-48 of the FEIS, Chapter II, displays an estimate of the number of spotted owl pairs which could be supported by each alternative, at various decades. The numbers displayed are reasonable, but we will never be able to give exact counts of the owl pairs present at any given time, under any given alternative. Our estimates are based on general knowledge of habitat requirements for spotted owls, including home range. Table II-48 also provides an estimate of available habitat for all alternatives, for a variety of decades; these figures give you another perspective on the issue

400. *COMMENT*: HIGHER ELEVATIONS MAY REQUIRE MORE HABITAT FOR SPOTTED OWLS, BASED ON RESEARCH ONGOING AT REDWOOD SCIENCES LAB OWLS ABOVE 3000' HAVE HOME RANGES NEARLY DOUBLE OF LOWER ELEVATION OWLS. THE 1000 ACRES OF SUITABLE HABITAT SHOULD BE INCREASED TO 2200 ACRES AS AN AVERAGE.

Response. The size of spotted owl habitat areas on the Siskiyou has been set at 1,000 acres based on direction in the Spotted Owl SEIS (USDA Forest Service 1988b). A mandatory review of direction in the SEIS is scheduled in 1993; a review of the SEIS may occur at other intervals, if needed.

401 *COMMENT*: IN AN ATTEMPT TO PLACE SOHA'S IN RESERVED AND UNSUITABLE (FOR TIMBER HARVEST) AREAS, THE HIGHEST QUALITY AREAS AND THOSE WITH EVIDENCE OF OCCUPANCY AND USE MAY BE PASSED BY AND THE SPACING OF THE SOHA'S WILL BE STRETCHED TO THE FARTHEST LIMIT ALLOWED. THIS TENDENCY MULTIPLIED OVER THE OWL'S ENTIRE RANGE COULD SERIOUSLY AFFECT THE OWL'S VIABILITY.

SOHA'S ARE JAMMED INTO DESIGNATED WILDERNESS TO AVOID DECISIONMAKING. IT SEEMS PROBLEMATICAL AT BEST THAT THE SOHA'S IN THE KALMIOPSIS ARE ACTUALLY SUITABLE GIVEN THE FACT THAT MANY ARE UNOCCUPIED AND THE HABITAT HAS BEEN ALTERED IN THE NORTH BY RECENT FIRE

Whenever possible, Siskiyou SOHA's were set up at locations where spotted owls had previously been detected Spotted owls have been found at all but three Designated Habitat areas (sites outside of wildernesses). Although SOHA's were located in areas with little or no programmed harvest whenever possible, actual SOHA placement was driven primarily by dispersion requirements. SOHA's were not unilaterally relegated to the least productive sites.

Wherever possible, spotted owl habitats were placed in lands not suitable for timber production, this minimized opportunity costs to the timber program However, to meet Management Requirements described in the Spotted Owl SEIS (USDA Forest Service 1988b), it is necessary to allocate some habitat areas in locations otherwise suitable for timber management.

Wildernesses on the Siskiyou contain large areas of habitat suitable for spotted owls. These areas are the heart of the Siskiyou habitat network. Spotted owls have been found at over 20 locations in Wildernesses, even though Wilderness owl habitat has not received as much survey attention as areas of general forest As far as the 1987 fires are concerned, more owl habitat was affected outside of Wilderness than inside. Slightly over five percent (25,000 acres) of the Forest's mature and old-growth habitat was lost in the fires, and much of this burned acreage was not part of the designated habitat network for spotted owls.

402 *COMMENT*: THERE IS NO MENTION OF OCCUPANCY OF THE SITES (DESIGNATED HABITAT) BY THE WILDLIFE IN QUESTION. THE NFMA REGULATIONS REQUIRE A REPRODUCTIVELY ACTIVE PAIR OF OWLS IN THE NETWORK.

Response· The "presence" of spotted owls has been found at all but three of the Forest's Designated SOHAs. Of the three, one site is an island of old-growth in a sea of serpentine, and the other two were recently added to the Designated SOHA network as a result of a 1987 Regional Office review All three sites are needed to meet distribution requirements; there were no other logical alternatives to these sites. Reproduction is known at only five of the Designated SOHA's, but intensive monitoring efforts were only recently begun (1987); we expect to ultimately find that most Designated SOHA's contain breeding pairs of spotted owls.

403 *COMMENT*: ESTABLISH WIDE CORRIDORS LINKING PROTECTED HABITAT. EVEN THIS METHOD MAY NOT BE OF MUCH VALUE TO SPECIES SUCH AS THE NORTHERN SPOTTED OWL, WHICH REQUIRE LARGE RANGES

Response· The Forest Service has not relied on narrow habitat corridors (riparian areas along streams) to meet the habitat requirements of wildlife species with large home ranges, such as the spotted owl. Management Area 8, Designated Wildlife Habitat, was designed to provide habitat for creatures like the spotted owl which use large areas of mature or old-growth forest (LRMP, Chapter IV, "Management Prescriptions") Moreover, large blocks of habitat such as SOHA's are connected by Riparian areas (150 feet either side of Class I and II streams; 100 feet either side of Class III). Vegetative cover (tree cover) will be maintained in Riparian corridors; these areas will essentially be managed in an unevenaged condition. The corridors will serve as travelways and flightways for wildlife traveling between larger habitat blocks. Put another way, the Riparian corridors will serve as a cover network connecting various large blocks of older seral stages not managed for timber harvest

404. *COMMENT*: ONE OF THE KEY CONCERNS AFTER THE RECENT RASH OF FIRES ON THE SISKIYOU IS THE IMPACT ON SPOTTED OWLS. ACCORDING TO THE FOREST BIOLOGIST, A NUMBER OF SPOTTED OWL SITES WERE LOST IN THE FIRES. AS MANY AS 12 SITES WERE IMPACTED, NEARLY 20 PERCENT OF THE SISKIYOU NETWORK. THE INFORMATION IN THE DEIS NEEDS TO BE UPDATED

IF A CERTAIN PERCENTAGE OF SITES (SOHA'S) WERE LOST DUE TO FIRES, WILL THE FOREST PROVIDE MORE IN THE FUTURE TO ACT AS A BUFFER?

Response: Sections on the "1987 Fires" in Chapters II, III, and IV of the FEIS review effects of the fires on old growth and Spotted Owl Habitat Areas. Figures for mature and old growth are "post-fire" in the LRMP

If SOHA's are lost to fires, adjacent suitable habitat will be substituted. If suitable habitat is not available, then capable habitat will be substituted (see Standards and Guidelines for Management Area 8, LRMP, Chapter IV).

405. *COMMENT*: IF AN ADDITIONAL 1200 ACRES AROUND THE CORE SOHA IS WITHDRAWN FROM TIMBER HARVEST FOR THE PLANNING PERIOD (10-15 YEARS), BUT STILL USED AS TIMBER BASE IN CALCULATING ANNUAL HARVEST DURING THAT TIME PERIOD, THEN THE COMMERCIAL FOREST BASE OUTSIDE THE SOHA'S WILL BE OVER-CUT FOR 10-15 YEARS WITH POTENTIALLY DISASTROUS IMPACTS.

Response: In areas managed for timber, each Siskiyou SOHA will be 1,000 acres No additional acres will be allocated to any of these SOHA's. Given the above scenario, the effects could likely be significant.

406. *COMMENT*: RECREATION SITES, TRAILS AND ROADS SHOULD BE AVOIDED NEAR SPOTTED OWL NESTS. VQO'S MIGHT SERVE AS CORRIDORS BETWEEN SOHA'S.

Response: We have established a Standard and Guideline which directs that recreation and other activities occur 1,000 feet or more from nest sites or roost areas. Minimum stand size is established at 60 acres per intent of a Standard and Guideline established in the Spotted Owl SEIS (USDA Forest Service 1988b). Retention and Partial retention may or may not serve as habitat corridors between Designated Wildlife Habitat areas; this value has not been given to visual areas in the Standards and Guidelines

407 *COMMENT*: WHY ARE ONLY 40 SPOTTED OWL HABITAT AREAS ALLOCATED ON THE SISKIYOU?

Response: NFMA directs that each planning area (National Forest) will provide habitat to maintain well-distributed viable populations of all existing native and non-native species Each Forest developed its own spotted owl habitat network based on these criteria For more information, see the Final Spotted Owl Supplement (USDA Forest Service 1988b).

408. *COMMENT*: MAKE THE PROTECTION OF OWLS VERY SMALL WHEN THERE ARE TOO MANY OF THEM, THEY KILL OTHER BIRDS.

Response: According to Forsman and others (1984), birds comprise a small percent of an owl's diet (FEIS, Literature Cited).

Management Indicator Species

409. *COMMENT*: THE INDICATOR SPECIES APPROACH TO ASSESSING WILDLIFE VIABILITY IN RELATION TO SPECIFIC HABITATS IS A THEORETICAL MODEL OF QUESTIONABLE VALIDITY

Response: The indicator species concept is theoretical However, NFMA requires that the indicator species concept be used in developing Forest Land and Resource Management Plans. Specific indicator species were selected because past research has indicated that these species were strongly associated with certain habitats More research will be conducted on many of the indicator species and monitoring of habitat will continue through the planning cycle (LRMP, Chapter V and Appendix D).

410 *COMMENT*: HOW MANY PILEATED AND MARTEN SITES ARE ACTUALLY OCCUPIED BY THE SPECIES? NO MENTION IS MADE ABOUT HABITAT REQUIREMENTS OR WHY THESE WERE CHOSEN AS INDICATOR SPECIES.

Response: Although sighting information has not been systematically gathered, pine martens have been found in eight Designated Wildlife Habitat areas; pileated woodpeckers in six At first thought this seems quite low, but in past years the Forest has concentrated survey efforts on spotted owls, not pileated woodpeckers and pine martens. We expect to find evidence of pileated woodpeckers in most, if not all areas designated for their use Marten use will be harder to ascertain, although we expect that marten are using many of the designated areas We believe the habitat areas designated for pileated woodpeckers and pine marten are suitable; monitoring plans for both species are designed to determine presence (LRMP, Appendix D).

Based on our knowledge of the Siskiyou, we feel that 100 years is a reasonable estimate of the time it takes the average stand to reach the mature stage. Pileated woodpeckers and pine marten are thought to adequately represent other species which use mature forest habitat; they were selected as Management Indicator Species through Regional coordination efforts Their habitat requirements are displayed in the description of Management Area 8 (LRMP, Chapter IV).

411. *COMMENT*· THE SISKIYOU SELECTED THREE INDICATOR SPECIES TO REPRESENT OLD GROWTH HABITAT: THE SPOTTED OWL, PILEATED WOODPECKER AND PINE MARTEN. THE FOREST SERVICE IS CURRENTLY IN THE PROCESS OF CONDUCTING A NEPA ANALYSIS OF THE HABITAT NEEDS FOR THE SPOTTED OWL. NO SUCH NEPA ANALYSIS EXISTS FOR THE OTHER TWO INDICATOR SPECIES FOR OLD GROWTH USED BY THE SISKIYOU.

Response: Protection of spotted owl habitat is being addressed on a Regional basis through the SEIS because habitat management to support viable populations of spotted owls is a coordinated effort between many National Forests NEPA analysis of habitat needs of the pileated woodpecker and pine marten is being conducted on the Forest level through the Forest Plan The Siskiyou's analysis of habitat needs for these species was open to comment upon publication of the DEIS (FEIS, Appendices D and J)

412 *COMMENT*: RESEARCH BY KIM MELLEN, OSU GRADUATE STUDENT, INDICATES A NEED TO MANAGE 495 ACRES AS A CORE AREA FOR PILEATED WOODPECKERS. THE FOREST IS ENCOURAGED TO INCORPORATE THE FINDINGS INTO THE FINAL PLAN.

Response: The Forest's habitat network for pileated woodpecker is organized per Regional direction (USDA Forest Service 1986b) Pileated woodpecker habitat needs has been identified as a research need in Chapter II (LRMP, "Information Needs").

413. *COMMENT*: THE FOREST HAS NOT SELECTED AN INDICATOR SPECIES FOR RIPARIAN HABITATS, MEADOWS, OR UNIQUE WILDLIFE HABITAT AREAS. ODFW AND FOREST BIOLOGISTS SHOULD DISCUSS THE NEED FOR AN INDICATOR SPECIES FOR RIPARIAN

HABITAT. FOR MEADOW HABITAT, DEER AND ELK SHOULD BE IDENTIFIED AS INDICATOR SPECIES OF THIS FORAGE PRODUCING HABITAT.

Response. Currently, we do not have a suitable indicator species for riparian habitat (such as meadows), there is also not enough information to select indicator species for many of the other special habitats Research which may provide this valuable information is identified in the LRMP (Chapter II, "Information Needs"). The Forest will be open to consider additional indicator species in the future.

414. *COMMENT*: THE GOSHAWK SHOULD BE LISTED AS SENSITIVE AND RECEIVE MORE PROTECTION. CONSIDER USING THE GOSHAWK AS AN INDICATOR SPECIES.

Response: The goshawk is a sensitive species in California, but not Oregon. The few known nest sites are protected. Goshawks are protected under the Standard and Guideline for Raptors (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Surveys have not specifically been conducted for goshawks. However, surveys for the California part of the Forest are planned as part of the capital investment program (LRMP, Appendix B). There is no estimate of population size.

The goshawk was not used as an indicator species because of the perceived difficulty in monitoring population trends. For this planning period, it is assumed to be represented by the spotted owl. Based on inventory information collected during this planning period, the species may be used as a management indicator species in subsequent planning cycles.

415 *COMMENT*: THE INDICATOR SPECIES APPROACH IS UNDERCUT BY THE SYSTEMATIC REMOVAL OF FOUR OF THE SIX SPECIES LISTED IN THE SPECIES MATRIX IN APPENDIX J. IT APPEARS, AFTER READING APPENDIX J, THAT ALL OF THE ANIMAL SPECIES WHICH DEPEND UPON THE OLD GROWTH HABITAT OF THE SISKIYOU ARE RELYING UPON FOREST SERVICE INVENTORIES OF THE NEEDS OF THE PINE MARTEN AND THE PILEATED WOODPECKER. EITHER THE TEXT IS ABSURDLY INADEQUATE, OR YOU MUST OFFER MORE EVIDENCE THAT ELK, WOLVERINE, OTTER, SALAMANDERS, AND OTHER NATIVES ARE IN FACT GOING TO SURVIVE IN THE SISKIYOUS.

Response: No Siskiyou species were dropped from the species matrix in Appendix J of the DEIS. As indicator species, the spotted owl, pileated woodpecker, and pine marten represent over 150 other species which use mature and old-growth forest. Riparian areas (not represented by an indicator species) act as corridors connecting the habitat areas set aside for the three species mentioned above. These corridors will provide travelways for salamanders and other species. Where needed, habitat requirements for non-game species are addressed in the Forest-wide Standards and Guidelines (LRMP, Chapter IV) Standards and Guidelines for Special Wildlife Sites (Management Area 9) protect specific wildlife habitats, such as meadows and rock sites. Thermal cover for deer and elk is not addressed in depth; however this cover type is plentiful on the Siskiyou. A comprehensive management plan for deer and elk is scheduled as part of the Forest-wide Standards and Guidelines; thermal cover distribution will be one of the topics addressed (LRMP, Chapter IV).

We believe the mix of land allocations in the FEIS Preferred Alternative S will maintain viable populations of all existing native and desired non-native vertebrate species inhabiting the Forest.

416. *COMMENT*: SUFFICIENT MATURE AND OLD-GROWTH FOREST MUST BE MAINTAINED TO SUPPORT VIABLE POPULATIONS OF PILEATED WOODPECKERS, PINE MARTINS, AND SPOTTED OWLS.

Response· All three of these animals are Management Indicator Species for other wildlife which utilize mature or old-growth forest. The Siskiyou has developed Management Requirements to insure that populations of the three species mentioned above (plus all native and desirable non-native species) are maintained at viable levels. All alternatives in the Forest Plan (except NC) contain these Management Requirements (FEIS, Appendix J) For more detail on the Forest's management of habitat for spotted owl, pileated woodpecker, and pine marten, see Management Area 8, Designated Wildlife Habitat (LRMP, Chapter IV).

417 *COMMENT*· FOREST PLAN P.D-9 WILL THE FOREST MONITOR HABITATS, POPULATIONS, OR BOTH, FOR PILEATED WOODPECKERS AND PINE MARTENS?

Response: The Forest will monitor habitat, and attempt to establish animal occupancy/presence/abscence. For more detail, see monitoring plan elements CW121(a) and (b) in Appendix D of the Forest Plan.

418. *COMMENT*: THE USFS HAS NOT DEFINED NUMERICALLY WHAT THE "VIABLE POPULATION" OBJECTIVES ARE FOR SPECIES OTHER THAN SPOTTED OWLS, PILEATED WOODPECKERS AND PINE MARTENS. THE MINIMUM "VIABLE POPULATION" LEVELS FOR THESE THREE SPECIES ARE SUBJECTIVE JUDGMENTS MADE BY THE USFS AND ARE NOT SUPPORTED BY BIOLOGICALLY SOUND DATA.

Response: The FEIS and Forest Plan deal with habitat capability rather than populations. Habitat capability, however, is quantified in terms of animal numbers to give relative comparisons of theoretical population levels that could be supported under different habitat management emphases (FEIS, Chapter III, "Wildlife"). These numbers should be viewed as a measure of habitat rather than of population levels since population levels vary for many reasons other than habitat quality. It is not necessary to numerically define "viable populations" for the three species; an interlocking network of habitat areas between adjacent Forests insures that populations of the three species will be maintained throughout the Region.

Game Species

419. *COMMENT*· THE PLAN DOES NOT APPEAR TO ADEQUATELY PROVIDE FOR THE HABITAT REQUIREMENTS OF DEER AND ELK ON MANAGEMENT AREAS 13 (PARTIAL RETENTION VISUAL) AND 14 (GENERAL FOREST). TIMBER HARVEST OBJECTIVES AND/OR THE ROTATION AGE SHOULD BE MODIFIED SO AS TO INSURE THERE WILL BE ENOUGH FORAGE AND OPTIMUM THERMAL COVER TO MEET OR EXCEED THE OREGON DEPARTMENT OF FISH AND WILDLIFE POPULATION OBJECTIVES.

Response: The Siskiyou elected to use Forest-wide Standards and Guidelines for deer and elk habitat, rather than provide specific direction for each Management Area (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). The Standards and Guidelines were revised between the DEIS and FEIS, but are still general in nature They direct that a comprehensive Deer and Elk Management Plan be completed within three years after release of the Forest Plan Many topics will be addressed in depth, including road closures, habitat improvement projects (including permanent forage areas), forage quality, elk reintroductions, winter range capability, cover/forage ratios, and cover types (hiding, thermal, optimal thermal)

For example, as part of a Forest-wide deer and elk management plan, the Forest will be seeding and fertilizing a number of clearcuts on all Ranger Districts; an administrative study will give us important

information on the relationships between forage improvements and reforestation success. The Forest also plans to reclaim meadow sites lost to forest encroachment. These will become permanent forage sites We estimate that 3,500 acres of meadow could be reclaimed Other sites could also be converted into permanent forage sites; this will be analyzed as part of the Deer and Elk Management Plan.

Rotation age on the Siskiyou's managed timber stands will average 100 years; short rotations will not be undertaken to increase the ratio of forage to cover. Under the Preferred Alternative, future habitat capability for deer and elk will be relatively stable. However, a number of forage improvement projects for deer and elk are scheduled as part of the wildlife capital investment program (including KV) (LRMP, Appendix B). Under the Forest's previous land management plans, more land was allocated to timber management than in the Preferred Alternative S of this Forest Plan. In the long-term, this is good news for wildlife species that depend on older seral stages. On the other hand, this better balance of habitats for all of the Forest's creatures means that timber will be harvested on fewer acres each year, and populations of animals dependant on early seral stages will not increase over the long-term.

The Siskiyou is currently working with tentative population objectives suggested by the ODFW in 1980. As part of the management plan the Siskiyou and state fish and wildlife agencies will set coordinated population objectives. Present suggested objectives are based on limited data, and do not reflect changes in management direction established in this Forest Plan. At present, the Siskiyou contains adequate optimal thermal cover. As more and more of the Forest is brought under management, this may no longer be the case. The Deer and Elk Management Plan will address this potential problem.

420. *COMMENT*: HOW CAN THE FOREST, WITH OVER 1 MILLION ACRES, PROVIDE ONLY 309 ACRES TO ROOSEVELT ELK? THE FOREST CANNOT SUPPLY ENOUGH ELK FROM THE CURRENT POPULATION LEVEL WHY WILL MORE HABITAT NOT BE PROVIDED? WHAT IS THE CURRENT HERD SIZE? CAN IT BE INCREASED WITH ADDED INVESTMENT IN HABITAT, SEEDING AND ROAD CLOSURES? THE DISCUSSION IN THE DEIS DOES NOTHING TO SUPPORT ELK REINTRODUCTION ON THE SISKIYOU.

Response: The 309 acres include a few identified small sites which contain important (special) habitat for elk, this category of Special Wildlife Site was not meant to be an all-encompassing list of habitat areas for elk. The Forest will continue to provide habitat for an elk herd estimated at 1,350 animals In past years elk have been transplanted at a number of sites on the Forest; more transplants may be made, depending on the outcome of the Deer and Elk Management Plan which will be written after release of the Forest Plan (LRMP, Chapter V, "Project Planning"). A number of capital investments projects are planned which will benefit elk (LRMP, Appendix B).

421. *COMMENT*: THREE TYPES OF COVER NEED TO BE ADDRESSED IN THE STANDARDS: HIDING COVER, THERMAL COVER, AND OPTIMUM THERMAL COVER THE DEFINITIONS FOR THESE TERMS ARE FOUND IN "MANAGEMENT OF WILDLIFE AND FISH HABITATS IN FORESTS OF WESTERN OREGON AND WASHINGTON" (BROWN 1985).

Response: Cover requirements and road management are addressed in general terms in the Forest-wide Standards and Guidelines; they will be addressed more specifically in the upcoming Forest-wide management plan for deer and elk (LRMP, Chapter IV)

422. *COMMENT*: PROTECT THE MEADOWS WHERE THE ELK GRAZE.

Response: Meadows will be protected or enhanced for use by wildlife under the Forest Plan Enhancement activities could include prescribed fire, removal of encroaching conifers, or fertilization and

seeding. Meadows will be managed under Special Wildlife Sites (LRMP, Chapter IV, "Management Area 9" and "Forest-wide Standards and Guidelines") In addition, the Forest Deer and Elk Management Plan will include some site-specific improvement/protection measures.

423. *COMMENT*: PROTECT ALL ELK WINTER-RANGE, AND ALL UNIQUE INTEREST AND SPECIAL WILDLIFE SITES.

Response: All Unique Interest (MA 5) and Special Wildlife Sites (MA 9) are protected under the Preferred Alternative S Elk winter range is not deemed to be a critical habitat need on the Siskiyou, nevertheless winter range for deer and elk will be addressed in a comprehensive management plan scheduled to be completed within a few years after approval of the Forest Plan (LRMP, Chapter IV, "Forest-wide Standards and Guidelines").

424. *COMMENT.* MANAGEMENT DIRECTION FOR GAME SPECIES IS PARTICULARLY DEFICIENT, AND FOR SOME SPECIES TOTALLY ABSENT. CONSTRAINTS ON TIMBER MANAGEMENT ACTIVITIES ARE INCLUDED ONLY FOR DEER AND ELK BEAR, BAND-TAILED PIGEONS, TREE SQUIRRELS, GROUSE AND QUAIL ARE NOT EVEN MENTIONED IMPLEMENTATION OF THE PLAN WITHOUT NECESSARY MANDATORY CONSTRAINTS WILL RESULT IN SEVERE LONG-TERM ADVERSE IMPACTS TO MOST HARVESTABLE WILDLIFE SPECIES

Response: Standards and guidelines were revised and expanded for the FEIS due to public comments The mix of land allocations was fine-tuned. Not every species is addressed directly, but all species benefit from the array of land allocations, and Standards and Guidelines in place No timber harvest is programmed in Management Areas 1 through 9, or on lands in Management Areas 10 through 14 which are unsuitable for the production of timber. These lands cover half of the Forest.

The mix of land allocations, Standards and Guidelines described in these Forest Plan documents will maintain viable populations of all species. Game and non-game animals alike will fare well, and habitat for many species will be maintained at high levels.

425. *COMMENT*· THE APPARENT SIGNIFICANT DROP IN DEER HABITAT CAPABILITY IN MOST ALTERNATIVES DOES NOT SEEM REALISTIC

Response: After a review of the methods for calculating deer habitat capability, a computation error was found. Affected tables and text have been revised to reflect the correction Estimated habitat capability for the Forest was underestimated by approximately 25 percent. However, all alternatives and benchmarks contained the same error, the RELATIVE differences between alternatives are similar in both the Draft and final documents.

426. *COMMENT*: THE FOREST NEEDS TO DESCRIBE THE TYPES OF PROJECTS THAT WOULD INCREASE HABITAT CAPABILITY FOR DEER AND ELK, AND THE REASONS FOR THEM

Response. Capital investment tables have been extensively revised in Appendix B of the LRMP. Examples of structural improvements include nestboxes and platforms, water developments, tree topping, road closures, and information/ education displays; for more details, contact any Forest office. Inventory and survey projects result in identification of habitat improvement projects Funds for wildlife forage enhancement in harvest units, such as those improving deer and elk habitat, are included in the annual program budgets as exemplified by "CWKV" in Table B-1 of Appendix B (LRMP)

Other Wildlife Comments

427. *COMMENT.* NEITHER THE PLAN NOR THE DEIS RECOGNIZE THE IMPORTANCE OF HARDWOODS TO WILDLIFE SUCH AS DEER, BEAR, BAND-TAILED PIGEONS AND TREE SQUIRRELS, OR THE CONSEQUENCES OF REMOVING THEM.

Response. A small percentage of the Forest's hardwood acres may be converted to conifer plantations or cut for fuelwood during the next 10 years. Management options will still be available for most stands at the end of this planning period.

The Siskiyou Forest Plan is designed to guide managers for the next 10 to 15 years; at that time the plan will be revised. At this stage in the life of the Siskiyou, we have elected to stop, take stock of all available information and options, and make the best land stewardship decisions we could Many research needs (including hardwood/wildlife relationships) are identified in Chapter II of the LRMP. New techniques, inventories, and information will be used to revise the Plan at the next update. If warranted by new findings, this Plan may be supplemented or amended before the end of the planning period.

428. *COMMENT*: THE 1980 AND 1985 "NATIONAL HUNTING AND FISHING AND OTHER WILDLIFE RELATED USES" SURVEYS BY THE USFWS ARE ARE AVAILABLE AND WILL PROVIDE MORE RECENT DATA ON NONCONSUMPTIVE USE. THIS DATA NEEDS TO BE USED IN THE ANALYSIS.

Response: The 1980 survey was referenced in Chapter III of the FEIS.

429. *COMMENT*· INCREASE WILDLIFE USER DAYS TO 81,700 DAYS ANNUALLY.

Response. In response to public input, the method of calculation for Wildlife User Days (WFUD's) has been revised in the FEIS (Appendix B). WFUD's attributable to game animals are still calculated based on available foraging habitat in a given decade. WFUD's for nongame are now calculated differently. WFUD's for the FEIS Preferred Alternative S are calculated at 83,100 per year for the first decade. This includes WFUD's resulting from capital investments.

For the situation prior to the implementation of the Forest Plan, total game/non-game WFUD's are calculated at 80,900 per year. The game portion of the WFUD's is 40,450 per year (based on ODFW and Forest Service data). There are no reliable figures available for non-consumptive use, although it is considered significant (more than equal to game use, according to the Fish and Wildlife Service [USFWS 1977]). Therefore, for planning purposes, current non-game WFUD's are assumed to be equal to game (40,450) In the DEIS, non-game WFUD's rode the charts in tandem with game WFUD's. In the FEIS, a base of 40,450 WFUD's (annual) for non-game is set This figure has been increased by 1/2 of 1 percent (0.005) per year compounded annually, which is the projected level of increase in use of Forest resources by recreationists for the next five decades (Gibbs and others 1979). This change was made because non-game WFUD's most likely do not follow the same trends as game WFUD's. A downturn in acres harvested for timber might well result in a reduction of game WFUD's; non-consumptive use would probably not suffer.

430. *COMMENT*: REINTRODUCE GRIZZLY BEARS.

Response: Although this is an intriguing idea, the Siskiyou National Forest has not seriously considered reintroducing grizzly bears. Grizzlies were native to the Siskiyou, but were probably exterminated by the turn of the century. Incompatibility between grizzly habits and human use of the land would present serious obstacles to bringing the grizzly back.

A feasibility study could be conducted on the potential for reintroduction; the proper agencies to petition are the Oregon Department of Fish and Wildlife and California Department of Fish and Game Because the grizzly is protected and managed through the Endangered Species Act, the USDI Fish and Wildlife Service would also be involved in the feasibility study, and any reintroduction plans would have to be a part of the Grizzly Bear Recovery Plan.

431. *COMMENT*: THE SITUATION OF CARNIVORES, EXISTING AS THEY DO AT THE TOP OF THE FOOD CHAIN, IS OFTEN INDICATIVE OF THE HEALTH OF THE ECOSYSTEMS THEY INHABIT ATTENTION SHOULD BE GIVEN TO THE CURRENT SITUATION OF COUGAR, BLACK BEAR, RING-TAILED CATS, AND GOLDEN EAGLES, AND HOW THEY WOULD FARE UNDER THE VARIOUS PLAN ALTERNATIVES.

Response: The species you mentioned all occur on the Siskiyou. However, none of them were used as Management Indicator Species. Hence, these animals are represented by other species. See Chapters II and III of the FEIS for more detail. Under Alternative S (FEIS, Chapter II, "Preferred Alternative"), all of these species would remain at viable levels

432. *COMMENT*: THE DEIS SEEMS TO BE BASED ON THE ASSUMPTION THAT WILDLIFE POPULATIONS ARE ADVERSELY AFFECTED BY TIMBER MANAGEMENT. WILDLIFE POPULATIONS MAY BE MORE ADVERSELY AFFECTED BY HUMAN HARASSMENT THAN STAND MANAGEMENT.

Response· Human harassment, intentional and unintentional, is a problem with some species, notably big game animals In Chapter IV of the LRMP ("Forest-wide Standards and Guidelines"), the Deer and Elk Management Plan is stated to be developed within three years after implementation of the Forest Plan (LRMP, Chapter V, "Project Planning"). One of the aspects of the management plan will be an analysis of the effect of roads on wildlife in general and big game in particular.

433. *COMMENT*. BAND-TAILED PIGEON POPULATIONS HAVE BEEN ON A STEADY DECLINE CAN THIS PROBLEM BE ADDRESSED, WHETHER THE CAUSE BE HUNTING PRESSURE OR LACK OF HABITAT? ARE THERE MORE OSPREY NEST SITES POSSIBLE ON THE FOREST? HOW MANY SURVEYS HAVE BEEN CONDUCTED? HAVE ANY SITES BEEN ENHANCED, WITH PLATFORMS CONSTRUCTED OR STICK NESTS MADE TO ORDER?

Response. Management of the migratory band-tailed pigeon will require a range-wide effort; the Forest would not be able to tackle it alone. The Forest's osprey population appears to be increasing; any new sites discovered will be managed under Forest-wide Standards and Guidelines Surveys are conducted annually (LRMP, Appendix D) We are in the process of installing osprey nest platforms in a few selected locations, but we intend to relay mainly on "natural" platforms in most areas

434. *COMMENT*· FOREST MANAGEMENT GOAL #6 ADDRESSES MAINTENANCE OF VIABLE POPULATIONS OF NATIVE SPECIES. THIS COULD BE AT THE EXPENSE OF HUMANITY, AN EXPENSE WE CANNOT AFFORD. TO THEN ADD THE STATEMENT "DESIRABLE INTRODUCED SPECIES" IS GOING WAY TOO FAR IT IS BAD ENOUGH TO SACRIFICE FOR THE SPECIES ALREADY HERE

Response: "Desirable introduced species" generally includes game species such as wild turkey and ring-necked pheasant; species like the house mouse and starling are not "desirable." There are no plans to import more "desirable species " The NFMA provides the following direction to the Forest Service: "Fish

and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native species in the planning area" (36 CFR 219 19). However, in reviewing the Forest goals, the statement relative to introducing desirable species has been deleted as this was not a priority element for management.

435. *COMMENT*: MANAGEMENT PLANS HAVE NOT YET BEEN PREPARED FOR MOST WILDLIFE. WITHOUT PLANS OR OBJECTIVES THERE IS NOT MUCH CHANCE THAT HABITAT NEEDS WILL BE MET, ESPECIALLY WHEN COMPETING TIMBER MANAGEMENT IS PLANNED IN DETAIL WITH QUANTIFIABLE PRODUCTION OBJECTIVES.

Land allocations and Standards and Guidelines were developed to meet the needs of the Siskiyou's wildlife species (LRMP, Chapter IV). The overall objective is to maintain viable populations of all wildlife species. Standards and Guidelines developed for the Siskiyou Forest Plan contain direction for specific management plans including: deer/elk, bald eagle, peregrine falcon, wildlife sites, and sensitive plants.

436. *COMMENT*: ESTABLISH STRICT STANDARDS TO PROTECT EXISTING NEST SITES FROM MANAGEMENT TECHNIQUES USED TO IMPROVE OR ENLARGE THE MEADOWS. PROTECTING EXISTING NEST SITES WILL MAINTAIN STRUCTURAL HABITAT DIVERSITY WITHIN THE PROJECT AREA

Response: Management of meadows is discussed under Management Area 9 (LRMP, Chapter IV) If trees are killed to meet objectives for meadow reclamation, they generally will not be removed. This will provide habitat for a variety of cavity nesters. In addition, Standards and Guidelines for wildlife provide for protection of raptor nests (LRMP, Chapter IV).

437. *COMMENT*: THE STANDARDS AND GUIDELINES DO NOT PROVIDE THE NECESSARY MITIGATION FOR· (A) REDUCED FORAGE AND THERMAL COVER CAPACITIES FOR BIG GAME ON COMMERCIAL FOREST LAND; (B) A PLANNED 57 PERCENT REDUCTION IN OLD-GROWTH HABITAT; (C) REDUCED RECREATIONAL HUNTING OPPORTUNITY; (D) A 40 PERCENT OR GREATER REDUCTION IN CAVITY-DWELLING SPECIES HABITAT IN TIMBER EMPHASIS AREAS

Response. There are no realistic mitigation measures for a reduction in old growth The Forest has set a Standard and Guideline of 60 percent habitat capability for woodpeckers (in areas managed for timber); there is no mitigation for the reduction from 100 to 60 percent. Forage and cover needs for deer and elk are adequate for the short term; their long-term needs will be addressed in a Deer and Elk Management Plan. Because of a computation error in the DEIS, deer/elk habitat capability will not drop as much as much as predicted. In alternatives with timber harvests at levels close to the situation prior to Forest Plan implementation, recreational opportunities for big game hunting will not diminish appreciably in the future

438 439 *COMMENT*: WHERE DID THE 1 3 PERCENT INCREASED DEMAND FOR WILDLIFE COME FROM? WAS THE INCREASED DEMAND FOR NONHUNTING RECREATION INCLUDED?

Response. The 1.3 percent per year figure for hunting demand came from the Regional Guide (USDA Forest Service 1984) In the FEIS, recreation demand for non-hunting recreation was set at 0.5 percent per year (Gibbs and others 1979).

440. *COMMENT*: SEED CLEAR CUT AREAS WITH GRASS AND CLOVER FOR ANIMALS.

Response Some clearcuts are already being seeded with wildlife forage mixtures as part of sale area improvement plans. Sites chosen for this treatment are generally those with favorable soils and exposure where competition between grass and seedling trees is not a concern During the past few years it has been found that good results can be achieved using lower seeding rates (eight pounds per acre) for wildlife forage, which has increased opportunities for post-harvest treatment In addition, spur roads, landings and roadcuts are often seeded to provide wildlife forage and reduce erosion hazard. See the Forest-wide Standards and Guidelines (LRMP, Chapter IV) for more discussion. Seeding for animals is included in the Capital Investment Program outlined in Appendix B of the LRMP.

441. *COMMENT*: THE FOREST SERVICE SHOULD GIVE PRIORITY TO IDENTIFYING AND PRESERVING HABITAT FOR WOLVERINES ON THE FOREST

Response· The Forest may or may not harbor wolverines. A wolverine inventory has been included as a budget item in the Forest Plan (LRMP, Appendix B) Forest-wide Standards and Guidelines for wolverine are listed in the LRMP, Chapter IV.

442 *COMMENT*· THE FIGURES IN THE TABLE FOR WOODPECKER'S HABITAT AREA DO NOT ADD UP CORRECTLY.

Response· The woodpecker figures were meant to add up on a pro-rated basis. Minor errors were present; they have been corrected in the FEIS.

SENSITIVE PLANTS AND ASSOCIATIONS

443. *COMMENT*: PROTECT ALL THE RARE PLANTS THAT GROW IN THE SISKIYOU.

Response. Land allocation and Forest-wide Standards and Guidelines are two means in which rare plants can be protected. Part of the management direction for Management Areas 3 (Research Natural Area) and 4 (Botanical) is to protect their unique plant resources Forest-wide Standards and Guidelines Direct the Forest Service to evaluate all proposed projects that involve significant ground disturbance and which may affect sensitive plants (LRMP, Chapter IV).

444. *COMMENT*. THE PLAN LACKS A COMPREHENSIVE ACCOUNT OF ITS EFFECTS ON NATIVE FLORA, INCLUDING SENSITIVE SPECIES.

Response: The Planning documents display much information about the Forest's native plants. Chapters II, III, and IV (FEIS) discuss various aspects of the native flora, while Appendix F (FEIS) goes into considerable detail on the Forest's rare plant concentration areas Chapter IV of the LRMP details the Standards and Guidelines used to manage sensitive plant resources Inventory efforts will continue (LRMP, Chapter V and Appendix D). New information will result in changes in management techniques The Forest Plan is designed to be dynamic, rather than static. In recognition of the need for better information about sensitive plants, this is included in "Information Needs" in Chapter II, LRMP

445 *COMMENT*· MORE BOTANICAL, SPECIAL INTEREST, AND RESEARCH NATURAL AREAS SHOULD BE PROPOSED THE "OREGON NATURAL HERITAGE PLAN" INDICATES A MUCH

GREATER POTENTIAL THAN INDICATED. RECOMMENDED BOTANICAL AREAS ARE TOO SMALL TO RETAIN THE AREA'S INTEGRITY, OR SHOULD HAVE LARGE BUFFERS AROUND THEM. THE MANAGEMENT PRESCRIPTION FOR BOTANICAL AREAS IS TOO VAGUE, AND SHOULD NOT ALLOW GRAZING OR OFF-ROAD VEHICLE USE.

Response· The need and demand for more Botanical areas was a consideration in developing alternatives. In all, the Preferred Alternative S includes 22 Botanical areas and seven RNAs (FEIS, Chapter II, "Alternatives Considered in Detail"). These areas include populations of most of the sensitive plant species on the Forest "Research Natural Areas of the Pacific Northwest" lists RNA needs for planning (Dyrness and others 1975). The Siskiyou RNAs were developed with the idea of including as many cells as possible (FEIS, Appendix F).

The "Oregon Natural Heritage Plan" (State Land Board) was released in December 1988, too late to be of benefit in this FEIS. A re-evaluation of land allocation for preservation of sensitive plant communities on the Forest will be conducted at a future date based largely on data in the Heritage Plan. The Heritage Plan is, in part, a product of input provided by the Forest Service's Zone Ecologist for the Siskiyou, Rogue River, and Umpqua National Forests. The recommendations contained in the Heritage Plan will be viewed, however, by the Forest and Region more in context of the natural range of the species and its distribution than political boundaries alone. Coordination with other agencies, particularly to the south of the Forest, will be made The Forest Plan can be amended or revised, if appropriate, to bestow "protected" status on representatives of specific plant communities.

The boundaries of most Botanical areas take advantage of topography, and all are designed to encompass the particular plant populations which make the area unique Any necessary buffering of specific populations was taken into account when the boundaries were mapped out (FEIS, Appendix F). The Standards and Guidelines for Botanical areas are designed to protect, preserve, and enhance the exceptional botanical features of these areas (LRMP, Chapter IV, "Forest-Wide Standards and Guidelines") Off-road vehicle use is not permitted within RNA's; motorized use may occur only on roads and trails within Botanical areas Grazing is not permitted in RNA's and Botanical areas, except at Bigelow Lakes (an active allotment exists; it will be monitored).

446. *COMMENT*: INCLUDE VARIOUS REDWOOD STANDS AS BOTANICAL AREAS. THE SNAKETOOTH REDWOOD BOTANICAL AREA IS NOT ADEQUATELY PROTECTED, BECAUSE "20 ACRES OF THIS 21-ACRE AREA ARE TENTATIVELY AVAILABLE AND SUITABLE FOR TIMBER PRODUCTION." BURNING IN THE WHEELER CREEK RNA (IN ORDER TO MAINTAIN REDWOOD) IS QUESTIONABLE. THE FOREST SERVICE SHOULD PREPARE A SUPPLEMENTAL DRAFT PLAN EVALUATING THE DESIGNATION OF 4,820 ACRES OF REDWOOD FOREST LAND (POSSESSING MORE THAN 20 TREES PER ACRE) AS SPECIAL REDWOOD MANAGEMENT AREAS WHERE LOGGING AND OTHER COMMODITY USES WOULD BE PROHIBITED.

Response· Table F-3 in the FEIS, Appendix F does show 20 acres of the Snaketooth Redwood grove as "tentatively available and suitable for timber production," (the other acre is an existing road). This statement, however, is used simply to describe the capability of the land to support timber production; figures for ASQ and Long-Term Sustained Yield (LTSY) are a way of displaying tradeoffs. Recommended Botanical areas will not be managed as timber-producing stands (LRMP, Chapter IV, "Management Prescriptions"). The Snaketooth Grove is recommended as an Old-Growth Botanical area in the Preferred Alternative S.

If fire is excluded from the Wheeler Creek RNA, the area will eventually develop into a climax forest Tanoak is the climax species in the RNA However, the redwood stand in the RNA is relatively young and could be expected to sustain itself for another 500 years. It is safe to assume that natural fire will burn through the RNA sometime during that timespan, regardless of suppression policies.

A supplement dealing with allocation of redwood stands was not prepared. However, after publication of the DEIS, the options for allocating redwood areas to other land use designations were analyzed in response to comments. More protection of redwood stands was a consideration in developing the FEIS Preferred Alternative S which includes the recommended Redwood Groves Old-Growth Botanical area (FEIS, Chapter II, "Alternatives Considered in Detail," and FEIS, Appendix F) This Botanical area contains the best examples of old-growth redwood groves on the Forest not already protected within the Wheeler Creek Research Natural Area.

Because of the interest and sensitivity of large redwood trees, stands, and groves in Oregon, with requests for the status as to how the redwoods are treated in the Forest Plan and at the project-level under existing direction, a "Management Plan for Coast Redwood" has been prepared by the Chetco Ranger District (Planning Records; available at either the District Office in Brookings or the Supervisor's Office) The Forest manages the very northernmost end of the redwood's range. As such, basic background information and specific management guidelines for this single species was documented to make more visible the Forest's management efforts. Specifically, the objectives of the document are to: (1) Describe the existing conditions, current land allocation, and management direction, (2) describe the silvicultural treatment options for managing the species; and (3) describe monitoring needs

Decisions as to land allocations and accompanying Standards and Guidelines have been dealt with in the FEIS and Forest Plan. Actual management of redwood, surrounding forest, and potential for establishment of additional redwood forest will occur at the project level. Public notice and involvement in these silvicultural treatments will occur during scoping and environmental analysis of any proposed project

447. *COMMENT*: AN INVENTORY OF ALREADY DESIGNATED WILDERNESS AREAS SHOULD BE DEVELOPED (IF ONE DOES NOT ALREADY EXIST) SO THAT NEW PROPOSALS FOR BOTANICAL OR OTHER LAND WITHDRAWALS MAY BE MATCHED AGAINST THOSE AREAS ALREADY SO PRESERVED.

Response: The botanical resources and plant associations of the Forest's Wildernesses were considered when allocations were set for Botanical areas and Research Natural Areas See the introduction of Appendix F (FEIS) for a short discussion on the occurrence of *Darlingtonia* bogs, also, see Appendix F for a discussion of selection criteria for Botanical areas The same general rationale was applied to other land allocations, such as Research Natural Areas. The Wildernesses were used to satisfy minimum requirements wherever possible. RNA cells are sometimes designated in Wildernesses. However, existing Wildernesses do not contain examples of all representative ecosystems (cells) under Forest Service management (these cells may also not be available in areas managed by other government agencies). It is necessary to designate areas outside of Wilderness to protect resources that are not present elsewhere.

448 *COMMENT*· ONCE IT IS DETERMINED THAT THE PLANTS WITHIN ANY BOTANICAL AREA (MA-4) ARE DOING AS WELL OR BETTER IN THE MA 12-14 AREAS, THEN CHANGE THE APPROPRIATE AREAS TO OTHER ALLOCATIONS.

Response· Sensitive plants will continue to be monitored in areas where timber is harvested (LRMP, Chapter V, "Sensitive Plants," and Appendix D). Monitoring may reveal that some sensitive plants do well or better in harvested areas However, we suspect that this will not be so in most cases, which is why Botanical areas were designated In addition, the majority of the acreage in Management Area 4 is land unsuitable for timber harvest

449 *COMMENT*. CLASSIFY THIS NATIONAL FOREST AS A NATIONAL BOTANICAL/BIOLOGICAL PRESERVE AND NATIONAL CRITICAL HABITAT AREA

Response. This option is not available to the Forest Service. Such designation would require Congressional action. The Forest does contain an array of plant resources unique to the National Forest System. In recognition of this fact, 24 new Botanical and Research Natural Areas are considered for allocation in the various alternatives (FEIS, Appendix F).

450. *COMMENT*: THE FOLLOWING FEDERAL CANDIDATE SPECIES SHOULD BE ADDED TO THE LIST OF PLANTS· GENTIANA BISETAEA AND HORKELIA HENDERSONI.

Response· *G. bisetaea* is on the Forest Service list of Sensitive Plants (see FSM 2670 for detailed discussion of sensitive plants) *H. hendersoni* is not on the sensitive plant list for the Siskiyou because this species is known only from southwest Jackson County; it is not known from the Siskiyou (FEIS, Appendix F).

451. *COMMENT*: ESTABLISH A THOMAS J. HOWELL NATIONAL BOTANICAL DRIVE AND VIEWPOINT IN THE BABYFOOT LAKE AREA.

Response. This proposal as described would require Congressional action, therefore is outside the scope of this Forest Plan However, the basic idea of a Botanical Drive and Viewpoint would focus interest on the Forest's unique plant resources. A road/trail could be designated as a "botanical byway," with appropriate signing, and a road/trail brochure prepared of a "Thomas J. Howell National Botanical Drive and Viewpoint" in the Siskiyou National Forest Your suggestion, as modified, has been incorporated into the Capital Investment Program for Endangered, Threatened and Sensitive Species (LRMP, Appendix B)

452. *COMMENT*. WITHIN THE FOREST SYSTEM THERE SHOULD BE AN AREA SET ASIDE TO COMPARE THE NATURAL PROGRESSION OF NATURE TO THE MANAGED FOREST AS A CONTROL AND A FUTURE GENETIC RESOURCE.

Response: Various land allocations serve this purpose. Research Natural Areas are specifically designated for this purpose Other land allocations can also be used as controls: Wilderness, Botanical, and Unique Interest, or virtually all other allocations from Management Areas 1-9. Also, as we better define our plant associations, new RNA's may be proposed in future Forest Plans as additions to the system.

453 *COMMENT*. AS AN ALTERNATIVE SITE FOR A VIEWPOINT OF BREWER'S WEEPING SPRUCE (PICEA BREWERIANA) OUTSIDE OF THE KALMIOPSIS WILDERNESS AREA, THE AREA JUST NORTH OF PEARSOLL PEAK SHOULD BE CONSIDERED

Response. The uniqueness of Brewer Spruce is recognized. The specific site mentioned is not allocated for a Botanical site or a Unique Interest Area in any of the alternatives The area would be managed as Backcountry Recreation (Management Area 6) in Alternatives S, G, E, and M (FEIS, Chapter II, Table II-3, "Special Area Assignments"), which would maintain the option and access (via trail) for viewing The area will be added just north of Pearsoll Peak to our list of areas to inventory before the next revision of the Forest Plan (10 to 15 years from now). Depending on inventory findings, the site may be recommended as a Botanical area. In the interim, little potential exists for affecting this stand of Brewer Spruce

454. *COMMENT*: RETENTION OF ALL PROPOSED RNA's AND BOTANICAL AREAS FOR THIS PLANNING PERIOD IS NEEDED. AFTER NEEDED RESEARCH AND INVENTORIES HAVE BEEN COMPLETED AND EVALUATED, AN INFORMED DECISION CAN BE MADE AS TO THE LONG-TERM ALLOCATION FOR THESE AREAS

Response: All RNA's and all or part of 19 Botanical areas are allocated in Alternative S (Preferred).

455 *COMMENT*: UNDER MANAGEMENT GOALS, THE ROLE RNA'S CAN PLAY IN MONITORING THE FOREST PLAN SHOULD BE MENTIONED.

Response: The monitoring role of RNA's is discussed in the description of Management Area 3 (LRMP, Chapter IV).

456. *COMMENT*: WHETSTONE BUTTE AND FIDDLER MOUNTAIN SHOULD BE ADDED AS BOTANICAL AREAS BECAUSE THESE AREAS CONTAIN HIGH CONCENTRATIONS OF *LEWISIA COTYLEDON.*

Response: These areas are not included as proposed or recommended as Botanical areas in the FEIS The sites will be inventoried before the next revision of the Forest Plan; if warranted, they may be proposed as Botanical areas during preparation of the next Forest Plan.

MINERALS

457. *COMMENT*: THE PREFERRED ALTERNATIVE PLACES TOO MANY RESTRICTIONS ON MINERAL RESOURCE EXPLORATION AND DEVELOPMENT. A MANAGEMENT AREA SHOULD BE ESTABLISHED FOR MINERAL RESOURCE DEVELOPMENT

Response: In response to public input, Alternative S was developed with fewer restrictions on mineral development than the Preferred Alternative K of the DEIS. The FEIS Preferred Alternative S would only slightly decrease the number of acres having some degree of restriction on mineral exploration and development. (See the FEIS, Chapter III, where the measure for minerals is how much of the Forest is accessible with limited restrictions). The areas of known mineral potential have been mapped (FEIS, III-4); as many acres as possible of high and moderate mineral potential have been maintained in the General Forest category which places the least restrictions on mineral exploration and development (FEIS, Chapter II, "Alternative Descriptions"; Chapter IV, "Mineral Deposits," "Environmental Effects by Land Allocation") No additional areas are recommended for withdrawal in any alternative in the FEIS, although minimal acres bordering the Elk, Chetco, and North Fork Smith Rivers will be withdrawn as a result of the recent Omnibus Oregon Wild and Scenic Rivers Act of 1988.

A Management Area for minerals is not included With nearly three-quarters of the Forest available for mineral entry, and specifics of exploration and development largely attributable to the mining proponent, a Management Area which emphasized this resource likely be of little value to the public or Forest Service. While most Management Areas permit some degree of exploration and development, access prescriptions vary depending on the Management Area's primary resource focus and protection of inherent non-mineral resource values. (FEIS, Chapter IV, "Mineral Deposits- Environmental Effects by Land Allocation.")

458. *COMMENT*. MINING AND PROSPECTING ARE ANOTHER VITAL MEANS OF SUPPORT TO OUR ECONOMY. WITH THE REGULATIONS NOW IN FORCE, THE COST OF MINING IS PROHIBITIVE FOR SOME LOWER GRADE MINES. IF MORE RESTRICTIONS ARE APPLIED AND MORE LAND IS RESTRICTED TO MINING AND PROSPECTING, THE MINERAL RESOURCE WILL BE RESERVED IN AREAS WHERE ONLY WEALTHY MINING COMPANIES CAN AFFORD TO MINE.

Response: In developing Alternative S, the map of known mineral potential of the Forest (FEIS Chapter III, Figure III-4) was used to identify areas where mineral potential was most significant. The Forest then

attempted to minimize adverse effects to mining on areas identified as having high or moderate mineral potential. The level of access restrictions has not changed significantly in those areas (see Table IV-5, FEIS). A comparison of Alternative A and Alternative S shows very little difference in the number of acres on the Forest accessible with low to moderate restrictions (See FEIS, Table II-3).

459 *COMMENT*. CONSIDERING THE IMPORTANCE OF MINERALS IN MULTIPLE USE MANAGEMENT OF THE FOREST, THE PLAN SHOULD INCLUDE AN EXPLANATION OF HOW FOREST MANAGEMENT GOAL NO. 17 [FACILITATE MINERAL EXPLORATION . WHILE PROTECTING SURFACE RESOURCES...] WILL BE IMPLEMENTED CONSISTENT WITH AGENCY-WIDE MINERAL POLICY WHERE PLANNED ACTIONS MAY FURTHER RESTRICT AREAS OPEN AND AVAILABLE FOR MINERAL ENTRY AND DEVELOPMENT (LOCATION, LEASING, AND SALES).

Response. The Forest Plan contains Management Prescriptions for 14 Management Areas (LRMP, Chapter IV, "Management Prescriptions"). These prescriptions outline restrictions that will be applied to activities, including mining. Mineral lease applications, permits, contracts, and operating plans will be evaluated for consistency with the Management Prescription for the area in which they are located (LRMP, Chapter V, "Implementation Direction"). It is the policy of the Forest Service to promote mineral development. Therefore, to be consistent with Forest Service minerals policy, restrictions on locatable mineral activities must also be reasonable and cannot materially interfere with the conduct of legitimate mining activities.

460. *COMMENT*: THE DRAFT DID NOT ADDRESS MINING THOROUGHLY. MINING IN THE FUTURE COULD HAVE AS LARGE AN IMPACT AS TIMBER HARVEST ON THE FOREST. THERE HAS BEEN LITTLE RECLAMATION DONE IN THE FOREST. OPEN PITS AND PILES OF ROCK AND DEBRIS REMAIN THE FOREST SERVICE NEEDS TO ENFORCE RESTORATION OF THE FOREST AS A RESULT OF MINING. THE DRAFT WAS INACCURATE BY STATING THAT CUSTODIAL (ROADLESS) AREAS, WILDERNESS AND WILD RIVERS ARE WITHDRAWN FROM MINERAL ENTRY. THE DRAFT'S DEFINITION OF CUSTODIAL (ROADLESS) AREAS, WILDERNESS, AND WILD RIVERS INCLUDES MINING.

Response: The issue of mineral withdrawal from certain land allocations has been re-evaluated since the DEIS. There is a significant reduction in acres recommended for withdrawal in most alternatives from the DEIS to the FEIS. Several Management Areas, such as the Backcountry Recreation (termed "Custodial (Roadless)" in the DEIS), do not show additional areas recommended for withdrawal in the FEIS

Withdrawal is mandated by Congress for Wilderness and Wild portions of Wild and Scenic Rivers (Management Areas 1 and 2). The Wilderness Act of 1964 contained a provision that withdraws all designated Wilderness from mineral entry effective January 1, 1984, subject to valid existing rights. In the case of Wild rivers, the act designating them usually withdraws the Wild section of those rivers.

The prescription for the Custodial (Roadless) Management Area in the DEIS was quite restrictive, as written, relative to the mineral resource. In the FEIS, this Management Area has been renamed to Backcountry Recreation and prescriptions provided which emphasize the importance of motorized access, exploration and development of the mineral resource in areas of moderate to high potential. Restrictions, thereby, have been considerably reduced.

The Code of Federal Regulations, 36 CFR 228.8g, Aug. 28, 1974, now requires specific reclamation activities. Completion of the required reclamation is guaranteed by a bonding process Regarding restoration of old mining sites, the Forest can rehabilitate areas through appropriated funds If a rock pile from old placer mining is within a timber sale boundary, collected dollars (K-V) may also be used. Many

areas which were the site of old dredging operations have rehabilitated naturally. Standards and Guidelines for minerals (Chapter IV-66 of the Forest Plan) provide for reclamation on any new mining. The application of the 36 CFR 228 regulations requiring reclamation is triggered any time a plan of operation for activities with significant disturbance to surface resources is filed with the agency.

Site-specific information is needed before the effects of future proposals can be evaluated. New mining projects are managed through operating plans. An environmental analysis is made on all projects to insure that resource protection and rehabilitation measures have been incorporated into the proposal.

461. *COMMENT*: THE MINERAL ISSUE HAS NOT BEEN ADEQUATELY ADDRESSED IN THE PROPOSED PLAN, AND THE FOREST SERVICE IS VIOLATING "...CERTAIN STATUTORY RIGHTS OF CITIZENS TO PROSPECT, LOCATE AND DEVELOP LOCATABLE MINERALS ON LANDS OPEN TO SUCH ENTRY."

Response: Any lands not specifically withdrawn from mineral entry are open for prospecting, location, and development of minerals. Of the 1,092,302 acres of land on the Siskiyou National Forest, only 272,751 acres are withdrawn. Most of the withdrawn area (232,495 acres) is in Wilderness designated by Congress

Chapter IV of the LRMP states that, "The prospecting, development, and production of mineral and energy commodities shall be facilitated." It is Forest Service policy that minerals are resources to be managed like any other on the Forest.

462. *COMMENT* THERE IS NOT ENOUGH EMPHASIS ON MINERAL DEVELOPMENT ACCESS IN ANY ALTERNATIVES.

Response: In the development of alternatives, the Forest placed emphasis on responding to concerns expressed by the public. One measure of responsiveness by which the alternatives were compared is number of acres accessible to mineral entry with low to moderate restrictions (See the FEIS, Chapter II, "Features Common to All Alternatives.") The effect of each alternative on accessibility of minerals is summarized in the FEIS, Table IV-5. Terms used to describe accessibility can be found in the FEIS, Chapter III.

463 *COMMENT*: A MAP SHOWING THE MINES AND MINERAL RESOURCE LOCATIONS SHOULD BE INCLUDED TO PROVIDE A BASIC UNDERSTANDING OF WHERE KNOWN OR EXISTING RESOURCES ARE FOUND.

Response. The Mineral Potential Map in Chapter III of the FEIS gives general mineral information (see Figure III-4). Numerous maps and publications about mining and minerals either reference or readily available at libraries or from the Oregon Department of Geology and Mineral Industries

464 *COMMENT* A LIST IS NEEDED OF CURRENT MINERAL WITHDRAWALS, ACRES INVOLVED, AND MINERAL POTENTIAL FOR LOCATABLE AND LEASABLE MINERALS

Response. The FEIS, Chapter IV, "Mineral Deposits," lists this type of information by alternative See Table IV-5 and Figures IV-1 and 2 for a comparison of "Estimated Mineral Potential and Accessibility Limitations" under the various alternatives. Current minerals withdrawals are listed under Alternative A which represents existing management of the Forest.

465 *COMMENT:* TABLE IV-A IN THE DRAFT FOREST PLAN DOES NOT INCLUDE AN ESTIMATE OF MINERAL OUTPUTS. CONSIDERING THE LEVEL OF MINERAL DEVELOPMENT AND EXPLORATION WITHIN AND ADJACENT TO THE FOREST, THIS APPEARS TO BE AN IMPORTANT OMISSION.

Response: Under the mining laws, the locatable minerals program is based on self-initiation; that is, the miner going out to locate minerals. It is not part of the role of the Forest Service to determine mineral potential or outputs. The U.S. Department of Interior, Bureau of Mines, annually reports on mineral commodity output in Oregon and California, but not from private or Forest Service land. Additionally, since this information is confidential, it is displayed by the Bureau of Mines as total amounts produced in the state. The existing information which may be published is described in the FEIS, Chapter III, "Mineral Deposits." In Chapter IV of the FEIS, the effects of the various alternatives on minerals is evaluated in terms of restrictions on access. The FEIS, Table IV-5 also uses acres of the Forest accessible to mineral entry as a measure of responsiveness to public concerns.

466. *COMMENT*: THE FOREST SHOULD QUANTIFY THE VALUE OF THE MINERAL RESOURCE, TO THE EXTENT FEASIBLE, AND FACTOR THAT VALUE INTO THE VARIOUS ALTERNATIVES.

Response: Because of lack of information about the extent of various mineral resources, it is not possible to quantify their value. Based on a map of the areas of high mineral potential (FEIS, Chapter III, Figure III-4), the FEIS displays and evaluates the effect of the alternatives on these areas in terms of access restrictions. The known information is included in the description of Mineral Deposits, FEIS Chapter III; Chapter IV of the FEIS contains a discussion of the effect of each land allocation on the mineral accessibility. Chapter IV also contains graphs and tables that further display the effects.

467. *COMMENT*: THE MINERAL POTENTIAL RATINGS NEEDS BETTER DEFINITION CITING OF EVIDENCE USED TO ARRIVE AT RATINGS AND A DISCUSSION OF DATA SOURCES WOULD IMPROVE UNDERSTANDING. METHODOLOGY EMPLOYED TO DERIVE TOTAL ACREAGE IN EACH CATEGORY SHOULD ALSO BE INCLUDED. BEFORE ANY LAND IS EXCLUDED FROM MINERAL ENTRY, A DETAILED AND COMPREHENSIVE INVENTORY OF ITS MINERAL RESOURCE CHARACTERISTICS SHOULD BE CARRIED OUT. A MORE THOROUGH DISCUSSION OF FOREST SERVICE POLICIES AND PROCEDURES FOR MINERAL DEVELOPMENT IN RELATION TO THE "SOCIOECONOMIC ASPECTS" OF MINING WOULD BE HELPFUL

Response: Minerals are a major resource deserving equal attention with other resources in the Forest Planning process. The nature of mining law has influenced the knowledge available concerning quality and quantity of mineral resources; without such information, discussion of market and value is difficult Mineral exploration is self-initiating (by the miner) under the law, with the result that the Agency does not inventory mineral resources generally

The Forest's mining engineer used various studies previously completed for this area and their own professional expertise to complete a map that identified areas of mineralization (FEIS Chapter III, "Mineral Deposits"). Next, our geologist attempted to describe the potential for minerals to occur in areas identified as mineralized. To accomplish this, the three descriptive terms of high, moderate and low were used A definition of these terms can be found in the FEIS, Chapter III

Other information used to produce the mineral resource potential map is listed in the "Bibliography of the Geology and Mineral Resources of Oregon," produced by the State of Oregon Department of Geology To produce this map, Forest mining geologists used information from a number of sources plus their own personal knowledge of the area. Among published information used was a report prepared by S.P. March, S J. Kropschot, and R G Dickinson in cooperation with the U.S Bureau of Mines, Geological Survey

Professional Paper 1300, titled "Wilderness Mineral Potential, Assessment of Mineral Resource Potential in US Forest Service Lands Studies 1964-1984." This report discussed mineral potential in designated Wilderness. Another report used extensively was a "Mineral Resource Study for Siskiyou National Forest," prepared under contract with Oregon Department of Geology and Mineral Industries The primary product produced from this study was a mineral resource planning map.

The Forest mining geologists also used information in data bases maintained by U.S. Geological Survey and U.S Bureau of Mines for background to assist in interpretation and extrapolation of information on mineral resources. The next step was to evaluate the effect of Management Prescriptions on the accessibility of minerals Descriptive terms were again used to describe this effect. A definition of these terms can be found in the FEIS, Chapter III.

Certain Management Prescriptions tend to limit the accessibility of minerals. The economic effect of this action would depend on the type of mining operation planned. The effect of each Management Prescription on the accessibility of minerals is described in the Forest Plan document in the LRMP, Table III-9

These effects are summarized in terms of acres restricted by a particular Management Prescription. No attempt was made to quantify economic costs to the community, the state, or to industry as a result of increasing or decreasing access restrictions to prospect and develop minerals because there is not sufficient data available to make any intelligent estimates of these costs.

468. *COMMENT*: MINERAL POTENTIAL DATA DEVELOPED BY THE STATE OF OREGON, U.S. FOREST SERVICE MINERALS PERSONNEL, U S. BUREAU OF MINES, AND INDIVIDUALS FROM THE GRANTS PASS AREA MUST BE STUDIED TO UNDERSTAND MINERAL POTENTIAL. POTENTIAL SHOULD BE RESTUDIED, AND PLANNING REVISED TO OPEN UP ADDITIONAL LANDS FOR CRITICAL AND STRATEGIC MINERALS RATHER THAN DOUBLE RESTRICTED AREAS ON THE FOREST.

Response: The Forest received a number of responses expressing a desire for increased consideration of mining activity on the Forest. The primary desire was to allow more land to remain open to exploration and development of the mineral resource.

Because the Mining Laws are written so that the activity is self-initiating, it is not primarily the agency's responsibility to estimate potential. The Forest does make decisions about access for exploration and development through land allocations and management prescriptions.

The Forest Plan strives to maintain a balance of resource management. Table III-9 (LRMP) shows the allocation of land on the Forest to the various Management Areas identified and the effect of each allocation on mineral accessibility. The analysis of the Plan indicates little change from current conditions. See also FEIS Table II-3 for a comparison of acres accessible to mineral entry under the various alternatives. A discussion of current conditions, and explanation of Mineral Potential and Mineral Access can be found in Chapter III of the FEIS. A comparison of the effect of each alternative on access to mineralized areas is in Chapter IV of the FEIS. Table IV-5 shows little change in access restrictions on areas identified as having high and moderate mineral potential.

469 *COMMENT*: NONE OF THE ALTERNATIVES, EXCEPT FOR "AS IS," SERIOUSLY TAKE INTO ACCOUNT THE IMPORTANCE OF MINERALS IN THE NATIONAL FORESTS.

Response. It is the policy of the Forest Service to facilitate mineral exploration and development consistent with other multiple uses of the Forest. (LRMP, Chapter IV, Forest Goals). In the FEIS, Chapter III, "Mineral Deposits" provides background information about minerals on the Forest from a historical

perspective. The Comparison of Alternatives in Chapter II includes minerals in its discussion of "Features Common to All Alternatives " To track Planning Problem 9, the analysis of alternatives evaluates the effects of the various alternatives by access restrictions to the mineral resource (FEIS, Chapter IV, "Mineral Deposits: Significant Interactions, and Environmental Effects") Table II-3 in the FEIS includes acres accessible for mineral entry as a measure of resource outputs in comparing the alternatives and as an indicator of responsiveness to public concerns.

470. *COMMENT*: MINING SHOULD NOT BE PERMITTED IN SENSITIVE PLANT OR ANIMAL HABITAT. RARE EARTH MINERALS PRODUCE RARE PLANTS. PROTECT THEM. SLOW DOWN ON MINERAL DEVELOPMENT.

Response The Forest Service can only recommend that the Bureau of Land Management withdraw areas from mineral entry. But, while the Forest Service does not have the authority to withdraw areas from mineral exploration, it plays a part in setting guidelines for exploration because of its responsibility for managing surface resources.

The Forest recognizes that the unique soil conditions on the Siskiyou National Forest are one of the reasons such a diversity of sensitive plants exists on the Forest Some areas with rare or sensitive plants on the Forest have been allocated to Botanical or Natural Research Areas, with Management Prescriptions designed to protect the plants for which these acres are set aside (FEIS, Appendix F). As an agency responsible for managing surface resources, the Forest Service does impose reasonable restrictions on surface-disturbing activities, including mining, where other resource considerations warrant (LRMP, Appendix F, and FEIS, Chapter II). See also FEIS, Chapter IV, "Mineral Deposits- Environmental Effects on Land Allocations."

471. *COMMENT*: MORE ATTENTION SHOULD BE GIVEN TO RECREATIONAL MINING AS AN ENHANCEMENT TO MULTIPLE USE AND ECONOMIC RESOURCES.

Response: In response to public interest, the Forest Service is trying to develop a process within the recreation program that would allow this activity on certain areas with a simple type of permit. An example of such a program already exists on a neighboring Forest. The Rogue River National Forest has a Recreational Panning and/or Dredging Management Plan on the Applegate Ranger District.

472. *COMMENT*: 75 PERCENT OF THE FOREST OPEN TO MINING (UNDER ALTERNATIVE K) IS WAY TOO MUCH. MINING CAN DEVASTATE AN AREA, AND IT TAKES YEARS FOR NATURE TO REPAIR THE DAMAGE.

Response: Minerals are recognized as an important resource on the Forest (FEIS, Chapter III, "Minerals") The 1872 Mining Law allows the exploration and development of minerals on public land which is not specifically withdrawn from mineral entry. The Preferred Alternative S (FEIS) attempts to restrict mineral development only where serious conflict with other land allocations may result. On areas open to mineral entry and development, the Forest will work with the miner to allow mineral development in an environmentally sensitive manner. Forest Service regulations governing minerals (36 CFR 228 and 43 CFR 3000 series), as well as Standards and Guidelines for minerals (Chapter IV, Forest Plan), provide for reclamation of disturbed lands upon cessation of activity. Mineral development on the Forest has been at a very modest level, and this is not expected to change in the near future (FEIS, Chapter III).

473. *COMMENT*: IMPACTS FROM MINING CLAIMS IN THE KALMIOPSIS WILDERNESS ARE A SERIOUS CONCERN; THERE SHOULD BE AN END TO MINING IN THE WILDERNESS. SHORT OF

ENDING MINING, INCREASED MONITORING AND ENFORCEMENT OF REGULATIONS BY THE FOREST SERVICE IS NEEDED.

Response: When the Kalmiopsis Wilderness was designated in 1964 and expanded in 1978, the existence of valid mining claims was specifically recognized. (A valid mining claim is one on which a discovery was made prior to the Wilderness designation.) Mining activity and development was allowed to continue on those claims. This includes the use and maintenance of existing roads. No new mining claims can be located within designated Wilderness. The Forest does monitor mining claims; under Federal regulations (36 CFR 228), miners must have approved operating plans. If a miner proposes an operating plan which impairs Wilderness resources, the Forest will check the validity of the claim and contest it if appropriate. On valid claims, the Forest will work with the miner to minimize any conflict with Wilderness values (LRMP, Chapter IV, "Management Prescriptions," and LRMP, Appendix A).

474. *COMMENT*: THE STANDARDS AND GUIDELINES SHOULD INCLUDE, IN ADDITION TO THE FEDERAL REGULATIONS CITED, THE CALIFORNIA SURFACE MINING AND RECLAMATION ACT (SMARA) AMONG THE LAWS CONTROLLING THE ADMINISTRATION AND RECLAMATION OF MINED LAND IN THIS STATE.

Response: The California Surface Mining and Reclamation Act (SMARA) was overlooked in the Draft. In the Chapter IV of the Forest Plan, under "Forest-Wide Standards and Guidelines" for Minerals 10-2, this oversight is corrected.

CULTURAL RESOURCES

475. *COMMENT*: I WOULD LIKE TO SEE MORE WORK DONE TO RE-ESTABLISH OLD HISTORICAL TRAILS.

Response. The re-establishment of historic trails is addressed in Chapter III of the FEIS, "Cultural Resources." Although historic trails are not specifically listed, they are one of the site types referred to in the paragraph dealing with enhancement opportunities. The interpretation of the history of selected trail routes using signs, brochures, and other techniques is planned. Also, a feasibility study is planned (FEIS, Chapter IV, Cultural Resources Capital Investments, and Appendix B) for the interpretation of the historic Silver Creek Trail, most of which is no longer maintained.

476. *COMMENT*: NO NATIVE AMERICAN CULTURAL SITES/AREAS SHOULD PLAY SECOND FIDDLE TO ECONOMIC REQUIREMENTS; THEIR RELIGION HAS SUFFERED NEGLECT AND ABUSE BY SELFISH COMMERCIAL NEEDS

Response: This concern is addressed in Chapter III of the FEIS, "Cultural Resources," where cultural resource protection and the American Indian Religious Freedom Act (AIRFA) is discussed. This law provides for the protection of American Indian rights to "believe, express, and exercise their traditional religions." The Siskiyou National Forest has and will continue to coordinate with all appropriate tribes in planning. During environmental analyses of projects, American Indian traditional religious rights and values will be considered.

FIRE MANAGEMENT

Fire

477. *COMMENT*: MORE ATTENTION AND STUDY SHOULD BE GIVEN TO THE EFFECTS OF SLASH BURNING MONITOR THE NUTRIENT CYCLING AND MYCORRHIZAL FUNGI SURVIVAL IN EXISTING CLEARCUTS.

Response: Currently, the Siskiyou National Forest has four installations monitoring short- and long-term disturbance on nutrients and mycorrhizal formulation, including clearcutting and slash burning. In addition, the Forest has gone to lighter spring burns which have less adverse effects on nutrients and mycorrhizal Current timber sale contracts require the timber purchaser to leave large amounts of woody material (logs) for long-term site productivity. In the future there are plans to work with COPE (Coastal Oregon Project Evaluation) on the long-term effects of slash burning on soil nutrients, organic matter levels and mycorrhizal fungi. Soil productivity will be monitored to assess effects of organic matter and nutrient levels following timber harvest and site preparation (which could include burning) as described in Chapter V and Appendix D, "Soil Productivity," LRMP.

478. *COMMENT*: NATURAL FIRES (LIGHTNING CAUSED) IN WILDERNESS AND ROADLESS AREAS SHOULD BE EVALUATED, BUT NOT ACTIVELY SUPPRESSED UNLESS ADJACENT MANAGED FOREST LANDS, LANDMARKS, OR DEVELOPED SITES ARE THREATENED. NATURAL WILDFIRES WERE PART OF THE CYCLE IN THE FOREST IN PRE-MANAGEMENT TIMES. IN MANY AREAS THEY KEPT THE FUEL ACCUMULATION UNDER CONTROL SO THAT THE FIRES TENDED TO BURN FAST AND RELATIVELY COOL AND NOT AS HOT CROWN FIRES INCREASE THE AMOUNT OF MONITORING OF WILDFIRES IN WILDERNESS.

Response: Under the LRMP, each ignition will be reviewed to determine the appropriate suppression response (Chapter IV, "Forest-wide Standards and Guidelines"). The Forest Plan allows for the use of unplanned ignitions (lightning ignitions) as prescribed fires in portions of the Kalmiopsis and Wild Rogue Wilderness when certain criteria are met. Further discussions of prescribed fire in Wilderness is presented in Chapter IV ("Management Prescriptions") and Appendix A of the LRMP

479 *COMMENT*: LET THE FOREST GO BACK TO PERIODIC BURNINGS, OR IT WILL CONTINUE TO BE LOST TO SERIOUS FIRES.

Response: The Forest-wide Standards and Guidelines, and Management Prescriptions presented in Chapter IV of the LRMP provide for the use of prescribed fire from both planned and unplanned ignitions This will allow for the manipulation of natural fuels complexes in most Management Areas and thereby reduce the probability of large, catastrophic fires

480 *COMMENT*: THERE SHOULD BE A STRONG EFFORT TO PREVENT A CATASTROPHIC FIRE SEASON LIKE 1987 FROM HAPPENING AGAIN WITH PROPER FOREST MANAGEMENT (THINNING BRUSH, ACCESSIBLE MAINTENANCE ROADS ETC).

Response: The fire protection organization identified in the Forest Planning Process (FEIS, Appendix B, "Analysis Done Outside FORPLAN"), the Forest-wide Standards and Guidelines, and the Fire Management Direction for each Management Area (LRMP, Chapter IV) provide a reasonable assurance that large areas of the Forest will not be burned by wildfire on a routine basis The use of prescribed burning from both

planned and unplanned ignitions, post-harvest slash treatment, and the proposed roading within the planning period will also contribute toward preventing a repeat of the 1987 experience.

481 *COMMENT:* FOLLOWING CLEARCUTS, PLANTATIONS ARE FULL OF BRUSH CREATING A PERFECT FIRE ENVIRONMENT. WHAT SPECIAL FIRE-FIGHTING TECHNIQUES ARE USED IN THESE SITUATIONS? THERE'S NOT ENOUGH MONEY TO ADEQUATELY PROTECT THE FORESTS

Response: The key to protection costly investments, such as plantations, is a thorough, well-designed, site-specific fuel treatment accomplished after timber harvest and before the site is reforested Excessive amounts of residual slash has a potential for a high rate of spread. Once a wildfire starts in an inadequately treated plantation, it will generally spread rapidly until there is a significant change in fuel type or fuel continuity. Suppression efforts in these situations are generally very costly and unsuccessful.

Additional comparative discussions of fuels complexes, silvicultural systems and the effects on fire behavior is presented in the FEIS, Chapter IV, "Fire - Significant Interactions" and in the FEIS, Appendix G, "Selection of Silvicultural Systems - Comparison of Systems." A discussion of the fire management organizational planning efforts is presented in the FEIS, Appendix B, "Description of the Analysis Process - Analysis Done Outside of FORPLAN."

482. *COMMENT.* EVERY BIT OF FOREST LAND NOT DESIGNATED AS WILDERNESS SHOULD HAVE ACCESS ROADS FOR FIRE PROTECTION AND CONTROL.

Response: Over 2,000 miles of road would be available for immediate fire access in all alternatives (FEIS, Chapter II, "Fire"), and another 600 miles would be closed but available after some maintenance The road system would be supplemented by a recreational and administrative trail system of approximately 450 to 550 miles (FEIS, Chapter II, "Improvements") The completed system will provide good access to most of the Forest outside Wilderness. However, if Management Areas remain fixed over the planning horizon, many alternatives would have large blocks of land remaining essentially unroaded or smaller areas contiguous to Wilderness The discussion of the effects by alternative is provided in Chapter IV

483. *COMMENT:* ALL SLASH SHOULD BE MADE AVAILABLE FOR FIREWOOD CUTTING

Response: Varying amounts of slash will be made available at harvest units. The actual amount will depend on such factors as the economics of making it available, site-specific resource needs, etc. A detailed discussion of fuelwood is presented in the FEIS, Chapter III, "Energy "

484 *COMMENT.* SET-ASIDE AREAS SHOULD INCLUDE A NETWORK OF ACCESS ROADS FOR FIRE PROTECTION.

Response: The Standards and Guidelines for each Management Area include direction on transportation facilities and fire protection requirements (LRMP, Chapter IV) Roads provide one of the access modes for fire protection The other modes are trails, lookouts, and aerial spotter (detection) systems These latter modes are in most cases more compatible with Management Areas with less development Fire suppression activities also utilize these same modes

AIR QUALITY

485. *COMMENT.* AN ALTERNATIVE NEEDS TO BE FOUND TO SLASH BURNING PRESENTLY EMPLOYED ON THE FOREST. SLASH BURNING HAS MANY ADVERSE EFFECTS, INCLUDING AIR POLLUTION (AFFECTING HEALTH AS WELL AS SCENIC VIEWS), LOSS OF VALUABLE FIREWOOD, LOSS OF SOIL NUTRIENTS (DECREASING FOREST PRODUCTIVITY), AND LOSS OF ANIMAL HABITAT.

Response: Prescribed burning operations are conducted in accordance with the Oregon State Smoke Management Plan, which has an objective of maintaining air quality and visibility. Forest Service research is actively seeking new techniques and methods to reduce the amount of emissions associated with prescribed burning (LRMP, Chapter II, "Information Needs"). Many of these techniques have been included in the Forest-wide Standards and Guidelines for Air Quality presented in Chapter IV of the LRMP Soil productivity is monitored to determine effects of slash burning (LRMP, Chapter V and Appendix D)

Each prescribed burn, or slash burn, is executed under a site specific prescription which considers resource and management needs, as well as impacts to the forest resource. At the present, prescribed fire is one of the most cost effective methods of treating large amounts of slash generated by timber harvest The slash must be treated to reduce the risk of high intensity wildfire and the associated resource impacts

486. *COMMENT.* THE PROPOSED PLAN INCLUDES ONLY THE EMISSIONS FROM PRESCRIBED BURNINGS FOR DETERMINATION OF WHETHER THE FOREST MANAGEMENT PRACTICES MEET THE APPLICABLE FEDERAL AND STATE AIR QUALITY STANDARDS.

Response. The Oregon Smoke Management Plan, which provides operational guidance applicable to all prescribed burning on forests in western Oregon, deals only with emissions from prescribed fires Emissions from wildfires are not included in either the Smoke Management Plan or the LRMP A detailed discussion to this effect is presented in the Fire and Air Quality sections of Chapters III and IV of the FEIS.

487. *COMMENT*: WHY NOT INCLUDE FIRES IN WILDERNESS AS PART OF THE TSP EMISSIONS?

Response: Prescribed fires from planned ignitions in Wilderness will fall under the operational constraints of the Oregon State Smoke Management Plan and the emissions associated with this burning will be accumulated in the Forest's baseline value. Emissions associated with lightning-caused fires in Wilderness, which are managed as prescribed fires, are considered a natural component of the Wilderness ecosystem and, therefore, are exempt from the Smoke Management Plan. Emissions from wildfires are not covered by either the Oregon Smoke Management Plan or the Forest Plan

488. *COMMENT*: THE PROPOSED PROCEDURES INCLUDE NO PLAN FOR MONITORING EMISSIONS OF OTHER REGULATED SUBSTANCES AS REQUIRED UNDER THE OREGON STATE IMPLEMENTATION PLAN (SIP). THE PLAN SHOULD INCLUDE MEASURES FOR MONITORING THESE COMPOUNDS AND FOR ENSURING THAT THEIR CONCENTRATIONS DO NOT EXCEED THE APPLICABLE STANDARDS

Response· Section 110(a)(2)(C) of the Clean Air Act (PL 88-206) identifies each State as the agency responsible for the monitoring of criteria pollutants associated with the National Ambient Air Quality Standards. Monitoring details developed by the Environmental Protection Agency are described in 40 CFR Part 58.

489 *COMMENT*· MORE ANALYSIS SHOULD BE PRESENTED ON PROJECTED VS BASELINE POLLUTANT EMISSIONS.

Response: The analysis presented in the Air Quality section of Chapter IV of the FEIS indicates that the projected emissions for the selected alternative does not exceed the 1975-1979 baseline value of 7300 tons of TSP. Many of the techniques developed by Forest Service research to reduce emissions from prescribed burning have been included in the Forest-wide Standard and Guidelines which are presented in the Land and Resource Management Plan.

OTHER COMMENTS

GEOLOGY

490. *COMMENT*: THE DESCRIPTION OF GEOLOGY IS TOTALLY INADEQUATE. A STATEMENT IS MADE THAT GEOLOGY IS DIVERSE, YET YOU DEVOTE ONLY ONE PAGE TO THIS CONSPICUOUS CONTROL OVER ALL ELEMENTS OF ENVIRONMENTAL MANAGEMENT OF THE FOREST. A FIRST STEP TO IMPROVE THIS SECTION SHOULD BE A GEOLOGIC MAP OF THE FOREST SIMILAR TO THE ONE IN THE SOIL RESOURCE INVENTORY (SRI). EACH MAJOR LITHOLOGIC UNIT SHOULD BE IDENTIFIED, DESCRIBED, AND INTERPRETED IN TERMS OF COMPOSITION AND STRUCTURE AS THESE APPLY TO FOREST PRODUCTION AND ENGINEERING PROPERTIES.

Response: The "Topography and Geology" section in Chapter III of the FEIS has been revised to include a more comprehensive discussion of the geologic elements, geologic history, and the associated hazards. Geologic information has also been added to the "Soil and Water" section in Chapter IV of the FEIS. Geology maps and lithologic unit descriptions are included in the Soil Resource Inventory and project level work

For a better understanding of Chapter III of a NEPA document, the intent is to descriptions that are no longer than is necessary to understand the effects of the alternatives. With this intent, the Chapter should succinctly describe the environment of the area to be affected or created by the alternatives under consideration While geologic information is without question very important to the understanding of the effects, sufficient information has either been presented in the FEIS, made available in the Planning Records, or has been referenced. The reference cited are excellent and provide the reader with a far more thorough review of the resource than can be presented appropriately included in Chapter III.

Even more importantly, soil and landform developed on any particular rock type are not sufficiently homogeneous to make valid generalizations for long-term planning. To be meaningful, evaluations of slope stability and engineering characteristics of soil must be made on a site-specific basis

491. *COMMENT*: MAPS AND A GENERAL DISCUSSION OF SEISMICITY, ACTIVE FAULTS, AND OTHER GEOLOGIC HAZARDS, E G , FLOODING, VOLCANISM, ETC , SHOULD BE INCLUDED TO PROVIDE A BASIC ENVIRONMENTAL FRAMEWORK FOR ANY FUTURE PLANS FOR FOREST LAND DEVELOPMENT OR UTILIZATION.

Response. Within the Siskiyou Forest, there are no active faults, areas of volcanic activity, or known hot springs Geologic faults are shown on published geologic maps available from the Oregon Department of Geology and Mineral Industries and other sources. The effects on wetlands and floodplains is discussed in the FEIS, Chapter IV, "Specifically Required Disclosures" Floods occur most years in the narrow

canyons. Almost all areas subject to flooding are managed as riparian zones and do not have developments or habitations

492. *COMMENT*: ARE THERE MAJOR SAND AND GRAVEL SOURCES ON THE FOREST? IF SO, WHERE? IF NOT, WHAT SOURCES ARE USED AND ARE THEY SUFFICIENT FOR FOREST NEEDS?

Response: The Forest is self-sufficient in sources of rock to make aggregate for roads and other purposes. Occasionally, small quantities for special purposes are purchased from off-Forest sources. The on-Forest supply is essentially unlimited, although in a few areas it may become necessary to use low-grade rock or transport it further than is now customary. Very little alluvial sand and gravel is used. Most rock sources are bedrock quarries found throughout the Forest. Inventories are kept at the Siskiyou National Forest Zone Engineering offices in Grants Pass and in Gold Beach.

RANGE

493. *COMMENT*: NO GRAZING SHOULD BE PERMITTED ON THE FOREST. GRAZING IS A GOVERNMENT-SUBSIDIZED FUNCTION THAT SHOULD NOT BE TOLERATED ON THE ECOLOGICALLY-SENSITIVE FOREST NATIVE VEGETATION, INCLUDING RARE SPECIES AND FRAGILE RIPARIAN HABITATS, IS AT RISK FROM THIS ACTIVITY.

Response: Grazing is a legitimate use of the National Forest as provided in the Multiple-Use Sustained-Yield Act and MFMA Grazing on this Forest is negligible Grazing is not allowed in Botanical areas unless it is shown to *not* detrimentally impact endangered, threatened, or sensitive species Grazing is prohibited in Research Natural Areas (LRMP, Chapter IV, Management Prescriptions). Standards and Guidelines provide direction for protection of wildlife, ecologically sensitive areas, and biological diversity where conflicts may exist with grazing (LRMP, Chapter IV, "Forest-wide Standards and Guidelines")

Grazing fees on National Forest Lands are calculated through the formula prescribed in Executive Order No. 12548 (2/14/86). The formula allows for adjustment of fees based on livestock prices and production costs during a given year. In this respect, it is comparable to recreation, timber harvest, and like resource activities and uses on the Forest.

494. *COMMENT*: THERE IS A LACK OF INFORMATION IN THE DRAFT DOCUMENTS ON THE LIVESTOCK GRAZING PROGRAM ON THE SNF. A VERY BRIEF PASSAGE IN THE DEIS STATES THAT ABOUT 3,000 ACRES OF THE SNF ARE GRAZED, YET LITTLE REFERENCE TO THE EFFECTS OF THIS GRAZING COULD BE FOUND. ONLY VAGUE AND INCOMPLETE S&GS ARE PRESENTED IN THE DRAFT PLAN TO INDICATE HOW THIS PROGRAM IS TO BE MANAGED.

Response: Livestock grazing on the Siskiyou National Forest was not identified as a key issue due to the very limited extent of the program and demands of the local industry Almost all of the forage available to livestock is a by-product of timber harvest, called "transitory range." Following the harvest of timber, a grass seeding program or natural revegetation occurs which often produces forage palatable to livestock. If this forage can be made available to livestock without any significant environmental or resource conflicts, a grazing allotmment may be made available to the industry. This type of range is usually available for 15-20 years, but gradually becomes unavailable as the new Forest reclaims the site. A brief general discussion of range can be found in Chapter III of the FEIS. In addition, each Management Prescription discussed in Chapter IV of the LRMP includes a brief consideration of range The Monitoring and Evaluation Program for Range (LRMP, Chapter V and Appendix D) has been expanded in response to public input.

FUELWOOD

495 *COMMENT*: CONVERT WASTE TO WOOD PELLETS TO BE BURNED, NEARLY POLLUTION FREE, IN INDUSTRIAL BOILERS AND PRIVATE WOOD PELLET STOVES.

Response: The wood products industry uses wood residue as an energy source for its facilities, though consumption varies depending market conditions and distance from the forest site to the mill (FEIS, Chapter III, "Energy"). There may be a future time when wood residue products could be developed for private energy use as well as industrial use. Substitution of wood for non-renewable energy sources is identified as a need (LRMP, Chapter II, "Information Needs").

496 *COMMENT*: SPECIAL FIREWOOD-CUTTING AREAS SHOULD BE DESIGNATED FOR THE HANDICAPPED AND THE ELDERLY WITH SAFE, CLOSE ACCESS

Response· Designation of firewood cutting areas is outside the scope of the Forest Plan, but within administration of individual Ranger Districts. Ranger Districts on the Siskiyou National Forest periodically designate special areas for handicapped and elderly people

OTHERS

497 *COMMENT*: INVOLVE LOCAL RESIDENTS IN STAND-TENDING OPERATIONS

Response· This topic is outside the scope of Forest Plan decisions; however, nothing in the Forest Plan precludes the use of this proposal It has been and will continue to be considered as an administrative option in project level planning The land manager could adopt this proposal where it provides an optimum combination of environmental, economic, and social benefits.

498 *COMMENT*: TRAPPING AND ALL FORMS OF PREDATOR CONTROL SHOULD BE ELIMINATED.

Response: The Forest Service, like the public, offers suggestions on trapping seasons to the Oregon Department of Fish and Wildlife, and the California Department of Fish and Game. Petitions to eliminate trapping or modify regulations should be directed to those state agencies The Forest does no predator control (coyote, etc.). We occasionally do localized direct control of various rodent species where serious damage is occurring to conifer seedlings, but most animal damage control is preventative (such as vexar tubing to keep rodents away from seedlings).

499. *COMMENT*· BECAUSE OF ITS DETRIMENTAL IMPACT OF THE RESOURCE, THE FOREST SERVICE SHOULD TERMINATE THE CHINA PEAK TIMBER SALE AND DESIGNATE THE AREA NORTH AND EAST OF THE GRASSY KNOB WILDERNESS AND WEST OF THE SIXES SOUTH FORK SUPPLEMENTAL RESOURCE AREA AS THE CHINA PEAK SUPPLEMENTAL RESOURCE AREA. SINCE THAT SALE HAS NOT BEEN HARVESTED AND IS OWNED BY GREGORY TIMBER RESOURCES, INC , IT IS PRUDENT THAT GTR INC. OFFER TO RETURN THIS SALE WITHOUT CHANGE TO THE SISKIYOU NATIONAL FOREST

Response. Alternative S in the FEIS allocates this specific area to Management Areas 11 and 14 (Riparian and General Forest). Resource impacts have been evaluated several times the China Peak Timber Sale was planned, layed out, sold, and the road constructed under existing direction of the Mt Butler-Dry Creek

Land Use Plan (FEIS, 1976) and the site-specific Environmental Assessment (1981) for the sale This timber sale area was specifically addressed in the Congressional Record during preparation of the Oregon Wilderness Act of 1984 Provisions were installed by Congress to not jeopardize viability of this sale. The excluded area is not a "unique island effect" as it and other harvested private lands in the North Fork Dry Creek are outside the Wilderness boundary. The road constructed for the China Peak Timber Sale is one of the access routes to the newly created Wilderness, and offers a multiple-use benefit to the Forest visitor. The visual, soil, and water conflicts suggested for this area have been reassessed in terms of the new land management prescriptions and direction for the Elk/Sixes Planning Basin (Chapter IV, FEIS) and Appendix C (Grassy Knob).

500. *COMMENT*: MORE EMPHASIS SHOULD BE PLACED ON RESPONSES FROM PEOPLE THE PLAN WILL DIRECTLY AFFECT.

Response: All responses received have been review, considered, and recorded. Substantive comments contained in the responses to the DEIS and Proposed Forest Plan have been summarized in this Appendix K of the FEIS along with Forest Service's responsive statements

The public participation and involvement process does not provide for emphasizing public responses based upon the respondent's perceptions of the Plan's effects However, those directly affected are more likely to be actively involved than those who may not be directly affected

501. *COMMENT*: MORE ATTENTION NEEDS TO BE PAID TO PUBLIC RELATIONS AND PUBLIC INFORMATION INFORMATION WAS GOOD DURING THE FOREST FIRES, IT DOES NOT CONTINUE ON THE SAME BASIS FOR OTHER CRITICAL FOREST ACTIVITIES DURING THE YEAR. THERE SHOULD BE MORE COORDINATION OF FOREST ACTIVITIES WITH VARIOUS GOVERNING BODIES, SCHOOL BOARDS, COUNTY COMMISSIONERS AND CITY COUNCILS IN THE VARIOUS COMMUNITIES.

Response: Although the Forest does have a high profile public information program, and regularly uses brochures, radio, TV, and newspapers to tell the public about management issues and activities, more information can always can provided Intense public involvement in the Forest Planning process has occurred periodically since 1979. Public meetings, presentations to groups, news releases to the media, planning news letters, briefings, and meetings with interest groups, coordination with other agencies and individuals have occurred on a frequent and recurring basis. The Planning Team, resource specialists, District Rangers, and others have maintained an open-door policy, offering to discuss the Forest Plan, its process, and resource data with individuals and groups.

Forest Supervisor
Siskiyou National Forest
P.O. Box 440
Grants Pass, Oregon 97526

Dear Forest Supervisor:

We support Alternative M as a management plan alternative in protecting the Siskiyou National Forest. Your preferred alternative K does not do enough to sustain Southern Oregon's world class fish resources; more protection needs to be given to the Siskiyou's rivers, riparian areas and streamside lands. The North Kalmiopsis needs more protection for its long-term value for fisheries, water quality, recreation and wildlife in lieu of short-term profits from logging. As custodian of this region for the public, you need to protect the Siskiyou's fragile and priceless roadless area resources from logging and roadbuilding. The Preferred Alternative (K) is unacceptable because of the environmental damage which will be caused due to its extreme emphasis on logging. The annual cut needs to be lowered below your proposed 150 million board feet/year level.

The Forest Service needs to study creation of the Siskiyou National Park as an alternative in your final draft of the Forest Plan. The Park would provide the best and most complete protection for the beauty and health of this forest. It would also bring increased economic diversity and community stability and create many jobs. It would increase the region's ability to market its many attractions to tourists across the country. The idea deserves formal study and you and the Forest Service have a moral and legal duty to include this as an alternative in the Final Forest Plan.

The Forest Service has to utilize better forestry methods, logging systems and cutting strategies including:

a. less dependence upon roads which are like extensive strip mines causing erosion that chokes hatching salmon and steelhead;
b. more attention and study on the effects of slash burning; these cause health problems and are responsible for reducted visibility throughout the NW;
c. abandon plans to turn the Siskiyou's diverse forest ecosystem into a large industrial tree farm;
d. longer time periods between cutting cycles;
e. abandon clearcutting unless it is the most environmentally sound method;
f. develop and utilize more research into problems with regeneration and reforestation;

We ask that the Siskiyou's fish habitat and water resources receive much greater protection through the use of wider "Riparian Zones" in which logging is prohibited and stronger prohibitions on logging near fish-producing streams. We recommend you to recommend "Wild and Scenic River" status for the Chetco River and Elk river.

We ask the protection of scenic areas not be reduced from the current levels. We also ask for protection of the scenic areas seen from roads, trails, rivers and communities. We insist on the full protection of the "viewshed" seen from the entire Rogue and Illinois Rivers trails. We ask for protection of much larger amounts of old growth ecosystems and protection (full) of the old growth habitat around all known pairs of Spotted Owls. We ask full protection of all remaining, old, large Redwoods within Chetco Ranger District. We request that the Forest Service do a complete inventory of the Siskiyou's old growth forests and perform more basic research on the impacts of turning the old growth forests into tree farm plantations. We ask for greater protection of the Siskiyou's valuable trail system and recreation sites.

We do not want the Forest Service to build roads into the North Kalmiopsis Roadless Area, or log it by helicopters, following the Silver Fire. We oppose any road construction on Bald Mountain or Silver Peak. The trees are now much less valuable for lumber than before the fire while the environmental damage that logging would cause will be even greater after the fire than before. It simply doesn't make economic or environmental sense to salvage this forest-the land needs to be left alone to heal naturally, not further injured by logging.

Tahana Whitecrow

SISKIYOU NAT'L FOREST
GRANTS PASS OREGON
DEC 28 1987
RECEIVED

REPLY TO ATTN OF: WD-136

Ronald J McCormick
Forest Supervisor
Siskiyou National Forest
P.O. Box 440
Grants Pass, Oregon 97526

Dear Mr. McCormick

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act, we have reviewed the Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (Plan) for the Siskiyou National Forest (SNF) The SNF is located near the coast in southwestern Oregon and includes 1,092,302 acres. The preferred alternative upon which the Plan is based provides for intensive timber management, wilderness, and special riparian areas. Designated wildlife habitat and supplemental resource areas are also emphasized Mineral exploration and development would be permitted.

Based on our review, we have rated the DEIS EC-2 (Environmental Concerns - Insufficient Information). Enclosed is an explanation of our EIS rating system. The primary reasons that we have environmental concerns are as follows

- The process for managing forest activities is not sufficiently explained so as to assure that adverse environmental effects, particularly to water quality, will be prevented We suggest more fully describing the management process of the SNF.

- Standards and Guidelines for water need to be more fully developed in the Final EIS/Plan, as does a water quality monitoring plan

The details of our comments are included in the enclosed review report. Several of the items identified in this review were discussed in the meeting we had with your staff on December 2, 1987. This interaction was very useful to us in becoming familiar with the issues and current management practices of the SNF.

We intend our comments to be constructive, and we are confident that by addressing our concerns and comments the SNF can present a Final EIS and Plan which more clearly show that important resources will be adequately protected, while providing SNF staff with the necessary flexibility to manage the forest on a day-to-day basis. While our comments are lengthy, we wish to acknowledge that certain components of the documents were particularly well done, such as the fisheries Standards and Guidelines and the fisheries monitoring plan.

Thank you for the opportunity to review the DEIS and Plan If you have any questions about our review, please contact Ann Uhrich of our Environmental Review Section at FTS 399-8516.

Sincerely,

for Robert S Burd
Director, Water Division

U S ENVIRONMENTAL PROTECTION AGENCY
COMMENTS ON PROPOSED LAND AND RESOURCE MANAGEMENT PLAN
AND DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE
SISKIYOU NATIONAL FOREST, OREGON

GENERAL COMMENTS

Forest Management Process

One of the ways we assessed the environmental effects of the proposed alternative was how well the Siskiyou National Forest's (SNF) Draft Environmental Impact Statement (DEIS) and Plan described the forest management process By forest management process we mean those components which describe the "how to" of forest management with regard to protection of natural resources They can include the set of actions, decisions or data which are needed to comply with environmental standards prevent adverse effects, and improve existing environmental conditions Important components of the forest management process as we see them are described as follows

A data base of existing conditions from which technical experts and the public can judge the expected effects and level of uncertainty of the predictions

Best Management Practices (BMPs) and management area prescription development and implementation

Selection of BMPs for a particular activity and how uncertainty of BMP effectiveness is factored into selection and implementation

Through on-site inspection and administration during an activity, verifying that a particular activity is occurring as prescribed in contracts, leases or permits

Environmental monitoring before during, and after the completion of certain activities to determine whether impacts were accurately predicted

A feedback loop that is built into the process such that forest activities causing significant problems will be corrected before they are allowed to continue

Upgrading of BMPs or prescriptions to correct inaccurate predictions

The use of NEPA for project implementation

The DEIS and Plan describe the interrelationship between most of these components fairly well The decision flow diagram in the DEIS (p II-5) was especially helpful with regard to alternative development When and how BMPs are selected how uncertainty of BMP effectiveness is factored into the decision process and the commitment and role of on-site inspections in meeting standards and guidelines are components that need further explanation

Final decisions on site-specific projects will determine to a significant extent the adequacy of the level of protection provided for water quality and other resources The Final Plan should summarize or cite the criteria that will be used to determine when categorical exclusions, environmental assessments and environmental impact statements will be used in Plan implementation, especially with regard to assessing impacts to water quality and beneficial uses This would provide guidance and direction to Forest staff, and a general awareness of how these assessments will be used to interested and affected publics It would also strengthen the accountability of the Forest in implementing the Plan

Current Water Quality Status and Water Resources Inventory

The DEIS needs more information on the status of current water quality conditions There is a fish habitat map and some general discussion of beneficial uses by basin No specific information which describes the level of the use e g spawning and rearing, is presented by stream segment, though 27 key streams or reaches are mentioned (DEIS p III-111) There are *numerous assumptions about water quality conditions stated in the DEIS, but* little citation or summary of historical water quality data to back them up For example, several statements appear in both the DEIS and the Plan which indicate riparian areas and water quality are in good condition However, specific information or data summaries to support these general statements are not adequately presented We are confident they do exist and should either be presented or cited in the Final EIS

The Plan does provide a good start towards identifying a watershed inventory For instance the Forest has been divided into defined planning basins Beneficial uses by planning basin have been presented in Table III-12 of the DEIS Maps highlighting the location of uses such as fisheries and recreation are also provided However, tabular summaries of other key information by stream segments would be very helpful For example, refer to Attachment A

A complete watershed resource inventory summarizes facts, recorded measurements observations and other evidence which can be used to determine management objectives for rivers and streams Oregon's water quality standards and water quality management plans, for instance, were developed using inventory information An inventory is a key element needed for effective resource management The drainage objectives derived from the resource inventory then provide a means of evaluating the effectiveness of plan implementation The watershed resource inventory information for the Siskiyou should be better organized and strengthened to allow an adequate assessment of whether water quality goals are being achieved

Water Quality Standards Compliance

As you are aware, forest activities conducted in the Siskiyou National Forest must be consistent with Oregon's adopted Statewide Water Quality Management Plan This includes compliance with Oregon's Water Quality

Standards (WQS) and monitoring the effectiveness of achieving compliance The Plan does recognize, at various points, the importance of these considerations However there is no specific reference to OAR 340, Division 41 (Oregon's adopted Water Quality Standards), in the Standards and Guidelines Section of the Plan or in the Minimum Management Requirements (We do note that this is mentioned in the DEIS, p IV-230)

From information provided in the DEIS there is no real assurance that Oregon Water Quality Standards will consistently be met For instance, the DEIS mentions that anadromous fish spawning occurs in the Siskiyou National Forest It also states that there are 443,000 acres of old growth habitat (p II-72) This is about 40 percent of the Forest The location of the spawning areas relative to the old growth is not identified If harvest occurs in old growth areas which also support salmonid spawning, use of the streams could be adversely affected due to sedimentation (DEIS, p IV-76 to 81) This could constitute a violation of the antidegradation policy of Oregon's Water Quality Standards Another example is in basins 2 and 4 These have been identified as areas with sensitive uses where intensive harvest could occur Compliance with Oregon Water Quality Standards must be assured for specific stream segments

The FEIS should address compliance with the State's antidegradation policy This policy states that "where the existing quality of the water is better than the standards set, that such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial uses of such water and will not result in water quality less than that prescribed in the standard " This policy is reiterated in Federal regulations (40 CFR 131 13(a 2)) Many of the rivers in the Forest are high quality waters The FEIS should describe how Standards and Guidelines BMPs and other measures designed to minimize water quality impacts from Forest activities (e g , road construction timber harvest grazing mining, dam construction/operation), will ensure consistency with the antidegradation policy

The status of Outstanding National Resource Waters is conferred to rivers designated as Wild and Scenic For these waters, the antidegradation policy of the Water Quality Standards Regulations explicitly prohibits any lowering of water quality (40 CFR Section 130 12) The FEIS should discuss in detail how degradation of these waters will be prevented, given the mining, timber harvest and roading activities which may occur in some of the Forest's drainage basins containing or tributary to Wild and Scenic rivers

Water Quality Monitoring Plan

The water quality management discussions in both the DEIS and the Plan lack key information to evaluate potential effects on water quality For instance increases in sediment which affect fisheries are identified in the DEIS Yet little is presented, based on data which shows where this occurs

on the Forest Furthermore, no plan for monitoring future increases is presented or cited It makes it difficult to evaluate effects on water quality which would result from implementing the various options identified in the Plan Based on conversations with SNF staff, we understand that sedimentation has not been as critical a parameter as stream temperature with regard to fisheries on this Forest This fact needs to be discussed further in the Final EIS Is this true for spawning areas or rearing areas or both?

Achievement of drainage objectives, conservation practices and improvement projects can only be assessed by water quality monitoring and fishery habitat surveys The Plan does not identify a specific water quality monitoring program nor criteria for evaluating riparian areas (temperature, streambank erosion, etc) though Section V of the Plan references STORET as EPA's system for storing Siskiyou Forest water quality data A summary of the Forest's "Riparian Policy" would be helpful (It is currently only discussed in the DEIS, p II-9) Some general reference to fisheries monitoring is given in Table V-1 and a more detailed plan describing how it will be implemented is provided in Appendix O This is very useful

The Plan (p IV-39) and DEIS (p IV-230) recognize that approved "208" BMPs are a means to achieve and maintain WQS It should be emphasized that implementation of BMPs does not constitute compliance with WQS Measuring WQS compliance is accomplished through water quality monitoring programs Evaluating the effectiveness of meeting water quality standards on the SNF will be difficult without a monitoring plan which includes stream-specific references, water quality parameters, and sampling frequency We would support the recommendation to establish a multi-agency technical work group in Oregon to address these concerns and to assist the USFS in developing a water quality monitoring program tailored to individual forests

Domestic Water Supplies

Other beneficial uses of the water resource may be affected and need to be more thoroughly addressed in the Plan For example, there are several municipal watersheds in the Siskiyou National Forest (DEIS Table III-11) Are these unfiltered surface-water supplies? Under an EPA proposed rule as required by the 1986 amendments to the Safe Drinking Water Act, an agreement must be reached with the Forest Service that would allow the municipalities to have watershed control in order for them to continue to use these sources without filtration This is generally recognized in the DEIS (Appendix Volume II, J-6) However the proposed Plan does not provide a specific indication of how protection of these water supplies will be achieved

The DEIS (p IV-232) states that "State and Federal water quality criteria for suspended sediment and turbidity may not be met temporarily nor in some specific locations, (emphasis added) because of the difficulty in preventing all soil erosion from newly disturbed sites ' As previously noted, many of the Forest's streams are considered high quality waters which exceed State and Federal water quality criteria These waters must be maintained at existing high water quality levels Where water quality standards may not be met, management activities should be modified or rehabilitation efforts initiated to ensure compliance with water quality standards

5

Fisheries/Riparian Areas

Page III-101 of the DEIS states that "[w]ater temperatures in all nine major river systems of the Forest exceed optimum temperatures for salmonid[s] and in some cases, exceed upper lethal temperatures " Given the dependence on well-shaded tributary streams to provide cooler inflow to support salmonid survival in all of the Forest's river systems, we strongly recommend management of riparian areas (Management Area 11) under Minimum Level and Prescription C Although maintenance of water temperatures is projected under Prescription B the DEIS documents existing water temperature problems Water temperatures would be reduced and watershed conditions improved under Minimum Level and Prescription C (DEIS p II-47)

Air Quality

It is not clear how many cords of firewood are projected to be taken for personal use from the SNF each year over the first decade This needs to be identified in the FEIS as there is a potential for indirect effects on winter air quality in local urban communities via the firewood provided by the SNF There are also potential associated health effects

Forest land managers that provide firewood have a unique opportunity to educate the public regarding fuelwood use and air pollution through the permit process Pamphlets discussing the association between wood stoves air pollution, and health concerns or providing tips on efficient wood stove operation, for example could be distributed with fuelwood permits If appropriate literature is not readily available, we would be happy to provide examples that are being used elsewhere

Page III-97 of the DEIS states that the DEIS/Environmental Impact Report (DEIS/R) for the proposed Cal-Nickel Corporation's Gasquet Mountain mining project indicates no project-induced adverse air quality values in the Kalmiopsis Wilderness EPA Region 9's review of the DEIS/R indicated that the document was inadequate in addressing potential air and water quality impacts The conclusion that no adverse impacts to air quality will result from the mining project should not be made based on the DEIS/R

6

SPECIFIC COMMENTS

Land and Resource Management Plan

II-9 With regard to item number 8 EPA would be pleased to assist the Forest in developing a water quality monitoring methodology suited to your needs Please see Attachment B To assist with such an overall water quality management program we developed a water quality summary sheet A draft copy for the Siskiyou National Forest is enclosed for your information Please see Attachment A The intent is to identify a form for watershed resource inventories which could be used by EPA and the Forest Service to address water quality concerns Streams listed under "Drainage Objectives" only represent a starting point The Forest Service is encouraged to expand this list If you have any comments or questions please call Bruce Cleland in our Oregon Operations Office at FTS 423-3689

III-2 This is a good table which enhances the discussion

III-4 It is stated that "soil and water values are maintained by limiting site-disturbing activity in each watershed to no more than 9 to 13 percent of the area per decade " Is this in addition to the MMR level for water quality and riparian management which is discussed in the DEIS (p S-7)? Please clarify in the Final EIS

IV-1,2 These forest management goals are good, and are clearly stated

IV-13 The definition of terms is very useful and we commend its use With regard to the word "should," how will "unacceptable hardship or expense" be determined and by whom? Will timber sale contractors make this decision?

IV-14 The statement "the NEPA process must be followed to make a significant departure from the Standards and Guidelines" is confusing Please clarify in the Final EIS

IV-27 The Standards and Guidelines (S&G) for salmonid habitat are very good We strongly support coordination with the Oregon Department of Fish and Wildlife (ODFW) and suggest strengthening this Standard by stating that "basin plans shall be prepared "

IV-29 The S&G for range are good, but we believe that where conflicts occur, "management shall favor riparian areas" would be more appropriate

IV-29 Regarding number 4 under Timber Management does this refer to use of herbicides? Please clarify in the Final EIS

IV-36	In general, the S&G for soil and water are very good
IV-37	Regarding S&G number 7-6 It would seem that dropping the timber sale or some portion thereof would also be an option Providing examples of "appropriate mitigation measures" would be helpful Also when this situation occurs it should be a trigger for an increased level of monitoring in the vicinity
IV-40	Protection of domestic water supplies should be addressed under the S&G in the Final Plan In particular, areas of serpentine soils are a concern due to the potential for asbestos to enter the water
IV-47	What is meant by "electronic sites"?
IV-48	S&G under number 10-7 are very good We commend their use
IV-50	S&G under number 11-2 are also good
IV-58	EPA commends and supports the management area designations such as Supplemental Resource, Wilderness, Botanical Custodial, Retention Visual and Riparian which preclude or limit programmed timber harvest and roading activities We believe that water quality and fisheries will benefit from these designations on the SNF
IV-80	S&G under MA7-3 are good, however, the first paragraph does not indicate whether near maximum protection "shall" or "should" be provided (level of restriction is missing)
V-6	The outline of the monitoring and evaluation program (MEP) is good
V-11, D-16 17	How will Fish/Water MEP priorities be established?
V-12	Based on discussions with SNF staff, we understand that the annual cost of the MEP for Soil/Water shown in the Plan is not reflective of the entire budget allocated for BMP and water quality monitoring This should be discussed in the Plan, as the $3,000 figure would otherwise seem very low
V-14	Under MMBF Sold the threshold of concern is 30% less or greater than the planned ASQ (150 MMBF) for 2 consecutive years In either case, the threshold seems rather high How was this determined? Has the threshold compared to sustainable yield (180 MMBF) instead?
D-20	A description of how "project monitoring," etc will be implemented along the lines of the discussion on page D-16 would greatly strengthen this section of the Plan (F2 Soil/Water) Please refer to the General Comments under Water Quality Monitoring Plan

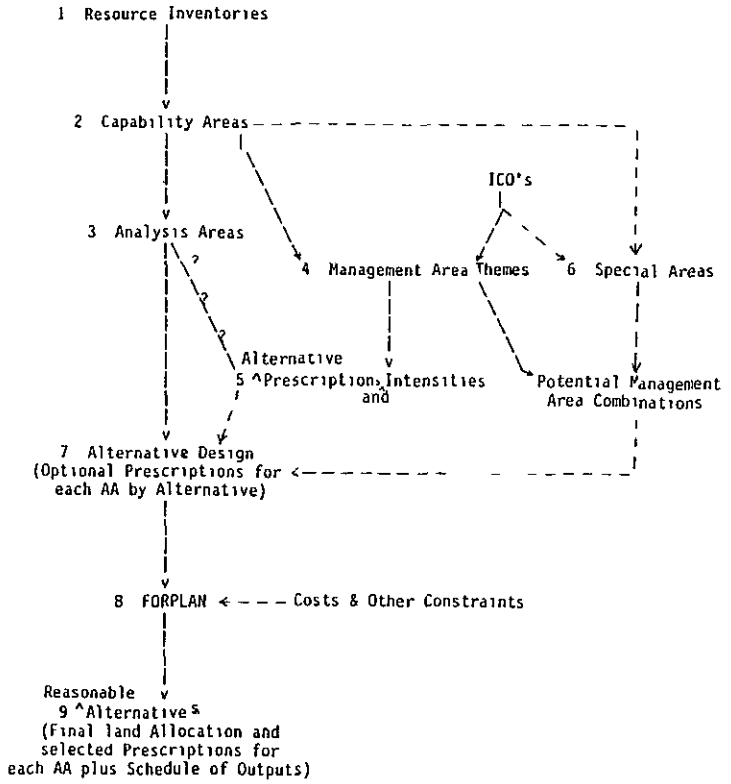

Figure II-1 Analysis Process During Alternative Development

8

Draft Environmental Impact Statement

S-9 We are pleased to see an alternative ("G") which emphasizes "the health and productivity of the Forest's water-related resources "

I-7 The scale of this map appears to be in error

II-3 through II-5 The discussion of the analysis process for developing reasonable alternatives was very useful Assuming the text is accurate, however, we would see the diagram looking a bit different (refer to Figure II-1, attached) Since *collections of Special Areas (6)* become the Management Areas, it would appear that what are generated in step (4) are really Management Area Strategies or Themes Also, we see nothing in the text linking step (3) with step (5)

II-8 We strongly support the use of Planning Basins and the Forest's effort to plan individual basin activities over space and time Please provide a *short description or citation* of the method used to determine that openings created by timber harvest be limited to 20% of the suitable land base per decade

II-23 The DEIS indicates that *herbicide use will be dealt with in separate* environmental analyses and NEPA documents at the Regional level We are concerned, however, that the programmatic EIS mentioned here may not be able to address specific cumulative impacts of herbicide use and other vegetation management activities within given basins on the SNF The Final EIS for the SNF should identify the process by which results of the programmatic EIS will be incorporated into the *Forest planning process, in order to ensure* that the environmental impacts of herbicide use and other forms of vegetation management activities are adequately assessed for the SNF

II-56 Soil and/or *sedimentation is not mentioned under Fish*, Soil, and Water This should be added in the Final EIS

II-126 It is stated that "fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures " However, on the previous page it is stated that under alternative K all planning basins except one would be under prescription B, with maintenance rather than reduction of water temperatures Please clarify

II-127 The discussion in the first paragraph is very good and bears repeating elsewhere in both documents *since the SRM areas are* essentially a special form of riparian management area

II-185 The table beginning on this page is different from that beginning on page 177 yet bears the same table number The table on *incremental* change is good but perhaps a bit difficult for the lay person For example, in order to compare planning problem #2 under alternative K to that under the no-change alternative requires 7 arithmetic calculations

9

II-213 Are natural sediment generation rates known for the Forest, or specific basins such that alterations could be compared to these rates as well as that of the Current Direction (A)? *This could be* important if sediment generation is currently very high relative to natural rates in the region If known, this should be included in the Final EIS

II-214 Figure II-21 seems to lack the "accompanying mitigation measures" discussed in the text above it

II-245 In the third paragraph, estimates of TSP production exceed the baseline value in six of the alternatives, not five

II-248 The subheading "Fish" is missing adjacent to the first full paragraph

II-249 *Application of Riparian Prescriptions B and C over entire* planning basins is very good We commend their use

II-260 The discussion of meadows is good A similar discussion for wetlands on the Forest *if any should be included in the Final EIS*

III-4 Comparing this figure with those on Pages I-7 and III-61 we note that planning basins 12 13, 14 16 and 17 are areas of very high precipitation and almost *all fall within the Chetco Ranger* District Comparing this information with other figures indicates that all have anadromous fisheries (p III-100) basins 12, 14, and 17 are still largely roadless (p III-34), basins 16 and 17 are especially sensitive with regard to erosion hazard (p III-65), and basins 13 and 16 have some of the highest densities of land tentatively suitable for timber (p III-87) The SNF could use this *information to emphasize the* Chetco Ranger District when developing and prioritizing its water quality monitoring plan for the Forest, as these are apparently basins in which land management activities have the potential to cause significant adverse effects

III-26 Are there major sand and gravel sources on the Forest? If so where? If not, what sources are used and are they sufficient for Forest needs?

III-59 The discussion of the Oregon nonpoint source inventory is good When you discuss conditions not exceeding "moderate in severity," *are you specifically referring to the Forest? Is natural* sediment production known for the Forest or similar areas in the region? What is the fate of sediment leaving the Forest? Does it accumulate at river mouths or elsewhere in the watershed? Does this have secondary impacts for harbors *such as the Coquille*?

III-60,61 Development and display of this information is very helpful to understanding water quality concerns on the Forest

10

III-65 We assume that by "regeneration" you generally refer to areas that have been harvested This should be clarified in the Final EIS

III-67 The last sentence on this page needs to be expanded upon For example, would "sufficient reason" be based on predictions that are based on past and future project monitoring, on modelling or on some other criterion? Does "significantly degraded " as used here, refer to exceedence of WQS?

III-110 With regard to Riparian Management, please add further discussion of the technical support for the assumption that 30 years will be required to fully realize the objective of Prescription C (2° F drop in temperature) Why would this only be applied to "basins where timber harvest already occurs"?

III-111 Under Habitat Maintenance, it would seem that harvest constraints of 9-13% per basin per decade would affect stream temperature as well as sediment and turbidity Also, how were the harvest constraints of 9-13% derived? For example was it a consensus process of managers and/or technical staff using best professional judgment, or some other methodology? A brief description and/or citation would be helpful and should be included in the Final EIS

IV-55 Regarding the term "moderate " does this definition imply that WQS would <u>not</u> be exceeded in this case? Regarding the tables following this page it would be good to present such tables based on natural sedimentation rates for the drainages (or at least one table with a Forest-wide average)

IV-64,65 The discussion beginning at the bottom of p IV-64 is excellent We endorse the use of basin-specific harvest constraints as appropriate

IV-76-IV-81 The discussion on these pages is also excellent We still have a question though with regard to how the terms "minor adverse" and "moderate adverse" relate to WQS Also, "moderate adverse" seems too high to allow for the Windruck basin under alternative K

IV-85 through IV-89 What land re-allocation allows the General Forest area to increase from 376 144 acres in alternative A to 470 818 acres in alternative K? Has this offset by allocating some of the Forest to Supplemental Resource areas? Pending the Forest's development of a water quality monitoring plan, we support the selection of alternative K as the preferred alternative at this point in time

IV-131 through IV-147 Under alternative K, if basins 2 4, 13, 15, 19, and 20 were managed under Riparian Prescription C, would this reduce the anticipated level of impact from "minor adverse" to "negligible"? In basins which are in a state of recovery or which have a large percentage of suitable lands with high erosion hazard due to roads and/or regeneration, we strongly recommend use of Prescription C

11

IV-232 Under Soils and Water, the DEIS indicates that BMPs S&Gs, and the Forest's MEP will more than offset any major or highly adverse soil and water impact In our view underlying assumptions are that the Forest will vigilantly implement these procedures and will receive a budget adequate to do so The Final EIS should discuss these or other assumptions, and how implementation would be affected by a reduced budget

IV-236 Under Soils and Water, the statement that 'no long-term effects to the water resource are known to occur from Forest management activities" appears to be used too broadly While this may be true given data based on current management practices it is surely in question with regard to past practices, as evidenced by the fact that certain drainage basins are presently in a state of "recovery " This issue should be clarified in the final EIS

SISKIYOU NAT'L FOREST GRANTS PASS OREGON JAN 19 19

January 14, 1988

ER 87/1155

Ron McCormick
Forest Supervisor
Siskiyou National Forest
P O Box 440
Grants Pass, Oregon 97526

Dear Mr McCormick

The Department of Interior has reviewed the Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (PLRMP) for the Siskiyou National Forest. The following comments are provided for use and consideration when preparing the final documents

GENERAL COMMENTS

The DEIS and PLRMP are well written, providing a detailed analysis of each of 13 alternatives This effort has resulted in a clear, descriptive definition of the environmental impacts associated with each alternative.

Fish and Wildlife Resources

The analysis presented indicates Alternatives E, G and M would provide greater protection and development of fish and wildlife resources The Fish and Wildlife Service (FWS) favors these alternatives over the selected Alternative K The FWS also suggests that further consideration should be given to protecting stream habitat by establishing wider riparian zones where vegetation is preserved or managed for fish and/or wildlife.

An interagency agreement signed on December 1, 1987, by the Director of the FWS and the Chief of the Forest Service commits the Forest Service to ensure the continued existence of a well-distributed northern spotted owl population throughout its National Forest range Under the agreement, both agencies have agreed to coordinate efforts, including research and monitoring An annual progress report will be supplied to the FWS and the agreement provides for emergency action if a viable population is not maintained The final documents should refer to this interagency agreement The terms of the agreement should be reflected in relevant sections such as standards, guidelines and monitoring, of the final document

The general habitat diversity issue concentrates on spotted owls, woodpeckers, wildlife user days and acres of special areas This overlooks the very important issue of interspersion of habitats throughout the Forest and the resultant habitat diversity available for the rest of the wildlife community The minimum management requirements for created openings (eg 20 percent of the suitable land base to be harvested in a decade) does approach this subject, but the relationship to habitat diversity is vague Is this a threshold beyond which further harvest within a drainage is to be curtailed?

Is there a way to establish adequate interspersion of habitats to enable full utilization by species which require more than one type within a home range, or which require a particular edge habitat?

Through soil disturbance and removing sources of woody material from the riparian zone, salvage logging has the potential of having a severe adverse impact on fish habitat and might conflict with the objective of a Supplemental Resource Area established to protect critical fisheries habitat

Much of the discussion of fish habitat centers on stream shading to achieve desirable water temperatures. While this is an important consideration, and it may be more easily measured than some other factors, water quality, sedimentation and riparian vegetation are equally important. These factors are mentioned in the plan and EIS, but most of the analysis and prescriptions focus on shading Partial harvest within a riparian zone may maintain adequate shade, but still result in streambank disturbance, erosion of soil into the streams and destruction of riparian habitat so important to both fish and terrestrial wildlife

Threatened and Endangered Species

The following comments regarding listed threatened and endangered species are provided as part of informal consultation (1-7-88-I-24)

One bald eagle nesting territory is known in the Oregon portion of Siskiyou National Forest (Forest) A site specific bald eagle management plan should be prepared for the active pair Completion of a bald eagle management plan should be scheduled into the final plan

A significant amount of potential breeding and wintering habitat for bald eagle exists along the Rogue, Chetco, Illinois, Sixes and Coquille River drainages These areas have not been adequately surveyed for the presence of listed threatened and endangered species If bald eagle winter roosts or breeding habitat are present on the forest, special management considerations are often necessary Where the level of existing use by a species in the forest is not well known, as is commonly the case with bald eagle winter roosting habitat, adequate pre-project inventories are important The Forest should plan for completing necessary inventories to identify existing and suspected bald eagle use areas These activities should be incorporated into the final documents

The Pacific States Bald Eagle Recovery Plan has been finalized. This Recovery Plan identifies stable or increasing winter populations of bald eagles as one of its requirements before delisting can occur Therefore, it is important for the Forest to provide for long-term monitoring of known winter use areas Annual winter monitoring of bald eagle populations in key locations within the Forest should be included within the Forest's monitoring scheme (Proposed Land and Resource Management Plan, page V-10 and D-6) This monitoring effort should be part of a coordinated regional effort and is thus somewhat different from the peak use mid-winter count currently being coordinated with the Oregon Department of Fish and Wildlife A possible key monitoring route is the lower Rogue River from Watson Creek to the mouth Winter monitoring efforts should be coordinated with other monitoring efforts of the Oregon Department of Fish and Wildlife, Pacific Bald Eagle Working Team, and National Wildlife Federation

Regarding bald eagle recovery, five potential bald eagle territories or breeding habitat areas within the Forest have been identified by the Oregon State University Cooperative Wildlife Research Unit There is need for additional management consideration of

project effects on identified potential bald eagle territories and essential habitat elements, i e forage base, nesting habitat, perch availability, etc , on projects occurring within identified potential bald eagle breeding territories The suitability of essential habitat elements for bald eagles within identified potential territories should be maintained

The effect of timber management and other Forest management programs on potential bald eagle habitat is difficult to assess with the available information The FWS recommends that the Forest carefully coordinate any action which may affect potential nesting habitat with the Oregon Department of Fish and Wildlife, the FWS, and/or other persons with expertise and involvement with bald eagle recovery activities

Peregrine falcon recovery efforts in the Pacific Northwest are gaining momentum The recent discovery of nesting peregrine falcon on Forest lands is testament to these efforts. Previous informal consultations with the Forest on peregrine falcons have documented the need for long-term monitoring of active breeding pairs to determine primary use areas for management purposes The Forest appears to be aware of the need to coordinate and cooperate with Federal, State and private organizations involved in these recovery efforts In addition, there will be a need to monitor historic and potential eyries within forest boundaries Monitoring efforts should be clearly identified within a Resource Element for Peregrine Falcon in Appendix D of the Plan The importance and magnitude of the monitoring will increase over the next 10 years The FWS encourages the Forest to define additional management directions to promote the conservation of the peregrine falcon

Oregon Caves National Monument

Much of the area around the Oregon Caves National Monument and the access road appear to receive some environmental resource protection in terms of management prescriptions The only area not afforded some protection is along the southern boundary of the Monument which is to be managed as General Forest and which calls for "multiple-use development opportunities that are visually dominant on the characteristic landscape " A mix of management prescriptions on the east, north and west boundaries will provide mature old-growth habitat, quality fisheries, water, wildlife habitat and recreation opportunities, and multiple-use development opportunities not visibly evident to the casual visitor. While these prescriptions appear to afford some resource protection, we are particularly concerned regarding any activity in the upper watershed which could lead to landslide or otherwise impact the cave or other Monument resources or the chateau or chalet or other developments of the Monument

Another issue of concern, "viewshed," is at present a non-issue since all areas close to the Monument have been logged within the last 10 years. However, we encourage the Forest to consider the view from the Monument when a long range plan or an update to the current plan is prepared Land classifications adjacent to the Monument that are supportive of the Monument's land management objectives are supported by the National Park Service (NPS)

Cultural Resources

The cultural resource review that is usually conducted by the National Park Service was not performed for this Forest Plan Because of heavy priority work loads, the Interagency Archeological Services (IAS) Branch has been unable to review this document In the absence of the IAS review, we encourage the Forest to consider the comments of the State Historic Preservation Officer

National Wild and Scenic Rivers

The evaluation of the North Fork Smith and Chetco Rivers acknowledges the exceptional water quality, wildlife habitat, vegetation, scenic resources and fisheries on both rivers Both are actively used for a variety of recreational activities, as well as being notably free of impoundments, diversions, riprap, and other inappropriate development and, according to the Plan, both are easily managed as designated rivers Based on the evaluation of resource qualities, the North Fork Smith and Chetco Rivers seem to be excellent candidates for Wild and Scenic River designation

It appears that the negative recommendation was based solely on a subjective assessment of the need for designation Several of the suggested denigrating factors--the presence of designated rivers nearby, the lack of appeal for out-of-state visitors, and sufficient ecosystem representation elsewhere--are irrelevant to Wild and Scenic suitability The wilderness status of the upper watersheds of both rivers, a valid consideration in determining the most suitable way to protect the North Fork Smith and Chetco, seems a better indication of the appropriateness of designation than of unsuitability

In addition, the North Fork Smith should be given additional consideration for designation The Siskiyou National Forest contains roughly half the length of the North Fork Smith River of which the California portion is a component of both the State of California and National Wild and Scenic Rivers Systems Both the Forest Plan and the 1982 Nationwide Rivers Inventory concur that the Oregon portion of the North Fork Smith is eligible for National Wild and Scenic River System designation The Oregon portion could not be included in the 1981 designation of the California segment because the designation was requested by the Governor of California under the provisions of Section 2(a)(ii) of the Wild and Scenic Rivers Act, and there was no authority to include the Oregon portion Consequently, the river is divided on a political rather than a resource basis Nevertheless, the Forest Service is bound by the Wild and Scenic Rivers Act, particularly under Sections 7 and 12, to manage the undesignated portion in such a manner as to protect the values for which the downstream portions were designated This is particularly critical for those activities that might affect fisheries and water quality, the existing high quality of which are trademarks of the Smith River System

Based on the facts that the Oregon portion of the North Fork is eligible for the National Wild and Scenic River System, that a sizeable portion of the segment is already in wilderness, that the total river is now one of the most pristine components of the Smith River System and that the Wild and Scenic Rivers Act requires management consistent with maintaining downstream values, exclusion of the Oregon portion of the North Fork Smith from the National System does not seem appropriate

It appears that the Plan would authorize increases in timber harvest and road construction and the deterioration of scenic quality through reduction in Visual Quality Objectives in the corridors of the North Fork Smith and Chetco Rivers It is possible that these impacts would permanently preclude Wild and Scenic River designation of both rivers Therefore, we recommend that the North Fork Smith and Chetco Rivers be recommended for designation into the Wild and Scenic Rivers System or that the decision on potential designation be delayed until a full and accurate evaluation of suitability is conducted In the meantime, the North Fork Smith and Chetco Rivers should be managed as de facto Wild and Scenic Rivers

Mineral Resources

The Plan does acknowledge that the Forest lies in an important mineralized area of Oregon Missing, however, is any specific mention by mineral commodity as to current or estimated future exploration and development activity, except as contained in Chapter III of the DEIS The Plan should either reference this discussion or include an executive summary Minerals are treated only in very general terms and largely from the standpoint from areas withdrawn from mineral entry or where specific management considerations, such as RNA's, Botanical, Custodial, Special Habitat or Riparian considerations, will limit or require stipulations for approval of operating plans.

The Plan would be materially enhanced by inclusion of a map depicting the various Management Areas listed in Table III-9 (p III-12) together with areas of high, moderate, and low mineral potential as shown in Figure III-4 of the DEIS Such a map would aid both the Forest planner and Plan reviewer in visualizing the spatial relationship between the more than 25 percent of the Forest withdrawn from mineral entry and the affected mineral resources which may include Jurassic rocks containing chromite, copper, manganese, known gold, copper, mercury mining areas, placer streams, and nickel laterite deposits, to mention only a few

Although the report has a mineral potential map, it should be at the same scale as alternative maps and in color. Good examples are found in plans for the Kootenai National Forest, Montana, and the Okanogan National Forest, Washington Illustrations of mineral potential for each of the roadless areas are also needed

An alternative Evaluation Criteria for Nonenergy Minerals, such as that from the Wallowa Whitman National Forest, Oregon, would be useful, as would an alternative to the definition of access categories such as that from the Beaverhead National Forest, Montana

A list of current mineral withdrawals, acres involved, and mineral potential for locatable and leaseable minerals is needed The Los Padres National Forest, California, plan has a good example

A narrative section on definitions of mining exploration and development terms, what the operations involve, and the effects these activities have on the Forest is also needed The Beaverhead National Forest has a good example This would fit nicely in the appendices

SPECIFIC COMMENTS

DEIS

Page III-39 first paragraph, third sentence The acreages allocated to roadless management should be listed for each alternative mentioned in the final document

Page III-111 last paragraph The capital investments discussed in this paragraph need to be specifically defined

Page III-113 Table III-29 Species indicative of tributary streams and wet meadows should be added to these tables in the final document

Page III-124 fifth paragraph It is not clear whether the acreages of old growth proposed for preservation are sufficient or that they will be preserved The final document should

1) clearly state how much wildlife needs to be preserved and 2) clearly describe how much will be preserved, where and how

Page III-124 sixth paragraph The final document should be expanded to include old growth as an essential habitat

Page III-125, Bald eagle and American Osprey Management direction for the bald eagle on the Forest should include improving searches for existing winter habitat The Pacific Bald Eagle Recovery Plan has been finalized and published

Page IV-25 Table IV-5 is excellent, however, the Bureau of Mines suggests a modification of this as shown in attachment 1, using percentages rather than acreages It maybe easier to envision the comparison and comprehend the effects each alternative may have on mineral resources

The potential classification consists of five parts, with a range from high potential to very low potential based on current knowledge The availability classification consists of four categories, including withdrawn, specific legal protection measures, special management conditions, and standard operating conditions

The visual comparison of the effect of the alternatives on minerals on page IV-26 is excellent, as was the discussion of how minerals fare under each of the alternatives

Page IV-45 last paragraph The specific improvements for fish and wildlife should be identified as to what will be done, when, where, and by whom in the final document

Page IV-149, Wildlife The analysis of impacts to elk habitat and populations is surprisingly short A major assumption is made that timber harvest benefits elk by providing additional forage Much of the literature indicates that the quantity of forage is rarely limiting to elk in western Oregon Other factors which have been shown to be important. road densities, thermal cover, forage quality, old growth stands (called "optimal cover" by some), are mentioned in the discussion, but are apparently not given much weight.

Page IV-229. The Medford District of the Bureau of Land Management (BLM) has identified several areas where the Siskiyou National Forest's visual resource objectives, under some alternatives, conflict with BLM's objectives Specifically, along the road from Agnes to Bear Camp, the BLM is managing this area for intensive forestry and the Forest has identified this area for partial retention and retention There is also a similar conflict with visual objectives along Highway 42 near Cave Junction The BLM's visual objectives are less restrictive than the Forest's in this area

The BLM has begun to develop its plans for the 1990's for its lands adjoining the Forest in Oregon The Forest should consider preserving options for managing spotted owl habitats centered on adjacent BLM lands (or vice versa) which would require joint agency management, so that those options might be addressed in the BLM planning effort

BLM's Coos Bay District has received a nomination to designate the Hunter Creek Bog area (portions of sections 13 and 24, T 37 S , R 14 W , W M) as a Research Natural Area This nomination is based on the diversity of plant species occurring in the area Many of the same species occur on adjacent Forest Service lands in Sections 18 and 19 T 37 S , R 13 W Several of the species identified are State-listed sensitive species

Page IV-247, fourth paragraph The paragraph should be updated to include the presence of peregrine falcon on the Forest

Appendix F The following Federal candidate species should be added to the list of plants Gentiana bisetaea and Horkelia hendersonii.

PROPOSED LAND AND RESOURCE MANAGEMENT PLAN

Page IV-2 The Plan should include an explanation of how Forest Management Goal No 18 will be implemented consistent with agency-wide mineral policy particularly with regard to consideration of the importance of minerals in multiple use management of the Forest when dealing with actions that may further restrict areas open and available for mineral entry and development (location, leasing, and sales)

Page IV-6 Table IV-1 does not include an estimate of mineral outputs Considering the level of mineral development and exploration within and adjacent to the Forest, this appears to be an important omission

Page IV-21 third paragraph, Informal consultation Informal consultation with the FWS is advisable whenever the Forest determines there is a question of effect or determines if a Forest action "may affect" any Federally-listed threatened or endangered species A brief summary of consultation requirements with the FWS and outline of Forest Service threatened and endangered species review process would be helpful at the beginning of Section 4-2, page IV-21 An alternative would be to cite another document or provide a cross-reference if this information is provided elsewhere

Page IV-22, Bald eagle nesting sites Bald eagle primary and secondary zones should be established by actual use observations and site-specific information Secondary zones should reflect local physiographic conditions and site-specific information The Forest should develop a site-specific bald eagle management plan within 1 or 2 years

Page IV-22, Bald eagle winter habitat Section 4-4 should be expanded to include consideration for identification and conservation of bald eagle winter habitat

Page IV-23, Peregrine falcon The status of peregrine falcons on the Forest should be updated in the Plan

Pages IV-28 and V-3 The Forest should check with the National Marine Fisheries Service to determine if notification is desired of any mineral development that would affect anadromous fish habitat

IV-27 last paragraph It is not clear whether the snag retention policy discussed will adequately maintain self-sustaining populations of cavity nesting species This should be clarified

Page IV-29 Within the PLRMP, under Forest-wide Standard and Guidelines, it appears that precommercial thinning should be included as part of 6-1 Timber Management.

Page IV-83 first paragraph, last sentence Total acres available are stated to be 153,400 while on page III-9 it says 181,000 acres will be maintained in old growth for the same species discussed This apparent discrepancy should be resolved in the final document

Page V-10, Table V-1, Bald eagle Bald eagle productivity should be reviewed annually Bald eagle winter populations should be monitored for stable populations over a 5-year

period Management plans for potential and known bald eagle habitat on the Forest should be prepared

Page V-10, Table V-1, Sensitive plants. The 10 percent identified threshold of concern does not appear to be consistent with the 20 percent threshold of concern identified on page D-8

Page V-10, Table V-1, Peregrine falcon Monitoring needs for active and potential peregrine falcon sites should be identified

Appendix D A Resource Element should be established for peregrine falcon

SUMMARY COMMENTS

Based upon available information, the preferred alternative appears to have incorporated adequate programmatic guidance to ensure compliance with Section 7(a)(2) of the Endangered Species Act of 1973, as amended (the Act) In conformance with the intent of Section 7(a)(1) of the Act, the FWS encourages the Forest to develop and implement conservation measures which will promote the recovery of listed species Should the Forest determine an action may affect a listed species, it is required to initiate consultation with the FWS.

Thank you for the opportunity to comment on your Proposed Plan and Draft EIS

Sincerely,

Charles S Polityka

Mr Ron McCormick, Forest Supervisor
Siskiyou National Forest
USDA Forest Service
P O. Box 440
Grants Pass, Oregon 97526

Dear Mr. McCormick

Bonneville Power Administration has reviewed the Draft Environmental Impact Statement (DEIS) on the Proposed Land and Resource Management Plan for the Siskiyou National Forest, and we offer the following comments

1. No Bonneville facilities are located or planned on the Siskiyou National Forest.

2 Although the EIS does address energy transmission corridors, it does not mention the long-range planning corridor that would connect the electrical transmission system near Murphy and Wilderville to the system near Agness and Gold Beach. This corridor, which provides a future corridor option across the Coast Range in southwestern Oregon, is listed in the 1980 Western Regional Corridor Study. The Study was prepared by the Western Utility Group and copies were provided to the National Forests We suggest that you refer to the Study for corridor information Also, we recommend that you include a map in the EIS showing the above-mentioned future corridor along with the existing corridors that were mentioned in the draft EIS

3. To be consistent with the treatment of energy corridors in other Forest Service EIS's, your EIS should establish corridor standards for management areas, specifically identifying corridor avoidance and exclusion areas The EIS and plan should address the impacts, if any, of the EIS alternatives on existing and planned energy transmission corridors

Reply to: 1920 Land and Management Resource Planning Date: November 12, 1987

Subject: Siskiyou National Forest Plan

Ron McCormick, Forest Supervisor

I have recently finished reviewing the Siskyou National Forest plan, concentrating on the treatment of Research Natural Areas (RNAs) In general, I was very pleased with how they were dealt with I do have some comments to make and will deal with each document separately.

LAND MANAGEMENT PLAN

p II-9. I am interested in your list of research needs for the forest In looking them over I can see that RNAs will play an important role in providing research field sites and in providing baseline information This section may not be the appropriate place, but I would like to see some mention of the role of RNAs in relation to the identified research needs

p IV-70 The section on standards and guidelines is generally very complete Under management goals I think it would be good to mention the role RNAs can play in monitoring the forest plan

p IV-71 In the section on lands I am in disagreement with your statement on roads The plan states that right-of-way grants for roads will be denied unless no other access is available The FSM states (4063.3 6) "Do not permit roads, fences, or signs on an established research natural area unless they contribute to the objectives or to the protection of the area." The statement in the plan seems to leave the door ajar for road building, this makes me nervous and seems to run counter to the manual intent

Appendix C In listing the timber sale plans for the coming decades it is very difficult, in fact impossible, to tell if any of them conflict with the established or proposed RNAs. My concern is not so much that there is a sale within an RNA, but the effects adjacent timber sales might have on the integrity of the RNAs I realize this is not something that can be dealt with in the plan, but I certainly hope that future timber sale planning will take into account the management of RNAs I look forward to working with the forest and the districts on this.

Appendix E-5. Under ORV closures only the established RNAs are listed I think the proposed RNAs ought to be listed as well This is consistent with the Regional Forester's direction that "candidate areas being seriously considered should be protected from uses which would negate their suitability for RNA designation".

DRAFT ENVIRONMENTAL IMPACT STATEMENT

S-13 The summary statement implies that the alternatives that include all four proposed RNAs will include representatives of all plant communities on the Siskiyou National Forest. This is not correct. There are a number of plant communities that are not included in established or proposed RNAs. It would be more accurate to say that "RNAs will include many representatives " Further on in the DEIS (p III-79) mention is made of the fact that more RNAs are needed to fill unfilled cell needs on the Siskiyou Forest This is good.

APPENDICES

I really have no comments on the appendices The coverage of the established and proposed RNAs is adequate

In summary I have very few problems with how the Siskiyou National Forest has dealt with RNAs I think the RNA program, its objectives and needs, have been well covered. I support the inclusion of all established and proposed RNAs in the forest plan alternative. I look forward to ongoing cooperation with the forest as we begin to work on the establishment records and land management plans

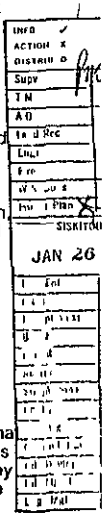
OFFICE OF THE GOVERNOR
STATE CAPITOL
SALEM OREGON 97310 1347

January 25, 1988

Ron McCormick
Forest Supervisor
Siskiyou National Forest
Grants Pass, OR 97526

Dear Mr McCormick



Active participation in federal forest planning is a high priority for all Oregonians It is essential that the hopes, needs and ideas of Oregonians be incorporated into these important resource plans In that context, this letter provides the State of Oregon's comments on the Siskiyou National Forest Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (LRMP)

It is imperative to the State of Oregon that all federal land management plans be environmentally sound and provide stable, predictable supplies of commodities and amenities The state depends upon the Siskiyou National Forest for resources critical to Oregon's economy and environment

These lands provide a significant share of the employment in Coos, Curry, Jackson and Josephine counties through their impact on the timber, mining recreation, and fishing industries, and much of the revenues accruing to these counties is derived from use of Forest resources The importance of federal timber receipts to the maintenance of sound school and road programs in these counties cannot be overstated

In addition, the Forest contains critical watersheds and big game habitats, anadromous fish streams, spectacular Wilderness areas and the scenic Rogue River corridor, and is the home to a multitude of wildlife species

The State's objectives for the management of the Siskiyou National Forest are twofold 1) that these lands be managed in an environmentally sound manner so that future generations have the same opportunities we do to enjoy the bounty the lands can provide, and 2) that these lands produce the flow of economic benefits that they have traditionally provided Our comments here focus on evaluating your resource management planning from these perspectives

All affected State agencies have reviewed the DEIS and LRMP In addition, we held public meetings in Grants Pass and Gold Beach to hear, from the public, what issues relative to the proposed Plan were of special interest This letter and the detailed agency attachments highlight the State of Oregon's questions, concerns, and recommendations on these documents Please consider them in development of your Final Environmental Statement

Before sending this letter and the detailed agency comments to you, we made them available for public review Many letters urged the State to take positions on various issues Other letters suggested improvements in our draft As a result, we have made significant changes and/or additions to our discussions of "short rotations", proposals for a Siskiyou National Park, compliance with the Coastal Zone Management Act, mineral exploration and the importance of forest receipts to county revenues Several other changes have also been made

We wish to compliment the Siskiyou National Forest on an informative and technically well-written DEIS and LRMP While these documents are the bulkiest we have reviewed for a national forest so far, their size is *justified by the data, maps,* and disclosures they contain The small scale management area and resource distribution maps proved especially helpful to our State agencies Unfortunately, these documents will still be extraordinarily difficult for lay people to understand which further increases the importance of the State effort as an outside evaluator of your effort

With your help, we plan to construct our own State alternative for your Forest We had hoped to do this during the comment period, but information needs that still exist *prevent our constructing a State alternative yet* We still plan to construct the State alternative, though, and view this letter as a vehicle to help you understand our difficulties with your analysis and the additional data about your Forest we feel we need

The rest of this letter highlights our major information needs In outlining these requests, we wish to emphasize that we hope to work with you in a cooperative manner to obtain them Both the Federal Plans Coordinator and the agency contacts mentioned on the attached list are willing to discuss these comments further and meet with you to explain our suggestions for clarification and improvement and clear up any misunderstandings that we *may have*

Our comments on your Plan are organized into five main sections A) development of alternatives, B) estimation of resource effects, C) estimation of economic effects, D) fire salvage, and E) other considerations

A. Development of Alternatives

We are concerned that your development of alternatives may be unduly restrictive and may overemphasize the conflicts between commodities, amenities and environmental effects more than need be We feel that a wider range of choices should be examined Toward that end, we suggest three major areas in which we wish you to widen your range of choices 1) timber management intensification, 2) control of timber harvest by watershed, and 3) provision of big game habitat In addition, as we discuss below, we believe that you should consider the environmental and economic effects associated with the land allocations commonly suggested by people who advocate a "National Park" for parts of your Forest Finally, we discuss the need for the DEIS to acknowledge the mandates of the Coastal Zone Management Act and to address possible land exchanges with the State to consolidate ownerships

1 Management Intensification

The harvest schedule for the Siskiyou National Forest displays the characteristics of *a "deficit timber inventory" in which the nondeclining yield harvest* level starts below the long run sustained yield of the forest Moving that starting harvest level toward long run sustained yield requires either increased growth on existing merchantable timber stands or earlier availability of young stands that now exist and that will be created when the existing timber is harvested The Forest should look at two ways in which this increased harvest level might be achieved a) shortening rotation length in existing young stands and b) applying fertilizer to existing and future stands

a Rotation length

All alternatives except D1 require stands to achieve 95 percent of culmination of mean annual increment (maximum average growth) before harvest On the Siskiyou, this requirement means that most stands cannot be harvested until they reach 90-100 years of age Alternative D1 releases that restriction and allows harvest to occur when the stands achieve an age of 70-80 years Allowing these shorter rotations, which would begin 40-50 years from now, would allow a 10-12 percent increase in timber harvest

When shorter rotations are allowed across all planning periods, as is done in *alternative D1, the long term sustained yield for the Forest* declines as stands are continually harvested at rotations short of maximum average growth The critical period during which these harvests are needed occurs 50-70 years in the future when the plantations that now exist are cut for the first time Rather than plan to apply 70-80 year rotations perpetually to the forest, with the resulting decline in long term sustained yield, you should develop an alternative in which they are applied only to initial harvest of existing plantations This latter approach could enable an immediate increase in the nondeclining harvest without any falldown in long term sustained yield Please see the comments of the Oregon State Forestry Department(OSFD) and the Economic Development Department(EDD) for more discussion of this issue

We realize that legal questions may be raised by this suggestion The National Forest Management Act(NFMA) states " assure that all even-aged stands scheduled to be harvested during the planning period will generally have reached the culmination of mean annual increment of growth" and " exceptions to these standards are permitted for removing particular species of trees, after consideration has been given to the multiple uses of the area being planned and after completion of the public participation process applicable to the preparation of a forest plan " You should examine whether our suggestion above that you consider a shorter cutting age for existing plantations is legal under NFMA

b Fertilization

Your preferred alternative allows numerous timber management practices to increase timber yield including release, precommercial thinning, and commercial thinning Fertilization is not among them Our discussions with you suggest that you believe stand fertilization would increase stand growth but that little of this increase would translate into increased harvest now because of the peculiarities of your particular timber schedule You should reevaluate this conclusion while paying particular attention to fertilization of existing stands Fertilization of 60-90 year old stands, as often done by the forest industry, could payoff in the near future Fertilization of plantations, combined with the shorter rotations discussed above, could help alleviate your deficit inventory difficulties You should consider fertilization on these stands, and also on future stands, with and without commercial thinning

2 Controlling Timber Harvest by Planning Unit

Fundamental to your analysis is the division of the Forest into 19 planning units which roughly follow watershed boundaries We applaud this geographic resolution and your use of it to portray the outputs and environmental effects associated with each alternative It goes a long way to making your proposal comprehensible to the public by enabling them to understand the implications of the plan for each watershed We wish however, that you would indicate the location of these planning units on your alternative maps, thus making them even more visible

Controlling activity rates, such as final harvest, in these watersheds is part of this approach Doing so ensures that the harvest and associated roadbuilding, will not concentrate in a particular watershed in some period beyond acceptable limits

Your approach focuses on controlling the acres of clearcutting per period by watershed, with a harvest limit per period of 9-13 percent of the available acres allowed in the preferred alternative More than any other restrictions, these "dispersion constraints" may control the possibility of increases in the timber harvest level We have some difficulty understanding both the rationale for setting these restrictions at the particular level chosen in the preferred alternative and also the benefits and costs of levels different from the ones chosen You should explain

your rationale and also portray the implications for the preferred alternative if the harvest limits are raised or lowered We are especially interested in your display of the level at which the constraints move from distributing the harvest among watersheds to controlling the overall harvest level Because of the central role that these constraints play in your analysis, and their impact on the ability of management intensification to increase timber harvest, we feel that a full understanding of the implications of setting them at different levels must come before we can develop a State alternative

3 Big Game Habitat

We are concerned that big game numbers appear to decrease under alternatives The Oregon Department of Fish and Wildlife (ODFW) believes that this decrease can be mitigated by increasing the production and distribution of quality forage and cover Toward that end, ODFW suggests that the forest seed and fertilize 1000 acres of well-distributed clearcuts per year for big game forage, while reducing the number of trees planted on these sites to prolong production of quality forage In addition ODFW suggests that the Forest establish permanent forage sites, five to ten acres in size, at a rate of 100 acres per year These sites would then be managed as meadows with desirable forage species planted and fertilizer periodically applied Finally ODFW suggests that timber stands adjacent to the forage areas be treated to provide cover for the foraging animals We request that your analysis include these suggestions so that we can assess the benefits and costs, including any timber yield effects, of their adoption

4 Proposals for a Siskiyou National Park

Numerous proposals have been made to establish a new national park centered on major portions of the Siskiyou National Forest The State will not take a position on these park proposals until completion of the forest plans and we feel that the forest planning process is the appropriate vehicle in which to consider the environmental and economic effects of the land allocations associated with these proposals We realize that some alternatives, such as Alternative M and Alternative E, already address this issue, but you should ensure that you systematically cover the land allocations associated with all reasonable proposals Without such an analysis, you may not meet the requirement of the National Environmental Policy Act that requires you to consider all reasonable alternatives

5 Compliance with the Coastal Zone Management Act

We could not locate in the DEIS and LRMP recognition that portions of the Siskiyou National Forest are located in Oregon's coastal zone and therefore are subject to the requirements of the federal Coastal Zone Management Act

The Siskiyou National Forest needs to identify the Land Conservation and Development Commission as Oregon's coastal zone agency and its role in administering the requirements of the federal consistency process Under this process, all federally conducted or supported activities (including development projects) directly affecting Oregon's coastal zone must be consistent to the maximum extent practicable with the mandatory, enforceable policies of the state's coastal zone program In Oregon, such policies consist of the adopted statewide planning goals, acknowledged city and county comprehensive plans and the statutory authorities and regulations of relevant state agencies See the Land Conservation and Development Department's comments for more details

6 Land Exchange

The State Land Board owns many parcels of land in and around the Siskiyou National Forest Many are geographically isolated from other state-owned forest lands making them difficult to manage efficiently In addition as discussed in the comments of the Division of State Lands, some of these areas border proposed botanical areas, supplemental resource areas or other areas of special environmental significance

The national forest planning process offers a unique opportunity for the State and the Forest Service to consolidate their land holdings Legislation enacted in the 1987-1989 session of the Oregon Legislative Assembly authorizes the Division of State Lands to dispose of isolated sections and fragments of state lands that are not suitable for management by the State Land Board Acting on behalf of the Land Board the Division is identifying scattered and isolated parcels in and near the national forests for possible sale or exchange

Your LRMP recognizes land ownership adjustment as a tool that can be used to support its management goals We request that you work with the Division of State Lands to assess whether mutually beneficial land exchanges can be made Toward that end, please see the detailed comments of State Lands and especially some proposed changes there in the wording of your DEIS and LRMP that might facilitate this process

B Resource Effects

The State agencies feel that you have done a credible job, in general, in estimating the effects of your activities on various resources The standards and guidelines in the LRMP are clearer and more objective than in any other forest plans we have received A number of questions and information needs remain, however, before we can develop a State alternative

We highlight here some of our major information needs relative to resource effects More detailed discussions about them can be found in agency comments, especially those of OSFD, ODFW, Water Resources Department, Department of Environmental Quality (DEQ) and the Natural Heritage Advisory Council addition to the comments by Division of State Lands Our discussion here is divided into seven parts 1) minimum management requirements, 2) timber, 3) fish and wildlife, 4) stream flow, 5) water and air quality, 6) roadless areas, and 7) rare plants

1 Minimum Management Requirements

All choices for managing the Forest must embody standards and practices to ensure basic protection of the environment such as maintenance of air quality, water quality, and the diversity of plants, animals, and ecosystems In fact, we rely on your setting of these requirements to ensure that any forest planning alternative will not deprive future generations of their rightful share of the commodities and amenities that your Forest can provide

You use "minimum management requirements" to disclose this baseline level of environmental protection, and, as you know, few aspects of national forest planning have generated more controversy In part because of this controversy, the requirements are still somewhat unsettled since both the Final Environmental Statement for the Northern Spotted Owl and a policy paper on development of minimum management requirements from the Secretary of Agriculture are due out soon

One of the major criticisms about the setting of these requirements is that they were done without public involvement Your "Sensitivity Analysis for Minimum Management Requirements (Appendix J)" is a major step toward alleviating this criticism We feel, however, that it should go further Specifically, we believe that you should more systematically demonstrate that you have examined the possible ways of meeting each management requirement and have selected an efficient method of doing so given the objectives and constraints of the preferred alternative Your analysis on the amount of old growth habitat compares designated vs managed habitat in the manner suggested here You should extend this analysis to your other requirements

2 Timber

The starting timber inventory and the yield projections for existing and future stands form the basis of any estimate of the sustainable timber harvest level Yet my staff had significant difficulty understanding how your modeling assumptions affected these key components Specifically, we would like to know 1) how the acres and volume by age class represented in your forest planning analysis for potentially suitable timberland relates to the results from your last timber inventory, 2) how the growth projected on your existing stands in that analysis relates to the growth found in your last timber inventory, and 3) the rationale for any differences uncovered between assumed and actual inventory and growth

We understand that you projected growth on existing young stands and on future stands with a modified version of a model called "DFSIM"-- a model that did not include information from your geographic area in its development Recently Oregon State University has finished a model called "ORGANON" that provides, for the first time, timber growth and yield projections specifically designed for Southern Oregon We request that you compare DFSIM and ORGANON results for representative sites and justify which model should be used

In the past regenerating timber stands has been difficult on parts of the Siskiyou National Forest Because the projected wood flow from the Forest depends, in part, on initial plantation success, we would like more information on recent plantation survival and growth and on procedures to avoid past difficulties

Further research is recommended in the area of Port Orford cedar root rot We encourage the Siskiyou to apply the appropriate silvicultural prescriptions and monitor efforts to control this disease

3 Fish and Wildlife

We have further broken our fish and wildlife discussion down into a) riparian and instream habitat b) supplemental resource areas, c) dead and down woody habitats, and d) road management

a Riparian and Instream Habitat

Streams and rivers on the Siskiyou National Forest provide the spawning and rearing habitat for a fishery of unparalleled value for both sport and commercial uses ODFW is concerned about the high summer water temperatures found in portions of all nine major river systems on the Forest We would like information on the benefits and costs of more or less use, than proposed, of the riparian management strategy that would manage vegetation to reduce water temperatures (prescription C)

In addition, sediment production can impact the fishery We are unclear about the range of measures considered in the Forest Plan to reduce sediment production On page II-212 you state that "the amount of accelerated sediment varies directly with the amount of road construction and timber harvest" How did you select the road building and logging methods to consider for each type of ground? Could other methods produce less sediment, although perhaps at higher cost? How does the riparian prescription chosen affect sedimentation? What about instream structures to control sediment?

b Supplemental Resource Areas

Areas considered highly productive (or critical) habitat for fish or wildlife, or necessary for the maintenance of high quality watershed conditions, have been designated by the Forest as supplemental resource areas No timber harvest is programmed for these areas The preferred alternative allocates the land along some, but not all, streams and rivers to this category, including the visual corridor along the Rogue River We do not understand the criteria used to include or exclude areas As an example, ODFW believes that the riparian areas in the Elk/Sixes Planning Basin should be added to the supplemental resource areas to protect the high fish values there We request that you explain further your criteria for including or excluding areas from this allocation

c Dead and Down Woody Habitats

ODFW believes that the Forest has established an excellent standard for amount of wildlife trees and down woody material to be planned for in timber sale areas However, the Forest has not displayed standards or methods for protecting these dead and down woody habitats from activities such as firewood cutting and prescribed burning during site preparation We would like that information in order to assess the adequacy of these standards and the benefits and costs of this dead and down policy

d Road Management

Road management and selective closure have gained prominence in recent years as a crucial element in maintaining habitat for big game You should work with ODFW and OSFD to develop specific criteria for establishing road closures to meet wildlife objectives that are fair to forest users These standards are especially important for roadless areas you propose to develop

4 Stream Flow

The Water Resources Department believes that the Siskiyou National Forest has done a good job at identifying the water resource issues for soil, water, and riparian zones in the forest and that the DEIS and LRMP have identified provisions to protect and improve watersheds and riparian areas In addition, the division of the Forest into planning units for analysis makes the presentation of resource effects more understandable to the Department

The Water Resources Department derives its goals from Water Resources Commission basin programs that provide direction for managing water resources important to the State Two basins (South Coast and Rogue River) encompass the forest boundary and both have approved basin programs The Department is especially concerned about the adequacy of summer low flows and effects

on downstream users in these basins We request that you utilize the programs for both basins as a reference for water resources information Forest activities should be compared to basin program goals and water policies As an example, the DEIS recognizes that the forest lands provide a majority of water for downstream users but fails to mention that minimum streamflows have been established on many streams in the area and explain how forest practices affect these flows

5 Air and Water Quality

Regarding air quality, DEQ's primary concerns are those of air quality impacts from prescribed burning and burning of the Forest's fuelwood by the public in nearby urban areas As pointed out by DEQ, prescribed burning smoke is a major source of fine particulate emissions within the State More analysis should be presented on projected vs baseline pollutant emissions and on the potential for intensive utilization of woody residues for industrial purposes Particulate emissions in the vicinity of the Siskiyou are of particular concern due to EPA's new PM-10 standard

Regarding water quality, DEQ's concern is that the Plan be consistent with Oregon's adopted Statewide Water Quality Management Plan for forest practices as required by the Clean Water Act The Plan recognizes goals of meeting water quality standards and protecting beneficial uses of water DEQ feels, however, that needed information is lacking in the DEIS and LRMP to assess adequately the water quality effects of activities, including analysis of baseline water quality conditions in individual steams and the effects of planned forest activities on those streams

6 Roadless Areas

You have a land allocation category called "Custodial Roadless Areas" that we have not encountered on other national forests In your DEIS (page II-209), you state one of the reasons why unroaded ares are allocated to this allocation in some alternatives "unroaded areas are allocated to Custodial (Roadless) management so that the effects of management on lands adjacent to designated wilderness are minimized, and wilderness potential maintained " Many reasons exist why you may wish to keep areas undeveloped including provision of dispersed recreation opportunities, maintenance of fish and wildlife habitat, and enhancement of natural diversity We do believe though, that the rationale quoted above runs counter to the intent of the 1984 Oregon Wilderness Act and request that you adequately explain the reasoning behind your custodial roadless allocations or not make such allocations

7 Protection of Rare Plants

The Siskiyou National Forest contains the highest concentration of sensitive and rare plant species of any National Forest in Oregon It has been estimated that over 9 percent of the plant species of concern in the state occur on the Siskiyou, and several species are found nowhere else The DEIS does an exceptional job in defining the Forest's responsibility with regards to sensitive plant species protection The information presented on individual species in Appendix F allows for careful review of the potential Research Natural Area and Botanical Area ability to protect the habitat of these plants

Because of the high number of rare plant species known to occur on the Siskiyou National Forest, it is important for the Forest to conduct searches in non-project areas for additional occurrences of these plants and for new varieties, including areas already in protective status such as Wildernesses According to our Natural Heritage Advisory Council, the importance of these basic botanical inventories is often overlooked in the overall management of rare species Therefore, we recommend that the Forest indicate in the LRMP that it intends to begin inventorying all potential habitat for sensitive species to further knowledge of such species

Botanical areas on the Forest are intended to contain the best representations of unusual plants indigenous to southwestern Oregon According to the Natural History Advisory Council, the Forest has done an outstanding job of identifying potential botanical areas that form the backbone for the protection of rare species across the Forest The preferred alternative lists eight sites for designation, but leaves out a number of sites that rank of equal importance as botanical areas We could not find justification of why some high-priority sites were listed and some were not and request that this information be provided

D Economic Effects

We have several suggestions for improving your analysis and portrayal of the economic affects associated with your preferred alterative We have highlighted eight major areas of concern here 1) enhancement of the fishery, 2) restriction of mining, 3) enhancement of tourism and recreation possibilities, 4) provision of visual quality, 5) portrayal of recreation activity value, 6) estimation of the supply and demand for recreational activities, 7) portrayal of the timber harvest and employment impacts of the preferred alternative, and 8) estimation of supply and demand for timber Please see the comments of EDD, the State Economist, Department of Geology and Mineral Industries, Parks and Recreation and OSFD for more details

1 Enhancement of the Fishery

The fishing industry plays an important economic role in Coos and Curry counties through the salmon and other fish harvested, and as part of the scenic backdrop that attracts tourists In addition, recreational fishing attracts a significant number of tounsts, and South Coast citizens have made major commitments to fishery improvement through our Salmon and Trout Enhancement Program

Environmental conditions on the Forest affect the size and quality of this fishery, even though we now lack the information to quantify exactly cause and effect Investments in fish structures and facilities can affect the capacity of the forest as a fish producer, but we are uncertain of the relationship between these investments and fish production in the preferred alternative This analysis should be expanded substantially, because we all need to know the opportunities here In that discussion you should document the past performance of such structures and the degree to which the preferred alternative depends on them to maintain the fishery

In the DEIS (page III-110), you point out that the "demand for the commercial fishery far exceeds supply" and that four "actions offer excellent means to potentially satisfy demand for salmonid fisheries derived from forest habitat production" 1) riparian management, 2) capital investment, 3) supplemental resource areas, and 4) timber harvest dispersion Then on III-112 you give a qualitative assessment of these four techniques to affect salmon habitat We could not find, however, a quantitative assessment of the benefits and costs associated with different combinations of the four fishery enhancement techniques As an example, we need to know the least cost way, in terms of timber production impact, of improving the fishery While this assessment in some ways is the flip side of the discussion above on the impact of basin constraints on timber harvest, it is complicated by the interaction of four possible ways to improve the fishery Information on this interaction will be an important ingredient in development of a State alternative

2 Mineral Exploration

The Siskiyou National Forest is a geologically diverse area with occurrence of gold, silver, nickel, chrome, cobalt, copper, manganese, molybdenum, mercury, coal, limestone, and other minerals The mining industry, partly though the use of Forest minerals, provides approximately 200 jobs and $2 9 million in payroll in the adjacent four county area While the demand for Forest minerals is highly variable, many are strategically important and maintaining access to them is of State concern In that light we view with apprehension the proposal in the preferred alternative that increases acreage on the forest under "moderate" mineral restriction from 196,000 acres to 353,000 We request further justification on a site-specific basis of why this reclassification is needed

In addition, the Forest should quantify the value of the mineral resource, to the extent feasible, and factor that value into the various alternatives These values can be very high on particular sites and should be considered in evaluating different alternatives

Finally, the Forest should better document the acres of prime mineral potential in each mineral restriction category A large number of acres in the "low" category of mineral restrictiveness may have little significance unless a substantial number of these acres have significant mineral potential

3 Enhancement of Tourism and Recreation Possibilities

Recreation plays an important role in the region's economy, especially in connection with use of the Forest's rivers Thousands of people each year raft the wild section of the Rogue and Illinois Rivers and journey up and down the lower Rogue in tour boats and rafts Protecting and enhancing those river-based recreation opportunities must be an important part of the Forest Plan We cannot tell whether the Forest has examined all investment possibilities for enhancing the river corridors and adjacent areas for recreation use As an example, could tourism be increased through an upgrading of the Grants Pass-Gold Beach road as suggested by the Division of Parks and Recreation?

Also, we did not find in the LRMP a schedule for reviewing the Wild Rogue Management Plan Given the importance of this plan to guiding use of the area, a regular review schedule should be established

4 Visual Quality

Maintenance of scenic quality in the Rogue River and Illinois River corridors should be a high priority in the Forest Plan Carefully protecting the view from the rivers is an important element in the management of these world-class attractions

On other parts of the Forest, we need more information about the costs and benefits of different visual catagories before judging their desirability

You have apparently reduced the acres in the "retention" and "partial retention" visual categories from the levels at which you currently operate We need to understand the benefits and costs to the preferred alternative of restoring all or part of these acres As an example, the Division of Parks and Recreation is especially interested in assuring that the area seen along the Bear Camp Road is allocated to retention

Discussions with your staff suggest that the "partial retention" visual allocation costs relatively little in foregone timber production Given the standards and guidelines of this allocation, however, OSFD believes that the cost may be greater than portrayed because of the masking effect by constraints such as those of harvest dispersion In addition, others worry that the small clearcut size allowed will raise logging costs resulting in the potential for below-cost sales We request that you provide us with more information on the factors controlling the costs of visual allocations

5 Improving Recreational Activity Valuation

Your analysis apparently reduced the value of recreational activities by 37 percent In addition, you assigned a 0 percent real price trend to these activites while applying a one percent real price trend for timber We believe that these assumptions can result in a serious undervaluation of the contribution recreation makes to the wealth derived from the Forest, and you should support these assumptions or change them

6 Estimating the Supply and Demand for Recreational Activities

The LRMP estimates that recreational use will increase overall at a rate of 5 percent annually It is not clear on what this growth rate is based If it is based on historical trends, they should be displayed by activity If it is based on projected population growth, the trend is too conservative We believe that you should base your projections of recreation use on historical use trends on the Forest and demographic trends from locations that provide a majority of your use where such data exists These trends should be activity specific and any population-based trends should be based on the latest state and federal estimates Your analysis should also highlight the different growth rates in demand by in-state and out-of state recreationists

7 Timber Harvest and Employment Impacts of the Preferred Alternative

The lumber and wood products industry provides a substantial portion of manufacturing employment in Coos, Curry, Jackson, and Josephine counties and a major share of these counties' budgets as pointed out by the State Economist, Economic Development Department, and the Intergovernmental Relations Division County road and school budgets depend heavily on their share of federal timber receipts A resource plan that maintains these economic benefits from timber production is a high priority for State involvement in planning for your Forest

Your DEIS compares the timber harvest and economic effects of the alternatives to the average for 1975-84 and to Alternative A (the "current situation") We feel that, in addition, the harvest for the last few years should serve as a benchmark

Comparing proposed future harvest to a past harvest reflecting occurrences for the past 10 years has some validity on a long term basis since these years include a number of industrial cycles The 1975-84 averages for timber harvest, timber sales and timber-based employment, however, do not represent what the surrounding counties have experienced over the last few years These counties recently have experienced a much higher timber-based employment level than the 10-year average as companies cut their accumulated timber-under-contract with the return of high stumpage prices

Your conclusion that the timber harvest under the preferred alternative will rise in comparison to the 10 year average may cause people to believe that the timber supply will expand under the new Forest Plan with associated economic growth and economic benefits In reality, though, the projected increase in jobs, personal income and payments to counties has already been realized through the higher harvest levels of the last few years In fact, the 1985-87 harvest level slightly exceeds the proposed maximum harvest level under the new Plan Thus, we actually face a possible contraction in timber-based employment under the proposed Plan in relation to the situation that now exists

In summary, we believe it is imperative that the Forest compare the proposed maximum timber harvest to the harvest of the last few years in addition to the 10 year average and alternative A

8 Estimating the Supply and Demand for Timber

The projected future timber supply from other ownerships presented in the DEIS is undocumented and seems inconsistent with projections made by the OSFD and Oregon State University It appears that the Forest may have presented an overly optimistic view of the potential future timber harvests on other public and private lands We request that you document your analysis and compare it to other published reports

E Fire Salvage

The recent catastrophic fires on your Forest have created the need, in your eyes, to proceed with a process separate from, and parallel to, the forest plan As we understand it, you plan to write Environmental Assessments on the less controversial fire-damaged areas and an Environmental Impact Statement on the Bald Mountain area Further, you have told us that about 230 MMBF of timber was damaged in the fires, that you could potentially salvage a maximum of 175 MMBF over the next few years, and that you will substitute salvage for green sales where possible

We support your general approach to this difficult problem with the following stipulations 1) the damaged timber should be quickly and thoroughly salvaged unless unacceptable environmental impacts will be created, and 2) you should ensure that the EIS covers all areas of controversy to avoid protracted legal delays

We have two further requests in the salvage of fire-damaged timber 1) that payment to the counties be based on gross receipts as done in ordinary timber sales rather than on net receipts as sometimes done in salvage sales, and 2) that green sales be mixed with salvage sales as needed to ensure timber offerings from all Districts on the Forest

We do not yet fully understand how the fires and their aftermath will affect your forest plan, including how they will affect the suitability of land for different allocations and the outputs that can be expected We request that you provide us with this information as soon as it becomes available

F Other Considerations

The Siskiyou National Forest is the fifth of the thirteen national forests in Oregon to publish a management plan When the aggregate effect of all of Oregon's national forest plans has been determined, the State of Oregon may need to modify its position and recommendations on individual plans Therefore, we urge you not to adopt any plan until the cumulative effects of all draft, revised draft, and supplemental national forest plans are known by the public

We urge you to continue managing the Siskiyou National Forest under the existing management plan until a new plan is in place or until amendments to the existing plan are developed and approved with participation by the State of Oregon New constraints should not be applied in the interim to existing plans in contemplation of the new plan without full public participation

Attached to this letter are reviews of the Siskiyou National Forest DEIS and LRMP completed by affected State agencies These reviews consider the economic, social, environmental, and legal aspects of the planning documents They contain substantive technical comments that should be considered an integral part of the State response

Thank you for the opportunity to respond to the Siskiyou National Forest DEIS and LRMP The State of Oregon stands ready to help you as you move forward to complete your Forest Plan For assistance on our comments about the overall planning process and procedures, feel free to contact Norm Johnson, Federal Forest Plans Coordinator For assistance on particular resource issues, please contact the appropriate individual on the enclosed list of agency contacts

Sincerely,

Neil Goldschmidt
Governor

STATE OF OREGON
Parks & Recreation Division

INTEROFFICE MEMO
378-6597

TO Norm Johnson
Federal Planning Coordinator

DATE December 2, 1987

FROM Don Eixenberger DE
Research Analyst

SUBJECT Review of the Siskiyou National Forest Plan

The U:S. Forest Service (U.S.F.S.) plays a major role in the provision of recreation in the State of Oregon. It is an indispensable element in maintaining a diverse quality of recreational opportunity which will gain even greater importance as the state's population grows and as out-of-state tourism plays an even more crucial role in the state's economy For example, federally administered lands provide over 30 percent of the state's campsites and picnic tables, 50 percent of its hiking and bridle trails and 60 percent of its ORV areas. Thus, while the plans assume that the U.S.F S provides 7 5 percent of outdoor recreation nationally, in Oregon, it is likely to be 3 to 4 times that amount if not more.

The U.S.F.S. is also the near sole provider of certain types of outdoor recreation in the state. Much river recreation and most snow activities and primitive and semi-primitive recreational opportunity are dependent on public lands managed by the U S.F S. Yet while demand for outdoor recreation opportunity of all types continues to grow, in many cases, the resources to provide those opportunities are shrinking. Forests such as the Siskiyou form a mosaic of irreplaceable recreational richness and diversity which will take on even greater importance for Oregon's future.

General Comments

There are two general issues which emerge from the Siskiyou Forest Plan that give cause for concern They are the

1. Economic valuation of recreation *
2. Projections of recreational demand.*

* These two issues are discussed in greater detail in the attachments.

Economic Valuation of Recreation

The economic values of recreational activities have been discounted by 37 percent.* In addition, recreational values have

*as stipulated by the 1985 R P A

been assigned a 0 percent per year real price trend throughout the life of the plan while a one percent per year real price trend for timber was used for harvest scheduling analyses.

We believe these adjustments to be unsupported and result in a serious undervaluation of the contribution recreation makes to Present Net Value (PNV).

These discounted values could have especially significant effects when specific areas of the forest are considered. PNV for recreation is presented forest wide, yet recreation is often feasible and/or concentrated in a specific area (e.g. an accessible roadless area, a river corridor). If an appropriate presentation of the economic benefits of recreation vis-a-vis other resource values is to be made, site or area specific analyses should be made. Otherwise there is a risk of trading of high recreation values for potentially marginal timber values.

Economic benefit analyses should be recast with recreational values appropriate to the Siskiyou Forest. They should also be formulated for specific areas of recreational use, especially where recreation and timber allocations may be in conflict. (One example of such a specific area would be the Rogue River corridor.)

Projections of Recreational Demand

The plan estimates recreational use to increase overall at a rate of .5% annually. It is not clear on what this growth rate is based. If it is based on historical trends in the forest those trends should be displayed. Such trends should also be estimated in terms of specific activities which have different growth rates. River based recreation, for example, is likely growing at a much faster rate than hunting. Such differential growth rates obviously require different planning strategies and allocation of resources.

If the .5% growth rate is based on population growth, it is likely too conservative. For example, from 1985 to 2005 the four county zone of primary influence for the Siskiyou are projected to have annual increases as follows: Coos - .5452, Curry- .5677, Jackson - .9750, Josephine - 1.0870. Western Oregon overall is currently projected to increase at .9305% per year *

* Preliminary Draft State Population, Employment and Income Forecasts (medium case), Oregon Department of Transportation, Policy and Planning (with the assistance of the Ad Hoc Forecasting Committee) October 8, 1987.

These projections are conservative. Using a .5% growth rate seriously risks mismanagement of recreation resources and development in meeting future need. If projected population growth is the basis for estimating future recreational use, it should also take into account the portion of forest recreationists from out-of-state. Use on the Siskiyou must be significantly influenced by visitors from California which has a higher projected growth rate than Oregon.

The importance of projections of recreation use not only affects planning, in estimating future R.V.D.s, it also affects the economic benefits of recreation, especially if focused on a specific recreational area. This has immense bearing if meaningful allocations are to be made between recreation and other resource.

We suggest the following:

1. Where possible, projections of recreational use should be activity specific.

2. Projections should take into account historical trends in the forest.

3 Where population projections are utilized, they be based on the current estimates of those state and federal agencies with responsibilities for formulating those estimates.

4. Recreational use projections should reflect the effects of those users from areas different population growth such as out-of-state.

Developed Recreation

Overall the plan does not address the placement of future recreational use of the forest. Over the next two decades, accelerated road construction is planned, especially in the existing roadless areas. This will provide greater access to the interior of the forest with the likelihood of changing current recreational use patterns and increasing recreational use overall. An analysis should be made to examine the flexibility of planned site development to address such potential changes.

The plan appears to adequately meet future need for developed camp sites in the forest, although this analyses should perhaps be recalculated using more exact demand projections as discussed previously. According to the 1983 State Comprehensive Outdoor Recreation Plan (SCORP), an oversupply of campsites in the four

county areas of the Siskiyou prevails through the year 2000. What is at issue is the placement of new campsites to utilize the full opportunity of the Siskiyou and respond to changing use patterns. For example, at present, the Galice District has only one developed site.

One identified shortfall indicated by the SCORP is in the number of picnic sites. SCORP shows the four county areas needing over 800 picnic tables by the year 2000. This implies a need for more day use and short term recreation facilities.

The SCORP also cites a need for over 500 more miles of hiking/walking trails and over 100 miles of bridle trails in the four county areas of the Siskiyou. The preferred alternative K plans for some 100 miles of new trail. Perhaps consultation should be made with other recreational land providers in the area to determine what portion of future demand is appropriate for the Siskiyou to meet. Type and placement of trail development is not apparent in the plan. For example, public comment described in the plan calls for greater emphases on day or loop type trails and interpretive trails.

Much recreation in the Siskiyou has and will continue to be oriented to back country wilderness use and to river activities. However, there appear to be many opportunities to accommodate a wider spectrum of the recreational user, the more casual and/or time limited recreationist who may be a local resident or a tourist whose destination lies elsewhere.

To meet the needs of such recreationists, we suggest more emphasis be placed on the following

1 development of accessible day use loop trails, perhaps less physically challenging to the average recreationist

2 development of interpretive trails and sites

A major area for this type development would be along the Grants Pass-Gold Beach Road. At present full utilization of this route by recreationists is limited by the condition of the Bear Camp section between Grants Pass and Agness Widening of this section would open up trans forest recreational and tourist travel between Grants Pass and Gold Beach. It would provide greater potential for the type of recreational development discussed previously.

In terms of developed recreation then, we suggest the following

1. Examine placement of developed campsites and trails for responsiveness to expanded recreational use of the forest.

2 Consider development of day use picnic sites, trails and interpretive sites to accommodate wider spectrum of recreational users.

3. Consider modifications to Bear Camp Road to allow greater recreational transit in the forest

Dispersed Recreation

We are supportive of the management direction calling for a broad range of recreational opportunities including the range of opportunities as delineated by the Recreational Opportunity Spectrum (ROS). Under the preferred alternative K, the supply of primitive and semi-primitive non-motorized outside of wilderness will fall short of demand by the second decade of the planning horizon. According to the plan, this unmet demand can perhaps be met by opportunities along various river corridors and wilderness areas of the Siskiyou or by opportunities in other neighboring forests. However, wilderness areas and river corridors of the Siskiyou will also gain in use through time. Wilderness use is expected to reach capacity by the fifth decade The plan does not examine what impacts additional use caused by the shrinkage of unroaded opportunities will have on these substituted areas. Quite likely limits of acceptable capacity may be reached during the life of the plan which will present serious management problems and recreational dislocations. Substitution of roadless areas in neighboring forests is also unfeasible; all the plans thus far issued in Oregon pose similar dramatic reductions of such areas. As the national forests in Oregon are the near sole suppliers of forested primitive and semi-primitive opportunities, the cumulative impact is a serious decline of recreational diversity throughout the state.* With these concerns in mind, we suggest the following

1. Within the forest, seek ways to provide a greater diversity of recreational opportunity For example, strategic location of wildlife MMR areas might also provide semi-primitive non-motorized opportunities.

2. Develop a region 6 wide plan describing potential cumulative impacts of forest planning on recreational diversity and

* See the enclosed attachment for a discussion of Recreational Diversity

prescribing how future demand as determined by the ROS will be met.

3. Schedule road building and harvesting in the Siskiyou in ways allowing future options to meet the goals of such a plan.

Scenic Rivers

We are supportive of management goals for the Rogue and Illinois Rivers, especially those goals for protection of the scenic viewsheds. In different ways, both rivers are unique recreational resources in Oregon. The Illinois provides a challenging rafting experience in pristine settings. The Rogue provides a diversity of opportunities unequalled elsewhere in the state and has very important economic values for both Gold Beach and Grants Pass. When appropriate the wild and scenic management plans for both the Illinois and the ROgue should be scheduled for review and/or change.

The Chetco River is on both state and federal inventories having potential for inclusion in the Wild and Scenic River system; the North Fork of the Smith is on the federal inventory. We urge that both rivers be managed to retain their eligibility until final designation can be decided.

Scenic Viewsheds

As mentioned, we support retention visual objectives for the Illinois and Rogue viewsheds as stipulated in alternative K. We also support retention visual objectives described for the Oregon Caves and Highway 199. Bear Camp under alternative K would receive only partial retention under option 1. As discussed previously, this travel route widened and properly managed has potential for becoming an important recreational tourist route. It should be considered for retention visual objectives.

In addition, we believe consideration should be given to visual protection along the Winchuck, Pistol, Elk, and Sixes Rivers.

The Bonneville Power Administration commissioned the Pacific Northwest Rivers Study with the purpose of identifying the importance of river resources so as to minimize conflicts with hydropower development and to conserve important river resources In the recreational segment of this study, the Winchuck, Pistol, Elk, and Sixes Rivers were all rated as "outstanding", primarily

for their anadromous recreational fishing values *

Visual values along major recreational trails in the forest should also be protected. While it seems apparent such values are protected along the Illinois and Upper Rogue River Trail, it is not evident that the Boundary Trail is. Other trails with historic value should also be considered for visual management.

* Recreational Values on Oregon Rivers, Oregon State Parks and Recreation, April, 1987

SISKIYOU.TXT

Recreational Issues in the 1986 Forest Plans
Oregon State Parks and Recreation Division

The Oregon Parks and Recreation Division has the responsibility for reviewing the National Forest Plans for recreational concerns in Oregon This charge stems from the focus of the Statewide Comprehensive Outdoor Recreation Plan and the state policy on outdoor recreation (ORS 390.010) In addition, the findings of the Governor's report on Oregonians Outdoors has provided direction to the division In the current round of planning three issues have risen which appear to be common to all the forest plans. This led to the creation of the following issue papers:

1 The Economic Value of Recreation

2 Recreational Demand and Forest Planning

3. Recreational Diversity

The accuracy of estimating future demand effects the economic benefits of recreation, the determination of value and demand are important to how forests should be managed for diversity and in ascertaining the trade off between recreation and other resource values on public lands

The underlying theme of these issue papers is to bring into discussion certain methodologies used by the U.S F S which are pertinent to recreation and which likely have bearing on the resource trade offs made in the forest planning process.

Issue Paper I

Economic Value of Recreation U S Forest Plans

The U S. Forest Service is now issuing its proposed forest management plans for review. Review of two forests have been completed· the Deschutes and the Wallowa-Whitman. It is now apparent that certain methodologies and assumptions regarding the economic contribution of recreation are being uniformly applied throughout the plans.

Choices among management alternatives in the plans are heavily influenced by what is called Present Net Value (PNV). The PNV for each alternative is the total monetary value of all resource products (such as timber and recreation) minus the costs of managing a planning area. Our anlysis concludes that the estimates of the contribution of outdoor recreation are seriously undervalued as a result of using inappropriate methodologies. This will have serious consequences for the preservation of a stable and diverse spectrum of outdoor recreational opportunity in Oregon.

A brief discussion of these methodologies follows

1. Through the 50 year "life" of the plans, recreation values are assumed to change at rates equal to inflation Other values, such as timber, are assigned real price increases in addition to inflation.

   This assumes that outdoor recreation is not subject to supply/demand ratios. Yet the resource base for most outdoor recreation is finite, limited For example, there are only so many miles of trout streams, so many slopes suitable for skiing, etc. Yet demand for these resources continues to grow It is a basic economic law that increasing demand for a limited supply creates a real increase in price

2. Each recreational activity has been given a value through *travel cost methodologies The current forest plans use such* activity values averaged across the northwest (Region 6) These values were then reduced by 37.5% Thus a day of trout fishing regionally valued at $75 is reduced to $14

   The use of regional values across all forests and the reduction of those values by 37 5% is unsupported. The quality and attractiveness of recreational activity varies widely from forest to forest The draw these forests have on tourism also varies greatly.*

*Attachment A contains a detailed discussion of these methodologies by Rebecca L. Johnson, Assistant Professor, Resource Economist, Department of Resource Recreation Management, Oregon State University, Corvallis, Oregon While these comments were made pertinent to the Deschutes National Forest, the same methodology is being used in all the forest plans

Issue Paper II

Recreational Demand and Forest Planning

Reliable estimation of demand for future recreation activities in the national forests is crucial for a variety of reasons. First, the current round of forest management plans recommend harvest levels and resource use decisions which will have serious impact on the supply of various types of recreational opportunities and settings. Should projections of recreation demand be underestimated, the potential for overuse and degradation of the remaining recreational resources will increase Second, resource allocations are in part determined by the economic benefits contributed by those resources The value of recreation is determined in part by estimates of recreational visitor days or demand. If this is not appropriately projected, an accurate estimate of recreational value cannot be determined and misallocation of resources may be made. Finally, if demand estimates are incorrect, proper development of management approaches and support facilities (campgrounds, picnic areas, trails, etc) is difficult

Thus far, the current round of forest plans measure current use in terms of developed recreation (e g campground use) and dispersed recreation (e g. hunting, hiking). Current recreational visitor days in these two areas are then projected to increase over the life of the plan at a rate equal to the projected state population growth

While questions have been raised as to the accuracy of various projections of state population growth, our contention is that population is not a reliable estimate of future recreational demand

To begin, the use of population projections assumes that forests are alike in their attractiveness and draw visitors solely from within Oregon The national forests in Oregon have diverse recreational offerings and attract recreationists from divergent locales. One only has to compare the offerings of the Deschutes National Forest, a major tourist attraction, with its rich diversity of recreation opoortunities and settings, to those of the Ochoco which principally attracts local resident hunting and fishing Growth in the Deschutes likely exceeds state population growth while that in the Ochoco may approach it or be less

As present and future recreational demand may differ from forest to forest, so does that demand differ by activity For example, it appears that winter sports are growing at a faster rate than hunting or camping. The demand for whitewater boating in Oregon is growing at a rate greater than population Yet the forest plans thus far group recreation use rates only as "dispersed" or "developed " Such "averaging" is like looking at the demand for ponderosa and lodge pole pine as a single entity, the greater demand and value of one activity or resource is masked by the lesser

Appropriately applied to a given forest, travel cost methodologies provide a sound valuation of recreational activity.

These methods, the 0 percent real growth rate assumption and the further 37.5 percent devaluation of recreation activity values seriously confound and underestimate the value of recreational resources and their contribution to Present Net Value. The result is that the formation of alternatives is distorted. Therefore, management decisions based on them risk serious misallocation.

The problem is further confounded when these values are applied uniformly from forest to forest. Some forests have exceptionally high quality recreational opportunities which draw many visitors from out-of-state. Recreational activities in these, properly estimated, will have high economic value

Other forests have lesser quality opportunities with less attraction for non-local visitation. Recreational activities there would likely have less economic value. Applying a uniform method not responsive to these differences risks trading high quality irreplaceable recreational opportunities for low value timber resources.

To address these concerns, the following should be done:

1. Develop some grounded measure of yearly real price increase for recreational resources

2. Reestablish appropriate travel cost and willingness to pay values for recreational activities.

3. Develop the measures in 1 and 2 specific to the recreational supply and demand in each forest.

4. Reformulate the alternatives based on the recreational values specific to each forest.

Issue Paper III

Recreational Diversity and the National Forests

The richness and variety of the Oregon landscape is often taken for granted In the space of a few hours drive a traveler can leave the hustle of a metropolitan area, visit the coast, climb the verdant Cascade mountains and descend to the high desert plateau. Much use is made of this landscape and its resources One of the most prominent is recreation.

The variety of natural resources translates into a diversity of recreational opportunity unparalleled elsewhere. Its spectrum ranges from that of a highly developed urban park with high social interaction to an isolated natural forest setting where a lack of man made developments and solitude are found. These resources and the diversity of recreational opportunity they represent, both existing and potentially, figure importantly in not only maintaining the quality of life Oregonians have come to expect, but also in meeting the expectations of visitors to the state.

U S. Forest Service (U S.F.S.) planning is particularly crucial where this diversity is concerned Overall, federally managed lands constitute 51% of the total state area Those under U S F.S management provide some of the most important recreational opportunities in the state, many of which are unobtainable elsewhere

Among the goals in National Forest management are "to maintain or increase the variety of recreational opportunities, to make those opportunities available to all segments of society, and to provide a range of quality recreation opportunities in an undeveloped forest environment " In recent years U S Forest Service planners have paid increasing attention paid to the motion that people not only seek out certain activities but also desire certain experiences in those physical and social settings appropriate for those experiences Out of this concept a planning system evolved called the Recreational Opportunity Spectrum (ROS)

Briefly stated, the ROS is a land management system currently comprising six classes designed to provide a particular array of activities, settings and experiences These classes are primitive, semi-primitive non-motorized, semi-primitive motorized, roaded natural, rural, and urban. Much U S F S planning now entails estimating demand for specific recreational opportunities defined along the ROS and appropriating land allocations to provide those opportunities *

In the current round of forest planning, a common feature seems apparent More and more forest land is being committed to timber production. Roadless areas of the forest are increasingly being

*A description of the ROS classes is contained in Attachment B

Using a generic measurement for recreation demand increases those problems described earlier; a rapidly growing activity such as cross country skiing would be managed with the same attention and energy as slower growing activities.

To address this issue, the following should be done*

1. Estimates of recreational demand should be based on the historical use and growth in each forest.

2 Within each forest, growth in demand should be activity specific.

scheduled for cutting. But "primitive" and "semi-primitive" recreational opportunities are dependent on these roadless areas These opportunities and settings are lost as lands are put into production and become "roaded natural" for recreational purposes. The problem is well documented in the plans. For instance as the Deschutes 1986 DEIS states:

> ". . . some aspects of the recreation opportunity spectrum, are becoming more difficult to retain
>
> For example, as remaining roadless areas are either designated as wilderness, or roaded and developed for other uses, there are fewer opportunities for the semi-primitive and primitive recreation experiences outside of wilderness areas. Related to this is the idea that as more and more roadless areas are either developed or designated as wilderness, future generations will have fewer options regarding how to best manage them to meet changing needs "

In the Wallowa-Whitman the plan aptly recognizes that in certain cases, opportunities will fall short of demand in 20 years. The plan assumes that those seeking primitive experiences can use the wilderness areas. Those seeking semi-primitive opportunities would use "roaded natural" areas or be replaced by other users

The trend appears obvious. As more roaded areas are converted to other uses, primitive and semi-primitive opportunities will diminish while demand for these opportunities continue to grow The shortfall in some cases will likely be critical within twenty years

Yet the Forest Service along with the BLM are virtually the sole providers of these opportunities They are important settings for such activities as hunting and fishing, whitewater boating, primitive camping and hiking, winter nordic touring, horseback riding and wildlife observation. Some are appropriate for management as semi-primitive motorized activities (e g trail bikes, snowmobiles) Above all, these areas provide those primitive and semi-primitive opportunities to people unable to utilize wilderness areas They also allow levels of management and use not allowed or restricted in wilderness areas. They provide in many areas the large scale vistas forests which both Oregonians and out-of-staters value. Indeed, the quality of both developed and dispersed recreational activities in the forest would be lessened by their diminishment.

To address this issue, the following should be done

1 Conduct a region wide analyses of the supply and demand for recreation on forest lands in terms of the ROS.

2 Reformulate the economic benefits of recreation so that trade offs between recreation and other resources might be more appropriately made (see issue paper #1 and #2 in this series).

3 Develop a plan describing how recreational diversity as determined by the ROS will be maintained to meet future demand

Attachment A

COMMENTS ON THE RECREATION VALUES FOR THE DESCHUTES NATIONAL FOREST PLAN

In summarizing the reationale for adjusting the initial values of the Resource Evaluation Group, the plan states that TCM values need to be adjusted to be comparable with marginal values of other forest outputs (p 193). The nationwide demand elasticity of 2 is used to show that if the Forest Service increases quantity of outdoor recreation in the nation by 7.5% (their current share of quantity), price should decrease by 37 5% There are several problems with this logic:

-- The prices which are being adjusted downward were estimated when the F S. land was a part of the total quantity. In fact, many of the studies which were used to generate the recreation values were done for F.S sites Studies that were done on non-F S sites would frequently have had F.S. sites as substitutes, and regional models would have included these F.S substitutes directly in the estimation. It is erroneous to assume that the F.S land is an addition to quantity which will lower these values which were estimated at a time when F S. land was already a part of the total quantity

-- A nationwide demand elasticity for outdoor recreation may be a poor representation of the elasticity for specific recreation activities Similarly, the percentage of the total quantity of outdoor recreation in the U S. that the F S land represents may be a poor representation of the percentage that is relevant in the Deschutes National Forest. If adjustments are to be done, an attempt should be made to use regional or Forest-related factors for adjustment whenever possible.

Other reasons stated for adjusting the values downward were related to problems with the TCM, including an assertion that TCM studies typically are done for higher quality sites, substitutes are not accounted for, and trip length is not accurately measured While any of these may be true for a particular study, several points should be made

-- Values for some activities were based on CVM studies instead of TCM studies. Adjusting these values downward for problems with the TCM is clearly erroneous.

-- Not all of the studies used single-site TCM models, and therefore an adjustment for substitutes may or may not be necessary There is clearly no single factor to adjust all of the values by to account for exclusion of substitutes - it would vary by site

-- Aside from the argument of whether or not TCM studies accurately measure trip length, there is no reason to believe that trip length is consistently over-estimated, and therefore no reason to adjust these values downward as a result of this contention

If the planners for the Deschutes National Forest are not satisfied with the activity values estimated by the Resource Evaluation Group, they should make an attempt to find recreation valuation studies which have been done in the Pacific Northwest region for specific activities which are provided on their Forest. It appears that planners want recreation values to be comparable to other forest resource values, and therefore the same effect should be made to find values which reflect as accurately as possible the conditions that exist on the Deschutes National Forest.

Attachment B

Recreation Opportunity Spectrum (ROS) - An array of recreational activities, settings, and experiences used as a basic framework in planning and managing the recreation resource This spectrum is divided into the following classes: primitive, semi-primitive non-motorized, semi-primitive motorized, roaded natural, rural, and urban.

Primitive - Area is characterized by essentially unmodified natural environment of a size or location that provides the opportunity for isolation from sights and sounds of people. The user has the opportunity to be a part of the natural environment, often with a high degree of challenge and risk in which to use a maximum degree of outdoor skills The area is managed to be as free as possible from evidence of people-induced restrictions and controls Only essential facilities for resource protection are used Motorized use within the area is normally not permitted.

Semi-primitive Non-motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people The user has the opportunity for a high degree of interaction with the natural environment. The area is managed in such a way that minimum on-site controls and restrictions may be present Facilities are primarily provided for the protection of resource values and safety of users Motorized use is not normally permitted.

Semi-primitive Motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people except for facilities essential for the use of motorized equipment. The area is managed in such a way that minimum on-site controls and restrictions may be present, but are subtle Facilities are primarily provided for the protection of resource values and safety of users Motorized use is permitted Limited primitive road construction to enhance recreation opportunity is permissible

Roaded Natural - Area is characterized by predominantly natural appearing environments with moderate evidences of the sights and sounds of people Such evidences usually harmonize with the natural environment Interaction between users may be low to moderate, but with evidence of other users prevalent Resource modification and utilization practices are evident, but harmonize with the natural environment Conventional motorized use is provided for in construction standards and design of facilities

Rural - Area is characterized by substantially modified natural environment Resource modification and utilization practices are to enhance specific recreation activities and to maintain vegetative cover and soil Sights and sounds of humans are readily evident, and the interaction between users is often moderate to high A considerable number of facilities are designed for use by a larger number of

people Facilities are often provided for special activities. *Moderate densities are provided far away from developed sites.* Facilities for intensified motorized use and parking are available.

Urban - Area is characterized by a substantially urbanized environment, although the background may have natural appearing elements. Renewable resource modification and utilization practices are to enhance specific recreation activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans, on-site, are predominant. Large numbers of users can be expected, both on-site and in nearby *areas. Facilities for highly intensified motor use and parking are* available with forms of mass transit often available to carry people throughout the site.

P O. Box 440
Grants Pass, OR 97526

Dear Mr McCormick.

Subject Siskiyou National Forest
Proposed Land and Resource Management
Plan. Draft Environmental Impact
Statement

These four following recommendations and "areas of concern" have been identified as not being adequately addressed in the draft EIS.

1. General Highway Impacts

The draft identifies U S. 199 (Redwood Highway) and Oregon 46 (Oregon Caves Highway) as major accesses to the Siskiyou National Forest area, but it does not evaluate or analyze the impacts the LRMP would have on them Varying amounts of logging and recreation traffic can affect advance construction and maintenance planning This is particularly crucial at access points A more specific explanation of the potential impacts would be very useful to us Also, please note that forest activities can impact U.S 101 (Oregon Coast Highway) and Oregon 242 (Powers Highway) to a slightly lesser degree Neither of these highways received attention in the draft.

2 Highway Vision Clearance

Thinning of the trees along highways is an important safety feature for the traveling public. Clear zones between the highway and the timber can benefit the motorist in two ways One is by reducing the potential for big game collisions. The other is the reduction of shading, which in turn reduces ice, snow, or frosty areas. The final document should include this information as a policy for timber harvesting and land management along state highways.

Form 734-1629

Mr Ron McCormick
November 18, 1987
Page 2

3 Protecting Material Sources

The Oregon Department of Transportation is interested in protecting aggregate and material sources The extraction and processing of aggregate is too often prohibited when conflicting uses are allowed to encroach on these resource sites. The draft document indicates a very good level of retention of these sites, but it lacks guidelines or language that protects them from the adjacent uses and zones or encroachment by them in the future

4 Maintaining Interagency Coordination

The final document should include some policy language that encourages coordination between the Forest Service and the Oregon Department of Transportation concerning maintenance or widening and improvements to state highways within the national forest boundaries It is important to our agency that these types of activities are allowed without extensive time delays for permitting and planning processes

Thank you for the opportunity to comment on the draft I hope the comments are constructive and useful for you. Please keep us informed about the status of your plan, and good luck

Cordially,

Ken Norton

STATE OF OREGON INTEROFFICE MEMO

December 21, 1987

TO Norm Johnson, Federal Plans Coordinator

FROM Pam Wiley, Planning and Management Analyst
Division of State Lands

SUBJECT DSL Comments on the Siskiyou National Forest LRMP and DEIS

Attached are final comments from the Division of State Lands on the Siskiyou National Forest Land and Resource Management Plan and Draft Environmental Impact Statement

As we have discussed, the national forest plans generally have little impact on the division or the natural resources under Land Board jurisdiction. Impacts are related primarily to potential conflicts between management objectives on national forest lands and adjacent state-owned lands, concerns over the plans' treatment of research natural and special interest areas identified through the State Natural Heritage Areas program, and opportunities presented by the plan for mutually-advantageous state/federal land tenure adjustments

All the attached comments relate to comment category #6 from the Governor's Executive Order, "comparison of the proposed plan to agency goals and state and federal legal requirements " We are also suggesting some new language to acknowledge and clarify the state's role in regulating activities in waterways in the forest

I have forwarded specific comments of the Natural Heritage Advisory Council (NHAC) previously under separate cover As I have stressed previously, comments on biological diversity and Research Natural Areas are made on behalf of the Natural Heritage Advisory Council and do not represent a formal Land Board position

Please let me know if you have any questions regarding these comments.

FINAL COMMENTS

DIVISION OF STATE LANDS
COMMENTS ON THE SISKIYOU NATIONAL FOREST LRMP AND DEIS

(NOTE This review responds to comment area #6 in the Governor's Executive Order, "comparison of the proposed plan to agency goals and state and federal legal requirements." The Division of State Lands has no comments regarding #1-5 and #7)

1 Impact of the plan on state-owned land and resource management - surface property interests/land tenure adjustments

The State Land Board owns some 132 000 acres of land in Western Oregon. This land is predominantly in forest use. Most of the acreage (96 000 acres) is consolidated in the Elliott State Forest, with the balance in isolated parcels scattered over the region

Day-to-day management of the Elliott State Forest is handled by the state Department of Forestry under contract with the Land Board While the balance of state-owned land is also certified to forestry use its isolated unconsolidated character makes it difficult to manage actively

A small portion of the state-owned land base in Western Oregon is located in, adjacent to or nearby land owned by the federal government. In the case of the Siskiyou National Forest, the state of Oregon has surface property interests in approximately 6,000 acres of such land Analysis of the management designations assigned to the federal lands, both under the current or "no change" alternative and the forest's "preferred alternative," shows the following state-owned parcels to be potentially affected by forest policies.

- Sec 16, T32S R13W - Curry County
  [Gov't. Lot 4 (39 92 acres) SW 1/4 (160 acres), SW 1/4 SE1/4 (40 acres), total acres 239.92]

  This parcel is bordered on the south and east sides by the Siskiyou National Forest (SNF) on the west side by BLM land and on the north by private land Current national forest management designations are general forest with a small designated wildlife habitat area to the south Under the preferred alternative, the bulk of surrounding lands remain in the general forest designation with part of the designated wildlife habitat area reclassified to "supplemental resource area "

The key management objective for supplemental resource areas, "maintenance of near natural conditions while permitting limited levels of activity such as through-road construction or habitat improvement projects " would not appear to present significant conflicts with management of state-owned lands. However, this is a highly mineralized area and the division may issue leases for mineral development on this parcel in the future Mineral development activity could affect wildlife habitat conditions

Sec 36, T35S R8W - Josephine County
[W1/2 (320 acres), W1/2 E1/2 (160 acres), Govt' Lots 1,2 3 and 4 (158 28 acres), total acres 638 28]

This parcel is bordered on the north west and south sides by the SNF and on the east by BLM Under the "no change" alternative, the majority of surrounding SNF lands are designated as general forest A small "partial retention visual area" abuts the western edge of the parcel and a small "designated wildlife area" is located near, but not adjacent. Under the preferred alternative, a small "special wildlife site" has been recommended directly adjacent to state-owned land The key management directive for this category "precludes programmed timber harvest activity but allows site-disturbing activities that are not contrary to the overall objective of preserving special wildlife habitats " Lack of access to this site makes it of limited value to the state for forestry purposes, making it a possible candidate for sale.

Sec 16, T35S R11W - Curry County
[E1/2 (320 acres) E1/2 W1/2 (160 acres) Gov't. Lots 1-4 (127.76 acres), total acres 607.76]

This parcel is bordered on all sides by national forest lands. Management area designations under the preferred alternative are substantially the same as under the "no change" alternative A new "special wildlife area" has been recommended just west of the parcel.

Although no prospecting permits have been issued on this parcel, minerals such as copper, asbestos, chromite and manganese are known to exist in the area The parcel has limited road access via National Forest Road 350 Prospecting permits may be issued in the future

- Sec 15, T35S R12W - Curry County
[Gov't Lot 2 (23 37 acres)]

This small parcel along the Rogue River near Agness is actually located outside the national forest, but within the Rogue River wild and scenic river boundaries

- Sec 16, T38SS R8W - Josephine County
[S 1/2 (320 acres), S 1/2 N 1/2 (160 acres), Gov't Lots 1-4 (173 54 acres), total acres 653 54]

This parcel is bordered on the west by the SNF and on all other sides by BLM land A small parcel of privately-owned land abuts the eastern boundary of the state-owned land This parcel includes a portion of Eight Dollar Mountain. It is located in a highly mineralized area, with considerable potential for future prospecting permits Several communication sites on the parcel are already under lease to the division

The "preferred alternative" identifies a large new "botanical area" bordering the western edge of the parcel The key management direction for botanical areas indicates that such sites "would not have programmed timber harvest, and other ground-disturbing or vegetation-manipulating activities may be significantly restricted " To the extent that these restrictions limit road development in the area, they may limit the division's ability to issue mineral prospecting leases in the area Conversely, to the extent that the rare plant resources found in this area extend into state-owned land, the division's management objectives on adjacent lands may be inconsistent with the forest's

- Sec 16, T41S R12W - Curry County
[Gov't Lots 13, 14, 15, 17, 18, 19, 20 (149 acres)]

This parcel is bordered on the north and east sides by the SNF, on the west by private land and on the south by the state of California The "preferred alternative" designates surrounding lands as "general forestry " Nearby there is a supplemental resource designation (along the East Fork of the Winchuck River) These lands may be located either within adjacent or close to the Winchuck Recreation Complex

To summarize, some 2,300 acres, or approximately 40 percent of the Land Board's holdings in this area may be affected by plan policies and management objectives

The Common School lands identified above are geographically isolated from other state-owned forest lands, making them difficult to manage efficiently The State Land Board has for many years pursued a policy of consolidating its scattered and isolated landholdings to allow better management of the land in keeping with its constitutional charge to "manage lands under its jurisdiction with the object of obtaining the greatest benefit for the people of this state, consistent with the conservation of this resource under sound techniques of land management." (Section 5, Article VIII, Oregon Constitution.)

To date most of the Board's consolidation activities have taken place in Eastern Oregon, where some 600,000 acres of state-owned rangeland are located Since 1969, Land Board consolidation efforts have involved the exchange of over one million acres of state and federal land The exchange program has resulted in more efficient management and more productive rangelands, and has greatly enhanced the Board's ability to meet its constitutional charge

Although consolidation efforts of the Land Board have thus far focused primarily on Eastern Oregon rangelands, opportunities exist to improve management of forest lands as well There remains in state ownership some 125,000 acres of scattered and isolated parcels of Common School lands. Most of this land -- some 80,000 acres -- is rangeland, but a significant 45,000 acres is forest land Of the forest land, an undetermined amount of acreage is located in, adjacent or in close proximity to U S. Forest Service land.

The national forest planning process offers a unique opportunity for the Land Board, acting through the Division of State Lands, to continue and expand its efforts to consolidate its land holdings Legislation enacted in the 1987-89 session of the Oregon Legislative Assembly authorizes the division to "dispose of isolated sections and fragments of sections of state lands which are not suitable for management according to longe-range policies of the State Land Board." Acting on behalf of the Land Board, the Division of State Lands is identifying scattered and isolated parcels in and near the forests for possible sale or exchange under this law.

Land ownership adjustment has been recognized by the Siskiyou National Forest as a tool which can be used to support its management goals The plan sets forth a general land adjustment policy in Section 9 of "Forest-wide Standards and Guidelines" (LRMP, IV-43 - IV-44) According to the stated policy, all non-federal lands inside the National Forest boundary, and a limited amount of National Forest land, shall be placed in one of five land ownership planning groups Group 1 - Congressional direction· Group 2 - Special management areas; Group 3 - General forest (private), Group 4a - Private land not to be acquired, Group 4b - National Forest land available for exchange, and Group 5 - Lands needing further study. The plan further states that proposals emphasizing consolidation of land ownership should be favored

(Figure IV-3 depicts proposed land adjustments on the forest Only one parcel of state-owned lands is identified as potentially suitable for a tenure adjustment. This parcel, Section 16, T35S, R11W in Curry County, is completely surrounded by the forest It is identified as "needing further study ")

More specifically, the same section of the plan identifies non-federal land in the Winchuck Recreation composite as an acquisition priority, but recommends against fee simple acquisition of non-federal lands in the Agness townsite area and within the Wild and Scenic River system

The State Land Board owns approximately 200 acres adjacent to the forest in the Winchuck area. The land, bordered on the north and east sides by the forest, is comprised of Government Lots 13, 14, 15, 17, 18, 19 and 20 in Section 16, Township 41S, Range 12W The Board also owns a parcel of land within the bounardies of Rogue River Wild and Scenic River Area The Board may be interested in selling this land to private parties. Alternatively the Board may wish to pursue land sale or exchange with the Forest Service involving these and numerous other parcels in or adjacent to the Siskiyou and other national forests.

Recommendation

The Division of State Lands suggests the following language change in the plan to facilitate a mutually beneficial exchange program between the Forest Service and the State Land Board.

On page IV-43 amend paragraph 1 of Section 9-3 to read

All non-federal lands inside the Siskiyou National Forest boundaries a limited amount of non-federal lands lying immediately adjacent to the Siskiyou National Forest boundaries and a limited amount of National Forest land shall be placed in one of the following land ownership planning groups (See Figure IV-3 Land Adjustment Map)

On Page IV-44, replace existing group 5 with a new "Group 5 - State-Owned Lands" as follows

Group 5 - State-Owned Lands

Definition - This group includes Common School lands owned by the State of Oregon and potentially available for sale or exchange to public and private entities It includes lands adjacent to special management areas within the forest which could be adversely affected by sales to private parties or state-permitted leasing activities. Adjustments will be made only after careful review and consultation with the Oregon Division of State Lands, the Oregon Department of Forestry, and the Oregon Department of Fish and Wildlife

Renumber existing "Group 5" to "Group 6"

Finally, amend the last paragraph on page IV-44 to read

The above guidelines should be followed, however, it may be necessary to deviate from this ranking to take advantage of opportunities as they arise Proposals that emphasize protection of special forest resource values and consolidation with land ownership should be found.

2 Comparison of the proposed plan to state legal requirements

The division administers the state of Oregon's Removal-Fill Law which regulates the removing and filling of materials from and in the waters of the state Filling or removal within the beds and banks of non-navigable waterways in forest lands for forest management practices in accordance with the Oregon Forest Practices Act is exempt from regulation under the Removal-Fill Law However, removing and filling for activities not related to forest management practices in accordance with the Forest Practices Act such as road or bridge construction construction of in-stream structures to improve fish habitat and mining are subject to the requirements of the law

Chapter III of the Draft Environmental Impact Statement "Affected Environment," discusses mineral policy and planning problem #9, "How should mineral resources of the Forest be developed in coordination with management of other resources?" This section notes that "[M]ining will most probably be from placer deposits located along and near various stream courses being known to contain gold-bearing gravels" and that "sand and gravel production for road-related purposes represents the highest continuing mineral use in the Forest."

Recommendation

Either of those uses could require a state removal/fill permit or state lease (for activities on navigable waters, described earlier). To clarify this, we suggest adding the following language on p. III-32, under the list of Forest Service policies regarding minerals management

Advise persons interested in aggregate or other hardrock mineral mining operations of the possible need to obtain state or local permits, e g , mining within streams may require a lease or permit from the Oregon Division of State Lands.

3 Research Natural Areas

(Comments forwarded under separate cover)

0551z
Page 7 of 7

COMMENTS ON THE SISKIYOU NATIONAL FOREST PLAN

Forest Plan comments from the Oregon Natural Heritage Data Base usually are restricted to addressing the following issues. the protection of threatened, endangered and sensitive species, the designation of special interest areas, unique habitats and Research Natural Areas; and the more general topic of conserving natural diversity on National Forests.

Our general overview of the Siskiyou National Forest Plan is that it appears to address all of the issues that are appropriate for the region. The Plan is exceptional in its identification of potential botanical areas and it recognizes the importance of the Forest in terms of rare plant endemism and protection in southwestern Oregon. Research Natural Areas that have been proposed by the area ecologist are slated for designation by the preferred alternative. One of the principal negative aspects of the preferred alternative is the almost complete entry into all remaining roadless areas on the Forest. This could have grave consequences for the conservation of natural diversity on the landscape level in southwest Oregon.

More specific comments, organized by subject matter, are detailed below.

Threatened, Endangered and Sensitive Species

Most of the concern for rare species on the Siskiyou National Forest is centered on plants, although there are several rare animal species that also occur there. The discussion that follows deals almost entirely with the plant species on the Siskyou but is also applicable to rare animal species that are found there.

The Siskiyou National Forest contains the highest concentration of sensitive and rare plant species of any National Forest in Oregon. It has been estimated that over 9 % of the plant species of concern in the state occur on the Siskiyou and several species are found nowhere else. The DEIS of the Forest Plan does an exceptional job at defining the Forest's responsibility with regards to sensitive plant species protection (Appendix F) and the information presented on individual species in Table F-2 allows for careful review of the proposed Botanical Areas in the various Forest Plan alternatives. Appendix F also describes the potential Research Natural Areas and Botanical Areas.

The management of sensitive plant resources is appropriately indexed to the Forest Service Manual (section 2670) and management practices are included in the Standards and Guidelines in Appendix F of the DEIS The only clarification that we would like to see in the Forest-wide Guidelines is in reference to the second

paragraph in that section on page F-7. It is stated that any proposed projects that involve significant ground disturbance and have the potential to alter habitat of plant species will be evaluated to determine if sensitive species are present. First, the term "evaluated" should be better defined as to include on the ground inventories and referral to professional botanists for management advice. Secondly, it should be noted that very little information on rare or sensitive plant species habitat has been collected to date which makes it difficult to predict the affects of management activities on habitat.

Because of the high number of rare plant species known from the Siskiyou National Forest it is important for the Forest to also conduct searches in areas that are non-project areas, especially areas that are already in a protective status such as wilderness. The importance of these basic botanical inventories is often overlooked in the overall management of rare species. However, the collection of such information can at times lead to the de-listing of some species when they are found to be in a significantly larger numbers than once believed and occurring in areas that are secure. Therefore we recommend that the Siskiyou National Forest indicate in the Forest Plan that they intend to begin inventorying all potential habitat for sensitive species in order to further the knowledge of such species.

Research Natural Areas
The Siskiyou Forest Plan preferred alternative proposes the designation of all of the sites that have been recommended by the area ecologist for the Forest. The Oregon Natural Heritage Data Base supports this position and would like the Forest to also include some language in the sections that concern Research Natural Areas (RNAs). Because it is believed that the existing and proposed RNAs are not sufficient representation of the natural diversity of this region it will be necessary in the future to identify and designate additional RNAs to protect areas. The Siskiyou National Forest should make note of this in the Forest Plan by indicating that additional RNAs will undoubtedly be recommended and that the Forest is committed to protecting these recommended areas until they can be fully evaluated by the area ecologist, the RNA Committee, and other knowledgable scientists

Special Interest Areas-Botanical
The 22 special interest areas that are proposed in the Siskiyou National Forest Plan include all of the known concentrations of rare plants on the Forest. Detailed investigations of boundaries of the proposed areas has not been conducted but because of the long standing commitment to protection of rare plants by the Forest it is believed that boundaries are for the most part adequate to protect the habitats intended. The selection of the areas that are recommended for protection in the preferred alternative is outlined in the DEIS and is open for comment. All of the potential botanical areas are ranked according to their importance.

The preferred alternative lists 8 sites for designation as botanical areas: Bear Camp Areas 1 & 2, Bigelow Lakes, $8 Mountain, Days Gulch, Iron Mountain and Iron Mountain addition. These areas all had a priority rank of 6 or higher.

Other areas that were not included in the preferred alternative that also had a priority of 6 or higher included Bigelow Lakes addition, Grayback Mountain, Oregon Mountain, Rough and Ready Flat, Snow Camp and Snow Camp addition, Sourgame, Vulcan, and Waldo Ridge. There was no justification presented for not including these sites for designation and the Oregon Natural Heritage Data Base recommends that they must be designated as botanical areas along with the areas proposed in the preferred alternative in order to follow the criteria established in the Forest Plan.

The Siskiyou National Forest has done an outstanding job identifying potential botanical areas that form the backbone for the protection of rare species across the Forest. It is critical that the Forest recommend all of the above mentioned areas and reconsider the areas that have not been recommended. In many cases there are few if any resource conflicts for these important areas, therefore the designation can only act to further the important work the Forest has begun for rare plants within its boundaries. The total acreage of proposed botanical areas is quite insignificant compared to the acreage of the general forest. If all of the proposed botanical areas were designated this would result in an increase of only 28,000 acres above the acreage recommended (7300 ac.) in the preferred alternative. This is a relatively small area that would lead to greatly enhanced protection of botanical resources on the Siskiyou National Forest.

Conservation of Natural Diversity
The rather unwieldy topic of planning for natural diversity on the Siskiyou National Forest is not addressed in a comprehensive fashion in the Forest Plan. Indications of how the preferred alternative will plan for natural diversity protection can be found in the description of the future condition of the forest (pg. IV-2, Forest Plan). The almost total conversion of the general forestlands to managed forests with an average rotation age of 100 years does little to provide for landscape level conservation of natural diversity. As large portions of watersheds are dedicated to timber production there is an increasing potential for loss of self-sustaining old growth forests.

The Siskiyou National Forest needs to look at conservation of natural diversity from the viewpoint of the entire Forest, including the timber producing lands, riparian zones, wilderness areas and botanical/research natural areas. Areas that are already protected will continue to function as important sites for the maintenance of natural processes and ecosystem functions. Managed lands adjacent to these natural areas will derive some of the benefits from the natural areas. But the vast majority of the

Forest may be too far from protected areas to actually utilize the areas as habitat The best solution to this dilemma lies in the roadless areas on the Forest.

Currently there are a number of roadless areas on the Forest that are quite well dispersed over the landscape. These areas are destined to be roaded during the term of the Forest Plan if the preferred alternative is chosen. Protection of the currently unroaded areas on the Forest is the most ready solution for the protection of natural diversity across the Forest. By maintaining a large system of roadless areas, of sufficient size to contain functioning ecosystems, ecosystem processes will be allowed to continue unimpeded. These roadless areas have innumerable benefits for wildlife resources, watershed, and recreation as well, thus their importance is truly multi-faceted.

The protection of roadless areas coupled with designation of long term rotation areas within commercial timberlands would help meet the needs of natural diversity on the Siskiyou National Forest for the foreseeable future. In the unlikely event that long term research shows that too much roadless land was set aside, then these areas can at a later date be allocated for other purposes.

This concludes the Oregon Natural Heritage Data Base's comments on the Siskiyou National Forest.

155 Cottage Street, N E
Salem, OR 97310

Dear Norm

Enclosed are our final comments to the Siskiyou National Forest DEIS and Proposed Land and Resource Management Plan Even though we have areas of concern with the proposed plan, we found the descriptions of the affected environment, environmental consequences, standards and guidelines, and monitoring to be thorough and specific

Two areas of concern are the projected decrease in big game populations in all alternatives and the management prescriptions to maintain water temperatures in all but one planning basin, even though those water temperatures are high

Sincerely,

Randy Fisher
Director

GENERAL COMMENTS

Oregon Department of Fish and Wildlife wishes to compliment the Siskiyou National Forest on an informative and well written DEIS and proposed plan. The proposed plan and DEIS are by far the bulkiest documents the Department has reviewed to date The increased size of this document is justified by the data, maps, and disclosures found on those pages. The small scale MA and resource distribution maps were especially helpful.

Habitats for fish and nongame wildlife appear to be well addressed in the forest-wide and management area standards and guidelines. Standards for big game habitat effectiveness are adequate on a site specific basis. However, optimum Forest-wide distribution of thermal cover and forage for deer and elk is not provided in any alternative, resulting in predicted declines in deer and elk populations in every alternative.

ODFW comments and recommendations are meant to be constructive and lead to positive results. The comments are based on ODFW understanding of the National Forest Management Act (NFMA), the Clean Water Act, Executive Order 11990, and key provisions of the Wildlife Policy of the State of Oregon

OREGON DEPARTMENT FISH AND WILDLIFE CONCERNS AND RECOMMENDATIONS

In March of 1985, the Department developed fish and wildlife habitat protection criteria for forested lands in Oregon These criteria establish the minimum standards, that ODFW feels are necessary to meet the Wildlife Policy for the State of Oregon (ORS 496 012) The focus of our recommendations is on the implementation of *ODFW fish and wildlife habitat* protection criteria.

ODFW finds any departure alternative objectionable because wildlife resources would be diminished by accelerated damage to habitat. Departure timber harvesting risks even flow of recreational and commercial opportunities associated with fish and wildlife

We feel our position on the amounts and condition of needed habitats is realistic and reasonable. The Department offers recommendations for the following

1 Big game habitat
2 Access and Travel Management
2 Riparian and instream habitat
4 Dead and down woody habitats
5. Land allocations

1 Big Game Habitat

ODFW is concerned with the projected decrease in big game numbers on the Forest

The following recommendations are designed to meet the Department's concern for the projected decrease in big game numbers These recommendations should also help meet ODFW benchmark of 32,400 black-tail deer and 6,700 Roosevelt elk. The recommendations would require additions to and modification of proposed standards and guidelines for Management Area 13 (Partial Retention) and Management Area 14 (General Forest) The objective of these recommendations is to increase *production and distribution of quality forage and* cover to meet the above deer and elk benchmarks. The desired level of forage production includes the quality of the forage, the length of time a site produces forage, and the distribution of the forage sites. Production of quality forage is determined by the forage species *that are seeded and the application of* appropriate fertilizers.

The Forest needs to seed and fertilize 1,000 acres of clear-cuts per year for big game forage. These clear-cuts need to be well distributed and adjacent to optimum thermal cover sites The Forest needs to reduce the number of trees planted on these sites to prolong the production of quality forage.

In-addition to the forage enhancement projects, the Forest needs to *establish permanent forage* sites, five to ten acres in size, at a rate of 100 acres per year for this planning period These permanent forage sites need to be managed under the MA 9 prescription for meadows Desirable forage species need to be planted on these sites as well as periodic applications of *fertilizer The effectiveness of this practice* will need to be evaluated at the end of this planning period

Three types of cover need to be addressed in the standards Hiding cover, thermal cover, and optimum thermal cover The definitions for these terms are found in "Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington" (Brown 1985)

Hiding and thermal cover are lost on clear-cut areas and thermal cover is reduced on thinned units The Forest has stated that Brown (1985) would be used as a guideline for management of cover Cover management objectives need to be tied directly to the management of forage sites The relationship of forage areas to hiding cover and thermal cover needs to meet the guidelines stated in Brown (1985) Cover areas adjacent to

forage areas should not be thinned until hiding cover for elk has developed in the forage area. All forage sites should have a visual barrier between the opening and adjacent roads. The visual barrier would reduce disturbance to deer and elk from vehicle use of the roads.

While thinned stands provide some forage and hiding cover, thermal cover is reduced by the thinning operation. When planning thinning projects, the Forest needs to ensure that adequate thermal cover is nearby.

When evaluating habitat effectiveness (HE), the Forest must use the Wisdom model adopted by Forest Service, BLM, and ODFW in February 1986. An HE of .5 would be an acceptable goal for the Siskiyou. Subbasins not to exceed 6,000 acres need to be used as permanent HE monitoring areas.

2. Road Management

The Department has documented that forest roading, as it affects habitat and hunting, was the number one concern of big game hunters attending elk workshops in 1984. Deer hunter surveys by the Coos Bay District of the Bureau of Land Management showed the majority of hunters support some road closures. Excess roading diminishes habitat effectiveness and fair chase, causes concern for poaching and increases stream siltation. The projected road density in the proposed plan averages over three miles of open road per square mile, reducing the effectiveness of elk habitat by nearly 70 percent.

The Department generally recommends open road densities not exceed 1 1/2 miles per square mile for resources protection. Demand for hunting quality may require a seasonal reduction in open roads in certain areas. The Forest states there are now 2.33 miles of open road per square mile of roaded Forest, and about 1 1/2 miles per square mile are arterials and collectors. The Department recommends that all existing and planned local roads be serious candidates for year-round physical closure with emphasis to protect forage areas. Seasonal "area closures" are one way of responding to demand for hunting quality.

The Department recommends that the Forest develop specific criteria, in cooperation with ODFW, for road and seasonal area closures separate from the ORV plan.

The Department recommends that all new road systems developed in the now existing roadless areas, be close to public vehicle use. This direction would help meet habitat objectives for big game and would not allow a use pattern to develop.

3. Riparian and Instream Habitat

The Department has a concern for the high summer water temperatures found in portions of all nine major river systems of the Forest. These temperatures exceed optimum conditions for salmonids and, in some cases, exceed the lethal limits for salmonids. The Forest was very explicit in stating the management direction for Riparian Prescriptions "B" and "C", (DEIS II-47); "Prescription B is designed to manage vegetation to maintain water temperatures, while Prescription C manages vegetation to reduce water temperature and improve watershed conditions."

High water temperatures on the Forest are the result of natural conditions and/or removal of stream cover. The Forest has identified 18 of the 19 Planning Basins as having high water temperatures that reduce smolt habitat capability potentials by 5 to 20 percent.

The Department recommends that the Forest identify which streams and rivers have high water temperatures due to removal of cover and which are from natural conditions. The Department recommends Riparian Prescription C, Minimum Level Prescription, or the Supplemental Resource (MA 7) prescription be applied to all streams and rivers that have or would have high water temperatures resulting from the removal of stream cover. For streams that have high water temperatures due to natural conditions the forest should look for enhancement opportunities to reduce the temperatures.

The Forest has stated "the more important instream cover components for survival of Forest salmonids include pool depth and instream wood debris." ODFW agrees with this statement.

Woody debris has been identified as a limiting factor in all 19 Planning Basins. While Riparian Prescription B would provide for some large woody debris in the streams, Riparian Prescription C, Minimum Level Prescription, and Supplemental Resource (MA 7) prescription would give greater benefits over time in both water temperature and long-term input of natural large organic debris to stream and river systems.

The Forest has defined "large woody debris" as material over 12 inches in diameter and 15 feet long. Brown (1985) states that large woody debris should be over 18 inches in diameter. The Department recommends minimum standard for large woody debris be 18 inch DBH with an average DBH of 22 inches.

Pool depth has also been identified as a limiting factor in all 19 Planning Basins. The Forest has an on-going program to increase the depth of pools on selected streams. ODFW recommends that the Forest continue this practice in all of the Planning Basins.

The Forest needs to better discuss the possible consequences of development in roadless areas that would potentially increase sediment levels in associated streams.

The Forest has direction to use structural fish habitat improvements to mitigate impacts from forest management activities. The effectiveness of the proposed improvements to mitigate losses in natural habitat conditions has not been fully demonstrated. Protection of existing natural habitat conditions is the desired approach. When the Forest does elect to use habitat improvement projects, the project needs to be evaluated to determine if project objectives have been met.

4. Dead and Down Woody Habitats

The Department has a concern for the management of dead and down woody habitats. The Forest has established an excellent standard for amount of wildlife trees (snags and green trees) and down woody material to be

planned for in timber sale areas However, the Forest has not displayed standards or methods for protecting these dead and down woody habitats Activities such as firewood cutting and the use of prescribed fire for site preparation can reduce dead and down woody habitats to unacceptable levels

The Department recommends that the Forest identify, by inclusion or reference, the methods that would be used to protect dead and down woody habitats. The protection methods should be stated in the Forest-wide Standards and Guidelines section of the Land and Resource Management Plan.

5 Land Allocations

The Department offers the following comments and recommendations for land allocations

MA 3 Research Natural Areas

limited inventories for sensitive plant species and habitat conditions. Areas with unique habitats or sensitive plant species, which are a reflection of unique habitats, may also provide unique habitats for nongame wildlife More research and inventories will be needed to determine the relationship of these unique habitats to nongame wildlife

For the above reasons, the Department recommends retention of all proposed botanical areas for this planning period. After needed research and inventories have been completed and evaluated an informed decision can be made as to the long term allocation for these areas.

MA 5 Unique Interest Areas

The standards for this MA meet some of the Department protection criteria All unique interest areas should be allocated to MA 5

MA 6 Custodial (Roadless)

The Department has a concern for the development of roadless areas The primary concern is the development and use of new road systems Vehicle use of roads reduces habitat effectiveness for deer and elk and diminishes the quality of the hunting experience for those preferring to hunt in areas of solitude.

The Department would support the proposed MA 6 allocation in Alternative K if ODFW recommendations under Big Game Habitat and Access and Travel Management are implemented Otherwise, the Department recommends retention, for this planning period, of all roadless acreages not assigned a more restrictive MA. This recommendations is made on the premise that all wildlife habitat protection standards would be met in all developed areas.

MA 7 Supplemental Resources

The Department supports the MA 7 allocations in Alternative "K". The Department strongly recommends the addition of all riparian areas in the Elk/Sixes Planning Basin to MA 7 The high fish values of the Elk/Sixes Planning Basin warrant the protection level of the Supplemental Resources prescription. The MA 7 allocation would also help protect the Department's Elk River hatchery. This planning basin is the Forest's third largest producer of Fall Chinook, second largest producer of coho and searun cutthroat, and the sixth largest producer of adult steelhead This planning basin also rates second for high erosion hazard due to regeneration and third for high erosion hazard due to roads.

MA 8 Designated Wildlife Habitat

The Department supports the allocation in Alternative "K" This management prescription along with more restrictive MA's at recommended levels, should maintain a satisfactory level of old growth ecosystems.

MA 9 Special Wildlife Site

All special wildlife sites (24,004 acres) not allocated to more restrictive MA's, should be allocated to MA 9 The limited amount of meadows in this management strategy represent the only permanent big game forage sites offered in the alternatives.

DEIS CHAPTER II

P.II-47 Management Area 11 Riparian

The Forest has stated that high water temperatures are a problem on most Forest streams. The high temperatures are a common problem in Southwest Oregon due to natural conditions and past cover removal

The Forest states "management activities shall have, as a major emphasis, the protection and enhancement of salmonid fish spawning, rearing, and migration habitat." In order to protect and enhance salmonid habitat, the Forest needs to compensate for the high water temperatures. Riparian Prescription C and the Supplemental Resources (MA 7) Prescription, are the only strategies stringent enough to accomplish this objective The Forest needs to adopt Riparian Prescription C for the MA 11 allocations or allocate the riparian areas to MA 7

P.II-130 (First paragraph) - Bald eagle and osprey habitat will be provided on 52,000 acres along rivers and streams Table I-67, Appendix I, however, indicates 34,165 acres of this habitat will be in wilderness Are these wilderness acres along the Wild and Scenic Rogue and Illinois Rivers? (DEIS II-130-1) Caution should be used when placing importance on the Illinois, Chetco, and other coastal streams which do not have anadromous fish runs at the time of bald eagle and osprey nesting There is an active osprey nest on the Illinois

P.II-153 Table II-15

This table shows that in Alternative "K", 26,888 acres are assigned to MA 11 as Minimum Level Prescription. On page II-259, Table II-64 indicates zero acres under the Minimum Level Prescription Judging from the rest of the document, Table II-15 is correct.

P II-207 Table II-33 Wildlife and Fish Habitat Structural Improvements

The Forest states that 95 percent of the 1910 structural projects are nest structures which are replaced inconjunction with meadow improvements.

The Forest objective for meadow improvements is desirable and supported by ODFW ODFW recommends the establishment of strict standards to protect existing nest sites from management techniques used to improve or enlarge the meadows. Protecting existing nest sites will maintain structural habitat diversity within the project area

P II-256 The Forest predicts a decrease in deer populations in all alternatives due to reduced forage and diminished habitat capability A decrease in population is not desirable and does not meet ODFW benchmarks The Forest needs to include standards in MA's 13 and 14 to increase big game habitat capability See ODFW recommendations for Big Game Habitat

AFFECTED ENVIRONMENT

P III-11 Why is the total botanical acreage in Figure III-3 less than the total acreage of the three identified areas? (DEIS III-3-1)

P III-13 The Regional Guide has established a refined definition of old growth for various plant communities. Did the Siskiyou use the refined definitions when mapping old growth? (DEIS III-13-1)

P III-33 How many miles of new road construction has occurred since 1984? (DEIS III-33-1)

P III-36 What is the direction for managing the 135 (plus) gates on the Forest? (DEIS III-36-1)

P III-70 As a result of the 1987 fires, this section needs to be updated The effects of the 1987 wildfires on MMR habitat distributions also needs to be addressed.

P III-81 Old Growth

"Old growth is well distributed throughout the Forest (Figure III-12)." Figure III-12 does not distinguish between mature stands (101 years plus) and old growth stands The Forest needs to make this distinction in the final EIS.

P III-85 Table III-17

The table displays 15,000 acres of riparian habitat as having had some timber harvesting. Page III-59 states "There are approximately 175,500 acres of riparian areas on the Forest..." What is the condition of the 160,500 acres of riparian area that is not displayed in Table III-17? (DEIS III-85-1).

(Last paragraph) Explain the statement "Old growth cannot be sustained forever."

P III-90 What is the relationship between the "Timber Types and acres listed in Table III-19 and the "Successional Stages" and acres listed in Table III-17 on page III-84? (DEIS III-90-1)

P III-99 The Department commends the Siskiyou on an excellent discussion of fish resources on the Forest How current are the stream surveys referred to in the discussion and what type of data were collected in the survey? (DEIS III-99-1)

P.III-113 The Forest has not discussed peregrine falcons that are on the Siskiyou. Endangered peregrine falcons have been observed in the Wild and Scenic Rogue River Corridor. Suspected eyrie locations are already protected by Wilderness and Wild River designations, but the plan should mention the presence of these birds along with the importance of maintaining the cliff habitats in the Forest.

P.III-117 The first paragraph states that natural and created openings provide the bulk of the feeding habitat for deer and elk These areas also provide the forage base for domestic sheep on the Forest How much forage is allocated to domestic sheep grazing and what is the season of use? (DEIS III-117-1)

(Second paragraph, fourth sentence) This sentence should read "The Oregon Department of Fish and Wildlife (ODFW 1985) has proposed a cover/forage ratio of 80 20 for the Siskiyou National Forest Thomas (1979) warned that habitat effectiveness rating methodology "is poorly related to, and therefore not a good predictor of, densities of big game animals." In 1980, the Department announced a benchmark of 32,400 (over winter) black-tailed deer for the Siskiyou National Forest. The Forest states the April population estimate for black-tailed deer is 26,000 animals. What year was the estimate made? (DEIS III-117-2)

Clarify the statement about the difference in population estimates from procedures used by the Forest and ODFW

Explain how the 90 year rotation would produce habitat capable of supporting 25-35,000 deer? (DEIS III-117-3) The proposed direction would not allow for the maintenance of a quality forage base What is the potential density of deer and elk on suitable timber lands managed for optimum big game habitat? (DEIS III-117-4)

P.III-119 Elk

The Forest should mention elk winter range capability and the ODFW elk population benchmark of 6,700 animals for the Siskiyou National Forest.

Habitat Types Not Represented by Indicator Species

The Forest has not selected an indicator species for riparian habitats, meadows, or unique wildlife habitat areas. ODFW recognizes the difficulty in selecting an appropriate indicator species for riparian habitats. Department and Forest biologists should discuss the need for an indicator species for riparian habitat. For meadow habitat the Department recommends deer and elk be identified as indicator species of this forage producing habitat.

The Forest states that scattered unique wildlife habitat areas amount to 25,004 acres. Most of these areas were identified because unique habitat was provided for a given species or a group of species, these species need to be the indicators for their specific habitats.

P.III-120 (Last paragraph) "Many citizens feel.. that the Forest, as a whole, must provide habitat to maintain viable populations of all native and desirable non-native wildlife species " The Forest should point out that the maintenance of viable populations is a legal requirement under NFMA.

P III-122 Nonconsumptive Use

The 1980 and 1985 National Hunting and Fishing and Other Wildlife Related Uses Surveys by the USFWS are available and will provide more recent data on nonconsumptive use The 1985 report will be out in November, and the Oregon data will follow sometime this winter. In 1985, 109.7 million adults spent $14 billion on nonconsumptive wildlife activities nationwide

Nonconsumptive wildlife use in the Rogue and Illinois Wild and Scenic Rivers is an important part of the boating and hiking experiences for thousands of users. This use, coupled with nonconsumptive uses elsewhere on the forest, will more than likely exceed hunter use figures for the forest.

Optimum Habitat Mix

The Forest needs to state that the optimum habitat mix is from the Forest point of view

P III-124 Meadow Habitat

ODFW endorses the management standard of protecting existing meadows and reclaiming those meadows that have been encroached upon by trees.

ENVIRONMENTAL CONSEQUENCES

P IV-4 Table IV-I

Fish habitat improvement (A) would have a direct effect on fish as well as an indirect effect

P IV-29 (Fifth paragraph) The purpose of road closures includes reduced harassment to big game and meeting demand for an increased quality hunting experience Roads that are closed for these purposes need to be closed to all motorized vehicles

P IV-151 (Fifth paragraph). The mitigation measures identified in ODFW recommendations would apply to all alternatives These measures should maintain or increase big game numbers on the Forest The Forest states ". as yet unidentified projects would increase total habitat capability .. " The Forest needs to describe the types of projects that would increase habitat capability for deer and elk

(Sixth paragraph) Acceptance of lower hunter success rates or increasing interest in nongame species are not mitigation

(Eight paragraph) The standards and guidelines do not provide the necessary mitigation for

a. Reduced forage and thermal cover capacities for big game on commercial forest land
b A planned 57 percent reduction in old-growth habitat
c. Reduced recreational hunting opportunity
d. A 40 percent or greater reduction in cavity dwelling species habitat in timber emphasis areas

P.IV-231 (Seventh paragraph) Add to end of 2nd sentence " . because necessary habitat standards are not integrated into management direction for MA 13 and 14 "

After 3rd sentence add "The goals are achievable with specific management direction to invest in forage enhancement projects, manage cover and access, and cooperate in restocking elk in their historical range."

PROPOSED PLAN

P I-2 (Fourth paragraph). The Forest needs to add the proposed "Roosevelt elk plan" and "black-tail deer plan" to the list of documents that will provide guidance for management activities These plans should be referred to as "habitat" plans. The elk plan needs to address a stocking program

P.IV-9 (Second paragraph) " .the Plan will manage 507,000 acres of selected suitable lands " Table III-I indicates 529,000 acres of selected suitable lands Which figure is correct? (PP IV-9-1)

STANDARDS AND GUIDELINES

Proposed modifications to the standards and guidelines (Forest-wide and Management Area) would apply to any alternative the Forest selects for implementation

P IV-13 The Department compliments the Siskiyou Forest for the definition of terms used in this section.

P IV-20 4-1 Fish, Wildlife, and Sensitive Plants

"Fish and wildlife habitat resources... shall be managed in cooperation with State Fish and Wildlife agencies " With this statement in mind ODFW recommends the next sentence be rewritten to read ". . habitat shall be managed to provide for optimum levels of all species of fish and wildlife and prevent the serious depletion of any indigenous species, (ORS 496.012)

P IV-23 Maintenance of Potential Nesting Habitat

ODFW compliments the Siskiyou Forest for proposing the standard for protecting potential bald eagle nesting habitat.

P IV-24 4-6

The Department should be a cooperator in the spotted owl surveys and selection of SOHA's.

P IV-25 4-11 Deer and Elk Habitat

The first paragraph states Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington (Brown 1985) should be used for management of deer and elk habitat Below this paragraph the Forest states "where practicable ", this line needs to be eliminated as the Forest has set direction in the first paragraph

"Blocks of hiding cover are most effective when at least 600 feet wide," needs to be rewritten to read "Blocks of hiding and thermal cover should be 600 to 1,200 feet wide."

The Forest needs to add the definition of optimum thermal cover (Brown 1985) to the glossary.

(Next to last paragraph) Change to read "Maintain thermal cover within 200 feet ..."

(Bottom of page) The term "where practicable," needs to be eliminated.

P IV-26 (Top of page) Change to read "Roosevelt elk herds should be reestablished ."

P IV-27 4-12 Salmonid Habitat

The proposed habitat quality standards and guidelines are very good and have the endorsement of ODFW See recommendation section for riparian and instream habitat.

4-13 Wildlife Tree Habitat

How would snags and down wood be protected from site preparation activities? (PP IV-27-2)

P.IV-29 5-1 Range

ODFW recommends the following addition to the standards

"Allotment plans shall contain utilization standards designed to maintain healthy riparian plant communities for the protection of soils, water quality, fish, and wildlife habitats."

6-1 Timber Management

Timber Management practices influence the potential value of big game habitat. Proposed reforestation stocking levels limit the production of forage and the proposed thinning levels limit the availability of thermal cover Proper management of these two activities can be beneficial to big game (See recommendations)

P.IV-33 6-9

(First paragraph, second sentence) Strike ". to the extent practicable" at the end of the sentence.

Who is responsible for management decisions to exceed the 60 acre limit for created opening? (PP IV-33-1)

P IV-34 6-10

Harvested areas are considered created openings until crop trees are at acceptable stocking levels and exceed 4 1/2 feet in height. Created openings are separated by areas not classed as created openings A concern to the Department is the amount of hiding and thermal cover that could be lost in areas where created openings are placed next to areas with 4 1/2 foot trees This concern may not materialize if the proposed standards and guidelines for 4-11, deer and elk habitat, are followed How would the Forest manage cover adjacent to created opening? (PP IV-34-1)

P IV-36 7 1 Soil and Water

The Forest has done an excellent job of establishing measurable standards that can be monitored and evaluated

P IV-37 7-5

(Second sentence). Change to read " cut and fill slopes shall be protected from erosion."

7-8 Terrestrial Ecosystems

How does this standard differ from the standards listed in 4-13? (PP IV-37-1)

P IV-38 7-10 Riparian Ecosystem

What is the Forest using as a standard for determining vegetative diversity? (PP IV-38-1)

P.IV-39 (Top of page) Generally large woody debris that are keyed into stream banks serve a useful purpose and are not the result of a management activity The Forest needs to make this distinction in the standard

P IV-52 (Top of page) "Road closures should be implemented .."

MANAGEMENT AREA PRESCRIPTIONS

P IV-68 The Department is concerned with maintaining the angling opportunities in the Wild and Scenic Rogue River The present cutoff date of September 15th for permit requirement, allows the *general public to enjoy angling this portion of the river in the* fall months ODFW would not favor any changes in river regulations which would adversely affect angling opportunities for the general public. This concern also applies to management of MA 10 areas

P IV-85 MA 8 Table IV-7

Research by Kim Mellen, OSU graduate student, indicates a need to manage 495 acres as a core area for pileated woodpeckers The Forest is encouraged to incorporate the findings into the final plan

P IV-91 MA 9-5 Wildlife and Fish

Strike "where practicable" at end of first sentence

MA 9-7 Meadows and Meadow Buffers

The Forest proposes to restore meadows to their former size using 1940 aerial photos as a reference point. ODFW recommends that the 1940 photos be used as a reference to locate the meadows, but that site specific surveys be used to determine the former size of the meadows.

The MA 11 Desired Future Condition

Desired future condition under ODFW proposal would be old growth riparian habitat

"The vegetation in the riparian zone will be a mixture of hardwoods, with some conifers scattered throughout." How much *conifer would be scattered throughout the riparian zone?* (PP IV-98-1)

P IV-99 MA 11-4 Wildlife

In the hardwood riparian habitats thermal cover would be for summer use only

P IV-106 MA 13 Partial Retention Visual

See recommendation section.

P IV-108 MA 14 General Forest

See recommendation section

P.V-10 The proposed monitoring for wildlife appears to be adequate. The size of monitoring areas for deer and elk should not exceed 6,000 acres and preferably would not exceed fourth order watersheds.

P B-7 Table B-4 Wildlife Capital Investments

The Forest should describe the reasons for and types of structural improvement projects for wildlife proposed in the plan. For example, what is the target species for approximately 180 nest structures to be constructed each year

The Forest needs to clarify some of the projects and units of *measure, (i e , Meadow Survey and Habitat Plan* has a unit of measure of structures)

In Table B-4, five of 14 projects relate to sensitive plant surveys Why are these charged as "Wildlife Capital Improvement?" (PP B-7-21) If there were funds allocated for wildlife forage enhancement of final harvest units, would they show in Table B-4? (PP B-7-3)

The Department will be particularly interested in the results of the Forest's planned surveys for bald eagle, black bear, beaver, wolverine, and big-eared bats (Table B-4).

P D-9 There is confusion as to whether the Forest will monitor habitats, populations, or both, for pileated woodpeckers and pine martens ODFW wishes to work with the Forest to select appropriate monitoring methods

P.D-13 C7 Black-tail Deer and Roosevelt Elk

An important component of deer and elk habitat evaluation is forage quality The Forest needs to include forage quality in the monitoring plan.

P D-14 (Paragraph A). The Forest needs to use "A Model to Evaluate Elk Habitat in Western Oregon," 1986 (Wisdom) when evaluating habitat effectiveness

D-16 Fish/Water Monitoring

The Forest needs to monitor the effectiveness of structural habitat improvements to meet planned production objectives

ODFW Fish and Wildlife Habitat Protection Criteria for Forested Lands
(March 1985, Rev. 9/86)
(copy attached)

The following is the ODFW interpretation of how well the Siskiyou Draft Forest Plan complies eith the ODFW criteria.

Old Growth

1 The Forest exceeds criteria

2 Cannot determine if existing populations of old growth dependent species will be maintained

3 Old-growth stands are dedicated, meets criteria.

4 Woodcutting is prohibited in dedicated old growth stands Cannot determine status of roads.

Snags

1 Inventory is included, meets criteria.

2 One-hundred percent criteria in old growth will be met.

3 Sixty percent criteria is met

4 Protection methods not discussed, compliance cannot be determined.

5 Monitoring is planned but is subject to funding, meets criteria

Dead and Down Woody Material

1 Standards are based on published guidelines, meets criteria

2 Protection strategies are not addressed

3 Monitoring is planned but is subject to funding, meets criteria

Hardwoods and Minor Conifer Species

1. Ten percent stocking criteria is met.

2 Criteria for at least 25 percent of stand to be left to natural succession appears to be met

3. Cannot determine amount of acres of hardwoods in migratory winter ranges.

Riparian

1. Acreage and condition are discussed

2. Evaluation parameters are met.

3 Management is to improve habitat values in Elk Sixes drainage and maintain conditions in other drainages on the Forest.

4 Habitat restoration is planned. However, shading level on Class III streams would be 75 percent.

5 Length of time for restoration is not addressed, compliance with criteria cannot be determined.

6 Monitoring is planned but is subject to funding, meets criteria.

Meadows, Freshwater Wetlands, Natural Openings

1. Criteria for effectiveness is exceeded

2&3 Criteria for peripheral vegetation is exceeded

4. Management activities are designed to protect natural value of habitats, meets criteria.

5. Current acreage is protected, some lost acreage will be restored, meets criteria

Cliffs, Rimrock, Caves, and Talus

1. Sites are allocated to MA 9 Special Wildlife Site. Protection is based on published guidelines, meets criteria.

Aquatic Habitats

1 Maintenance, enhancement, and restoration are described, meets criteria.

2 Changes by decade are displayed, meets criteria.

3. Baseline is current level, meets criteria.

4. Monitoring is planned but is subject to funding, meets criteria

In-Stream Habitat

1 Maintenance, enhancement, and restoration are planned, meets criteria

Water Quality

1 Desired temperature and sediment levels may not be met.

2 Monitoring is planned but is subject to funding, meets criteria

Water Quantity

1. Cannot determine the overall effects on water yield and timing of discharge.

2. Monitoring is planned but is subject to funding, meets criteria

Elk and Deer Habitat

1 N/A

2 ODFW benchmarks would not be met

3 a N/A
b. Recordkeeping would be based on TRI compartments Standard is met if TRI compartment does not exceed 6,000 acres

4. Road density is described, amount of cover and forage are not addressed. Forage quality is not addressed

5. a1. N/A
a2 Distribution of cover is not addressed.
b1. N/A
b2. Optimal thermal cover with 21" dbh trees is not addressed

6 Special habitat areas are addressed and most are allocated to MA 9

7 Descriptions of current condition and changes by alternative are included Maximum potential population is not described

8 Monitoring is planned but is subject to funding, meets criteria

9 Habitat management procedures in Brown (1985) would be followed Forest needs to use Wisdom HE model to evaluate effectiveness.

Species of Special Concern

Bald Eagle 1&2. Recovery plan would be followed.

3. Monitoring is planned but is subject to funding

Peregrine Falcon 1 Inventory is not displayed.

2. Existing sites are not addressed
3. Monitoring is not addressed

Northern Spotted Owl Defer to SEIS comments.

Western Snowy Plover, Western Spotted Frog N/A

Road Management

1 No specific plan to meet criteria is included.

2 Impacts of roading are addressed.

3 Standard of new road construction is to avoid important wildlife habitat

4. Management of existing roads to minimize conflicts needs to be planned

Grazing

1 The grazing program on the forest is small but is not addressed or described in the affected environment chapter

2. Allocation of forage is not described

Salem, Oregon 97310

Dear Norm

After evaluating the Draft Environmental Impact Statement (DEIS), and proposed Land and Resource Management Plan (LRMP), for the Siskiyou National Forest, the Oregon Economic Development Department (OEDD) would like to offer a few comments on the proposed plan

OEDD's primary goal is to provide jobs for Oregonians Through promotion of Oregon's business climate, OEDD provides leadership, assistance, and incentives to businesses in order to retain Oregon's industrial base, recruit new business to the state, and create a climate that welcomes expansion and start-up businesses in Oregon

In this light, our comments on the Siskiyou National forest Plan and DEIS are intended as an analysis of the Forest Service LRMP's impacts on Oregon's industrial base in Southern Oregon Specifically, OEDD will look at the impacts on Forest Products, Fisheries, Mining, Tourism, and Recreation

FOREST PRODUCTS INDUSTRY

The forest products industry in Southern Oregon produces numerous products including saw timber, plywood, shakes, pulp, arrows and others Lumber and wood products manufacturing, including logging, is the largest employer in Coos, Curry, Jackson, and Josephine counties The level of employment ranges from about 13 percent to 25 percent per county

Neil Goldschmidt
Governor

The goals of the Siskiyou National Forest as outlined at Page IV-1 of LRMP include providing a sustained yield of resource outputs at a level that will maintain a healthy Forest ecosystem and that will promote the stability of local communities and provide for regional and national economic needs

The Forest's preferred alternative represents the Siskiyou's effort to balance economic and other environmental considerations to meet the above goals

Members of the forest products industry desire an alternative that is based upon maintaining the historic supply of timber from the Forest One industry group, Southern Oregon Timber Industries Association (SOTIA) has proposed such an alternative Although we have not investigated every aspect of the proposal, there are some elements that we support and suggest that the Forest Service investigate and consider in the final EIS.

The SOTIA proposal suggests that the Forest Service may increase the Allowable Sales Quantity (ASQ) for the Forest by using shorter rotations on some existing plantations for one rotation Industry suggest that this could increase the ASQ between 10 and 14 mmbf.

The SOTIA proposal also suggests that the Forest Service could increase the ASQ by 1 mmbf by using a more accurate conversion factor and by incorporating the effects of fertilization into their forecast

If these aspects of the SOTIA proposals do result in the increases in ASQ that they suggest, that would bring the ASQ up from 150 mmbf annually, to a number that will provide stability to the local communities

The Forest Service Analysis suggests that the trade-off for alternatives within ASQ above 150 mmbf is a decrease in water quality and significantly less old growth Shorter rotations on existing timber stands will have little, if any, impact on old growth The Forest should seriously consider this proposal, however we would not support it if impacts on water quality are too severe

After listening to the public comments during the State meetings in Grants Pass and Gold Beach, the local industry people also voiced concern over the amount and timing of fire salvage that will be available off the forest Although this issue is not addressed in the planning documents, the impacts on community stability of the region would be detrimental if the fire damaged areas on the Siskiyou and surrounding forests were not open for salvage in a timely manner.

It is likely that the amounts of salvage timber will be very high, particularly on the neighboring forest in California

Also voiced in our public meetings, however, was a concern over the impacts of fire salvage operations on the sediment levels of the area's streams and rivers It is important that sediment impacts be at a level to insure maintenance of the high quality water and fish habitat

FISHERIES INDUSTRY

The Siskiyou National Forest is one of the premiere forests in the country in production of commercial and recreation fisheries There are only two dams on the Rogue System and the rest of the rivers run free. The fish species on the Forest include: chinook salmon, coho salmon, steelhead, trout, sturgeon, and shad.

Demand for anadramous sport fishing is very high and will increase as the tourism and retirement communities in Coos and Curry Counties grow Maintenance of and improving the current supply of fish is crucial to meeting this demand and supporting this growing economic base in the community.

Coos and Curry counties rank high in terms of total commercial fish landings in the state, accounting for as much as one-third of the total commercial fish and seafood landings in the state The fishing industry supports jobs in food processing second only to wood products in the region.

The Forest Service's proposed plan addresses the importance of the fishery industry in a very thorough manner The proposed alternative in terms of riparian management, capital investment, habitat maintenance and improvement, timber harvest dispersion and the proposed supplemental resource areas goes a long way toward satisfying the excess demand for fisheries off the Forest.

A particular concern to the industry raised at the state public meeting is the level of sediment in the streams and rivers that is the result of road building, and fire salvage logging Again, OEDD would like to stress the importance of maintaining or lowering the sediment levels in the streams and rivers to support a growing commercial and sport fishing industry

MINING INDUSTRY

The Mining Industry provides approximately 200 jobs and $2 9 million in payroll for Coos, Curry, Jackson and Josephine counties The Siskiyou National Forest is a geologically diverse area with occurrence of gold, silver, nickel, chrome, cobalt, copper, manganese, molybdenum, mercury, coal, limestone, and other minerals In 1984 there were 8,100 mining claims recorded with BLM, most are for placer gold In 1984 there were 125 approved operating plans, two coal leases and 27 active mineral permits. Demand for minerals found within the Forest is highly variable, dependant on markets and cost of production Currently, gold, sand, and gravel are in high demand Strategic minerals, nickel, cobalt, chrome and manganese,

are currently not in high demand However, for those minerals where other primary sources are in politically volatile areas, demand could surge at any time

The mining industry expressed it's concern with the Forest Service plan during the State meetings in Grants Pass Their primary concern is with accessibility to the Forest Citizens have a statutory right to prospect, locate, and develop minerals on lands open to such entry Of the 268,000 acres of land withdrawn from mineral entry, 34,400 acres have high mineral potential, 83,200 acres have medium potential and 151,200 acres have low potential

The Forest preferred alternative proposes an increase in the acreage on the Forest that is under "moderate" mineral restriction, from 196,000 acres to 353,000. A "moderate" restriction for mineral access applies to lands that are managed so that other forest resource considerations require special mitigative measures An example of this, and the primary reason for the increase, is mineral development in visually sensitive areas, along travel routes or rivers. In this case, the mining operation may occur with special lease stipulations or plan of operation considerations Using visual corridors as an example, this means that a mineral exploration or extraction operation would have to be shielded by trees or terrain so as to not significantly alter the landscape from the road or river

Another industry concern relates specifically to the number of botanical research areas, and the existence of threatened and/or endangered plant species in some of the mineralized areas Specifically, the rare soil types that are indicative of nickel laterite deposits also support these rare threatened and endangered plant species.

The Forest has indicated in the LRMP that the conflicts that could arise in these situations will be resolved on a case-by-case basis, according to Forest Standards and Guidelines OEDD suggests that in interpretation of these Standards and Guidelines, a fair evaluation of the community's economic needs be considered in their final determinations

TOURISM AND RECREATION INDUSTRIES

The Siskiyou National Forest and the Southern Oregon Coast serve as the access point for hundreds of thousands of tourists annually into Oregon The sport fishing and other river recreation, primitive and developed recreation on the forest all serve as a crucial draw to tourists from around the world Maintenance of high quality viewshed from the rivers, roads, and trails is imperative for the development of a fast growing industry in Southern Oregon. Also, maintenance of high quality sport fishing enhances and increases the demand for the regional tourism facilities

The Forest's preferred alternative manages fewer acres for visual protection than the current direction The reduced visual assignments were made in areas that do not have heavy recreation use and will be allocated to general timber production. The emphasis in the Forest proposal is on visual quality along major travelways and rivers OEDD is cautiously supportive of the Forests proposal on this issue We will be spending more time in the near future on the Forest to further evaluate this aspect of the Forest proposal.

CONCLUSION

The Siskiyou National Forest has done an outstanding job in development of a lengthy but thorough plan and DEIS. OEDD is very supportive of the general direction of the Forest preferred alternative However, we would suggest that the Forest consider the impacts of shorter rotations, fertilization and a different conversion factor on the ASQ in the final EIS Also, we would like to emphasize the importance of water quality and sediment levels to Southern Oregon tourism and fishing industries The impact of the scenic values of the Siskiyou National Forest can not be over emphasized Visual quality contributes substantially to the area's potential as a tourism and retirement destination

If you have any questions on these comments, or if OEDD can help you in any other way, please do not hesitate to call.

Sincerely,

David H. Lohma

David H Lohman
Deputy Director

STATE OF OREGON INTEROFFICE MEMO

TO Norm Johnson DATE November 18, 1987

FROM William H Young, Director, Water Resources Department

SUBJECT Comments on the Siskiyou National Forest Resource Management Plan and Draft Environmental Impact Statement

In response to the Governor's Executive Order for forest plans, the Water Resources Department submits the following comments for the Siskiyou National Forest.

The Water Resources Department believes the Siskiyou National Forest has done a good job at identifying the water resource issues for both soil, water and riparian zones in the forest. Both the DEIS and LRMP have identified provisions to protect and improve watersheds and riparian areas. In order to evalaute the success of those provisions, we suggest initiation of an annual review to verify the adequacy of the specific measures.

The comments that follow offer suggestions as to methods or ways to improve the alternatives and the planning documents

1. The forest should incorporate Water Resources Commission basin program provisions for the two basins (South Coast and Rogue River) that encompass the forest boundary Basin programs provide direction for managing water resources important to the state. Adequate streamflow during the low flow months and effects on downstream water use are major concerns. Currently, summer flows are inadequate in those two basins. Hopefully, forest practices will complement state efforts to maintain or improve existing flows and not create additional water resource problems.

The Forest Service identifies the Rogue River report as a reference for water resources information In addition, we suggest the Forest Service use the basin programs when dealing with the varied forest management activities on the forest. Forest activities should be compared to basin goals and water policy Finally, we recommend the Forest Service inform hydro electric applicants the Water Resources Department administrative rules for hydroelectric development (OAR 690-74 Standards for consideration of Applications involving hydroelectric projects) must be fulfilled.

2 The alternatives allowing higher timber harvests could be improved by using the more restrictive timber harvest methods to protect watersheds Even though the alternatives provide some protection by using forest standards, minimum management requirements, and resource

management areas, we suggest, whenever possible, the highest protection procedures be imposed on timber harvest methods to protect the watersheds.

3. The Forest Service should develop better maps that portray the data by planning units. Planning units should also be put on all maps Currently, the maps only identify the alternatives. Better mapping could assist the readers to judge the adequacy of the forest service alternatives and protection by designated management areas.

We appreciate the opportunity to review and comment on the Siskiyou National Forest. If you have any questions, please contact Jake Szramek at 378-3671.

REVIEW OF THE SISKIYOU NATIONAL FOREST DEIS & LRMP

The Water Resources Department has organized its comments into 5 sections

I. Comparison of DEIS & LRMP with Agency Policies and Programs
II. Suggestions for Improving Alternatives
III. Comments on Management Area Goals and Strategies
IV Assessment of Forest Service Alternative
V. Specific Comments

I. Comparison of DEIS & LRMP with Agency Policies and Programs

The Siskiyou National Forest is encompassed by parts of two of Oregon's drainage basins the South Coast Basin and the Rogue River Basin. The Water Resources Department has produced basin reports for each basin The Rogue River Basin Study is dated January 1985, and the South Coast Basin report is dated January 1963. In addition, the Water Resources Commission has adopted basin programs which identify the water resources policies for each river basin Those basin programs contain findings and policies as to how the water resources will be managed in those basins. The Rogue River Basin Program was most recently revised in June 19, 1984, and the South Coast in September 25, 1984 In both basins, water use is important for a variety of beneficial uses including. municipal, industrial, domestic, irrigation, fish life, mining, recreation, wildlife and power development

For example, water uses in general are limited in certain parts of each basin. In the South Coast Basin, the surface and ground water resources are classified for domestic, livestock, municipal, industrial, fire control, irrigation, agricultural use, mining, power development, recreation, wildlife and fish life uses (For additional information, see South Coast Basin Program pages 5-12). In the Illinois River Basin, the waters are classified for domestic, livestock, municipal, irrigation, agricultural use, power development, industrial, mining, recreation, wildlife and fish life uses including propagation (for additional information see Rogue River Basin pages 34-44 and pages 45-49). For a more concise review of program findings and policies for the Rogue River portion of the Siskiyou National Forest, the Middle Rogue (pages 26-44) and the Lower Rogue Basin (pages 45-49). Those finding should be incorporated into the forest plan

A hydroelectric discussion is included in the mineral resources section The Water Resources Department believes the hydropower resources should be discussed in the water resources section. As part of that section, the hydropower rules and basin program hydro restrictions need to be addressed

For example, in the Illinois River, the basin program specifies that in order to protect, maintain and perpetuate anadromous fish habitat and propagation, several stream reaches are not to be diverted, interrupted or appropriated for hydropower development purposes The Forest Service discussion on forest hydro restrictions should be consistent with state standards as found in the basin program (See pages 38 -41 and pages 47-49 in Rogue Basin Program for a complete list of the restricted streams).

The Forest Service identifies 20 planning basins as represented in Figure III-8, page III-61 DEIS The basins should correspond to the drainage basins as identified by the Water Resources Department. We would suggest that those planning units be highlighted on all the mapping in the planning documents. The Forest Service cited the Rogue River Study as an excellent description for the water resources conditions within the entire Rogue River Basin However, there was no mention of any reports for the South Coast basin. The South Coast basin report, although dated, contains information on water supplies. The Freshwater Resources of the Oregon Coast, 1974, is also an applicable reference Finally, one additional report that could be of assistance to the Forest Service as it pertains to water resources is the Josephine County Water Resources Management Work Program June 1987. The county is actively involved in the management of the water resources within the county.

The Forest Service describes the water resources on the forest in section III-57 Soil and Water The 20 planning basins are identified and tables provided to list forest lands that affect municipal watersheds and beneficial uses on the forest (Figure III-8 and Table III-11 &.12). The Forest Service does an adequate job in the portrayal of the forest's water resources, but in many instances, the basin programs were not used to characterize water management in the 20 planning units. For example, Bear Creek on the Winchuck River has 1 cfs reserved for municipal use. In addition, the basin program for the South Coast identifies reservoir sites that need to be protected· SF Coquille River at Eden Ridge site 430 (Forest Service does mention this site), Wheeler Creek site 241 and EF Winchuck River site 243 The Forest Service recognizes that the forest lands provide a majority of water for downstream users but the plan fails to mention that minimum streamflows have been established on many of the streams in the area Since those flows are important for fish life, the Forest Service should be sure that upstream forest management practices do not reduce streamflows below recommended levels (See Minimum Flow Tables)

The basin programs also list the state's scenic waterways including the Rogue from the Applegate to Lobster Creek Bridge and the Illinois River from Deer Creek to the mouth. In addition to the federal designation, the state designation should be cited including the state's management plans for those areas.

Finally, one last point that needs to be addressed is the groundwater resources on the forest The Water Resources Department did not find any discussion on groundwater. Since this is an important resource in the area, we would suggest the Forest Service inform the Water Resources Department of any potential groundwater problems encountered We believe problems could come to your attention during the review of forest management activities

II. Suggestions for Improving Alternatives

A Additional Alternatives

The alternatives that are described in the DEIS cover a wide range of possibilities for forest management The WRD suggests that the Siskiyou National Forest consider and evaluate alternatives that provides full consideration to the water and soil resources, including estimates of current water uses, instream flow requirements, protection of water quality, watershed conditions and protection of wetland and floodplain values and groundwater resources.

In summary, the Forest Service should review existing alternatives and modify the hydropower sections by including all stream restrictions as identified in the basin programs and listed in the administrative rules.

The WRD recommends that all areas with minimum streamflows be protected Any forest activity that would produce adverse effects to the watershed should be avoided and or mitigated. Inventories should be made to determine which forest lands need special management practices to protect streams with minimum streamflows.

Data currently available suggests that all the alternatives with the management prescriptions and management area restrictions have sufficient safeguards to protect the water resources to at least minimum levels

III Comments on Management Area Goals and Strategies

A Modifications to Forest-Wide Standards and Guidelines

In the review of the Forest-Wide Standards and Guidelines (LRMP IV-13-57), and the Management Prescriptions (LRMP IV 58-110), we offer the following comments.

The text on page IV-13 describes the type of direction and degree of restrictions with four different levels by the terms, "shall", "should", "practicable", and "may" As part of the following comments regarding the type of direction and degree of restrictions, we would prefer the term "shall" be used to make the action mandatory in all cases we identified, as opposed to the term "should" where the action is required unless a justifiable reason is presented for not taking action The Water Resources Department believes the distinction between shall and should is so minor that the tougher standard needs to be applied

Recreation 1 1-9 The Forest Service is mandated to provide sufficient maintenance to protect soil and water values as part of recreation sites As part of this recreation program, the Forest Service should develop a process to accomplish adequate maintenance as soon as needed and determine what would trigger the maintenance. In order to accomplish this task, we would suggest an inventory be made of existing sites that require maintenance and identify sites that have a potential for soil erosion

Fish and Wildlife 4 4-2 This section should include some reference to the variety of upstream timber harvest activities and how those activities can affect downstream flows needed for the support of aquatic life

Salmonid Habitat 4-12 As part of the stream inventory, flow needs for the rearing, spawning and migration components of habitat improvement should be identified.

Range 5 5-1 In any range improvement activities, the range requirements should include or identify the water needs for livestock Water supply requirements for livestock can be important because of the low summer flows on the forest. We would also suggest programs be developed to maintain streambanks from animal use that would create streambank erosion.

Timber 6 6-1 When selecting a timber harvesting method for any proposed sale, an analysis should be made to determine the potential water flows that could result from the selected harvesting method Effects on downstream users need to be considered

Soil and Water 7 7-2 *Soil Compaction or Puddling* The standard of 85% of affected areas should be in a non-compacted and non-puddled condition is somewhat confusing. The 85% standard needs more explanation. It is unclear why or for what purpose one would use the 85% percentage without using the percentage compacted with roads.

Soil Erosion 7-4 A list should be developed to include all areas that are subject to erosion or already eroded *The list should identify* the location, nature of the problem, cause and what it would cost to repair the damage The list could be used to budget and schedule the repair and maintenance of the sites The list could be used to review the effects of timber harvesting mitigation programs

7-9 In this section, the term "should" be changed to "shall". Any activity that has the potential to affect the water resources must be analyzed. Water yield improvements and other enhancement activities need to be given higher standards. Forest Service activities should not impair the water conditions downstream. It is not acceptable to allow conditions that would degrade the water resources especially during the summer low flow period

Riparian 7 7-11 The standard for activity created debris should be changed to "shall" Additional safeguards need to be placed upon activity created debris entering the waterway With all the protection being afforded to Class I-IV streams, it appears ill-advised to allow activity created debris to enter a waterway other than by accident Granted this debris will be cleaned out, but any activities that could create instream problems need to be prevented before it happens.

7-12 The Forest Service should inventory forest lands and determine areas with significant water for domestic and municipal systems As part of this inventory, the Forest Service should attempt to identify possible problems

that could occur from forest practices and develop a process to inform downstream users in case of emergencies The Water Resources Department can assist with this task

7-15 A report should be prepared describing basin conditions for the 20 planning basins. It should be kept updated with past, current and future proposed activities. This report could describe water yield, vegetation cover, land use and other water uses This might be accomplished in conjunction with the long-term Watershed Analysis Area maps being produced by the Forest Service.

Lands 9 9-6 B. Non-recreation uses. Any water use activities on the forest that require water right permits should be coordinated with the WRD.

Minerals 10 This section should refer to both the basin program restrictions to hydro development and the hydro rules. We would suggest, however, that this section be moved to the soil and water section, because hydro power is not part of the forest mineral base.

Road Building 11 11-2 & 11-5 Construction and Reconstruction The specified construction methods shall include provisions for reducing environmental impacts with particular emphasis or protecting soil and water values. This protection scheme should be expanded to include a section describing how the road system will be monitored to detect potential hazards and what methods will be used to repair any erosional problems as soon as detected

B. Modifications to Management Prescriptions

MA 1-9 Wilderness A list is needed to identify all existing degraded sites that could affect water resources As part of this task, a maintenance schedule should be prepared.

MA 7-5 Timber We believe a section is needed to explain the statement that timber harvest *can be permitted in some areas to produce specific benefits* for fisheries and water resources. This new section needs to explain how and what timber harvest benefits will result to fisheries and water resources from the long-term effects from timber harvest

MA 7-8 Soil and Water The degree of protection from accelerated soil erosion resulting from management activities within supplemental resource areas "shall" be minimized or preserved This standard needs to be mandatory

MA 7-9 Water Quality efforts "shall" be made to rehabilitate degraded sites or other areas yielding high levels of sediment or turbidity. This standard needs to be mandatory.

IV Assessment of Forest Service Alternatives

The WRD assessed three representative alternatives:
Alternative C with emphasis on timber management opportunities;
Alternative G promotes the health and productivity of the forest water related resources, and
Alternative K the preferred alternative

As a general rule in the review of the Forest Service alternatives, the WRD would prefer alternatives that minimize disruption to the natural forest ecosystem Those types of alternatives provide the greatest benefit to the water resources in both quantity and downstream effects on water use
In the alternatives that provide for the greatest amount of timber harvest, the standards and prescriptions for soil and water, and fish life should alleviate some of the undesirable effects for water supply and require mitigation to protect and enhance the resource. Those planning basins would contain the following provisions· no more than 20% of any planning basin will be harvested during a 10-year period and prescription levels B and C would be used for riparian management In addition, the direction and restrictions as described in the forest wide standards and guidelines, and management areas would assist in providing protection to the water resources. Those three conditions provide some type of analysis and or action before any activity is performed that could affect water resources

The WRD believes that those items provide a degree of resource protection to the water resources. We would recommend, however, that monitoring programs be established to identify and mitigate potential problems as soon as discovered to protect the resource.

Alternative C would have one of the highest impacts on the water resources Alternative C would result in the largest amount of sediment and largest peak sediment loads due to high harvest levels Alternative C has the highest amount of land selected as suitable for timber production This creates some concerns for the various management areas that have large acreages tentatively suitable for timber production. Lands in management area Supplemental Resource classification would be lost to the timber classification Alternative C also provides the lowest expenditures for capital investment for fisheries and riparian management. In many instances, planning basins with low level timber harvests would come under increasing harvest levels creating the potential for more soil erosion and water degradation problems.

According to the various protection proposals for classification, basins would not receive more that a 20% harvest per decade and riparian protection would be at level B The tables list the various harvest levels over time, many of the planning basins do not attain the 20% level of harvest, but the percentages could reach that level. The effects on the basins with relatively low harvest levels would be unknown if harvest levels went up to 20% Losses to timber harvest would be high within the Supplemental Resource Management Areas Only two streams would be protected under this category We would recommend the Forest Service re-evaluate the 30 streams

with exceptional salmon and steelhead rearing capabilities and make sure the streams are protected All streams with minimum streamflows should also be added to the list and protected. Minimum flows is one of the methods used to protect aquatic life and we suggest the Forest Service take this protection policy into consideration

Alternative G emphasizes the protection and enhancement of the Forest's non-timber resources and is designed to encourage the health and productivity of the Forest's water related resources. Soil disturbances would be limited to 9-13% of the area in all 20 watershed planning basins per decade and riparian prescription C standard would be used. The land around all 30 creeks would be allocated to Supplemental Resources Management Area. The forest would require less capital outlay to repair because the forest would not be subject to major timber harvesting. Protection would be afforded to 13 of the 14 management areas. This alternative would provide maximum protection to the water resources.

Alternative K the preferred alternative
Alternative K is a compromise between a high timber harvest and a low timber harvest. It attempts to address the desires of a wide range of users and still supply goods and services to the economy Soil disturbing activities are limited to 9-13% of the planning basins per decade and 13 of the 30 streams would be part of the Supplemental Resource Management Area Riparian prescription B would be employed in all areas except for the Elk/Sixes River where riparian prescription C would be used for Class I and II streams. We would recommend that all 30 streams and streams with minimum streamflows be protected for aquatic life. Protection of those flows should include all tributaries which provide the water

Summary

In many of the alternatives, conflicting resource problems have been recognized The Forest Service has done an adequate job of identifying possible problems that could result from conflicting uses. We believe the Forest Service has used the various. planning questions, forest-wide standards, management areas, minimum management requirements and the type of direction and degree of restriction afforded by the terms "shall" and "should" in an attempt to determine the best methods to protect the resources on the forest.

V
Specific Comments

DEIS

Table S-1 Riparian page S-21
According to the 3 riparian prescription levels of management, the forest minimum is designated as level B. In Table S-1 there is a row for a " Pre Minimum" level It is unclear as to what "pre minimum" means.

Page 11-8 & 11-9 The text describes 3 levels of riparian prescriptions

being level A,B, and C. The text on II-9 omits the description for level C

II-39 MA 7 Supplemental Resource Areas should list the 30 streams for reader assistance.

The List of Tables on viii. lists Table II-16 Special Assignment Areas as being on page II-140 but in fact the table is located on page II-155.

Page II -27 to II -53 The 14 management areas list the total amount of acres listed in each area and the amount of acres that is tentatively suitable for timber production A map is provided to identify the lands in the management area. We would suggest that the map for each management area identify both the acres for the management area and those acres suitable for timber production.

II-195 Hydropower is of special interest to the state and a better discussion is needed to identify the hydropower sites on the forest and how the Forest Service will coordinate with the Water Resources Department on hydro power applications. Additionally, the Forest Service should consider the Water Resources Department administrative rules for hydro and use the basin programs to determine what streams are restricted for hydro development.

II-213 Soil and Water The Forest Service should set-up a monitoring program to measure the effects of timber harvest on sediment and water yields and the effects of watershed improvements on water yield

III-22 Hydropower This section should list existing power claims on the forest and identify under what conditions development can occur

III-40 Water Storage Development Reference the potential storage sites in the forest area with those listed in the WRD basin programs.

III-42 Water storage Developments. In certain areas of the report the discussion centered around the fact that the forest had low summer flows and water-users were in short supply This section needs to be expanded to include the need to create or save water for downstream users to offset low summer flows.

PROPOSED LAND AND RESOURCE MANAGEMENT PLAN

Resource Management Protection

II-8 Fish habitat and Watershed Condition This section should clarify the difference between watershed conditions and conditions for fish habitat Most of the improvements are for instream modification with large woody debris to benefit fish life There is no information as to how the watershed will be managed to provide better conditions to the stream.

II-9 Research and Information Needs A section should be added to address 1. the needs for more information on forest runoff, forest management techniques and streamflow, 2. the benefits of maintaining additional

riparian areas along stream courses to protect the quantity and quality of the water supply, 3. determine the forest harvesting techniques or streamflow The forest does allude to this, but we would suggest a section on forest harvest and streamflow.

III-4 3. This section should list the streams that are protected It seems $350,000 will be spent to maintain and enhance fish habitat improvements. Is money available to protect or make land improvements that could be beneficial to streamflow? This section is not clear as to where the money will be spent and if there is a difference between actual fish improvements benefits and watershed benefits from increased sedimentation and erosion.

IV 2 Forest Management Goals We would suggest the Forest Service add a goal to this section to include the protection of watersheds The goal should reference the policies of the Water Resources Commission as found in the basin programs

IV -11 The Forest Service mentions improving watershed conditions on more than 450 acres yearly. How does this compare with acres needed for improvement? On page IV-12 some of the projects listed the need to prevent erosion, establish stream thermal protection and other improvements in the soil and water regime of the forest A complete list of projects should be provided.

IV -36 7-2 Soil and Water This section should include the goals of the WRC as defined in the basin programs for the Siskiyou National Forest

IV -37 7-5 & 7-6 A process should be included to make sure the system for mitigation is working

IV-38 7-9 Water yield improvements activities need to be given a higher priority

IV -39 7-13 Instream Flow The flows for instream uses need to be maintained and protected on the forest lands.

IV -40 7-15 Forest management activities should be referenced to basin programs for water use and coordinated with the WRC The watersheds identified in the watershed analysis area (WAA) maps should reflect the state's watershed basins

Finally, the Forest Service should develop a section that addresses the question of monitoring for the protection of water resources.

Re Draft Environmental Impact Statement for the Siskiyou National Forest Plan

Dear Mr Johnson

The Department has reviewed the draft Environmental Impact Statement (DEIS) for the Siskiyou National Forest Plan and provides the following draft comments for use in preparing the coordinated state response. These comments are related to air quality and water quality impacts of the proposed Plan. The Department does not recommend a "preferred alternative" at this time. The deficiencies outlined below reflect a need for background information that is necessary for the Department of Environmental Quality to evaluate before selecting an alternative After this information is included in the DEIS, the Department would be more capable of recommending a preferred alternative.

Regarding air quality, the Department's primary concerns are those of air quality impacts from forest prescribed burning and the burning of the Forest's fuelwood by the public within urban areas It is important that the Forest Plan DEIS clearly demonstrate that the Forest Service is not subsidizing the public's use of fuelwood. Both of these issues focus on the Forest's policy of the highest and best practicable use of forest residues. The Forest Plan should work toward better developing management alternatives that will minimize prescribed burning smoke while supporting the utilization of woody residues

Regarding water quality, the Department's concern is that the Plan be consistent with Oregon's adopted Statewide Water Quality Management Plan for forest practices as required by the Clean Water Act It is important to ensure that the proposed activities of timber harvest, road construction, chemical handling and usage, sewage disposal, livestock grazing and other forest land activities comply with Oregon's Water Quality Standards and Guidelines and be monitored for their effectiveness in compliance The Plan does recognize goals of meeting water quality standards and protecting beneficial uses of the water We are pleased with the consideration and detail given to water quality protection and management However, important

information is lacking in the Plan and DEIS necessary to adequately assess the water quality effects of the activities in a multiple use forest, including water quality analysis of baseline water quality conditions in individual streams and the effects of the planned forest activities on those streams. In particular, there is a need for plans to protect domestic water supply water quality in intensively managed watersheds as a result of stricter safe drinking water act requirements.

Thank you for allowing us the opportunity to review the draft EIS. The Department looks forward to reviewing the proposed state response

Sincerely,

Lydia Taylor for

State of Oregon
Department of Environmental Quality

Comments on the Draft Environmental Impact Statement
for the Siskiyou National Forest Plan

I Air Quality

The following comments summarize Department of Environmental Quality, Air Quality Division concerns that should be addressed in the Draft Siskiyou National Forest Plan Comments are organized into 4 major sections, each of which should be addressed in the Draft Forest Plan

A Attainment and maintenance of air quality standards

B Prevention of significant deterioration requirements

C. Visibility protection of Class I areas

D. Consistency with respect to Federal and State of Oregon environmental policies.

The principal issue of concern to the Department is that of air quality impacts related to forest prescribed burning, urban air quality impacts resulting from residential use of fuelwood from the Forest and the highest and best practicable use of forest residues A basic requirement of all National Forest Plans is presentation of an analysis of planned prescribed burning in relation to past burning activities If it can be shown that projected annual and daily air pollutant emissions do not exceed, or are expected to be less than that which occurred during the 1978 baseline period (using emission estimation methodology for baseline and future years developed by Sandberg, et al, USDA Forest Service), then issues discussed in Sections A and B are satisfied and no additional technical analysis of these issues is required. Work recently completed by Sandberg was part of the USDA Forest Service Region 6 Vegetative Management EIS This work should be included in the alternative analysis

A Attainment and Maintenance of Air Quality Standards

Management alternatives should be evaluated with respect to the Clean Air Act and Oregon Clean Air Implementation Plan requirements. The first issue that must be addressed is that of impacts on air quality standard attainment and maintenance. Table 1 lists Federal and State of Oregon air quality standards. Specifically, analysis of the alternatives should demonstrate that the proposed action will not cause or significantly contribute to air quality standard violations Air quality impacts within attainment areas must not exceed Prevention of Significant Deterioration (PSD) increments (Table 2) or cause violations of air quality standards.

B. Prevention of Significant Deterioration

Part C of the Clean Air Act, requires the Department to insure that pollutant increments in Class I areas (Table 2) do not exceed specific limits adopted by Congress irrespective of the originating source. To assure that these increments are not exceeded due to planned increases in prescribed burning emissions, a technical analysis of the impact of planned burns on nearby Class I wilderness (Kalmiopsis Wilderness) and Class II lands would be required. As noted above, such an analysis would not be required if it can be shown that the proposed burning activity would not exceed that which occurred during the baseline period. If the analysis indicates significant impacts, specific quantifiable measures designed to mitigate the impacts must be described in the Draft Forest Plan.

C. Visibility Protection For Class I Areas

The Oregon Visibility Protection Plan requires the protection of visibility within Class I areas during the period of the July 4th weekend to Labor Day, inclusive. During this period, the Siskiyou Forest Smoke Management Program must be conducted such that smoke is not intentionally transported into Class I wildernesses. The Draft Forest Plan should evaluate the impact of proposed increases (if any) in prescribed burning activities on the Visibility Protection Plan specifically with respect to assuring the continued protection of visibility within Class I areas.

D. Consistency With Federal and State Environmental Policies

Department policy (OAR 340-20-001) requires that Highest and Best Practicable Treatment and Control be applied to pollution sources within Oregon OAR 340-13-005, Environmental Standard for Wilderness Areas, set forth policy on environmental impacts within wilderness lands while USDA Forest Service Region VI policy (Service Manual No. 2400, Supplement 347, March 1985) requires that, in recognition of the value of forest residues utilization, prescribed burning only be accomplished for those units where all other alternative treatments are unacceptable.

1. Fuelwood cutting program consistency with environmental policies:

The Department has become increasingly concerned about residential wood smoke impacts on urban air quality. Fuelwood cutting programs managed in the Siskiyou National Forest are a major and inexpensive source of fuelwood for Southern

Oregon and Northern California residents. The Draft Forest Plan should evaluate and discuss the serious environmental consequences of the fuelwood program and it's consistency with Federal and State environmental policies. Specifically, the DEIS should clearly demonstrate that woodcutting fees are not subsidizing the public's use of fuelwood

2 Highest and best use of wood residues:

Department policy (OAR 340-20-001) requires that highest and best practicable treatment and control be applied to pollution sources within Oregon. Since prescribed burning smoke is the largest source of fine particulate emissions within the State, the Draft Forest Plan should include consideration of an alternative that assures the highest and best practicable treatment of forest residues focusing on intensive utilization of woody residues for industrial purposes It is important that the Forest Service work toward alternatives that will minimize prescribed burning smoke while supporting the utilization of woody residues for industrial purposes.

Table 1
National Ambient Air Quality Standards

SO2	Primary	80 ug/m3, annual arithmetic mean 365 ug/m3, 24 hour average

Class III Areas Pollutant	Annual	24-Hour	8-Hour	3-Hour
SO2	40.0	182.0		700 0
TSP	37 0	75 0		

For further information regarding air quality, contact John Core(229-5380)

II. Water Quality

The Management Plan and DEIS were reviewed within the concept that land management activities have the potential to beneficially or adversely impact the quality of the waters in the forest land downstream from the forest. The Management Plan has the opportunity to improve existing degraded resources and to maintain or protect existing desired resource conditions. The level of emphasis placed on water quality conditions and the processes used to protect that quality, play an important role in providing guidance to the managers on a project-by-project basis in the future

The Water Quality Division comments are detailed in the following five sections

A. Consistency with Provisions of the Clean Water Act.

1. Policy

Fish habitat, recreational uses and water for domestic use are all recognized beneficial uses of the waters within and emanating from the Siskiyou National Forest. The Department of Environmental Quality's statutory obligation is to protect, maintain, and improve water quality for these uses. The Department does this, in part, with the help of the Federal Clean Water act and Oregon water quality standards contained in the Oregon Administrative Rules.

The draft Siskiyou Forest Plan provides goals for water and environmental quality while managing the forest's other natural resources. To strengthen these statements and avoid misinterpretation of goals, we suggest specific reference to Oregon's water quality standards (OAR 340, Division 41) be made for Goals 18 and 21 (Plan, p. IV-2). Reference to Oregon's forest practice rules (OAR Chapter 629, Division 24) should also be made for Goals 19, 20 and 22 since these rules are currently recognized as best management practices (BMPS) for silviculture in Oregon.

The forest staff should be commended for their definitive work that went into producing the Forest-Wide Standards and Guidelines section of the proposed plan. To further strengthen items in this section we offer the following comments.

1. We agree with the definitions of degrees of restriction provided on page IV-13.

2. We suggest adding reference to OAR Chapter 340, Division 41 (Oregon Water Quality Standards) and applicable USFS references to the Oregon DEQ/USFS Region 6 Memorandum of Understanding dealing with nonpoint source pollution management The reference to these documents tend to get lost by only mentioning them in the DEIS.

3 This section of the plan must provide standards for wastewater systems. We request that the following language be added to page IV-26 of the Proposed Plan. "Sewage treatment and disposal facilities shall be approved by the Department of Environmental Quality or its contract agents and shall be in compliance with rules of the Environmental Quality Commission".

4. We request that directional tree falling be included in the standards discussion of Item 7-11 on page IV-38

5. The DEQ agrees with the process described for establishing, revising, and monitoring for compliance with best management practices in Item 7-14 on page IV-39. The monitoring aspects of this effort are of particular interest to the DEQ. We make comments regarding monitoring and evaluation later in this letter.

6. We request that the words "should", "will" and "where practical" be replaced by the word "shall" in the "WATER AND SOIL" section on page IV-81 It is our opinion that the plan can not achieve the Goal of Management Area 7 without the word "shall" as defined on page IV-13 The current language on page IV-81 allows too much flexibility and interpretation to achieve the stated goal. The word "shall" makes the activity mandatory rather than discretionary.

7. We are concerned about salvage logging after fire We recognize the value of the damaged timber after fire and the need to log it out as soon as possible However, we are concerned that salvage logging focuses intense, concentrated management activities in a watershed where the proposed plan may have intended to disperse intense management over time and geographic areas to minimize cumulative impacts In light of the current problem on the forest due to fires, how will the forest minimize impacts on streams and water quality during salvage logging? Can the logging be dispersed geographically over a two year period? If not, then how will the streams be protected?

When reading the whole plan and the draft environmental impact statement, it is apparent the staff knows the water quality problems and how to correct and protect water quality The discussions of effects on fisheries and water quality by each alternative in each planning basin was helpful in our review However, more specific stream quality discussions are necessary to be able to compare proposed management activities against existing stream conditions. The comparisons we did make generated some concerns.

1. The basic assumption that timber harvest and roads cause sediment production is accurate However, what is disturbing throughout the environmental consequences discussion in the DEIS, is the basic erroneous assurption that sediment production can be controlled only by cutting fewer trees and constructing fewer roads It is the DEQ

opinion that water quality protection can be achieved if the proper BMP is installed and maintained, and that it be monitored and evaluated for its continued effectiveness to achieve water quality goals.

2. The discussions beginning on pg IV-131, regarding environmental consequences, should be expanded to discuss in more detail the specific BMPs that need to be applied on specific streams to meet water quality and fish habitat goals. References need to be made to USFS technical manuals that describe these BMPs. This type of discussion is very important for the planning basins proposed to have significant amounts of timber removed and which have streams currently in degraded conditions (e.g., Basin 2, 4) From the discussion in the DEIS and Plan, it is hard for the reader to understand how streams and water will be improved with increased timber production using the basic assumption that timber harvest and roads cause uncontrollable sediment production

B Review of Water Quality Monitoring Plans

The proposed plan addresses the issue of monitoring and evaluation of management activities on various resources including soil, water, fish and cumulative effects We agree with the approaches displayed in the plan. However, we do have concerns for what is proposed and the need to improve the approach to be most effective.

1. The goal of a monitoring program to protect the water resource should be assessment of the changing water quality, not assessment of BMP effectiveness. The BMPs are tools to achieve water goals and should be monitored for their effectiveness to achieve water quality protection. However, BMPs are not the end products.. Good water quality is the end product and, therefore, should be the focus of monitoring.

   We suggest the forest staff use the Nez Perce National Forest final plan, Appendix A, Forest Fishery/Water Quality Direction by Prescription Watershed approach and specific elements as a starting point for improving the Siskiyou monitoring plan Please pay particular attention to the focus on beneficial uses of water in the streams and to the stream and water quality parameters monitored.

2 It is unclear in the proposed plan how the results of the water monitoring efforts will be displayed to the resource managers to modify their management strategies as necessary

A more frequent contact with the resource managers is necessary to ensure timely and effective decisions to protect water quality. We suggest that the plan be improved to show (a) the mechanism for the results of water quality monitoring to be transmitted to other resource managers and (b) how frequently these communications will be made.

3. Adequate and guaranteed funding of a monitoring program is necessary. The proposed plan displays costs for monitoring but doesn't ensure that the monitoring will take place. It is our position that monitoring of the plan implementation is not voluntary or optional, but mandatory. Our position is based on an interpretation that monitoring is a requirement of the National Forest Management Act (NFMA) to, "(E) insure that timber will be harvested from National Forest System lands only where —

   (iii) protection is provided for streams, streambanks, shorelines, lakes, wetlands, and other bodies of water from detrimental changes in water temperatures, blockages of water courses, and deposits of sediment, where harvests are likely to seriously and adversely affect water conditions or fish habitat" (Section 6, NFMA).

   If the Siskiyou National Forest staff cannot ensure that water quality monitoring will occur, then they cannot ensure that they are indeed protecting the resources described in the above NFMA citation. It is our opinion that this is a violation of NFMA requirements.

C. Review of Management Strategies and Alternatives

The DEQ made no attempt to determine a preferred alternative for water quality. We recognize that this is a land management plan, so we are concerned with the various levels of potential water quality impacts from those land activities We also recognize that differences in management intensity of an activity will create varying potential impacts on water quality.

We reviewed all alternatives and management strategies and prescriptions found in the Plan and DEIS with interest in the potential for water quality impacts and the opportunities available to ensure water quality protection We assumed that the higher the level of soil disturbance by activities, the greater the potential for erosion problems; also the greater the encouragement for recreation, the greater the potential for additional water quality problems.

If the proposed preferred plan alternative can maintain water quality standards or improve water quality to meet those standards, then the DEQ could support the preferred alternative. However, the assumption by the forest staff that the only way to reduce water quality impacts is by less timber production and road building makes it difficult to use the projected impacts in Figure IV-3 through IV-15 and still accurately access the effects of the management alternatives.

In addition, the DEIS and plan lack important information such as baseline water quality data for specific streams to assist in judging the effects of alternatives on water quality Appendix B of the DEIS cites sources of data For our assessment, lists of streams and their condition would be more helpful. We suggest the forest staff consider constructing lists similar to those used in the Nez Perce National Forest Plan and Final EIS.

D Review of Management of Special Use Watersheds

We looked specifically at how the plan intends to manage domestic water supply watersheds Municipal water supplies are identified in Table III-11 of the DEIS. The proposed plan recognizes the need for protection of the water quality for this beneficial use via the broader goal statement #21 on page IV-2 of the proposed plan

Our comments relative to protection of water quality for domestic use center on the current Safe Drinking Water Act that requires municipalities to obtain written agreements with land owners to control pollution in their respective watersheds. The proposed plan must comply with the Safe Drinking Water Act requirements This requirement is accurately stated on page J-6, DEIS Appendix Volume II Our concern is that the proposed plan does not offer a plan. It offers only broad statements for protection of water quality We request that the proposed plan develop and then display the management direction and environmental impacts for managing the resources in the identified municipal water supply watersheds This could be accomplished by specific discussion of domestic water supply watershed needs within Management Area 7 - Supplemental Resource beginning on page IV-79 of the proposed plan. Doing this still does not relieve the forest from developing agreements with each municipality

E Review of the Plan for Groundwater Quality Protection

The plan virtually ignores the groundwater component of the hydrologic cycle Although groundwater probably will be minimally

affected by forest management activities, the plan should recognize the importance of groundwater quality protection and discuss the following points:

1. Activities that affect groundwater quality will eventually affect surface water quality. Conversely, changes in surface water quality might be reflected in groundwater quality.

2. Lakes with unique pristine water quality may need special groundwater protection requirements to prevent nutrient enrichment, particularly with regard to sewage disposal practices associated with intensive recreational use

3. All sewage disposal practices need to be in compliance with state requirements Please refer to these requirements in the plan.

4. Groundwater protection planning should be included in all chemical handling practices, in the forest. This would include, but not be limited to herbicides, pesticides, fertilizers, and degreasing solvents at maintenance shops.

5 Activities and procedures that minimize erosion, and surface water runoff also will increase infiltration, allowing for more stable year round stream flows.

MEMORANDUM

SUBJECT DEPARTMENT OF FORESTRY REVIEW OF THE SISKIYOU NATIONAL FOREST PLAN

TO K Norman Johnson, Federal Planning Coordinator

FROM James E Brown, State Forester

DATE November 25, 1987

Attached is the Department of Forestry's review of the Siskiyou National Forest Draft Environmental Impact Statement and Proposed Land and Resource Management Plan for use in the State of Oregon s coordinated response to the USDA Forest Service

The primary emphasis of the Department s review is to insure that the Siskiyou National Forest plan provides an acceptable balance of environmental and economic conditions A primary measure of the economic performance of the plan is the level of timber harvest which supports jobs and local government

The Siskiyou planning team should be commended for the considerable amount of work they have done in producing the planning documents and for their cooperation with the state agencies as we have reviewed the draft forest plan

Our review has concluded that the potential exists to meet the needs of the Siskiyou's resource users as well as the goals and objectives of the Board of Forestry's Forestry Program for Oregon The Department s review points out opportunities to achieve this potential Areas where further analysis should be provided for public review in the Final EIS are also indicated

Two points should receive particular emphasis in the state s response First, management of the Rogue River corridor should be treated as a unique and separate part of the forest plan Second, given the release language of the 1984 Oregon Wilderness Act, land allocations to the Custodial (Roadless)" Management Area are inappropriate in this round of planning Other management areas are presented in the DEIS which provide a full range of options for the management of the Siskiyou National Forest's remaining unroaded lands

The Department of Forestry looks forward to working with the Governor s office, other state agencies, the Forest Service and the people of Oregon in developing a sound, balanced plan for the Siskiyou National Forest

OREGON STATE DEPARTMENT OF FORESTRY
REVIEW OF THE SISKIYOU NATIONAL FOREST'S
DRAFT ENVIRONMENTAL IMPACT STATEMENT AND
PROPOSED LAND AND RESOURCE MANAGEMENT PLAN

The Oregon State Department of Forestry s Resource Planning Section in cooperation with other Department staff, has reviewed the Siskiyou National Forest s Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (LRMP) Our comments focus on six areas of importance

1 Comparison of the DEIS alternatives with the basic objectives of the Board of Forestry's Forestry Program for Oregon -- Page 2

2 Coordination with Department of Forestry programs -- Page 3

3 Effects of the Siskiyou s modeling assumptions and proposed activities on timber yields -- Page 5

4 Factual errors and omissions in the planning documents -- Page 17

5 Economic considerations -- Page 20

6 Needed clarification of planning direction -- Page 26

A summary of this review is provided on page 31

COMPARISON OF THE DEIS ALTERNATIVES WITH THE BASIC OBJECTIVES OF THE BOARD OF FORESTRY S FORESTRY PROGRAM FOR OREGON

(DEIS page II-240) The Oregon State Board of Forestry s 1982 Forestry Program for Oregon (FPFO) contains three basic objectives for the management of national forest lands They are

1 Maintaining the maximum potential commercial forest land base consistent with other resource uses while assuring environmental quality

2 Identifying and implementing economically feasible levels of intensive forest management required to achieve cost effective growth and harvest

3 Maintaining community stability by considering the projected timber harvests from other ownerships in setting the harvest from national forest lands

The Department of Forestry appreciates the discussion in the Siskiyou National Forest DEIS devoted to the Forestry Program for Oregon Unfortunately, the forest has not addressed the FPFO in the format specified in the May 2, 1985, July 15, 1985, and May 13, 1986 Regional planning directions As a result, the Siskiyou has incorrectly compared the DEIS alternatives to the FPFO objectives An August 14 1987 memorandum from the Department of Forestry to the Siskiyou National Forest (See Attachment 1) contains an explanation of this situation

The Siskiyou has also failed to produce the table, required by the Region, which compares the assumptions used in developing the FPFO with the structure and assumptions used in developing the alternative that most closely meets the FPFO objectives This information should be provided in the Final EIS

The revised comparison of the DEIS alternatives as shown on Attachment 2 indicates that only Alternative C fully meets the compatibility standards for all three objectives None of the alternatives meet the timber harvest targets provided to the forest in an April 2 1985 correspondence from the Department of Forestry These targets were revised downward at that time to account for the reduction in the commercial forest land base on the Siskiyou that had occurred since the 1980 Oregon Timber Supply Assessment was published

These timber harvest targets for the first five decades are

Decade 1	40 7	MMCF/Year
Decade 2	39 1	
Decade 3	36 5	
Decade 4	37 2	
Decade 5	40 8	

Management constraints, inventory differences, and yield table differences may prevent direct comparison of these targets with the DEIS alternatives However, they provide a tangible measurement of the Forestry Program objectives These targets should be provided to the public in the Final EIS

The failure of several DEIS alternatives, including the preferred, to meet the basic FPFO objectives indicates that the Siskiyou National Forest has embarked on a management direction that is different from the management envisioned by the Board of Forestry in 1982 A primary reason for this result is the continued reallocation of commercial forest lands (in addition to the allocations in the existing management plan) in each alternative to strategies that prohibit timber management or reduce timber management opportunities below the full yield potential

The Department of Forestry believes that the Siskiyou still has the potential to mold additional alternatives that fully satisfy the FPFO objectives The forest is encouraged to construct such alternatives incorporating the other recommendations by the Department and to provide an opportunity for public review

COORDINATION WITH DEPARTMENT OF FORESTRY PROGRAMS

Fire Management - (LRMP page IV-52) The Department of Forestry supports a policy of applying aggressive, cost effective suppression action to wildfires that threaten life, private property public safety improvements, or investments Coordination of protection planning and suppression efforts with other protection agencies, including this Department, should be included as a part of these guidelines

The Final EIS should more thoroughly discuss how large areas of unroaded and unmanaged forest land increase the hazard and risk of catastrophic wildfires as well as the cost and difficulty of suppressing them The brief reference to this issue on page C-123 of the Appendices prophetically warned of the risks of large high intensity fires in the North Kalmiopsis roadless area The Silver Fire has provided tangible evidence of the magnitude of these risks It also will serve as a costly and potentially long lasting reminder of the continuing threat to the resources on the Siskiyou National Forest resulting from large, inaccessible unroaded areas

Smoke Management - (DEIS, pages IV-116, 231) The Siskiyou should more clearly emphasize compliance with the Oregon Smoke Management Plan since the Environmental Protection Agency (EPA) has approved Oregon s plan as meeting the requirements of the Clean Air Act as amended in 1987 Unplanned ignitions should be used as prescribed fires only if compliance with the Oregon Smoke Management Plan can be assured

Even though wildfires are random events on the forest this summer's experience indicates the extreme magnitude of the negative effects that natural fires can have on air quality The DEIS text makes several references to the contribution of prescribed fires to airshed degradation However, it fails to note that the management activity of prescribed burning reduces the risk of catastrophic natural and man-caused fires which can generate severe and unplanned reductions in visibility

Forest smoke will originate on the Siskiyou whether or not prescribed burning occurs Through the use of smoke management techniques and by employing sophisticated controlled burning methods, the effect of prescribed fires on visibility can be minimized The Department of Forestry supports full use of this and other management tools in order to prevent the significantly greater air quality problems and the other social and environmental costs which result from wildfires in areas of untreated fuel accumulations

Oregon Forest Practices Act - (DEIS, page IV-230) The Oregon Forest Practices Act provides minimum standards for soil and water protection and for the maintenance of forest productivity The Environmental Protection Agency has certified the Forest Practices Act as providing the 'best management practices for protecting fish life and water for domestic uses from non-point pollution sources on forest lands and as meeting the requirements of the Clean Water Act as amended

To demonstrate consistency with the Clean Water Act, the Siskiyou Final EIS should discuss how the alternatives will satisfy the requirements of the Forest Practices Act Particular attention should be given to the newly adopted rules for riparian area management The forest s standards and guidelines for riparian areas should reflect the full intent of the Forest Practices Act as well as demonstrating consistency with the approved rules

The Final EIS should also expand on the statement on page IV-229 of the DEIS which reads

> " conflicts may exist between State administration and enforcement of Best Management Practices (BMP's) on private timber harvest activities versus those practices implemented through the Forest s policies, and Standards and Guidelines

What are these potential conflicts and how could they be resolved? It would seem that the Forest Service s actions should be compatible with the practices required on private land since both are intended to satisfy the Clean Water Act Instead there is some evidence that the Forest Service s standards are more costly to implement and provide less flexibility and less opportunity for timber management than the Forest Practices Act riparian rules

EFFECTS OF MODELING ASSUMPTIONS AND PROPOSED ACTIVITIES ON TIMBER OUTPUT LEVELS

Minimum Management Requirements - (App , page B-105 J) The Board of Forestry has recognized in the Forestry Program for Oregon that forests are important for providing a full range of uses and benefits including wood production water quantity and quality, recreation wildlife fisheries, and forage As a result the Board has adopted a policy to encourage and promote forest management practices which will maintain and enhance the full range of social and environmental benefits of the forest

Based on this Board policy, the Department of Forestry supports the maintenance of viable populations of indigenous forest plants and animals It is therefore appropriate that the U S Forest Service provides a minimum level of protection for forest resources in its national forest plans and presents the public with a range of alternatives which meet or exceed this minimum level

However the Department believes that two basic improvements in the application of minimum management requirements (MMRs) proposed for implementation by the Siskiyou or the proposed revisions suggested by the Regional Office are needed First there is a need for further documentation and analysis by the Forest Service Second increased public involvement in the MMR decision making process must be permitted

Please consider the following specific concerns and recommendations

Need for Further Documentation and Analysis

1 Data Uncertainty - The credibility of the plan could be increased significantly if the MMR s were submitted to peer review That review would help assure that the most current data and a broad base of professional expertise are reflected in the plan

2 Alternative MMR Strategies - Only one set of MMR strategies is proposed in the plan and the sensitivity analysis provided in Appendix J only varies the intensity of that one set Where alternative methods for achieving the same objectives are available displaying them would be beneficial and possibly avoid later conflicts with NFMA and NEPA public disclosure requirements

3 Inconsistency Among National Forests - Based on the information provided in the forest plans published in Region Six to date, it appears that similar national forests may be modeling their MMRs differently, thereby providing inconsistent levels of protection and inconsistently applied constraints on other resources No published documentation supports these differences or explains how each forest's MMR package provides for the minimum level of protection, as required or suggested by NFMA If alternatives are displayed, as recommended in number 2 above, this concern would be overcome

The need for and design of each MMR should be clearly explained in the forest plan A display similar to the August 22, 1984 Wildlife MMR matrix produced by the Region should be included in the Final EIS This now outdated matrix provided important data on the number of habitats being designated by each national forest for each indicator species, the acres of suitable land involved, and a measure of the effect of these allocations on timber management Similar displays could be constructed for soil, water quality, and riparian MMRs

Increased Public Involvement in MMR Decisions

4 Public Review - The decision making process consists of two elements

a *The identification of the level of protection or* management that will be the "minimum level" target suggested by NFMA

b The methods chosen to effect this level of protection and management

In the Siskiyou s planning process to date, these decisions and assumptions used in developing the MMRs were finalized and incorporated into all alternatives without the provision of any opportunity for full public review as required by NEPA and NFMA This action by the Forest Service makes the planning process vulnerable to legal challenges and prevents the agency from gaining the valuable input that the public and other resource professionals could have provided the Forest Service

The process for implementing MMRs must be opened up fully to public review By doing so, the Forest Service may be able to develop new alternatives that are more responsive to public concerns

5 Legal Sufficiency - Minimum management requirements were developed by the Forest Service based on the Region s interpretation of the NFMA requirements Other parties, including other Forest Service Regions, have interpreted these requirements differently Unless the Forest Service improves the analysis of MMRs by adequately considering the concerns of environmentalists, forest industry representatives, and other parties, litigation of the MMR issue seems likely

Snag Management - (DEIS, page II-255, App , page B-108) The text states that

"[t]he present Siskiyou Wildlife Tree (Snag) Guidelines are designed to maintain woodpecker populations at 60 percent of the maximum habitat capability in managed stands'

The cost of this 60 percent level of snag habitat on timber yields is less than one percent of the allowable sale quantity Yet, the Siskiyou has modeled Alternatives B C , 'D , and "D1' so that they can only provide the MMR snag habitat at the 20 percent level while all other alternatives provide a 60 percent minimum It seems that the FORPLAN model was only given two options for snags on managed lands, 60 percent or 20 percent No intermediate choices were permitted The DEIS provides no explanation for this enforced inflexibility in the model

Since there is apparently no significant timber benefit for this lower level of habitat, it appears that all alternatives could provide 60 percent of the maximum habitat capability on managed lands and, thereby, an even higher forest-wide average If this is possible without a reduction in timber harvests or a significant increase in fire risk, the Department of Forestry would support such a modification

The Siskiyou National Forest should continue to insure that its methods for providing snag habitat at or above the MMR level are as efficient as possible and that the chosen methods are the least constraining on timber management

Two Forest Service publications, Wildlife Habitats in Managed Forests and Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington discuss ways of providing snag habitat while minimizing the effects on timber management Please consider these points

1 High stumps may provide adequate habitat for some species

2 Emphasizing snag retention downslope from roads protects snags from firewood cutting

3 Snags do not have to be evenly distributed Some clumping of snags into small patches may actually enhance nesting habitat for some species as well as improve efficiency

4 Selecting individual trees or small clumps of trees for snag retention or snag creation may be preferable to imposing a long rotation over a larger area, especially in terms of the effects on timber harvest levels

5 The selection criteria for replacement snags should include the economic value of the tree Limby, deformed, and broken topped trees should be selected over sound, straight, clear boled trees if wildlife habitat is the purpose for retention

6 Areas not suitable for timber management should be managed to provide 100 percent of their snag habitat potential Active management can include the creation of snags to achieve this potential where custodial management can not

Also note that the 1987 Oregon Legislature has passed HB 2152 which removes the requirement in Oregon law that snags be felled within 250 feet of the exterior boundaries of harvested units planned for burning. This change in the law should allow the Forest Service and other landowners more flexibility in retaining wildlife snags in clearcut harvest units

Unroaded Area Allocations - (App C) The Oregon Wilderness Act of 1984 states that unroaded areas which were not designated as Wilderness

". shall be managed for multiple-use in accordance with land management plans. .'

and that

" such areas need not be managed for the purpose of protecting their suitability for wilderness designation. "(Emphasis added)

In keeping with the intent of this law, the Department of Forestry strongly recommends the elimination of the "Custodial (Roadless)" Management Area 6 as an option in this round of planning

Consideration of unroaded area retention outside of Wilderness is entirely appropriate to meet specific resource demands such as semiprimitive recreation, botanical areas, or wildlife habitat The Siskiyou has provided other Management Area choices (3, 4, 5, 7 8, and 9) which will set aside vast areas of unroaded lands in most DEIS alternatives for these purposes

It is not appropriate that

" unroaded areas are allocated to Custodial Roadless management so that the effects of management on lands adjacent to the designated Wildernesses are minimized and wilderness potential maintained. ." (DEIS, page II-209)

The 1984 Wilderness Act clearly states that

"Congress does not intend that designation of wilderness areas in the State of Oregon lead to the creation of protective perimeters or buffer zones around each wilderness area The fact that nonwilderness activities or uses can be seen or heard from the areas within the wilderness shall not, of itself, preclude such activities or uses up to the boundary of the wilderness area"

The Department of Forestry recommends that unroaded lands which support productive forests be returned to the suitable land base and that the timber volume from these productive lands be included in the regulated timber harvest schedule On the Siskiyou, this would mean that 153,466 acres of the 314,025 acres of unroaded areas of the forest would still be retained to meet MMR requirements, and to provide semiprimitive and primitive recreation, research natural areas, wildlife habitat, and scenic vistas This total would be in addition to the 234,538 acres of Wilderness and Wild River lands on the forest, meaning that even under the most timber-oriented alternative 36 percent of the Siskiyou would remain roadless.

Management of the South Kalmiopsis roadless area deserves a special reexamination by the Forest Service This 105,421 acre area contains only 25,359 acres of suitable land unconstrained by MMRs A significant portion of this area could be retained for unroaded use with no effect on timber management Nevertheless, many of the DEIS alternatives assign all or part of the South Kalmiopsis to General Forest Management Area 14, even though no access or harvesting is planned

The Siskiyou should consider establishing a new Management Area designation for the South Kalmiopsis which emphasizes the management of the unsuitable lands for both their present unroaded use and their potentially high future mineral values

Old Growth Habitat - (DEIS, page II-22) According to the DEIS 85,537 acres, or 7 8 percent of the forest must be maintained as old growth to satisfy minimum management requirements It is important to note that under the most aggressive timber alternative presented by the Siskiyou (C), 36.9 percent or nearly five times the MMR level of old growth would be present after the ten year life of the plan. More than twice the MMR level of old growth acreage would still remain 140 years in the future.

From this analysis, two conclusions can be drawn First, the potential exists to maintain timber harvest levels near the existing plan s potential yield and still provide an abundant reserve of old growth timber during the life of this proposed plan Second, it seems that the Siskiyou has presented a very narrow range of alternatives for public review A broader decision space' of choices should be provided in the Final EIS The result would be a planning document that more closely meets the intent of NEPA and NFMA

Timber Yield Tables - (App , page B-33) The Siskiyou National Forest should consider the use of the recently released SW ORGANON timber yield model in the forest plan A preliminary analysis of this state-of-the-art model indicates that forest management may generate significantly more wood from the Siskiyou than the DFSIM model estimates with the same rotation lengths (See Attachment 3)

It appears that by substituting the SW ORGANON model the Siskiyou may be able to increase timber sale levels while continuing to maintain and protect other forest resource uses Another benefit of the use of SW ORGANON is the flexibility it allows in modeling initial stands below 300 trees per acre The Siskiyou s DFSIM model lacks this capability

The Siskiyou s empirical yield tables were developed using a process that the Region 6 Planning Task Force working paper described as a make do system which includes the statistically undesirable feature of interacting regression equations Growth models such as SW ORGANON would provide a more valid and accepted mechanism for estimating these yields The Forest Service should investigate the potential of this new model for both empirical and managed yield tables and utilize it where it is applicable

The Final EIS should also discuss and justify the forest's failure to develop separate yield tables by site and the incorporation of a 5 percent basal area cap on regression equation estimates These two assumptions could significantly influence the resulting timber yield projections and indicate that problems may exist in the development of the Siskiyou s empirical yield tables

Wild and Scenic Rivers - (DEIS, page III-51, App E) It is clear from the public input have received that maintaining the integrity of the Rogue River corridor is supported by most southwest Oregon residents To emphasize the importance of this resource, the Forest Service should consider the management of the Rogue River as a separate and unique part of the Siskiyou plan The Department of Forestry supports a level of management which preserves those qualities which are critical to maintaining the recreational experiences that the Rogue River currently provides

The Department of Forestry also supports the Siskiyou National Forest s recommendation not to include the inventoried segments of the Chetco and North Fork Smith Rivers in the Wild and Scenic Rivers System The low level of public interest in formal designation of these rivers and the close proximity of more outstanding Wild and Scenic Rivers are the primary reasons for this conclusion Other management strategies in the forest plan are available to preserve the existing character of these rivers

Visual Management - (DEIS pages III-127 IV-170, App page B-28, LRMP, page IV-105) The Siskiyou has chosen to impose constraints for visual management in every alternative Like the MMRs previously discussed, the standards and guidelines for visuals have been implemented without public review, without the exploration of alternative strategies, and without an adequate tradeoff analysis

Discussions with the planning team have revealed that the primary reason for these minimum visual standards was to present only "politically implementable alternatives in the DEIS Since the purpose of the DEIS, as required by NEPA, is to include the public in the decision making process, the Siskiyou must justify this action which has significantly narrowed the decision space of the plan

Because timber outputs are directly affected by these requirements, the Department of Forestry has several additional concerns about visual management on the Siskiyou

1 The Forest cites the need to maintain visual quality adjacent to Wilderness areas to preserve opportunities for primitive recreation in spite of a specific Congressional direction that this buffering action is not intended

2 The Forest provides visual corridors along Wild and Scenic Rivers that average 3 to 5 miles in width even though the Congressionally designated boundaries are only one-eighth to one-fourth of a mile on each side of the rivers These additional visual corridors include background and unseen areas, yet these areas are assigned to a management allocation with very restrictive constraints on timber management

3 The standards and guidelines for Partial Retention Management Area 13 are extremely constraining on timber management They include a target tree size of 30 inches DBH, rotation lengths of up to 130 years, and the designation of harvest units as 'openings until regenerated vegetation reaches 20 feet In "seen areas clearcuts are limited to a maximum size of eight acres with a harvest dispersion rate of 8 percent Retention standards and guidelines are still more restrictive

4 Under Alternative "C , the alternative least constrained for visuals, 86,551 acres, including 67,657 suitable acres, are allocated to Partial Retention Management Area 13

5 All alternatives are constrained to provide a minimum level of visual management, but the purpose, rationale and tradeoffs for this decision are omitted from the 'common constraints discussion in the DEIS Appendices

6 Unseen" areas which are not visually sensitive are included in the Retention and Patial Retention management areas in each alternative The DEIS is not clear in describing the management direction for these unseen areas

According to the Siskiyou planning team the cost of these visual constraints is a reduction of about 1 percent on allowable sale quantity in the preferred alternative The impact on timber volume is low because timber harvesting is also constrained in all drainages by a 9 to 13 percent harvest dispersion requirement Alternatives with the MMR harvest dispersion level of 20 percent on most drainages would have a much greater allowable sale quantity reduction for visuals

Neither the DEIS or the planning team have discussed the economic cost of these constraints in terms of present net value returns to the federal government, and payments to counties It is likely that reductions in these factors would be more significant than 1 percent Such restrictive dispersion constraints may also make road construction and the resulting timber sales impractical and uneconomical

The Department of Forestry requests that the following information be provided in the Final EIS by the Siskiyou

1 A summary of the costs, in terms of present net value and allowable sale quantity of the level of visual management included in each of the DEIS alternatives

2 An analysis of the tradeoffs that would occur if the visual management diameter and harvest dispersion constraints were increased, reduced, or eliminated

3 An explanation of how the diameter and harvest dispersion requirements were selected and an analysis of the tradeoffs that would occur if more restrictive and less restrictive requirements were used

4 A summary of the anticipated recreation use, by decade of each corridor designated for visual management

Departure From a Nondeclining Even Flow Harvest Schedule - (DEIS, page IV-192) 36 CFR Part 219 .6 provides direction to the Forest Service on utilizing timber harvest schedules in alternatives which depart from a nondeclining even flow schedule Such alternatives are to be evaluated if it is reasonable to expect that overall multiple use objectives would be better attained

Regional direction goes on to require consideration of departure alternatives in several situations Among these are

1 When timber harvests from other ownerships are expected to decline

2 When needed to meet Forestry Program for Oregon objectives

Clearly, these two situations exist on the Siskiyou National Forest They point out the necessity that a departure harvest schedule be given serious consideration in the decision making process

The Siskiyou has presented three implementable departure alternatives However, none of these departures address the harvest declines on southwest Oregon industrial lands that are projected to occur from 1990 until 2030 Departure alternatives which accelerate harvests in these decades would be more useful than those presented in the DEIS

It is important to note that any of the alternative land allocations could be managed under a departure harvest schedule Such departure schedules should be formulated so that they increase the level of timber harvest from 1990 to 2030 while existing private forests are growing to harvestable size The Siskiyou should also coordinate its timber harvest schedule with adjacent national forests and other public ownerships This action will assure that the timber supply issue is addressed as effectively and efficiently as possible

Coordinated departures which take into account the differing age distributions of these different ownerships should be considered All departures should be regulated by a 10 percent decadal harvest change constraint to avoid the environmental, economic, and management disruptions that are likely with large changes in timber harvest levels

Culmination of Mean Annual Increment - (App B-116) Region 6 has implemented a minimum management requirement, based on Forest Service regulations, that even-aged stands scheduled for harvest will generally have reached the culmination of mean annual increment of growth (CMAI) The constraint, when combined with the nondeclining even flow requirement and the existing Siskiyou National Forest timber inventory, significantly reduces the allowable sale quantities of the DEIS alternatives

The Siskiyou appears to lack timber on suitable lands in the 50 to 70 year old age classes Because of this there is a shortage of harvestable timber in decades 5 to 7 as available old growth stands are depleted Under NDEF, this shortage limits timber harvests in all previous decades After this critical time period, timber harvests increase dramatically as fast growing, regenerated stands reach merchantable size

According to Forest Service regulations, exceptions to the minimum rotation age requirement are to be " evaluated if it is reasonable to expect that overall multiple use objectives would be better attained"

Specifically, exceptions are permitted

> for removing particular species of trees after consideration has been given to the multiple uses of the area being planned and after completion of the public participation applicable to the preparation of a Forest Plan" (36 CFR Part 219 16)

The Siskiyou has formulated Alternative "D1" which shortens rotation lengths from a forest wide average of 100 years at 95 percent of CMAI to an average of 80 years This harvest schedule reduces the effect of the inventory gap on harvest levels, resulting in an increase in allowable sale quantity of 15 1 million board feet per year. It is important to note that the environmental costs of these shorter rotations appear to be minimal Final harvest acres under Alternative D1 are actually less than for Alternative "D" in the first decade as shorter rotations give FORPLAN more flexibility for timing choices As a result, more high site areas are harvested sooner The DEIS states that shorter rotations would also increase big game habitat capability on the Siskiyou

In addition to shortening rotations in all decades to address this scheduling problem, the Siskiyou s Final EIS should consider

1 Shortening rotations only during the critical decades

2 Increasing intensive management practices in those stands planned for harvest during decades 5, 6 and 7

3 Coordinating the Siskiyou s harvest schedule with adjacent national forests and other public ownerships These other forests may be able to depart from NDEF during the decades that the Siskiyou has an inventory shortage

4 Use the FORPLAN model to maximize timber output by allowing timber harvests to vary within a plus or minus 10 percent range by decade This would permit the model to more efficiently deal with the Siskiyou inventory as it changes over time

All of these harvest schedule scenarios could be utilized under any of the DEIS alternatives The Department of Forestry urges the Forest Service to seriously consider such creative strategies for maintaining a higher level of allowable sale quantity

Geotechnical Methodology - (App , page B-33) A Department of Forestry geotechnical specialist has reviewed the Siskiyou National Forest plan to evaluate how mass soil erosion, surface erosion, and the cumulative effects of soil movement were described and modeled The 'best management practices to be used in road construction and timber harvesting were also reviewed (See Attachment 4)

From this review the following conclusions have been made

1 The surface erosion model appears to be based on sound methodology

2 The landslide inventory is limited by two problems
  a The aerial photo inventory may not have detected landslides hidden by forest cover
  b Road failures based on older practices may overestimate future failures and sediment production using current best management practices

3 Utilizing actual sediment delivery as calculated using the model, inventory and FORPLAN would probably be more appropriate for assessing geologic hazard than using slope steepness and rainfall

4 A more complete discussion of the best management practices, especially relating to mass soil movement and the transportation network, is needed in the Final EIS

5 It is unclear how the results of the cumulative effect model were used to generate the harvest dispersion factors and riparian prescriptions in the DEIS alternatives

6 The Final EIS should consider the effects of mass soil movement on other resources, such as stream structure and downstream water uses, in addition to sediment delivery by streams

Fertilization - (LRMP, page IV-29) The Siskiyou may not have fully considered the opportunities for fertilization to increase timber yields on the forest The Department of Forestry requests a more thorough analysis of the potential use of this management tool Our review of the planning documents indicates this has not been done For example

1 The Forest-wide Standards and Guidelines state that fertilization may occur "as practicable" with no specific criteria provided

2 The costs of fertilization have been provided in the DEIS Appendices but the benefits, including gains in tree growth have not

3 The Siskiyou has only considered one fertilizer application, based on Regional direction and has only considered one age for application for each site

4 The Siskiyou's managed yield tables indicate that without commercial thinning, one fertilization could shorten 95 percent of CMAI rotation lengths by 10 to 20 years depending on site It is not clear if this potential has been considered in addressing the harvest scheduling problems the Siskiyou has in future decades

The Final EIS should examine a wider range of options for the use of fertilization and fully discuss the costs and benefits these options would generate

FACTUAL ERRORS AND OMISSIONS IN THE PLANNING DOCUMENTS

Sediment Yields - (DEIS, page II-213) Table II-20 indicates the 'mean percent change in estimated accelerated sediment compared to current program. .", with Alternative "A" selected as the current program The table shows that the percent change in sediment will vary from +14 percent for Alternative "C" to -81 percent for Alternative "M" This table is misleading in that it only addresses the small amount of sediment produced in addition to background sediment

According to the DEIS on page III-59, 88 percent of the sediment produced on the Siskiyou is the result of natural erosion processes and past harvesting and road building Only 12 percent is the result of new activities It would be more informative for the Siskiyou to describe how total sediment production will vary by alternative

Using the data for decades 1, 2 and 5 provided in Table II-17, it appears that Alternative "M' would reduce total average sediment for these decades by 10 percent More importantly, Alternative "C", which allocates the most land to timber management, would increase the average total sediment for these three decades by only 2 percent.

The Siskiyou should provide this information to the public and describe the benefits and costs, if they are measurable of this 2 percent increase and discuss the margin of error of these sediment production estimates

Optimum Wildlife Habitat Mix - (DEIS, page III-123) Table III-31 provides the Siskiyou s estimate of the "optimum' land allocation for wildlife on the forest The term optimum is undefined and the potential populations that would be supported by such an allocation have not been presented It is also uncertain if the demand for game fish and wildlife were considered in developing this mix

Clearly, this habitat mix would not be optimum for deer since this land allocation would allow only 453,000 acres to be managed for timber production The DEIS states on page III-117 that to maintain the existing deer population of 26,000, " 600,000 acres of the forest would need to be managed for timber harvest' Even then, the Oregon Department of Fish and Wildlife population objective of approximately 32,600 animals would never be met Shorter timber rotations were not considered despite the statement on page III-126 that they would increase the habitat capability for big game The Final EIS should more adequately discuss the meaning and implications of this subjective land allocation

Opportunity Costs of Fixed Land Allocations - (DEIS, page III-160) The Siskiyou states that in addition to minimum management requirements, old growth timber on 20 percent of the forest will be preserved through fixed land allocations, particularly Wilderness The DEIS also states that no opportunity costs are displayed for this old growth that has already been set aside Unfortunately, very real and very significant opportunity costs do exist that should be displayed in the Final EIS

This example illustrates a larger problem in national forest planning The public has not been fully informed about the timber values that have been lost through land allocations which limit or prohibit timber management Therefore the public cannot easily determine the actual or potential levels of values produced by the national forest They also cannot examine the tradeoffs that have been made by previous land allocation processes nor trace the continued erosion of the commercial forest land base Since these fixed land allocations involve 22 percent of the Siskiyou National Forest acreage, this issue must be addressed to fulfill NEPA and NFMA requirements

Jackson County Employment - (DEIS, page III-141) The typographical error on Jackson County's 1983 covered employment in the agriculture, forestry, and fisheries sector should be corrected. This number is 796 jobs, not 74.

Effects on Lifestyles, Social Organization, and Attitudes - (DEIS, page IV-201) Table IV-15 presents a very subjective analysis of a topic that is nebulous to begin with. It is unclear to the reader what information is being communicated. In addition, the table seems to contain several errors. For example, Alternative "D1" is assigned a "-" rating for the "Timber Related" parameter, while Alternative "D" received a "+". Since timber harvests are higher in "D1", a "+" rating should be expected. The same illogical relationship exists with Alternatives "K" and "K dep".

Alternative "D1" is assigned another incorrect relationship for "Primitive Recreation Acres". This alternative has the same land allocation as Alternative "D" but "D1" is given a "+" rating while "D" received a "-".

This portion of the DEIS is of little value to the public in its present form and should be revised to include additional explanations or deleted in the Final EIS.

Alternative Illustrations - The DEIS and the accompanying maps include illustrations which presumably are intended to show the public what the landscape will look like under each alternative. These visual interpretations are very subjective and nothing in the text explains their meaning.

Since all of the scenes depicted in these 13 illustrations will exist somewhere on the forest under every alternative's land allocation, their use in this context for comparison purposes is inappropriate. The Department recommends deleting these oversimplified and biased drawings from the Final EIS.

Major Values Relating to the Resource - (App., page B-90) The text provides a lengthy discussion of the values, attitudes, and opinions of southwest Oregon residents. The conclusions made in this discussion are purely subjective and are based on undocumented assumptions and opinions. A more scientific survey of the values of a random sample of southwestern Oregon residents was conducted by the consulting firm of Moore Information in 1986 for the Oregon State Board of Forestry.

Some of the results of this survey include:

1. Sixty-nine percent of the area's residents believe forests are important to the state as a source of wood products, jobs, and tax revenues.

2. Fifty-five percent believe timber harvesting is necessary to keep forests healthy.

3. Seventy-three percent believe avoiding future timber shortages is an important state policy.

4. Eighty-three percent support the practice of harvesting old growth timber.

More specific information, such as this survey which will be provided to the planning team, would be more useful in the DEIS than the text that is now present. The Final EIS should revise this section to provide a more accurate, documented discussion on this topic.

ECONOMIC CONSIDERATIONS

Fixed and Variable Costs- (App., page B-53) The criteria for identifying fixed and variable costs and for including those costs in FORPLAN appear to be based upon simplifying the model formulation rather than seeking the most economically justifiable solution. Only selected costs are considered as variable costs in FORPLAN, even though all costs, except those which are legally mandated, are probably variable over the 50 year planning horizon. All fixed costs are determined outside the model and, in effect, are "protected" from the model's optimization decisions.

The DEIS provides no way to judge the appropriateness of these costs or the resulting benefits as compared to other possible combinations. Given the magnitude of change proposed among the alternatives, a less arbitrary process is needed. The FORPLAN model is a powerful tool for this analytic purpose; therefore, all variable costs and fixed costs can and should be included. The conclusions reached by the forest may be valid but documentation is needed to support them, and to inform the public of the data, the tradeoffs, and the rationale used for decision making .

Logging Costs - (App., page B-65) Stumpage values used in the FORPLAN model were derived from sold timber sale data. It is not possible to determine from the text if logging costs were also based on sold volume or on harvested timber sale data. If different data sources were used for these two factors, a distorted economic analysis would result. The Final EIS should provide this information. Both stumpage value and logging costs should be based on harvested volume instead of sold volume so that timber sales which were returned to the Forest Service under the provisions of the Timber Contract Payment Act of 1984 are not inappropriately included in this analysis.

Existing stands which average 30 inches in DBH were assigned General Forest logging cost of $622 per thousand board feet (MBF). Future managed stands in General Forest were given an average logging cost of $556 per MBF for trees 24.1 inches in DBH or larger. It does not appear reasonable that logging costs for managed stands will be less than for existing stands of significantly greater diameter. The Siskiyou should explain the derivation of this assumption in the Final EIS.

Historical Costs - (App., page B-60) According to the text, the costs used in the economic analysis were derived from a variety of sources. Forest-wide average costs were derived from 1980 data. Cost for species type conversion were developed from 1980 data from one Ranger District. Logging costs are based on a 1973 to 1982 average while other variable costs used a 1975 to 1980 time frame. Overall, the Siskiyou has used inconsistent and outdated cost information which may not provide an accurate, recent historical average. In particular, the utilization of one year's data is totally inadequate for developing a new 10 to 15 year forest plan. The economic analysis should use the most recent cost information available and a standard time reference that includes several years.

Precommercial Thinning and Other Management Costs - (App., page B-62) The Siskiyou's precommercial thinning cost of $242 per acre is significantly higher than costs assumed by other landowners and agencies. Cost estimates from the Pacific Northwest Regional Commission, the Forestry Incentives Program, and from the Department of Forestry's own land managers indicate a cost of about $110 per acre is appropriate for southwest Oregon. The Southern Oregon Timber Industries Association cites an even lower cost on industrial lands.

Even if lower costs do not affect the land allocations of the alternatives or the outputs produced, they do affect the present net value, returns to the federal government, and payments to counties that each alternative can provide. The Siskiyou should examine all cost estimates, especially those with high administrative cost components, and seek opportunities to reduce them to a level that is comparable to other landowners in the area.

Regional Timber Demand and Supply Projections - (DEIS, page III-145; App., page B-52) All timber availability projections for southwest Oregon predict large drops in timber harvests on industrial ownerships during the next several decades. The most recent work by Forest Service Economist Kent Connaughton may support these conclusions (See Attachment 5).

This decreased supply comes at the same time as demand for wood products is predicted to increase. For example, building remodeling is expected to utilize 15 billion board feet (BBF) of the total 50 BBF of United States lumber consumption. At the same time, the 15 percent surcharge on Canadian lumber imports will reduce this imported supply source. Recent projections by Clear Vision Associates show that the bid price for westside Douglas-fir Forest Service stumpage is expected to jump from $187 per thousand board feet (MBF) in 1987 to $224 per MBF in 1988.

Japanese housing starts will total 1.71 billion in 1987, more than is expected this year in the United States. Because of the lowering of the value of the dollar relative to the yen, American lumber and logs will be more attractive in the Japanese market. The import share of softwood timber arrivals at Japanese sawmills will increase from the 1985 level of 52 percent to 60 percent in 1988. Douglas-fir log exports to Japan from Oregon and Washington in 1988 are expected to be 19 percent higher than in 1987. Total overseas exports from the two states will be more than 3 BBF next year.

These trends indicate that competition for a scarce resource, Oregon's timber stumpage, could increase dramatically in the coming years, benefiting those owning standing timber. Those companies without adequate fee timber could be severely damaged, unless adequate supplies of timber are available from the public ownerships in southwest Oregon.

With this intense competition for southwest Oregon stumpage, it is unrealistic for the Siskiyou to conclude that a horizontal demand curve exists for the forest's timber. A demand function could be calculated for use in FORPLAN. If this is not possible at a forest level, it is possible at a timbershed level. The southwest Oregon Subregional Market Model will soon be available to make reasonable estimates of stumpage demands for various ownerships. Region 6 may use this model in their analysis of the cumulative effects of the forest plans. A similar analysis should be incorporated in the Final EIS for the Siskiyou National Forest and provided to the public for review.

The alternative to recognizing the possibilities for increasing demand for public stumpage is a return to the destructive speculative bidding of the late 1970s. Such an action combined with restrictive monetary and fiscal policies on a national level could force Oregon's economy into another recession.

The Final Plan should also provide the analysis required by former Chief Peterson in his January 12 1987 memorandum to the Regional Forester The memorandum, entitled Planning the Management Of the Timber Resource on National Forest Lands provides specific guidelines for improving the discussion of timber supply/demand relationships by acknowledging recent events, changed conditions, and new information As Chief Peterson stated, " the rationale [behind the forest s conclusions] must be clearly articulated in the appropriate planning documents and our assumptions regarding potential future demand be reasonable and supportable

Historical Local Timber Supply and Demand - (DEIS, page IV-195) The Siskiyou National Forest has chosen to use the period 1980 to 1984 to represent historical timber consumption in the four county area Because of the recession the use of this time frame is inappropriate Using data from the years 1968 to 1977, the forest could have used a harvest level of 1,325 million board feet (MMBF), compared to the DEIS figure of 869 MMBF This older number is larger than the Siskiyou s high projection' for consumption until at least the year 2015

The 1986 Oregon Timber Harvest Report shows the four-county timber harvest level at 1,179 MMBF, up from the 1985 level of 1,125 MMBF Both of these years exceeded the Forest Service s high projections for the years 1986 to 1995 The harvest level may have been even higher if additional stumpage had been available for harvest

The Siskiyou s analysis appears to minimize demand by using recession-influenced historical data and undocumented future projections This analysis should be revised using the southwest Oregon Subregional Market Model as soon as it is available

Future Local Timber Supply and Demand - (DEIS, page IV-195) The projected future timber supply from other ownerships discussed in the DEIS is undocumented and is inconsistent with projections made by the Department of Forestry Oregon State University and the Forest Service s own researchers It appears that the Siskiyou has presented an overly optimistic view of the potential future timber harvests on adjacent national forests and other ownerships that downplays the importance of Siskiyou timber in meeting future demand in southwest Oregon

Attachment 5 of this review presents the most recent harvest projection for this part of the state It illustrates the dramatic drop in industrial harvests that will occur after 1990 The Siskiyou must improve it treatment of this critical issue in the Final EIS

Historical Economic Data - (App page B-84) The historical information presented on economic trends in the four-county area contains data that is at least four years old Since that time, the lumber and wood products industry has recovered and unemployment rates have decreased dramatically from the recession levels of the early 1980s More current information would not support the conclusions drawn from the text and the tables on pages B-84 to B-88

For example, except for Coos County, wage and salary employment for the first five months of 1986 was 2 8 percent greater than for the same period in 1985 This increase was greater than the Portland metropolitan area experienced According to 1987 Employment Division projections lumber and wood products employment statewide has increased by 7 percent since 1983 Payments to counties and stumpage prices have also increased during this period

By updating the data presented in this discussion, the Siskiyou will provide a more accurate summary of the economic trends in southwest Oregon

Community Stability - (App , page B-93) The Forest Service appears to be avoiding the community stability issue by stating that [c]hanges in national economic factors cause a much more profound impact on the economy of southwest Oregon than do changes in Siskiyou National Forest policies and actions" In fact, both of these factors are important As industrial timber harvests temporarily decline and as available supplies of old growth timber are reduced second growth timber will provide a greater proportion of the timber supply However, much of Oregon s competitive advantage lies in the unique strength and appearance qualities of old growth The Forest Service along with the Bureau of Land Management, will be the only available sources of high quality old growth timber in the coming decades

Opportunities for growth in personal income and employment lie in increasing the value added to the timber harvested The wood qualities needed for some kinds of remanufacturing are best provided by old growth Since the Siskiyou National Forest is a major supplier of old-growth in southwest Oregon, changes in the amount and quality of timber supplied by the forest can also cause profound impacts on the economy of southwestern Oregon.

Estimated Timber Selling Value - (App , page B-56) The Siskiyou s analysis appears to grossly overestimate the value of small diameter timber The table on page B-57 shows that 8 inch DBH trees are expected to have 62 percent of the selling value of 30 inch DBH trees However, current market conditions would probably require a tree to be a minimum of 12 inches DBH to make it profitable to haul it to the mill Therefore, trees less than 12 inches DBH should be expected to have a negative value These assumptions by the forest should be reconsidered

Benefits Used in the Economic Analysis - (App , page B-55) The economic analysis in the Final EIS should document the effect of the alternatives on timber harvest (privilege) taxes, public road use fees and taxes, and property taxes These are major sources of local government incomes and of highway construction and maintenance funds within the Siskiyou s zone of influence

Dependence on Larger Forest Budgets - (DEIS, page II-170) The preferred alternative calls for an annual budget of 21 7 million dollars, which is a 35 percent increase in funding over the 1987 budget of 16 1 million dollars (in 1982 dollars) Most of the other alternatives also require budget increases It may be unrealistic to assume Congress will approve such increases If funding is not approved, the plan provides no information on how the Siskiyou s activities and outputs would be modified

Without the inclusion of a budget constraint in the FORPLAN model, the capability to provide more efficient solutions cannot be explored A full range of possible management intensities may not have been presented Therefore, the tendency under a reduced budget is to cut programs rather than to manage the forest differently

A series of FORPLAN analyses for each DEIS alternative utilizing multiple levels of budget constraints could provide information on such management options These analyses will allow the forest plan to be implementable under a wider range of future conditions Disclosure of such detailed analyses will also help the Siskiyou satisfy NEPA requirements

NEEDED CLARIFICATION OF PLANNING DIRECTION

Salvage of Fire Killed Timber - As a result of this year s wildfires on the Siskiyou a significant amount of valuable timber has been killed or damaged Salvaging this material would reduce future fire danger and the risk of insect epidemics in addition to providing economic benefits by providing a needed supply of wood to local processors

The Department of Forestry supports the prompt salvage of this burned timber where it can be accomplished in an economical and environmentally sound manner However, before any salvage operations begin, more specific information is needed on the extent of the current and potential future damage to timber, soils water quality, and wildlife habitat (particularly spotted owl habitat areas) resulting from these fires

Any road construction for timber salvage access should be part of a long range transportation plan and not one-entry use roads Harvest units should be designed to facilitate future timber management and other resource uses

On a related subject, the Siskiyou should consider rehabilitating the burned lands inside Wilderness areas boundaries as these damaged forest lands could potentially affect resources outside the Wildernesses Increased sediment production, insect damage, and fire danger could all occur if no rehabilitation is done in these areas

Timber Inventory - (DEIS, page IV-93) The discussion of resource tradeoffs among the Siskiyou s proposed alternatives should include information on the long-term effects of these alternatives on the timber resource Data on the relationship between timber inventory harvests and growth, as well as the changes over the planning horizon in the number of working group acres by age class for each alternative should be provided in the Final EIS These reports are readily available from the FORPLAN model (Reports 10 6 and 10 8) and should be constructed to provide this information for suitable, tentatively suitable and-total forested lands

In addition, the Siskiyou s Final EIS should clarify the inventory discrepancies that appear in the planning documents and the FORPLAN reports The number of acres of mature, immature, and total suitable timber lands vary significantly among the Analysis of the Management Situation the DEIS, and FORPLAN reports 10 1, 10 8, and 10 9

Given the fact that inventory gaps may be a limiting factor on the Siskiyou s allowable sale quantity, it is essential that the Siskiyou insure that such gaps are not artificially created According to the Region 6 Task Force Working Paper on planning issues, artificial age gaps could result from inaccurately portraying any of the following factors

1 The number of acres of timber not yet merchantable

2 The volume and growth rates of merchantable stands

3 The time required for presently immature stands to reach 95 percent of culmination of mean annual increment

4 The time required for newly planted stands to reach 95 percent of culmination of mean annual increment

5 Age class assignments in the model

The Final EIS should document that these factors have been modeled accurately and explain how the first period FORPLAN inventory and growth correspond with the most recent empirical yield tables and field inventory plot data The Final EIS should also discuss the statistical validity of breaking the inventory down into individual analysis areas and the affects of this action on FORPLAN outputs

Nonchargeable Salvage Volume - (DEIS, page II-237) Table II-48 indicates that the existing timber management plan provides up to 5 MMBF per year of nonchargeable salvage volume The corresponding volumes under all the DEIS alternatives are unestimated" according to the table The Final EIS should display these volumes if they will be produced by the alternatives

O&C Lands - (DEIS page III-43) The Siskiyou National Forest manages 173,000 acres of Oregon and California Railroad (O&C) lands The lands are particularly important to local governments since 50 percent of the revenue generated by these acres is transferred to the counties for use in funding need services such as road projects and schools and in reducing property taxes Other Forest Service lands contribute only 25 percent of their revenue During the years 1980 to 1986, O&C lands contributed 22 percent of the Siskiyou s payments to counties while comprising only 16 percent of the forest land base

The Final EIS should provide information on the location of these O&C lands on the Siskiyou National Forest, how they are allocated among the alternatives and their contribution to payments to counties Opportunities should be explored to maximize the number of O&C acres retained in the suitable land base The Siskiyou DEIS alternatives currently allocate only as much as 89,000 acres, or 51 percent, of these lands to timber management

Road Management - (LRMP, page IV-50) Although not identified as a planning issue road construction and use is an important public issue on the Siskiyou National Forest The Department of Forestry supports a transportation policy which recognizes the importance of closing unneeded existing roads either seasonally or permanently and designing new roads to the minimum standard necessary to meet management and safety considerations

Benefits of regulated road closures include

1 An increase in the amount of effective big game habitat

2 Improved animal hiding cover effectiveness

3 More opportunities for high quality, semi-primitive hunting experiences

4 Reduced conflict between timber and big game management

5 Reduced road maintenance costs by reducing hunter traffic during wet fall months

6 Reduced potential for adverse effects on water quality from forest road use

Contrary to the discussion on page IV-149 of the DEIS it is the use of roads, not the existence of the roads themselves, which significantly affects big game habitat The Final EIS should emphasize this point and strive to manage road development and wildlife habitat so that both can coexist on the forest

Roads provide vital access on this rugged forest which is valuable in reducing the losses and costs from wildfires This summer s fire experience in southwest Oregon graphically demonstrated that the ability to quickly contain and control forest fires was directly proportional to the amount of road access The DEIS incorrectly assumes that roading only increases fire risk The Final EIS should also discuss the importance of roads in providing access vital to protecting all of the Siskiyou s valuable resources from wildfire

The "No Change Alternative - (DEIS, page II-63) The addition of the No Change alternative by the Forest Service is an attempt to address the concerns raised by the Northwest Forest Resource Council in its appeal of the formulation of the Current Direction" alternative These concerns, many of which are also voiced by this Department, involved the legal adequacy of a "no-action" alternative that included new yield tables a new land suitability analysis and the addition of MMR constraints

The Department appreciates the efforts of the Siskiyou to provide a meaningful alternative which, in our opinion, more adequately satisfies the requirements of NEPA and NFMA The No Change alternative appears to be a compromise approach that presents a more accurate, unaltered historical reference for public review in the DEIS

Research and Information Needs - (LRMP, page II-9) The Forestry Program for Oregon encourages research to improve forest productivity the economics of intensive forest management, and to identify the habitat needs of old growth preferring wildlife The Department of Forestry supports the research program outlined by the Siskiyou In addition to the list provided in the LRMP, we also believe more research is needed to

1 Develop new technology to return some of the 163 362 acres removed from the suitable land base because of regeneration difficulty back to timber management status Utilization of the latest Forestry Intensified Research (FIR) information is a key element of this process

2 Improve the knowledge of the habitat needs of old growth preferring wildlife species

3 Improve the forest s capability to estimate supply and demand relationships for Siskiyou timber

4 Develop a regeneration model for SW ORGANON

5 Develop methods for controlling the spread of Port Orford root rot

Monitoring and Evaluation - (LRMP, Chapter V & Appendix D) The Siskiyou s proposal for monitoring and evaluating the forest plan once it is implemented, is one of the most important sections of the planning documents It appears that the Siskiyou has developed a comprehensive monitoring program which will provide useful information on the performance of the plan Funding for this important program should be given a high priority by the forest

Some areas of the monitoring and evaluation program require revision First, the Siskiyou's use of very broad 'thresholds of concern" for several activities is inappropriate and could result in wide variations in forest outputs For example timber sale volumes would be allowed to be reduced by as much as 45 million board feet (30 percent) for two consecutive years before the forest would consider a plan modification In contrast, recreation and visual management activities use a 5 percent variability standard

It is essential that the Siskiyou recognizes that the cornerstone of the economic health of southwest Oregon is at least as important as the recreational and scenic opportunities on the forest The monitoring program should reflect this point The economic and social disruptions resulting from a 30 percent reduction in allowable sale quantity would be unacceptable and that potential could be avoided if a narrower variability standard of 10 percent was used This same standard should be used for all activities which affect community stability

Second, at least two important economic criteria are missing entirely from the monitoring program Personal income, and returns to counties should be monitored along with job numbers with a variability standard of 10 percent

Third the threshold of concern for timber demand appears to be incorrect Logic would conclude that a plan amendment or revision should be considered when the bid price to advertised price ratio exceeds 1 2 rather than when it is less than 1 2 Timber sales which are purchased at or slightly above the advertised price are entirely appropriate and should not trigger a change in the plan The occurrence of bid prices which exceed a ratio of 1 2 would be a reasonable threshold of concern in the measurement of timber demand

Finally, it is also unacceptable that the decision to amend or revise the plan be based solely on a subjective judgement by the Forest Supervisor For each monitored activity specific actions should be identified which will take place if the threshold of concern is exceeded For example if the appropriated budget for the forest prevents the Siskiyou from providing at least 90 percent of the allowable sale quantity (ASQ) proposed by the plan, the monitoring program should describe the plan amendment or revision process that will be implemented

Please refer to the Department of Forestry s November 6, 1986 correspondence to the Regional planning staff (See Attachment 6) for additional comments on this important issue

SUMMARY

1 Alternative "C is the only DEIS alternative that meets the objectives of the Forestry Program for Oregon The potential exists for the Siskiyou to craft additional alternatives in the Final EIS which fully satisfy the FPFO objectives and provide a balance of resource uses, benefits and values

2 The forest plan should demonstrate closer coordination with Department of Forestry programs, particularly in the areas of fire management smoke management and riparian area protection Specific discussion is needed to explain the potential conflicts that the Forest Service perceives will exist between the administration and enforcement of the Forest Practices Act on private lands and the Siskiyou s policies, standards, and guidelines

3 Planning assumptions and decisions on the subjects of minimum management requirements, snag management, unroaded area allocations, old growth habitat managed yield tables, Wild and Scenic River designations, visual management, harvest scheduling and geotechnical methodology all have a direct effect on timber output levels These assumptions and decisions require additional discussion and potential revision in the Final EIS

4 Factual errors and omissions in the planning documents may lead the public to conclusions that are incorrect Discussions in the Final EIS on the subjects of sediment yields optimum wildlife habitat mix, fixed land allocations, and economic and social background information

5 Shortcomings in the Siskiyou s economic analysis have likely distorted the costs and benefits associated with the DEIS alternatives In particular, the assumptions on timber supply and demand may be underestimating the importance of this output from the Siskiyou National Forest to Oregon's economy

6 Additional information should be provided in the Final EIS in the areas of salvaging fire killed timber, timber inventory, O&C lands, road management, research needs, and the Siskiyou s monitoring and evaluation program

GEOTECHNICAL REVIEW OF THE SISKIYOU NATIONAL FOREST
DRAFT ENVIRONMENTAL IMPACT STATEMENT

Keith Mills, Geotechnical Specialist, P.E
Oregon State Department of Forestry
Forest Practices Program

October 28, 1987

The purpose of this review is to evaluate the geotechnical methodology found in, and used in development of the Siskiyou Proposed Land and Resource Management Plan This methodology includes the description and models of mass and surface erosion, the Best Management Practices for the transportation network and silvicultural harvesting operations, and the cumulative effects model The Siskiyou National Forest has a geology and climate significantly different from other forest lands in Oregon. The complex, highly folded and faulted metamorphic geologic units, and the variable and generally high amounts of precipitation are together unique to the southwest corner of the state This review considers the relevant data and literature available to the forest, and what assumptions the planning team used with this information to prepare those portions of the plan addressing geotechnical problems

Two models and one inventory were used in development of the soils-sediment portions of the plan. The models and inventory are discussed only briefly in the plan itself. Descriptions of the models and inventories were available to OSDF, and were evaluated for this review. The models describe the surface erosion process and cumulative effects. A landslide inventory for the Siskiyou Forest was used for data on mass soil movement

The surface erosion model uses site specific soil resource inventory and geomorphic indices, combined with reported literature values, to determine base surface erosion levels, and effects of forest practices The cumulative effects model consider four factors. The geologic factor is the only one considered here. The geologic factor is based on slope steepness (between 55% and 90%) and rainfall The mass movement inventory was based on a detailed aerial survey of about 10 percent of the forest To calculate total sediment delivery for the various alternatives, the sediment model and landslide inventory were included in FORPLAN Thus, accelerated sediment production was based on anticipated levels of harvesting and road construction

The surface erosion model is based on the best available information I am impressed with the methodology used. The landslide inventory appears rather complete except for two limitations

- An air photo inventory, as used to identify failures, is biased against landslides hidden under forest cover, and
- road failures are based on older practices, and may overestimate failures and sediment production with current Best Management Practices.

It is not clear why slope and rainfall were used in the cumulative effects model Actual sediment delivery could have been calculated for a geologic hazard rating using the sediment model and the mass-movement inventory There

does appear to be some correlation between actual problems and the geologic index However, no correlation data was included in the description of the cumulative effects model

In the plan, the discussion of specific silvicultural systems and their effects is quite complete On the other hand, the impacts of the transportation network are only briefly described Similarly, surface erosion is described in great detail, especially related to burning, yet there is almost no discussion of mass soil movement The plan refers to Best Management Practices (silvicultural nonpoint from section 208), USFS standards and guidelines, and Water Quality Management Guidelines for National Forests in California, for guidance on water quality protection

Because of its rather unique geology, the Siskiyou has a few special needs for certain management practices, especially those associated with roads What location and design factors are considered for roads through land flow, or steeply dissected terrain in folded-faulted metamorphics? The plan states that BMP's will be developed after the plan is final How can they be evaluated unless they are included in the draft plan?

The planning team has a lot of experience on the Siskiyou National Forest, and represent a wide range of professional fields The two soil scientists on the team have a good understanding of erosional processes I talked to Mike Amaranthus, one of the soil scientists, on the phone He answered my questions regarding the models and inventory There was no geotechnical professonal (a person with training and experience in both the field of geology and engineering) on the planning team The plan includes only a minimal discussion of mass soil movement, especially as related to road construction practices, even though the landslide inventory shows a great increase in the rate of mass soil movements associated with roads (over background, or related to harvest unit levels) There is information available on road building practices which mitigate landslide problems, though nothing specific was found in the plan. A geotechnical professional could have helped in this aspect of the plan preparation

Conclusions

1 The surface erosion model appears to be very well designed

2 The use of the landslide inventory to calculate sediment has two limitations

   a. The aerial photo inventory probably did not detect all landslides in forested terrain, as they may have been difficult to see under the trees

   b Road failures based on older practices may over estimate future slides and sediment production using current best management practices

3. Utilizing actual sediment delivery as calculated using the model, inventory, and FORPLAN would probably be more appropriate for assessing geologic hazard, than using slope steepness and rainfall

4 A more complete discussion of best management practices, especially those relating to mass soil movement and the transportation network, is needed in the final EIS

5. It is unclear how the results of the cumulative effects model were used to generate the harvest dispersion factors and riparian prescription in the DEIS alternatives

6 The final EIS should consider other impacts, in addition to sediment delivery to streams For example, mass soil movement may impact the transportation network, in-stream structures, or downstream water users

Department of Geology and Mineral Industries
ADMINISTRATIVE OFFICE
910 STATE OFFICE BLDG , 1400 SW 5th AVE , PORTLAND, OR 97201-5528 PHONE (5

November 18, 1987

Bob Brown, Director
Oregon Department of Forestry
2600 State Street
Salem, OR 97310

Dear Mr. Brown

The Oregon Department of Geology and Mineral Industries has reviewed the Draft Environmental Impact Statement for the Siskiyou National Forest. From our minerals perspective some very fundamental key issues seem to arise in the Environmental Impact Statement. This letter briefly summarizes the issues in the hopes of enabling the Forest Service to better address the minerals problem.

A major concern is the need to quantify the value of the resource and need to factor the resource value into the various alternatives for land use. In terms of quantification, we find that numerical dollar values for the mining resource are not provided From an economic standpoint, this is particularly troublesome because the per-acre value of mining land greatly exceeds any other per-acre value for other uses. In terms of alternative land uses, we find very little discussion of minerals access or mineral policy direction in the alternatives.

We are concerned that mineral resource potential apparently was not used as a constraint factor in the computer development of alternatives This is a severe and fundamental shortcoming in the analyses.

Thirteen of the fourteen management areas have some negative impact on mineral resource development all the way from minimal, for #13, to complete prevention, as with #1 (Wilderness), #2 (Wild River), #3 (Research Natural Area) and #4 (Bontanical).

Area #5 (unique Interest Area) and Area #6 (Custodial Roadless) are highly restrictive to mineral resource development. Area #7 (Supplemental Resource) allows mining subject to mining regulations and an approved operating plan. In area #8 (Designated Wildlife Habitat) mining could be done where activity is not detrimental to habitat In area #9 (Special Wildlife Site) mining can be conducted; but must insure that activities detrimental to identified special site values be minimized Area #10 (Scenic/Recreation River) is withdrawn from mineral intry In area #11 (Riparian) mining can be done, but operating plans shall include measures to protect or regenerate riparian vegetation, protect water quality, and provide stream bank stability. In area #12 (Retention visual) mining plans need to protect visual objectives. Area #13 (Partial Retention Visual) is the same as 12. Area #14 (General Forest) calls for multiple use retention

Most of the known nickel laterite areas that lie outside the wilderness have been proposed or designated as "Botanical areas" (e.g., Iron Mtn , Red Flat, Snow Camp, Cleopatra, Rough and Ready Flat, Eight Dollar Mtn , and Oregon Mtn). The Hoover Gulch Research Natural area (Page F-147) is an area of known small, but rich gold deposits An active mine being worked (Gold Blanket and Windfall claims on Pocket Knoll in Sec. 14) about 1/4 mile south of the RNA.

If it can be determined that the mineral deposit is clearly of economic importance, (i e., a potentially profitable mining operation) adjustment should be made to allow this mining operation, provided a suitable reclamation plan is developed This is especially true of strategic mineral deposits such as chromite, platinum, and cobalt Economic mineral deposits are rare and unusual occurrences in the earth's crust. Availability should be protected in order to remain open and accessible to the most efficient production methods. The withdrawal of lands from mining access is an economically undesirable solution. Unnecessary encumbrances and restricitons to mineral resource exploration and development should also be avoided whenever possible It is inappropriate to overlook mineral resource values as an analytical factor leading to ratings in the development of alternatives.

A major goal of the Department is to maintain a strong well-planned mineral resource base for the State of Oregon and to see that mined lands are reclaimed This Forest plan makes the attempt to recognize that there are minerals and

mining, but does not adequately consider minerals in designing alternatives or recommendations for land classification The data that are provided are not utilitzed in a meaningful way and do not dispaly the impact of the various alternatives on mineral production.

For Oregonians, the economic productivity of National Forests in Oregon needs to be evaluated in terms of all potential revenue sources, not just timber and recreation Our declining economic yield from forest lands in terms of employment, tax base and Federal revenues is due in part to historical overdependence on timber and recreation values Mineral resource values should be vigorously evaluated in the current U.S Forest Service planning process

Sincerely,

John D. Beaulieu
Deputy State Geologist

STATE OF OREGON INTEROFFICE MEMO

TO K Norman Johnson DATE January 22, 1988
Federal Forest Plan Coordinator

FROM Ann Hanus, State Economist
Executive Department Office of Economic Analysis

SUBJECT Summary of Findings and Recommendations for the Siskiyou National Forest Plan -- FINAL

Overview

I have reviewed the Draft Environmental Impact Statement and Proposed Land and Resource Management Plan for the Siskiyou National Forest The Employment Division provided analyses which have been used in my response

The Siskiyou National Forest is situated in the southwest corner of Oregon and northern California Coos, Curry, Jackson, and Josephine counties rely most heavily on the Forest, particularly for its wood products, fishery resources, tourism and recreation attractions, visual and wildlife amenities, and minerals

The four counties are a study in contrasts While all four counties depend greatly on their lumber and wood industry, they have not enjoyed the same rate of growth In 1986, Coos, Curry, Jackson, and Josephine counties had 73 percent, 89 percent, 65 percent, and 60 percent of their manufacturing workers employed in the lumber and wood industry (Table 1) In comparison, the statewide proportion was 32 5 percent

Coos, Curry, and Josephine counties suffered higher unemployment rates than the statewide average in 1986 Coos and Curry counties have yet to recover to prerecessionary employment levels In 1986, Coos County had only 84 percent of the employment it enjoyed in 1979 Further, since 1980, Coos and Curry counties lost 6 5 percent and 0 8 percent, respectively, of their population

Jackson County, on the other hand, ranks among the fastest growing counties in the state While still heavily dependent upon lumber and wood, its economy is more diversified It surpassed prerecessionary employment levels by 6 5 percent in 1986 -- considerably better than other southern Oregon counties and even better than the state, which just attained prerecessionary levels

Jackson County's population grew by 5 7 percent, more than double the statewide rate Salazar, Schallau, and Lee revealed that immigration of retirees was an important component of population growth in Jackson County (Table 1) Josephine County also demonstrated considerable population growth, expanding by 15 8 percent since 1980

The recession of the early 1980's hit the four counties hard, especially in the wood products industry From the peak of 1979 to 1986, the four counties lost 17 4 percent (2,556) of their wood products jobs and 13 0 percent (54) of their firms (Table 2) Payroll rose a mere 4 3 percent over the same period Coos County suffered the most, losing 30 1 percent or 1,600 workers At the same time Coos County payroll dropped $16 7 million or 17 2 percent

Recently, employment has moved upward in all four counties because of an improving wood products industry The volume harvested in fiscal year 1987 amounted to 194 4 MMBF -- the highest since 1979 (Graph 1) The volume sold hit 203 3 MMBF, the highest since 1976, but this includes buyouts that were reoffered The 10-year average (1978-1987) was 128 8 MMBF, but this figure includes the 1981-83 recession years when only a fraction of the current level was harvested

From 1975 to 1984 timber purchasers bought an average of 193 2 MMBF and cut an average of 144 9 MMBF annually (all products, including sawtimber, salvage, and submerchantable material) The severe recession of the 1980's caused lumber and plywood prices to plummet and resulted in less timber being harvested than sold Many purchasers retained a large volume of high priced timber under contract with the Siskiyou National Forest As a result, timber harvests declined to 39 4 MMBF in 1982 from 202 MMBF in 1979 (Graph 1) Also, purchasers harvested their less expensive timber in order to stay competitive

According to the Forest Service, the average bid price in 1982 for timber in the Forest was $129/MBF (all products), while the average price paid for timber cut on the Forest was $82/MBF (all products) The volume sold in 1985 amounted to -230 0 MMBF because a buy-out adjustment of -412 5 MMBF was made Likewise, the higher numbers shown for volume sold in 1986 and 1987 (197 2 MMBF and 203 3 MMBF) includes reoffered buyouts Since the recession so skewed the volume sold and harvested during this period, they should be viewed with caution

Recreation plays an important role in the region's economy In 1987, 15,800 people rafted the wild section of the Rogue River Commercial operators claimed 7,800 of the rafters On the lower Rogue, 47,000 people journeyed the river in tour boats Another 8,000 covered the same stretch on rafts

The commercial fishing industry also plays an important role, especially the harvesting of anadromous fish Environmental conditions in the forest directly affect the size and quality of commercial harvests Further, recreational fishing also attracts a significant number of tourists

In addition to timber, recreation, and fishing, the Siskiyou contains occurrences of gold, silver, nickel, chrome, cobalt, copper, manganese, molybdenum, mercury, coal, limestone, and other minerals Of these, nickel cobalt, chrome, manganese, and mercury are classified as strategic minerals According to the Forest Service, gold has been the most sought

after mineral in the Forest, with a prospecting and production history (from both placer and lode deposits) dating back to 1850 Exploration has taken place for nickel, cobalt, and chromium, but no mining is taking place

The Forest Service recommends Alternative K as their preferred alternative The Forest Service proposes to harvest 150 MMBF per year that would result in a gain of 380 jobs (compared to 1975-84 historical conditions), $9 0 million increase in personal income, and $12 4 million to counties Most of the job gain is related to the higher harvest level In terms of present net value, Alternative K is ranked ninth among the 13 alternatives

Comments

1 The Forest Service intends to manage 507,000 acres of selected suitable lands for some form of timber outputs at the annual rate of 150 4 MMBF under their preferred Alternative K Compared to the 1975-84 average, employment would rise by 380 while personal income would increase a corresponding $9 0 million Most of the jobs increase (371) is due to a higher timber harvest when viewed against the 1975-84 average of 144 9 MMBF

These time frames must be taken into consideration, however, in evaluating the impact of the plan Current harvest levels compared to the levels proposed by the plan yield different results Harvest levels for 1986 and 1987 were considerably above the 1975-84 average (150 7 MMBF and 194 4 MMBF, respectively) As a result, the estimated job gain of 381 has already been realized Since the proposed harvest is below the 1987 level, job losses might even occur

Compared to the current direction, the proposed allowable sale quantity of 150 MMBF is a reduction of 13 MMBF Again comparing to the current direction level of 163 MMBF, the proposed plan would mean a reduction in the potential number of jobs by 200 (over all activities, but heavily determined by the timber output effect)

The range of employment change over all alternatives and all activities compared to the past decade spans from a decrease of 1,650 jobs (Alternative M) to a gain of 1,230 jobs (Alternative B) The preferred alternative falls somewhat to the positive side of midpoint between those figures It attempts to balance the many conflicting demands made by the many forest resource users

2 The Forest Service should consider the impact of projected falldowns in private industrial harvests occurring during the 1990's through 2020, and try to mitigate the impact of the sharp decline if possible The Forest Service should coordinate and consider the cumulative impact of its timber sale program with other forests and land ownerships

3 In Appendix B, in the sections on employment and income, much of the information and data regarding labor market status, employment, unemployment, income, and county revenues from forest receipts are old and should be updated Most of the latest economic data is from 1983 when the state was still in a deep recession More recent information will paint a very different picture

4 About 230 MMBF of Siskiyou National Forest timber was damaged in the recent forest fires The Forest Service plans to salvage about 175 MMBF beginning within the next year The Forest Service will substitute the salvage for green sales although some green sales will still be made in order to make logical units As a result, the Oregon sales should not be much different from the most recent harvest levels for the next two years California sales, however, will amount to 1,600 MMBF, and this quantity will significantly impact the market since some of the Southern Oregon mills purchase timber from California In order to maintain the value of the timber, it should be salvaged promptly The longer the delay, the more likely that bugs and rot will lower the value of the timber

Further, counties will probably not realize as much revenue from the salvage sales compared to green sales for two reasons First, salvage timber will not command as high stumpage prices, and thus gross revenues will be lower. Second, instead of receiving a share of gross sales as would be the normal situation, counties receive a share of net sales under a salvage sale

5 Most of the effect of this plan will occur in Curry and Josephine counties which have been the main users of the forest's timber supply in the recent past In the last decade, the amount of timber coming to the local mills from the Siskiyou National Forest declined in Curry County from about 75 percent to just over 50 percent, while that for Josephine County remained at just over 25 percent Coos and Jackson counties draw about five percent or less of their timber from the Siskiyou National Forest (DEIS, Table III-45). Lately, with mill openings since this data was gathered, Curry County probably receives a greater share of the timber

6 Recreation, an important segment of tourism, is expected to have no increase or decrease in either jobs or income under the preferred alternative The Forest Service should take care to protect the view shed of the Rogue River which is important for the tourism it attracts Diversification of the economy benefits the region because its dependence on the wood products industry makes it subject to boom/bust cycles

7 The Forest Service uses IMPLAN which relies upon 1977 data for determining linkages between industries Much change has occurred in the structure of the local economies and in the structure of the areas' wood products sectors since that time Much of that change has been driven by the real economic events of declining demand

(especially during the recessionary years for Curry and Josephine counties), technological change, lower average real labor costs, and the rapid cutting of a sizeable portion of private timber land

It would appear that a more realistic mode could be constructed if more up-to-date information were employed The effects of these changes, many of them national in character, on the projected trends in employment, income, payments to local jurisdictions and other economic variables could be considerable, but the most recent data are not part of the model used for this plan

Given the data and time frames used, however, the timber employment response coefficients appear to be sufficient to model relative changes in employment among the alternatives Caution should be added when using them to determine the absolute number of jobs produced by each alternative or for comparing alternatives among forests for several reasons

Different IMPLAN modeling techniques are used by different forests, and it would be inappropriate to add them together In addition, the employment estimates are imprecise Final demand is usually changed at the sawmill and plywood sectors, and transportation beyond the mill is not counted nor is any secondary processing Also not taken into account is the frictional and structural employment which would result as timber harvests are lowered Mills may be reluctant, for example, to lay off workers, they might opt to keep work forces larger than would be optimal

Complicating the situation are mills which would close because of lack of timber, such as cutting mills and mills with marginal operations rather than dimension mills The result would be that the employment effect of lowering harvest levels would be greater than what might have been anticipated if average production functions are used

8 Significant differences exist between alternatives on the amount of O&C land managed for timber production The range varies from Alternative M, which only manages 29,000 O&C acres for timber production to Alternative C which manages 89,000 acres Alternatives NC and C have the most O&C land managed for timber production with Alternatives A, A-departure, B, D, D1, K, and K-departure not far behind (DEIS, p IV-188) Allocation of these acres have a significant effect on counties and induced employment and personal income This is because counties receive 50 percent of O&C receipts versus 25 percent on remaining Forest land The Forest Service should consider maximizing timber production on these lands in order to increase county revenues

9 Relative demand for Siskiyou timber is higher than any other Oregon national forest according to Forest Service appraisals for both the value of Siskiyou timber at the mill and from logging (Graph 2) The reasons could be high timber quality, perceived shortage of

timber in the zone of economic influence, and high value end products Highly valued species such as the Port Orford Cedar, which the Japanese covet, contribute to the high demand figures These figures underscore the value of Siskiyou timber to wood processors in Southwest Oregon The Port Orford Cedar, however, is threatened by fatal root disease The Forest Service may want to review its plan to take highly valued species into account when finalizing their plan

10 The Forest Service should revise their comments about exports to the Pacific Rim counties The Forest Service states that "projections of exports to the Pacific Rim countries show a continuing slow economic growth" (DEIS, p III-145) In light of large export increases over the last year and the falling dollar, export prospects look very bright Further, Japanese housing starts may equal or exceed U S housing starts, thereby keeping the demand for Northwest wood products high

11 The Forest Service should not assume that the demand for timber harvest in the area surrounding the Siskiyou National Forest is infinitely elastic Since the Siskiyou National Forest is a major supplier for many mills, its actions will affect price and market conditions National economic trends play a major role, but the impact of the Siskiyou National Forest plan will be critical to the region

12 The Forest Service should improve their plan for monitoring economic variables In addition to the unemployment rate, employment by major SIC code, personal income, and population should be tracked

13 The Forest Service will be releasing its final guidelines for the Spotted Owl in the near future If its final guidelines significantly change the land allocations and proposed management under the new plan, the regional economy will be affected A lower harvest, due to more habitat needed for the spotted owl, could translate into fewer jobs and lower personal income

14 In addition to revealing the effect on county revenues, the Forest Service should also estimate the effects on timber harvest taxes, public road use fees and taxes, and property taxes These revenues are important sources for local governments and schools Furthermore, a chart of how O&C revenues are distributed by county, and projected National Forest and O&C county revenues should be included

15 Implementing the preferred Alternative K would require an annual budget of $21 7 million -- a 35 percent increase in funding over the 1987 budget of $16 1 million (in 1982 dollars) Given Congress' drive to lower the federal deficit, the Forest Service may face a difficult task to have this higher budget approved

16 Restrictions on land use could adversely affect mining efforts if the restrictions place too high of costs on operators to operate their mines profitably The Forest Service should consider how plans will affect the operations of miners

IN REPLY REFER TO
RES JH
R&S 2

December 3, 1987

TO Ann Hanus, State Economist

FROM D R Steward, Ass't Administrator
Address for Research & Statistics

Subject Siskiyou National Forest DFIS

The attached comments from John Anderson, regional economist for Southern Oregon, address the seven issues you identified In addition to these comments, the following points are offered to assist you in responding to the Siskiyou NF Draft Plan

1 In Appendix B on pages 79-80, there is conflicting information on the degree to which Curry County mills are dependent upon Siskiyou NF timber supplies The table on page 80 indicates that Curry's log flow dependency has declined from 73% in 1972, 54% in 1976 and to 25% in 1982 However, the narrative on page 79 states that "Curry County is also the most dependent on the Siskiyou, receiving more than half of its timber supply from this source" Which is correct?

2 In Appendix B in the sections on employment and income much of the information and data regarding labor market status, employment, unemployment, income and county revenues from forest receipts seems to be old and in need of updating For example, on page B-84 the counties' status as "labor surplus" and "economically lagging" areas in 1981 and 1982 are cited, rather than using more current 1986 or 1987 information

3 In 1987, the timber harvest on the Siskiyou NF will be close to 200 mmbf due to very strong market demand for wood products Since this year's level of harvest is well above the average annual levels of the preferred Alternative K, Alternative A, and the past decade, the comparison's relating to employment and income changes between the preferred alternative and the "current direction" (Alternative A) should not be confused with the current year level of economic activity In other words, the 200 job loss shown in the table on page II-170 between the preferred alternative and the "current direction" Alternative A, is likely to be significantly higher if compared to the 1987 level of employment and economic activity

4 The economic impacts from the recent forest fires on the region's economy are still largely uncertain While about 230 mmbf of Siskiyou NF timber was burned, much of this wood is still salvagable, if logged within a couple of years It appears, at present, that Forest Service officials plan to have this timber logged within the existing limits of annual allowable sale quantities so the impact on logging activity in the next few years may not be that much different than if the fires had not occurred The actual level of harvesting which occurs will be determined much more by overall market conditions and demand for wood products One of the biggest impacts, however, in the next couple of years will be in reforestation activity, which is a fairly labor intensive activity

I hope these comments are helpful Please let me know if you have any questions or need additional information

Subject Siskiyou National Forest Proposed Land and Natural Resource Plan

In releasing the draft plan for comment, the Siskiyou National Forest planners correctly understand that any plan involves choices among alternatives They correctly state that an increase of any particular forest output requires the reduction of other outputs or outputs no matter which of the alternative outlined in the draft plan are selected As with any carving up of a scarce resource among competing users, tradeoffs will need to be made between and among the various forest products. A posture of "more of everything" is ruled out by reality and the finite nature of the resource base

Most of the effect of this plan will occur in Curry and Josephine counties, which have been the main users of the forest's timber supply in the recent past In the last decade the amount of timber coming to local mills from the Siskiyou National Forest declined in Curry County from about 75% to just over 50%, while that for Josephine County remained at just over 25% Coos and Jackson County draw about 5% or less of their timber from the Siskiyou National Forest (DEIS, Table III-45) The forest plan rightly makes the point that these areas have become not just timber dependent but forest dependent The Siskiyou National Forest must balance a broad range of demands upon all of its resources, not just satisfy the current and future demand for commercial logs

The Siskiyou National Forest currently is in a deficit position in terms of of its timber inventory while it could harvest a maximum of 180 mmbf over the first decade and still maintain a non-declining yield during subsequent decades, it would do so only by meeting only the minimal management required for all other outputs This would prove politically difficult to accomplish

To balance competing uses for forest resources the Siskiyou National Forest plans as its preferred alternative to reduce the annual timber sale quantity to 150 mmbf from the current direction's 163 mmbf (see DEIS, p II-169) This the plan states will allow an increased cut in future decades when young stands have matured to a harvestable size

This means that wood products users and communities may need to become used to having slightly less timber than has been supplied recently from the Siskiyou National Forest in the short run to insure a sustainable non-declining flow in future years

The employment result of the preferred alternative is to reduce the potential number of jobs by 200 (over all activities, but heavily determined by the timber output effect) from the current management direction However, when the preferred alternative results are compared with the actual average harvest of the recent (1975-1984) period, the plan anticipates an actual increase in employment of about 380 The range of employment change over all alternatives and all activities compared to the past decade is from a decrease of 1,650 jobs (Alternative M) to a gain of 1,230 jobs (Alt B) The preferred alternative falls somewhat to the positive side of the midpoint between those figures It attempts to balance the many conflicting demands made by the many forest resource users

In terms of annual income the preferred alternative predicts a reduction of almost $5 0 million when compared with the income generated by the current direction (Alternative A), but an increase of $9 million when compared to the average harvest levels of the 1975-1984 period (see DEIS, p II-170)

The fisheries resource is enhanced and maintained by good water quality Road building and timber cutting can reduce the water quality upon which fish species depend by fostering erosion and sedimentation The preferred alternative has less road construction and timber harvest overall than does the current direction and several other alternatives Increased harvesting in some now-roadless old growth areas may require careful attention to soil stability and to water quality There could be some real tradeoffs in these areas between timber output and fisheries output

Wildlife user days in the first decade are expected to decline from 76,400 under the current direction to 75,400 under the preferred alternative (see DEIS, p II-168)

Recreation, an important segment of tourism, is expected to have no increase or decrease in either jobs or income under the preferred alternative The current direction seems to swap a limited amount of jobs and income from developed recreation to wild and scenic rivers recreation

Of concern to residents in each locale is the amount of governmental service that will be paid for by O & C and other forest receipts The preferred alternative envisions a decrease in the amount of revenue of about $1 million per year when compared to alternative A, the current direction Effected most heavily by this will be Curry and Josephine counties (see DEIS, Table III-42)

The Siskiyou National Forest draft plan uses IMPLAN which relies upon 1977 data for determining linkages between industries Much change has occurred in the structure of the local economies and in the structure of the areas' wood products sectors since that time. Much of that change has been driven by the real economic events of declining demand (especially during recessionary years in Curry and Josephine), technological change lower average real labor costs, and the rapid cutting of a sizeable portion of private timber land It would appear that a more realistic model could be constructed if more up-to-date data were employed The effects of these changes, many of them national in character, on the projected trends in employment, income, payments to local jurisdictions, and other economic variables could be considerable, but the later data are not part of the model as it derives its results

In addition, the plan should not be considered completed unless the management plans of all other sources of timber supply, public and private alike, are taken into account Reductions in cut on Siskiyou National Forest lands will mean increased competition and higher prices for the reduced supply of merchantable timber on the other public and private lands The input/output model and analysis should consider at least all other forest resources within a reasonable region in considering the economic impact of changes in forest management

While the public has been contemplating forest plans, the region has experienced its worst spate of forest fires in recent memory The full impact of the fire on the Siskiyou National Forest and on the economies of the region will not be assertainable until the fires are actually out for one thing For another, an inventory of the areas burned by the fire will need to be done to see how much of the timber is merchantable Decisions will need to be made as to what and how much might be offered for sale, to whom, and how it will be scheduled for harvest

OFFICE OF THE GOVERNOR
STATE CAPITOL
SALEM OREGON 97310 1347

January 13, 1988

TO Norman Johnson
Federal Forest Plan Coordinator

FROM Robert Schumacher, Administrator
Executive Department
Intergovernmental Relations Division

SUBJECT Intergovernmental Relations Division Preliminary Review of the Proposed Siskiyou National Forest Plan Impacts on Community Stability, Local Government and School Financing

Our preliminary review of the proposed Siskiyou National Forest Plan relates principally to the three counties (Coos, Curry and Josephine) and the sixteen public school districts in these counties whose financial structure is directly impacted by the 1,002,522-acre Siskiyou National Forest located within these counties The counties and schools are third and fourth party recipients, respectively of timber sales from these federal forest lands sharing 25 percent of the receipts (75 percent designated to county roads and 25 percent to public schools), with 75 percent going to the federal treasury

The proposed plan contains thirteen different alternative management plans from the one now existing, five of which, including its preferred Alternative K plan, will cause substantial unemployment in the forest products and related industries This is a direct contradiction to Governor Goldschmidt's agenda for economic development and the Economic Development Department's primary goal of developing jobs for Oregonians and assisting in resolving the State's major problem of financing public schools

The resurgence of Oregon's timber-based economy during the past few years following the major recession years in the early 1980's is not reflected in the proposed Siskiyou Plan, nor does the plan consider the contribution of the other federal forest lands in the region which also impact community stability in the counties in which the Siskiyou National Forest is located

In addition, the present financing programs of county government and public schools from federal timber receipts have been again threatened in Congress this past year in a proposal to change the distribution formula from payments to counties and public schools on the present gross receipts basis to payments on a net receipts basis Such a reduction would add further to the existing problem of financing public school support and would be a financial disaster for some counties

The Siskiyou Plan preferred alternative proposed decrease of over 10 percent in the annual sales quantity is a continuation of a steady erosion of the declared annual cut and comes at a time when the future availability of private timber in the same region appears to be headed into a decline The accuracy of timber supply to provide the current level of jobs in this region in the next ten-year period of the proposed plan is seriously questionable

The information upon which the proposed plan is based was outdated by the three major fires in the Siskiyou National Forest in 1987, which burned over 110,000 acres of the federal forest land The impact of timber receipt revenue to local government and public schools is a key element in establishing any position on the presently proposed forest service alternative until final salvage data is available

Another key element requiring more data in responding to the proposed plan is the lack of information in the plan on the direct and indirect economic impact of changes in timber supply on the Coos Bay port, the railroad serving the area, and highway improvements between the valley and coastal regions

This division suggests the State's response at this time recommend that the Siskiyou National Forest respond to the concerns addressed herein and that the State's posture be one of providing a State alternative to the proposed plan which will provide for environmentally sound intensive forest management in cutting practices on the Siskiyou National Forest to assist in forestalling any major downturn in Oregon's timber-based economy, due to shortage of timber supply

It is our understanding that this response will be open-ended so that we can continue to assist in forming the State's alternative

We appreciate the opportunity to participate

EXECUTIVE DEPARTMENT

Department of Energy

625 MARION ST. NE, SALEM, OREGON 97310 PHONE 378-4040 TOLL FREE 1-800-22

TO: Norm Johnson, Federal Plans Coordinator

DATE: December 14, 1987

FROM: Mike Byers, Technical Assistance Program

SUBJECT: Siskiyou National Forest Proposed Plan

The Oregon Department of Energy (ODOE) has reviewed the Siskiyou National Forest Proposed Land and Resource Management Plan, DEIS, and Appendices. The comments below are for the coordinated state response.

For the Siskiyou National Forest ODOE is interested in policies and standards for siting large power projects and transmission line corridors. The proposed forest plan and DEIS address both of these interests

Hydroelectric and Wind Resources

The DEIS (pp III 21-24) correctly describes several factors that limit the need for, and development of, hydroelectric and wind resources under current conditions.

Please note, however, that specific information on the proposed Eden Ridge pumped-storage facility (p. III 24) is not correct. The Eden Ridge project size was 90 megawatts, not 4,000,000 kilowatts as described in the DEIS. (A 4,000,000 kilowatt project would be about 2/3rds the size of Grand Coulee Dam.) And, the Eden Ridge project was terminated by FERC notice of January 20, 1984.

The forest plan does not provide guidance or standards for the evaluation and siting of large power generating plants within the forest. Although the possibility of developing such a plant during the next decade or two is low, the plan should still reference federal and state standards for major power projects.

Transmission Lines

Oregon's Energy Facility Siting Council (EFSC) is responsible for the review and approval of electric transmission lines in excess of 230 kilovolts and natural gas lines at least 16 inches in diameter.

ODOE generally agrees with the Forest Wide Standards and Guidelines #9-6 regarding the use of existing corridors for new utility line requests. The Standards further states that:

> "Additional corridors which may be needed by major utilities should be designated through an interagency environmental analysis following procedures set forth in the Regional Plan." (Proposed Land and Resource Management Plan, pp. IV 46,47)

Major transmission lines may cross several political and regulatory boundaries. The development of new utility corridors requires the coordination and action of several agencies.

Standard #9-6 should be made mandatory by using 'shall' in place of the word 'should'. This change would be consistent with the description of the intent of 'shall' and 'should' as described in the Forest Wide Standards and Guidelines .

If you or Bob Brown have questions or need additional information, please call me at 378-2856.

OREGON DEPARTMENT OF AGRICULTURE
COMMENTS ON THE SISKIYOU NATIONAL FOREST
PROPOSED LAND & RESOURCE MANAGEMENT PLAN
AND DRAFT ENVIRONMENTAL IMPACT STATEMENT

The Department of Agriculture is impressed with the overall quality of the above-referenced documents. Forest staff are to be commended for the professional manner in which these documents were prepared.

The department is pleased to present the following comments relating to several resource management issues:

Livestock Forage

There is little demand (3,000 AUMs current permitted grazing forestwide) for livestock forage on the Siskiyou. This is due, no doubt, to two primary factors: (1) the small number of large-scale commercial ranches bordering forest lands; and (2) the presence of shrubs, rather than grasses, as the predominant understory ground cover on forest lands.

The forest plan projects no change from current levels of grazing use through the fifth decade of plan implementation. While the department has no serious concern with this projection, a case could be made for planning for a level of grazing increase to correspond with potential population increases and resulting increased demand for livestock products.

In the discussion of range resources in Chapter 4 of the plan, references are made to potential conflicts between livestock grazing and other uses. The plan states "...where conflicts occur, management should favor riparian areas, and deer and elk forage needs and cover requirements." It is strongly recommended that management decisions related to such conflicts seriously consider and accommodate the economic and management needs of permittees whose grazing practices may be adjusted to help resolve these conflicts.

Other Resource Concerns

Additional areas of statutory interest to the Oregon Department of Agriculture include endangered and threatened plant species, riparian habitat, and soil and water values. In each of these areas, the department views the proposed management strategies as adequate to address resource needs. However, the department was disappointed to find no significant treatment of weed control in the plan. Because of our statutory responsibilities for weed control in Oregon and the extensive manner in which our weed control staff cooperates in its efforts with each of Oregon's national forests, we would prefer to see weed control strategies addressed in this plan.

With these exceptions, the Oregon Department of Agriculture views the Siskiyou National Forest Plan as adequately addressing major resource needs.

October 7, 1987

TO: Norm Johnson, Federal Plans Coordinator

FROM: Jim Knight, Special Assistant for Coordination

SUBJECT: Preliminary DLCD Issues on Siskiyou Forest Plan

Our Department's comments on the Siskiyou Forest and DEIS fall under the general heading of comparing the proposed plan with agency goals and state and federal legal requirements.

A preliminary review of the Siskiyou documents reveals a lack of any specific discussion concerning the compatibility of the various forest alternatives, including the proposed plan, with the acknowledged comprehensive plans of Coos, Curry and Josephine Counties and their affected cities.

Also absent is any apparent recognition by the Siskiyou that the forest is located in Oregon's coastal zone and therefore is subject to the requirements of the federal coastal zone management act.

The Siskiyou plan needs to identify LCDC as Oregon's coastal zone agency and our role in administering the requirements of the federal consistency process. Under the federal consistency process all federally conducted or supported activities (including development projects) directly affecting Oregon's coastal zone must be consistent to the maximum extent practicable with the mandatory, enforceable policies of the state's coastal zone program. In Oregon, such policies consist of the adopted statewide planning goals, acknowledged city and county comprehensive plans and the statutory authorities and regulations of relevant state agencies.

Please let me know if you have any questions regarding our comments on the Siskiyou.

SISKIYOU NAT'L FOREST
GRANTS PASS, OREGON
SEP 14 1987
RECEIVED

September 9, 1987

Ron McCormick
Forest Supervisor
Siskiyou National Forest
P.O. Box 440
Grants Pass, Oregon 97526

Dear Mr. McCormick:

Thank you for the opportunity for me and my staff to become familiar with the details of your Preferred Alternative Forest Management Plan for the Siskiyou National Forest. I applaud your efforts to arrive at a balanced and far-sighted plan for using and conserving the invaluable resources contained within the Siskiyou National Forest.

My particular concern is to see a balance between timber harvest and other natural resource uses, such as the sport and commercial anadromous fisheries which clearly rely on stream water quality for their very existence. Obviously, neither use should be developed at the cost of the other, and your most difficult job is finding the management point which strikes a balance among these and other economic alternatives.

Consequently, after reviewing the Preferred Alternative with Susan Auer, I have several requests to assure protection of the anadromous fisheries resources:

North Fork of Lobster Creek

A portion of the North Fork of Lobster Creek is protected as a Supplemental Resource (7) for much of its length. However, a fairly extensive section right in the middle of the North Fork is designated as General Forest (14) land. Since the upper and lower reaches of the North Fork are designated to protect water quality, fisheries and wildlife, it seems inconsistent to not continue that protection along the full length of the stream.

I would like to see the middle portion of the North Fork of Lobster Creek included in the area designated for Supplemental Resource protection.

North Fork of Smith River

The North Fork of the Smith River is an important spawning area for several species of anadromous fish and I was pleased to see the Supplemental Resource protection for that portion running along the most Southwestern edge of the Kalmiopsis Wilderness. However, I would like to know why the protection afforded is so narrow on the west bank of the North Fork. From the map, it appears approximately a hundred feet of protection separate General Forest land from the stream.

Is it appropriate to broaden the Supplemental Resource protection along the west bank of the North Fork of the Smith River to assure water quality?

I hope these comments and requests are useful in your quest for a forest management plan. Please let me know if you have any questions.

My best,

Bill Bradbury
Oregon State Senator

December 3, 1987

Ron McCormick
Supervisor
Siskiyou National Forest
P.O. Box 440
Grants Pass, Oregon 97526

Dear Supervisor McCormick:

We, the undersigned Oregon State Legislators, wish to express our solid support for THE EVERGREEN ALTERNATIVE, a forest management proposal for the Siskiyou National Forest, which has been prepared by the Southern Oregon Timber Industries Association in response to the Forest Service's draft forest plan.

Our support for THE EVERGREEN ALTERNATIVE, rather than the Forest Service's Preferred Alternative, is based on the following considerations:

First, the Siskiyou draft plan will trigger the loss of 289 local jobs in our Southwestern Oregon economy. Our many timber dependent communities are just now beginning to recover from the recession of the early 1980's. Economic development in Southwest Oregon is measured one job at a time. We cannot, in good conscience, support a forest plan that will cause the loss of 289 jobs.

Second, it is our belief the Siskiyou National Forest planning team has greatly underestimated this forest's tree growing potential. Our review of THE EVERGREEN ALTERNATIVE has convinced us the Siskiyou is capable of growing substantially more timber for harvest than is reflected in the Forest Service's Preferred Alternative. A more aggressive forest management regimen is necessary. We believe this can be accomplished - over time - with no adverse impact on non-timber resources now protected by law.

Third, we believe THE EVERGREEN ALTERNATIVE projects an excellent conservation ethic - evidence of the forest products industry's willingness to strike a fair balance between timber and non-timber forest values. For this reason, we are calling upon the Forest Service to ensure that the major technical discrepancies addressed in THE EVERGREEN ALTERNATIVE are corrected in the Siskiyou's final forest plan.

Fourth, we are very strongly opposed to any actions or proposals that result in custodial or roadless area management on the Siskiyou National Forest. 21% of the Siskiyou - more than 232,000 acres - is now designated as wilderness. We view the custodial designation for still-to-be-roaded areas as an open invitation to future wilderness designation. The Oregon Wilderness Act of 1984 specifically released all remaining roadless areas on the Siskiyou for multiple use forest management. It is long past time for the Forest Service to implement the terms of this Act. 30% of the Siskiyou's timber sale program for the next 10 years is standing in roadless areas. Systematic and necessary road construction must begin immediately.

Fifth, we are deeply concerned about the cumulative impact of reductions in annual sale quantities on the national forests of Southwest Oregon. Timber harvest receipt revenues account for approximately 50% of the revenues necessary to fund county government in our counties. County funded emergency and social services within our counties are already at minimum levels. If our county governments are unable to provide even the most basic services for their constituents, how can we be expected to remain stable, much less grow stronger in the years to come.

Sixth, in summary, it is our belief that THE EVERGREEN ALTERNATIVE is a thoughtfully prepared, well balanced forest management plan for the Siskiyou National Forest. It ensures an adequate timber supply for our primary industry and a predictable flow of timber receipt revenues for our county governments. These ingredients are fundamental to the stability of our many timber dependent communities.

Sincerely,

Bill Markham

Comments on National Forest Plan

First, may I express my appreciation for the tremendous amount of work you and your staff have put into the Forest Plan and into soliciting public input.

Second, to let you know where I am "coming from": I have lived on the South Coast adjacent to the Siskiyou for about 28 years.(Coquille from 1949 through 1956 , and Gold Beach from 1967 to the present). During most of those years, while serving as a County Extension Agent, I have been involved in resource management education, conservation of natural resources, and economic development.

As an outdoorsman I spend considerable time hiking and camping in wilderness and non-wilderness areas, float the Wild Rogue as often as I can get a permit and the time, serve as a USFS volunteer maintaining trails, and have covered much of the western portion of the Siskiyou on foot, horseback, trail bike, and rubber raft. And though I have not penetrated much of the North Kalmiopsis roadless area I have traveled the Rogue, and Illinois trails many times from beginning to end, have been to Silver Prairie a number of times and have hiked in the Kalmiopsis Wilderness area many times. I have also participated in several of your information meetings and workshops.

You have a very difficult job trying to satisfy the many varied interest groups as you carry out your assigned responsibilities. Now I'd like to add my "2 cents worth".

My major concerns are the same as those stated in the draft of the State of Oregon's recent response. viz. that these lands be managed in an environmentally sound manner so that future generations have similar* opportunities to enjoy the bounty these lands can provide; and that these lands produce the flow of economic benefits that they have traditionally provided.

* I relaced same with similar as a more appropriate term. The experiences I can enjoy today are not the same I enjoyed even five or ten years ago because of changes in trail designations, roads, new areas opened, etc.

I favor most of the Evergreen Alternative as my first choice. because I believe their suggestions will continue to provide the opportunities I have addressed. There are some exceptions and I will attempt to outline my agreements and disagreements below;

1. Wilderness: I agree with the USFS plan and Evergreen that no additional wilderness areas be designated. Though I might go a step further in relation to the proposal by some that Copper Mountain be added to the "custodial " category. I wholeheartedly support the need to protect the tremendous fishery of Elk River. But I question the premise that the Copper Mountain area needs to be designated as a "de facto wilderness" when careful supplemental resource management can do the job. I am reminded of a conversation I had with Jim Rogers, the person most responsible for having Grassy Knob designated a wilderness area. Jim admitted they got a lot more than they needed or even wanted for the protection of Elk River. If Copper Mtn. is so designated, I would propose that some of the Grassy Knob Wilderness be placed back into the multiple use category. Yes I know, the trap door only works one way!

2. Wild River: In agreement with USFS proposal.

3. Research Natural Areas: Agreement with USFS and Evergreen.

4. Botanical: The USFS plan lists eight sites for designation while Evergreen notes seven. I am not sure which one is left out in Evergreen. I hope that Iron Mountain and Snaketooth Redwood area are both included. I would also like to see a trade with BLM to obtain the Hunter Creek Bog and retain is as a botanical area.

5. Unique interest: I support both USFS and Evergreen.

6. Custodial: RARE I and II studied the area thoroughly.The Wilderness Act of 1984 released the North Kalmiopsis and other areas from further wilderness designation. Yet the roadless designation is a de facto wilderness. I do not favor placing these areas in custodial areas but instead propose the supplemental resource category.

During the well-done information meetings your staff conducted on salvage in the Silver Complex burn, I asked, " What were the reasons the area was not roaded before?" If the reasons were for unstable soils, lack of economic feasibility, or similar reasons, the fire should not dramatically alter that reasoning. However, if the reason was because the working circle had not yet reached the necessity of tapping that area, now is the time to go in there, salvage only the timber that is economically feasible to do so without inordinately damaging the watershed, and put the topic to rest.

7. Supplemental Resources: This is possibly one of the most important parts of the plan. The USFS is doing an excellent job of protecting streamside vegetation and fish habitat. In some areas this may require more than a buffer strip of varied width.

In addition to the USFS proposal, I favor the Evergreen proposal to continue and expand the work being done in the construction of weirs and rearing pools in the salmon and steelhead streams of the Forest.

I also propose special consideration to all tributary streams of Elk River including , but not limited to, Bald Mtn and Rock Creeks, and the South Fork of the Sixes.

8 and 9. Designated wildlife habitat and special wildlife sites: I support the Evergreen alternative. In addition I support the efforts of the USFS to maintain open prairies for wildlife habitat, such as the Adams Ranch along Rogue River, and High Prairie in the Chetco drainage.

10. Scenic/Recreation River: For optimum protection of Elk River, that system could be designated a wild and scenic river.Barring that possibility, the supplemental resource plan should prohibit any logging or road building within one-fourth mile of the north and south forks and the main stem portion within the Siskiyou boundary.

11. Riparian: See No. 7.

12. Retention Visual and 13, Partial visual retention: I agree with the Evergreen alternative. No matter how carefully done, logging operation aftermath is not attractive. Present efforts need to be continued on the major traveled roads such as the Oregon Caves highway, Bear Camp Road, Chetco and Elk, but let's not get carried away beyond the sensible direction USFS is now following. Some of us even believe that young growing timber is extremely attractive.

14. General forest: The major portion of the Siskiyou, not now in wilderness or other special designations, should be managed for multiple use. The Siskiyou is a recreationists delight as well as an economic resource to the surrounding communities. It provides outdoor activities as well as jobs to our people.

I have followed USFS management activities for a number of years. Thinning, fertilization, superior tree selection . etc. are all worthy activities and should increase the amount of product that can be grown in a given period of time. For this reason I support the Evergreen alternative of shortening the cutting cycle for one rotation and increasing the annual allowable cut to 188 mbf.

National Park: Legal requirements may force you to included this as an alternative. But after studying the proposal in view of our local situation as well as the actual happenings in Del Norte county with the Redwood National Park, I am opposed to the designation of a Siskiyou National Park.

Campgrounds and Trails: I support your proposal to develop ten new recreational sites. I urge considerably more attention to trail development and maintenance through additional financing and through involvement of more volunteer groups.

I love the Siskiyou but I also like to eat and see my fellow citizens be able to eat and enjoy their lives in the areas served by the Forest. I pray that through all of this process you will be able to come up with a program that is fair and equitable even though it may not be well received by everyone.

Sincerely,

Walt Schroeder

Dear Ms. Wood:

Subject: SCH No. 87090104 - Draft Environmental Impact Statement/Land and Resource Management Plan for Siskiyou National Forest

The North Coast Regional Board staff has reviewed the above referenced documents and submit the following comments for the portion of Siskiyou National Forest in California. The North Coast Regional Board has found the USFS 208 Best Management Practices (BMPs) Program to be highly successful in meeting Basin Plan objectives.

1. Page IV-39: The plan recognizes approved 208 BMPs as a means to achieve and maintain water quality goals. The plan should also recognize that the State of California and federal water quality standards are the North Coast Regional Board's Basin Plan water quality objectives and waste discharge prohibitions. BMPs are not a measure of compliance as stated on this page of the plan; rather BMPs are required practices which normally result in meeting water quality standards. Measuring compliance is accomplished through water quality monitoring programs.

2. Page V-12: A Monitoring and Evaluation Program for determining compliance with water quality objectives needs to be established. Using BMPs as a unit of measure is not consistent with the legal BMP definition established by the Court in the GO-Road decision.

3. Page IV-39: The plan states that exceptions to BMPs will be allowed if in conflict with Region policy or direction. This is an apparent deviation from the 1981 Management Agency Agreement between the State Water Resources Control Board and the U.S. Forest Service. We request that this plan's statement be developed and clarified.

4. Intensive, large scale logging activity in single watersheds, and its resulting impacts to water quality beneficial uses, has been a long standing issue. We support the forest's effort to plan individual basin activities over space and time. We assume that the percent watershed disturbance allowed under this plan was derived from a method similar to that now used on other forests in California. The discussion on Page II-8 of the Draft EIS is not clear on the method used.

5. The plan should specify at what step in the process the BMPs for individual Timber Sale Units will be identified and specified. It has been staff experience that this needs to occur in the project level Environmental Assessments to help ensure adequate field implementation.

Thank you for the opportunity to comment.

Sincerely,

Dear Mr. McCormick:

The State has reviewed the Land and Resource Management Plan, Siskiyou National Forest, submitted through the Office of Planning and Research.

Review was coordinated with the North Coast Regional Water Quality Control Board, and the Departments of Conservation, Fish and Game, Forestry and Fire Protection, Parks and Recreation, and Water Resources.

Attached for your consideration are comments that reviewing departments have prepared.

Thank you for providing an opportunity to review this project.

Sincerely,

Gordon F. Snow, Ph.D
Assistant Secretary for Resources

Subject: DEIS and Forest Plan for Siskiyou National Forest
SCH #87090104

From : Department of Conservation—Office of the Director

The Department's Division of Mines and Geology (DMG) has reviewed the Draft Environmental Impact Statement (DEIS) and Land and Resource Management Plan (Plan) for the Siskiyou National Forest in the northern Klamath Mountains, California. The DMG review involves both documents and addresses the geology, mineral resources, slope stability and erosion/sedimentation issues. Our specific comments ate as follows:

DRAFT EIS

1. Reorganization of the DEIS would aid reviewers and provide for an improved planning document. Repeated cross-references tend to confuse, rather than clarify key issues. All information regarding the various alternatives should be summarized in one place, rather than spread throughout the document.

2. The discussion of the geology of the Forest, page III-5, et seq., is much too brief to allow a comprehensive analysis or evaluation of current geologic hazards in general, and slope stability problems in particular. A slope stability map or landslide propensity map should be included to fully describe this process and its impact on each land use alternative. The characteristics of each of the geologic units (formations) should be expanded upon and evaluated in terms of weathering products, soil types, slope stability habit, erosion potential, and engineering characteristics. In addition, maps and a general discussion of the seismicity, active faults, and other geologic hazards, e.g., flooding, volcanism, etc. should be included to provide a basic environmental framework for any future plans for Forest land development or utilization. A map, showing the mines and mineral resource locations, should be included to provide a basic understanding of where known or existing mineral resources are found.

3. The DEIS lists many mineral commodities which are found in the Forest, several of which are classified as strategic (page III-24, et seq.). However, in the discussions of Forest Mineral Lands, page III-27, et seq., a mineral potential rating scale of high, moderate, low, and unknown is defined, using only very general, imprecise terms and concepts to the point that a reviewer is not sure just what is being defined or characterized.

In the case of a high rating, evidence used to show that mineralization has taken place should be cited; be it public or private reports and documents, geologic or mining maps, analyzed samples, remote sensing data, or any other reliable data.

A moderate rating is based on evidence of mineralization that is "less clear" or which "has not yet been formed", and a low rating is based on land characteristic that are "unfavorable for resource accumulation." A more rational explanation of the criteria used is essential in order to understand how these ratings were established. We recommend that the Final EIS include, as an integral part of the document, a comprehensive discussion of the data sources, rationale, evaluations, criteria, and analyses that went into this classification system. The discussion should also address the methodology employed to derive the total acreage listed in each category.

Figure III-4, Mineral Potential-1985 Map, shows the entire Forest classified as either "high", "medium", or "low", with no "unknown" lands. The reasons and rationale for this omission should be included in the DEIS. It would be informative to be able to compare the two maps (Potential and Access) used to produce this figure.

The DEIS does not indicate that a comprehensive mineral resource evaluation of the Forest has been made; and it does not adequately document and reference the source of figures, data and facts used in the discussion of mineral lands. We recommend that before any Forest land are excluded from mineral entry that a detailed and comprehensive inventory of their mineral resource characteristics be carried out in a rational manner and based on objective criteria which may be readily comprehended.

4. In the discussion of the resolution of Planning Problem #9, "How should mineral resources of the Forest be developed in coordination with management with other resources?" no information or reference is made to the factors influencing the cost of extraction and processing mineral commodities. The Forest Service policies and practices governing the extraction of minerals, e.g. reclamation, revegetation, road construction, etc. may greatly affect the cost of developing and operating a mine. We recommend, therefore, that the FEIS and Forest Plan include a more thorough discussion of the Forest Service policies and procedures for mineral development in relation to the "socio-economic aspects" of mining vis-a-vis the Gasquet Mountain Project, as well as the exploration, development and extraction of "minerals" in general.

5. The list of mining laws and regulations cited on page III-32 should also include California's Surface Mining and Reclamation Act (SMARA).

FOREST PLAN

Chapter IV, Standards and Guidelines: Minerals, page IV-48, et seq. mentions only briefly the policies, regulations, laws, directions, and guidelines that may influence the prospecting, development and production of mineral resources on Forest lands. In addition the federal regulations cited, the California Surface Mining and Reclamation Act (SMARA) should also be listed among the laws controlling the administration and reclamation of mined land in this state.

If you have any questions regarding these comments, please contact Zoe McCrea, Division of Mines and Geology Environmental Review Officer, at (916) 322-2562.

Sincerely,

Dennis J. O'Bryant
Environmental Program Coordinator

State of California — The Resources Agency

Memorandum

To: Honorable Gordon K. Van Vleck
Resources Agency
1416 Ninth Street
Sacramento, CA 95814

Attn: Projects Coordinator

Date: December 21, 1987

From: Department of Fish and Game

Subject: SCH 87090104, Land and Resources Management Plan, Siskiyou National Forest

The California Department of Fish and Game (Department) has reviewed the subject documents describing the Siskiyou National Forest's proposed Land Management Plan (Plan) and environmental analysis of various alternatives. The Plan, whatever the final form, will determine land uses and management practices for at least the next 10 years and, probably, for many decades into the future. These land uses and management practices will result in profound habitat changes over thousands of acres. Man's understanding of ecological systems is not sufficient to predict all of the biological consequences of implementing any of the proposed alternatives, but it is obvious that fish and wildlife will be profoundly impacted. It is apparent that, insofar as fish and wildlife resources are concerned, these impacts have not been fully identified nor adequately considered in the selection of alternatives as required under the National Environmental Policy Act (NEPA) and the National Forest Management Act (NFMA).

It is extremely difficult to analyze the material contained in the Plan because it is based on a computer model and the U.S. Forest Service (USFS) has presented very little information regarding the assumptions used in FORPLAN runs. Based on what we see, however, it is obvious that timber management is the driving force in the development of the Plan. In "The Genesis of FORPLAN", a USFS publication, the authors (David C. Iverson and Richard M. Alston) state "that FORPLAN was inherently incapable of modeling forest planning because it was a barely camouflaged enhancement of a functionable model representing the views of Timber Management; and that the specific capability of the model was inadequate to address forest planning problems." They stated further "that being a functional model [FORPLAN] would inevitably prove to be inadequate for the multifunctional, integrated planning required under the NFMA." We believe this inadequacy is clearly demonstrated in the subject plan.

Because FORPLAN was developed as a timber management model, most other resources are dealt with merely as "constraints" limiting the principal management objective of maximizing priced outputs. Rather than according equal weight to each of the forest planning

considerations specified in NFMA regulations (see 36 C.F.R. 219 (1986)), the Plan treats the maximization of Present Net Value (PNV) as the base line to which other possibilities and tradeoffs must be compared. This approach inevitably favors forest uses that produce easily quantifiable economic benefits over uses for which economic benefits have not yet been determined.

Even the "constraints" placed on the dominating timber management activities to protect other natural resources are minimal and couched in terms which allow decision makers to modify or ignore them. For example, the total timber harvest level is modified by regional USFS direction which requires retention of sufficient old-growth habitat to support only the minimum viable population of spotted owls. Only a few threatened, endangered and sensitive species actually receive land allocations as constraints. Most wildlife habitat needs are handled through "Standards and Guidelines." The "Standards and Guidelines" are only mandatory if they contain the word "shall." Those containing the words "should", "where practicable" and "may" are not required to be followed. Constraints for deer and elk habitat, as an example, are permissive rather than mandatory. Based on our past experience with the USFS decision-making process, we can only conclude that these "Standards and Guidelines" will not be followed diligently unless they are mandatory and will, therefore, not provide adequate protection for fish and wildlife resources.

A major part of the problem in the treatment of fish and wildlife resources in the planning process is the regional guidelines which establish minimum standards. Theoretically, forest plan implementation can opt for higher standards but cannot go below the minimum set by the region. This Plan, as well as all the other land management plans prepared by the USFS that we have reviewed, provides only for managing wildlife at minimum levels. Unfortunately, the minimum standards are flawed because they are directed towards maintaining what the USFS calls "viable populations." There is no definition of what constitutes a minimum "viable population" for the more than 270 species found in the Siskiyou National Forest. In fact, there is no biological basis to support the use of the concept of minimum viable populations in this manner. Furthermore, life history information for many of the species in the Forest is insufficient to assess the impacts of Plan implementation.

Management objectives directed only towards maintenance of minimum viable populations are an invitation to disaster. Once populations are at or near minimum viability levels, any further loss due to disease, unfavorable weather conditions or habitat destruction may result in elimination of the species. A clear example of this danger could be seen in the wildfires of 1987. On the Klamath National Forest, adjacent to the Siskiyou National Forest, approximately 250,000 acres burned. This included over 30 percent of the spotted owl management areas, scheduled for retention. The viability of spotted owl populations on the

Klamath Forest may well be in jeopardy since it will take many decades for the necessary old-growth habitat to be regenerated.

The Plan contains very specific management direction and objectives for commodity products. Harvest and silvicultural techniques are covered in great detail. Fish and wildlife, on the other hand, have few quantifiable objectives, other than references to maintaining minimum population viability. If fish and wildlife resources are to be given equal consideration as required by law they must be treated with the same degree of management specificity as timber.

For fish and wildlife, the large-scale clear-cut and shelterwood treatments proposed will have far-reaching impacts. Most of the general forest zone is scheduled to be treated under this even-aged management scheme. The USFS claims that habitat for early-successional species will be improved under their preferred alternative. We believe, however, that the intensity and methods of reforestation will largely negate such beneficial claims. Although some short-term benefits may result for some species, over the long-term most wildlife will be adversely impacted as a consequence of the trend to monotypic forests. The NFMA specifically states that regeneration cutting is to be carried out only where consistent with fish and wildlife protection. It seems to us that the Plan is in conflict with federal law and legislative intent.

Management direction for game species is particularly deficient, and for some species totally absent. Constraints on timber management activities are included only for deer and elk. None of these constraints are mandatory. Bear, band-tailed pigeons, tree squirrels, grouse and quail are not even mentioned. Implementation of the Plan without necessary mandatory constraints will result in severe long-term adverse impacts to most harvestable wildlife species. The conversion of hardwoods, loss of hardwoods in clear-cut blocks of mixed conifer/hardwoods, the encouragement of commercial hardwood sales, and increases in hardwood cutting for fuel are good examples of the problem. Deer, bear, band-tailed pigeons and tree squirrels are dependent upon mast produced by older age-class hardwoods. The Plan would allow up to 7,500 acres of hardwood conversion/harvest per decade. In 50 years this would mean a loss of up to 37,000 acres. Such losses would be expected to cause substantial decreases in the Forest's capability to support mast-dependent species. Neither the Plan nor the Draft Environmental Impact Statement (DEIS) recognizes the importance of hardwoods to wildlife or the consequences of removing them.

Since the protection of fish and wildlife resources is totally dependent on "constraints" placed on the dominant timber production activities, the sufficiency of these "constraints" to accomplish the objectives becomes the critical issue. If the Plan is to work, insofar as fish and wildlife are concerned,

these "constraints" must be very specific, very comprehensive and they must be diligently adhered to. Based on what the Plan proposes, we can only conclude that the "constraints" described will not provide the necessary degree of protection to prevent substantial adverse impacts to wildlife and habitat diversity.

The methods by which the USFS intends to evaluate the success of these "constraints" are also critical. The USFS proposes a system which involves the monitoring of eight so-called indicator species, eight species which are intended to represent the estimated 270 wildlife species that occur on the Siskiyou National Forest. It is assumed by the USFS that these eight species will adequately measure the well-being or "viability" of all Forest wildlife and the diverse habitat conditions they require. This approach is, at best, a gross simplification of an ecosystem that is extremely complex, much more complex than the Plan recognizes.

The monitoring system proposed is simply incapable of doing the job it is designed to do. It cannot measure the status of all species and it cannot guarantee the maintenance of "viable populations". Some of the obvious reasons are:

1. There is no biological basis for establishing what a minimum "viable population" is for any species.

2. The USFS has not defined numerically what the "viable population" objectives are for species other than spotted owls, pileated woodpeckers and pine martens.

3. Minimum "viable population" levels for the three species listed above are subjective judgments made by the USFS and are not supported by biologically sound data.

4. The constraints which are supposed to ensure the viability of all wildlife species have not been tested or validated. For example, the most recent literature on spotted owls indicates that the habitat requirements of a breeding pair will not be met by the minimum standards established by the USFS. The same is true for the goshawk. Recent studies in California by the Department indicate that nesting territories require a 150-acre core protection zone. Minimum standards for "other raptors" provide no such requirement in the Siskiyou Forest LMP.

5. Management plans have not been prepared for most wildlife, including the most important harvestable species. Without plans or objectives there is not much chance that habitat needs will be met, especially when competing timber management is planned in detail with quantifiable production objectives.

6. The assumption that the viability of all wildlife species can be measured by monitoring an indicator species is

biologically unsound. Such an assumption implies an ecosystem of great simplicity which, in this case, is far from accurate. Although groups of species may occupy similar habitat types, each species has developed its own specific needs based on individual habitat components. For example, the pine marten and fisher occupy similar habitat and have similar food habits, but the pine marten occupies elevational ranges above those normally used by fishers. Monitoring pine martens, therefore, does not provide information on fisher populations. The adequacy of habitat to fulfill the needs of 270 species cannot reasonably be measured by monitoring only eight species.

7. Any monitoring program based on maintaining species viability at minimal levels is inadequate. Even the most sophisticated monitoring techniques only measure trends over time. It usually takes several years for such a program to establish a clear population decline. If habitat loss is the causative factor in a population decline, it may well be too late to reverse the trend since the regeneration of habitat requires a great deal of time, particularly if old-growth forest, hardwoods, snags or some other age-dependent component is involved. Also, management for the minimum standards of a supposed population viability level leaves no cushion for unexpected future events, that is, if a given population is, in fact, at minimum viability population levels, any further loss due to disease, weather conditions, fire or other mortality/habitat loss factors may result in the elimination of the species.

8. There is no guarantee that the monitoring program will actually be carried out over time. If the necessary manpower and funding is not provided, the monitoring system will fail and with it the entire fish and wildlife resource management scheme. Full funding and staffing for accomplishing all fish and wildlife activities is absolutely essential.

The general comments presented on the preceding pages demonstrate our very real concerns regarding the adequacy of the USFS preferred alternative to protect and maintain vegetative diversity and fish and wildlife resources. We do not believe the Plan is in conformance with either the Multiple Use Sustained Yield Act or the NFMA insofar as its treatment of fish and wildlife is concerned. The Plan clearly places timber production as the dominant land use without equal consideration for non-commodity product resources. The documentation of environmental impacts which would result from implementation of the preferred alternative (Alternative K) is flawed, both by omission and subjective judgment not supported by facts. The DEIS, as a consequence, does not meet NEPA requirements as a full disclosure document.

Additional comments relative to the details of the Draft Land and Resource Management Plan and DEIS are attached. Only those sections relative to the preferred alternative (Alternative K) are addressed.

The Department believes that the Plan could be improved substantially with the addition of appropriate constraints, modifications of timber harvest and silvicultural techniques, longer rotation cycles, increased allocation of habitat for wildlife and higher Minimum Management Requirement standards. We would be pleased to meet with the USFS with a view toward clarifying and resolving our stated concerns.

Any questions regarding our comments should be directed to Mr. A. E. Naylor, Regional Manager, Region 1, 601 Locust Street, Redding, CA 96001. The telephone number is (916) 225-2363.

Pete Bontadelli
Director

ATTACHMENT 1

Siskiyou National Forest Proposed Land
Management Plan and Draft EIS
Specific Comments of the Department of Fish and Game

I. Forest Plan

Page 1, Purpose of Forest Plan

This document does not really provide a plan of management for all forest resources. Basically, it is a timber management plan that addresses most other resources as constraints on the dominant use. There are no positive programs for wildlife management with quantifiable goals, only Minimum Management Requirements (MMR) which are intended to establish the lowest population level to which wildlife species will be allowed to fall from the impacts of timber management. Insofar as wildlife are concerned, it is a plan of population reduction and, perhaps for some species, elimination. Obviously, these losses are fully acceptable to the USFS. We do not believe that the public would agree.

We are not suggesting that the USFS wants to reduce wildlife but rather that they are more concerned with producing timber products and are, consequently, reluctant to reduce production for the sake of other resources.

Page II-1, Preserved Old Growth

The demand for preserving old-growth timber should not be hard to quantify. Several public opinion surveys have been conducted in recent years to determine the public's feelings about wildlife conservation. In each case, including the 1986 study conducted in California by Chico State University, a substantial majority of the people expressed their desire to preserve and protect wildlife, even if this would require higher costs or reductions in the availability of some commodity products.

Page II-2, Wildlife Habitat

The increased demands projected for big game recreation cannot be met under this Plan.

Page II-2, Resource Supply Conditions

We have a great deal of concern with the planning process, its direction, the values used and apparent shortcomings with the primary planning model, FORPLAN.

The goal is to maximize public net benefit (PNB) defined in terms of present net value (PNV). Economic efficiency as determined by the difference between discounted value of all priced outputs and USFS management and investment costs is not the only direction given within the regulations promulgated by NFMA. Those regulations also determine that cost is only one factor that should guide the development of alternatives in forest planning (see 36 C.F.R. 219.1 (b)(13) 1986). Despite these regulations, it is apparent that maximized PNV is the base line from which all tradeoffs and combinations must be compared among alternatives.

Non-timbered outputs are at a large competitive disadvantage for a number of reasons. The Renewable Resources Planning Act (RPA) values used are substantially lower than actual values for outputs such as Wildlife or Fishing User-Days (WFUD) and Recreational Vehicle Days (RVD). The fact that timber is the only commodity that is price-trended for planning creates an even larger competitive disadvantage.

Page II-9, Research and Information Needs

Based on statements made elsewhere in the Plan and DEIS, there is a serious lack of information regarding wildlife habitat requirements and vegetative diversity. The list presented here does not address the identified problems. The LMP should be revised to include the following minimum objectives:

1. Determine the impacts of various timber management activities over time on deer and elk. The objective should be to develop timber management strategies that are less harmful to big game and are capable of increasing habitat quality.

2. Determine adequacy of present spotted owl management areas in view of new information regarding habitat requirements, territory size, number of territories and distribution.

3. Determine habitat needs of the fisher.

4. Determine habitat needs of goshawk.

5. Determine impacts of intensive timber management on black bear.

6. Determine impacts of hardwood reductions on wildlife.

7. Determine potential for re-establishing peregrine falcon nesting on the forest.

Page III-10, How should Wildlife Habitats on the Forest be Managed?

One of the forest's most important wildlife habitat components is just barely mentioned in the Plan: hardwoods. Hardwoods, particularly older-age classes, are of extreme importance. The Plan does not address hardwood management adequately and provides no constraints for hardwood retention. This is a major deficiency in the Plan and DEIS.

Only about 450 acres of habitat restoration per year is prescribed for the forest. This is certainly beneficial and we support it, but habitat improvement at such low levels will produce only very localized benefits and will not have any measurable influence forest wide. This is another indication of the extremely low priority accorded to noncommodity resources. Much more benefits could be provided for wildlife at no direct cost by simply modifying timber harvest methods and silvicultural practices.

Page IV-1, Forest Management Goals

We do not believe this Plan achieves a good balance of resource management, but rather one which is heavily weighted towards commodity products, specifically timber.

We do not believe that high quality wildlife habitats capable of supporting viable populations of all native species will be maintained within the General Forest Zone. We do not believe that the plan will provide high quality and quantity of wildlife habitat to ensure diversified recreational use. A predicted reduction of deer, elk, bear, squirrel and band-tailed pigeon populations ranging from 20 percent to over 50 percent (see other supporting comments) does not indicate the retention of high quality habitat and would not meet anticipated recreational demands.

Page IV-4, The Forest in 2036

The assumption that designated old-growth habitat areas will remain relatively unchanged relies on a further

assumption that such areas will not be impacted by fire or some other destructive force. The large fires in California and Oregon in 1987 provide good evidence that this assumption is incorrect: Approximately 30 percent of the designated old-growth spotted owl territories were lost on the Klamath Forest in a period of about two months. Also, substantial areas of riparian habitat were destroyed. This points out one of the fatal flaws in the Plan, in terms of maintaining wildlife, and that is that management for minimum viable populations leaves no margin for error or natural disaster.

Page IV-11, paragraph 1

The silvicultural systems selected for the majority of the forest are the systems which are also the most destructive *for fish and wildlife. For example,* no harvest should be permitted in the riparian zone unless it is designed specifically to improve stream or wildlife habitat.

Page IV-13, Forest-Wide Standards and Guidelines

Standards and guidelines must be mandatory. The terms "should", where practicable, and "may" are almost useless in assuring compliance. Our experience has shown that unless constraints are mandatory they will usually not be adhered to.

Page IV-20, Fish, Wildlife and Sensitive Plants

The assumption that the monitoring of eight indicator species will be adequate to measure population status and trends for 270 species is totally invalid. There is no biologically sound basis for making this assumption. This approach is, at best, a gross simplification of an ecosystem that is extremely complex, much more complex than the Plan and DEIS recognize.

Page IV-23

We do not believe that the number, size, or dispersal of spotted owl territories proposed by the USFS to meet MMR are sufficient to assure species viability. In addition, the Plan does not provide sufficient levels of habitat to allow for losses to fire or other unforeseen factors.

Page IV-25, Other Raptors

No special provisions are made in the Plan for managing goshawk habitat. Based on studies conducted by the Department, goshawk populations are declining significantly as a direct result of intensive timber management. All existing goshawk nesting territories should be identified and allocations made for the retention of sufficient habitat to assure population maintenance. Each territory must contain at least a 150-acre protected core area around the nest site. A larger secondary zone around the core area should be managed to ensure suitable habitat will be available over time to maintain territory viability. (The Status of the Northern Goshawk in California, CDFG Administrative Report 85-1).

Page IV-25, Deer and Elk Habitat

Since constraints are not mandatory we suspect deer and elk will not benefit from this Plan. This is unfortunate because the intensive timber management program will have significant adverse impacts on big game. It is also unfortunate because timber management, if modified and with proper constraints, has great potential for increasing deer and elk carrying capacities.

Page IV-28, Dead and Down Woody Vegetation

The Plan should allow for the retention of large logs and snag trees. For example, studies of the black bear in northern California show that cavities at the base of large live or dead trees, and large down logs are the primary denning sites. The elimination of larger trees and snags over time in the General Forest Zone will reduce denning habitat.

Page IV-28, Hardwood Habitat

Contrary to what is stated, it is well known that hardwoods provide a significant and seasonally crucial part of the food for deer, bear, turkeys, band-tailed pigeons, tree squirrels, and many other wildlife species. One of the most serious problems in habitat quality recognized in California is the loss of older-age class hardwoods. Not only is the problem serious on private land, but also on public lands. The Six Rivers National Forest LMP allows the elimination of 90 percent of the hardwoods on the General Forest Zone. Although the Siskiyou LMP does not quantify the total loss over time, we expect it will amount to about the same since timber management intensities are

alike. This will have substantial adverse impacts on wildlife and those impacts are not fully disclosed in the DEIS.

Mandatory constraints which provide for retention of older-age class hardwoods and recruitment over time must be initiated on all timber sites. Hardwood conversions should not be permitted unless it can be substantiated that such conversion will not adversely impact wildlife. The USFS should prepare a hardwood management plan which ensures that hardwood resources would be managed to meet wildlife habitat requirements.

Page IV-29, Timber Management

Timber management practices are based entirely on economic (FNV) considerations and not on the compatibility of the practice with other resource values. The preferred methods in Alternative K are the most damaging to fish and wildlife. The constraints are not sufficient to protect fish and wildlife resources. If fish and wildlife were given equal consideration in forest management as required by law we would expect to see a mixture of harvest techniques, including selective cutting, and a variation in cutting rotations that provide for more diversity in timber age classes above 100 years.

Page IV-33 (6-9)

This section provides for 60 acre maximum even-aged clear-cuts. The National forests in the Pacific Southwest Region (Region 5) are directed to utilize a 60 acre maximum on douglas fir stands only. All other conifer species are to be clear-cut to a maximum of 40 acres.

Page IV-33, paragraph 2

Often this competing vegetation is the forage which provides the benefits to early successional stage species and is claimed as a plus for wildlife. Control (elimination, reduction, suppression, whatever the term) means negating or drastically reducing any benefits which resulted from timber harvest.

Page IV-34 paragraph 6

This provision allows for and, in effect, encourages the establishment of large areas of monotypic habitat. An entire drainage could be in dense stands of young trees

with little or no understory for many years. This does not increase diversity; it reduces it.

Page IV-36, paragraph 1

See previous comments on value of hardwoods and environmental impacts. Such conversions should not be considered except in very special circumstances. Before conversions are permitted the USFS should prepare a hardwood management plan that provides for retention and recruitment of older-age class hardwoods over time.

Page IV-38, Riparian Ecosystems

No logging should be permitted in riparian zones unless it is specifically done to improve fish or wildlife habitat. Removal of older-age class trees reduces the fish and wildlife values in streamside areas. Sufficient old-age class trees should be left along stream borders to provide large woody debris for recruitment into the stream channel. This will allow natural maintenance of stream channel diversity including catchment of spawning gravel and establishment of pools and cover. These older conifers will also become increasingly important for cavity nesters, raptors and other wildlife when adjacent General Forest Zone forests are cut and placed in even-age management.

Page IV-52, paragraph 1

Road closures must be required to meet wildlife needs. Open road densities should not exceed 1 mile per square mile.

Page IV-57, Integrated Pest Management

Chemical control of vegetation should not be used for reforestation except in special circumstances. This kind of treatment reduces big game forage, eliminates hardwoods and reduces diversity.

No toxic materials which are hazardous to nontarget wildlife species should be permitted.

Page IV-85 (Table IV-7), Spotted Owl

Spotted owl needs should be adjusted to reflect the final recommendations of the Spotted Owl Supplemental Environmental Impact Statement.

Page IV-86, Spotted Owl

Recent information on spotted owl habitat requirements indicate the prescriptions listed here are not sufficient to maintain the species.

The number of territories preserved are not sufficient to ensure continued population viability (see other comments, i.e., loss of 30 percent of Spotted Owl Management Areas on Klamath N.F. from fire in 1987).

Page IV-87, Pine Marten

There is no guarantee that these prescriptions will ensure maintenance of population viability. It is better to err on the side of too much habitat rather than too little. We urge that the USFS allocate additional habitat until more precise information on pine marten population dynamics and habitat requirements are available.

Also, preservation of pine marten habitat does not necessarily assure maintenance of fisher. Although both species occupy similar habitat, they do so at different elevational ranges. The Six Rivers National Forest funded a study of fisher habitat needs and impacts of timber management. The study included recommendations for their protection and management. These prescriptions should be included in the Plan if fishers are still found on the forest.

Page IV-89, Special Wildlife Site

Goshawk management areas should be identified and protected as per "The Status of the Northern Goshawk in California, CDFG Administrative Report 85-1".

We recommend meadow buffer strips be at least 300 feet. No logging should be permitted in this buffer except to prevent meadow encroachment by conifers.

Page IV-100, Timber

No logging should be permitted in riparian areas unless it is needed to improve habitat for fish and wildlife. (See our previous comments for page IV-38)

Page V-4, Budget Proposals

The assurances for the protection of fish and wildlife included in the plan cannot be fulfilled unless all scheduled fish and wildlife programs are fully funded. There is no guarantee that this will be the case. Implementation for other aspects of the Plan should, therefore, be conditioned on carrying out fish and wildlife programs.

11. Draft Environmental Impact Statement

Page IV-2, paragraph 1

Assumption that even-aged timber management and predominant use of clear-cut harvest illustrates a bias towards commodity production. Such management is the most environmentally damaging alternative available, and it is also contrary to NFMA which states that regeneration cutting is to be carried out only where it is consistent with fish and wildlife protection.

Page IV-93, paragraph 4

Conversion of hardwood stands and the continued loss of older-age class hardwoods to clear-cut logging, commercial hardwood harvest, and fuel-wood cutting will result in substantial adverse impacts to wildlife. The Plan allows 7,500 acres per decade in conversion projects alone. Deer, bear, band-tailed pigeons, tree squirrels, and a host of nongame species are dependent on hardwoods for mast or den trees. Since many hardwoods do not produce high yields of mast or become good den trees until they are quite old, the short cutting rotation cycles will drastically alter long-term habitat capability. Impacts will be highly significant and will be forestwide in nature, contrary to what is stated in this paragraph. Effects will also be cumulative.

Page IV-105, paragraph 1

The assumption that 17 percent of the forest remaining at decade 10 is sufficient to meet MMR goals may be true. Whether or not it is sufficient to maintain viable populations of all species is not known. USFS assurance that it is sufficient is based on subjective judgement, not biological fact.

-10-

Page IV-149, paragraph 2

Recreation can have major impacts on wildlife resources. Vehicular traffic, for example, is known to adversely impact deer, elk, and other wildlife especially when road densities are greater than 1 mile per section. ORV use can have major impacts, both directly from disturbance and indirectly through habitat degradation.

Page IV-149, paragraph 3

Timber management could improve food resources for black-tail deer, Roosevelt elk, and some other species under proper prescriptions. The timber harvest and silvicultural programs proposed, however, are not likely to result in the benefits claimed. Wildlife dependent on younger seral stages will not necessarily benefit as a result of land disturbance and vegetative management. How they respond will not depend so much on how much early seral stage acreage is produced, but on the quality of habitat created and what has been lost to create it. For example, the serious loss of older-age class hardwoods and the mast crops upon which deer (and other wildlife as well) are seasonally dependent may offset any benefits produced. Likewise, the intensive silvicultural practices used to reduce vegetative competition and accelerate conifer canopy closure may well negate claimed benefits, particularly over the long term. The proposed timber management will, eventually result in the establishment of large tracts of dense, young, closed canopy conifers with little or no understory. This habitat is one of the least productive types, insofar as wildlife are concerned.

Mountain quail may benefit, but grouse, band-tailed pigeons, and tree squirrels will be adversely impacted from habitat simplification, loss of hardwoods, and other mast-producing vegetation.

Timber management will not just limit the habitat of many wildlife species, but will substantially reduce their populations forestwide as well.

Page IV-149, paragraph 4

Wildlife tree guidelines are not mandatory and, therefore, will not ensure maintenance of 20 to 60 percent of woodpecker species populations. Maintenance of 20 to 60 percent implies a loss of 40 to 80 percent of the populations. Is this magnitude of loss acceptable to the USFS in view of their mandate to give equal consideration to all resources?

-11-

Page IV-149, paragraph 6

Increased vehicular access has long-term detrimental effects on all species. Increased traffic means increased road mortality, illegal killing, heavier legal hunting pressure and loss of habitat.

Page IV-149, paragraph 7

There is nothing in the Plan (mandatory constraints) to assure roads will be closed to protect wildlife, nor is there any assurance that they will be seeded. If these claims are made as mitigation for adverse impacts as part of the DEIS, they must be substantiated through inclusion of mandatory standards and guidelines. As a minimum, not more than 1 mile of open road should be permitted per section.

Page IV-150, paragraph 4

There is no biological basis for claiming that the land allocations made for wildlife will, in fact, assure maintenance of viable populations. On the contrary, recent studies of spotted owl and goshawk habitat requirements clearly indicate that MMR standards are not sufficient. For many other species, we just don't know enough about them to be certain of anything.

Page IV-150, paragraph 6

As previously stated, there is no guarantee that MMR will ensure viable populations because there is no biological basis for what minimum population viability is and because most constraints on timber management are not mandatory or sufficient to adequately protect wildlife.

Page IV-151, paragraph 5

We cannot understand why the USFS continues to equate higher timber harvest directly with higher deer numbers. Under this assumption, the greatest number of deer could be produced by cutting all the forest. This just simply isn't true. Northwest California forests have experienced a reduction of deer numbers of over 50 percent in the past 20 years. It is interesting to note that this decline took place during the years of greatest timber management intensity on these forests.

aside for spotted owls, pileated woodpeckers, goshawks, pine marten, etc., is not sufficient to sustain minimum viable populations of any given species, that species is irretrievable.

Forage reserved for wildlife within grazing allotments is not an irretrievable loss to permittees, since it is still there and can be reallocated at any time.

Mr. Ron McCormick, Supervisor
Siskiyou National Forest
P. O. Box 440
Grants Pass, OR 97526

Dear Mr. McCormick:

We welcome the opportunity to provide our thoughts and comments on the Draft Environmental Impact Statement (DEIS) and the Proposed Land and Resource Management Plan (LRMP) for the Siskiyou National Forest.

By way of explanation, the Association of O & C Counties is an organization whose membership includes all 18 Oregon counties in which the O & C lands are located. Some 173,000 acres of O&C lands are in the Siskiyou National Forest and are subject to this planning effort. While the primary interest of the Association is with the management of O & C lands, the Association has a near equal interest in the management of national forest lands located in Western Oregon.

Many goods and benefits flow from the O & C and national forest lands. Principal among these goods and benefits is timber production which provides a major source of raw material for the lumber and woods products industry. In Coos, Curry, Josephine and Jackson Counties', this industry provides the majority of manufacturing employment.

Another important benefit is the annual payment to the counties of a percentage share of receipts generated from these lands. Most of the receipts come from the sale of timber. In the case of O & C lands, 50% of the gross receipts are distributed to and shared by all 18 counties; in the case of the national forest lands, 25% of the forest receipts are distributed to the counties in which the lands are located. In combination, these annual payments are a vital and sustaining part of the various counties' operating budgets. Any disruption in timber availability has serious ramifications to local communities and industry.

If deer are to increase as a result of timber management as claimed, why have they declined drastically under 20 years of the kind of management proposed in the LMP? We agree that timber harvest can increase deer forage, under the right circumstances. However, the combination of hardwood removal, elimination of competing vegetation, shortening of successional stages and other high yield forestry practices negate many of the potential benefits. Large acreages of young, closed canopy plantations with little or no understory do not produce much forage for deer.

Page IV-151, paragraph 6

Where a loss of WFUD is the result of a decline in habitat capability for deer or elk, hunter acceptance of lower success rates is not mitigation for environmental impacts and should not be claimed as such.

Page IV-151, paragraph 7

Standards and guidelines do not provide necessary provisions to mitigate any major adverse consequence of the alternatives. These Standards and guidelines only limit the magnitude of loss, they do not mitigate for the loss. Based on information in the Plan and on estimates made by the adjacent Six Rivers National Forest in their LMP under similar alternatives we could expect the following losses in wildlife populations in 100 years:

Old-growth species	- 57 percent
Deer	- 20 percent
Woodpeckers	- 40 percent
Band-tailed pigeon	- 51 percent*
Goshawk	- 26 percent*
Western gray squirrel	- 51 percent*
Black bear	- 42 percent*

*Six Rivers National Forest estimates of population reductions in similar habitat with comparable management alternatives.

The average magnitude of loss for the seven species and species groups is 41 percent. If this average is applied to all forest wildlife the overall wildlife population loss can be expected to be at least 41 percent of present levels. This is a very significant impact, especially when it is considered that the same magnitude of losses will occur on other northwestern forests. Adequate mitigation for these losses is not provided.

Page IV-164, paragraph 2

We do not agree that this alternative does a good job of providing habitat diversity; rather, under the proposed management it simply reduces the percentage of old-growth forest and increases the percentage of younger-age class forest. In the process, even-age timber management, short harvest rotation cycles, type conversions, reduction of hardwoods, suppression of competing vegetation, compaction of successional stages and acceleration of conifer canopy closure will actually tend to reduce diversity. The more monotypic young age classes of conifers with little understory are not going to provide much vegetative diversity and consequently will be less productive for wildlife.

Page IV-164, paragraph 3

Significant habitat diversity is not likely to be provided as indicated in the preceding comment. We do not see how wildlife habitat improvement projects will result in increased carrying capacity for many species. From what is presented in the DEIS, the indicator species, which are supposed to be representative of all 270 species of wildlife on the forest, are all going to decline in numbers substantially. As an example of the problem, the improvement of 400 acres of deer habitat a year for 10-years results in 4,000 acres. During this same 10-year period over 7,000 acres of hardwoods will be converted to conifers. This may equate to a net loss in carrying capacity for deer.

Page IV-165, paragraph 4

The cumulative impacts are understated. The rotating supply of habitat for early successional stage species will not be as productive as the USFS predicts (see many comments on intensive timber management/habitat problems previously stated). This, along with the admitted 57 percent loss of old-growth species, will result in significant wildlife losses over time. Land allocations and standards and guidelines are not sufficient to guarantee that wildlife objectives will be met nor do they provide adequate mitigation for losses.

Page IV-241, Wildlife

Because old-growth habitat, once harvested, cannot be replaced over the planning horizon (150 years), obviously if the number, size and dispersal of old-growth blocks set

We find the DEIS and the LRMP an imposing set of documents. Those responsible are to be commended for the time and effort devoted to the documentation of this planning effort. It is not our purpose to provide a page by page critique of the documents; rather it is our purpose to relate our concerns with regard to the Preferred Alternative as described in the DEIS and LRMP; to comment on the land allocation process; and to provide suggestions for the design of a new alternative.

The Preferred Alternative - No Endorsement

The Association is concerned with the direction that the Preferred Alternative is taking with regard to the management of the Siskiyou National Forest. Because of these concerns, the Association is unwilling to endorse the Preferred Alternative.

We are concerned that the Selected Suitable Timber acreage available for timber production under the Preferred Alternative is the least amount of such acreage for any of the commodity oriented alternatives. Of some 624,240 acres of land classed as tentatively suitable for timber production, only 349,000 acres is available for unconstrained timber production while another 180,000 is available on a limited production basis.

We are concerned that the Annual Sale Quantity (ASQ) under the Preferred Alternative represents a 10% reduction from the current ASQ level. We are concerned that the ASQ for the preferred Alternative fails to meet the Forest and Rangeland Renewable Resources Planning Act by 24%. We feel that the Preferred Alternative fails to reckon with the importance of federal timber supply to the economic well being of dependent industries and communities.

We are concerned that in a period of federal budget belt-tightening a curtailment of funds for intensive timber management practices will negate the benefits of the allowable cut effect and require corresponding reductions in the ASQ.

We are concerned that the Preferred Alternative projects a loss of some 200 jobs -- a very untimely trade-off for the Coos, Curry, Josephine and Jackson County area as these communities struggle to recover from the recent period of economic adversity.

We are concerned that payments to the counties of their shares of receipts are projected to decline.

Finally, we are concerned that five of the six national forests in Western Oregon have selected as the Preferred Alternative in the land use planning process an alternative which requires a substantial reduction in the ASQ. The cummulative impact of such reductions is certain to have an adverse effect on those areas of Western Oregon dependent upon Federal timber to sustain a primary industry. We feel that the Preferred Alternative fails to take into consideration the cummulative effects of reductions in the ASQ and Long Term Sustained Yield on a Western Oregon-wide basis.

Land Allocation Process

The key issue with the Preferred Alternative (and all other alternatives for that matter) goes directly to the land allocation process which assigns each and every acre of land managed by the Siskiyou National Forest to one of 14 management areas. As we read the DEIS and studied the land allocation process we are left with the definite impression that all management catagories, other than the General Forest Catagory, have a preference right to the land which is superior to the General Forest catagory. And that when all preference rights have been satisfied, that land which remains is assigned to General Forest.

We understand that some of these preference rights are driven by law as in the case of Wilderness and Wild Rivers. We understand that some of these preference rights are driven by the need to meet Minimum Management Requirements (MMR"s) for other management areas. We also understand that the process permits the exercise of differing levels of preference under different alternatives. But the net result of the process is the same -- after the preference rights have been satisfied, the land remaining is assigned to General Forest.

It occurs to us that what is missing in this process is an MMR for timber production in order to put timber on an equal footing (Wilderness and Wild Rivers excepted) with other resource values. Taking this a step further, we recommend a MMR for timber production which specifies a ASQ equal to current production levels without the benefit of intensive management practices.

Land use planning is a matter of trade-off between competing resources. Land use planning requires a knowledgeable blending of uses. But it does appear that the land allocation process used in this planning effort treats timber as trading stock.

Suggested New Alternative

Since the Association is unable to endorse any of the alternatives presented in the DEIS, it is incumbent upon the Association to suggest a new alternative embodying the Association's objectives for management of the Siskiyou National Forest.

It is suggested that the Siskiyou National Forest design a new alternative which seeks to maximize the availability of selected suitable acreage for timber production while providing for allocation of acreage to the various management areas sufficient to meet minimum management requirements. As we understand the DEIS, all alternatives except "No Change" meet the MMR's. Thus there must be considerable flexability in acreage assignments to meet MMR's.

In designing the alternative, we suggest that acreages by management area approximate the following:

- For management Areas 1, 2, 3, 4, 5, 10 and 11 as per the Preferred Alternative
- For Management Areas 6,8, and 9 as per Alternative A
- For Management Area 7 as per Alternative C.
- For Management Areas 12 and 13 as per Alternative B

When the land allocation process has been completed in accordance with the alternative design described above, the following computations should be made:

1. ASQ and Long Term Sustained Yield (LTSY) calculated with benefit of intensive management practices, including fertilization.
2. ASQ and LTSY calculated without benefit of intensive management practices.
3. ASQ and LTSY calculated under a scenario which permits departure from nondeclining yield for the next 2-3 decades when federal timber supply takes on increased importance.
4. ASQ and LTSY calculated using the "minimum harvest size" concept adopted by the Bureau of Land Management in Oregon for use in timber management plans approved in the early 1930's.

We believe that an alternative such as this will go a long way towards maintaining the economic benefits from timber production while at the same time providing for the amenity values.

Summary

The Association of O & C Counties is unwilling to endorse the Preferred Alternative because of concerns relative to diminishing economic benefits.

The Association believes that the land allocation process is faulty and that the timber resource needs to be placed on an equal footing with other resources.

The Association has proposed a design for a new alternative which seeks to maximize the base acreage for intensive timber management purposes while still providing for minimum management requirements for other resources.

The Association requests your written response to our comments prior to proceeding with development of the Final Environmental Impact Statement.

Respectfully submitted,

Ray E. Doerner

Ronald McCormick
Forest Supervisor
Siskiyou National Forest
200 N.E. Greenfield Road
P.O. Box 440
Grants Pass, OR 97526

Dear Mr. McCormick:

This is our preliminary response to the Proposed Land and Resource Management Plan of the Siskiyou National Forest contained in four bound volumes published in August 1987, some of which data has since been outdated by changes resulting from the major forest fires beginning on August 30, 1987, which burned over 110,000 acres, or some ten percent, of the entire Siskiyou National Forest.

The sharp and long lasting reduction in private industrial timber supply projected for Coos, Curry and Douglas Counties, beginning in 1990 and continuing for forty years to the year 2030 as indicated in preliminary information made available recently by the U.S. Forest Service Research Station, contradicts the proposed plan comments which do not indicate such a decline in private timber supply.

The major changes in the forest resulting from fire damage, and the omission of more current and correct data on the potential of private timber supply, coupled with the proposed plan's lack of recognition and discussion of the cumulative impact of upcoming changes in timber supply from other National Forests that directly affect the economy of Coos County, make impracticable a quality public input at this time.

The forest products industry is the mainstay of the economy of Coos County and the revenues from timber sales from the Siskiyou National Forest constitute a significant part of the county budget. These receipts also provide financial support for public schools in the county.

The timber supply from the Siskiyou National Forest provides a large number of jobs in logging and trucking in the county, and in manufacturing in the Bandon area. There are also substantial volumes of manufactured forest products from Siskiyou National Forest timber that originate outside Coos County and move through the regional port at Coos Bay.

The major regional port at Coos Bay and its economic impact on the region, and the State of Oregon's recent investment in this port, was not addressed in the Proposed Siskiyou National Forest Plan. More forest products move through the port at Coos Bay than through any other port in the world.

The Proposed Siskiyou National Forest Plan alternatives, including the preferred Alternative K plan, that would reduce timber supply and jobs in forest products manufacturing, transportation and port related jobs, runs counter to new Oregon law enacted by the Sixty-fourth Oregon Legislative Assembly in 1987 to improve the economy of the state, including its forest--based economy. House Bill 3011, relating to the "Oregon Comeback", is the Regional Economic Development Act that led to the establishment of the Oregon Economic Development Department Regional Strategy Program, and specifically to the Coos County Regional Strategy with substantial state and local emphasis on improvement of the port at Coos Bay to sustain and expand facilities for the export of forest products.

The 1987 Legislature provided further support of the regional port at Coos Bay by enacting Senate Bill 962, which elevated the International Port of Coos Bay to a semi-quasi state agency placing it somewhat on a governmental par with the State's Port of Portland.

The Proposed Siskiyou National Forest Plan also fails to properly reflect one of the most important issues in the plan, which is the volume and location of identifiable acreages of old-growth timber as it relates to timber sales in the future. The Siskiyou National Forest is basically an old-growth forest, with 8.6 billion board feet, or eighty-one percent of the standing timber in the forest being old-growth timber.

Instead of a reduction in the commercial forest land base and restriction in harvest of old-growth timber the Siskiyou National Forest should be accelerating the harvest of old-growth to make room for new-growth and to forestall any pressure on the harvest of immature trees now in re-growth on lands other than on National Forest lands to meet market demands for wood products.

An artificial shortage of timber supply caused by unsubstantiated reductions in National Forest annual sales quantities combined with a harvesting of re-growth from other forest lands, will contribute to a major recession in the forest based economy in the Southwestern Oregon counties of Coos, Curry and Douglas, in the long term, and in losses of financial support of local government and public schools of major proportion.

The shrinkage of the forest land base, annual sales quantity and jobs that would result from the Siskiyou National Forest's proposed Alternative K management plan at a time when the forest products industry and its facilities, compels Coos County to oppose the preferred Alternative K management plan and all alternatives that reduce the forest land base, annual sales quantity and employment. Our opposition is also based, in part, on the fact that the maximum potential of the timber producing lands in the Siskiyou National Forest not legally withdrawn from timber production are not being managed as

intensively as they should be, and as a consequence do not provide the maximum harvest potential of these lands.

Our opposition is further based on the fact that the major forest fires in 1987, substantially changed the commercial timber supply and other resources and that such changed conditions were not considered or addressed in formulating the plans now before us for comment.

Contrary to the reductions in the proposed Siskiyou National Forest Plan we feel that the Forest Service should outline a major departure timber cut policy from its present even-flow policy of annual timber supply (without it exceeding the long-term sustained yield capacity of a forest) to increase the annual sales quantity to the maximum harvest potential and in an environmentally sound manner to assist in alleviating the impending short fall of private industrial timber supply and its impact on employment, the economy and support of public schools.

Enclosed is a copy of a December report on the "The Impact of Forest Resources on the Economy of Coos and Curry Counties, Oregon" for the South Coast Business Employment Corp., Coos Bay, Oregon, which was instigated by us and can be used as a reference in connection with our comments at this time.

Sincerely,

COOS COUNTY BOARD OF COMMISSIONERS

Chairman

September 15, 1987

Forest Supervisor
Siskiyou National Forest
200 NE Greenfield Rd.
P.O. Box 440
Grants Pass, OR 97526

Dear Gentlemen:

The Board of Commissioners of Coos County wishes to express our thanks for the fine presentation and explanation of the Proposed Land and Resource Management Plan of the Siskiyou National Forest.

We are pleased to offer the following comments on the Proposed Land and Resource Management Plan:

On page IV-1 and 2 you state your goals. Goal #1 states that you will maintain a healthy Forest ecosystem, and help to supply local, Regional and National social and economic needs. In looking at the charts on pages III-2 through III-12, it appears that over 48% of the Siskiyou National Forest has been taken out of timber production and used for some type of preservation. Approximately 13,691 acres of this is what is termed as custodial (roadless). This area seems to be the bone of contention. Its inclusion into preservation instead of production has caused the allowable cut to be reduced in the preferred alternative. When nearly one-half of the forest is already taken out of production for nearly every reason imaginable, it seems unreasonable to include the Custodial area also.

Goal #2 states you will provide a sustained yield of resource outputs that will promote the stability of local communities and provide for Regional and National needs. You have fallen short of this goal already with the withdrawals made in the past for such things as Wilderness areas, Supplemental Resource, Designated Wildlife, Riparian, etc. To include the Custodial area also would be a greater deviation from the goals. You would no longer have a balance in your management process, adding insult to injury so to speak.

Goal #3 states that you will maintain a healthy, diversified, visually pleasing forest. This cannot be done in Roadless areas because of the lack of ability to reduce fire hazards, fight fires and to control soil erosion, diseases, and infestation problems. It does not take an expert to know that diseased, infested, or charred forests are not visually pleasing. The result of the last few weeks should be proof enough of that. Besides, the birds, bugs,

Forest Supervisor

animals nor humans will get any use out of what was lost in the recent fire. Had it been harvested and resceded, there would not have been as much fuel for the fire and you could have gotten in to fight the fires much easier. Knowing this, it is hard to understand why you would want to jeopardize even more of our timber base in this way.

In Goal #6 you talk of maintaining viable populations of native species. This could be at the expense of humanity - an expense we cannot afford. That in itself raises questions about your priorities. To then make the statement - "and desirable introduced species" is going way too far. It is bad enough to sacrifice for these species already here. You have no right to ask us to import more to sacrifice for.

Nearly 80% of your goals are geared to preservation, some repetitive, and many in direct opposition to timber production. You need to reevaluate your priorities, as it appears you are beginning to place the human species below the animals and birds and plants.

We urge you not to further unbalance the process by adding more Roadless areas.

Because of the things we have pointed out to you, plus many not mentioned, we would urge you to adopt alternative D and reject alternative K.

We thank you for the opportunity to comment and hope our comments are considered.

Very truly yours,

RE: SISKIYOU NATIONAL FOREST PLAN

Gentlemen:

Coos County has historically supported a balanced approach to managing our National Forests. These forests provide jobs, recreational opportunities and scenic amenities for all people. In addition, proper forest management is a key component to insuring community stability. This is especially true for the timber dependent communities of Southern Oregon.

The Southern Oregon Resources Alliance recently offered a series of recommendations regarding the Siskiyou National Forest Plan. Specifically, the organization recommends a continuation of current road building activities, continued multiple use management that promotes both jobs and recreation and the immediate completion of fire salvage studies and rehabilitation of recently fire-damaged areas. In addition, the organization recommends that no plan be adopted until all questions and concerns are addressed.

We support this reasonable and pragmatic approach to a complex problem, and urge the Siskiyou National Forest to adopt the recommendations as the basis for future forest planning.

Traditionally, the National Forests have supported a multiple use approach to forest management thereby benefiting everyone. The Resource Alliance proposal maintains this tradition.

More detailed comments from the Coos County Board of Commissioners will follow.

Sincerely,

COOS COUNTY PLANNING DEPARTMENT

CURRY COUNTY OREGON BOARD OF COMMISSIONERS

Thomas M. McKenzie Rocky McVay T.V. Skinner

BOX 746 GOLD BEACH, OREGON 97444 (503) 247-7011

January 22, 1988

Ronald McCormick
Forest Supervisor
Siskiyou National Forest
200 N.E. Greenfield Road
P.O. Box 440
Grants Pass, OR 97526

Dear Mr. McCormick:

This is our preliminary response to the proposed land and resource management plan of the Siskiyou National Forest contained in four bound volumes published in August 1987.

The data in the proposed plan are outdated on timber supply from the Siskiyou National Forest and on the projections on the availability of private industrial timber supply in Southwestern Oregon, including Curry, Josephine, Coos and Douglas Counties.

The changes in timber supply from the national forest resulting from the major forest fires beginning on August 30, 1987, after the plan was published, and which burned over 110,000 acres, or some ten percent of the forest, are not addressed in the plan.

The potential of private industrial timber supply is overstated in the plan according to the preliminary results of the U.S. Forest Service Pacific Northwest Research Station data made public in October 1987, which indicates a severe and long-lasting drop in private industrial timber supply beginning in 1990 and continuing for forty years to the year 2030.

Another, and most important subject not adequately discussed in the proposed plan, is the impact and need of the receipts from timber sales from the Siskiyou National Forest to county government, and the eight public school districts in Curry County.

The eight public school districts in Curry County have been the principal recipients of the share of timber sale receipts from the Siskiyou National Forest over the past three year period.

The total receipts from timber sales from the Siskiyou National Forest are divided 75 percent to the federal treasury and 25 percent for county roads and public schools. The 25 percent for roads and schools is divided 75 percent for roads and 25 percent for schools. During the most recent three years the average of the 25 percent share of national forest timber receipts for county roads has been $2,224,397, of which $1,766,986, or 79%, has been turned over for the support of public schools. This is in addition to the percentage of the national forest timber receipts directly mandated for public school support.

Examples of the importance of national forest timber receipts for the support of public schools is reflected in the operating budget of two school districts in Curry County. During the past three years, an average of 18.2 percent of the operating budget of the Brookings School District (District 17-C), with a pupil population of 1453 and 74 faculty members, was from national forest timber sale receipts. During the same period, 10.4 percent of the operating budget of the Agness School District (District 4), with a school population of nine and one faculty member, was from national forest timber sale receipts.

The closure of one school in Curry County and eleven elections at which voters opposed increased property tax levies, and a failure to pass a new tax base in two elections, during the past three year period make timber sale receipts from national forest lands more important than ever.

Fifty-five percent of the acreage of the Siskiyou National Forest is located in Curry County, and three major forest products manufacturing plants, two of which are located in Brookings and one in Gold Beach are, for all practical purposes, almost totally dependent on timber supply from the Siskiyou National Forest. These three mills provide most of the manufacturing jobs in the county, and their property taxes, and those of their employees and others from which materials and services are obtained, including retail establishments, constitute a substantial portion of the property tax base which support the public schools in the county.

The lack of current and correct data in the proposed plan before us for comment, coupled with the proposed plan's lack of recognition and discussion of the cumulative impact of upcoming changes in timber supply from other national forests in Oregon and Northern California that effect the economy of Curry County, make impracticable a quality public input at this time.

The proposed Siskiyou National Forest plan alternatives, including the preferred Alternative K management plan that would reduce the commercial timberlands base, reduce the annual sales quantity by ten percent, and cause a direct loss of over two hundred jobs, would unquestionably undermine support of public

schools and cause a negative impact on the economy and stability of all communities in the county.

The Proposed Siskiyou National Forest Plan also fails to properly reflect one of the most important issues in the plan, which is the volume and location of identifiable acreages of old-growth timber as it relates to timber sales in the future. The Siskiyou National Forest is basically an old-growth forest, with 8.6 billion board feet, or eighty-one percent of the standing timber in the general forest being old-growth timber.

Instead of a reduction in the commercial forest land base and restriction in harvest of old-growth timber the Siskiyou National Forest should be accelerating the harvest of old-growth to make room for new-growth and to forestall any pressure on the harvest of immature trees now in re-growth on lands other than on national forest lands to meet market demands for wood products.

An artificial shortage of timber supply caused by unsubstantiated reductions in national forest annual sales quantities will contribute to a major recession in the forest based economy in the Southwestern Oregon counties of Curry, Josephine, Coos and Douglas, in the long term, and in losses of financial support of local government and public schools of major proportion.

The shrinkage of the forest land base, annual sales quantity and jobs that would result from the Siskiyou National Forest's proposed Alternative K management plan at a time when state and local governments are moving to sustain and improve the forest products industry and its facilities, compels Curry County to oppose the preferred Alternative K management plan and all other alternatives in the proposed plan that reduce the forest land base, annual sales quantity and employment.

Our opposition is also based, in part, on the fact that the maximum potential of the timber producing lands in the Siskiyou National Forest not legally withdrawn from timber production are not being managed as intensively as they should be, and as a consequence do not provide the maximum harvest potential of these lands.

Our opposition is further based on the fact that the major fires in 1987, substantially changed the commercial timber supply and other resources and that such changed conditions were not considered or addressed in formulating the plans now before us for comment.

Contrary to the reductions in the proposed Siskiyou National Forest Plan we feel that the Forest Service should outline a major departure timber cut policy from its present even-flow policy of annual timber supply (without it exceeding

the long-term sustained yield capacity of a forest) to increase the annual sales quantity to the maximum harvest potential and in an environmentally sound manner to assist in alleviating the impending short fall of private industrial timber supply and its impact on employment, community stability and support of public schools.

Enclosed is a copy of a December 1987 report on the "The Impact of Forest Resources on the Economy of Coos and Curry Counties, Oregon" for the South Coast Business Employment Corp., Coos Bay, Oregon, which was instigated by us and can be used as a reference in connection with our comments at this time.

Sincerely,

CURRY COUNTY BOARD OF COMMISSIONERS

T. V. Skinner, Chairman

Thomas M. McKenzie, Commissioner

JOINT RESOLUTION

BY THE BOARDS OF COMMISSIONERS OF

CURRY, JOSEPHINE, COOS AND DOUGLAS COUNTIES, OREGON

IN THE MATTER OF CURRY, JOSEPHINE, COOS AND DOUGLAS COUNTIES, OREGON, OPPOSING THE SISKIYOU NATIONAL FOREST PROPOSED PREFERRED ALTERNATIVE K PLAN FOR MANAGEMENT OF THE NATIONAL FOREST FOR THE NEXT TEN TO FIFTEEN-YEAR PERIOD.

RESOLUTION

WHEREAS, the Siskiyou National Forest is located in Curry, Josephine and Coos Counties, Oregon, and the annual timber supply from this national forest supports jobs in the forest products and related industries in Curry, Josephine, Coos and Douglas Counties and provides substantial revenues to counties and public schools from the receipts of timber sales in Curry, Josephine, and Coos Counties, and

WHEREAS, the current Timber Management Plan of the Siskiyou National Forest is effective until September 30, 1988, and

WHEREAS, the Siskiyou National Forest has expended more than two million dollars over the past eight years in developing a new forest management plan which includes thirteen alternative plans for management of the forest for the next ten to fifteen-year period, and

WHEREAS, the Siskiyou National Forest proposed preferred alternative management plan designated as Alternative K would reduce the commercial forest land base; reduce the annual sales quantity of timber; reduce employment in the wood products and related industries and cause a substantial detrimental effect on community stability and a profound impact on the financing of county government and public schools in Curry, Josephine and, Coos Counties.

LET IT THEREFORE BE RESOLVED, THE BOARD OF COMMISSIONERS OF CURRY, JOSEPHINE, COOS AND DOUGLAS COUNTIES, oppose the Siskiyou National Forest proposed preferred Alternative K management plan and support a forest management plan that will maximize multiple use and intensive forest management to provide a level of timber harvest from the Siskiyou National Forest that will sustain and

SISKIYOU NATIONAL FOREST RECEIPTS, ROAD AND SCHOOLS

YEAR	ROAD 75%	(25% OF GROSS) SCHOOL 25%	TO SCHOOLS FROM ROAD 25%	TOTAL TO SCHOOLS

Grants Pass, Oregon 97526

Dear Ron:

Re: Response to the Proposed Land and Resource Management Plan for the Siskiyou National Forest

This letter will constitute the official response of Josephine County to the draft Ten-Year Management Plan for Siskiyou National Forest.

The management of the national forests is of major concern to the citizens of Josephine County as well as the various taxing distticts and governing bodies within the County. We would like to express our appreciation to the staff resources that have made time available to the County in helping us understand the contents of the proposed Plan and the impact of the resultant Land and Management Resource Plan on the local communities. It would be a difficult, if not an impossible task to review and provide meaningful comment without the involvement of those who were instrumental in the preparation of the proposal.

OVERVIEW:

The paramount concern of the community and this Board is the volume of timber that would be available for processing as a result of the land allocations and the management techniques utilized on the forest. After reviewing the inventories, allocations and allocation criteria, we feel that the amount of fiber available is higher than identified in the Preferred Alternative. Understanding the range of resources that must be managed, we believe that the MMR's can be met, unique interest and botanical sites protected, while maintaining the Annual Sale Quantity at or above the existing levels.

As reflected in your Goals 2, 3 and 4 we fully support the concept of consistency and the resultant community stability. For local businessmen to feel comfortable in investing meaningful capital in primary, secondary and tertiary wood processing facilities, they need reasonable assurance that the raw materials will be available to justify this expenditure. Understanding the increasing demands upon the Siskiyou National Forest by a range of interests locally and nationally, we would hope and expect that each one of these pressures would be held up against your proposed Goals in the Standards and Guidelines. Additionally, the revenue from the responsible management of the forest is of major importance to the local schools and transportation systems. This fact must be one of the major considerations in the determination of a response to these pressures.

Your Goal 2, to "provide a sustained yield of resource outputs at a level that will promote the stability of local communities and provide for regional and national needs..." is the key statement in the document. It is our expectation that once a ten-year management plan is adopted the volume of raw materials produced from the forest would be held at that committed level. Should additional demands be placed upon meeting other newly identified needs or issues, be it new allocations, adjusted inventories, or changes in management techniques, it is our feeling that those needs should be met in a fashion that would allow for the continuance of the committed level as determined in meeting Goal #2. In 1985 our mills were producing 1,419,600 board feet of timber each day. Understanding that economics and the market will affect this operating level, our workers and mill operators need assurance that an adequate volume of logs will be available on a sustained basis to maintain this operating level. As the Plan notes, this is absolutely necessary for community stability and to serve as a basis for future plans.

Noting your proposed Goal 3: "to maintain a healthy diversified and visually pleasing forest setting that enhances local tourism, provides an attractive visual backdrop to surrounding communities." Again we support the this proposed Goal. As you are aware, the Governor of the State of Oregon has instituted a program that encourages counties to work as a region in economic development and the implementation of a strategy that would serve as a basis for future plans and growth. Josephine County, as one of these jurisdictions, has determined that tourism will be our primary focus to augment lumber manufac[illegible]ng. Thus, we support the proposed capital expenditures, the land allocations and the other components of your plan that recognizes the importance of tourism and the role that the forest will serve in that effort.

Departures

For three of the alternatives offered in the Plan, departure timber harvests have been proposed. Although we have grave concerns about the availability of timber in the second and third decades, it is our view that maintaining a consistent harvest, especially during the next twenty year period, is the more desirable approach. Economic factors are impacting the private sector at this point in time and higher than normal cuts are occurring on private lands. The percentages of privately owned timber currently being processed in Josephine County is less than 6% of the logs consumed by local mills while the timber supply provided by the Siskiyou is roughly 30%. Therefore the consistency of your production is of paramount importance.

Monitoring

Because of the high percentage of timber from the Siskiyou that is processed in the County and the dependency we have on that supply, we fully support the proposals to establish a range of monitoring devices to insure that the Allowable Sale Quantity is maintained. Understanding the importance of the other resources managed by Siskiyou and the role of those resources on the various sectors and the forest itself, we would encourage that special consideration be given to the monitoring program to insure that, on a yearly basis, the volume of timber being provided to the community is such that the ability for timber to justify for capital investments is recognized and supported. From that perspective we encourage that a further refinement of the proposed monitoring methodologies and the resultant course correction activities be spelled out in the Standards and Guidelines. We also feel that methodologies need to be implemented to allow for adjustments in cuts to offset the effects of appeals and held up timber sales.

Rotation Periods:

Reviewing the proposal that has been made regarding the utilization of a shorter rotation period as a management technique on appropriate lands, we find no problem with this concept. Recognizing the need for the use of sound timber management activities that would result in a sustained yield, we would encourage the use of all tools and techniques available for competent silvicultural management. From this perspective we would encourage a review of the administrative determination to not harvest before 95% of the culmination of the mean annual increment. Upon

reviewing management techniques used by both private and other public sectors, it would appear that adhering to the 95% rule is an unnecessary administrative constraint when applied to the entire forest, especially on a one time basis. We would support a review, and change, of this policy at whatever levels would be appropriate, and for a shorter rotation to be used on existing plantations.

Basin Harvest Constraints:

As we understand it, the current management for the forest has a 20% limitation on timber removal per any basin for the planning period. The preferred alternative reduces this percentage downward to a range of 9 to 12 percent. Upon review of the Plan, we are finding inadequate justification for this proposal and would encourage that the harvest constraint for the basins be increased back up to 14 to 16 percent. We feel that the impact on the other resources identified in the Plan would be minimal and as a management technique this would be an appropriate level of harvest on a forest wide basis. We do recognize the sensitivity of specific areas and/or the political realities of those areas interfaced with various levels of private ownerships, but these issues can be dealt with through the allocation and/or other components of the Standards and Guidelines and should not be adopted as an artificial constraint in timber management on a forest wide basis.

Old Growth:

In 1985 old growth (as defined as timber that is 100 years and older by Howard) constituted approximately 3/4 of the logs consumed by sawmills in Josephine County. Because of the wide range of definitions that are being utilized for "old growth", we would encourage that a clear articulation of the role that old growth timber plays in a healthy forest be provided in general, and the Siskiyou National Forest specifically. Beyond the wilderness what percentage of the forest should be managed for old growth? Understanding that there is a considerable amount "old growth" timber in existence in the Kalmiopsis Wilderness area we would request that further determination be made as to the necessary amount and resultant location of "old growth" provided in other parts of the forest be identified in the final plan. We disagree with the concept of custodial as a land allocation and will make further comment of this in our critique. We feel that if it is responsible to be growing "old growth" it's location can and should identified. Because of the emotive nature of this resource any determinations as to the

role of old growth timber must be clearly articulated in the final product and propose the possibility that it be identified as a specific allocation, or at least a clear component of the land allocations, and a precise policy made as to how much, where, and at what point, are lands going to be managed as "old growth".

Inventory:

The Allowable Sale Quantity will depend upon the land allocations within the various management areas based upon the assumptions that:

A. Inventories are correct,

B. Full funding will be available, and

C. The full range of management tools will be available and utilized in the development and care of the forest.

In general we feel that all three of the assumptions are questionable and specifically we have grave concerns as to the completeness and accuracy of the inventories. We would request that sufficient resources be allocated to acquire the necessary inventories which can be used as a basis for Plan updates.

In the context of silvicultural techniques, we continue to support aggressive, effective reforestation that ensures that future generations of Oregonians will enjoy those resources that we do today. We fully expect this reforesting effort to incorporate good management support techniques such as:

A. Effective and economical vegetative management of plantations,

B. Use of genetically improved planting stock,

C. Pre-commercial and commercial thinnings,

D. Forest fertilization, and

E. protection from fire and other destructive forest pests.

In October 1978, the FIR Program (Forestry Intensified Research) was established with its base for operations being located in Medford, Oregon. FIR's primary purpose was to solve regeneration problems associated with harsh sites in Southwest Oregon. To this end, a tremendous amount of technical information has been

developed that suggests regeneration is possible on these sites within 5 years. We feel that with this information, the Forest Service should be re-examining those areas identified as having potential regeneration problems, and were subsequently withdrawn from the timber base. Any appropriate areas in which the research would provide for successful reforesting should be put back into the base and be included for calculating Allowable Sale Quantity.

Additionally, we would request that any decrease in timber output that results from adjustments of inventory, yield tables, or shortfalls in funding be made up by adjustments in management policies and or land allocations so that timber volumes available to the community are not revised downward. As per the proposed Goal 2 this consistency is of paramount importance to the citizens of Josephine County. Also, we would request that modeling be conducted in which:

A. A less optimistic view of inventories is taken;

B. A reduction in funding is anticipated; and

C. The assumption that a prohibition on the use of herbicides is made.

The resultant allowable cut and impact on the community should be the basis for the analysis.

Special Needs:

As we noted earlier, tourism, as well as the use of the forest by the local community members, is an important aspect of the forest. Because of this view we are fully supportive and encourage even greater efforts towards the identification and resultant development of recreational sites. We feel that the proposal for trail and recreational site development, as well as visitor centers would greatly benefit the forest, all those who use it, we would also request serious consideration be given the Rogue-Illinois Scenic River Special Initiative funding proposal. We think that this Special Initiative should be incorporated directly into the plan proposal and the necessary budget requests be made for allocations to implement this proposal.

Siskiyou National Park Proposal:

We are exceedingly concerned regarding the possibility that the Park Proposal should be considered as part of the development of the Land and Resource Management Plan. It is our strong view that any discussions,

should they occur, are extraordinary and are totally outside the purview of this planning effort. The procedural steps for analyzing and considering merits and impacts of the formation of a Park are completely separate and distinct from the activity that you are currently engaged in and any effort to integrate the two would be completely inappropriate if not illegal.

OVERLAY:

Ater reviewing the proposed Management Areas we have come to the conclusion that a more exact land use tool needs to be utilized. This view is based on the exceedingly diverse geologic formations and resultant ecosystems, the limitation of a comprehensive site specific inventories, and the topographic and climatic extremes that exist on this forest.

There is a concept in land use planning that is termed an "overlay". An overlay is an area within a land or management allocation in which the resultant standards or activities may be greater or less than is prescribed for that particular allocation. This deviation from the prescription may occur when:

A. Specific types of physical characteristics are pre-identified, e.g. rock outcroppings, bodies of water, etc.;

B. specific criteria are met, e.g. nesting areas, marshes, unstable soils, etc. are identified in the field;

C. Time certain, e.g. at the time of the ten-year plan review;

D. Activity certain occurs e.g. a final EIS or spotted owl is adopted.

The primary benefit of this tool is that it:

A. Insures that specific attributes will be protected even before being physically located on the ground.

B. That the exact physical area meeting the overlay criteria can be identified thus eliminating the inclusion of lands that do not contain the attributes desired.

In our judgment, those areas included in an overlay should not be calculated in the Allowable Cut Determination.

REVIEW OF MANAGEMENT AREAS:

General Forest:

The General Forest is the essence of what the Siskiyou National Forest is about. It is this Management Area that provides the meaning and substance to the full range of forest uses for the local communities and citizens who enjoy the forest. It is our position that the full range of management techniques and resultant benefits be utilized on as large an area as possible. It is our proposal that when insufficient inventories exist, lands be placed in this allocation but the overlay concept be utilized to protect valuable resources. Thus, the allocation is made but site specific delineation and resultant management techniques can wait until on-the-ground surveys can be accomplished. When an area is surveyed for a harvest the criteria will be reviewed to insure protection of resources and appropriate actions can be taken.

Custodial:

As a result of the efforts of the Rare I and Rare II analysis, Congress, in 1984, determined that those areas outside of the Wilderness in the Siskiyou National Forest need to be managed for multiple use. Understanding the definition of resources offered in the Plan, it is our sincere belief that consideration needs to be made on the entire forest for some form of balanced, active management of the timber resource as well as all other identified resources. It is from this perspective that we object to the use of the Custodial (Roadless) Management Area as a land use allocation. Upon reviewing the stated goals for the proposed Custodial Management Area, we believe that the stated objectives of providing an area in a natural state has already been met by the Wilderness and the Wild Rivers Management Areas. Additionally we believe that the stated need to protect and preserve riparian environments has already been met by the Riparian Allocation as well as the Supplement Resource as identified in its stated purpose. We understand the dynamics that have led to this allocation but we feel, considering the history of the review that went into the Planning effort regarding the multiple use concept and the possible designation of additional wilderness area, that this is not an appropriate allocation. As an alternative to this allocation we would recommend the use of the overlay concept.

We would recommend that those lands placed in the Custodial allocation in the preferred alternative be reviewed and, in general, be placed in the General

Forest allocation with certain sub-areas being placed in an overlay zone as appropriate for the resources needing protection.

Some specific recommendations for re-allocation of those lands in Proposed Alternative K Custodial would be the following:

1. Identification of those areas being studied for spotted owl as an indicator species and place an overlay on those study areas. This would serve as a reserve until the issue is resolved through appropriate channels. Once a final determination is made then change the overlay to the designation that would allow whatever level of resource management came out of the final decision.

2. For the North Kalmiopsis area, identify those areas of the Lower Illinois River that are either in the viewscape or are of such questionable quality from a timber management point of view as to raise concerns as to them being managed at any level and place a overlay on those that would preclude the harvest techniques allowed in the General Forest.

3. For those areas proposed for Custodial east of the Kalmiopsis Wilderness review to determine if some form of overlay, above and beyond what is identified under the General Forest management area, is necessary.

Should additional concerns regarding Custodial areas of the North Kalmiopsis become a paramount factor in the final adoption, the overlay concept can be utilized to place a temporary site specific management region on whatever resource is an issue in these areas, but then identify a time or action specific when that overlay will be removed. This time can be at the termination of this planning period or until whatever additional study is determined necessary is completed.

Supplemental Resource:

Upon reviewing the description and management goals of the supplemental resource allocation, we find that there are some lands that have been placed in this designation that do not appear to meet the management goals of the enhancing key fish and wildlife habitats. We request a review of the allocations in relation to the criteria for Management Area 7 and suggest that some of the areas may be better designated utilizing the overlay concept proposed under General Forest. An example of some areas for reconsideration are:

1. Lower Rogue. This area could be placed in the General Forest but have an overlay on those lands in which the criteria would preclude any clear cutting of lands visible from the river or access roads.

2. Other areas are Mislatnah and possibly Emily Creek.

Visuals (Retention and Partial Retention:

Retention:

Generally we agree with the concern with the maintenance of some visual quality on the more highly used roads within the forest. We agree with the concern around the Bear Camp Road and the other proposed use of this allocation throughout the forest. We feel that the proposed timber management as well as management for other resources reflected in the Standards and Guidelines for this allocation is appropriate.

Partial:

After closely reviewing this management area it is our recommendation that it be completely deleted. Those lands under this allocation that are unsuitable for the production of timber management could and should be placed in the full retention status. For those lands that have timber value, it is our recommendation that they be placed into the General Forest Management Area and resultant land allocations and utilizing an overlay for protection of the visual values on a site specific basis. This will be determined on the ground at the time that lands are reviewed for proposed management programs.

Although the Board is aware of the need for some level of visual buffering for major travel routes, rivers and high public recreational use areas we are not in agreement that they need to be protected to the extent that the timber management is completely subordinate to the character of the landscape, thus limiting the timber production potential. Rather, those acres allocated within these partial retention visual management areas should be managed more intensively for the production of timber. Concern over forest openings created by management activities should be de-emphasized in the adopted alternative. In this light, we would encourage the use of

vegetative buffers to help screen management areas and incorporate "feather-edging" where appropriate. Partial cutting should be increased along with the use of clear cuts. Rotation ages over culmination, as general rule, should not be encouraged. Final harvest decisions should be governed by sound timber management principles that emphasize growth, and not to provide for near natural conditions. It is our belief and position that timber management does not necessarily disrupt the attractiveness of the scenery nor spoil the visitors visit. Young, healthy stands of regenerated conifers have a singular beauty of their own and provide for esthetically pleasing contrasts to larger stands of conifers and natural openings. Should the causal forest user desire a more natural encounter, then certainly that need has been provided for in other management areas of the forest.

Riparian Habitat:

We feel that the fisheries are an important resource to all levels of interest. On reviewing the allocations and the proposed management of these areas, we believe that a very responsible effort has been made and the results of this effort would be beneficial to all concerned. Because of this importance we would fully support the capital expenditures proposed for the improvement of this resource. Again, though, we would ask that only those areas that meet the allocation criteria be placed in this designation.

Botanical:

We understand and fully support the need and the importance of the protection of those unique botanical areas on the Siskiyou National Forest. We do have a concern about the fact that a lot of the botanical species also has a symbiontic relationship with valuable mineral deposits. We believe that, depending on the politics of the world market, there may be increased demands placed on the minerals in the forest in years to come. Because of this concern we would encourage additional consideration be given as to the method and resultant administrative process utilized on gaining access to the mineral resources, the protective limitation measures to be utilized, and the standards that will employed to ensure resource protections.

MINERALS ASSESSMENT

The Board views the proposed Forest Service direction concerning mineral exploration and development as one in

which minerals are being relegated to a subordinate importance to all other resources and concerns. As you are aware, the Siskiyou Forest contains some of the most unique concentrations of mineral deposits in Oregon. These deposits are, as noted in the DEIS, very important nationally as many are classified a having strategic value.

In reviewing the information provided in the DEIS, it appeared that the preferred direction adopts an all inclusive approach in the allocation of lands for sensitive, rare plant species protection, maintenance, and enhancement over that of potential mineral resource. In depth, detailed documentation and discussion is encountered in the DEIS and related documents concerning sensitive plants, where as that portion devoted to minerals is cursory in content and always considered subordinate in value.

We are considerably distressed to note that the level of mineral exploration and development restrictions, by management area, has increased by a significant percentage over what the current direction is - as modified by minimum management requirements. Total acres in "low restrictions" are decreasing from 608,168 to 451,440. This represents 156,728 acres that are being assigned to a higher level of restrictions. The high restriction category is changing from 20,256 acres to 15,259, or a 4,997 acre decrease, but the withdrawn category is increasing from 267,692 to 272,751 acres.

These changes are going to effectively restrict mining activities and in our view does not appear to facilitate mineral exploration and development. Much of the mineralized land, of which a large proportion has a moderate to high mineral potential, has been allocated into management areas that require the Forest Service to administratively review impacts on plants and other resources. This increases the uncertainty of investments rather than facilitating exploration.

The decision to further restrict the Siskiyou Forest exploration and mineral development is not in the best interest of our local mining interests and those at a national level. It is our request that the Forest Service reconsider the whole issue surrounding minerals, and develop a policy that is equitable to all resources. Within the scope of this reassessment of the problem, we encourage the Forest Service to:

A. generate an economic analysis of the mineral importance in our region,

B. devote new effort to further exploration, inventorying and mapping of the forests mineral resources,

C. develop a transpiring mineral events monitoring program that provides a written record of all mineral events, but one that would also aid in determining any changes needed to meet proposed standards and guidelines, and

D. utilize registered mining professionals to conduct the inventories and participate in the assessments that determine balanced resource management.

Unique Interest:

We believe the Siskiyou National Forest is an important resource to the community, State and the nation. Since there are so many unique features, this allocation is appropriate and we would fully encourage that appropriate management techniques and preservation of the sites be aggressively followed. We would anticipate that information packets be developed to let the community and its visitors know the special attributes of the forest. For both the research natural areas and the botanical areas, informational access needs to be provided so that all can benefit from these special areas.

In summary, we would like to express our appreciation for the thorough and sensitive job that you and your staff has done on the development of a Plan and the Preferred Alternative. We think the direction/intent shows an awareness and concern of the management of the forest and the role of that the forest plays in the communities surrounding it. We hope that our comments will prove beneficial and would like to offer any assistance that may be necessary in gaining the adoption of a final plan in as expeditious manner as possible so that we can get on with the business of managing our forest lands.

Ron McCormick, Supervisor
Siskiyou National Forest
P. O. Box 440
Grants Pass, OR 97526

Dear Supervisor McCormick:

It becomes increasingly evident, after reviewing the Proposed Siskiyou National Forest Plan, that there appears to be a definite and direct battle being waged between groups and people of two different views.

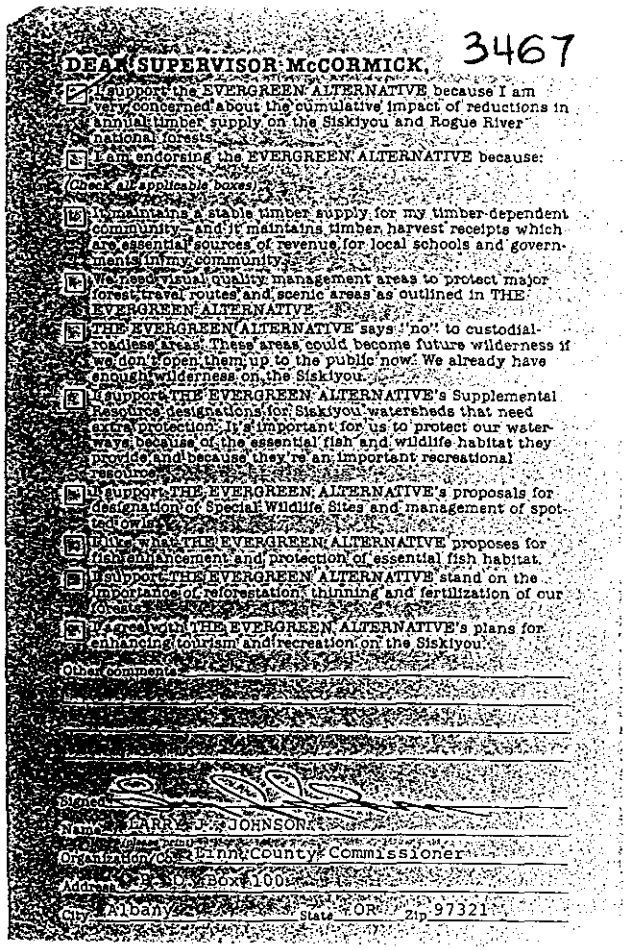
The next question would be, "Should or will there be a middle ground or a compromise reached that would be reasonable to both sides of the issue?" Following this and one step further, "Should there be a middle ground or compromise?"

There are never any easy answers to hard questions but there are always ways and means to successfully resolve problems. One successful way is to lay the pros and cons of a particular argument out and weigh each one on its own merit. Another method is through public input into a specific issue. Whatever method is used, the process will require a group of selected officials to sit down to determine what course of action to take.

As with any decision-making process, there is an easy way and a hard way. One way that will "ruffle the least feathers" and one that will subject you to tremendous heat from groups and individuals of both persuasion. Somewhere into this process you must interject just plain old common sense and maintain the ability to make a conclusion based just on facts, cutting out all the hoopla, threats and rhetoric.

The main reasoning for reducing the allowable cut always seem to fall on environmental concerns. If this were 40 years ago, this could be understood but logging practices have changed considerably over the years. With the current logging practices being exercised at this time and the strict reforestation laws being enforced, it is really hard to understand the position that a small group of individuals holds to.

It is our hope and wish that you will sit down, take a careful and full look at what effect any decision reducing the allowable cut would have on the economy in your affected area and decide to allow the current practices to remain as they are. Please realize what effects your decision will have on all the residents (the average taxpayer, busineses and schools).



One thing must be remembered about our woods and forests in Western Oregon. We do the best and grow the finest timber, a renewable resource. Regardless of what else is said, the one thing that we do the best is your trees.

History has a funny way of analyzing our deeds and thoughts. Years down the road, let our future generations say of us that we saw the problem, took a stand and decided that it was time that we started to utilize our natural resources for the total benefit of all.

Sincerely,

Larry J. Johnson
Linn County Commissioner

3467

DEAR SUPERVISOR McCORMICK,

- [ ] I support the EVERGREEN ALTERNATIVE because I am very concerned about the cumulative impact of reductions in annual timber supply on the Siskiyou and Rogue River national forests.
- [x] I am endorsing the EVERGREEN ALTERNATIVE because:

(Check all applicable boxes)

- [x] It maintains a stable timber supply for my timber-dependent community -- and it maintains timber harvest receipts which are essential sources of revenue for local schools and governments in my community.
- [x] We need visual quality management areas to protect major forest travel routes and scenic areas as outlined in THE EVERGREEN ALTERNATIVE.
- [x] THE EVERGREEN ALTERNATIVE says "no" to custodial-roadless areas. These areas could become future wilderness if we don't open them up to the public now. We already have enough wilderness on the Siskiyou.
- [x] I support THE EVERGREEN ALTERNATIVE's Supplemental Resource designations for Siskiyou watersheds that need extra protection. It's important for us to protect our waterways because of the essential fish and wildlife habitat they provide and because they're an important recreational resource.
- [x] I support THE EVERGREEN ALTERNATIVE's proposals for designation of Special Wildlife Sites and management of spotted owl habitat.
- [x] I like what THE EVERGREEN ALTERNATIVE proposes for fish enhancement and protection of essential fish habitat.
- [x] I support THE EVERGREEN ALTERNATIVE stand on the importance of reforestation, thinning and fertilization of our forests.
- [x] I agree with THE EVERGREEN ALTERNATIVE's plans for enhancing tourism and recreation on the Siskiyou.

BOARD OF SUPERVISORS
COUNTY OF DEL NORTE
STATE OF CALIFORNIA

RESOLUTION NO. 87-123

A RESOLUTION IN OPPOSITION TO THE
FOREST SERVICE PREFERRED ALTERNATIVE
AND IN SUPPORT OF THE EVERGREEN ALTERNATIVE

WHEREAS, the Del Norte County Board of Supervisors is concerned about the economic and social well being of Del Norte County; and

WHEREAS, the Del Norte County Board of Supervisors supports diversification of the Southern Oregon and Northern California economy, including the continued development of the tourism industry; and

WHEREAS, the Del Norte County Board of Supervisors believes the retention and expansion of existing businesses is necessary to achieve further economic diversification; and

WHEREAS, our community is significantly dependent upon a steady supply of timber from National Forests, including the Siskiyou National Forest, to provide the base for employment, incomes, and county funding for schools and roads; and

WHEREAS, this County has reviewed the Forest Service Preferred Alternative for managing the Siskiyou National Forest; and

WHEREAS, the Preferred Alternative proposes to reduce employment by approximately 290 jobs; and

WHEREAS, the Preferred Alternative proposes to reduce timber receipts to county governments by $1.4 million annually; and

WHEREAS, the Preferred Alternative proposes preserving 1,000 acres per pair of spotted owls, prior to the completion of critical research to determine the habitat needs of spotted owls; and

WHEREAS, the Preferred Alternative proposes to preserve 14,000 acres as inaccessible "Custodial/Roadless" management areas, in addition to the 232,000 acres of existing Wilderness on the Siskiyou National Fores; and

WHEREAS, this County has also reviewed the Evergreen Alternative, a framework for managing the Siskiyou National Forest; and

BOOK PAGE

WHEREAS, the Evergreen Alternative proposes to increase the annual Siskiyou National Forest timber supply, through the use of scientifically sound, aggressive forest management, by 21 million board feet; and

WHEREAS, the Evergreen Alternative proposes to increase jobs by approximately 360; and

WHEREAS, the Evergreen Alternative proposes to increase timber receipts to county governments by $1.7 million annually; and

WHEREAS, the Evergreen Alternative proposes maintaining options for spotted owl management until critical research on the owl's habitat needs have been completed and a sound management decision can be made; and

WHEREAS, the Evergreen Alternative, like the Forest Service Preferred Alternative, proposes protection for the Rogue River corridor, which is the focus of 25% of all recreation use in the Siskiyou National Forest; and

WHEREAS, the Evergreen Alternative proposes to allocate the management of 19.6 thousand MORE acres of the Siskiyou National Forest to Visual Management Areas than does the Preferred Alternative; and

WHEREAS, the Evergreen Alternative rejects the concept of "Custodial/Roadless" management areas because 21% of the Siskiyou National Forest is currently designated as Wilderness and receives only 3% of the total recreational use; and

WHEREAS, this County supports the immediate harvest of fire damaged and killed timber in the Siskiyou National Forest.

NOW, THEREFORE, BE IT RESOLVED, that the Board of Supervisors, County of Del Norte, State of California, goes on record in OPPOSITION to the Forest Service Preferred Alternative, and in SUPPORT of the Evergreen Alternative for managing the Siskiyou National Forest. The Del Norte County Board of Supervisors urges the Forest Service to work with supporters of the Evergreen Alternative to fully develop it before a final Siskiyou forest plan is implemented.

PASSED AND ADOPTED this 14th day of December, 1987, by the following polled vote:

RESOLUTION NO. 402-87

BE IT ORDAINED by the Common Council of Port Orford that it hereby approves and adopts the following resolution.

"A RESOLUTION IN SUPPORT OF THE EVERGREEN ALTERNATIVE"

and:

WHEAREAS, City of Port Orford is concerned about the economic and social well being of Curry County, and

WHEREAS, City of Port Orford supports diversification of the Southern Oregon economy, including the continued development of the tourism, industry, and,

WHEREAS, City of Port Orford believes the retention and expansion of existing businesses is necessary to achieve further economic diversification, and,

WHEREAS, our community is significantly dependent upon a steady supply of timber from National Forests, including the Siskiyou National Forest, to provide the base for employment, incomes, and county funding for schools and roads, and,

WHEREAS, this organization has reviewed the Forest Service Preferred Alternative for managing the Siskiyou National Forest, and,

WHEREAS, the Preferred Alternative proposes to reduce the annual timber supply of the Siskiyou National Forest by 17 million board feet, and,

WHEREAS, the Preferred Alternative proposes to reduce employment by approximately 290 jobs, and,

WHEREAS, the Preferred Alternative proposes to reduce timber receipts to county governments (principally Josephine and Curry) by $1.4 million annually, and,

WHEREAS, the Preferred Alternative proposes preserving 1000 acres per pair of spotted owls, prior to the completion of critical research to determine the habitat needs of spotted owls, and,

WHEREAS, the Preferred Alternative proposes to preserve 14,000 acres as inaccessible "Custodial/Roadless" management areas, in addition to the 232,000 acres of existing Wilderness on the Siskiyou National Forest, and,

WHEREAS, the communites and industry of southern Oregon have developed an "Evergreen Alternative" that meets the economic and environmental needs of the area, and;

BE IT HEREBY RESOLVED that the Common Council of Port Orford that, the Siskiyou National Forest fully develop and adopt the "Evergreen Alternative" as purposed for final implementation. WE feel this alternative uniquely balances economic and environmental tradeoffs, while maintaining a stable raw materials base for our forest products industry, therefore maintaining and ultimately increasing employment and economic stability in the region.

The foregoing resolution was fully approved at the regular session held on the 14th day of December, 1987.

Ron McCormick, Forest Supervisor
Siskiyou National Forest
P.O. Box 440
Grants Pass, Oregon 97526

Dear Mr. McCormick:

The City Council of the City of Brookings, Oregon, by unanimous vote at its regular meeting on December 14, 1987, instructed that a letter be written to the Forest Service, U.S. Department of Agriculture, urging adoption of the "Evergreen Alternative" plan for the future management of the Siskiyou National Forest. This alternative more reasonably matches the Siskiyou National Forest potential with the needs of the local communities which support it.

The City of Brookings is also deeply concerned that while the Preferred Alternative generally admits the importance of preserving high quality water resources for downstream water users there is no requirement whatsoever to ensure that recommended management practices will protect domestic water resources. Both the City of Brookings and the Harbor community, aggregating some 10,000 people, are totally dependent on the Chetco River for municipal water supplies. We insist that this critical resource be identified and that specific protection policies together with effective implementation measures be included in the Land and Resource Management Plan.

We offer our assistance to you in any reasonable manner to identify and protect this additional critical forest resource.

Sincerely,

Roy G. Rainey
City Manager

RE: GREGORY ALTERNATIVE FOR MANAGEMENT OF THE SISKIYOU NATIONAL FOREST

The City of Glendale is a small community located at the southern tip of Douglas County and is almost solely dependent upon the operation of its two local mills. The management of the Siskiyou National Forest is of major concern to all citizens in the area. Therefore, the City Council has reviewed the Draft Forest Plan.

Based upon that review the Council would like to endorse the Gregory Alternative through a vote of confidence. The basis for our support of this alternative is briefly highlighted:

..Community stability and additional jobs
..Increased O&C and NFF receipts of $15.4 million to counties
..Encouragement of prompt salvage and rehabilitation of fire areas
..Promotion of tourism

While our major concern is for the economy of the area it is also important to address the recreational and aesthetic needs. Gregory's Alternative does this by recommending the following:

..Addition of North Fork Smith River and Chetco River to the National Wild and Scenic Status
..Increasing wildlife user days to 81,700 days annually
..Promotes fish enhancement improvements
..Proposes development of trails and campsites

The reduction in annual timber supply recommended by the Draft Forest Plan would have a significant impact and place an even greater economic

Forest Supervisor
Page 2

burden on the communities of Southern Oregon. We are asking that you comment again on the Siskiyou draft forest plan and support the Gregory Alternative which was developed in response to the Siskiyou Draft Plan.

Your consideration in this matter is greatly appreciated.

Sincerely,

CITY OF GLENDALE

Re: Siskiyou National Forest Management Plan

Dear Mr. McCormick:

The Medford City Council has requested me to communicate to you its opposition to the proposed Forest Service plan and its support for the EVERGREEN ALTERNATIVE proposed by Southern Oregon Timber Industries Association (SOTIA). Enclosed is a certified copy of a resolution setting forth the Council's position.

The Council is concerned about the disastrous loss of jobs and local government revenue which would result if the Forest Service's preferred alternative harvest level is implemented. On the other hand, the EVERGREEN ALTERNATIVE would increase local employment by 357 jobs and increase timber receipt payments by about $1.7 million annually while preserving vital resource areas, fisheries and wildlife habitat. The EVERGREEN ALTERNATIVE supports more intensive forest management practices such as reforestation with genetically superior seedlings, thinning stagnant timber stands, fertilization for faster growth and clearing of hardwood species to make way for timber crops. Such practices are vital to insure the economic health of our region.

We strongly urge the Forest Service to work with SOTIA and other interested groups so that the EVERGREEN ALTERNATIVE can become a reality.

Sincerely yours,

Jerry Lausmann
Mayor

Encl.

RESOLUTION NO. 6047

A RESOLUTION supporting the Evergreen Alternative.

NOW, THEREFORE, BE IT RESOLVED BY THE CITY COUNCIL OF THE CITY OF MEDFORD, OREGON that the City Council hereby expresses its support for the Evergreen Alternative proposed by Southern Oregon Timber Industries Association.

PASSED by the Council and signed by me in open session in authentication of its passage this 7th day of January, 1988.

Re: Evergreen Alternative

Please find enclosed a copy of Resolution No. 2695 which was adopted and passed by the North Bend City Council at their regular meeting of January 12, 1988 in support of the "Evergreen Alternative".

Thank you for the opportunity to comment on this issue which is so very important to our community.

CITY OF NORTH BEND

Joseph Mulloy
City Administrator

a
Enclosure

RESOLUTION NO. 2695

BE IT RESOLVED BY THE COUNCIL OF THE CITY OF NORTH BEND AS FOLLOWS:

1. Coos County is economically dependent on the forest products industry for a financial foundation and well being.

2. The raw materials for this industry are obtained almost exclusively from Bureau of Land Management and Forest Service lands in Douglas, Lane, Coos, Curry, Jackson, and Josephine counties.

3. The practice of sound forest management principals that mainatin a constant flow of timber from all available commercial forest land is important to the industry and economy.

4. We believe that a forest management plan should be based on the principals of multiple-use which allows for many different uses on the same acre and minimizes the trade-offs between timber harvest and other uses.

5. The proposed Siskiyou National Forest Land Management Plan would reduce the allowable harvest level by 11 percent or 17 million board feet per year.

6. The proposed reduction in allowable harvest would result in approximately 300 forest products jobs being lost, many of these in Coos County.

7. Several well respected forest scientists and consultants including Mason, Bruce, and Girard of Portland have examined the technical aspects of the Siskiyou National Forest Land Management Plan and have determined that the allowable harvest should be raised 33 million board feet above the forest service proposed harvest level, without environmental degradation.

8. The ability to increase the allowable harvest level would produce approximately 400 new jobs in the forest products industry, therefore being consistent with Governor Neil Goldschmidts "Oregon Comeback".

9. The communities and industry of southern Oregon have developed an "Evergreen Alternative" that meets the economic and environmental needs of the area.

BE IT HEREBY RESOLVED BY THE North Bend City Council that the Siskiyou National Forest fully develop and adopt the "Evergreen Alternative" as proposed for final implementation. We feel this alternative uniquely balances economic and environmental tradeoffs, while maintaining a stable raw materials base for our forest products industry, therefore maintaining and ultimately increasing employment and economic stability in the region.

Passed and adopted by the Council of the City of North Bend this 12th day of January, 1988.

Mayor

RESOLUTION NO. 2695

03569

POSITION STATEMENT FOR THE EVERGREEN ALTERNATIVE
ON THE
SISKIYOU NATIONAL FOREST LAND MANAGEMENT PLAN

WHEREAS, the City of Powers is economically dependent on the forest products industry for a financial foundation and well being, and;

WHEREAS, the raw materials for this industry are obtained almost exclusively from Bureau of Land Management and Forest Service lands in Douglas, Lane, Coos, Curry, Jackson, and Josephine counties, and;

WHEREAS, the practice of sound forest management principals that maintain a constant flow of timber from all available commercial forest land is important to the industry and economy, and;

WHEREAS, we believe that a forest management plan should be based on the principals of multiple-use which allows for many different uses on the same acre and minimizes the trade-offs between timber harvest and other uses, and;

WHEREAS, the purposed Siskiyou National Forest Land Management Plan would reduce the allowable harvest level by 11 percent or *17 million board feet, and;*

WHEREAS, the purposed reduction is equal to enough lumber to build approxiamtely 2000 three bedroom homes, and;

WHEREAS, the purposed reduction in allowable harvest would result in approximately 300 forest products jobs being lost, many of these in Powers, and; surrounding area's.

WHEREAS, several well respected forest scientists and consultants including Mason, Bruce, and Girard of Portland have exmained the technical aspects of the Siskiyou National Forest Land Management Plan and have determined that the allowable harvest could be raised 33 million board feet above the forest service purposed harvest level, without environmental degradation, and;

WHEREAS, the ability to increase the allowable harvest level would produce approximately 400 new jobs in the forest products industry, therefore being consistant with Governor Neil Goldschmidits "Oregon Comeback", and;

WHEREAS, the communities and industry of southern Oregon have developed an "Evergreen Alternative" that meets the economic and environmental needs of the area, and;

BE IT HEREBY RESOLVED BY THE COUNCIL OF THE CITY OF POWERS THAT, the Siskiyou National Forest fully develop and adopt the "Evergreen Alternative" as purposed for final implementation. We feel this alternative uniquely balances economic and environmental tradeoffs, while maintaining a stable raw materials base for our forest products industry, therefore mainataing and ultimately increasing employment and economic stability in the region.

BE IT FURTHER RESOLVED THAT, this resolution be sent to all members of the Oregon Congressional Delegation, Chief of the Forest Service, Forest Service Region Six Regional Forester, and Supervisor of the Siskiyou National Forest.

Illinois Valley Soil and Water Conservation District
Cave Junction, Oregon 97523 · Phone (503) 592-3731

December 14, 1987

Mr. Ron McCormick
Siskiyou National Forest Supervisor
Grants Pass, Oregon 97526

Re: Siskiyou National Forest Plan Draft.

Dear Mr. McCormick:

First, to explain our entity; our Soil & Water Conservation District in Illinois Valley was established by state law in 1949, governed by a seven man, publicly elected, Board of Directors. The primary objectives of the district is to help educate youth and the general public in ways to conserve and maintain the natural resources. We offer technical asssistance from Soil Conservation Service (SCS), for developing conservation plans that include a proper balance for production and economy of the area.

Aside from agricultural lands, timber management has been one of our primary concerns.

We have reviewed both the Siskiyou National Forest's proposed Land Resource Management Plan, and the Evergreen Alternative. Some members have actively attended hearings on this subject.

After considerable discussion at our Dec. 9, 1987 Board meeting, we concluded that the community needs a certainty of maintaining the present level of our economy that is so dependent on timber industry receipts, which substantuates the local property tax offset, and provides jobs in compatibility with tourism.

Since there are so many conflicting view points, we also agree that the 10-15 year Forest Plan must be in keeping with Congressional mandate with careful forethought of intrusion that would jeopardize the watershed's natural environment, to retard potentials for turbidity and pollution.

Our final concensus is: That the "Evergreen" management alternative best sums up the need for a sensible balance between economic and environmental considerations.

Sincerely,

Walter B. Freeman
Board Chairman

POSITION STATEMENT FOR THE Port of Bandon
ON THE
SISKIYOU NATIONAL FOREST LAND MANAGEMENT PLAN

WHEREAS, Port of Bandon is economically dependent on the forest products industry for a financial foundation and well being, and;

WHEREAS, the raw materials for this industry are obtained almost exclusively from Bureau of Land Management and Forest Service lands in Douglas, Lane, Coos, Curry, Jackson, and Josephine counties, and;

WHEREAS, the practice of sound forest management principals that maintain a constant flow of timber from all available commercial forest land is important to the industry and economy, and;

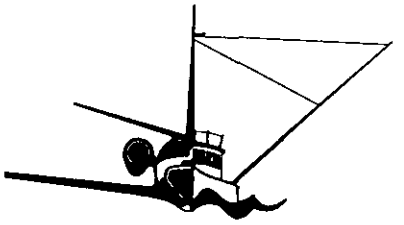
WHEREAS, we believe that a forest management plan should be based on the principals of multiple-use which allows for many different uses on the same acre and minimizes the trade-offs between timber harvest and other uses, and;

WHEREAS, the purposed Siskiyou National Forest Land Management Plan would reduce the allowable harvest level by 11 percent or 17 million board feet, and;

WHEREAS, the purposed reduction is equal to enough lumber to build approxiamtely 2000 three bedroom homes, and;

WHEREAS, the purposed reduction in allowable harvest would result in approximately 300 forest products jobs being lost, many of these in Coos County, and;

WHEREAS, several well respected forest scientists and consultants including Mason, Bruce, and Girard of Portland have exmained the technical aspects of the Siskiyou National Forest Land Management Plan and have determined that the allowable harvest could be raised 33 million board feet above the forest service purposed harvest level, without environmental degradation, and;



WHEREAS, the ability to increase the allowable harvest level would produce approximately 400 new jobs in the forest products industry, therefore being consistant with Governor Neil Goldschmidits "Oregon Comeback", and;

WHEREAS, the communities and industry of southern Oregon have developed an "Evergreen Alternative" that meets the economic and environmental needs of the area, and;

BE IT HEREBY RESOLVED BY THE Port of Bandon
THAT, the Siskiyou National Forest fully develop and adopt the "Evergreen Alternative" as purposed for final implementation. We feel this alternative uniquely balances economic and environmental tradeoffs, while maintaining a stable raw materials base for our forest products industry, therefore mainataing and ultimately increasing employment and economic stability in the region.

BE IT FURTHER RESOLVED THAT, this resolution be sent to all members of the Oregon Congressional Delegation, Chief of the Forest Service, Forest Service Region Six Regional Forester, and Supervisor of the Siskiyou National Forest.

U4562

PORT OF GOLD BEACH

BOX 1126 247-6269

GOLD BEACH, OREGON 97444

A RESOLUTION IN OPPOSITION
TO THE FOREST SERVICE PREFERRED ALTERNATIVE, AND,
IN SUPPORT OF
THE EVERGREEN ALTERNATIVE

WHEREAS, Port of Gold Beach is concerned about the economic and social well being of Port District of Gold Beach, and,

WHEREAS, Port of Gold Beach supports diversification of the Southern Oregon economy, including the continued development of the tourism, industry, and,

WHEREAS, Port of Gold Beach believes the retention and expansion of existing businesses is necessary to achieve further economic diversification, and,

WHEREAS, our community is significantly dependent upon a steady supply of timber from National Forests, including the Siskiyou National Forest, to provide the base for employment, incomes, and county funding for schools and roads, and,

WHEREAS, this organization has reviewed the Forest Service Preferred Alternative for managing the Siskiyou National Forest, and,

WHEREAS, the Preferred Alternative proposes to reduce the annual timber supply of the Siskiyou National Forest by 17 million board feet, and,

WHEREAS, the Preferred Alternative proposes to reduce employment by approximately 290 jobs, and,

WHEREAS, the Preferred Alternative proposes to reduce timber receipts to county governments, (principally Josephine and Curry) by $1.4 million annually, and,

WHEREAS, the Preferred Alternative proposes preserving 1000 acres per pair of spotted owls, prior to the completion of critical research to determine the habitat needs of spotted owls, and,

WHEREAS, the Preferred Alternative proposes to preserve 14,000 acres as inaccessible "Custodial/Roadless" management areas, in addition to the 232,000 acres of existing Wilderness on the Siskiyou National Forest, and,

Resolution 88-11

Position Statement for the City of Myrtle Point
on the
Siskiyou National Forest Land Management Plan

Whereas, Myrtle Point is economically dependent on the forest products industry for financial foundation and well being; and,

Whereas, the raw materials for this industry are obtained almost exclusively from Bureau of Land Management and Forest Service lands in Douglas, Lane, Coos, Curry, Jackson and Josephine counties; and,

Whereas, the practice of sound forest management principles that maintain a constant flow of timber from all available commercial forest land is important to the industry and economy; and,

Whereas, we believe that a forest management plan should be based on the principles of multiple-use which allow for many different uses on the same acre and minimize the tradeoffs between timber harvest and other uses; and,

Whereas, the proposed Siskiyou National Forest Land Management Plan would reduce the allowable harvest level by 11 percent (17 million board feet); and,

Whereas, the proposed reduction is equal to enough lumber to build approximately 2000 three bedroom homes; and,

Whereas, the proposed reduction in allowable harvest would result in approximately 300 forest products jobs being lost; and,

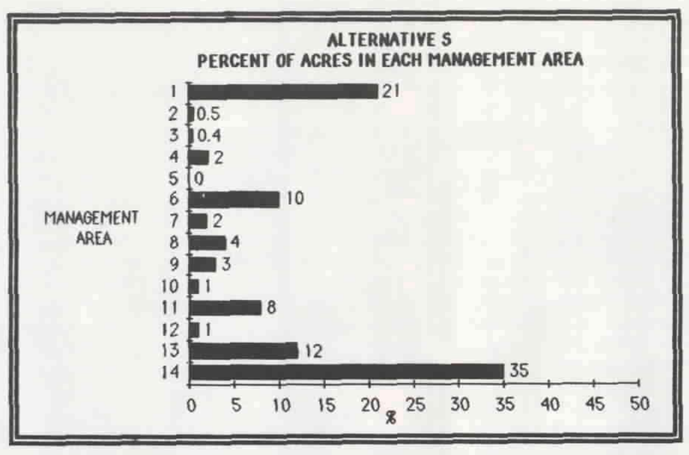
Whereas, several well respected forest scientists and consultants, including Mason, Bruce and Girard of Portland, have examined the technical aspects of the Siskiyou National Forest Land Mangement Plan and have determined that the allowable harvest could be increased 33 million board feet above the Forest Service proposed harvest level (without environmental degradation); and,

Whereas, the ability to increase the allowable harvest level would produce approximately 400 new jobs in the forest products industry, therefore being consistent with Governor Neil Goldschmidt's "Oregon Comeback"; and,

Whereas, the communities and industry of southern Oregon have developed an "Evergreen Alternative" that meets the economic and environmental needs of the area;

Now, therefore, be it resolved by the Myrtle Point City Council that the Siskiyou National Forest fully develop and adopt the "Evergreen Alternative" as proposed for final implementation. We believe this alternative uniquely balances economic and environmental tradeoffs while maintaining a stable raw materials base for our forest products industry, therefore maintaining and ultimately increasing employment and economic stability in the region.

Be it further resolved that a copy of this resolution be sent to all members of the Oregon Congressional Delegation, Chief of the Forest Service, Forest Service Region Six Regional Forester and Supervisor of the Siskiyou National Forest.



The foregoing resolution was duly adopted this 21st day of December 1987.

Land and Resource Management Plan

Siskiyou National Forest

PREFACE

This National Forest Land and Resource Management Plan (Forest Plan) is developed to direct the management of the Siskiyou National Forest The goal of the Forest Plan is to provide a management program reflective of a mixture of management activities that allow use and protection of the Forest resources; fulfill legislative requirements, and address local, regional and national issues and concerns. To accomplish this, the Forest Plan

Establishes the management direction and associated long-range goals and objectives for the Forest for the next 10 to 15 years,

specifies the Standards and Guidelines and the approx.mate timing and vicinity of the practices necessary to achieve that direction, and

establishes the monitoring and evaluation requirements needed to ensure that the direction is carried out and to determine how well outputs and effects were predicted.

The Forest Plan will be reviewed (and updated if necessary) at least every 5 years It will ordinarily be revised on a 10-year cycle, or at least every 15 years

Preparation of the Forest Plan is required by the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act (NFMA) Assessment of its environmental impacts is required by the National Environmental Policy Act (NEPA) and the implementing regulations of NFMA (36 CFR 219) The Forest Plan replaces previous resource management plans prepared for the Siskiyou National Forest Upon approval of the Forest Plan, subsequent activities affecting the Forest must be in compliance with the Forest Plan In addition, permits, contracts and other instruments for the use and occupancy of National Forest System lands must be in conformance with the Forest Plan

If any particular provision of this Forest Plan, or the application thereof to any person or circumstances, is held invalid, the remainder of the Forest Plan and the application of such provision to other persons or circumstances shall not be affected thereby

CHAPTER I

INTRODUCTION TO THE FOREST PLAN

Siskiyou National Forest Vicinity Map

Chapter I

INTRODUCTION TO THE FOREST PLAN

PURPOSE OF FOREST PLAN

The Land and Resource Management Plan (LRMP or the Forest Plan) establishes the direction for the Siskiyou National Forest for the next decade It guides all natural resource management activities and establishes a dynamic management system for future decisionmaking It establishes goals and objectives for forest management, and Standards and Guidelines for the Siskiyou National Forest The Forest Plan establishes Management Area direction including prescriptions as well as Standards and Guidelines specific to each Management Area It describes the availability and suitability of lands for resource management, levels of resource production and management, and monitoring and evaluation requirements

The Forest Plan embodies the provisions of the National Forest Management Act of 1976 (NFMA), the implementing regulations, and other guiding documents Land use determinations, prescriptions, and Standards and Guidelines are a statement of the plan's management direction, however, the projected outputs, services, and rates of implementation are dependent on the annual budgeting process

The Forest Plan will ordinarily be revised on a 10-year cycle, or at least every 15 years It also may be revised whenever the Forest Supervisor determines that conditions or demands in the area covered by the Plan have changed significantly or when changes in Resource Planning Act policies, goals, or objectives would have a significant effect on Forest level programs The Forest Supervisor will review the conditions on the land covered by the Plan and the demand of the public at least every 5 years to determine whether either has changed significantly

RELATIONSHIP OF THE FOREST PLAN TO OTHER DOCUMENTS

This Forest Plan sets forth the direction for managing the resources of the Siskiyou National Forest The Forest Plan results from extensive analysis of 12 alternatives which are considered in the accompanying Final Environmental Impact Statement (FEIS) and Record of Decision It is based on Alternative S as presented in the FEIS and as modified in the Record of Decision Many aspects of the Forest Plan reflect numerous suggestions from the public in response to the Draft Environmental Impact Statement and accompanying Proposed Land and Resource Management Plan The planning process, including the analytic procedures that were used to develop this Plan, are described or referenced in the FEIS The FEIS also describes and analyzes the other alternatives considered in the planning process Information in the Forest Plan incorporates inventory adjustments for the 1987 fires and timber land suitability in the Silver Fire Recovery Project area as described in Chapters II and III of the FEIS

The Forest Plan establishes rules for making future decisions about the management of the national forest but it does not make most of these decisions Activities and projects will be planned and implemented to carry out the direction in this Plan The Forest will perform environmental analyses on these projects and activities Project-level environmental analysis will use the data and evaluations in this Plan and FEIS as its basis Documentation of project-level analysis will be tiered to the FEIS

REGIONAL GUIDE

The Regional Guide for the Pacific Northwest Region (FEIS, 1984) and the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines, Final SEIS, 1988) provide direction for National Forest Plans and develop standards and guidelines addressing major issues and management concerns considered at the Regional level to facilitate Forest planning

SPECIAL AREA PLANS

The regulations (36 CFR 219 2 (b)) guiding the development of Forest Plans state that "(if), in a particular case, special area authorities require the preparation of a separate special area plan, the direction in any such plan may be incorporated without modification " For this reason the Rogue National Wild and Scenic River Management Plan (1972) and the Illinois Wild and Scenic River Management Plan (1985) will be incorporated unchanged in the Forest Plan

RELATIONSHIP TO OTHER PLANS

The Forest Plan serves as the single land management plan for the Siskiyou National Forest All other management plans are replaced by the direction in this Forest Plan (see Chapter V for a list of existing plans that this Forest Plan supersedes) The management direction provided by this Forest Plan comprises the framework within which site-specific project planning and activities take place

PLAN STRUCTURE AND ORGANIZATION

The Forest Plan document is composed of five chapters, literature cited, acronyms and glossary, and six appendices Chapter I is the introduction which describes the purpose of the Forest Plan, summarizes the content, describes the Forest's geographic location, and discusses the Plan's relationship to other documents

Chapter II is a summary of the Analysis of the Management Situation Included are summaries of the current management situation for each resource, a brief socioeconomic overview of the Forest and related communities and counties, potential supply for various resource goods and services, and a brief look at demand Chapter II also includes a list of further research and information needs for the Forest

Chapter III summarizes the public issues and management concerns identified and briefly explains how each was treated in the Forest Plan

Chapter IV is the heart of the Plan and contains the multiple-use resource goals which the Forest has established for the planning period Accompanying this are the projected resource outputs and activities necessary to achieve the goals The outputs and activities are the objectives the Forest should meet to implement the Plan; they are based on available inventory data and assumptions, subject to the annual budget

Chapter IV contains the Standards and Guidelines for Plan implementation They apply to the everyday on-the-ground projects and cover a wide range of resources Some are specific and others provide procedures to follow There are Forest-wide Standards and Guidelines in addition to Standards and Guidelines specific to Management Areas Also in Chapter IV are Management Area Prescriptions which describe the Management Areas and define the types of activities that can occur in those areas The specific locations of the various Management Areas within the Forest are shown on the map labeled "Land and Resource Management Plan"

Chapter V contains the implementation direction, a plan for monitoring and evaluating Forest Plan implementation, and a description of the process for Plan amendment and revision Project-level planning and schedules are discussed As the Forest Plan is implemented, it will be monitored to determine whether the outputs and Standards and Guidelines in Chapter IV are being met and whether the Standards and Guidelines are effective in achieving the desired results

Following Chapter V is a list of literature cited as well as abbreviations and terms used in this document The appendices provide Wilderness Plans, activity schedules for the projected budget, Ten-year Timber

Sale Action Plan, background information on the development of the Monitoring and Evaluation Plan, Off-Road Vehicle Plan, and Best Management Practices The activity schedules are flexible and subject to on-going change

FOREST DESCRIPTION

The Siskiyou National Forest is located in southwestern Oregon, with a small portion in extreme northwestern California The Forest lies within 50 miles of the Pacific Ocean Its boundaries embrace both the Klamath Mountains and Coast Range geologic provinces The largest part of the Forest lies within Curry County on the coastal side and Josephine County on the east The California portion is in Del Norte County Coos County covers a northern area Net acreage of the Siskiyou National Forest is 1,092,302 acres Other ownerships occupy only three percent, or 69,728 acres, of the total area within the National Forest Boundary

The larger service centers are in the cities of Grants Pass, Medford, and Coos Bay Smaller communities in close proximity to the Forest and with close socioeconomic ties are Cave Junction, Brookings, Gold Beach, Port Orford, and Powers The Forest Headquarters is in Grants Pass, Oregon Ranger District Offices are located in Grants Pass (Galice), Cave Junction (Illinois Valley), Brookings (Chetco), Gold Beach, and Powers

CHAPTER II

SUMMARY OF THE ANALYSIS OF THE MANAGEMENT SITUATION

Chapter II

SUMMARY OF THE ANALYSIS OF THE MANAGEMENT SITUATION

INTRODUCTION

This chapter briefly summarizes the user demands and resource potentials and conditions for the Siskiyou National Forest. Included are demand projections, resource and economic supply potentials, and development opportunities. The major questions at issue are timber production, old-growth preservation, fish habitat and watershed condition, sensitive plant areas, scenic values, wildlife habitat, recreation opportunities, and mineral development. Consequently, potential, current, and planned outputs of significant goods and services are presented along with projected demands by users of the Forest Also included in this chapter are further information needs for the Siskiyou National Forest

RESOURCE DEMAND PROJECTIONS

The discussion of demand is essential to making an informed decision on allocation of the Forest resources and productive capacity.

DEMAND FOR TIMBER HARVEST

The total amount of wood processed within the six county area of Coos, Curry, Del Norte, Douglas, Jackson, and Josephine for 1972 and 1976 was 3,419 MMBF and 2,885 MMBF, respectively. The latest (1984) figure for the same area is 2,455 MMBF. The 350 or so firms that process wood produce a variety of products including sawtimber, plywood, shakes, pulp, arrows, and other miscellaneous products. Douglas-fir is the species most often bought, although pine, hemlock, red-cedar, and Port-Orford-cedar are also utilized The demands for timber harvest are most affected by regional and National economics as well as costs from other markets including foreign markets, while the demand for Port-Orford-cedar is affected by its use in Japan.

OLD GROWTH

The demand for preservation of old-growth timber is significant but difficult to quantify. The demand for retention of old growth for wildlife habitat, aesthetics, biological diversity, and its perceived intrinsic value will intensify as old-growth stands are harvested and development takes place. With increasing public awareness, the demand for preservation will also increase

FISH HABITAT, WATER QUALITY, AND SOIL PRODUCTIVITY

While each of these resources are unique, they are also highly interrelated. For example, a reduction in soil productivity is commonly the result of soil and organic matter loss Soil loss affects water quality and can result in an effect on fish habitat. Consequently, the demand for fish indicates a demand for water quality and soil productivity.

The demand for the fisheries resource has grown steadily A regional projection of a 1.6 percent annual growth results in demand for an additional 16,900 fish user days by the year 2000. As people have more leisure time, the recreational demand for fisheries is increased. In addition, as the competition for the offshore fishery increases, so does the demand for smolt habitat.

The greatest demands on recreation are the result of more people having more leisure time, the awareness of the Forest's opportunities (particularly rivers), and the local governments' desires to promote tourism

SENSITIVE PLANTS

The demand for preservation of sensitive plants has been expressed. Anticipated concern is assumed to be increasing The demand will rise as development encroaches on sensitive plant habitat and as public awareness increases.

VISUALS

Increased harvest and development will bring increased concern for visual management An increase in the number of people having the perception that a forest should have an unmanaged, undisturbed appearance is also increasing the demand The present demand level is assumed to increase as additional landscapes are modified by timber harvest and more people use the Forest

WILDLIFE HABITAT

Many people are interested in wildlife habitat The concerns include maintaining habitat for viable populations of old-growth species (displayed as part of the preservation of old growth habitat), adequate wildlife tree habitat (snags and culls), and suitable areas for big-game habitat

The demand for big-game-associated recreation is assumed to increase at 1.3 percent per year as projected throughout the Northwest region The recreation demand associated with non-game wildlife is predicted to increase at one-half of one percent per year. The demands are most affected by the increasing numbers of recreationists and the publics awareness of the part the habitat plays in wildlife numbers Future demand for wildlife will exceed supply

MINERAL RESOURCES

The demand for mineral resources is difficult to anticipate Demand will be determined by future conditions in world markets. Gold, silver, nickel, cobalt, chromite, copper, and coal are the minerals most likely to be affected on the Forest.

RESOURCE SUPPLY CONDITIONS

Table II-1, "Benchmark Outputs and Effects", displays the maximum supply of various resources constrained by legal requirements for managing National Forest land, such as those relating to the habitat needs for viable wildlife populations and multiple use requirements Timber production is also constrained to meet the nondeclining flow policy These benchmarks help to define the range of potential outputs the Forest could produce to respond to the above demands

These benchmarks developed in the Analysis of the Management Situation are

1 Current Direction - Estimates the outputs and effects of maintaining direction found plans and policies existing prior to development of this Forest PLan

2 Present Net Value - Estimates the maximum PNV that might be attained by maximizing the net value of priced outputs under a nondeclining flow policy. This benchmark serves as a basis for an economic comparison between benchmarks and alternatives, as well as a basis for determining the effects of various constraints on outputs and costs.

The benchmarks developed in the Analysis of the Management Situation are:

1. Current Direction - Estimates the outputs and effects of maintaining direction found plans and policies existing prior to development of this Forest Plan

2 Present Net Value - Estimates the maximum PNV that might be attained by maximizing the net value of priced outputs under a nondeclining flow policy This benchmark serves as a basis for an economic comparison between benchmarks and alternatives, as well as a basis for determining the effects of various constraints on outputs and costs

3 Recreation - Determines the Forests ability to satisfy recreational demand.

4. Visuals - Estimates the outputs and effects of allocating the maximum amount of Retention Visual and Partial Retention Visual Management Areas.

5. *Unroaded - Determines the outputs and effects of allocating all unroaded areas to minimum* maintenance management.

6 Watershed/Fisheries - Determines the Forest outputs with the most improved fisheries habitat and watershed conditions.

7. Wildlife - Estimates the effects and outputs of a land allocation designed to optimize wildlife habitat diversity and maintain the viability of all species

8. Timber - Determines the highest level of timber production possible with a policy of nondeclining flow, subject to Management Requirements (MR's).

9. Minimum Level - Determines the minimum costs of maintaining Forest lands in federal ownership which are necessary to protect life, health, and safety of incidental users.

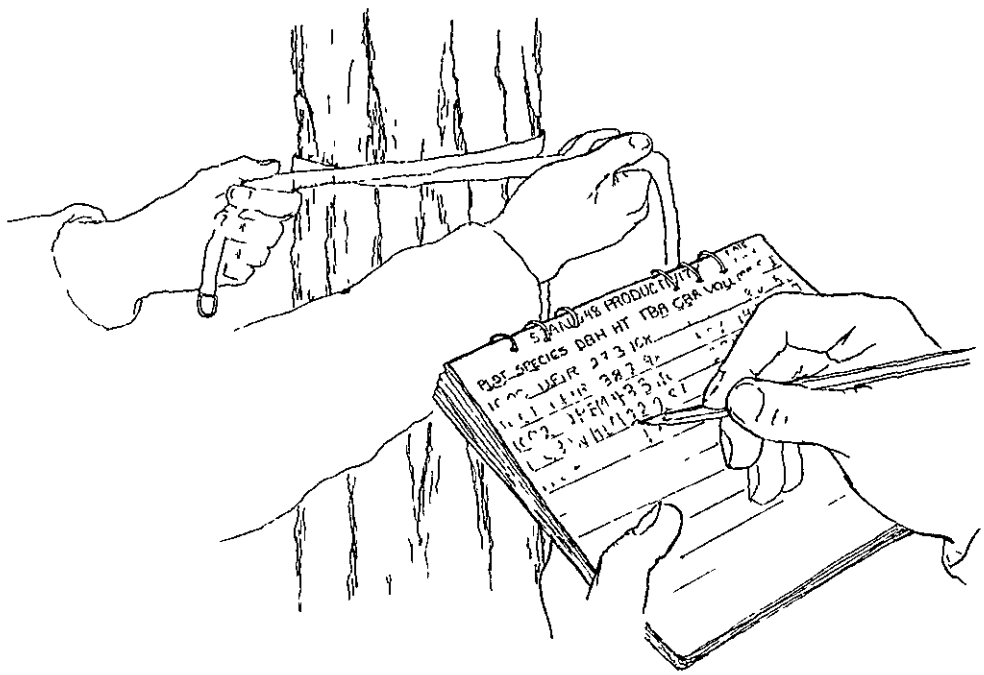

Table II-1. Benchmark Outputs and Effects

Output/Effect	Current 1/ Direction	Maximum PNV	Benchmark: Recreation	Visuals	Unroaded	Watershed/ Fisheries	Wildlife	Timber	Minimum Level

Restricted Areas	<----------				246	----------			----->

1/ "Current direction" estimates the outputs and effects of maintaining direction found plans and policies existing prior to development of this Forest Plan.
2/ NE - Not Estimated
3/ Benchmark values were calculated for current direction and maximum amounts only

For the benchmark analysis, timber revenues account for approximately 80 percent of the total revenues generated by the Forest After timber, nonwilderness recreation and fisheries values generate the greatest amount of revenue (approximately 10 percent and 5 percent respectively)

The outputs for soil, water, fisheries, wildlife, minerals, and sensitive plants are shown for each benchmark to illustrate interactions with the maximum production capacity of the Forest One example of such interaction is the increase in old-growth habitat with decreased harvest of timber Trade-offs between unroaded areas, old-growth habitat areas, visual areas, and timber outputs account for the major differences between the benchmarks

Though the potential supply of the Forest is important, it is meaningless by itself until the planned outputs of the Forest and demands of forest users and consumers are considered (Table II-2) This process involves the resolution of more than one question at a time.

TIMBER

The maximum amount of timber that could be offered in the first decade without a departure is 34.1 MMCF. That is less than the RPA target of 36 8 MMCF The Forest Plan provides less timber at 28 4 MMCF for the first decade, but gradually increases to the long-term sustained-yield of 48 MMCF in the 12th decade

OLD GROWTH PRESERVATION

The maximum amount of mature and old growth that exists during the planning period is 393,000 acres (minimum level benchmark) The plan gradually converts old-growth stands until 209,000 acres remain in the fifth decade

FISH HABITAT AND WATERSHED CONDITION

The maximum amount of fish produced as reflected by fishing user days (in WFUD's) is 73,000 WFUD's per year as determined by the benchmark analysis However, new information on the role of large woody material in stream courses provided new investment opportunities for increasing fish production Consequently, the planned output is an estimated 72,000 WFUD's per year, increasing to 87,000 WFUD's in the second decade The increased outputs are due to increased capital investments. There is an opportunity to look for and develop habitat and improve conditions using Knutson-Vandenberg Act and Capital Investment funds

RECREATION

The demand for recreation is less than the maximum and planned capacity for all forms of recreation The maximum capacity of Primitive (including Wilderness) and Semi-primitive recreation is in excess of the projected use However, the demand for unroaded recreation could exceed capacity in the future in areas outside of designated Wildernesses There are about 20 undeveloped recreation sites that could be developed in the future

SENSITIVE PLANTS

The maximum area of reserves for sensitive plants are 40,071 acres The Forest Plan provides 23,870 acres of Botanical areas and Research Natural Areas, which is over three times as much as the direction prior to the Forest Plan (6,432 acres)

VISUALS

The direction prior to the Forest Plan for visual management has nearly as many acres in retention and partial retention as the maximum visuals benchmark (307,000 versus 330,000 acres). The Forest Plan provides fewer acres (231,000) for visual management

WILDLIFE HABITAT

The maximum supply of habitat for spotted owls as provided by the wildlife benchmark is 371,000 acres for the first decade, then decreases to 214,000 acres in the fifth decade The Forest Plan provides 371,000 acres in first decade and 196,000 acres in the fifth decade This is a 42 percent decrease from the *benchmark*

As the anticipated demand for big game habitat increases with time, the Forest capacity to supply that habitat decreases. In the first decade, a 28 percent decrease in habitat capability occurs with the wildlife benchmark. However, that capacity increases in the fifth decade to a 4 percent increase. The plan has a 20 percent decrease in the first decade, but the habitat level remains at 16 percent below the level prior to the Forest Plan in the fifth decade. There is an opportunity to look for and develop habitat using funds from the Knutson-Vandenberg Act and capital investments appropriations.

MINERALS

There are insignificant differences between the maximum amount of acres available for mineral extraction prior to implementation and after the Forest Plan

The need to change direction from conditions prior to Forest Plan implementation is due to demands for timber production, fish production, old-growth habitat and sensitive plants The future increases in public demand for all Forest uses project a need for informed and innovative management. Such management requires some questions to be asked and answered for better resolution of emerging issues, concerns, and opportunities

1/ "Current direction" estimates the outputs and effects of maintaining direction found plans and policies existing prior to development of this Forest Plan
2/ Includes 48 M acres of Administrative Study Areas in General Forest.

INFORMATION NEEDS

This section lists the information, inventory, and research needs that have been identified for the Siskiyou National Forest. This recognizes gaps in data or scientific knowledge that would be desirable to fill prior to preparation of the next Siskiyou National Forest Land and Resource Management Plan The concept used to organize and develop these needs recognizes that biological, physical, and social ecosystems are the foundation for the planning process. This list may expand if additional needs are identified through monitoring and evaluation (see Chapter V and Appendix D).

FOREST NEEDS·

1. Develop timber growth and yield functions specific to the Siskiyou National Forest or within the local physiographic area.

2 Obtain up-to-date reliable information on the application of uneven-aged management under local conditions.

3. Explore better methods of controlling the spread of Port-Orford-cedar root disease (*Phytophthora lateralis*) and other diseases which could threaten the viability of tree species

4. Expand acceptable methods of managing lands now classified as unsuitable due to potential for irreversible resource damage.

5. Derive successful methods to reforest land now classified as not reforestable within five years.

6. Improve understanding of interaction of soil, seedlings, and environment as it affects reforestation and site productivity.

7. Define more clearly the plant associations.

8. Determine the desired amount and distribution of seral stages to be maintained within each of the Forest's plant associations. Determine how the Forest should manage for biological diversity Use *Research Natural Areas for baseline information and monitoring*

9. Better determine wildlife use of and needs for snags and large woody material for the Siskiyou National Forest (includes territorial needs of woodpeckers and their snag requirements per unit area)

10. Derive on-Forest rates of woody material accumulation and decay, and better establish how that should influence our management

11 Document the spatial and temporal pattern of wildfire intensity as influenced by management activities

12 Record the influence of previous stand history, disturbance frequency and intensity, and rehabilitation efforts on rates and direction of succession

13 Explore and document mechanisms for managing soil organisms and the importance of these organisms to ecosystem development and stability, and long-term productivity

14 Determine the effect of current road construction and timber harvest practices on the rate of landslides

15. Determine the effect of landslides on long-term conifer growth, water quality, channel and riparian condition, fish habitat, and off-site cumulative effects

16. Complete better documentation of response of fish populations to activities.

17 Re-analyze fishery economics for southwestern Oregon

18 Determine over-wintering requirements for juvenile anadromous salmonids, what are important components of habitat, and what happens to distribution during high flows

19 Obtain better on-Forest and downstream information on baseline channel condition, water quality, and fish habitat Continue to obtain long-term trends in channel condition, water quality, and fish populations

20. Inventory key aquatic habitats for invertebrate species composition Special attention needs to be directed toward local caddisflies listed as candidate species for endangered and threatened status by the U.S. Fish and Wildlife Service Initiate research on insect species associated with endemic plant species, especially serpentine endemics

21 Develop additional and innovative monitoring methods which are sensitive and efficient for sampling wildlife populations, water quality, fish production, and site productivity (including concept analysis of featured wildlife species versus species richness).

22 Accurately assess the recreation demand for and use of non-game wildlife on the Siskiyou National Forest

23 More specifically determine the limiting factor(s) for black-tail deer and Roosevelt elk populations (include analysis of impacts of timber management activities)

24 More precisely determine habitat requirements (localized for the Siskiyou National Forest) of management indicator species which depend on direct land allocations pileated woodpeckers, pine marten, and spotted owls. Habitat area required per breeding unit needs to be better determined, habitat suitability indexes need to be developed

25. Determine the habitat requirements of wildlife species which may be used as indicator species in future planning cycles, may require direct land allocation, or may need special management (includes marbled murrelet, goshawk, black bear, fisher, and water ouzel)

26. Inventory endangered, threatened, unique, and sensitive animals, e.g., bald eagles, peregrine falcons, wolverines, Townsend's big-eared bat, Siskiyou Mountain salamander, western pond turtle, white-footed vole, western spotted frog, and Gold Beach and Pistol River pocket gophers.

27. Inventory and better define the habitat, environmental, and propogational requirements of sensitive plants.

28. Complete more thorough inventory of Botanical Areas

29 Study the function and more thoroughly understand the value of hardwood, serpentine, and riparian areas to the Siskiyou National Forest ecosystem. Develop logical management indicator species for each of the three habitat types

30 Obtain additional inexpensive techniques for measuring and monitoring the Forest, including satellite and shuttle technology.

REGIONAL NEEDS:

1 Increase understanding of biological diversity and how the Siskiyou National Forest functions as a part of the whole.

2 Better comprehend the importance of old-growth ecosystems on the biological diversity of the Pacific Northwest

3 More thoroughly understand the effects of forest management and wood residue management on long-term site productivity and nutrient cycling for tree growth, wildlife populations, and fish populations

4. More appropriately quantify the economics of fire fighting, fuel hazards, and risks commensurate with resource values

5. Derive methods to quantify smoke emissions more accurately

6 Obtain and/or consolidate additional data on the effectiveness of Best Management Practices

7. Obtain more information about utilizing wood as a substitute for non-renewable resources now used in construction and energy production

CHAPTER III

RESPONSE TO ISSUES, CONCERNS, AND OPPORTUNITIES

Chapter III

RESPONSES TO ISSUES, CONCERNS, AND OPPORTUNITIES

INTRODUCTION

This Chapter presents the response of the Forest Plan to the Planning Problems developed in the scoping process. A major step in the development of this plan was the identification of issues, concerns, and opportunities (ICO's) related to management of the Siskiyou National Forest. These ICO's were identified through citizen participation including public meetings, interagency coordination, personal contacts with individuals and groups, and the comments to the DEIS and Proposed Forest Plan. Appendix A of the FEIS describes the process used to summarize the original issues, concerns and opportunities into Planning Problems Chapter I of the FEIS describes how the Planning Problems have evolved since the publication of the DEIS.

Taken individually, complete resolution of a Planning Problem (within the physical limits of the Forest) is not particularly challenging. The physical capability of the Forest to resolve each Planning Problem was presented in the previous chapter. Collectively, however, complete resolution of all Planning Problems simultaneously is impossible. Tradeoffs and compromises must be made to remain in compliance with the Multiple-Use, Sustained-Yield Act of 1960 which provides that equal consideration be given to all competing resources

The complexity of resolving the often conflicting, sometimes mutually exclusive resource needs inherent to the Planning Problems, can best be understood by reviewing several chapters and appendices in the FEIS Chapter I and Appendix A present the identification of issues, concerns, and opportunities leading to the development of Planning Problems Existing physical conditions of the various environmental components are described in Chapter III of the FEIS, which also includes a discussion concerning the demands on those resources and the Forest's ability to satisfy demands. Changes as a result of the 1987 fires and the Silver Fire Recovery Project are also summarized in the FEIS. Information in the Forest Plan incorporates these changes. Chapter IV of the FEIS displays the environmental consequences for each alternative.

The response for each Planning Problem reflects the recommendations associated with Alternative S as presented in the accompanying FEIS and as modified in the Record of Decision A number of "tools" are utilized in resolution, including land allocations, capital investments and Standards and Guidelines The Forest is allocated to 14 Management Areas having specific requirements for each resource program Expenditures of money for capital improvements increase the physical capacity of a limited land base. Standards and Guidelines (both Forest-wide and specific to Management Areas) give direction to practices for protection of resources and are described in Chapter IV of this document Monitoring, the mechanism for ensuring compliance with the management direction, is described in Chapter V.

RESPONSE TO PLANNING PROBLEMS

1 How Much Timber Should the Forest Produce?

The Forest will be managed to provide an average of 28.4 MMCF plus a one percent estimate of salvable dead for a total of 28 7 MMCF (160 0 MMBF) of chargeable timber volume per year during the first decade Governed by a policy of nondeclining flow, average annual sale offerings will gradually increase in subsequent decades to reach the long-term sustained yield level of 48 8 MMCF Harvest should generally occur when timber stands reach culmination of mean annual increment (average age of 100 years on this Forest)

Timber production is supported by a land base of 510,000 acres (selected suitable), which includes 34,624 acres of standing hardwood Hardwood conversion is limited to no more than 7,500 acres per decade, subject to marketability Table III-1 displays the management areas that provide timber management opportunities

Table III-1 Acreage Selected as Suitable for Timber Production by Management Area

	Acres (1988 Inventory)	
Management Area Name	Management Area	Selected Suitable
Wilderness	232,495	0
Wild River	5,029	0
Research Natural Area	4,608	0
Botanical	16,275	0
Unique Interest	2,015	0
Backcountry Recreation	40,871	0
Supplemental Resource	26,921	0
Designated Wildlife Habitat	50,287	0
Special Wildlife Site	28,762	0
Scenic/Recreation River	10,317	8,000
Riparian	96,623	70,000
Prescription B - 11 Basins	(43,308)	
Prescription C - 7 Basins	(26,778)	
Minimum Level	(26,537)	
Retention Visual	9,861	7,000
Partial Retention Visual	133,931	105,000
General Forest	434,307	320,000
TOTAL	1,092,302	510,000

Projections from the FORPLAN model indicate that at least 212 miles of new road construction and 1,353 miles of reconstruction is needed to support the timber program in this next decade The pattern projected by the model generally underestimates the miles of road needed in the first two or three decades and over estimates the miles needed in subsequent decades (see discussion in Appendix B of the FEIS) Actual miles of road to be constructed and reconstructed in this first decade may be greater than the projection above

Appendix C lists the timber sales expected to occur during the first decade Probable location, timing, harvest method, and road construction requirements are listed for each sale area, but these may change as site-specific information is collected.

2. How Much Old-Growth Forest Should be Preserved?

The Forest will be managed to reserve 179,700 acres having mature and old-growth forest characteristics With the exception of the reserved areas, existing mature and old growth will be metered out to accommodate the harvest sale schedule The old-growth and mature inventory updated from 1984 to include reduction due to the 1987 Fires and Silver Recovery Project is about 418,000 acres Special groves of old growth, especially redwood, have been set aside to preserve some unique and magnificent examples for recreational and aesthetic enjoyment These old-growth groves total 1,321 acres The most significant of these areas are the 720 acres of redwood groves

Anticipated harvest activity during the first decade will reduce the amount to approximately 371,000 acres Except for isolated tracks, riparian, and other areas, most unprotected mature and old growth will be removed by the year 2089 (10th decade) Figure III-1 depicts the protected and non-protected mature and old-growth forest Table III-2 shows the Management Areas that preserve old-growth characteristics Management direction for land allocations beneficial to old-growth preservation is described in Chapter IV

Table III-2 Protected Acres with Old-Growth Timber Characteristics by Management Area (Includes Mature Stands)

	Acres (1988 Inventory)	
Management Area Name	Management Area	Protected Old Growth
Wilderness	232,495	83,726
Wild River	5,029	1,915
Research Natural Area	4,608	2,757
Botanical	16,275	3,563
Unique Interest	2,015	624

Supplemental Resource	26,921	14,879
Designated Wildlife Habitat	50,287	41,566
Special Wildlife Site	28,762	12,122
Scenic/Recreation River	10,317	169 1/
Riparian	96,623	41 1/
Retention Visual	9,861	64 1/
Partial Retention Visual	133,931	964 1/
General Forest	434,307	4,206 1/
TOTAL	1,092,302	179,737

1/ Old-Growth Stands Unsuitable for Timber Management

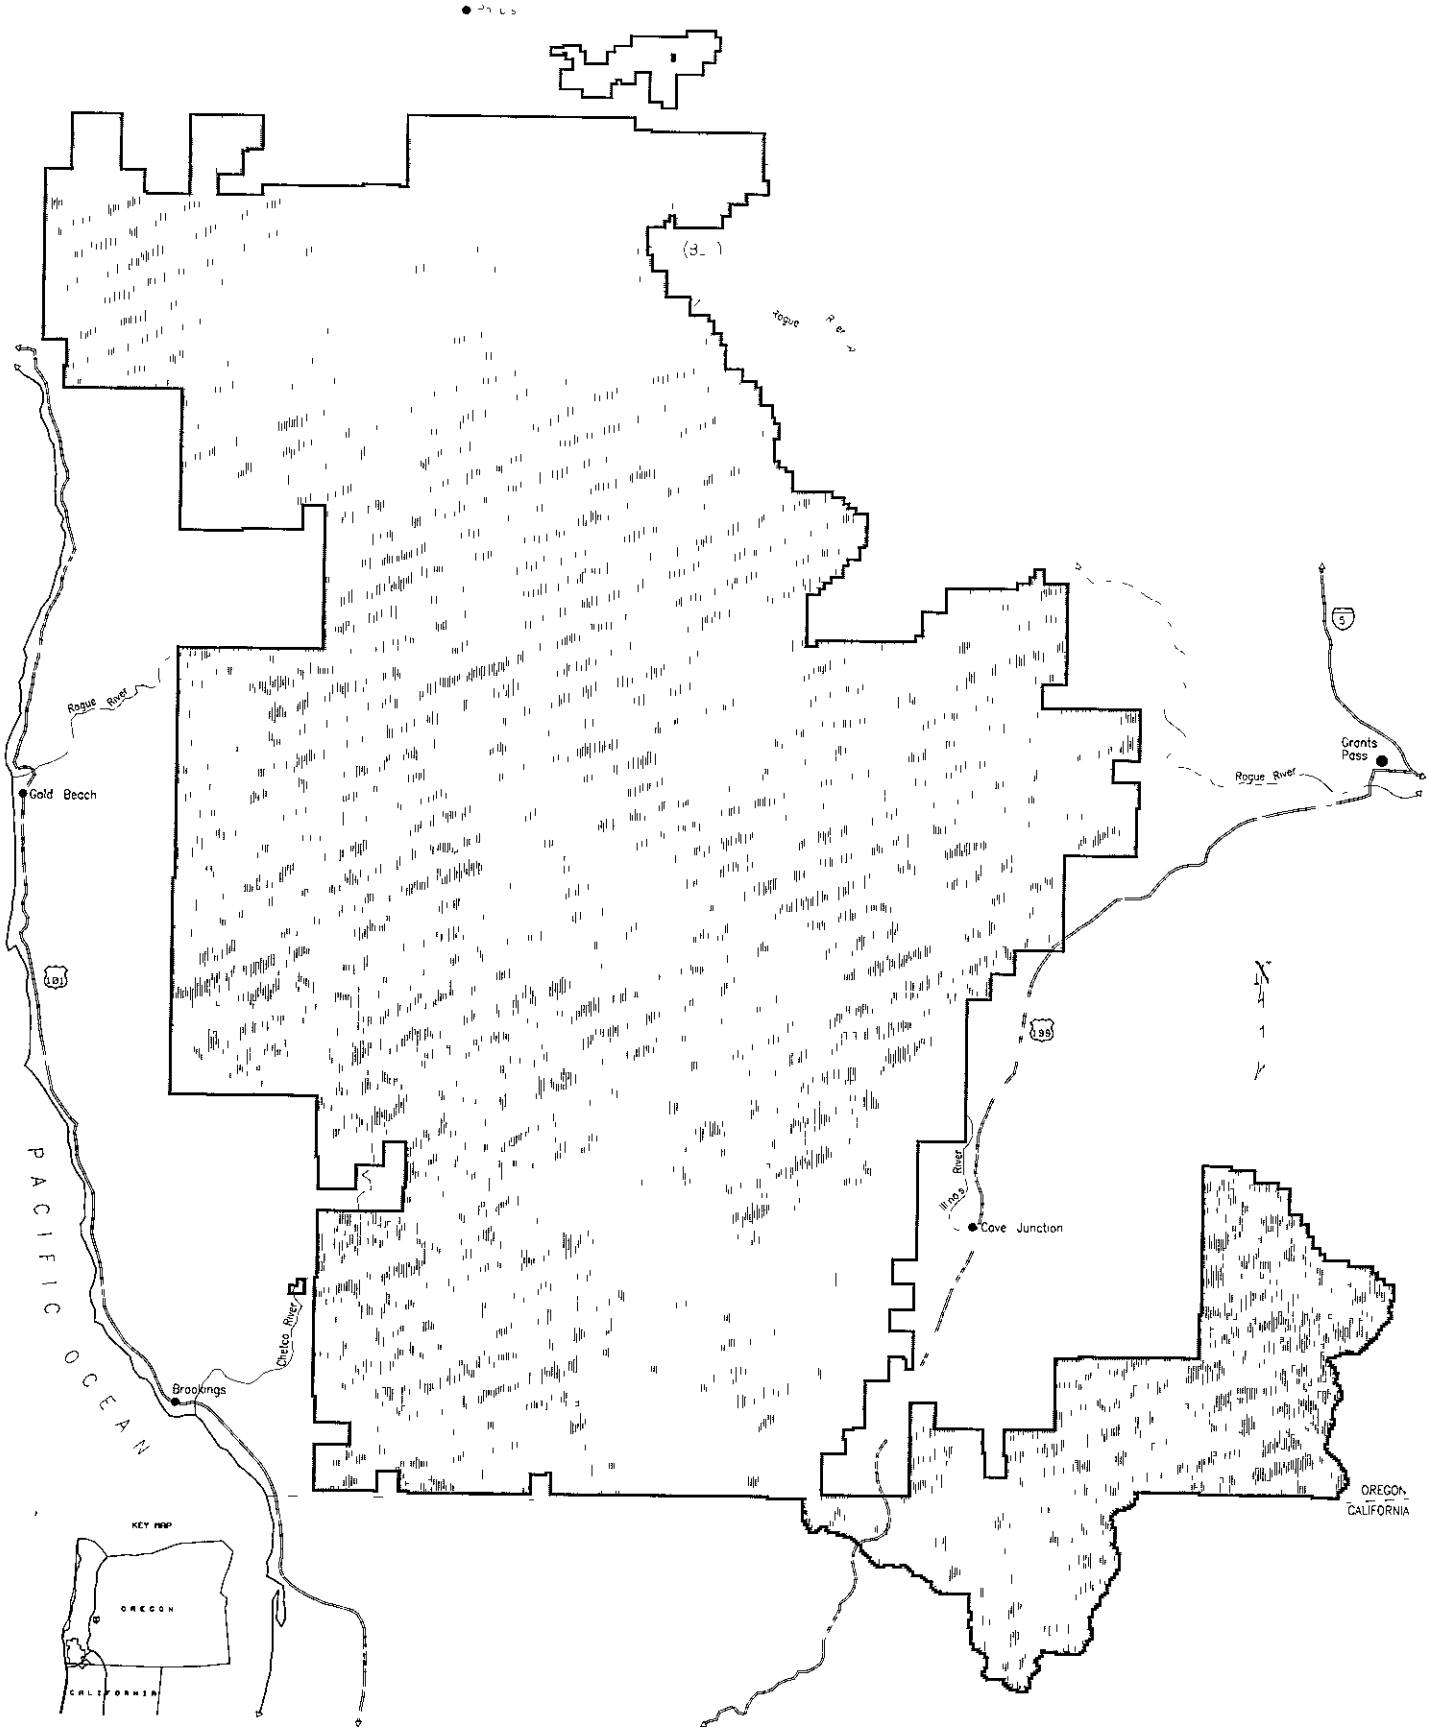

Figure III-1. Protected and Non-protected Mature and Old-growth Forest

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Protection is given to fish habitat, water quality, and soil productivity by allocating 407,263 acres (37 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest. The balance of the Forest will be managed under the Standards and Guidelines which reflect a sensitivity to the maintenance of a healthy ecosystem

Potential impacts of timber harvest are mitigated by distributing activities through time and space. This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 7 to 17 percent per decade specific to each Planning Basin

Salmonid fish habitat is improved through (1) land allocations that minimize soil disturbance and maintain summer water temperatures, (2) riparian prescriptions which protect streamside areas, and (3) fish habitat improvement projects. Watershed conditions are improved in areas presently degraded. Watersheds currently in good condition will be maintained in good condition.

Riparian vegetation will be managed to maintain or improve water quality and fishery habitat. Vegetative disturbance within riparian areas suitable for the production of timber are controlled by either Riparian Prescriptions B or C. Prescription C is applied on the Elk/Sixes, Lobster, Lower Rogue, Indigo, Silver, Pistol, and Lower Chetco basins, and is designed to produce a two-degree decrease in summer water temperature by the third decade. Riparian Prescription B, designed to maintain existing water temperatures, is applied in the remaining basins Table III-3 shows how riparian habitat is affected by various Management Area designations.

A high level of capital investment is proposed Approximately $581,000 per year will be spent on fish habitat and watershed improvement projects

Standards and Guidelines (Forest Plan, Chapter IV) and accompanying Best Management Practices (Forest Plan, Appendix F) are specifically designed to maintain or protect water quality, site productivity, and fisheries. Areas which have active landslides or risk irreversible soil loss are designated unsuitable and have no programmed timber harvest. Many additional inner gorge areas which have high watershed sensitivity and Supplemental Resource Management Areas also have no programmed timber harvest.

Table III-3. Protected and Managed Riparian Vegetation by Management Area

	Acres (1988 Inventory)

Partial Retention Visual	133,931	0	0
General Forest	434,307	0	0
TOTAL	1,092,302	102,803	72,690

4. How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve and Enhance Wild and Scenic River Attributes?

A variety of Management Areas are designed to protect Wild and Scenic River attributes The existing Wild and Scenic Rivers (the Rogue, Illinois, North Fork Smith, Chetco and Elk Rivers) have their respective sections assigned to either Wild River or Recreation and Scenic Management Areas. Often these rivers corridors are overlapped by another Management Area with a more protective status, such as Wilderness. All viewsheds surrounding the rivers have a natural or near-natural appearance as lands are managed to meet their inventoried VQO's.

Both the North Fork Smith and Chetco Rivers have a 2-mile segment designated "Scenic," but these segments are carried as inventoried "Wild " In each case, the Forest reviewed classification and concluded that the areas meet "Wild" status. This Plan protects their inventoried values in the interim until further analysis or River Management Plans dictate another course of action. Table III-4 shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River values.

Table III-4. Management Areas Directly Affecting Wild and Scenic River Attributes in Designated River Corridors

	Acres		
		Contributing to Wild and Scenic River Values	
Management Area Name	Management Area	Rogue/ Illinois	Chetco/Elk/ NF Smith
Wilderness	232,495	0	0

Partial Retention Visual	133,931	39,615	13,727
General Forest	434,307	7,183	53,567
TOTAL	1,092,302	105,282	109,443

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest are managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (Forest Plan, Chapter IV). Research Natural Areas and Botanical Management Areas provide special emphasis to the preservation of ecotypes and sensitive plants Four new Research Natural Areas, added to the three existing areas (for a total of 4,608 acres), result in the preservation of 25 ecotypes Nineteen new Botanical areas, combined with the three existing sites, total 19,632 acres (3,357 of these acres are overlapped by Management Areas 1 through 3, for a total of 16,275 acres in Management Area 4).

Table III-5. Sensitive Plant Distributions by Management Area

	Acres	Percent
Management Area Name	Management Area	Sensitive Plant Habitat
Wilderness	232,495	65
Wild River	5,029	75
Research Natural Area	4,608	65
Botanical	16,275	95
Unique Interest	2,015	65

Partial Retention Visual	133,931	35
General Forest	434,307	35
TOTAL	1,092,302	--

6. How, and to What Extent, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives are achieved by designing to meet VQO's on 658,502 acres. Twelve viewsheds (of 44 total) are governed by their respective inventoried VQO's, four of which encompass heavily used recreation travel corridors. Management of Forest scenic values are designed to complement high recreation use travel corridors and viewsheds. Seven high priority viewsheds (of the 12) managed to meet or exceed their respective inventoried VQO's are: the Upper Illinois, Rogue-Illinois, Oregon Caves, Highway 199, Game Lake, Bolan Lake, and Rough and Ready.

Table III-6 shows the number of acres in each VQO category by Management Area. Approximately 433,800 acres have an unmodified appearance (Preservation). While management activities are evident but visually subordinate (Partial Retention) on 150,168 acres, another 21,373 acres are managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (486,961 acres) is assigned Modification where management activities may dominate the characteristic landscape, but resemble *naturally occurring patterns when viewed in the background.*

Table III-6. Visual Management Objectives by Management Area

	Acres				
Management Area Name	Management Area	Preservation	Retention	Partial Retention	Moderate/ Maximum Moderate
Wilderness	232,495	232,495	0	0	0

General Forest	434,307	0	0	0	434,307
TOTAL	1,092,302	433,800	21,373	150,168	486,961

1/ These areas do not have Preservation VQO's They are managed to preserve the natural character until facilities such as roads or campgrounds are constructed.

7 How Should Wildlife Habitats on the Forest be Managed?

The combination of assigned Management Areas and capital expenditures prescribed provide a wide range of effective habitat conditions capable of sustaining viable populations of all native and desired non-native vertebrate species Designated Wildlife Habitat Management Areas meet MR's for wildlife inhabiting mature and old-growth forest Special Wildlife Sites (Management Area 9), include approximately 15,000 acres of mature and old-growth forest habitat, which are not suitable for timber management They do serve, however, as "stepping stones" between a number of Designated Wildlife Habitat areas. In total, 179,737 acres of mature and old-growth forest wildlife habitat are maintained through the tenth decade.

The Forest will provide habitat for the following species

	Number of Habitat Areas (Decades)	
	2nd	5th
Spotted Owl	139	97
Pileated Woodpecker	604	384
Pine Marten	2,380	1,552

Table III-7 shows a variety of Management Areas that contribute to overall wildlife habitat diversity Standing dead trees (snags) in areas managed for timber provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds Approximately 53,995 acres of prime bald eagle and osprey habitat are provided along rivers and streams that have a protected status Approximately 46 percent of the Forest provides an adequate combination of cover and forage for deer to sustain an average herd of 28,500 animals for the first five decades

Capital investments for wildlife habitat improvements should result in higher carrying capacity for many species Approximately $364,000 per year are prescribed to complete an average of 328 structural improvements and treat about 1614 acres

Table III-7 Management Area Contributions to Selected Wildlife Habitat Conditions

	Acres (1988 Inventory)				Percent

1/ Old-Growth Stands Unsuitable for Timber Management

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Non-motorized Primitive and Semi-primitive recreation opportunities are provided principally through Backcountry Recreation and Wilderness Management Areas. Backcountry Recreation includes (1) Primitive and Semi-primitive recreation opportunities in non-motorized areas, and (2) Semi-primitive recreation opportunities in areas with some designated motorized use (4-wheel drive roads and motorbike trails).

Primitive and Semi-primitive recreational capacity are increased in the Backcountry Recreation and Wilderness by constructing 70 miles ($484,000) and reconstructing 24 miles ($110,000) of trail during the first decade Overall, 293,500 acres of unroaded Primitive and Semi-primitive recreation opportunities are provided Table III-8 shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

Table III-8. Acres of Primitive and Semi-primitive Unroaded Recreation Opportunities by Management Area

	Acres	
Management Area Name	Management Management Area	Unroaded Primitive/Semi-Primitive
Wilderness	232,495	232,495
Wild River	5,029	1,956

Partial Retention Visual	133,931	0
General Forest	434,307	28,520
TOTAL	1,092,302	293,500

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development are facilitated by retaining 75 percent of the Forest (822,994 acres) in an accessible category. Approximately 91 percent of accessible acres (747,843 acres) have low to moderate restrictions which do not limit mining activities Approximately 9 percent (75,151 acres) have access restrictions in the high category that make many types of mining activity uneconomical. Appendix I, Table I-87 (S) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in Chapter IV of the Forest Plan for each Management Area.

Table III-9. Level of Mineral Exploration/Development Restriction by Management Area

	Level of Restriction (Acres/1988 Inventory)				
Management Area Name	Management Area	Withdrawn	High	Moderate	Low

CHAPTER IV

FOREST MANAGEMENT DIRECTION

Chapter IV

FOREST MANAGEMENT DIRECTION

INTRODUCTION

This chapter describes the long-range management direction for the Forest. This direction will guide the process for program development and budgeting so that the goals and objectives of the Plan can be realized. This chapter is divided into three sections The first includes a list of the Forest's goals, followed by a description of the desired future condition of the Forest, and the outputs and activities necessary to achieve the goals The second contains the Forest-wide management requirements which set the conditions that must be maintained as the goals are accomplished Last is the management area direction which indicates the management practices or prescriptions that will be applied to specific land areas

FOREST MANAGEMENT GOALS

The Forest Plan is designed to achieve the following Forest-wide goals The management objectives and direction in the subsequent sections are aimed toward achieving these goals.

The goals for the Siskiyou National Forest are to:

1. Provide a balance of resource management that will maintain a healthy Forest ecosystem, and help to supply local, regional and National social and economic needs.

2 Provide a sustained yield of resource outputs at a level that will promote the stability of local communities.

3 Maintain a healthy, diversified, and visually pleasing forest setting that enhances local tourism and provides an attractive visual backdrop to surrounding communities.

4. Fully implement the National Recreation Strategy through the development of partnerships with other local and federal agencies (e g , counties and states), and other groups and individuals Support local economic development strategies that focus on increased recreation and tourism

5. Recognize special areas and resources for their unique values and manage them to protect and perpetuate those values.

6. Provide diverse, high quality water and fish habitat capable of maintaining or enhancing populations of game fish species with emphasis on anadromous fish habitat

7. Maintain viable populations of existing native animal and plant species. Maintain or improve all existing seral stages of terrestrial and aquatic plant associations in a distribution and abundance to accomplish this goal.

8. Provide habitat to contribute to the recovery of threatened and endangered plant and animal species in accordance with approved recovery plans.

9 Recognize and promote the intrinsic ecological, social, and economic value of wildlife and wildlife habitat Provide sufficient quantity and quality of wildlife habitat to ensure diversified recreational use and public satisfaction.

10 Offer a wide range of dispersed recreation opportunities by providing recreational settings, access, facilities, and education necessary to meet public demand.

11 Protect and enhance identified, outstandingly remarkable values and free flowing condition of Wild and Scenic Rivers.

12. Protect the values and character of designated Wildernesses.

13 Provide firewood for personal use in a fair and equitable manner

14 Inventory and interpret significant prehistoric and historic cultural resources.

15 Plan, design, operate, and maintain a safe and economic transportation system to provide efficient access for the movement of people and materials involved in the use and protection of National Forest Lands.

16 Protect and enhance resource values through cost-effective fire and fuels management programs, emphasizing fuel treatment through the utilization of prescribed fire

17 Protect resource values through the practice of integrated pest management.

18. Facilitate mineral exploration and development while protecting surface resources and environmental quality

19. Meet or exceed state and Federal requirements which provide protection to the air, water, and cultural resources of the Forest.

20. Provide water of sufficient quality and quantity for local and downstream beneficial uses.

21. Maintain health and function of riparian ecosystems (including stream channel stability) for the protection or enhancement of riparian-dependent resources

22. Provide administrative sites and facilities that effectively and safely serve the public and accommodate the workforce.

23. Provide for biological diversity and long-term productivity by maintaining ecosystem function, maintaining large woody material, and minimizing adverse impacts to the soil resource.

24. Perpetuate Port-Orford-cedar as a functioning part of the Forest vegetation throughout its natural range and maintain it for economic and noneconomic uses.

DESIRED FUTURE CONDITION OF THE FOREST

The present condition of the Forest is detailed in Chapter III of the FEIS. As the Forest Plan is implemented, the condition of the Forest will change over time. This section summarizes the physical changes which are anticipated to result from carrying out planned management practices at two points in time: at the end of 10 years and at the end of 50 years (the RPA planning horizon).

THE FOREST IN 10 YEARS

At the end of the first decade, there will be a perceivable change in the overall character of the landscape within the Forest boundary. The landscape in the parts of the Forest managed for commodity production will be modified by new roads and harvest units. Sensitive viewsheds will be in a natural or near natural visual condition. By the end of the first 10 years, many of the unroaded areas allocated to General Forest objectives would be entered.

Areas with no timber harvest, such as Wilderness, Research Natural Areas, Botanical Areas, Supplemental Resource Areas, and dedicated habitats will remain essentially unchanged, modified only by natural processes.

Areas in those viewsheds undergoing identified rehabilitation work will be approximately 50 percent recovered.

The Project Opportunity Analysis system will be fully implemented for timber planning Areas with programmed timber harvest will have new harvest units distributed through the mature forest Existing harvest units and plantations will continue to develop through sapling and pole stages with some stands reaching large pole to small sawtimber size. Trees will be somewhat uniformly spaced and the species present will be representative of the natural diversity in the local areas

Opportunities for roaded recreation will increase. Recreational capacity will keep pace with demand as some new sites are developed and others are expanded. The National Recreation Strategy will be fully implemented, and the Forest will actively seek partnerships to accomplish a variety of recreation projects Access to wilderness areas will be enhanced by the construction and maintenance of several access trails.

Habitat to support threatened and endangered species will be protected in accordance with recovery plans Designated mature and old-growth habitat areas will remain essentially unchanged. Seral stages of terrestrial and aquatic plant associations will be provided in a distribution to maintain native and desired non-native plant and animal species and communities. Habitat for species favoring early seral stages will begin to be distributed through areas where timber harvest is programmed. New harvest units will continue to provide high quality forage for deer and elk. Riparian ecosystems in harvest areas would have been managed to maintain water quality and a diverse vegetative condition for the rich variety of wildlife utilizing riparian and aquatic areas.

Habitat for species utilizing dead or downed trees will be provided throughout the Forest. Snags and trees for replacement snags will be left in areas where timber harvest is occurring. Dead logs will be left on the ground for species utilizing such material as habitat and to provide woody material for nutrient cycling.

Salmonid rearing, spawning, and migration habitat capability will improve Forest wide. Streamside management prescriptions will maintain or lower summer water temperatures, with additional protection of the fisheries habitat occurring in designated Special Fisheries and Wildlife Habitat areas. Habitat improvement projects will increase habitat diversity and maintain stream channel stability.

Forest soil productivity will have been maintained. Water yield and quality will not be substantially altered.

Mineral development on the Forest in 10 years will increase. The most active mining activity will probably continue to be for gold, although interest in nickel-laterites and chromite areas may be increasing. Physical and biological impacts will have been minimized; however, short-term effects on water quality will continue to be a concern. New discoveries of minerals will bring additional demands for access into the unroaded portions of the Forest.

The principal access roads will be readily identifiable. They have paved or gravel surfaces and look suitable for passenger car use. Signs will assist travelers in finding their destination. Some roads will appear less inviting for use. These less inviting roads will look rough or primitive, but most will be available for use by the more experienced traveler in vehicles with high ground clearances. Continued road system development and improvement will be taking place in areas where resource development activities are planned. Some roads will be closed.

THE FOREST IN 50 YEARS

By the end of the fifth decade, there will be a very apparent change in the overall character of the landscape within the Forest boundary. The majority of roads needed for resource management will have been constructed The landscape in parts of the Forest managed for commodity production will have a heavily altered appearance. Sensitive viewsheds will have a natural or near natural appearance. Rehabilitation objectives in some areas of the viewsheds will have been realized and these areas will have returned to a more natural condition.

Areas with no timber harvest, such as Wilderness, Research Natural Areas, and Botanical Areas, would still remain essentially unchanged except for the effects of fire and the slow process of natural succession. Management activities will maintain or restore meadow areas and avert the encroachment by trees and shrubs.

Areas with programmed timber harvest will be a mosaic of stands of various sizes and ages Some mature stands would remain, but the majority would now be managed young stands ranging from freshly harvested units to plantations that have reached sawtimber size. The desired condition is a regulated forest where the stands exist in age and size class proportions and grow at rates such that a high level of yield can be sustained Trees will be somewhat uniformly spaced and the species present will be representative of the natural diversity in the local areas

Habitat to support threatened and endangered species will be protected in accordance with recovery plans Designated mature and old-growth habitat areas will remain essentially unchanged, although some substitution of areas may have occurred Contiguous mature and old-growth forests will generally be limited to Wilderness, Research Natural Areas, Botanical Areas, Supplemental Resource Areas, Backcountry Recreation Management Areas, Wild River Corridors, Unique Interest Areas, Designated Wildlife Sites, and Designated Wildlife Habitats

Habitat for species favoring early seral stages will be distributed throughout areas where timber harvest is programmed. Deer and elk habitat will be approaching a more balanced state as harvest units are distributed through time and space. Riparian ecosystems in harvest areas would have been managed to maintain water quality and a diverse vegetative condition for the rich variety of wildlife utilizing riparian areas.

Habitat for species utilizing dead or downed trees will be provided throughout the Forest. Snags and trees for replacement snags will be left in areas where timber harvesting has occurred. Dead logs will be found on the ground in various stages of decay providing habitat for species utilizing such material as woody debris for nutrient cycling

Salmonid rearing, spawning, and migration habitat capability will be maintained at a fairly constant level after the second decade Habitat improvement work will be done primarily to replace failing structures and maintain the gains achieved in earlier decades.

Forest soil productivity will have been maintained. Water yield and quality will not be substantially altered.

Mining for gold will continue to be important in 50 years with increased activity in nickel-laterites and chromite areas Protection or reclamation of surface resources will continue to be important. Biological impacts will be kept to acceptable levels through improved mining and reclamation technology and competent administration of the activity. Major access requirements needed for the development of minerals on the Forest will have been completed

The principal access roads will be readily identifiable. They have paved or gravel surfaces and look suitable for passenger car use. A few roads may have State Highway designations Signs will assist travelers in

finding their destination. More roads appear less inviting for use. These less inviting roads will look rough or primitive, but most will be available for use by the more experienced traveler in vehicles with high ground clearances. Road system development will be nearly complete. Continued improvements will be taking place in areas where resource development activities are planned. More roads will be closed.

By the end of the fifth decade, nearly 90 percent of the planned Forest development road system will be in place and providing efficient travel into and through the Forest. All of the arterial and collector road system will be complete, while some local roads will be needed to complete the overall system. The majority of the 1,000 miles of new Forest development roads built during the last five decades to utilize the timber resource will have been classified as local road facilities.

Because of the continuing need to protect watershed conditions, provide for wildlife needs, and control costs, a portion of the road system will be managed in a self-maintaining state with no vehicle traffic planned. Some of these self-maintaining roads will be in the process of being opened to accommodate future cycles of timber management activities

FOREST MANAGEMENT OBJECTIVES

PROPOSED OUTPUTS

This section projects the future outputs and resource activities expected to meet the previously stated goals and desired future conditions.

The projected Forest outputs (Table IV-1) are average values for a year's activities. Actual outputs for individual years may vary from the projected outputs due to fluctuations in conditions, funding, personnel, and priorities.

Table IV-1. Average Annual Forest Outputs

RESOURCE ACTIVITIES

This section summarizes the various resource programs which are integrated into an overall Forest management program by this plan. The narratives describe the activities necessary to produce the outputs displayed in Table IV-1. These planned activities (listed in detail in Appendix B) will be the foundation for developing the Forest's annual budget proposal and program of work

RECREATION

The Siskiyou National Forest has the ability to provide recreation experiences across the range of the Recreation Opportunity Spectrum. The Forest received considerable comment on all aspects of recreation after the publication of the Draft Forest Plan. Increased emphasis has been placed on the Recreation program, the focus of which will be toward meeting the needs of the recreating public (primarily through facilities construction) and toward working with four Southern Oregon Counties to assist them in developing their Economic development goals. These goals are based on the development of the Recreation/Tourism industry. The Forest program will emphasize the development of the National Recreation Strategy, Developed Recreation, Dispersed Recreation, Wilderness, and Wild and Scenic Rivers. Expected outputs for Developed, Dispersed and Wilderness recreation are summarized in Table IV-1.

The recreation capital investment schedule for the first five years (shown in Appendix B) includes:

1. Construction, reconstruction, or rehabilitation of 17 developed recreation sites.
2. Construction or reconstruction of approximately 114 miles of trails, trailheads, and bridges in the existing wilderness, backcountry recreation, and other areas of the Forest
3. Maintenance of the existing (453 miles) trail system and additional funding required as additions to the system are added.
4. Development of Management Plans for the Elk, Chetco, and North Fork Smith Wild and Scenic Rivers.

The Recreation Information Management (RIM) inventory will be updated annually to monitor levels and types of recreation use on all areas of the Siskiyou National Forest All sources of information will be used to gather data for the RIM report, including: trailhead registration boxes; river registration; permits; and employee or public observation. Monitoring in all areas of the Recreation program will insure maintenance of the recreation settings that are necessary for the high quality recreation opportunities offered in all areas of the Forest.

National Recreation Strategy

This program focuses on the establishment of partnerships in developing the Recreation Resource. Toward this end the Forest has developed a partnership involving four Southern Oregon Counties (Josephine, Jackson, Curry, and Douglas), the State of Oregon, four National Forests (Siskiyou, Rogue, Umpqua, and Winema), and two Bureau of Land Management Districts (Medford and Roseburg). The partnership has embarked on the initial phase of the program which involves marketing Southern Oregon recreation opportunities through the development of an interactive video system and subregional recreation map. Subsequent phases will focus on project development at various levels.

Developed Sites

Public comments centered on the continued availability of developed recreation sites. The developed sites capital investment program has been increased over that identified in the Draft Forest Plan. The program will emphasize the rehabilitation or upgrade of existing sites to modern standards and the construction of nine new recreation sites within the first decade of the planning period. In addition, maintenance funding

has been increased so that all sites will be maintained a full level Additional new developed sites can be constructed as the need arises in the future.

Dispersed Recreation

Motorized Recreation opportunities are expected to increase over current levels as new roads are built There will also be an increase in Semi-Primitive (Motorized and Non-motorized) recreation opportunities due primarily to allocations to Backcountry Recreation Management (108,000 acres). Portions of the area will be open to motorized uses (primarily ORV's) while the remainder would be closed to motorized uses and be accessible only by foot, horse, or mechanized vehicles (mountain bicycles) Increased emphasis is being given to the construction of facilities near local communities Briggs Valley equestrian trails and the Page Mountain Sno Park are examples

Wilderness

The Forest contains two Wildernesses, the Kalmiopsis and Grassy Knob, and portions of the Wild Rogue, Red Buttes, and Siskiyou. The five designated Wildernesses total 232,495 acres of National Forest Land No additions to the Forest Wilderness system are proposed in this plan.

Goals for Wilderness management include the implementation of Management Plans that emphasize the nondegradation of the Wilderness resource while providing for Primitive and Semi-primitive recreation opportunities. Development within the Wildernesses includes a modest level of trail construction and reconstruction in the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses Trail construction will focus on the development of loop systems to provide access, disperse recreation use, and add diversity to Wilderness recreation experience Existing trail systems will be fully maintained every other year (one-half the system will be maintained each year). Trailheads will be upgraded to modern standards and signing will be provided to insure public safety.

Wilderness management direction is described under Management Area 1. Management Plans for the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses are located in Appendix A.

Wild and Scenic Rivers

The Forest is best known for its Wild and Scenic River System. The Rogue Wild and Scenic River was one of the original eight rivers designated in 1968. The Illinois Wild and Scenic River was designated in 1984. Existing Management Plans for these rivers will not be affected by the implementation of this Forest Plan Recently (October, 1988), the Elk, Chetco, and North Fork Smith Rivers were designated as Wild and Scenic. Management Plans will be developed for these rivers during the planning period. The management plan for the Rogue Wild and Scenic River is scheduled for review (and possible revision) upon completion of the Forest Plan.

Management of the designated Wild and Scenic Rivers will emphasize the maintenance of the natural/near natural character of the river corridors and the continued availability of a high quality recreation experience that is described in the goals and objectives identified in each of the river management plans.

Trails

Trail Management Objectives will be developed for all trails included in the Forest Trail System These Management Objectives will be used to identify the maintenance level required for each of the Forest system trails. The goal will be to fully maintain one-half of the Forest Trail System annually to the standards identified. Annual inspections of all trails will identify trail maintenance needs

VISUAL RESOURCES

The Forest will implement a program of Visual Resource Management that will emphasize the maintenance of the natural or near natural character of the landscape within the viewsheds adjacent to heavily recreation travel routes or use areas All National Forest lands are assigned a Visual Quality Objective ranging from Preservation (no programmed harvest) to Modification (General Forest). Forest lands within sensitive viewsheds are managed under the Retention and Partial Retention Visual objectives which provide for timber harvest at constrained levels and emphasize the maintenance of the existing character of the Forest landscape. In addition, the existing character of the landscape will be retained on approximately 407,000 acres allocated to Management Areas 1 through 9 which are managed under the Preservation Visual Objective. Visual allocations include:

Preservation	433,800 acres
Retention	21,373 acres
Partial Retention	150,168 acres
General Forest (Modification)	486,961 acres

CULTURAL RESOURCES

The cultural resource program will be fully integrated with other resource management activities. Cultural resource surveys will precede all ground-disturbing projects. All sites located during these surveys will be documented in accordance with Regional standards. The impacts to all significant cultural resources will be mitigated, as set forth in the National Historic Preservation Act of 1966.

Over the next decade, the Forest plans to inventory an average of 26,500 acres annually in support of the timber program and approximately 3,750 acres for landownership adjustments, recreation, minerals, wildlife, range, fire, engineering, watershed, and special cultural resource projects Areas not impacted by resource projects (Wildernesses, withdrawals, and General Forest areas not subjected to disturbance) require inventory for completion of the Forest data base. These inventories will be conducted according to the following priorities.

1. Areas which are being impacted by natural processes or intensive public use.
2. Areas with reported but unverified sites.
3. High probability areas which are currently undisturbed and are unlikely to be disturbed in the near future.

Formal site evaluations will also be carried out for potentially National Register eligible sites located outside project areas. These will continue at a rate of approximately five sites annually.

Data recovery projects, undertaken as mitigation procedures for adverse impacts to prehistoric sites are expected to average one per year (the current average) during the planning period Approximately three documentation projects, serving as mitigation measures for adverse impacts to historic sites will be carried out over the next decade.

Enhancement projects will be undertaken at a rate of approximately seven per year. Some of these projects will be funded through the cultural resources capital investment program (Appendix B, Table B-9). Others may be funded through partnerships with states, counties, and the private sector The increase in the number of these projects is a result of stronger Agency emphasis on the enhancement and interpretation of cultural resources.

Protection activities (including stabilization, restoration of resource damage, and law enforcement) are expected to increase as the site data base grows. Cultural resource plans prepared for enhancement, research, protection, and interpretation will average five per year The Forest cultural resource overview and the inventory plan will be updated approximately once every five years, to incorporate new data

FISH, WILDLIFE, AND SENSITIVE PLANTS

Habitat needed to support viable populations of various fish and wildlife species, including threatened, endangered and sensitive species, is discussed in the following narrative. Forest-wide Standards and Guidelines and land allocations for fish, wildlife, and sensitive plants are listed later in this chapter.

Fish Habitats

The Forest's fisheries program focuses on both administrative and improvement goals. There are currently two Basin Plans (Chetco and Winchuck Rivers) in effect which guide management activities Priority is being given to writing such plans for the rest of the Forest's streams. Central to this effort will be the completion of detailed habitat and population assessments using survey methods adopted for the Region (Hankin and Reeves 1986). The Forest will coordinate its efforts with the Oregon Department of Fish and Wildlife, who is also in the process of generating fisheries basin plans

Maintenance of present fish habitat capability focuses on protecting existing high quality salmonid habitat by minimizing adverse impacts from proposed management activities or mitigating effects from past activities. Habitat capability information is utilized in planning road construction, timber harvest, and other projects in order to reduce the potential impacts from excess sedimentation, or water temperature increases. A key factor in the maintenance of Forest salmonid resources is management of riparian areas to benefit fish. Coordinating with other Forest resource uses will continue to be a priority for Siskiyou fish biologists Management direction supporting the maintenance of fish habitat is contained in the Soil and Water section of the Standards and Guidelines, and in Management Areas 7 and 11.

An aggressive fish habitat improvement program is in response to public desires and realization that National fishing demand is expected to nearly double in the next five decades. Increased National, Regional and Forest emphasis on the fisheries program was realized in 1987 with development of the "Rise to the Future Fisheries Program." Through this program a strengthening of partnerships with States, other Federal agencies, Tribal governments, conservation groups and publics is occurring in fish habitat management.

Fish habitat improvement project work will continue with construction of approximately 480 instream structures per year. Most of the work will be performed in areas where access is available, hydrological conditions are favorable, and preliminary surveys have identified good potential for enhancement benefits Few or no structures will be installed in areas that have minimal anticipated benefits (because of excellent pre-existing habitat conditions, or poor water quality condition from off-Forest activities). This work should result in an overall net increase in adult fish available for both sport and commercial harvest, an anticipated increase of 13,360 Wildlife/Fish User Days (WFUD's) and 164,000 commercial pounds annually.

The prime emphasis for fish habitat will continue to be good land management practices that will not degrade from existing fish habitat capability. The monitoring requirements for fish habitat are outlined in Chapter V and Appendix D

Wildlife Habitats

Forest management efforts consider all native vertebrate species. Several groups of species have special management needs These groups include: (1) species dependent on specialized habitat conditions; (2) species requiring early, mature, or old-growth forest conditions for optimum habitat; (3) popular game species; and (4) endangered, threatened, or sensitive species.

Seven forest wildlife species, and one group, have been selected as management indicator species. An indicator species represents all other wildlife which utilize the same habitat type. Indicator species act as barometers for the health of various habitats and will be monitored to quantify habitat changes predicted by implementation of this Plan.

Management Indicator Species - Wildlife

Species	Habitat Represented
Bald eagle	Habitat corridors along major rivers
Osprey	Habitat corridors along large rivers
Spotted owl	Old growth forest
Pileated woodpecker	Mature forest
Pine marten	Mature forest
Black-tailed deer	Early successional forest stages
Roosevelt elk	Early successional forest stages
Woodpeckers	Wildlife trees (snags)

Habitat necessary for maintenance of viable populations of the three indicator species dependent on mature and old-growth forest habitat is protected under Management Area 8, Designated Wildlife Habitat. This Management Area defines the minimum habitat requirements for each of these species. During the planning period (first decade), the Forest will maintain habitat capability for 139 pairs of spotted owls, 604 pairs of pileated woodpeckers, and 2,380 reproductive units of pine martens

A Forest-wide management plan for Roosevelt elk and black-tail deer will be prepared within three years after implementation of the Forest Plan. The management plan will identify where deer and elk management is the primary focus; provide guidance for third to fourth order watersheds, and be developed in cooperation with state fish and wildlife agencies Further details are described in Forest-wide Standard and Guideline 4-11.

Monitoring of indicator species populations is detailed in Appendix D (a summary appears in Chapter V). Monitoring for deer and elk will determine whether suggested State wildlife objectives are being met Inventories are planned for sensitive animals and plants (see Resource Element CT121(A) in Appendix D, and Capital Investments for CT and CW in Appendix B).

Special wildlife habitat sites and botanical sites which are important components of overall habitat diversity are addressed under Management Area 9. These sites include meadows, dispersed old growth sites, springs and swamps, lakes and ponds, hardwood sites, rock sites, botanical sites, areas with special values for wildlife, and important habitats for elk, osprey, and band-tailed pigeon. Direction for inventory of new special sites is listed under Forest-wide Standards and Guidelines. The unique characteristics of these habitats will be protected or enhanced

Threatened, Endangered, and Sensitive Species

The bald eagle is the only Federally-listed Threatened species on the Forest. The eagle is listed as Endangered on the California portions of the Forest, but no occupied habitat has been identified there. Annual inventories for eagle habitat and occupancy are conducted in cooperation with Oregon Department of Fish and Wildlife and the National Wildlife Federation. Identified eagle habitat will be protected and managed in accordance with the Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986).

The American peregrine falcon is the only Federally-listed endangered species on the Forest. Falcon use has been confirmed at several sites since publication of the draft Forest Plan. Habitat for peregrines will be managed according to the Pacific Coast Recovery Plan for the American Peregrine Falcon (USDI Fish and Wildlife Service 1982). Two management plans have been written to better define management goals and methods. During the planning period, a comprehensive Forest-wide habitat inventory for peregrine falcons will be completed and a management plan will be written.

Sensitive wildlife species in Oregon include: the northern spotted owl (discussed above under indicator species); Siskiyou mountain salamander; Western pond turtle; white-footed vole; California wolverine; and Townsend's big-eared bat Sensitive species in California, in addition to the spotted owl and wolverine,

include northern goshawk; willow flycatcher, fisher; and pine marten. Guidelines for management of sensitive wildlife are included in the Forest-wide Standards and Guidelines.

There are 64 sensitive plant species on the Forest. Thirty of these species have not been located on the forest but may occur here. Another ten species are candidates for listing as sensitive (nine of these are known to be on the Forest). Habitat is managed to ensure that the species do not become threatened or endangered because of management activities. Protection of known or potential populations of sensitive plants is accomplished through Forest-wide Standards and Guidelines and land allocation Land allocations include Research Natural Areas and Botanical Areas described under Management Areas 3 and 4, respectively

All proposed projects that involve significant ground disturbance and have the potential to alter habitat of sensitive wildlife or plant species will be evaluated to determine if any sensitive species are present, in conformance with direction in FSM 2770, Threatened, Endangered and Sensitive Plants and Animals. Where such species are present, field evaluation data will be used to determine mitigation measures consistent with Forest program goals. A Forest-wide inventory for sensitive plants will be initiated during the planning period to provide baseline data for management activity planning.

RANGE

The Forest currently administers 11 cattle allotments totaling 3,246 AUM's, of which 1,613 AUM's are actually grazed Three of the allotments are inactive. In the future, the range program will center on administration of existing permits and allotments, with all Allotment Management Plans to be updated during the first decade

Concern over the spread of noxious weeds surfaced in 1984 when State, Federal, County, and private agencies and individuals entered into a formal Cooperative Resource Management Program (CRMP) agreement to deal with the spread of noxious weeds. The Forest's response to that agreement was preparation of a Noxious Weed Management Plan (1986) which guides the program on the Siskiyou. Goals include prevention or control of spread of noxious weeds, with gorse, tansy ragwort, and knapweeds receiving priority. Control projects utilizing biological or mechanical methods presently affect about 50 acres annually on the Forest. Concern over noxious weeds is expected to grow in the future and will demand increasing allocation of Forest resources to meet obligations under the terms of the CRMP agreement

TIMBER

Information necessary for timber planning implementation includes land suitability, allowable sale quantity, and planned sale and harvest methods Net acreage of the Forest is 1,092,302 acres. With implementation, the Plan will manage 510,000 acres of selected suitable lands for some form of timber outputs (see Table IV-2).

Timber harvest is scheduled from the selected suitable lands at the rate of 28.4 MMCF (158.4 MMBF) per year. This quantity was calculated by using the FORPLAN model. The Siskiyou National Forest is characterized as a "deficit" inventory Forest when examining the scheduling of potential timber harvest. The amount of existing mature and old-growth timber volume is insufficient to begin harvesting at the long-term sustained yield level and maintain that level To follow a nondeclining-flow schedule, the existing inventory in mature stands must be metered out until regenerated stands become available for harvest

The Allowable Sale Quantity (ASQ) is 28 7 MMCF for the first eight decades This includes a one percent estimate for chargeable salvage volume. As younger stands become merchantable, the amount of commercial thinnings increase, and the growth levels exceed harvest levels (Figure IV-1). The ASQ increases to 30 0 MMCF for the ninth decade and reaches the long-term sustained yield of 47.5 MMCF in

yield of 47.5 MMCF in decade 10. In general, existing mature and over-mature stands are scheduled for harvest over the first seven decades, or until the regenerated stands reach rotation age

The ASQ to be harvested within the first decade is allocated among the General Forest, Riparian, Retention Visual, Partial Retention Visual Management Areas (Table IV-3). The amount programmed for harvest in the Scenic/Recreation River Management Area is incidental and not included in Table IV-3. A more detailed presentation of the planned timber harvest can be found in Appendix C. The listed acreages and volumes are yearly averages for the decade. Individual years may vary considerably from the average due to adjustments based on field reconnaissance and individual sale conditions. Timber outputs will be monitored and any significant deviations from those projected will trigger an analysis to determine whether a change is needed.

Two categories of land have potential to contribute to ASQ that were not utilized by FORPLAN; the separate suitability component (SSC) lands, and those lands currently stocked with hardwood species The Forest Plan contains the flexibility to manage these lands under changing market conditions without amendment or revision. The SSC lands do not have programmed timber harvest, but site specific opportunities may be scheduled in accordance with Forest-wide Standard and Guideline 6-2 (7) There is considerable variation in the vegetation conditions existing on these sites. The individual site evaluation will provide the flexibility to take advantage of opportunities such as overstory removal harvests that require low investment

Lands currently stocked with noncommercial species or hardwoods have a negligible contribution to ASQ in the FORPLAN model, but are included in the suitable land base. Bringing these lands into production through the harvest of hardwood stands and replanting with conifers does have the potential to increase future timber outputs, and supply fuelwood or other products in the short term. Any actual treatment on these acres will depend on site-specific conditions and market demand for hardwoods (see Forest-wide Standard and Guideline 6-13).

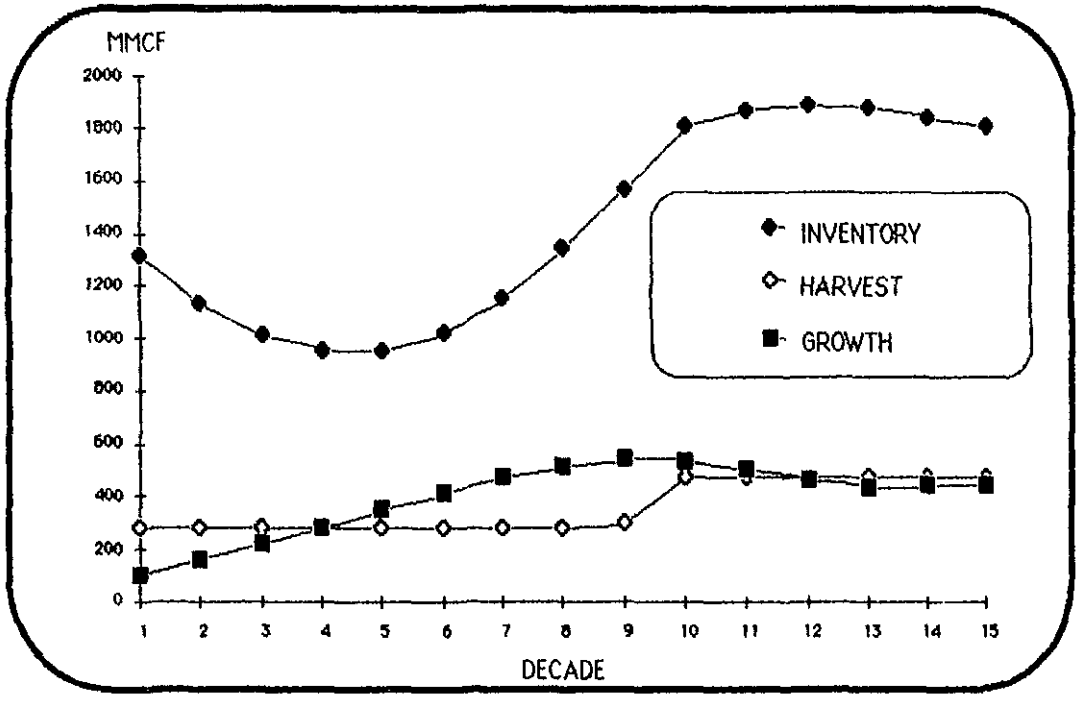

Figure IV-1. Timber Harvest Schedule

Table IV-2 Land Availability and Suitability Summary

Land Category	Acres			
	Withdrawn 1/ or Physically Unsuitable	Tentatively Suitable for Timber Management	Suitable for Timber Management	Total
LAND STATUS				
TOTAL NATIONAL FOREST AREA				1,162,030
Other Ownerships	69,728			
NET NATIONAL FOREST AREA				1,092,302
LAND SUITABILITY				
Non-Forest Land				
Water	1,570			
Administrative Sites/Roads	15,367			
Less than 10% Tree Cover	38,217			
Forested Lands				
Withdrawn from Timber Production 1/	240,548			
Irreversible Soil Damage	25,639			
Regeneration Difficulty	155,251			
Tentatively Suitable Forested Land		615,710		
Separate Suitability Component (Growing <20 Cu Ft /Acre/Year)		(18,336)		
TOTAL	476,592	615,710		1,092,302
LAND ALLOCATIONS IN THIS FOREST PLAN				
MANAGEMENT AREA (MA) LAND ALLOCATIONS				
1 - Wilderness	232,495			232,495
2 - Wild River	5,029			5,029
3 - Research Natural Area	3,172	1,436		4,608

Commercial Thinning	MMCF	--	0 4
Regeneration Harvest	Acres	786 0	786 0
General Forest (MA 14) 1/			
Commercial Thinning	MMCF	0 8	1 7
Regeneration Harvest	Acres	3,700 0	3,600 0
Practices Not Projected by Specific Area			
Precommercial Thinning	Acres	2,397 0	2,397 0
Vegetation Release	Acres	4,469 0	4,874 0

1/ 25 6 MMCF of Regeneration Harvest will occur in Retention Visual, Partial Retention Visual, and General Forest Management Areas

A range of silvicultural systems will be used depending on the specific site conditions and management direction. Methods may include clearcutting, shelterwood, seed-tree, group selection, and individual tree selection (see Appendix G of the FEIS for descriptions of systems). The even-aged systems of clearcutting, shelterwood, and seed-tree will be the most common for the General Forest and Visual Management Areas. Selection harvest will be the dominant harvest system within the Riparian Management Areas, while salvage harvest may occur in all Management Areas with programmed timber harvest.

The General Forest Management Area includes allocation "overlays", or subparts, designating some lands for extensive management, and some lands as administrative study areas. The extensive management areas are distinctive in that they lack the operability to gain reasonable road access for intensive timber management and will be managed under a less intensive schedule with little or no roading. The administrative study areas are in two locations; one is the Silver Fire Recovery Area which was burned in 1987 and is still recovering from the effects of the fire, the other is known as the South Kalmiopsis which is a large area of very poor soils and generally sparse vegetation.

Reforestation activities include site preparation, planting, control of animal damage, and vegetation management (release). Vegetation management activities may include thinning or the use of herbicides as a means of reducing competitive vegetation to selected crop trees. Because of the public concern regarding herbicide use, the Pacific Northwest Region's EIS for Managing Competing and Unwanted Vegetation (USDA 1988c.) has been prepared. Any proposals to utilize herbicides in vegetation management would require preparation of a Forest site-specific environmental analysis tiered to the Region's vegetation management EIS.

Coordination between the timber program and other resource programs is essential if Forest management goals are to be met. Acres proposed for harvest or road construction, plus additional acres which require an assessment of cumulative effects, must be examined to determine resource values and opportunities. The major resource areas are visual resources (25,000 acres examined annually), watershed (23,000 acres), wildlife and fisheries (23,000 acres), and cultural resources (20,000 acres). The major Management Areas where examinations will occur are: Riparian, Retention Visual, Partial Retention Visual, and General Forest.

The Forest provides fuelwood for both personal and commercial use The Forest will continue to provide opportunities for fuelwood cutting by placing nonmerchantable material in piles at designated locations. Fuelwood availability is not expected to change dramatically during this planning period

Inventory is planned and implemented at least every ten years. The process for future planning is being developed now. Managed stand survey and vegetation mapping contracts will be awarded for the first time in spring 1989. The Managed stand survey will measure young stands on the Forest to validate predicted timber yields The vegetation mapping will map and describe the vegetation as it currently exists. The Forest will also be ecotyped to series or groups of plant associations. A Forest resource inventory will measure timber growth on all mature stands and gather basic information for all forest resources. An old growth inventory will also be conducted to describe and characterize this component of the forest. These maps and inventories will collectively serve as the foundation for the next round of timber planning.

SOIL AND WATER (WATERSHED MANAGEMENT)

Soil and water resources are managed to protect and enhance long-term productivity of the forest, water quality and associated beneficial uses, and aquatic ecosystems. These goals will continue under the implemented Forest Plan All management activities will be subject to the Forest-wide Standards and Guidelines which deal with site productivity, water quality, physical and biological changes in the soil, erosion and mass movement, and riparian ecosystems. Public interest in the management of soil and water resources is expected to continue at a high level.

Soil is a fundamental, largely nonrenewable resource that is the basis for high-level sustained yields of all other resources. The primary goal for management is maintenance of long-term productivity Program emphasis has centered on mitigating the impacts of management activities and rehabilitating soils that have been impacted by management and natural events This emphasis is expected to continue through the planning period

Current Soil Resource Inventory (SRI) information will be refined and updated as suitable lands are managed for resource activities. Lands classified unsuitable for timber production due to marginal reforestation and potential for irreversible damage will continue to be identified and removed from the timber base. Inventories are scheduled for soil, e.g , Curry County Soil Survey, and for geology and landslides. Assessments of the cumulative effects of all activities by site, watershed, and basin on the soil and water resource will be provided.

Watershed specialists identify watershed improvement needs which are included on the Forest's Watershed Improvement Needs Inventory (WIN), and help design and implement watershed improvement treatments based on project priority. Barring the occurrence of catastrophic events such as wildfire and flood, an estimated 480 acres per year of watershed improvement work will be completed under the Forest Plan. This includes projects covered under timber sale activity (KV; approximately 60 percent) and normal appropriated funds.

All resource management activities will be designed to enable compliance with State requirements in accordance with the Clean Water Act for the protection of waters of the states of Oregon and California Best Management Practices (BMP's - Appendix F) will be applied in planning, implementation and maintenance of all Forest activities Forest resource management personnel will receive BMP implementation training

Assessments of the cumulative effects of all activities by site, watershed, and basin on the soil and water resource will be provided. Cumulative watershed effects will be analyzed on a basin level for management planning purposes For Plan implementation, the Forest's 18 major Planning Basins will have been divided into Watershed Analysis Areas of from 600 to 2,500 acres in size to accommodate more detailed cumulative effects analyses on a project basis.

Riparian areas will continue to receive special attention Riparian-dependent resources (fish, water quality, wildlife habitat) will receive preferential consideration when conflicts occur among land use activities. The various riparian management prescriptions have been designed to maintain or, in some cases, reduce water temperatures.

Monitoring will be accomplished to assess the effectiveness of BMP implementation with special attention to turbidity, sediment, and chemical parameters Monitoring is scheduled to determine if soil productivity is being maintained. Landslide monitoring of selected sites will also continue for the primary purposes of improving interpretations, recommendations for reducing the risk of failures in projects, and to increase reliability of preventative measures in project design.

AIR QUALITY

The Forest currently maintains a visibility monitoring program in the Class I area associated with the Kalmiopsis Wilderness Emissions reporting is accomplished through the Oregon Department of Forestry Smoke Management Program for prescribed burning activities on the Forest. Implementation of the Forest-wide Standards and Guidelines should ensure maintenance of air quality at a level adequate for the protection and use of National Forest resources, and which meets or exceeds applicable Federal and State standards.

LANDS

Approximately 67 percent of the Forest's boundaries are surveyed, marked and posted to standard Landline location activities for the planning period will concentrate on property lines adjacent to timber harvest or other activities with the potential to impact adjacent private property.

Landownership may be adjusted, as opportunities arise, through purchase, exchange, or other methods of acquisition as appropriate. Reasons for adjustments include consolidation of National Forest Lands, reduction of landline location work, reduction of administration costs, needed rights-of-way, and to protect scenic qualities of Wild and Scenic Rivers. Land acquisition priorities are reflected in the land allocations of this Plan, and described in the Land Acquisition program outlined in the Forest-wide Standards and Guidelines.

MINERALS

Interest in mineral deposits on the forest is concentrated on gold, with numerous other minerals represented. Placer dredging is the most common form of mining, with some activity on lode claims. Currently, the Forest receives about 100 to 125 operating plans each year, and a large number of Notices of Intent for small operations Additionally, the Forest is host to numerous unpermitted "recreational miners", who enjoy gold panning or other nondisturbing mining activities Without new major discoveries, technological improvements, or substantial changes in the demand for minerals, the number of new mining claims is expected to remain constant for the planning period.

There are no coal or energy-related leases on the forest There has been some demand for building stone (25,000 tons in 1984) and it is expected that this use will continue and possibly increase in the future.

A total of 268,800 acres on the Forest have been withdrawn from mineral entry, primarily in Wilderness Although additional withdrawals along the three newly designated Wild and Scenic Rivers are anticipated, there are no proposals for such withdrawals at this time.

During the next decade the Forest minerals program will emphasize administration of operating plans and validation of claims located within Wilderness

FIRE AND PEST MANAGEMENT

The Forest Fire Management program has responsibility for wildland fire suppression and fuels management. Operational specifics for the program can be found in the Fire Management Action Plan. As management activities have expanded, the role of fire management in reduction of activity-generated fuels has increased Currently, the Forest plans to treat approximately 100 acres of natural fuels and approximately 5,000 additional acres of activity-generated fuels annually Exact acreages depend on the extent of timber harvest activities. Under the implemented Forest Plan, natural fuel management activities are expected to increase to 400 acres per year, and treatment of activity-generated fuels is expected to drop slightly to approximately 3,500 to 4,000 acres per year for the duration of the planning period.

The integrated pest management program requires special emphasis because of the high level of interest and concern by both the agency and the public. Insect and disease levels are continually monitored so that prevention is the mode of action rather than correction. Of special concern to this Forest is Port-Orford-cedar root rot disease, *Phytophthora lateralis*. The disease is always fatal in Port-Orford-cedar. Special practices and monitoring are being implemented to maintain the viability of Port-Orford-cedar in the forest for genetic diversity, as well as economic and noneconomic uses. Future management for this species will be governed by the Region 5 and Region 6 cooperative Port-Orford-Cedar Root Disease Action Plan established in June 1988. Management is intended to be site specific, consistent, and visible

FACILITIES

Transportation System

Continued need to respond to resource management objectives will require the development, maintenance, and management of the Forest development road system Many road-related activities will occur in support of the timber management program, with additional activities undertaken to facilitate recreational use, Forest administration, and resource protection.

Road development activities include, but are not limited to· transportation planning; route location; route survey; road design; contracting; and road construction and inspection Road maintenance activities include the use of personnel, equipment, and contracts to provide a roadway that meets established road management objectives. Road management activities include the establishment and maintenance of a Road Development Plan and a Road Management Plan which support implementation of this Land and Resource Management Plan. Other management activities include planning, organizing, and controlling application of actions to develop and maintain the Forest road system, and the organizational management of people, equipment, and funds

Timber sale activities will be primary impetus and funding source for the construction and reconstruction of accompanying (ancillary) roads. When available and desirable, capital investments could be used to support construction and reconstruction of needed roads. Funding needs to sustain transportation system activities are shown in Appendix B. Unforeseen conditions, such as damage from storms, may require additional project funding.

The projected operational status of the forest development road system is shown in Table IV-4. This projection is based on FORPLAN modeling, which does not have the spatial resolution to exactly portray the roading program needed to support the timber harvest scheduled in any particular decade (see discussion in Appendix B of the Final Environmental Impact Statement). This is due to the variability in the mix of harvest areas scheduled requiring new roads versus those that are accessed by existing roads, and to the situations where initial entry into an area may require more road per acre harvested than subsequent entries when units may be harvested along previously constructed roads The model generally underestimates the miles of road needed in the first two or three decades and over estimates the miles needed in subsequent decades. The actual mileages will vary depending upon site-specific decisions for timber sale planning, road location, and management needs.

Table IV-4 Projected Operational Status of Roads (Miles and Percent of Total Mileage) 1/ 2/

At End of Decade	Open and Maintained For: Passenger Cars Miles	Percent	High Clearance Vehicles Miles	Percent	Long Term Road Closure Miles	Percent	Total Forest Mileage
First	1,308	46	898	31	656	23	2,862
Second	1,370	45	923	30	780	25	3,073

1/ Based on FORPLAN projections
2/ Miles and Percent of Total Mileage

Administrative Sites

Development, maintenance, and management of administrative sites and facilities will be needed to support this Land and Resource Management Plan Administrative site development activities include, but are not limited to: site survey; contracting; site construction; and inspection. Site maintenance activities include those actions necessary to be able to occupy the site in a safe and orderly manner Site management activities include the establishment and maintenance of Site Development Plans for each site, and the prioritized compilation of projects found in these development plans into a Facilities Master Plan. The Master Plan will support implementation of this Land and Resource Management Plan. Other management activities include planning, organizing, and controlling application of actions to develop and maintain administrative sites, and the organizational management of people, structures, equipment, and funds. The funds necessary to provide adequate administrative facilities are shown in Appendix B.

FOREST-WIDE STANDARDS AND GUIDELINES

The following Standards and Guidelines state the bounds or constraints within which all practices will be carried out in achieving the planned objectives of the Forest The management of the Forest is subject to all applicable laws and regulations; particular reference is made to the management requirements of 36 CFR 219.27 The Standards and Guidelines are intended to help the manager achieve the goals and objectives, while staying within the constraints prescribed by law, along with the constraints designed to provide environmental safeguards The nature and design of the Standards and Guidelines are intended to mitigate effects, to cause an action to become less harsh or severe. Mitigation is extremely important in the design and implementation of all projects The monitoring prescribed in Chapter V will be required to assure that the Standards and Guidelines are followed and that the anticipated results are achieved

Two categories of Standards and Guidelines are applied to management of the Forest Forest-wide Standards and Guidelines apply to all Management Areas, unless specifically excepted by direction for an individual Management Area The Standards and Guidelines specific to the Management Areas are presented in the following section of this chapter, Management Prescriptions

The type of direction and degree of restriction are identified by the terminology in the Standards and Guidelines To understand the intent of the direction, the interpretations of the terms used are critical.

> The first intent is conveyed by the word **"shall "** With this degree of restriction the action is mandatory in all cases.
>
> The second is conveyed by the word **"should."** With this degree of restriction, action is required, unless justifiable reason exists for not taking action This direction is intended to require a practice unless it entails unacceptable hardship or expense. Exceptions to "should" restrictions are expected to occur infrequently
>
> The third type of direction uses the word **"practicable"** and acknowledges that a given practice is not always feasible and practical in every situation It is intended to encourage, but not require, a practice
>
> The fourth uses the word **"may"** and has to do with activities which may or may not be appropriate, depending on circumstances For example, grazing may be consistent with the objectives of certain Management Areas, but specific sites may or may not contain suitable forage. This direction is intended to allow for taking advantage of compatible opportunities, or to provide for exceptions when objectives of a particular standard can be met through alternate methods

Levels of resource management prescribed in the Standards and Guidelines must be met. Consistent with the goals of each Management Area, however, land managers will employ all available inventory information to maximize enhancement and minimize impairment of every resource value involved.

The Standards and Guidelines describe what will and will not occur in a particular area to achieve the desired goal Because of the great variety of resources and circumstances, however, provision has been made for unusual and unforeseen implementation problems. Some of these problems will be the result of insufficient or inaccurate inventory data. The NEPA process will guide project planning and Forest Plan implementation, and must be followed to make a departure from the Standards and Guidelines. This could result in an amendment to the Forest Plan. A situation must be fully described, alternatives developed, and costs evaluated. Mitigation measures will be employed to produce a result as close as possible to that called for. The long-term goal for a particular Management Area will not change.

The river management plans and wilderness management plans remain in force upon approval of the Forest Plan. All other planning documents, except for contingency plans responding to special

circumstances, are superseded by the Forest Plan Other operational plans and policy statements which do not provide resource management direction will remain in force but are not tied in writing to the Forest Plan.

As an aid to the user, the direction statements are in bold type so they can be quickly discerned from the explanatory information and examples that are present in some sections.

RECREATION

1-1 **Management of the Forest shall provide a broad range of recreation opportunities in a dispersed and developed setting, including Primitive, Semi-primitive Non-motorized, Semi-primitive Motorized, Roaded Natural, and Roaded Modified Recreation Opportunity Spectrum (ROS) and Wilderness Recreation Spectrum (WRS) classes.**

DEVELOPED RECREATION

1-2 **As management activities are programmed in areas adjacent to identified potential development sites, they shall be protected in order to maintain their character until scheduled for construction. The level of development shall be compatible with the ROS class inventoried for each site.**

Level of Development	ROS Class
1	Primitive
1 or 2	Semi-primitive Non-motorized
1 or 2	Semi-primitive Motorized
3 or 4	Roaded Natural/Roaded Modified

1-3 **The potential and existing developed recreation sites shall be designed to minimize annual maintenance and operating costs. The design should discourage vandalism to the extent that is possible to avoid a high level of surveillance and operating requirements. Recreation facilities should be developed only where private facilities cannot fill the need for the recreational service or facility. Competition with private enterprise should be avoided.**

Developed Sites

1-4 **The Forest Service should provide for developed recreation opportunities throughout the Forest commensurate with projected need.**

The Forest Service should manage use of existing facilities to protect resources and areas that would otherwise become degraded as a result of use.

Service Level

1-5 **The levels of service for administration, operation and maintenance of developed sites shall be based on site capacity, site protection needs, and seasonal demands for public use. Selected sites should be open for public use during the managed use season, at the minimum level of service as specified below:**

1. **Administration. Administration of public use at developed recreation sites shall include inspection for public health and safety and for prevention of resource damage.**
2. **Operations. Cleanup and sanitation of facilities at developed sites should occur to accommodate public use. This activity shall include testing of potable water when provided.**

3. **Maintenance. Site facilities shall be maintained in a condition to meet standards for public health and safety. Facilities should be maintained to a Recreation Information Management (RIM) Condition Class I or II level.**
4. **Resource Management Treatment. Other resource management treatments should be accomplished for public safety and site protection (e.g., vegetation management, rehabilitation, etc.).**

DISPERSED RECREATION

1-6 **Enhance dispersed recreation opportunities where practicable as other management activities are planned.** For example, access can be provided to recreation attractions or wilderness entrance points from timber sale road development; conversely roads can be closed to public access in order to protect the quality of non-motorized recreation opportunities.

1-7 **Recreation users should be educated about the proper disposal of human waste and to the principles of no-trace camping (pack it in - pack it out). This should be accomplished through the use of public contact, brochures, and media.**

1-8 **Displacement of Forest system trails by new roads should be avoided. Where displacement occurs, and recreation use warrants, new trails should be constructed to replace those sections lost in order to protect the integrity of the system and to insure the quality of recreation experiences.**

1-9 **The Forest Service should provide for use of the existing trail system that serves the needs of recreationists, and satisfies demand levels in a condition that protects the resource and meets minimum requirements for health and safety. Trails should be managed to accommodate both motorized and non-motorized uses, depending on location and Management Area goals.**

Trail Management Objectives shall be developed for all trails included in the Forest Trail System. Management objectives should be used for the identification of the maintenance level required for each of the Forest system trails.

All trails included in the Forest Trail System should be inspected annually to identify trail maintenance needs. Sufficient maintenance shall be provided to protect soil and water resources.

Management activities along Forest System Trails shall be implemented with sensitivity to the experience of recreation users. Appropriate techniques to mitigate effects or avoid management conflicts should be identified in the individual trail management objectives. Measures to mitigate the effects of activities could include: vegetative screening, re-routing of a portion of the trail for a period of time, temporary closure notification; or interpretive signs in appropriate locations

RECREATION MANAGEMENT

1-10 Public information is integral to the management of the Recreation resource. **The public should be informed on a continual basis using the media outlined below. Maps should be reviewed, and updated if needed, at intervals not to exceed five years for recreation maps and ten years for wilderness maps.**

Forest Recreation Maps
Wilderness Brochures
Wild and Scenic River Brochures and Maps
Trail Pamphlets
Radio & TV Spots and Videos
News Releases
Coordination with Individuals, private organizations and other agencies

1-11 **Project environmental analysis should consider the potential impact that the proposed activity would have on ROS classification and the recreation use capacity of the area. Potential developed recreation sites should not be bisected by through roads, and the vegetation of the site should be managed to enhance the potential recreational values of the site. *Programmed timber harvest shall not be scheduled from identified potential or* developed recreation sites, but opportunities to manage the vegetation at the site and to improve safety and aesthetics should be taken.**

The Recreation Information Management (RIM) inventory shall be updated annually to monitor levels and types of recreation use on all areas of the Siskiyou National Forest. All sources of information should be used to gather data for the RIM report including trailhead *registration boxes, river registration, permits, employee or public observation, etc.*

CHANGED ENVIRONMENTAL CONDITIONS

1-12 Recreational settings, facilities or opportunity may be affected by unforeseen changes in environmental conditions. Changed conditions may result from events, such as catastrophic fire, or by projects that are allowable under law, regulation or approved management direction, such as minerals development

When changed conditions occur, environmental analysis shall be conducted to determine the effects of the changed conditions on recreational opportunity, and to re-evaluate and consider modification of existing recreational management objectives.

VISUAL RESOURCES

2-1 **Management activities shall be designed to achieve the allocated Visual Quality Objective (VQO) for the area (Agriculture Handbook 462, Visual Management System, USDA 1974).** Allocations may be different than the inventoried VQO's Land allocated to achieve the VQO's of Retention or Partial Retention, not overlapped by a more restrictive allocation, are in Management Areas 12 and 13 respectively. Modification and Maximum Modification areas, not overlapped by a more restrictive allocation, are in Management Area 14, General Forest.

2-2 Few resource inventories are static upon completion and the process for change is invaluable to successful resource management **If field analysis identifies a need to correct the inventory**

of VQO's, the correction should be recorded in environmental analysis documents and approved by the Forest Supervisor, whereupon the Forest Inventory will be updated.

Conditions that could warrant a change in inventoried visual objectives are:

1. Discrepancies in Landscape Variety classification
2. Changes in Viewer Sensitivity level.
3. Discrepancies in Seen Area mapping.

2-3 **Mitigation treatments for impacts to the visual resource shall be completed within one year after the completion of the project (Agriculture Handbooks 462 and 559, USDA 1974).**

CULTURAL RESOURCES

The following standards comply with all applicable legal requirements for management of cultural resources, including the National Historic Preservation Act of 1966, the National Environmental Policy Act of 1969, the American Indian Religious Freedom Act of 1978 and the Archaeological Resources Protection Act Standards for each aspect of the cultural resources program are provided to ensure that procedural requirements are satisfied These cultural resource management procedures apply to all Federal undertakings, Federally-funded undertakings, and undertakings requiring Federal permits Appendix B displays the schedule of cultural resource management activities on the Forest for the current planning period

OVERVIEW

3-1 **A cultural resource overview of the Forest shall be completed and maintained.** The overview will summarize all previously recorded cultural resource information for the Forest, provide a framework for evaluating cultural resources identified through the inventory process, develop a preliminary research design to guide future surveys, inventories, and scientific investigations, and identify opportunities for interpretation of a range of cultural properties.

IDENTIFICATION

3-2 **A cultural resource inventory program shall be conducted under the leadership of an Archaeologist on a project-specific level for major ground-disturbing activities in compliance with applicable Federal historic preservation legislation (Forest Service Manual 2360; Kaiser and others 1983).** The results of project-level cultural resource inventories will be documented in the Cultural Resource report.

The Forest's cultural resource inventory strategy, the Sample Survey Design, shall guide the inventory of all National Forest lands to identify all reasonably located cultural resources. The Sample Survey Design should be reviewed annually and updated as needed to reflect advances or changes in the site inventory data base, management objectives, legislation and Regional or Forest research designs.

EVALUATION AND ASSESSMENT

3-3 **The significance of inventoried sites shall be evaluated by applying the criteria for eligibility to the National Register of Historic Places.** Sites can be treated as individual properties, thematic groups, or historic districts. Priority will be given to those properties that may be affected by project activities. **A plan should be developed to evaluate all other cultural resources through cost effective means as the Forest-wide inventory nears completion.**

Cultural resources that meet the appropriate criteria for eligibility to the National Register of Historic Places shall be nominated. Nominations will be scheduled incidentally until completion of the Forest-wide inventory of cultural resources.

The effects of all Forest Service undertakings on significant cultural resources shall be considered, and measures shall be developed to avoid or mitigate any adverse effects.

PROTECTION AND ENHANCEMENT

3-4 **Measures shall be developed in consultation with the Oregon State Historic Preservation Officer (SHPO), or the State Historic Preservation Office of California and, if necessary, the National Advisory Council, to protect significant sites from adverse effects due to ground-disturbing activities.** In Oregon, the National Forests have a Programmatic Memorandum of Agreement with the SHPO to simplify and expedite the review process A small part of the Forest is in California and cultural resource reports are reviewed and given comment on a case-specific basis. Measures developed to protect specific values range from complete avoidance of the site and corresponding protection of its environmental setting to mitigation procedures which conserve the historic values of the resources. Examples of the latter include: data recovery through excavation of subsurface cultural resources, photo documentation of surface features and standing structures, and in some cases, site restoration

3-5 **Eligible cultural resources should be protected from degradation due to vandalism or unauthorized public use.** Protection plans could include, but are not limited to, scientific study and collection, the use of fences and barriers, proper use or removal of signs, stabilization techniques, closure orders, patrol and site monitoring, maintaining site anonymity, and gaining public understanding and support through education programs. Cultural resources determined eligible to the National Register of Historic Places should be monitored by means of a recurring inventory to determine whether their condition has been affected by vandalism or unauthorized use.

3-6 **Eligible cultural resources should be protected from degradation due to natural deterioration such as that caused by fire, flood, earthquake, precipitation, or wind.** Cultural resources evaluated as having National Register significance should be monitored by means of a recurring inventory to assess whether their condition has been affected by environmental factors

3-7 **Opportunities may be provided for scholarly/scientific use of designated prehistoric sites after coordinating selection of appropriate sites with the relevant Native American groups.** This could require "banking" of sites for future use, and processing of antiquities' permits for testing and excavation of sites by qualified professionals.

MAINTENANCE OF HISTORIC SITES AND TRAILS

3-8 **Eligible historic sites and historic trails shall be maintained or adverse effects shall be mitigated. Stabilization or rehabilitation may be carried out for significant sites which have been damaged.** Decisions on the maintenance level for eligible historic structures should be based on an analysis of utility, interpretive value, public interest, existing site or area allocation, funding sources, existing agreements, and other relevant considerations. Historic trails require inventory, evaluation, and preservation either in place or through documentation.

INTERPRETATION

3-9 **Suitable cultural resource properties may be interpreted for the recreational use and educational benefit of the general public. The measure of suitability should be based on**

accessibility to the public, feasibility for protection, condition of the property, compatibility with other resource management activities within or adjacent to the area, thematic representation, and value to public groups. Interpretive services and facilities should be compatible with the nature, qualities, and integrity of the cultural sites selected for enhancement. Preferred methods include brochures, signs, displays, interpretive trails, tours and video or slide programs.

MITIGATION

3-10 **Mitigation measures established during the environmental analysis of a given project shall be monitored to ensure all stipulations are being met.** Current records are necessary to indicate compliance with legal mandates. Tracking of the mitigation plan is necessary during and following ground-disturbing activities where cultural resources are present.

MANAGEMENT

3-11 **The long-term management of cultural resources shall be coordinated with the State Historic Preservation Office and others as necessary. Cultural resources shall be assigned to appropriate management categories for present and future uses such as interpretation, scientific investigation, adaptive uses, and preservation in place for developing future scientific needs. A data redundancy category should be developed in the future when inventory and excavation data become sufficient to make such a judgment.**

The following are management priorities for Cultural Resources

1. Preservation in-place of cultural resources for future scientific study.
2. Controlled data recovery by means of professional excavation, mapping, photo documentation and reporting to answer questions about prehistoric/historic use and development.
3. Adaptive use of historical structures; for example, administrative sites, residences, interpretive centers, etc
4. Interpretive use, such as directing public attention to a site for educational/entertainment purposes.

3-12 **Management of traditional religious sites shall be coordinated with American Indian groups. Information about planned project activities shall be presented to American Indian groups for coordination concerning effect on traditional religious sites.**

FISH, WILDLIFE, AND SENSITIVE PLANTS

4-1 **Fish and wildlife habitat resources on the Siskiyou, in particular the habitat of management indicator species, shall be managed in cooperation with State and Federal Fish and Wildlife agencies. At the Forest level, fish and wildlife habitat shall be managed to maintain viable populations of all existing native and desired non-native plant and animal species. Distribution of habitat shall provide for species viability and maintenance of populations throughout their existing range on the Forest.** Monitoring and inventory plans have been developed for indicator species and others (see Chapter V).

The Forest will adhere to all pertinent state statutes and laws. This includes ORS 496.012, which deals with providing for optimum levels of all species of fish and wildlife and preventing the serious depletion of any indigenous species. Also included are the Oregon Endangered Species Act (Oregon Revised Statutes 496.004, 498 026, and 564.040), the California Endangered Species Act (1984 Amendments), and California Native Plant Protection Act (1977)

ENDANGERED, THREATENED, OR SENSITIVE SPECIES - GENERAL

4-2 **Endangered, threatened and sensitive species shall be identified and managed in cooperation with the USDI Fish and Wildlife Service, Oregon Department of Fish and Wildlife (animals), and Oregon Department of Agriculture (plants), and California Department of Fish and Game (animals and plants). Legal and biological requirements for the conservation of endangered, threatened and proposed plants and animals shall be met.**

Habitat for existing Federally-classified threatened and endangered species shall be managed to achieve objectives of recovery plans.

Biological evaluations shall be prepared for each project authorized, funded, or conducted on National Forest land to determine the possible effects the proposed activity will have on endangered, threatened, proposed, or sensitive species (FSM 2672.4, including R-6 Supplement 41). For sensitive plant species, it may be helpful to consult with local knowledgeable and interested botanical authorities. The biological evaluation consists of five steps

1. Pre-field review of existing information.
2. *Field reconnaissance of the project area*
3 Determination of whether local populations of endangered, threatened, proposed, or sensitive species will be affected by a project (consult with USDI Fish and Wildlife Service if endangered, threatened, or proposed species are found)
4 *Analysis of the significance of project effects on local and total populations of sensitive* species.
5. If Step 4 cannot be completed due to lack of information, a biological or botanical investigation is completed to complete the analysis of significance.

If endangered, threatened, or proposed species are found in a project area, consultation requirements with the USDI Fish and Wildlife Service shall be met in accordance with the Endangered Species Act (Public Law 93-205) and FSM 2671.45. Before a project can be carried out, protection or mitigation requirements shall be specified (NFMA, 36 CFR 219.27(a)(8)). Four interrelated factors determine the type of review and consultation procedures to follow in determining effects on listed or proposed species They include: presence of listed or proposed species; Forest Service determination of effect in the biological evaluation, type of project (construction or not); and extent of environmental impact. See FSM 2671 4 for detailed consultation procedures.

Species management guides should be prepared to address the effects of land management activities on local populations of sensitive species at a broader scale, and to identify opportunities to enhance and develop habitat.

Lists of endangered, threatened and sensitive plant and animal species shall be maintained and updated periodically as new information is collected. Pertinent information will be submitted to the Regional Office for updating the Regional Forester's Sensitive Species Lists, and to the appropriate agencies for inclusion in State-wide data bases.

Forest personnel shall not identify (to the public) specific location information that could jeopardize the welfare of an endangered, threatened, proposed, or sensitive species (FSM 2671.2).

Standards and Guidelines 4-3 through 4-8 contain direction specific to the Threatened, Endangered, and Sensitive Species of the Siskiyou National Forest.

BALD EAGLE HABITAT (THREATENED SPECIES)

4-3 **Bald eagles and their habitat shall be protected and managed in accordance with the** *Pacific Bald Eagle Recovery Plan* (USDI Fish and Wildlife Service 1986) **The suitability of sites in key areas shall be maintained or enhanced.** As part of the recovery plan, the Rogue River is designated as a key area (current wintering population of 10; two existing territories, plus four target territories) Other key areas include the Sixes, Chetco, Illinois, and Coquille Rivers, each with one "target recovery territory". Although the "key areas" apply to all ownerships within a drainage basin, five sites on the Forest (four on the Rogue River, one on the Illinois River) have been identified as potential nesting sites, as per coordination requirements of the recovery plan.

Within two years after implementation of the Forest Plan, a management plan should be prepared for known nest sites and potential bald eagle habitat (including wintering habitat) on the Siskiyou National Forest. Consult the *Pacific Bald Eagle Recovery Plan* (USDI Fish and Wildlife Service 1986), Brown (1985), the *Bald Eagle Management Guidelines for Oregon and Washington* (USDI Fish and Wildlife Service 1981) and FSM 2670 for specific management guidelines.

Occupied Bald eagle habitat will be monitored to determine the effectiveness of planned action and recovery efforts.

4-4 **Prior to development of the management plan, interim requirements for management of bald eagle habitat shall include the following standards (interim management plans for individual active sites shall be prepared as necessary):**

Nesting Sites

Bald eagle nest sites shall be protected, including existing active and inactive nest sites, and designated recovery (potential) sites. Manage each area under the territory zone concept (Brown 1985). **Primary and secondary zones should be established by actual use observations and site-specific information. Secondary zones should also reflect local physiographic conditions.**

Primary Zone. Not less than 330 feet from the nest, with actual size and shape of zone adjusted to include all the area near the nest tree that is actually utilized. Zone size can vary, reflecting local topography, potential for blowdown, and location of important habitat components There will be no timber harvesting in the primary zone unless designed to enhance stand characteristics for the benefit of nesting eagles Human activities in the primary zone will be controlled year-round to insure that the site remains suitable as nesting habitat.

Secondary Zone The secondary zone extends from 330 feet out to a minimum of 660 feet from the nest, it minimizes disturbance and protects the primary zone Zones need not be circular, but will reflect local physiographic conditions and the tolerance of the nesting pair to disturbance factors (Brown 1985) The width of the zone could be considerably wider, depending on the degree to which vegetation or topography screens the nest from potential disturbance. The zone will contain important roosting sites, perching sites, and alternate nest sites. Timber may be harvested in the secondary zone, provided eagle habitat requirements take precedence. Management steps may be taken in the secondary zone during the period when the birds are present, normally between January 1 and August 31.

Feeding and Roosting Sites

Regularly used feeding and roost sites (including wintering habitat) shall be protected. Human activities will be controlled if they adversely affect the eagles' use of a feeding area Only those Forest practices that maintain the suitability of the area for eagle roosting will be used. The area encompassed will have at least a 330-foot radius, and possibly up to one-fourth mile Wildfires will be controlled.

Maintenance of Potential Nesting Habitat

Forest land within one mile of the Rogue River is potential bald eagle nesting habitat; they have historically nested here and a food base exists. **For every 1,280 acres within one mile of the *Rogue River, a 30-acre stand with an open view of and clear flight path to water should be* managed as a potential nest site.** Habitat provided at potential nest sites must be in mature or old-growth forest and possess characteristics outlined in Brown (1985). In general, this 30-acre *area would be managed to provide a large number of trees per acre greater than 11 inches DBH*; of which 18-21 trees per acre would be 75-125 feet high and 14-16 would be more than 125 feet high (USDI Fish and Wildlife Service 1981).

PEREGRINE FALCON HABITAT (ENDANGERED SPECIES)

4-5 Peregrine falcons are known to nest on the Forest. **Sufficient existing nesting and feeding habitat shall be protected to meet the objectives of the Pacific Coast Recovery Plan for the American Peregrine Falcon (USDI Fish and Wildlife Service 1982). All existing nest sites and any new nests shall be protected. Feeding areas may be enhanced.**

Within three years after implementation of the Forest Plan, an inventory should be completed which catalogues Siskiyou habitat suitable for peregrine falcon. Within one year after finishing the inventory, the Forest should complete a habitat management plan or nest site management plans for peregrine falcons.

NORTHERN SPOTTED OWL HABITAT (SENSITIVE SPECIES)

4-6 **Spotted owl habitat shall be managed in accordance with direction specified in the Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide** (USDA 1988).

The Forest shall assist the Regional Office in meeting the terms of the 1988 Interagency Agreement on spotted owl *The four agencies* (USDA Forest Service, USDI Fish and Wildlife Service, Bureau of Land Management, and National Park Service) have agreed to cooperate in an effort to maintain population viability for spotted owls.

Nest sites and important (heavily-used) roost sites outside of Management Area 8 (mature and old-growth habitat for wildlife) shall be protected As needed, develop an individual prescription for each nesting or important roosting site found in areas suitable and available for timber harvest (a 300-foot buffer zone around the site would provide minimum protection - the actual zone configuration would depend on the location of other nearby harvest units, location of riparian corridor, topography, etc.). The prescription would include the size and shape of the protection zone, any restrictions on human use of the site (e g., seasonal closures, road management), and monitoring. Heavily-used roost sites are often near nest sites. The need to protect spotted owl nest or principal roost sites which occur outside designated habitat areas is discussed in Forsman and others (1984)

Areas proposed for harvest which contain habitat suitable for spotted owls should be surveyed according to standard inventory protocols. Perform ground surveys of each sale unit once during daylight (optional); **if no owls are found, all units of the sale should be surveyed at night at least twice before discontinuing survey efforts. Night surveys should be scheduled at least two weeks apart.** Maintain survey results in the Ranger District resource inventory and forward to the Forest Coordinator annually. Data gathered from these surveys will be important in assessing adequacy of Management Requirements for spotted owls.

WOLVERINE HABITAT (SENSITIVE SPECIES)

4-7 **Reported sightings shall continue to be evaluated. In cooperation with State Fish and Wildlife agencies, attempts should be made to verify the presence and distribution of the species. Direction for occupied essential habitat shall be provided through a species management guide or plan if the species is determined to occur on the Forest.**

OTHER SENSITIVE ANIMALS

4-8 Other sensitive species on the Siskiyou National Forest include:

In Oregon	In California
Siskiyou Mountain salamander	Fisher
Western spotted frog	Pine marten
Western pond turtle	Northern goshawk
Townsend's western big-eared bat	Willow flycatcher
White-footed vole	

The standard below applies to all these species, except pine marten, for a description of Management Requirements for marten, see Designated Habitat (MA-8). The marbled murrelet is not currently listed as sensitive by the Forest Service. See Appendix D for a discussion of inventory efforts proposed for the murrelet

Habitat use of the Siskiyou by these species shall be evaluated. In cooperation with State Fish and Wildlife agencies, attempts should be made to verify the presence of these species on the Siskiyou National Forest. Occupied essential habitat shall be provided through a species management guide, or plan. Each plan will cover only the area (state) where the species is classified as sensitive.

OSPREY HABITAT

4-9 **Osprey nesting and feeding habitat on the Forest should be maintained. Three overlapping habitat zones should be established on the Rogue River** (the most restrictive guideline takes precedence). **Along the Illinois, Chetco and South Fork Coquille Rivers, only the first two standards should apply.** The areas of consideration will be: the Rogue and Illinois within the Forest boundaries, the Chetco upstream to the Kalmiopsis Wilderness boundary, and the South Fork Coquille upstream to Coquille River Falls Osprey habitat needs will be incorporated into the next revision of the Siskiyou Wildlife Tree (Snag) Guidelines.

1. **No timber harvest should be programmed within 200 feet of the river** (Jackman and Scott 1975) Trees may be cut to meet safety needs and to meet other necessary management needs, such as road crossings.
2. **Up to 1,320 feet from the river, a minimum of two dominant live trees and two large snags (at least 45 inches DBH and 80 feet tall) should be retained per acre** (Zarn 1974).

3. **Up to three miles from the Rogue River, or the nearest major ridge line (whichever is closer), one potential nest site should be maintained in each quarter-section** (160 acres). In each quarter-section, a circle 600 feet in diameter will contain all of the separate habitat components needed for each potential nest site. Components are at least one usable nest tree, one or more snags or snag-top perch trees, and five or more other large trees (mature) that will be available for use as nest or perch trees in the future

Active nests anywhere on the Forest should be protected during the nesting season. Human activities that would disturb nesting osprey should be restricted from March 1 to August 31 within a 1,320 feet radius (depending on specific conditions at the site, the distance could vary - boating and rafting activities generally do not disturb nesting osprey). The most critical period during the nesting season is May through June, when there are eggs or very young chicks in the nest.

Nest trees should be protected until they are no longer usable A no-cut zone should be established around all Forest nest sites Size and shape of the zone will depend on topography, vegetation, and other relevant factors; include any nearby perch trees. Where appropriate, nest sites may be created.

OTHER RAPTORS (BIRDS OF PREY), AND COLONIAL NESTING BIRDS

4-10 **Active roost and nest sites (including rookeries) should be protected.** Depending on the individual situation, timber harvest may be foregone in a primary zone extending up to 500 feet from the nest or roost site. **At some sites it may be necessary to establish a secondary Restricted Activity Zone outside the primary zone; timber management and road building activities may be prohibited or curtailed during the nesting season.** This secondary zone could range up to 1,000 feet or more from the nest or roost site, depending on the individual situation (in most cases the distance would probably be less).

DEER AND ELK HABITAT

4-11 **The publication "Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington" (Brown 1985), Chapter 11, Deer and Elk, should be used as the basic guideline for management of deer and elk habitat on the Siskiyou National Forest.** This publication is the basis for the following general guidelines

Where deer and elk are a primary focus of management (Management Areas 10-14):

1. Lay out timber harvest units so that all portions of the unit are within 600 feet of hiding cover.
2. Blocks of hiding cover should be at least 600 feet wide; areas of thermal and optimal thermal cover are adequate if at least 30 to 60 acres in size and from 400 to 1,200 feet wide.
3. Manage riparian vegetation to provide hiding cover, thermal cover, and travel corridors along Class I, II, and III streams.
4. Develop plans for habitat improvements, especially forage enhancement.

Timber harvests should be distributed to individual Watershed Analysis Areas (see Standard and Guideline 7-15) to achieve objectives for deer, elk, or other species. Timber sales should be planned to accommodate ODFW (1985) cover criteria for deer and elk: maintain 50 percent of a subbasin in well distributed thermal cover stands (of which at least 25 percent is optimal thermal cover) and 20 percent in forage areas.

Big game habitat capability models (such as developed by Wisdom and others 1986) should be used in project planning to provide the quality, quantity, and distribution of cover and forage needed to reach management objectives for the Forest.

A Forest-wide Management plan for Roosevelt elk and black-tail deer should be prepared no later than three years after implementation of the Forest Plan. The management plan will identify where deer and elk management is the primary focus The plan will provide guidance for third to fourth order watersheds. The plan will be developed in cooperation with state Fish and Wildlife agencies.

For Roosevelt elk, the management plan will evaluate capable, suitable, and available habitat, to determine extent of transplanting or reintroduction. **Roosevelt elk herds may be reestablished in areas they historically occupied.**

The plan should address the following variables common to both species:

1. *Habitat.* Address forage and cover (hiding, thermal, optimal thermal) needs, including relative proportions of each type (forage/cover ratio) and juxtaposition. Evaluate habitat types used by elk and deer. Identify calving and fawning areas, migration routes and corridors, and other special use areas. Identify minimum and optimum width for travel corridors.
2. *Seasonal Use.* Analyze the appropriateness of allocating timber harvest units and habitat improvement projects by winter range zone, using existing computer-generated maps as a base (maps depict primary winter range, secondary winter range, and non-winter range; see discussion in Chapter III, FEIS).
3. *Herd Size.* Establish habitat capability (population) goals for deer and elk herds.
4. *Habitat Improvement.* Analyze the costs and benefits of potential habitat improvement projects; fully explore the opportunities to use K-V funds for mitigation and improvement projects Assess the effectiveness of forage seeding and fertilizing.
5. *Hunting.* Include the effects of hunting regulations; analyze recreation (hunting) demand projections
6. *Disturbance.* Design management activities to reduce risk of disturbing deer and elk in important habitat areas such as winter ranges, thermal cover areas, known elk breeding areas, riparian areas, and dedicated old-growth stands.
7. *Timber Management.* Assess interrelationships with timber management and silviculture. Incorporate standards and guidelines into thinning prescriptions and other vegetation management activities Address competition between tree seedlings and forage plantings.
8. *Road Access.* Design road management objectives to protect fish and wildlife habitat values, minimize disturbance of fish and wildlife, and promote increased quality of fish- and wildlife-related recreational experiences. Address impacts of roads as related to overall habitat effectiveness evaluations for deer and elk (also see Standards and Guidelines under Facilities: Transportation Systems).

SALMONID AND AQUATIC HABITAT

4-12 Salmonid indicator species selected for evaluating habitat in this plan include fall chinook salmon, winter and summer steelhead, and resident trout. **Streams shall be managed to maintain or improve the present level of salmonid habitat capability. Stream inventories shall be maintained and updated to: (a) assess habitat capability; (b) monitor changes due to natural or management-related events; and (c) identify opportunities for rehabilitation or enhancement.** Use of the Hankin and Reeves (1986) inventory procedures would provide a comparable estimate of habitat and fish population over the survey area

Fisheries habitat enhancement shall be conducted according to Forest basin priorities. Basin plans should be prepared in cooperation with the Oregon Department of Fish and Wildlife and will evaluate the current condition of habitat, fish populations, opportunities for enhancement, and the associated costs and benefits. Enhancement projects should be monitored to evaluate effectiveness. Emphasis will be placed on maintenance or improvement of salmonid spawning, rearing, and migration habitats. The major components of these habitats are.

1. Rearing. Water temperatures, pool depths, overhead and instream cover, instream woody debris and low-gradient habitats (e g side channels, glides and overwintering areas).
2 Spawning. Gravel quantity, quality and stability; instream cover for adults in the form of pools and woody debris.
3. Migration. Upstream and downstream passage for both juvenile and adult salmonids.

The quality of these components is related directly to management of the watersheds Supporting management standards and guidelines are addressed under Soil and Water in this section, and in the prescriptions for Management Areas 7 and 11.

The desired conditions of salmonid habitat are.

1. Summer water temperatures at or below present levels.
2. Sufficient quantities of instream large woody material to support the functions of nutrient cycling, hiding cover, channel stabilization, pool formation, and collection of spawning gravels.
3 Existing or enhanced pool/riffle condition with summer pool depths greater than 3 feet
4. Existing or enhanced stability of low gradient spawning and rearing areas.

WILDLIFE TREE (SNAG) HABITAT

4-13a **Habitat capability for woodpeckers (indicators for cavity-nesting species) should be continually maintained throughout the Forest at not less than 60 percent of potential population levels.** ("throughout the Forest" covers all timber sale areas, including salvage sales). This will result in maintenance of self-sustaining populations of cavity nesting species. **The Siskiyou Wildlife Tree (snag) Policy and Guidelines and District supplements should be followed for all project activities.** Existing direction is supplemented by the following Guidelines.

Designated wildlife trees should be protected from woodcutting and Forest management activities.

Older timber sale units (pre late-1970's) often contain low numbers of wildlife trees. **In new sale areas, additional wildlife trees may be left to offset lower numbers in older units in the vicinity.** In these situations the objective is to maintain an average 60 percent habitat level within as small an area as feasible (such as a small drainage basin).

Wildlife tree management standards established for Forests in Region 6 shall be followed (1920/2600 letter from Regional Forester dated September 9, 1988). **Within one year after approval of the Forest Plan, the Siskiyou Wildlife Tree (snag) Guidelines shall be revised to incorporate this new Regional Direction.** This direction provides, in part, that snag densities needed to meet Management Requirement direction for cavity excavators must be provided within land areas that are generally no larger than normal unit size (not more than 60 acres) *These densities will be maintained through the full rotation on these areas by providing for green* replacement trees that will become snags of adequate size when existing snags fall.

Wildlife trees may be clumped where this technique is practicable, feasible, and meets the 60 percent standard

Tables IV-5 through IV-10 below should be used to meet the 60 percent habitat capability level. Wildlife tree habitat needs for woodpeckers on the Siskiyou vary depending on the woodpecker species present (Brown 1985). Five habitat groupings represented by different woodpecker species occur on the Forest; the snag needs for each area are listed in the tables below (these tables supplement the Siskiyou's existing guidelines). The proper table to use in a given timber sale area will depend on the woodpecker species and seral stage(s) present

In Tables IV-5 through IV-9, the habitat capability level for woodpeckers is set at 60 percent. Requirements are for conifer snags per 100 acres; snags should be present in these numbers at all times during a rotation. The relative numbers of hard and soft snags in various size classes are listed as a guide to habitat needs of the different woodpecker species. Personnel laying out timber sales *are not* expected to keep detailed records of soft and hard snags in the various height classes; personnel *will* strive to meet the objectives for total snags per acre.

It is assumed that natural mortality will provide suitable snags during the last 30 to 35 years of a managed rotation (100 years). An assumption is also made that the average snag will last 30 to 35 years before falling. This means that during harvest operations, enough wildlife trees must be designated to serve through the first two-thirds of a rotation. Consequently, to calculate how many wildlife trees must actually be left standing after harvest operations cease, the snag numbers listed in Tables IV-5 through IV-9 should generally be doubled (see Brown 1985 for specific data on snag longevity).

Snags with the largest DBH last longer and make the best wildlife habitat, and should be selected whenever possible, however, wildlife trees which will continue to grow for another 30 to 35 years before becoming snags may be of smaller diameter than those which must die at the beginning of a rotation. Snags with diameters (DBH) over 20 inches meet the Standard and Guideline for Large Woody Material (7-8). Wildlife trees designated in riparian areas may be counted towards snag objectives only if they are excess to those needed to provide shade in stream corridors (essential shade trees cannot be killed to provide snag habitat, see prescription for Management Area 11).

Table IV-5. Snag requirements per 100 acres in FORESTED HABITAT for the five most common woodpeckers on the Siskiyou National Forest.

Snag Diameter Class (in, dbh)	Snag Decay Stage		Total Snags by Diameter Class
	Hard, Stage 2-3	Soft, Stage 4-5	
11+	–	10 Downy Woodpecker	10
15+	27 Red-breasted Sapsucker	115 Hairy Woodpecker	142
17+	–	29 Northern Flicker	29
25+	4 Pileated Woodpecker	–	4
Total Snags	31	154	185

Table IV-6. Snag requirements per 100 acres in FORESTED HABITAT for the five most common woodpeckers on the Siskiyou National Forest, *plus* the acorn woodpecker

Snag Diameter Class (in, dbh)	Snag Decay Stage		Total Snags by Diameter Class
	Hard, Stage 2-3	Soft, Stage 4-5	
11+	–	10 Downy Woodpecker	10
15+	27 Red-breasted Sapsucker	115 Hairy Woodpecker	142
17+	42 Acorn Woodpecker	29 Northern Flicker	71
25+	4 Pileated Woodpecker	–	4
Total Snags	73	154	227

Table IV-7. Snag requirements per 100 acres in FORESTED HABITAT for the five most common woodpeckers on the Siskiyou National Forest, *plus* the white-headed woodpecker.

Snag Diameter Class (in, dbh)	Snag Decay Stage		Total Snags by Diameter Class
	Hard, Stage 2-3	Soft, Stage 4-5	
11+	–	10 Downy Woodpecker	10
15+	27 Red-breasted Sapsucker	115 Hairy Woodpecker 36 White-headed Woodpecker	178
17+	–	29 Northern Flicker	29
25+	4 Pileated Woodpecker	–	4
Total Snags	31	190	221

Table IV-8. Snag requirements per 100 acres on the Siskiyou National Forest for the three most common woodpecker species inhabiting SHRUB/OPEN SAPLING-POLE HABITATS.

Snag Diameter Class (in, dbh)	Snag Decay Stage		Total Snags by Diameter Class
	Hard, Stage 2-3	Soft, Stage 4-5	
11+	–	–	–
15+	7 Red-breasted Sapsucker	79 Hairy Woodpecker	86
17+	–	29 Northern Flicker	29
25+	–	–	–
Total Snags	7	108	115

Table IV-9. Snag requirements per 100 acres on the Siskiyou National Forest for the three most common woodpecker species inhabiting SHRUB/OPEN SAPLING-POLE HABITATS, *plus* the acorn woodpecker.

Snag Diameter Class (in, dbh)	Snag Decay Stage		Total Snags by Diameter Class
	Hard, Stage 2-3	Soft, Stage 4-5	
11+	–	–	–
15+	7 Red-breasted Sapsucker	79 Hairy Woodpecker	86
17+	120 Acorn Woodpecker	29 Northern Flicker	149
25+	–	–	–
Total Snags	127	108	235

Table IV-10 Minimum tree diameters (inches DBH) and heights (feet) acceptable to various woodpecker species (Brown 1985)

Species	DBH (Inches)	Height (Feet)
Downy woodpecker	11	10
Red-breasted woodpecker	15	20
White-headed woodpecker	15	10
Acorn woodpecker	17	30
Northern flicker	17	10
Pileated woodpecker	25	40

DEAD AND DOWN WOODY MATERIAL

4-13b Wildlife habitat requirements for dead and down woody material correspond closely to needs identified for long-term productivity in terrestrial and aquatic ecosystems. See Standard and Guideline 7-8, Large Woody Material, and Standard and Guideline 7-10, Riparian Ecosystems.

Charring of down material should be minimized in prescribed burning where practicable. The suitability of logs as vertebrate and invertebrate habitat is reduced by charring.

Project planners should consider leaving live or dead standing trees as substitutes when Class I and II logs are not available on the ground.

CLIFFS, CAVES, AND TALUS HABITAT

4-14 **Individual Projects should be designed to protect the value of cliffs, caves, and talus habitat for wildlife. Rock quarries should be located at sites exhibiting the least desirable characteristics as wildlife habitat.** These standards refer to sites not included in Management Area 9.

HARDWOOD HABITAT

4-15 Hardwood and mixed hardwood with conifer stands on the Siskiyou make a substantial contribution to biological diversity. **The wildlife habitat values of hardwood and mixed stands should be considered as part of the environmental analysis for individual harvest or stand conversion projects. The same standards governing unit size and placement of conifer harvest sites should be applied to hardwood stands considered for harvest or conversion (see Standard and Guideline 6-9).**

The habitat values of hardwood stands to wildlife are just beginning to be understood, and the importance and partition of the acorn crop among wildlife consumers on the Siskiyou has yet to be determined (Werschkul and Swisher 1983). Not more than 7,500 acres would be harvested or converted during the next decade. The interrelationship of wildlife and hardwood stands has been identified as a research need (Chapter II). A few specific hardwood stands are allocated as special wildlife habitat under Management Area 9.

MEADOWS

4-16 **Small openings should be maintained, and may be created, as a forest habitat component (created openings may be incorporated into regeneration and thinning prescriptions).** Small meadows and openings less than one acre in size contribute to vegetative diversity, and are important to many wildlife species; they provide small forage sites for deer and elk within optimal thermal cover areas, and are especially important during severe weather (Brown 1985) **In many**

cases, a buffer of shrub or tree vegetation may need to be preserved on the perimeter of the opening; this need will be addressed during the environmental analysis process for specific management activities Meadows one acre or larger are addressed in Management Area 9

MISCELLANEOUS WILDLIFE SITES

4-17 During the life of this Forest Plan, habitat sites will be found which have special value for wildlife or botanical resources and are not otherwise addressed in the Standards and Guidelines (see Management Area 9). **Management of these sites should be dealt with individually as part of the environmental analysis process for specific management activities. Each Ranger District shall maintain a list of sites to be considered for allocation as Special Wildlife Sites at the next revision of the Forest Plan.**

PLANT COLLECTING (INCLUDING SENSITIVE SPECIES)

4-18 Federally listed Threatened and Endangered species are protected by the Federal Endangered Species Act (1982 amendments). The Forest Service *cannot* issue permits to collect these species for any purpose. This authority is granted only to the U.S. Fish and Wildlife Service

Collecting for scientific or educational purposes (FSM 2673.2). **The Forest Supervisor may issue permits to collect Sensitive or Restricted plants or plant parts for legitimate scientific or educational purposes.** Such collection must not jeopardize the continued vigor or existence of a plant population. **Sensitive or Restricted plants shall not be collected for commercial or personal use.**

Collecting of plants or plant parts in Management Areas 1 through 4 (Wilderness, Wild River, Research Natural Area, and Botanical) shall not be allowed except by permit issued by the Forest Supervisor for scientific or educational purposes.

Commercial Collecting (FSM 2431 42, including R-6 Supplement 383 and 390). Collecting of plants or plant parts for any commercial purpose requires a commercial use permit issued by the Ranger District where the collecting activity is proposed. **District Rangers shall issue or deny commercial permits after review of a proposal presented by the collecting party. When evaluating applications for commercial collecting permits, consideration should be given to the impacts on all forest resources, including biological diversity.**

General Botanical Collections. **Botanical collection permits may be issued by the Forest Supervisor to authorize collection of species other than endangered, threatened, sensitive, or restricted (FSM 2673.2(3), R-6 Supplement 41). Miscellaneous forest products, including some plant materials, may generally be collected for personal use without a permit.** For specific rules, see FSM 2467.16, including R-6 Supplement 380.

Restricted plants are determined by the Forest Supervisor to be in jeopardy due to their limited abundance, fragile habitat or potential for over collection Restricted plants include such plants as orchids and insectivorous species. Current lists of Threatened, Endangered, Sensitive and Restricted plants are available at the Forest Supervisor's office.

The above Standards and Guidelines do *not* apply to the harvest of trees for timber and firewood

RANGE

5-1 **Where opportunities exist, the range resource may be managed for range benefits. Range management practices are generally compatible with wildlife needs, but where conflicts occur, management shall favor protection of riparian areas and should favor deer and elk forage needs and cover requirements.**

Opportunities exist for transitory range within timber harvest units **Livestock use of recently harvested areas should not be allowed to impair seedling survival or growth. Livestock should not be permitted to graze in developed recreation areas.**

Allotment plans, including transitory range, shall be prepared in coordination with other resources as directed by FSM 2210. In allotment plans, livestock use should be evaluated for its effect on biological diversity, specifically sensitive plants. Coordination should be done during the planning of any resource management activity. Allotment plans shall contain utilization standards designed to maintain healthy riparian plant communities for the protection of soils, water quality, fish, and wildlife habitats.

Transportation systems in range allotments should be designed and constructed with consideration of livestock objectives and established grazing systems.

Improvement and development of the range resource should be consistent with public needs and environmental requirements.

Maximum acceptable annual utilization levels for meadow sites are included in Special Wildlife Sites (Management Area 9).

TIMBER MANAGEMENT

6-1 **The following timber management practices may apply on all lands selected for timber production, including reduced-yield areas, according to the land allocation:**

1. **Site Preparation, including the treatment of the residual logging slash, using all site-appropriate methods.**
2. **Genetic improvement of tree stock.**
3. **Reforestation using genetically improved seedlings as rapidly as they become available consistent with the need to manage biological and genetic diversity.**
4. **Animal damage control using all site-appropriate methods.**
5. **Release using site-appropriate methods as determined through separate environmental analyses (Regional FEIS) and subsequent tiered analyses, or as superseded by future NEPA documents.**
6. **Precommercial thinning.**
7. **Commercial thinning as defined under Standards and Guidelines for individual management areas.**
8. **Fertilization in managed plantations and natural stands.**
9. **Salvage**
10. **Final Harvest**

6-2 **Harvest activities shall occur only on lands classified as suited for timber production, except timber cutting may occur on other lands for the following purposes:**

1. **To remove timber from road locations needed for the harvest of timber from selected suitable lands or for other management purposes.**

2 **Construction or protection of capital improvements such as campgrounds, buildings, fuelbreaks, and dispersed recreation sites; or to accomplish projects designed to enhance other resource values.**
3. **Removal of hazards to human life and health.**
4. **Removal of timber killed by catastrophic events, such as fire, windthrow, drought, insects or disease (36 CFR 219.27 (c)(1)). The decision to salvage-harvest an area shall be based on an analysis of existing conditions following the disturbance, and shall include consideration of the economic, social and environmental consequences.**
5 **Where small inclusions in harvest units that otherwise are suitable will allow use of more logical management units and road locations resulting in less resource impacts.** Reduced impacts might be achieved by reducing landing or road construction, by enabling construction away from unstable soil, or by reducing soil and vegetation disturbance caused by dragging logs.
6 **As part of a research study to test the feasibility of silvicultural and harvesting practices that could be successful on these lands.** This could provide useful information for the 10-year re-evaluation of these lands
7 **In the case of Separate Suitability Component (SSC) lands, timber harvesting may occur where a site-specific analysis shows timber management to be economically efficient and consistent with established goals and objectives.** This recognizes the variability in this land class and provides the flexibility to take advantage of opportunities such as overstory removal harvests that require low investment.

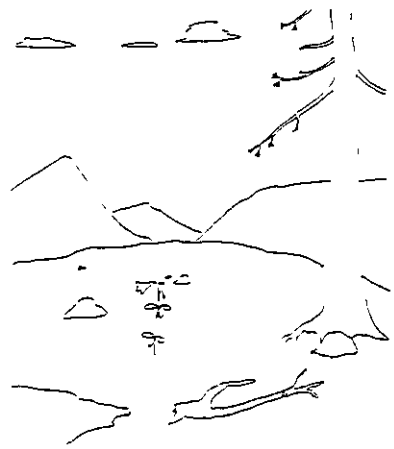
6-3 **If field analysis during project planning identifies a need to correct the inventory of suitable lands, the following process shall be followed:**

1. **Boundary adjustments to refine mapping lines shall be documented in the project records and maintained in the Ranger District resource inventory.**
2 **Where changes in classification are indicated, the analysis and rationale for the needed change shall be documented and retained at the Ranger District as an interim record until monitoring, as defined in the Monitoring Plan, indicates the need to consider adjustment at the Forest level.**

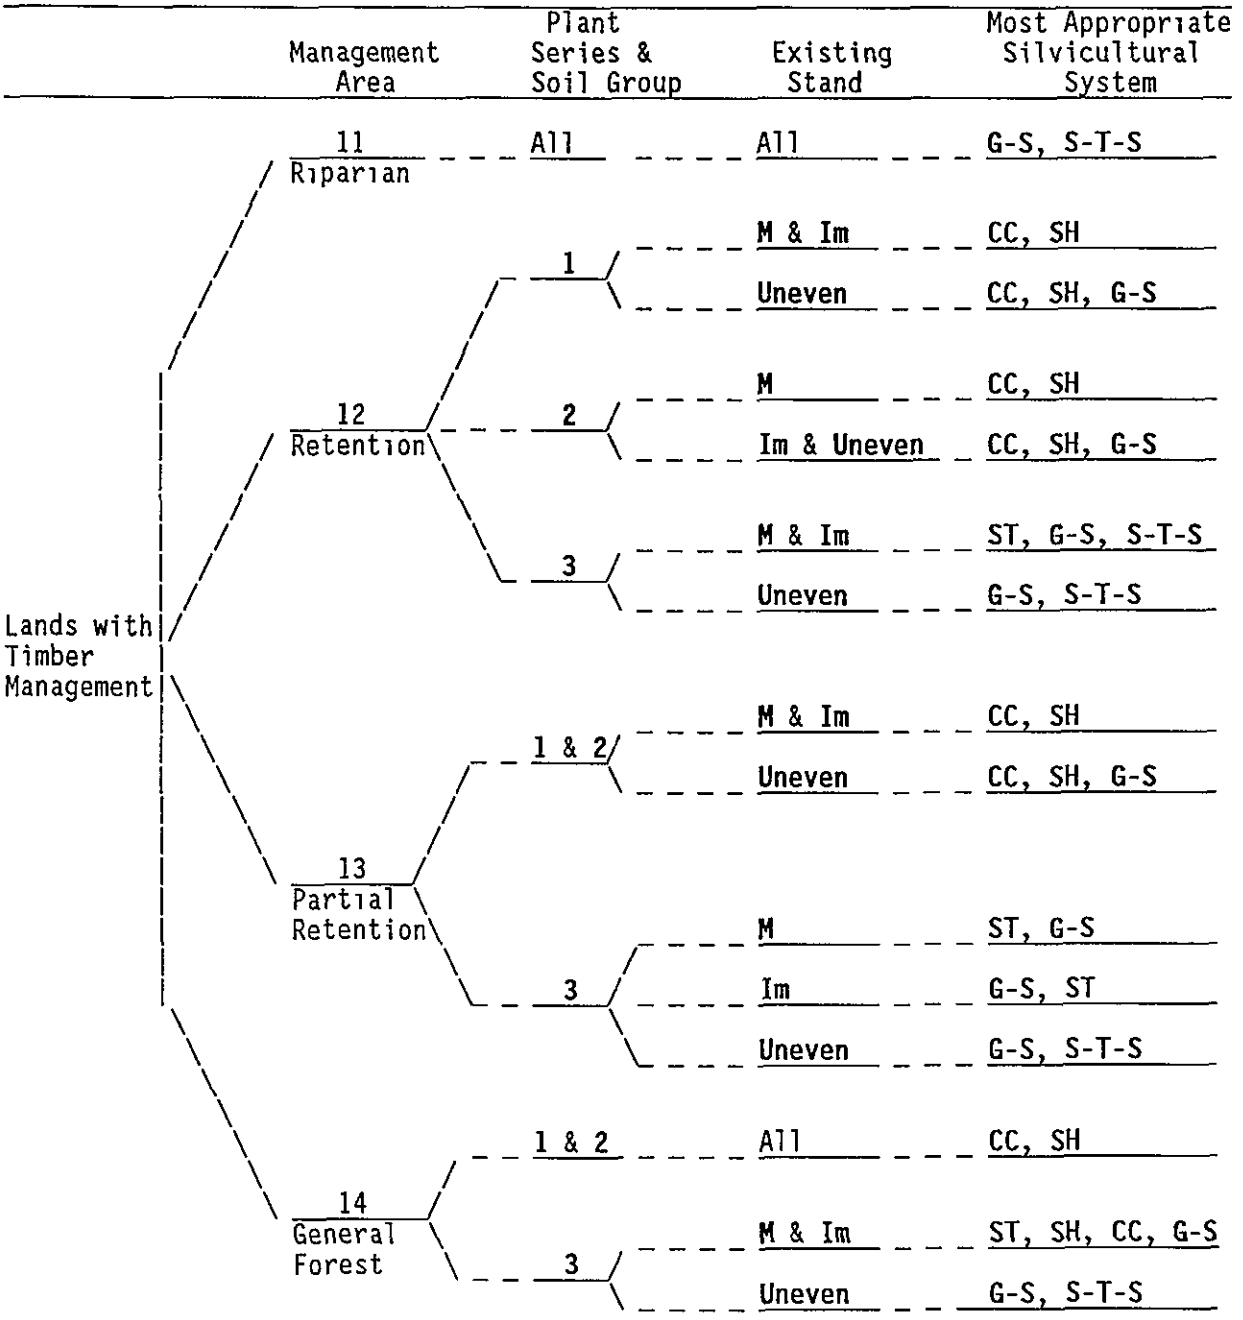
The inventory of suitable lands is reviewed periodically. The review will focus on documentation of changes in classification, consistency of evaluation of suitability, and new information or technology that may affect the capability to manage the land.

6-4 **An environmental analysis shall be conducted for areas considered for harvest according to the procedures found in Forest Service Manual 1950, Environmental Policies and Procedures. An economic analysis shall be included when areas have alternatives with substantial roading and harvesting, and choices that maximize net public benefits are not obvious from environmental and resource considerations.** Present Net Value or Least Cost are appropriate measures of economic efficiency to use for this analysis. Appropriate analytical techniques are described in the Timber Sale Economic Analysis Guide (Kramer and Owen, n d.).

6-5 **Timber stands shall not be scheduled for final harvest before stand age has reached or surpassed the age of 95 percent of culmination of mean annual increment in cubic feet. Exceptions may be made where special resource considerations require earlier harvest, or where small inclusions of young stands in harvest units that otherwise meet this requirement will result in more logical management units allowing greater efficiency or less resource impacts. The age of 95 percent of culmination shall be taken from the managed yield table used in the planning analysis (Craig 1984) for the appropriate prescription and intensity unless site-specific yield projections are made as part of the silvicultural prescription; in which case the more specific data may be used for this determination.**



6-6 **The final selection of harvest cutting method shall be made for specific areas in silvicultural prescriptions or environmental assessments. Clearcut, shelterwood, seed-tree, group selection, or single-tree selection may each be used on specific sites where appropriate for the combination of site conditions and management objectives. The method selected should best meet the resource and vegetation management objectives of the management area, including objectives for biological diversity and long-term site productivity.** The systems that are generally most appropriate for given conditions are displayed in Figure IV-2. (Discussion of the selection of systems may be found in Appendix G of the FEIS) The final selection of harvest methods will be based on site-specific environmental analysis. Even-aged management with regeneration harvests by clearcutting, or shelterwood will be the most commonly used methods Clearcutting will only be used where it is the optimum method Uneven-aged management may be used on specific sites where analysis indicates it will meet resource objectives Examples of where this could be appropriate are: to meet objectives for streamside, visual management, or biological diversity to provide for slope stability, or for timber management where the natural stand has an uneven-aged structure.



6-7 **Timber harvesting shall be done in such a way that there is assurance that each area can be adequately restocked within 5 years after final harvest (36 CFR 219.27(c)(3)).** Five years after final harvest means 5 years after either clearcutting, final overstory removal, seed tree removal, or selection cutting. **Exceptions may be made for specific sites where environmental analysis and silvicultural prescription indicate a restocking period of more than 5 years would produce a more desirable combination of net public benefits.** This does not allow harvest of sites where regeneration could not be achieved within 5 years if that were the objective

Competing vegetation should be controlled where there is no assurance that timber harvest areas can be reforested within a 5-year period without vegetation control.

Where heavy animal damage may prevent reforestation of timber harvest areas within 5 years, animal control or methods of protecting plantations from unacceptable damage should be used.

6-8 **Appropriate species mix for regeneration shall be included in the silvicultural prescription prepared during the environmental analysis for harvesting the area. The prescription should consider natural regeneration potential and advanced regeneration as part of this analysis. Consideration should be given to regenerating and maintaining minor species, where appropriate for the site, as viable components of future stands, and for enhancement of vegetative diversity.** Special consideration will be made for Port-Orford-cedar, as outlined under Integrated Pest Management

Symbols Used: SH = Shelterwood, CC = Clearcut, ST = Seed-tree, G-S = Group Selection, Uneven = Uneven-aged, S-T-S = Single-tree Selection, M = Mature Stand, Im = Immature Stand

Plant Series and Soil Groups: 1 = High Vegetative Competition - Balanced Soils
2 = Moderate Competition - Balanced Soils
3 = Lower Competition - Ultrabasic Soils

Figure IV-2 Silvicultural Systems Analysis

6-9 **Forest openings created by even-aged silviculture shall not exceed 60 acres.** (This is a maximum, the average may well be less than 30 acres.) **The openings should be shaped or blended with the natural terrain to achieve aesthetic, biological diversity, and wildlife habitat objectives to the extent practicable. Exceptions are permitted for catastrophic events (such as fires, windstorms, or insect and disease attacks) or on an individual basis after a 60-day public notice period and review by the Regional Forester. In addition, the 60-acre limit may be exceeded by as much as 50 percent without necessitating review by the Regional Forester *or a 60-day public notice when exceeding the limit will produce a more desirable* combination of net public benefits and when any one of the following criteria is met:**

1 **When a larger created opening will enable the use of an economically feasible logging system that will lessen the disturbance to soil, water, fish, riparian resources, or residual vegetation.** Such lessening might be achieved by reducing landing or road construction, by enabling construction away from unstable soil, or by reducing soil and vegetation disturbance caused by dragging logs
2 **When created openings meeting this size limit cannot be centered around groups of trees infected with dwarf mistletoe or root disease and therefore need to be expanded *to include these trees in order to avoid infection of susceptible adjacent conifers.***
3 **When VQO's require openings to be shaped and blended to fit the landform.**
4. **When larger openings are needed to achieve regeneration objectives in harvest areas being cut by the shelterwood method and when destruction of the newly-created stand would occur as a result of delayed removal of shelter trees. This exception applies only to existing shelterwood units and to shelterwood units under contract prior to approval of the Forest Plan. Newly-planned shelterwood units should not exceed the opening size limitations.**

6-10 **The following limits on scheduling and distribution shall be met by all regeneration harvest *activities. Exceptions are permitted for catastrophic events (such as fires, windstorms, or* insect and disease attacks), or where more stringent standards are required for specific resource values (visual, wildlife, riparian) as specified in the applicable management area standards and guidelines.** Contiguous harvest units are not precluded, but will be considered as a single opening subject to the standards defined for created openings

1. **Created openings shall be separated by areas not classed as a created opening. The areas between created openings shall contain one or more logical harvest units.**
2. **A harvested area of commercial forest shall no longer be considered a created opening when stocking surveys carried out in accordance with instructions in the Reforestation Handbook (FSH 2409.26b R6) indicate that crop trees are at prescribed stocking levels and are at or above 4-1/2 feet in height and free to grow.** See Management Prescriptions for Management areas 12 and 13 for standards for visually perceived created openings.

Crop trees per acre (TPA) required to meet minimum acceptable stocking levels are indicated below. (These are not objectives and would not provide sufficient stocking to attain timber production goals if a large proportion of acres are carried at these minimum levels.)

Type	Minimum TPA	Minimum Spacing Between Crop Trees (Feet)
DF Site Class III and Better	150	6
All Others	125	6

6-11 Minimum utilization standards to be used in timber harvest operations for the next decade are specific to. mature and young-growth (commercial thinning) stands **The standards in the following table apply where practicable.** Where individual market areas or specific products present opportunities for utilizing a higher proportion of the tree, the following standards could be exceeded. **In some cases, other resource objectives may require leaving a higher proportion of woody material on site.** These utilization standards do not apply to materials left to meet fish and wildlife and soil management objectives, or to unmerchantable species

Stand Type	Minimum DBH (Inch)	Minimum Top DIB (Inch)
Mature	9	6
Young-growth (Commercial Thin)	7	4

6-12 **Maximum utilization of products created during timber harvesting and other management activities should be encouraged to the extent practicable and consistent with all resource objectives including objectives for biological diversity. Utilization of residue may be encouraged by the following:**

1. **The placement of nonmerchantable material in piles at designated locations both on or off the Forest for woodcutters, chip manufacturers, energy conversions, or other users.**
2. **The sale of minor products, such as commercial wood contracts, chip logs, etc., and the issuance of firewood permits.**

6-13 **Lands classified as suitable for timber production and currently not stocked with conifers may be programmed for conversion to site-appropriate conifer species where a site-specific environmental analysis considering the effects on other resources, including wildlife habitat and vegetative diversity, shows the project to be cost-effective and without significant adverse impacts that cannot be mitigated. Such projects are also be subject to the following limitations:**

1. **Not more than 7,500 acres should be programmed for treatment during the next decade.**
2. **Conversion of hardwood stands should only be done where it can be accomplished through commercial harvest.** (Stands containing substantial potentially usable volume will not be slashed and burned.)
3. **Management activities in hardwood stands shall comply with all standards and guidelines applicable to timber management activities, e.g., unit size, dispersion, etc.**

6-14 **Stand treatment in managed commercial forests shall provide for species diversity. Tree species used in planting harvest units should be based on the potential of the site as indicated by plant associations. Thinning, commercial and precommercial, should retain a diversity of species based on site potential. Vegetation management activities and hardwood management prescriptions should allow for all natural species to function. None should be eliminated from the site.**

SOIL AND WATER

7-1 **Land management activities shall be planned and conducted to maintain soil productivity and stability.**

Forest management activities shall meet or exceed the stated objectives in the Organic Administration Act of 1897, the Multiple Use-Sustained Yield Act of 1960, NFMA of 1976, FSM 2550, FSM 2520 R-6 Supplement 50, and FSM 2550.3 Siskiyou Supplement 2. The few wetlands and floodplains that exist on the Forest shall be managed according to Executive Order 11988, Floodplain Management, and Executive Order 11990, Protection of Wetlands.

DETRIMENTAL SOIL CONDITIONS

7-2 Detrimental soil conditions include compaction, displacement, puddling, and severely burned soil conditions **The total area of detrimental soil conditions should not exceed 15 percent of the total acreage within the activity area, including roads and landings.**

Detrimental conditions occur when one or more of the following criteria are exceeded: (See FSM 2520, R-6 Supplement 50, for a complete definition of detrimental conditions)

Compaction. Leave a minimum of 85 percent of an activity area in a condition of acceptable productivity, measured by an increase in soil bulk density of 15 percent or more and by a reduction of macro-pore space of 50 percent over the undisturbed soil

Puddling. Leave a minimum of 85 percent of an activity area in a non-puddled condition Soil puddling is a physical change in soil properties due to shearing forces that destroy soil structure and reduce porosity

Displacement Leave a minimum of 85 percent of an activity area unaffected by detrimental soil displacement Detrimental displacement is the removal of more than 50 percent of the topsoil or humus enriched A1 or AC horizons from an area of 100 square feet or more which is at least 5 feet in width.

Severely burned. Leave a minimum of 85 percent of the soils of an activity area unaffected by severely burned condition. Soils are considered to be severely burned when the top layer of mineral soil has been been significantly changed in color, usually to red, and the next 1/2 inch blackened from organic matter charring by heat conducted through the top layer.

7-3 **Area used as temporary roads shall be rehabilitated to productive condition for timber or wildlife. Temporary roads left from past activities should be evaluated as they are encountered during project environmental analysis. These areas should be rehabilitated where practicable.**

SOIL EROSION

7-4 **Management activities, except permanent facilities, shall be planned to retain the soil duff and litter. Mineral soil exposure (loss of duff and litter) should not exceed the following limits (*Boyer and Dell 1980*):**

1. **Forty percent mineral soil exposed on soils classed low-to-moderate erosion hazard, as defined in the Siskiyou National Forest Soil Resource Inventory (Meyer and Amaranthus 1979).**

2. **Thirty percent exposure on high erosion hazard soils.**
3. **Fifteen percent exposure on very high erosion hazard soils.**

7-5 **Permanent facilities (roads and landings) shall be managed to expose a minimum of mineral soil.**

Cut and fill slopes should be protected from erosion. Plan for natural vegetation to stabilize cut and fill slopes where practicable.

Landings and temporary roads should be restored and placed in condition to minimize the erosion potential.

Drainage for all roads and landings should be developed and maintained.

7-6 **Where the above standards for soil erosion cannot be met because of specific site conditions, appropriate mitigation measures shall be developed in the project environmental analysis, documented in the project record, and implemented prior to fall rains.**

MASS MOVEMENT

7-7 **The scheduling of timber harvest and road building shall consider the increased potential for mass movement. When management activities would increase potential for mass movements, an alternative prescription should be developed and evaluated considering the environmental impacts and management costs over the life cycle of the project. Qualitative landslide hazard maps and risk assessment should be used for planning of timber harvest activities.**

LARGE WOODY MATERIAL

7-8 **Management activities shall be planned to maintain enough large woody material (dead and down) to maintain a healthy forest ecosystem. Site-specific needs shall be considered in environmental analyses. Five to twenty pieces of large woody material per acre should remain on each site where management activities take place. Material should be from a range of decomposition classes; each piece should be at least 20 inches in diameter at the large end and contain at least 40 cubic feet volume.** Considerations for achieving desired results are:

1. Leave all class III, IV, and V logs
2. 10-20% of the pieces should be class I or II (most special and utility culls meet the definition of decomposition classes I or II)
3. Conifer logs are preferable, but where unavailable, hardwood logs can be substituted
4. 20 inch diameter or larger pieces are preferred; if not available, leave pieces as close to 20 inches diameter as possible.

SOIL AND WATER RESOURCE IMPROVEMENTS

7-9 **Programs of work shall be initiated to reduce sedimentation, to improve water quality and to stabilize peak flows. High priority projects should be those that increase channel stability, improve effective stream shading, reduce sedimentation and stabilize areas of mass failure.** Annual adjustments in project priority will reflect targets, available funding, severity of problem, site conditions, benefits, values at risk, and effectiveness of treatment control.

RIPARIAN ECOSYSTEMS

7-10 **Riparian habitat management shall emphasize the role of riparian ecosystems in landscape ecology, vegetative diversity, slope and channel stability, fisheries, wildlife, and water quality.**

No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses, or deposits of sediment shall be permitted within riparian areas which seriously and adversely affect water conditions or fish habitat (36 CFR 219.27(e)).

Present and future sources of large woody material should be provided. Existing instream material should be maintained or enhanced.

Management activities shall be planned and conducted to limit impacts on streams and water quality. Standards and Guidelines for the management of Class I, II, and III streams are found under Management Area 11. Additional direction is found in Siskiyou Riparian Ecosystems Management Policy (FSM 2520 3 Siskiyou Supplement 1).

7-11 **Class IV streams shall be managed to minimize adverse downstream impacts on Class I, II, and III streams that could result from movement of soil, debris, or chemicals into perennial stream courses:**

1. **The bank and channel stability of Class IV stream courses should be protected. The minimum area of consideration should be 25 feet horizontal distance on each side of the stream channel.** Stream course protection needs will often be met by retaining selected hardwoods or conifer trees directly adjacent to the stream channels
2. **Burning prescriptions should plan to protect streamside vegetation and maintain stream channel stability.** In most instances, minimal or no burning would be prescribed within 25 feet horizontal distance on either side of stream channels
3. **Activity created debris should be cleared from stream channels except for large woody material keyed into stream banks that contribute to water quality, stream channel and bank stability, and fish habitat. Clearing should be accomplished prior to fall rains.**
4. **Efforts should be made to yard away from stream channels. Logs yarded over Class IV streams should be fully suspended where practicable.**

Where the above measures cannot be implemented, appropriate mitigation measures shall be developed in the project environmental analysis, documented in the project record, and implemented prior to fall rains.

7-12 **Where domestic water uses occur within small watersheds subject to management activity, an indepth field evaluation and determination of water quality protection needs should accompany any reclassification of stream Classes I-IV for each tributary. Management prescriptions for the riparian corridor should be tied to site-specific conditions relative to the type and extent of proposed activity and expected impact on water quality.**

INSTREAM FLOW

7-13 **Instream flow on National Forest System Lands should be protected through environmental analysis of proposed water uses, diversions, transmission applications, and renewal of permits. Protection of instream flow needs may be achieved through filing protests with states where applications are made that adversely affect National Forest resources,**

asserting claims for this water under Federal or State laws where applicable, inserting protection measures into special use permits, or reaching formal agreements over use. Purchase of water rights and impoundments are other means for reducing these impacts

BEST MANAGEMENT PRACTICES

7-14 **State requirements shall be complied with in accordance with the Clean Water Act for protection of waters of the State of Oregon (Oregon Administrative Rules, Chapter 340-41) and the State of California (Porter-Cologne Water Quality Control Act, Division 7) through planning, application, and monitoring of Best Management Practices (BMP's) in conformance with the Clean Water Act, regulations, and Federal guidance issued thereto.**

In cooperation with the States of Oregon and California, the Forest shall use the following process:

1. **Select and design BMP's based on site-specific conditions, technical, economic, and institutional feasibility, and the water quality standards for those waters potentially impacted.**
2. **Implement and enforce BMP's.**
3. **Monitor to ensure that practices are correctly applied as designed.**
4. **Monitor to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards.**
5. **Evaluate monitoring results and mitigate where necessary to minimize impacts from activities where BMP's do not perform as expected.**
6. **Adjust BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluate the appropriateness of water quality criteria for reasonably assuring protection of beneficial uses. Consider recommending adjustment of water quality standards.**

The process agreed to in the following Memoranda of Understanding (MOU) shall be used to implement the State Water Quality Management Plan on lands administered by the USDA Forest Service:

1. **The Oregon Department of Environmental Quality and U.S. Department of Agriculture, Forest Service (February 12, 1979 and December 7, 1982), and "Attachments A and B" referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest December, 1978, and Best Management Practices for Range and Grazing Activities on Federal Lands, respectively).**
2. **The State Water Resources Control Board, State of California, and U.S. Department of Agriculture Forest Service, Pacific Southwest Region, 1981.**

For a more complete explanation, refer to Appendix F, "Best Management Practices "

Individual, general Best Management Practices are described in *General Water Quality Best Management Practices*, Pacific Northwest Region, November, 1988. This provides guidance but is not a direction document. Also included in this document is a description of the process, and limitations and use of these BMPs. Each BMP listed includes the Title, Objectives, Explanation, Implementation, and Responsibility, and Monitoring. Evaluations of ability to implement and estimated effectiveness are made at the project level.

Not all of the general BMPs listed will normally apply to a given project, and there may be specific BMPs which are not represented by a general BMP in this document.

The sensitivity and significance of the project determines whether the site-specific BMP prescriptions are documented in an EA, EIS, sale plan, project plan, or in analysis files

Best Management Practices relating to protection of water quality shall be followed for any chemical application projects. In the event of an accidental spill of hazardous materials, procedures shall be followed as set forth in the Oil and Hazardous Substances Pollution Contingency Plan (FSM 7443).

7-15 **Management activities, particularly road building and timber harvest, shall be scheduled to minimize long-term detrimental changes in watershed conditions.** Spatial distribution and timing of activities will be the principle factors used to reduce unacceptable cumulative impacts. Harvest will vary between planning basins depending upon each basin's unique physical environment.

Project planning shall assess the potential for adverse effects beyond the immediate activity site. The watersheds identified on the Watershed Analysis Area (WAA) Maps (on file) should be the primary unit for this assessment. When more than five percent of a WAA is proposed to be part of the road system (including temporary roads), a detailed analysis should be made and safeguards shall be taken to ensure that the watershed's condition will not be irreversibly and detrimentally altered. If more than 20 percent of a WAA is proposed to be harvested in a single decade, a more detailed evaluation shall demonstrate that watershed conditions will not be impaired.

AIR QUALITY

8-1 **Management activities shall be planned to maintain air quality at a level adequate for the protection and use of the National Forest resources, and meet or exceed applicable Federal and State standards and regulations (36 CFR 219.27(a)(12)).**

The Forest shall coordinate with the appropriate air quality regulatory agencies. Prescribed burning operations shall comply with the procedures identified in the Smoke Management Operations Plan (Oregon State Forestry Directive 1-4-1-601) and Open Burning Regulations for California North Coast Air Basin.

Reasonable progress shall be demonstrated in reducing total suspended particulate (TSP) emissions. Projected TSP should not exceed 7,300 tons on an annual basis. TSP emissions associated with wildfires and wilderness prescribed fire from unplanned ignitions will not be included in the annual total.

The best available predictive methods and models and the most cost efficient technology should be utilized to minimize the impact of prescribed burning on smoke sensitive areas and designated Federal Class I areas. Smoke from prescribed fires initiated from lightning caused ignitions occurring inside wilderness is considered a natural component of the ecosystem and does not constitute a violation of the Class I area ambient air quality standards. (The original portion of the Kalmiopsis is currently the only Class I airshed on the Forest Studies are underway to consider classification of other wilderness area on the Forest.)

The adherence to sound smoke management principles is the key element in mitigating the impacts of smoke on air quality and Air Quality Related Values. Smoke management approaches the concept of maintaining air quality by avoiding unacceptable combinations of concentration, duration and placement of smoke (Cramer 1974); or, more simply stated - risk avoidance. Pierovich (1976) states that the central principle of smoke management is to avoid overloading natural clearance mechanisms--both pulmonary and environmental

Three basic strategies may be used to manage prescribed fire smoke: reduction, dilution and avoidance.

The strategy of *reduction* focuses on reducing the amount of smoke (particulates) produced by increasing the efficiency of burning and reducing the amount of fuel consumed by fire. This may be accomplished by such methods as:

1. Increasing wood utilization standards and the continued use of YUM and PUM specifications (yarding or piling of unmerchantable material), consistent with the objectives for large woody material, in timber sale contracts.
2. Specifying logging methods that reduce timber breakage and minimize creation of unmerchantable debris (e g directional felling, tree lining)
3. Selection of fuel moisture parameters which reduce the total consumption of fuel and reduce the smoldering phase of combustion.
4. Selection of ignition (fire starting) methods and techniques which lower the TSP production.
5 Utilizing alternative slash treatment methods, such as chipping or burying, in lieu of prescribed fire.
6 Requiring prompt and vigorous mop-up (extinguishing of remnant traces of fire, to prevent its recurrence).
7 Increasing the air supply to slash piles and burn bays (specially created areas along roads for accumulating and treating slash).
8. Changing the specification of a "utility log".

The *dilution* or dispersion strategy may also be utilized to mitigate air quality impacts. This strategy is governed by weather-related processes The capacity of these processes determines the amount of fuels that may be consumed, as well as the time, location and amount of particulates that could be released into the atmosphere. Specific mitigation measures that could be utilized in respect to the dispersion strategy include:

1 The scheduling of burns over a period of several days, rather than all on a single day.
2 Igniting the units during unstable atmospheric conditions.
3. Limiting burning when transport wind speeds are less than nine miles per hour and the morning mixing height is less than 1,500 feet above the burn site.
4. The selection of a combination of prescription parameters, i.e., fuel conditions, weather conditions and ignition techniques, that will generate an elevated plume that will mix well with the surrounding air mass.
5. Utilizing precipitating cloud systems as a "scrubber" to remove particulates and soluble gases.
6. Coordinating prescribed burning activities with adjacent agencies and land managers to reduce the total impact on local airsheds.

The third strategy, *avoidance*, may also be utilized in a Forest smoke management program. This strategy involves the selection of on-site and meteorological conditions that will either put the smoke up and over smoke-sensitive areas or away from these areas. Practices that may be followed include.

1. Burning when wind direction is favorable for avoiding smoke-sensitive areas.
2. The selection of a combination of burning prescription parameters that will generate an elevated plume that will exceed the ceiling of the smoke-sensitive area and then move quickly over or away from the area.
3 Using the combination of terrain elevation and inversion layers to prevent smoke from settling into sensitive areas.

Public understanding of prescribed fire and smoke management will be most helpful in assuring that any one of the strategies, or a combination of strategies, is successful Some measures that may be employed include:

1. Educating the public as to the objectives of prescribed fire use in the local environment, the steps taken to reduce smoke, and how smoke is managed
2. Informing the public before the ignition of potentially troublesome units

Coordination with other local agencies which also have responsibilities for the maintenance of air quality is a key in assuring a viable air quality maintenance program for the Forest. Some measures that may be taken to ensure overall air quality are:

1. Cooperating with local air pollution authorities in monitoring activities which may result in new or modified sources of emissions that may impact Class I areas
2 Completing review of any air quality studies that are part of new source permits.

LANDS

9-1 Acquisition of non-Federal land in the Winchuck Recreation Composite should be completed as parcels become available.

9-2 Acquisition of non-Federal land in the Agness townsite area should not be planned.

In the case of privately-owned parcels within the Wild and Scenic River system, the values which provided the basis for Congressional designation should be protected through cooperation with Josephine and Curry Counties in utilizing the zoning powers of the state and local governments. Where this is not practicable to protect these values, the Forest should seek to acquire conservation easements to accomplish this goal. Fee simple acquisition of private property would be a last resort to protect Wild and Scenic River values

Public interest in non-Federal land should be acquired by one of the following methods which best supports the Forest Plan:

Land exchange
Purchase
Donation
Partial interest - scenic easements, conservation easements, etc.

9-3 All non-Federal lands inside the Siskiyou National Forest boundary and a limited amount of National Forest Land shall be placed in one of the following landownership planning groups: (see Figure IV-3, Land Adjustment Map)

Group 1 - Congressional Direction

Definition - This group includes those lands where Congress has either directly or indirectly instructed the Forest Service to retain National Forest ownership and acquire non-Federal lands for a designated purpose. Land management allocations which could be associated with this group include Wilderness Areas and Wild and Scenic Rivers.

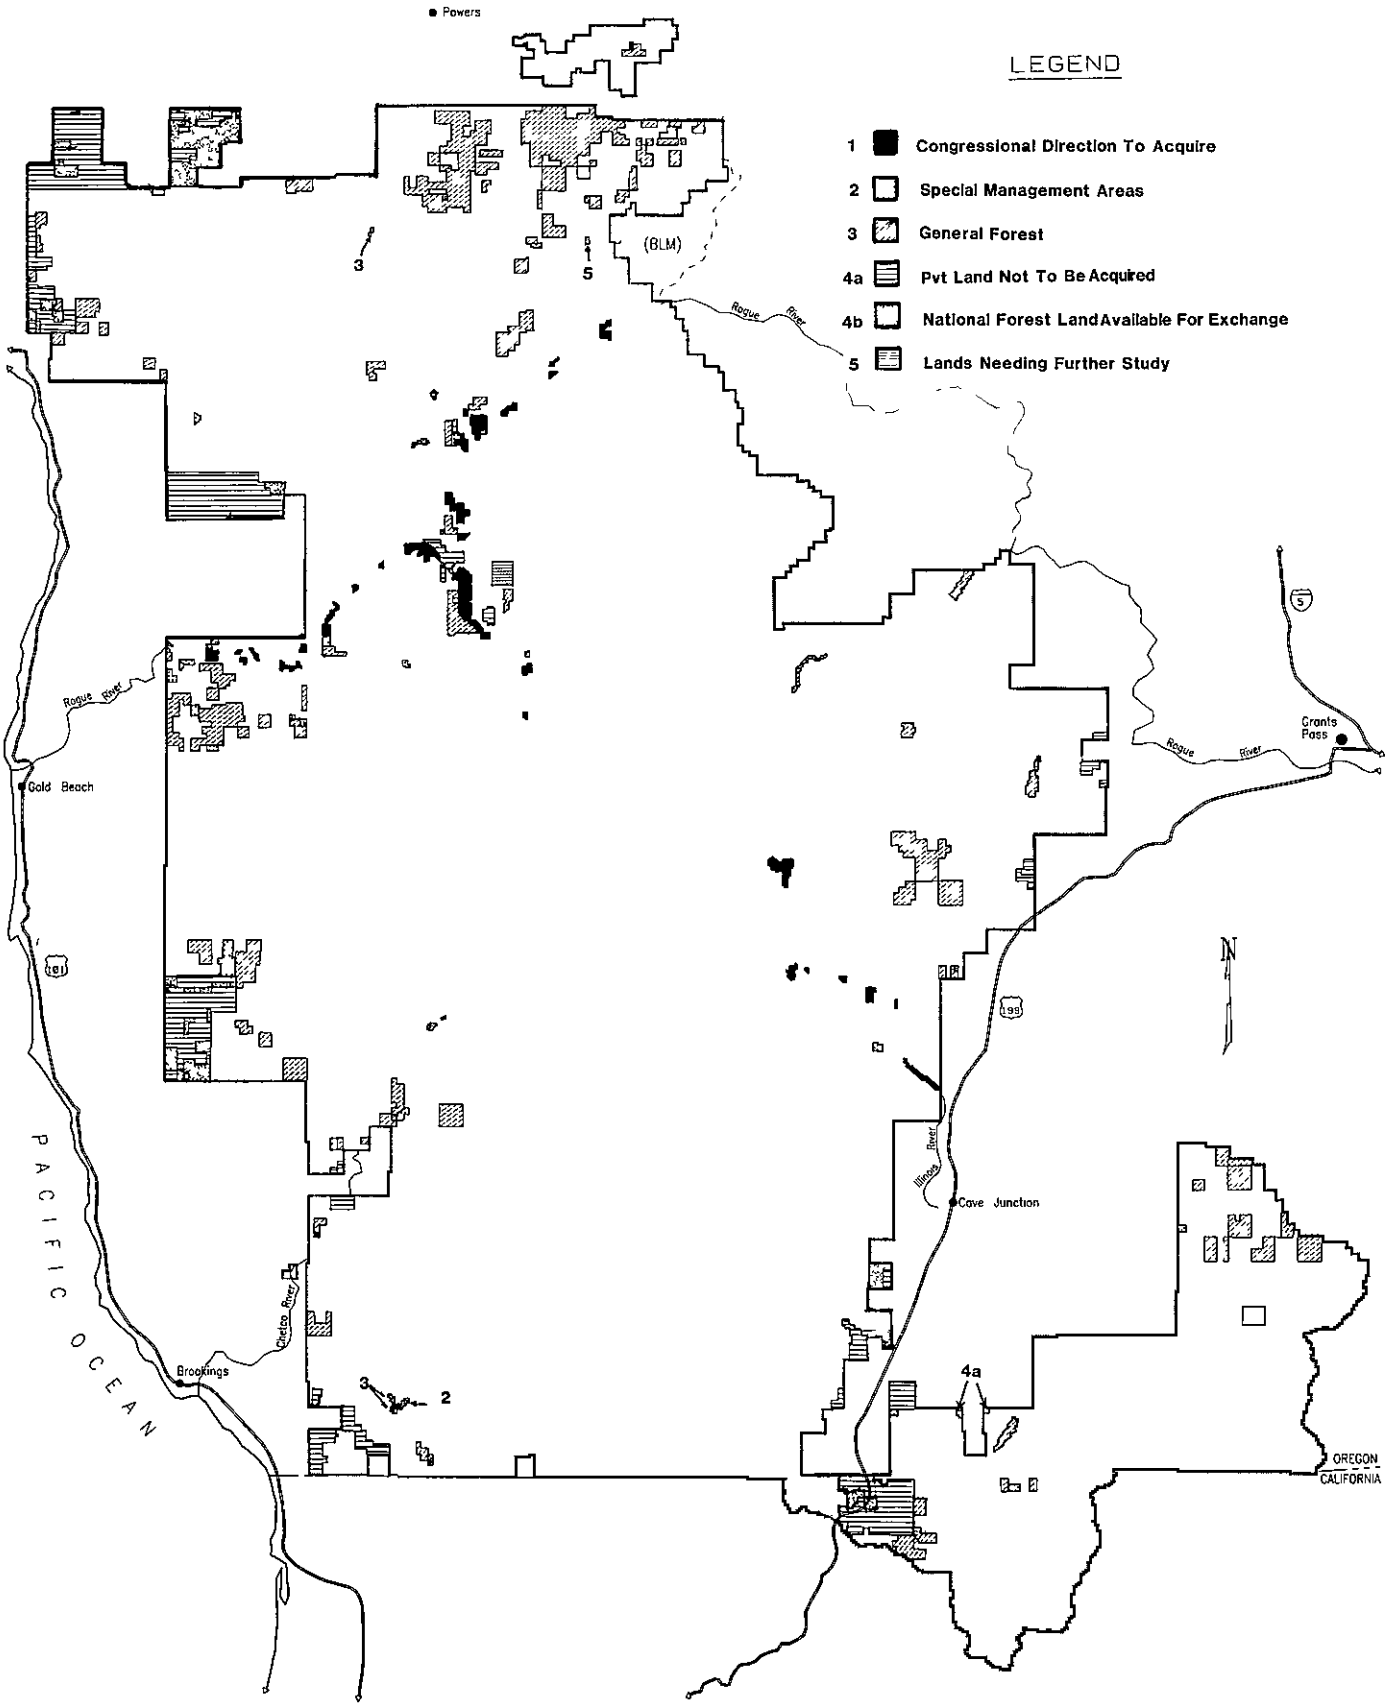


Figure IV-3. Land Adjustment Map

Group 2 - Special Management Areas

Definition - This group includes those lands where the Forest Service, through the land and resource management planning process, has recognized the need for a special kind of management or determined that National Forest ownership is necessary to meet objectives. The target is to retain National Forest ownership and acquire private land as the opportunity and/or need occurs. The special land management allocations which could be associated with this group include Retention Forest, Partial Retention Forest, Mature Old-Growth Habitat Areas, Supplemental Resource Areas, and Inventoried Wild and Scenic Rivers.

Group 3 - General Forest (private)

Definition - Land in this group would characteristically be in the General Forest allocation, where management direction emphasizes commodity production. These lands could be considered for land adjustment and usually would provide most of the land involved in exchange projects.

Group 4a - Private Land Not To Be Acquired

Definition - Land in this group is highly developed and not suited for National Forest purposes. These lands would not be acquired.

Group 4b - National Forest Land Available for Exchange

Definition - This group generally includes small, isolated tracts of National Forest Lands that are situated away from contiguous blocks of the National Forest, are costly to administer, and contain no special resource features. These areas could be parts of land management allocations associated with groups 2 and 3.

Group 5 - Lands Needing Further Study

Definition - This group includes situations where it is determined that more intensive study and planning are necessary before landownership decisions can be made. Non-Federal lands which could be acquired to meet essential National Forest management needs are assigned to following land adjustment priorities:

Priority 1 - Group 1 lands
Priority 2 - Group 2 lands
Priority 3 - Group 3 lands

The above guidelines should be followed; however, it may be necessary to deviate from this ranking to take advantage of opportunities as they arise. Proposals that emphasize consolidation of landownership should be favored.

9-4 **The objective of Special Use Management is to provide for the use and occupancy of the National Forest land when such use is consistent with Forest Management area goals and objectives. This use must be in the public interest and such that it cannot be served by reasonable development on private land. Special use applications should be evaluated through environmental analysis before the permit is issued, and appropriate site-specific requirements and mitigation measures developed for inclusion in the permit.**

Uses should not be authorized beyond a unit's ability to provide minimum administration.

RECREATION USES

9-5 **Existing special use permits for recreation residences shall be reviewed prior to scheduled termination (five in 1989 and one in 1990) to determine if:**

1. **The land will be needed for a higher public purpose within the following 20 years.**
2. **The land should continue to be occupied as a recreation residence for an additional 20 years.**
3. **The land could best serve the public need by being in private ownership.**

Applications for new recreation residences shall be denied.

All recreation special uses shall be compatible with the ROS classification of the area. Facilities shall be designed to meet the designated services to be provided. The number of permits for a specific use should be limited in order to create or maintain economical operations, reduce administrative costs, and provide high quality services. Prospective permittees must demonstrate that they have the financial resources to undertake the proposed venture or the permit shall not be issued.

Commercial rafting and guide permits on the Illinois and Rogue Rivers shall be issued in accordance with requirements of the management plans for these rivers.

Permits for commercial services may be issued in campgrounds or other developed sites when the public interest can best be served by such service.

NONRECREATION USES

9-6 **Existing Transportation Corridors, as identified in this Plan shall be managed by the agency which acquired the rights-of-way. The viewsheds of these corridors shall be managed as provided for in the individual land allocation which they are within.**

Future Transportation Corridor planning or subsequent interagency environmental analysis shall be in accordance with the requirements of exclusion areas, avoidance areas, sensitive areas and other areas as for future utility corridor planning.

The utilization of residual capacity in existing special use permit corridors and designated Utility Corridors shall be given the first priority for right-of-way requests by utilities. Wherever practicable, locate small utilities in other corridors or roadways. Install underground where practicable.

Existing utility corridors, as identified in this Plan, shall be managed in accordance with existing permits. An exception is the Happy Camp corridor, which should be relocated outside the view of Happy Camp Road when the opportunity arises. These corridors shall be considered a part of the Management Areas which they cross; analogous to roads, developed recreation sites and administrative sites. An attempt should be made to manage and protect other resources in accordance with the land allocations made for this Plan. Existing utility lines crossing the Recreation and Scenic portions of the Rogue River (these lines not designated as a utility corridor) should be relocated, eliminated or combined into fewer crossings, as opportunity permits.

Additional corridors which may be needed by major utilities shall be designated through an interagency environmental analysis following procedures set forth in the Regional Guide. Future utility corridor planning and subsequent interagency environmental analysis shall be in accordance with the following allocations:

1. **Exclusion areas, which are land areas determined to be unavailable for corridor allocation or facility siting. Exclusion areas include Wilderness (MA-1) and Wild River (MA-2) Management Areas.**
2. **Avoidance areas, which are land areas that pose particular environmental impacts which would be difficult or impossible to mitigate, or which impose unusual engineering constraints. Avoidance areas include Research Natural Area (MA-3), Unique Interest (MA-5), Backcountry Recreation (MA-6) and Special Wildlife Site (MA-9) Management Areas.**
3. **Sensitive key values, identified by a thorough analysis of the potential effects, should be avoided in the Botanical (MA-4), Supplemental Resource (MA-7), Designated Wildlife Habitat (MA-8), Scenic/Recreation Rivers (MA-10) and Retention Visual (MA-12) Management Areas.**
4. **Other areas may contain site-specific key values, such as recreation or administrative sites. These key values shall be considered in the Riparian (MA-11), Partial Retention Visual (MA-13) and General Forest (MA-14) Management Areas.**

Applications for uses associated with dams, reservoirs, and water transmission may be recommended for approval if they are consistent with management goals and objectives for the area. Water rights acquired for developments on National Forest lands shall be obtained by the applicant in the name of the United States.

Existing sites used for electromagnetic communications shall be protected from interferences generated by power transmission lines. This may require the power transmission lines to be rerouted or redesigned to protect those sites, or may otherwise require the power line proponent to equitably mitigate the uses established for those sites.

The following actions should be taken in connection with electronic sites:

1. **Develop site plans for existing sites which have facilities in place.**
2. **Identify potential sites for future development during environmental analyses.**
3. **Develop site plans for new sites prior to development.**
4. **New permits should be issued to direct use of the sites in the following order:**
   a. **Utilize residual capacity of existing sites.**
   b. **Utilize identified potential sites.**
   c. **Utilize other sites deemed suitable through environmental analysis after preparation of a site plan.**

Application for other uses shall be considered and evaluated, and decisions made as a result of appropriate environmental analysis. If funds are not available to process applications, an applicant may pay the cost of processing, including the cost of environmental analysis, in order to obtain faster service.

LAND LINE LOCATION

9-7 **Property lines adjacent to timber harvest or other activities with the potential to impact adjacent private property shall be surveyed, marked, and posted.**

MINERALS

10-1 **The prospecting, development, and production of mineral and energy commodities shall be facilitated.** Under the mining law, claimants are entitled to access to their mining claims **Access for exploration and development of locatable mineral resources should be analyzed in response to a proposed operating plan. A decision on approval of reasonable access should be made as a result of appropriate environmental analysis.** Specific direction and guidelines are found in FSM 2800 (Minerals and Geology).

10-2 National Forest lands are part of the land base available for mineral exploration and development; **withdrawals from mineral entry should be held to a minimum. Areas with mineral potential should be recommended for withdrawal from mineral entry only when mitigation measures would not adequately protect other resource values which are of greater public benefit.** Those coincident values may include, but are not limited to, administrative sites, sites that meet eligibility criteria for inclusion into the National Register of Historic Places, and developed recreation sites. In most cases, P.L 69 STAT 367 (Multiple Use of Surface of Public Land) 36 CFR 228, 36 CFR 261, and the California Surface Mining and Reclamation Act will be used to provide adequate protection of surface resources. Withdrawals from entry under the general mining laws will be in conformance with Section 204 of the Federal Land Policy and Management Act of 1976 (P.L. 94-579)

10-3 **Review of mineral lease applications shall include any special stipulations needed to protect surface resources.**

10-4 **Operating plans and permits for mineral-related operations shall comply with 36 CFR 228, Subpart A. Mineral material requests shall be processed in accordance with procedures in 36 CFR 228.4 (C).**

10-5 **Reasonable and economically-feasible requirements for timely and effective environmental protection and reclamation should be incorporated in operating plans and permits.**

10-6 **Timely responses (as per FSM 2800) shall be made to such activities as (1) operating plans, (2) minerals lease applications, (3) mineral patent applications, and (4) mineral resource potential of selected areas involved in landownership adjustments.**

10-7 **In developing plans of operation and administering minerals activities, emphasis should be given to addressing areas of high risk of surface disturbance and water quality impacts. This includes requiring reasonable, operationally feasible measures to protect other resources. Adequate bonding should be required to insure that provisions of the operating plan are accomplished.**

Development of reclamation requirements should emphasize:

1. **Identification of reasonable reclamation objectives. The following objectives should be considered:**
   a. Restoration of vegetative and habitat productivity, using natural vegetation where possible.
   b. The condition of disturbed land does not contribute to short-term or long-term environmental degradation, either in the form of air or waterborne material, or chemical pollution.
   c. The disturbed land will be left in a condition that is aesthetically acceptable and safe for intended future use.

2. **Identification of reasonable reclamation opportunities.**
3. **Achieving these objectives in the shortest practicable time.**
4. **Requiring reasonable interim reclamation measures to mitigate effects on water quality and provide for treatment and disposal of solid wastes.**

10-9 **Unauthorized use and occupancy should be eliminated. Occupancy should be approved only if it is reasonably incident to and required for the proposed mining activity.** Relevant considerations include: (1) the stage of mineral activities; (2) the expected size and life of the proposed operations; (3) the remoteness of the site; and (4) the kind of equipment protection needed Occupancy and structures must be identified and approved in the operating plan.

10-10 **Removal of common mineral materials shall be administered on a permit basis in areas where development does not conflict with other resource objectives. Mineral material requests shall be processed in accordance with procedures in 36 CFR 228. Proposed mineral material sources should have a development plan as outlined below.**

10-11 **A development and rehabilitation plan for mineral materials needed for resource management (e.g., road gravel) should be included in the plan for the resource project. Rock sources should be located in areas with the least other resource values. A rock material resource management plan should be prepared that assesses the long-term resource potential and makes a projection of public and Forest Service needs. This plan should be coordinated with the land management plan and transportation system planning. The plan should include procedures for:**

1. **Site investigation.**
2. **Material source development and operation.**
3. **Identification of reclamation objectives and planned procedures.**
4. **A uniform inventory process.**

FACILITIES: TRANSPORTATION SYSTEM

TRANSPORTATION PLANNING

11-1 **Transportation planning analysis shall be conducted to compare feasible alternatives where choices that maximize net public benefits are not obvious from environmental and resource considerations.** Direction for transportation planning is found in FSM 7710, Transportation Planning, and the Transportation Planning Handbook, FSH 7709 55

The analysis for transportation alternatives should:

1. **Identify viable alternative routes from the planning area to available access points.**
2. **Identify the long- and short-term needs for each road (service life).**
3. **Determine the traffic criteria for each route.**
4. **Evaluate existing and potential mineral material sources considering Site development and rehabilitation as described under Minerals.**
5. **Estimate development, maintenance, and user costs for economic comparison of alternatives.**
6. **Recommend the road system and standards to meet the needs identified.**
7. **Document the analysis, decisions, and management direction for preferred routes.**

CONSTRUCTION AND RECONSTRUCTION

11-2 The Road Development Plan includes the multiyear Capital Investment Program, the multiyear Timber Sale Program, and the Transportation Information System (TIS).

Design standards shall be based on resource management objectives, environmental constraints, user safety, environmental factors, traffic requirements, vehicle characteristics, road user, and economics.

New and reconstructed roads shall be planned, constructed, and managed to carry the anticipated traffic safely with a minimum impact to the land and other resources. In coordination with project interdisciplinary teams, specified construction methods shall include provisions for reducing environmental impacts, with emphasis to:

1. **Minimize impacts to soil and water values.**
2. **Establish or protect native vegetation on cut and fill slopes and other disturbed sites off the roadway.**
3. **Limit the spread of Port-Orford-cedar root disease where risk is present, and**
4. **Limit the spread of noxious weeds where risk is present.**
5. **Protect other resource values.**

TEMPORARY ROADS

11-3 **Construction of "temporary roads" should normally be discouraged. Roads planned and constructed as "temporary roads" should be obliterated as part of the project work. Methods used, timing, and mitigation measures should be in accordance with the site-specific project plan. Such roads should be planned and designed to re-establish vegetative cover on the disturbed area within a reasonable period of time, not to exceed 10 years after the termination of contract, lease or permit (36 CFR 219.27(a)(11)). Those roads which subsequently are determined to be needed for additional use, or those not obliterated as planned, shall be entered into TIS with appropriate road management objectives developed.**

MINING ROADS

11-4 **Roads built by miners within the scope of an approved operating plan shall meet the minimum safety and water quality protection standards for local roads. Where practicable, location should promote orderly development of the mine and accommodate future Forest transportation system needs. A Forest Service representive should inspect the road construction. Road entrance management and road maintenance requirements shall be identified in the approved operating plan. Reasonable provisions for termination of road use by the miner should identify the future status of the roadway, e.g., obliteration by the miner, operation and maintenance assumed by the Forest Service, etc. Bonding adequate to obtain conformance with roadway-related agreements in the operating plan should be required.**

ROAD MAINTENANCE

11-5 **Arterial roads, major collector roads and local roads open to passenger car use should have maintenance emphasis of Level III or higher. Some collectors and most local roads should have a Level II or lower maintenance emphasis, depending on the stated objectives for the road. Any road with less than the average daily traffic (ADT) stated in the Road Management Objectives for that road should be considered for reduction of one maintenance level below that assigned above. Road maintenance objectives shall consider emphasis items one through five listed above in Standard and Guideline 11-2, Construction and Reconstruction.**

Prior to roads in Level I maintenance emphasis being blocked at the entrance, they shall be put into condition to be self maintaining with low potential for resource damage.

OPERATIONAL MANAGEMENT

11-6 **The Forest shall maintain a Road Management Plan for the total road system. This plan shall include information on: road management objectives, commercial use rules, road development, road maintenance, traffic surveillance, and the Forest Highway Program by inclusion or by reference. Other traffic management plans or direction may also be included. All permanent roads under Forest jurisdiction and all other roads within the Siskiyou National Forest boundary should be listed in TIS. Objectives for Forest roads shall be identified in project environmental documents and be coordinated with Commercial Road Rules. The public should be kept informed of operational changes. All commercial road use shall be in accordance with Forest Commercial Road Rules.**

ROAD CLOSURE

11-7 **Road closures may be implemented to meet wildlife needs, fire protection, other resource needs, or to reduce road damage and maintenance costs. Existing roads determined not to be needed for future use may be obliterated.**

Travel restrictions may be imposed on Forest road users to reduce or eliminate conflicts between user groups, or provide for public safety.

FACILITIES: ADMINISTRATIVE SITES

SITE PLANNING

11-8 **Administrative site development planning analysis shall be conducted to compare feasible alternatives where choices that maximize net public benefits are not obvious from environmental and resource considerations.** Direction for site planning is found in FSM 7300 and FSH 7309.11.

The analysis of alternatives should:

1. **Identify viable alternative facilities.**
2. **Identify the long- and short-term needs for each site.**
3. **Determine the management criteria for each alternative.**
4. **Evaluate existing and potential site development and rehabilitation needs.**
5. **Estimate development and maintenance costs for economic comparison of alternatives.**
6. **Recommend the structures, supporting utilities, and standards to meet the identified needs.**
7. **Document the analysis, decisions, and management direction for preferred uses.**

CONSTRUCTION, RECONSTRUCTION, AND OPERATIONAL MANAGEMENT

11-9 The Facilities Master Plan clarifies existing Forest Plan direction and guides the acquisition, continued use and disposal of facilities.

Design standards shall be based on site management objectives, environmental constraints, user safety, national and local uniform building codes, traffic requirements, and economics.

All new sites shall be planned, constructed, and managed to provide the anticipated uses safely with a minimum impact to adjacent uses and landowners. Completed projects shall include provisions for reducing adverse environmental effects of sight, sound, odor and drainage.

Site or structure closures may be implemented to meet health and safety needs, or to reduce damage and maintenance costs.

Building maintenance funds and quarters collections should be allocated to cover operation, maintenance, and management proposals for facilities according to the following priorities:

1. **Health and safety - hazard elimination.**
2. **Condition inspections - of District facilities, and site development plan preparation and updates.**
3. **Prevent further deterioration - of facilities, grounds maintenance, and other site improvement.**
4. **Program Support - facilities that contribute to increased resource production and/or decreased unit costs for projects.**
5. **Energy Conservation.**
6. **Comply with other laws and regulations.**
7. **All others.**

TEMPORARY STRUCTURES

11-10 **Construction of "temporary facilities" should normally be discouraged. Structures planned and constructed as "temporary" should be removed or obliterated when the need is finished. Methods used and timing should be in accordance with the project plan. Structures which subsequently are determined to be needed for additional use, or those not removed or obliterated as planned, shall be included in the Site Plan.**

FIRE AND PEST MANAGEMENT

FIRE MANAGEMENT

12-1 **All wildfires shall receive an appropriate suppression response. The response shall be safe, timely, and cost efficient, and meet management objectives for the area including objectives for biological diversity.**

Any suppression strategy--confine, contain or control--may be preplanned at Fire Intensity Level 1 (FIL 1). A control strategy should normally be preplanned at FIL 2 or greater. A confine or contain strategy may be preplanned at FIL 2 or greater as deemed appropriate by a site-specific analysis. Each wildfire shall be surveyed in a timely manner to confirm the appropriateness of the preplanned strategy. The preplanned strategy may be changed at that time to more accurately reflect the site specific situation and further minimize the sum of fire suppression costs plus resource damage costs, and the potential for adverse resource, safety, air quality impacts and political concerns.

12-2 **The fire hazard presented by natural, activity or prior activity fuels should be reduced to appropriate levels, considering the site specific risk, and utilizing economically efficient treatment methods. The selected treatment methods should meet fuel management objectives which integrate consideration for all resource values.** The photos listed below from "Photo Series for Quantifying Forest Residues in the Coastal Douglas-fir/Hemlock Type and Coastal Douglas-fir/Hardwood Type" (Maxwell and Ward 1976) depict the standard for post

treatment, downed woody fuel loadings on cutting units and other project sites. The photos can be used individually or in combination

1 *Clearcuts and Hardwood Conversions:* 1DF4CC, 2DF4CC, 3DF4CC, 6DF4CC, 1DFHD4CC, 2DFHD4CC, 3DFHD4CC, 4DFHD4CC
2. Partial Cuts: 1DF4PC, 3DF4PC, 1D3PC, 2DF3PC, 1DFHD4PC
3. Precommercial thinning (roadside and fuelbreaks only): 1DF1TH, 2DF1TH

12-3 **Prescribed fire may be used in natural fuels: to reduce fire hazard by enhancing horizontal and vertical diversity in fuels; to enhance diversity in the structure and composition of plant communities; to enhance the production and protection of commercial timber yields; and to enhance other resource outputs such as wildlife habitat, forage, and browse. Prescribed fire may include both planned and unplanned ignitions.**

Prescribed fire from both planned and unplanned ignitions shall be used in wilderness areas only to reduce the risks and consequences of wildfire within or escaping from wilderness, and to permit lightning-caused fires to play their natural ecological role.

12-4 **Proposed activity units (harvest, thinning, conversion, release, etc.) should be designed and coordinated on the ground so that size, shape, location, timing, spatial distribution, and management risk are considered for fire management and other resource requirements and help make the fuel treatment and fire protection of the units as practical and economical as possible.**

The following techniques and practices are examples of those that can be used to help meet Forest-wide fire management standards.

1. Project or sale area subdivisions could be designed so that treatment of activity-created fuels in any one unit or logical grouping of units can start before the second burning season after the residue fuels are created.
2 Grasses and other vegetation used for rehabilitation and erosion control work could be selected for low fuel volume and low flammability characteristics whenever possible.
3 Roads can be planned and managed to accommodate short-term and long-term fuel treatment and fire protection needs as well as other resource treatments. The fire management needs will be documented in the road management objectives.
4 Activities could be planned and developed to avoid the buildup of fuels adjacent to sensitive areas such as riparian areas, Spotted Owl Management areas, partial cuts, thinning areas, plantations, Class IV streams, and private property.
5. Activities in riparian areas could be planned to minimize the risk from fire associated with treatments in adjacent units. Riparian areas will be protected from prescribed fire unless burning is prescribed through the environmental analysis
6 Wildlife trees and snags could be located to minimize risks of escaped fire and threats to safety Dangerous trees (snags) may be removed after on-site review of fire management, safety, and wildlife needs

A number of mitigating measures (operational procedures or practices) are available to reduce the impacts of prescribed fire and, in some cases, wildfire, on Forest resources. The key to reducing fire impacts is to reduce the intensity or duration of the fire. Mitigation measures will be consistent with resource objectives.

Fire intensity can be reduced by implementing such measures as:

1. Reducing the total fuel load, especially fuels in the 0-3 inch diameter class, which will reduce the damaging effects of the flaming front on soil and vegetation
2. Reducing the amounts of large-diameter fuels on the site, which will reduce the total burning time and reduce the total amount of heat pulsed into the soil.
3. Scheduling prescribed burning to periods when fuel moistures are higher to lessen the amount of heat generated by the fire.
4. Utilizing ignition patterns and techniques which will produce shorter flame lengths and slower spread characteristics.

Fire duration can be reduced by utilizing such techniques as.

1. Removing large material from the fuels complex to be burned, prior to ignition.
2. Scheduling prescribed burning to periods when fuel moistures are higher, to reduce the glowing or smoldering stage of the fire

The erosion problems associated with both wildfire and prescribed fire can be reduced by such practices as·

1. Seeding the burned area with grasses and forbs to hold the soil in place and reduce the impact of raindrops on the soil surface Seeding will use species that occur naturally on the site wherever possible.
2. Constructing waterbars in firelines to reduce the velocity of overland flow and divert it to undisturbed areas.
3. Taking full advantage of natural barriers, other terrain features, and environmental conditions when locating control lines for prescribed fire and wildfire suppression purposes.

The visual impacts, especially in high-use areas, may be mitigated to some degree by such actions as:

1. Seeding to increase the amount of vegetation on the site and, thereby, camouflaging the blackened soil.
2. Removing fire killed trees and brush
3. Restoring firelines to natural-like conditions, once they are no longer needed
4. Keeping logging slash and amenity uses of the Forest separate, in both time and space.

Impacts to soil productivity may be lessened by:

1. Mulching to improve the soil microclimate.
2. Fertilizing to replace volatilized nitrogen and other minerals

The most substantial mitigating measure for the slash disposal (activity fuels) program is an aggressive utilization program that removes most of the woody biomass in excess of the amount desired to be retained on site (see Standard and Guideline 7-8). The program will actively support continued research and marketing efforts for new uses of woody biomass residues

Table IV-11 summarizes the specific fire management direction and the intensity of fire management activities as outlined in the management prescriptions for each of the land allocations on the Forest. This direction is based on the Forest-wide Standards and Guidelines and is presented in the table to provide a quick reference and comparison of the direction for each management area.

Table IV-11. Summary of Fire Management Direction by Management Area

Management Area	Preplanned Suppression Strategy and Acre Objective: Strategy 1/	Objective 2/	Attack Emphasis	Range of Suppression Technology/Equip.	Prevention Emphasis and Level of Visibility	Activity Fuels Treatment Emphasis	Natural Fuels Treatment Emphasis
1 Wilderness							
Kalmiopsis	Contain	3/	Indirect	Modified	Moderate w/high vsby	N/A	Direct 4/
Wild Rogue	Control	90	Indirect	Modified	Moderate	N/A	Direct 5/
Grassy Knob	Control	30	Direct	Limited	Moderate w/low vsby	N/A	N/A
Red Buttes/Siskiyou	Control	30	Indirect	Modified	Moderate w/low vsby	N/A	Direct

6 Backcountry Recreation	Control	30	Direct	Modified	High	N/A	Direct
7 Supplemental Resource	Control	30	Direct	Limited	Low	N/A	N/A
8 Designated Wildlife Habitat	Control	30	Direct	Modified-full	High	Direct	Direct
9 Special Wildlife Site	Control	30	Indirect	Modified	Low	Direct	Direct
10 Recreation River	Control	30	Direct	Modified	Moderate	Direct/Indirect	Direct
Scenic River	Control	30	Direct	Modified	High	Direct/Indirect	Direct
11 Riparian	Control	30	Direct	Modified	Keyed to adj. lands	Direct	N/A
12 Retention Visual	Control	30	Direct	Modified-full	High	Direct/Indirect	Direct
13 Partial Retention Visual	Control	30	Direct	Full w/modifications	High	Direct/Indirect	Direct
14 General Forest	Control	30	Direct	Full	High	Direct	Direct

1/ At Fire Intensity Level 2 and above (flame lengths greater than 2-4 feet).
2/ Firefighting efforts shall be such that a wildfire is suppressed at the acre objective or less, 90 percent of the time
3/ To be determined through a wilderness fire management plan, a 30-acre objective will be used in the interm.
4/ Includes the use of unplanned ignitions.
5/ Includes the use of unplanned ignitions at FIL 1 (flame lengths less than 2 feet).
6/ Planned ignitions are appropriate as part of ongoing research in the RNA.

INTEGRATED PEST MANAGEMENT

12-5 **All planned activities shall include integrated pest management practices. All insect, disease and vegetation control projects shall be carried out in ways that meet management area objectives.**

12-6 **Control of noxious weeds should be accomplished in cooperation with state, county, and private organizations through Weed Control Districts or Coordinated Resource Management Agreements.** Preventive management is critical to an effective control program.

12-7 **Silvicultural methods and cultural treatments should be applied to reduce susceptibility to hazards of insects and diseases (36 CFR 219.27(c)(7)). If normal insect surveillance indicates the threat of an epidemic, project level detection and control operations, including coordination with other land ownerships, shall be accomplished on a Forest-wide basis.**

MANAGEMENT OF PORT-ORFORD-CEDAR

12-8 **Strategies for Port-Orford-cedar management shall be integrated into environmental analyses and project planning for all areas that support Port-Orford-cedar.** An example is to interplant existing plantations that are scheduled for planting or have been planted. **Port-Orford-cedar should be managed as a major component of the appropriate plant association in areas of low to moderate risk of infection.** Representative areas within plant associations containing Port-Orford-cedar will be identified and protected.

Appropriate practices identified from experience and research should be applied on a site or drainage-specific basis to prevent or reduce the spread and severity of Port-Orford-cedar root disease. Additional information and suggested practices can be found in *Port-Orford-cedar Root Rot on the Siskiyou National Forest* (Harvey, Hadfield, and Greenup 1985); *Siskiyou National Forest Tree Improvement Plan* (Tibbs, Brady, and Vagle 1988); *Port-Orford-Cedar Root Disease* (Roth, Harvey and Kliejunas 1988) and *Ecology, Pathology, and Management of Port-Orford-cedar (Chamaecyparis lawsoniana)* (Zobel, Roth and Hawk, 1985).

Of special significance to the support of management of Port-Orford-cedar is the Region Five-Region Six Port-Orford-cedar Root Disease Action Plan dated June 29, 1988 This is a formal commitment by both Regional Foresters for (1) Inventory and Monitoring, (2) Research, (3) Public Involvement and Education, and (4) Management Policy. In short, this commitment provides the support to insure the viability and continued presence of Port-Orford-cedar in the ecosystem throughout its native range on Forest Service managed lands.

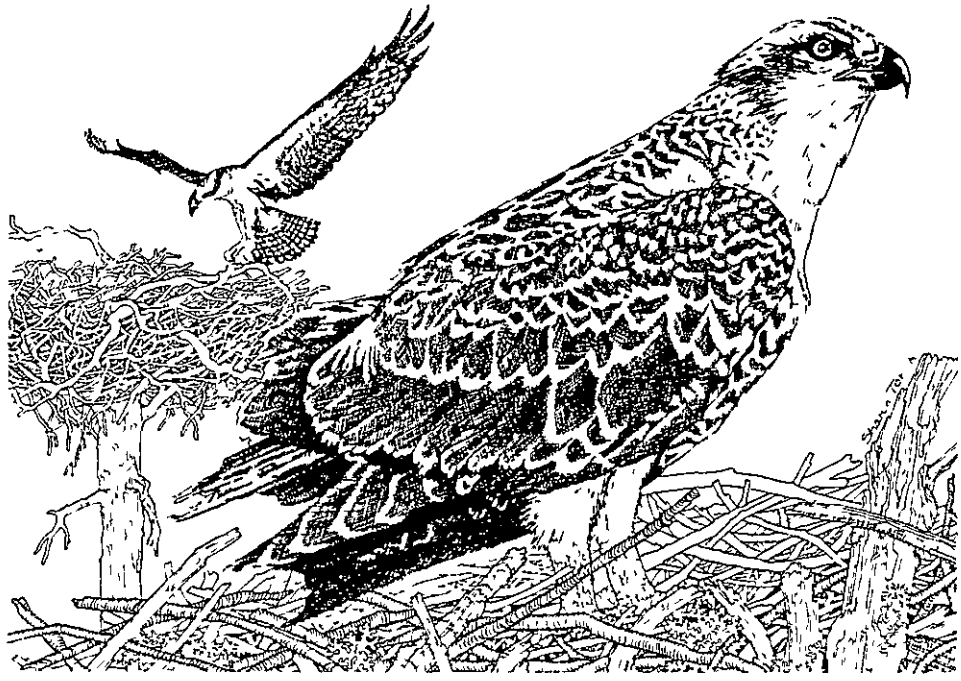
To emphasize the importance of achieving success in this effort, specific examples of requirements are listed below:

1. Silvicultural prescriptions for sites having potential for growing Port-Orford-cedar will provide for the establishment of the species through natural or artificial regeneration and maintenance as a viable stand component through the current and future rotations. Prescription analysis will also consider distribution of Port-Orford-cedar so that spacing will inhibit spread of the disease, particularly in susceptible habitats.

2. Road construction and use that can potentially affect Port-Orford-cedar will be evaluated and appropriate control measures used that limit the spread of the disease. Road closures or controlled access can be used as part of the overall management scheme to reduce the risk of contamination of individual areas (such measures should be documented in the road management objectives).

3 Logging systems used in infested Port-orford-cedar stands should minimize disturbance and redistribution of soil In a given case, this might exclude use of ground yarding equipment such as tractors or rubber-tired skidders. In other situations, it might require full suspension of logs during yarding operations with skyline systems or helicopters. It might also, be necessary to operate during the dryer time of the year to reduce soil movement

BIOLOGICAL DIVERSITY



13-1 Site specific management prescriptions developed in project planning should consider biological diversity and ecosystem function in keeping with Forest-wide Standards and Guidelines 4-1 through 4-20, 5-1, 6-1, 6-6, 6-8, 6-9, 6-12 through 6-14, 7-5, 7-8, 7-10, 7-15, 10-7, 11-5, 11-7, 12-1 through 12-5, and 12-8. The following management actions will contribute to maintenance of biological diversity:

1. Evaluate opportunities to maintain or enhance stand, basin and Forest level components of biological diversity on a project by project basis as commensurate with watershed *analysis direction (see Standard and Guideline 7-15).*

2. Plan management activities so that riparian habitats serve as corridors linking later seral stages of forest stands.

3. Complete species management guides for sensitive species during the period of the plan to ensure viable populations are maintained.

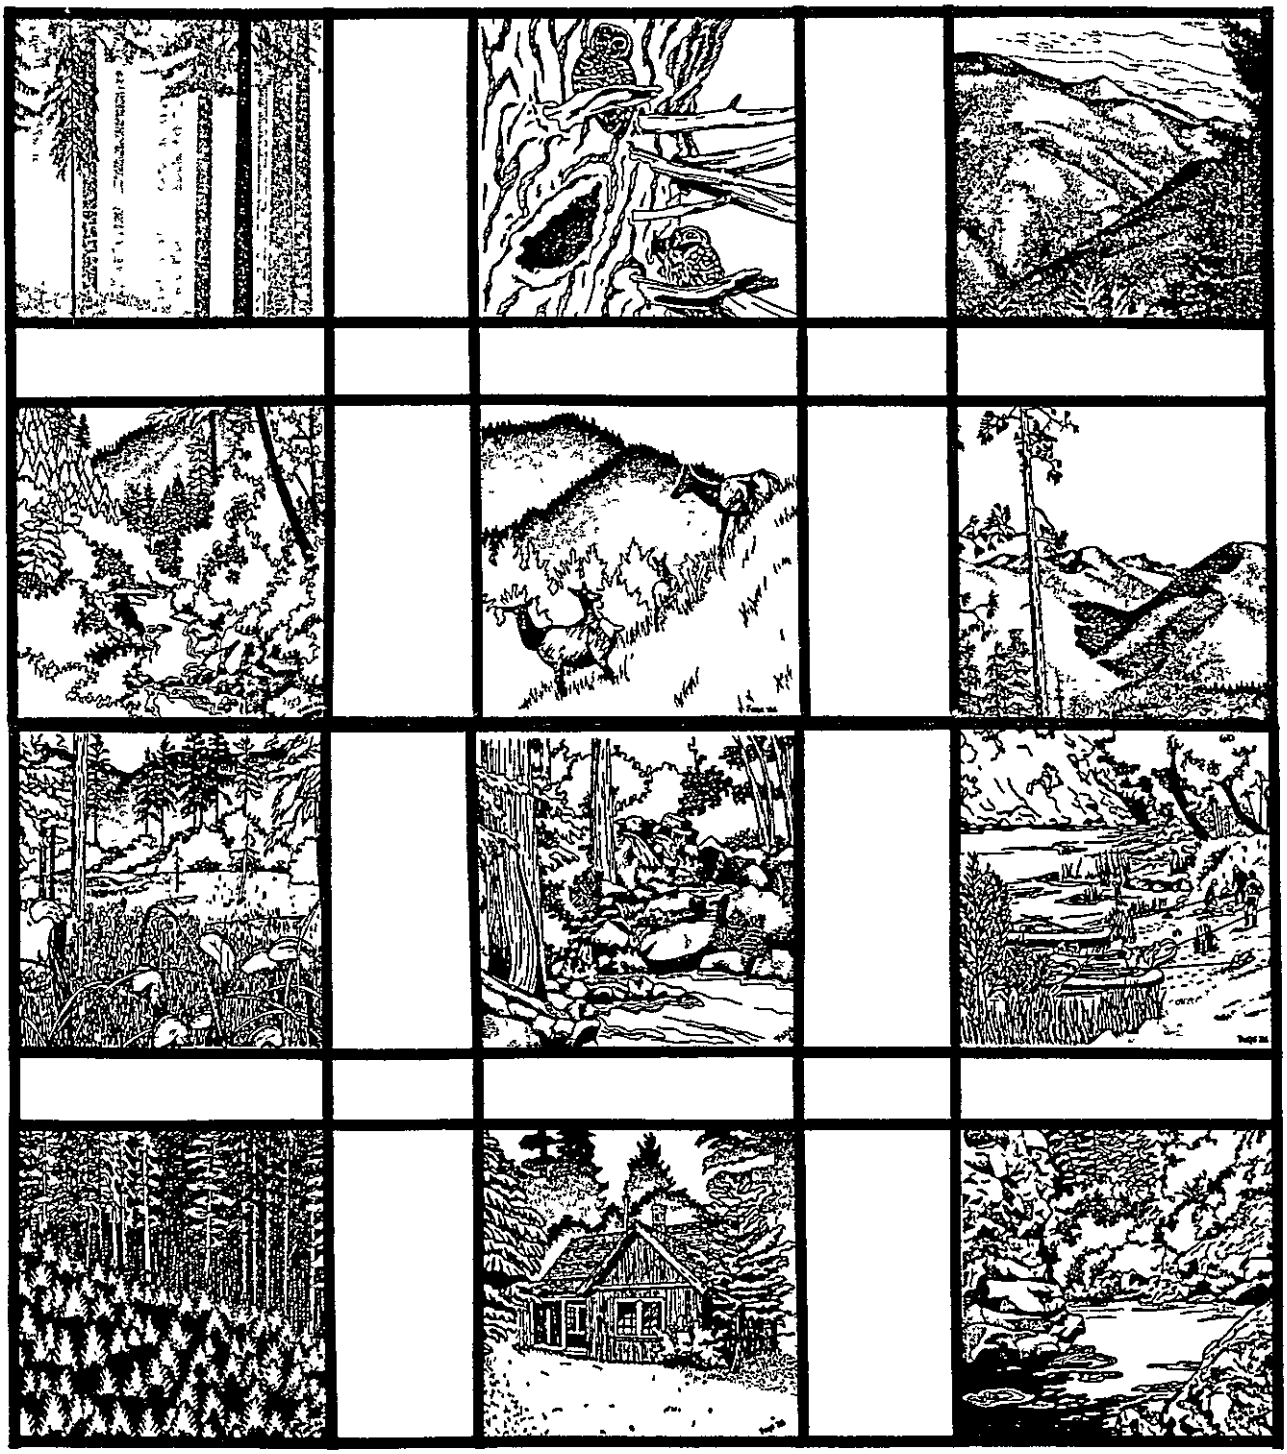
4. Develop a process in the next five years to periodically evaluate the spatial location of allocations and habitat conditions on and off Forest, and the potential to reduce or *minimize fragmentation.*

MANAGEMENT PRESCRIPTIONS

The National Forest Land within the Siskiyou National Forest has been assigned to fourteen management areas, each with different management goals, resource potential and limitations (The objectives of each are listed in Table IV-13) The acres assigned to each management area and the acres selected for timber management within each are displayed in Table IV-12 The management areas are shown on the accompanying map, which can be used for reference The management area maps of record are two inches equals one mile scale and are located in the Forest Supervisor's Office

Except for Congressionally established or special administrative boundaries, the management area boundaries are not firm lines and do not always follow easily found topographic features, such as major ridges The boundaries represent a transition from one set of opportunities and constraints to another with management direction established for each The boundaries are flexible to assure the values identified are protected and to incorporate additional information gained from further on-the-ground reconnaissance and project-level planning.

The Forest-wide management direction including the Standards and Guidelines apply to all management areas unless specifically excepted in the management area prescription The Standards and Guidelines of individual management area prescriptions are only to define exceptions to, or additions to the Forest-wide direction



The following section contains a description of the 14 management prescriptions, including a description of the management area, management goals, desired future conditions, and Standards and Guidelines Where overlap occurs between management area allocations, or with Congressionally or administratively designated areas, the most stringent restrictions shall apply.

Table IV-12 Management Area Acres

	Acres	
Management Area No and Name	Management Area	Selected Suitable for Timber
1 - Wilderness	232,495	0
2 - Wild River	5,029	0
3 - Research Natural Area	4,608	0
4 - Botanical	16,275	0
5 - Unique Interest	2,015	0
6 - Backcountry Recreation	40,871	0
7 - Supplemental Resource	26,921	0
8 - Designated Wildlife Habitat	50,287	0
9 - Special Wildlife Site	28,762	0
10 - Scenic/Recreation River	10,317	8,000
11 - Riparian	96,623	70,000
12 - Retention Visual	9,861	7,000
13 - Partial Retention Visual	133,931	105,000
14 - General Forest	434,307	320,000
Total	1,092,302	510,000

Table IV-13. Management Areas

Management Area No and Name	Objective
1 - Wilderness	Maintain wilderness character in its natural condition and provide opportunities for solitude and recreation
2 - Wild River	Maintain the natural, free-flowing, and primitive character of Wild segments of the river corridor
3 - Research Natural Area	Provide opportunities for research, observation and study of ecosystems influenced only by natural processes
4 - Botanical	Provide exhibits of plants, plant groups and communities with exceptional botanical and ecological value
5 - Unique Interest	Provide opportunities for understanding the earth's unique geologic, historical, and archaeological features
6 - Backcountry Recreation	Provide both motorized and non-motorized recreation opportunities in a largely undeveloped setting with the minimum management necessary for resource protection
7 - Supplemental Resource	Provide quality fish habitat, water, wildlife habitat and recreation opportunities in a largely undeveloped setting
8 - Designated Wildlife Habitat	Provide mature and old-growth habitat for dependent wildlife species
9 - Special Wildlife Site	Provide an array of unique plant and animal conditions that contribute to overall wildlife habitat diversity
10 - Scenic/Recreation River	Provide river-oriented recreation in an area of high quality scenery and largely undeveloped shoreline of Scenic and Recreation segments of the river corridor
11 - Riparian	Protect intrinsic values of ecosystems bordering bodies of water and wetlands while providing limited multiple-use development opportunities.
12 - Retention Visual	Protect scenic values while providing multiple-use development opportunities that are not visually evident to the casual Forest visitor
13 - Partial Retention Visual	Protect scenic values while providing multiple-use development opportunities that are visually subordinate to the characteristic landscape
14 - General Forest	Provide multiple-use development opportunities and a high yield of timber, subject to multiple use constraints

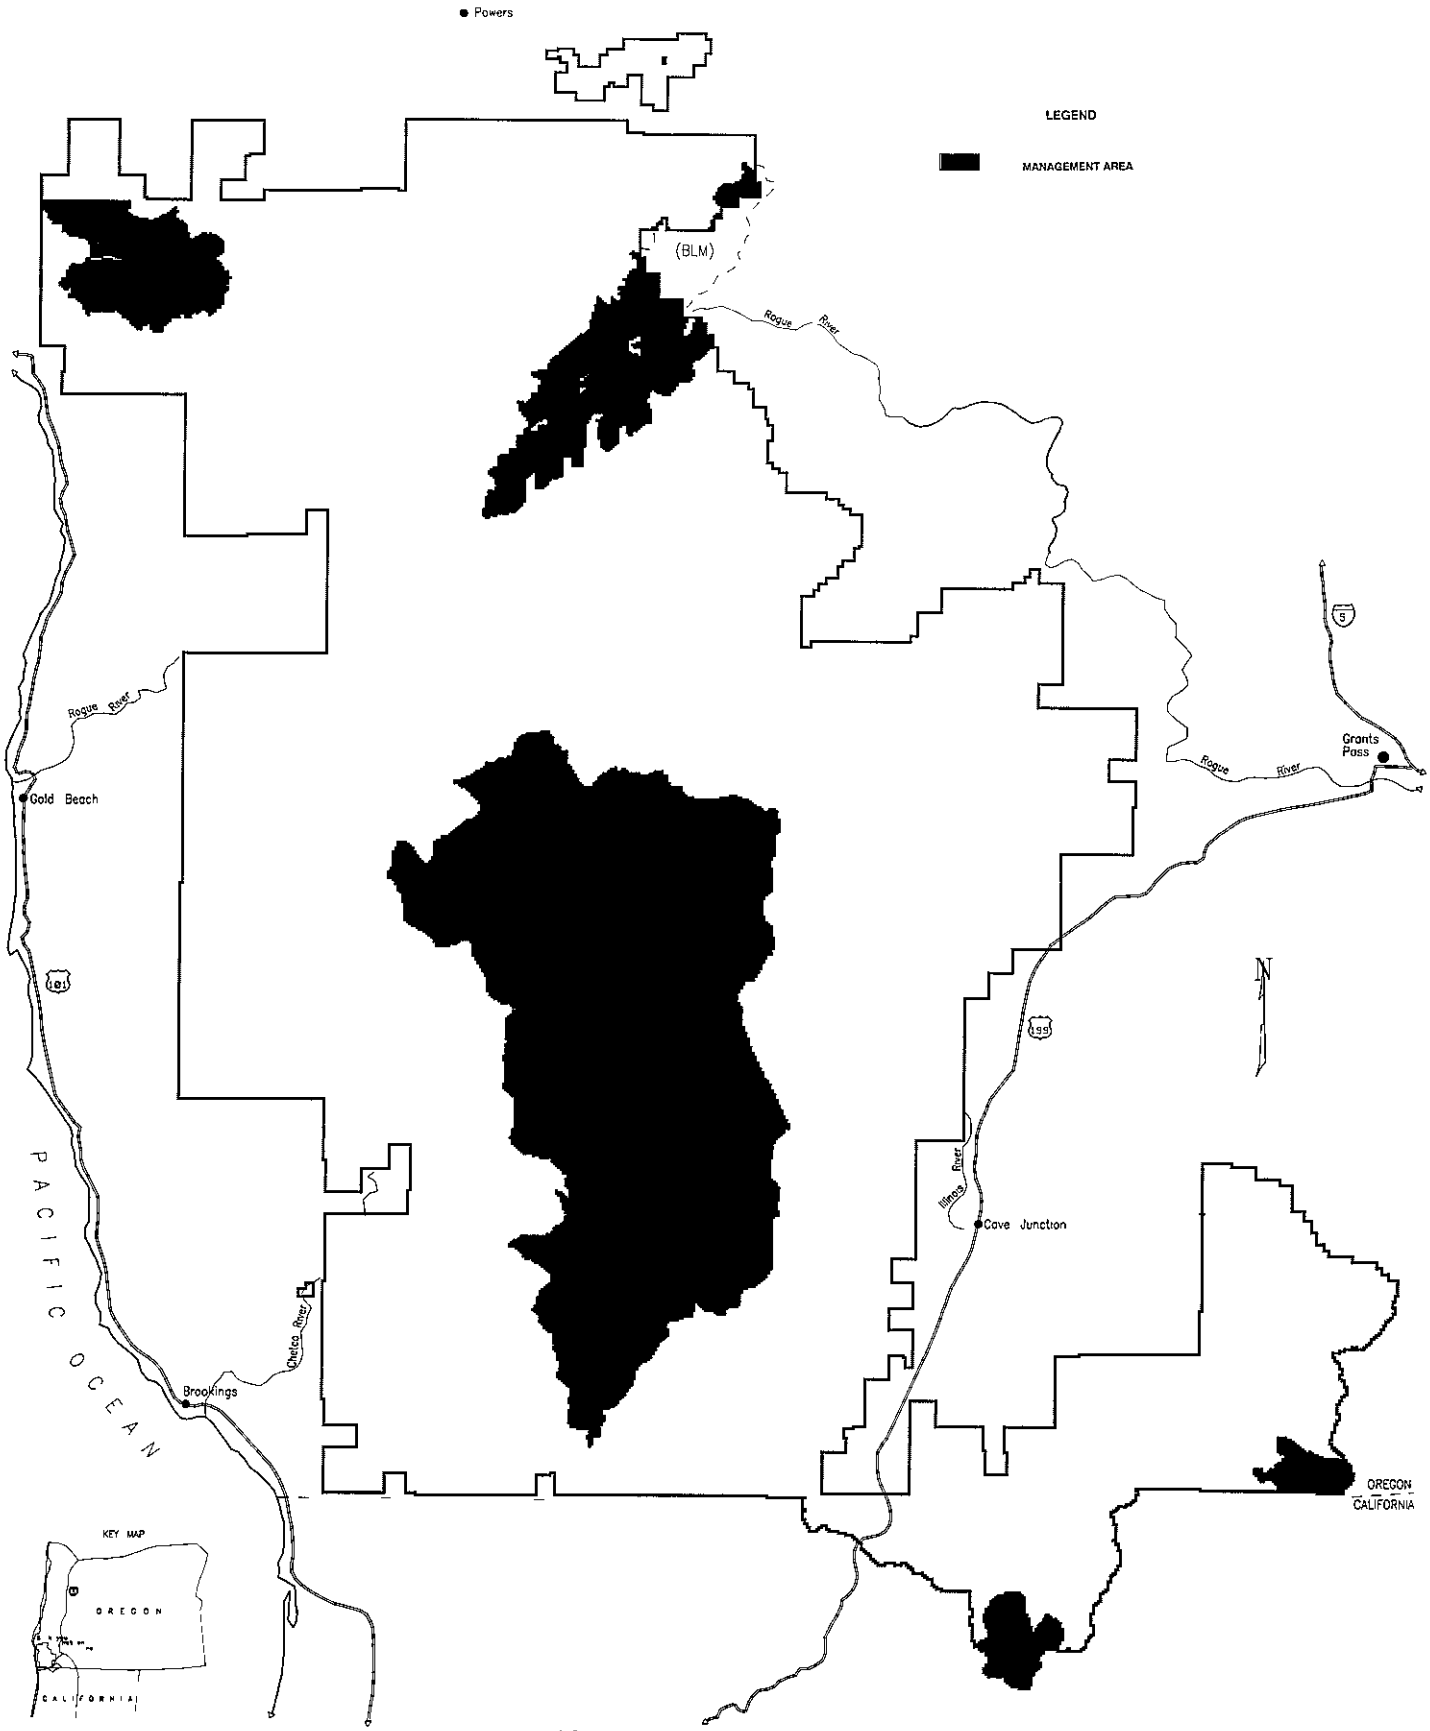


Figure IV-4. Wilderness Management Area Map

MANAGEMENT AREA 1 - WILDERNESS

DESCRIPTION

This prescription applies to the following wildernesses: Kalmiopsis, Wild Rogue, Grassy Knob, and those parts of Red Buttes and Siskiyou within the Siskiyou National Forest. These wildernesses are pristine, scenic landscapes that are preserved as "vestiges" of wild America, and provide an opportunity for solitude The wilderness areas on the Siskiyou are characterized by deep, rugged canyons containing clear rushing streams. Refer to Figure IV-4 for a map displaying allocated acres within the management area.

Table IV-14 Acres Allocated to Wilderness

	Acres		
Name	Management Area 1	Overlap by Management Area	Total Area
Grassy Knob	17,200	0	17,200
Kalmiopsis	179,850	0	179,850
Red Buttes	3,414	0	3,414
Siskiyou	5,323	0	5,323
Wild Rogue	26,708	0	26,708
Total	232,495	0	232,495

These wildernesses must be managed according to the Wilderness Act of 1964, the Endangered American Wilderness Act of 1978, the Oregon Wilderness Act of 1984, the California Wilderness Act of 1984 and regulations pursuant to those acts Refer to Figure IV-4 for a map displaying allocated acres within the management area

MANAGEMENT GOALS

The goals of this management area are to:

1. Preserve the wilderness character and maintain the natural conditions of each wilderness (nondegradation policy);
2. Assure that changes which take place in the natural conditions are the result of natural rather than human processes; and
3. Provide Primitive and Semi-primitive Non-motorized recreational opportunities.

DESIRED FUTURE CONDITION

Each of the wildernesses will appear to be affected primarily by the forces of nature, with the imprint of human activities substantially unnoticeable. Natural processes, including fire, will continue to be the primary forces which are affecting the condition of these areas The areas will have been managed so as not to have degraded the wilderness attributes for which they were designated There will be some evidence of human influence due to the existence of valid mining claims; however, mitigation techniques will have been utilized to minimize the impact of these activities

Foot-trails and camping spots will be the only permanent modifications in these areas; developed commensurate with the desired high level of primitiveness. Most of the area will be essentially unmodified, with large areas between the trails in which the probability of experiencing solitude will be very high. The Limits of Acceptable Change (LAC) concept will have been implemented and monitoring of recreation use and its attendant impacts will be under way. Recreation use will still be relatively light compared to other Forests in the region.

Management plans in areas adjacent to the wildernesses will have been fully implemented so that all influences to the wilderness environment will have been felt. The overall character of the wilderness will have been maintained

STANDARDS AND GUIDELINES

Administration

MA1-1 While seeking to achieve the stated goals for Wilderness, a nondegradation policy of management shall be followed This policy recognizes that in Wilderness a range of natural and social settings exist from the most pristine to those where the natural feeling and opportunities for solitude have been diminished by established uses It is the intent of this policy to assure that appropriate diversity and existing wilderness character are maintained The most pristine areas should not be reduced to the minimum acceptable standard of natural state simply to disperse and accommodate more use.

Periodically, usually on an annual basis, meetings should be held between adjacent forests administering the same wilderness to:

1 Maintain continuity and consistency in Wilderness management decisions;
2 Review and set priorities for the use of available administrative resources,
3. Review trail maintenance schedules;
4 Review outfitter and guide permit administration.

Recreation

MA1-2 *Pristine Wilderness Recreation Spectrum (WRS).* This area is characterized by an extensive unmodified natural environment. The area should be managed so that the natural processes and conditions that currently exist will not be measurably affected by the actions of users Access to these areas shall be limited to cross country travel Use of motorized or mechanized equipment is prohibited unless authorized by the Forest Supervisor or Regional Forester. Encounters with other users should be infrequent (one encounter per day or less).

Primitive WRS. This area is characterized by an essentially unmodified natural environment. This area should be managed so that it remains essentially free from human induced restrictions and controls. Access to these areas shall be limited to trails. Trails shall be planned to disperse use. No facilities for the comfort or convenience of wilderness users shall be provided. Use of motorized or mechanized equipment is prohibited unless authorized by the Forest Supervisor or Regional Forester. Encounters with other users should be infrequent (three to five encounters per day).

Semi-primitive WRS. This area is characterized by a predominately unmodified natural environment. The area should be managed so that natural processes and an unmodified character are maintained. Access is limited to trails and minimum controls, and restrictions may be present but are subtle. Facilities are only provided for the protection of wilderness resource values. Motorized or mechanized equipment is prohibited unless authorized by the Forest Supervisor or Regional Forester. Encounters with other users should be infrequent (five to seven encounters per day)

As use approaches calculated recreation visitor day (RVD) capacity levels, management policies should be reviewed and revised as needed to maintain the desired degree of recreation experience. The LAC concept should be used to accomplish this objective

Signing within the wilderness shall be at the minimum level necessary to insure the safety of the public Signs should be checked for accuracy throughout the year

The wilderness trail map should be checked periodically for accuracy and updated when necessary to insure public safety and convenience

Visitors should be advised and educated in waste disposal to assure sanitary conditions are maintained

If wilderness use exceeds the degree of impact established through the LAC or the capacities identified for each, the corrective actions shall be taken·

1 Initiate public information and site restoration activities.
2 If the first action is unsuccessful, recreation activities should be restricted by regulation
3 If the second action is unsuccessful, the level of use should be restricted.
4. If the first three actions are unsuccessful, a zone should be closed to all recreation use until the area is rehabilitated and restored to wilderness conditions

Kalmiopsis Wilderness The carrying capacity for recreation use is calculated to be 32,000 RVD's. Vegetative impacts that result from recreation use should be monitored and restrictions applied to areas where impacts are changing the natural characteristics of the area

Wild Rogue Wilderness The carrying capacity for recreation use is calculated to be 6,000 RVD's. (This does not include use on the Wild River)

Grassy Knob Wilderness. The wilderness should be managed to provide a Semi-primitive (trailess) recreation experience. Minimum recreation opportunities should be offered. No trail systems or trailheads should be constructed. The wilderness area should be maintained in a condition that would provide an estimated 4,000 RVD capacity.

Red Buttes Wilderness. The Siskiyou National Forest portion of this wilderness should be managed to provide a Semi-primitive (trailed) recreation experience Standards and Guidelines developed by the Rogue River National Forest shall be adhered to in this planning effort. The Siskiyou portion of the Wilderness should be maintained in a condition that would provide an estimated 4,500 RVD capacity.

Siskiyou Wilderness. The Siskiyou National Forest portion of this wilderness should be managed to provide a Semi-primitive (trailed) recreation experience. The Forest shall adhere to the Wilderness Standards and Guidelines developed by the lead Forest in this planning effort (Klamath National Forest). The Siskiyou portion of the wilderness should be maintained in a condition that would provide an estimated 2,000 RVD capacity.

Visual

MA1-3 All management activities within the wilderness shall meet the Preservation VQO (Agriculture Handbook #462, Visual Management System, and FSM 2320); except mineral entry as approved in operating and rehabilitation plans.

A visual analysis should be completed prior to construction of any new trail to insure the trail will not detract from the natural character of the landscape.

Cultural

MA1-4 To date, no cultural sites within the wildernesses are listed on the National Register of Historic Places, however certain historic and/or prehistoric properties may be eligible for nomination. Due to the rugged nature of much of the wilderness acreage, there is limited potential for a high quantity of sites. However, those present are likely undisturbed except for the deterioration caused by natural weathering

Further cultural resource inventory work should be conducted in the wildernesses in order to ascertain the nature, distribution and condition of cultural sites present The survey work should be designed to provide an inventory of the high probability sites. Inventory priorities will be focused on finding and recording those sites threatened by loss or serious deterioration during the next decade

Inventoried cultural resources in wilderness should be protected until evaluated Priorities should be set for site evaluations. Those sites that are threatened with loss or deterioration should receive highest priority. Other evaluations may be conducted in order to gain data relevant to the past use of the National Forest. All evaluation work shall comply with the preservation of the wilderness resource.

All actions, direct or indirect, that will have an effect on a significant cultural resource are subject to compliance with Section 106 of the National Historic Preservation Act, as amended, and through its implementing regulations, 36 CFR 800. Adverse effects to significant cultural resources (eligible and listed) shall be mitigated. Decisions to abandon a significant historical structure and allow it to deteriorate naturally, or to remove one, shall be preceded by the consultation process defined in 36 CFR 800, including agreement on appropriate mitigation measures

Cultural resource research within the wilderness shall meet the following criteria: (a) must be necessary to support the values set forth in Section 4(b) of the Wilderness Act, or (b) must be done in compliance with preservation ethic for the wilderness resource.

The works of human beings within wilderness should not be designated for protection as cultural resources unless they are (a) necessary to support the values set forth in Section 4(b) of the Wilderness Act, (b) serving administrative purposes as necessary for protection of the wilderness resource (Section 4(c)), or (c) essential to cultural resource management (FSM 2323.83) Thus we will nominate to the National Register of Historic Places only those sites deemed worthy of preservation and protection.

On-site interpretation of sites shall not be done. Interpretation may be done off-site through brochures and audio-visual programs.

Wildlife and Sensitive (Rare) Plants

MA1-5 Wildlife and plant habitat will be subject to natural processes. Fire may play its natural ecological role in maintaining specific habitats Fire may maintain meadows in grass cover and reduce encroachment of trees, or may maintain the habitat of rare plants such as the *Kalmiopsis leachiana.*

Fish

MA1-6 Management direction is to maintain existing fish habitat subject to natural processes

Range

MA1-7 New allotments for livestock range shall not be allowed. The use of pack stock by wilderness users will be permitted Users should be encouraged to carry feed for their stock

Timber

MA1-8 No timber management practices are allowed inside designated Wilderness areas.

Water and Soil

MA1-9 Degraded sites created as a result of past human activities should be rehabilitated to a near natural condition A rehabilitation site plan shall be prepared for each site prior to any on-the-ground rehabilitation. Revegetation efforts shall use only those plant species indigenous to the area.

Minerals

MA1-10 Mineral entry was permissible as provided by the Wilderness Preservation Act of 1964. After December 31, 1983, mining only on valid claims is permitted, subject to approved operating plans. Provisions in operating plans shall satisfy the rights of the claimant while creating the least impact on wilderness values. Provide for restoration of the disturbed lands as near as practical to their natural condition as soon as possible during or after the mining activity Site specific mitigation shall be required seasonally for active mining operations. Rehabilitation of the surface area shall be required upon completion of all mining activities.

Facilities

MA1-11 Roads shall not be constructed or reconstructed within designated Wildernesses except those that are permitted within the constraints specified in approved operating plans for mineral development. Close any existing mining roads if they are abandoned or determined that the claim is invalid. Trails should be maintained to keep the trails passable and drainage structures functioning (Level 2). Fire protection facilities may be constructed, provided they meet the intent of the Wilderness Preservation Act of 1964. Future utility corridor siting shall be excluded from this Management Area

Fire Management

MA1-12 *Kalmiopsis Wilderness* A Wilderness Fire Management Plan shall be developed within 3 years following approval of this Land & Resource Management Plan The plan will incorporate suppression strategies which reflect fire's role in the local ecosystems as follows:

1. For ecosystems in which fire plays a significant role (high intensity, stand replacement fire), the fire management plan should contain fires from unplanned ignitions (lightning only) in the area classified as primitive in the Wilderness Recreation Spectrum classification system (WRS) Human-caused fires shall receive an appropriate response as determined in the wilderness fire planning process.
2 For ecosystems in which fire plays only a minor role, (ground or surface fires), all wildfires should be evaluated using the fire management plan The plan will provide specific

decision criteria for determining the suppression strategy as well as the kinds and amounts of suppression action (tactics) to be taken on the fire.

3. In "nonfire" dependent ecosystems, all fires should be controlled in accordance with a Wilderness Fire Management Plan which provides criteria for determining the suppression tactics to be taken on the fire.

Prior to the development of the plan, all wildfires occurring at FIL 2 and above should be detected and controlled at 30 acres or less, 90 percent of the time. Safe and cost effective suppression tactics which adhere to Wilderness fire fighting principles will be used. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A moderate level of prevention should be provided. Public contacts should be emphasized through the wilderness rangers. Emphasis should also be placed on prevention techniques that accomplish the fire prevention mission prior to the user entering the wilderness. Fuel Treatment may be used for hazard reduction at heavily-used sites

A prescribed fire program as determined by the wilderness fire planning process, using both planned and unplanned ignitions, should be initiated to: (1) reduce the risks and consequences of wildfire within the Wilderness, or escaping from the Wilderness and (2) allow fire to play its natural ecological role. Planned ignitions could be used to maintain a fuels complex commensurate with levels of protection. Unplanned ignitions may be used, outside the "Primitive" WRS areas, at FIL 1 to supplement planned ignitions.

In a fire management situation where prescribed fires from unplanned ignitions are allowed in the Primitive WRS areas, an aggressive program of planned ignitions should be used to develop a fuels mosaic around the Primitive WRS areas

MA1-13 *Wild Rogue Wilderness.* All wildfires occurring at Fire Intensity Level FIL 2 or above should be controlled at 90 acres or less 95 percent of the time Indirect attack should be emphasized utilizing a modified range of suppression technology and equipment and adherence to the basic wilderness fire fighting principles This is necessary due to the physical layout and topography of the Wilderness and adjacent resource values Wildfires occurring at Fire Intensity Level FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A moderate level of prevention activities should be provided. Public contacts should be emphasized through the use of the Wilderness rangers. Emphasis shall also be placed on methods that accomplish the fire prevention mission prior to the user entering the Wilderness area Hazard reduction should be accomplished around heavily used sites

A prescribed fire program as determined by the wilderness fire planning process, using both planned and unplanned ignitions, should be initiated to reduce the risks and consequences of wildfire within the Wilderness, or escaping from the Wilderness. Planned ignitions could be used to maintain a fuels complex commensurate with levels of protection Unplanned ignitions may be used at FIL 1 to supplement planned ignitions.

MA1-14 *Grassy Knob Wilderness.* All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less, 90 percent of the time. A limited range of suppression equipment and technology emphasizing direct attack and adherence to basic wilderness firefighting techniques should be used in the suppression of wildfires. Wildfires occurring at FIL 1 shall be handled as outlined in the basic suppression direction for the Forest.

A low level of prevention activities should be provided Public contacts should be limited, with most of the prevention efforts concentrated on techniques that accomplish the fire prevention mission prior to the user entering the area.

MA1-15 *Red Buttes and Siskiyou Wildernesses.* All wildfire occurring at FIL 2 or above should be controlled at 30 acres or less, 90 percent of the time. A limited range of suppression equipment and technology emphasizing indirect attack and adherence to basic wilderness firefighting techniques should be used in the suppression of wildfires Wildfires occurring at FIL 1 shall be handled as outlined in the basic suppression direction for the Forest.

A moderate level of prevention with a low level of visibility should be provided. Limited field contacts should be made by Wilderness Rangers, with the emphasis placed on prevention efforts through the media and Wilderness Permit System. Hazard reduction should be accomplished around heavily-used sites.

A prescribed fire program utilizing both planned and unplanned ignition may be used to maintain a fuels complex commensurate with levels of protection as determined by the wilderness fire planning process, initiated by the lead National Forest for each wilderness

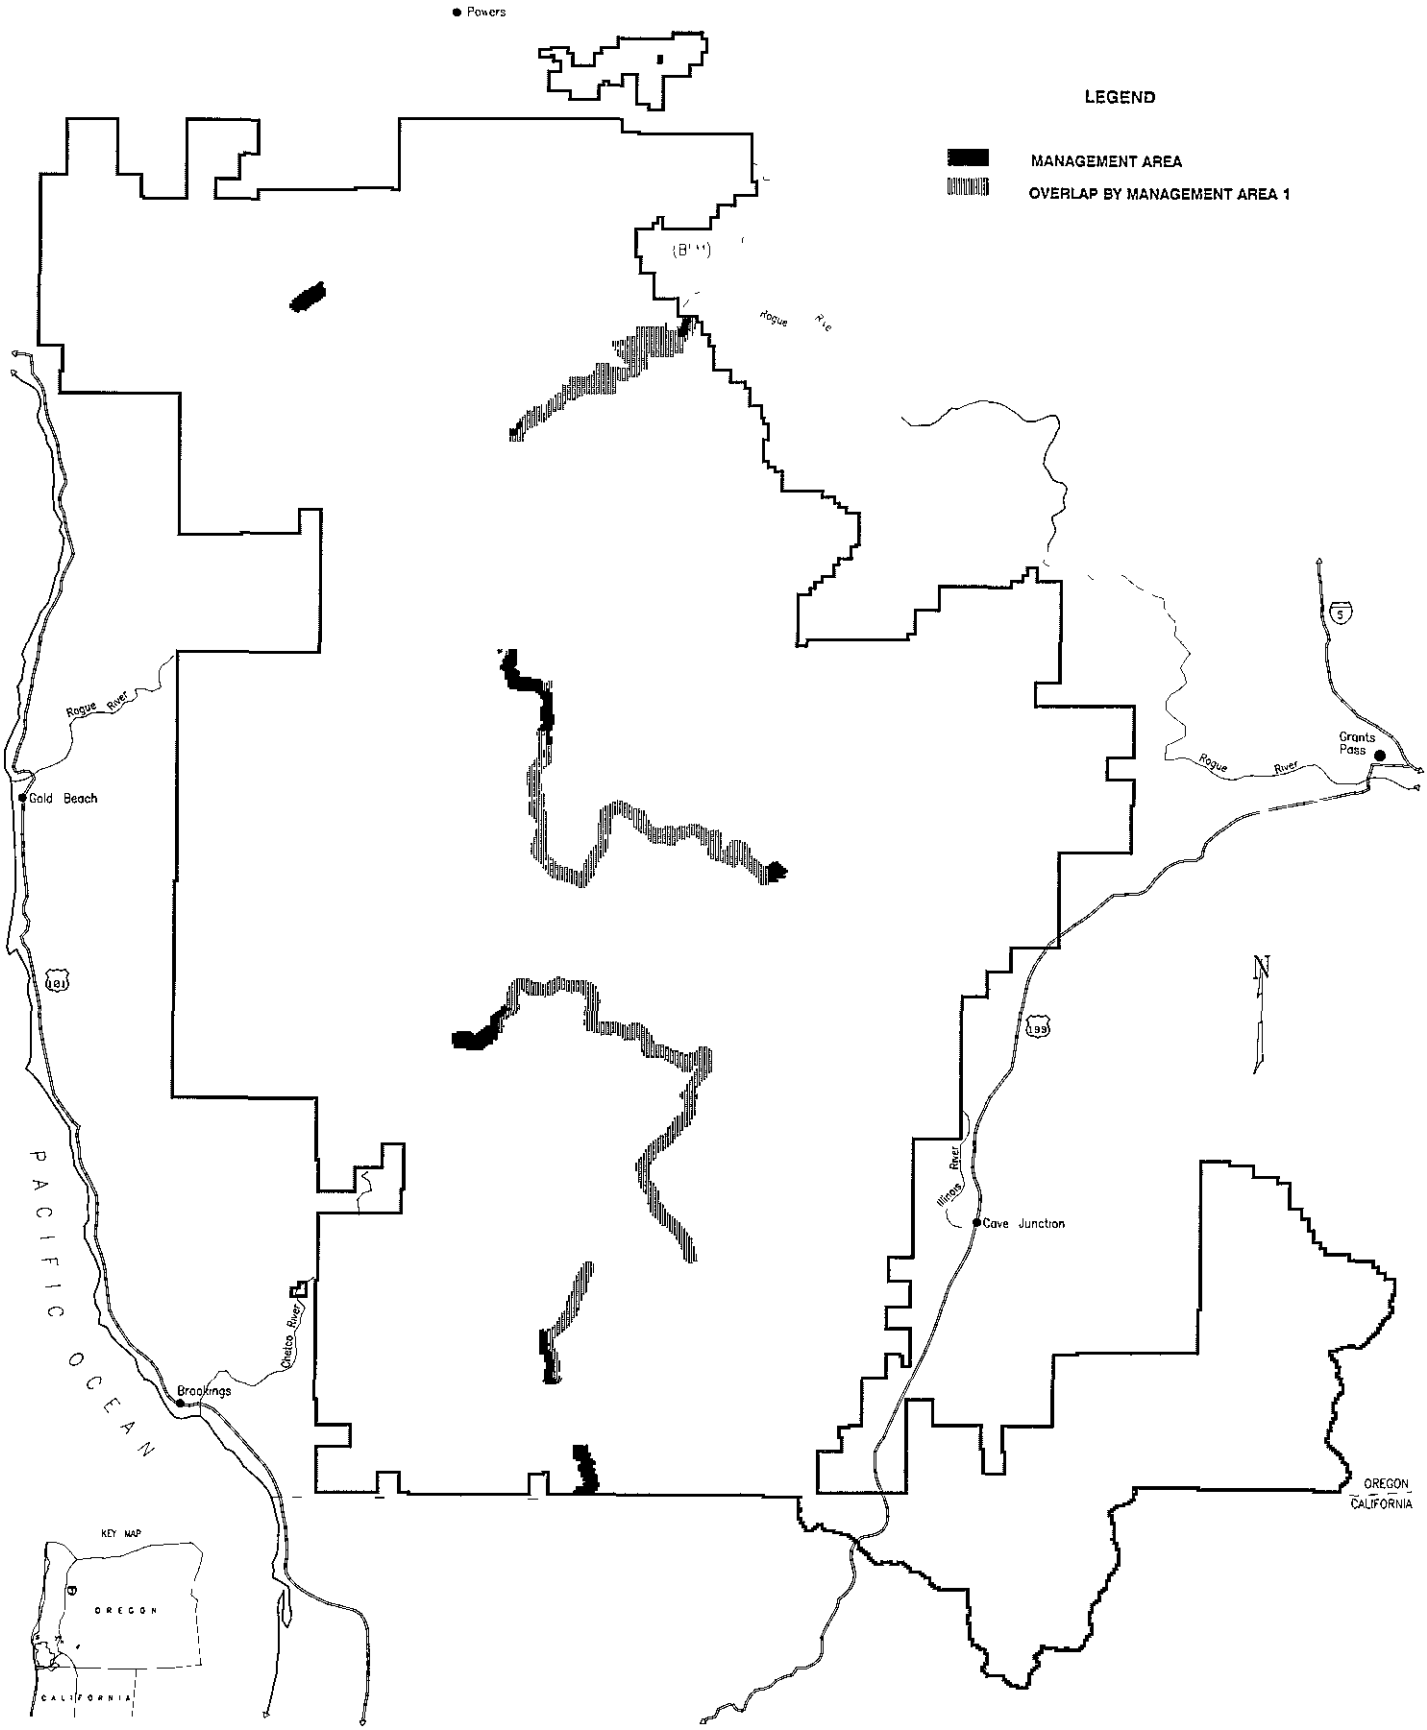

Figure IV-5 Wild River Management Area Map

MANAGEMENT AREA 2 - WILD RIVER

DESCRIPTION

This prescription is applicable to those "Wild" segments of the Rogue, Illinois, Chetco, North Fork Smith, and Elk Rivers which were designated by Congress under the National Wild and Scenic Rivers Act. The Wild designation was reserved for those rivers that are free flowing, free of impoundments and generally inaccessible except by trail. The rivers are incised into deep, often shear-faced rock canyons

The Wild segment on the Rogue extends from Grave Creek downstream to Watson Creek near Foster Bar for a total of 33 miles On the Illinois, the Wild section begins at Briggs Creek and encompasses 28 7 miles down to Nancy Creek. The Wild segment on the Chetco is from the headwaters to Boulder Creek, about 25.5 miles. On the North Fork Smith, there are two wild segments: from the headwaters 6.5 miles to Horse Creek; and from Baldface Creek 2 miles to the Oregon and California stateline The Wild segment of the Elk River is the North Fork Elk, from the falls to its confluence with the South Fork. The corridor boundary averages 1/4 mile on each side of the rivers.

Although the rivers are designated "Wild," the character of each is significantly different and consequently management objectives for each river differ. These objectives are defined in the individual river management plans. The management plans for the Rogue and Illinois rivers are not affected by this Forest Plan It is expected that the popularity of white water rafting and other river-related recreation will continue to increase, so that modifications to these plans can be anticipated at some point in the future. Development of management plans for the Chetco, North Fork Smith and Elk rivers is scheduled to begin in fiscal year 1989. Refer to Figure IV-5 for a map displaying allocated acres within the management area

Table IV-15 Acres Allocated to Wild River

	Acres		
Name	Management Area 2	Overlap by Management Area 1	Total Area
Chetco River	1,008	7,967	8,975
Elk River	607	0	607
Illinois River	1,819	7,456	9,275
North Fork Smith River	1,371	1,674	3,045
Rogue River	224	5,002	5,226
Total	5,029	22,099	27,128

MANAGEMENT GOAL

The goal is to maintain the river environment in a natural state while providing for recreation opportunities.

DESIRED FUTURE CONDITION

The character of the wild section of the Rogue River within the Forest boundary will be maintained. Most of the lands adjacent to this river segment are within designated Wilderness and will be influenced only by natural processes. Impacts due to river-related recreation will be monitored according to the Rogue River Management Plan and any restrictions on use may have been implemented according to that Plan.

The character of the wild section of the Illinois River will be maintained. Within the Kalmiopsis Wilderness, recreation use, both from wilderness and river users will have been monitored and impacts assessed according to the Illinois River Management Plan. The section of the river between Pine Flat and Colliers bar and the lands adjacent will be maintained in a trailess condition. The lands outside the river corridor and within the viewshed adjacent to the last six miles of the wild section of the river will have been managed

in an unroaded status in order to maintain the pristine character of the river corridor. The river is expected to remain among the "wildest" in the western United States; a gem in the Nation's Wild and Scenic River system.

The character of the wild sections of the Chetco, North Fork Smith and Elk rivers will be maintained as well. Development of the individual river management plans will include descriptions of the desired future conditions.

STANDARDS AND GUIDELINES

Many standards and guidelines for the river corridors are in the management plans for the respective rivers and will not be repeated here

Fire Management

MA2-1 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. A modified range of suppression technology and equipment emphasizing indirect attack *should be used. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire* management direction for the Forest.

A high level of wildfire prevention activities with a low level of visibility should be maintained. Only limited field contacts should be made, with most of the contact effort handled through the media and river permit system Hazard reduction activities keyed to heavily-used sites may be used.

Both direct and indirect methods should be emphasized in the treatment of activity fuels Direct treatments should be used where visuals or management risks carry a high priority. Indirect treatment is encouraged outside visually-sensitive or high-risk areas Direct treatment of natural fuels is encouraged

MA2-2 Future utility corridor siting shall be excluded from this Management Area

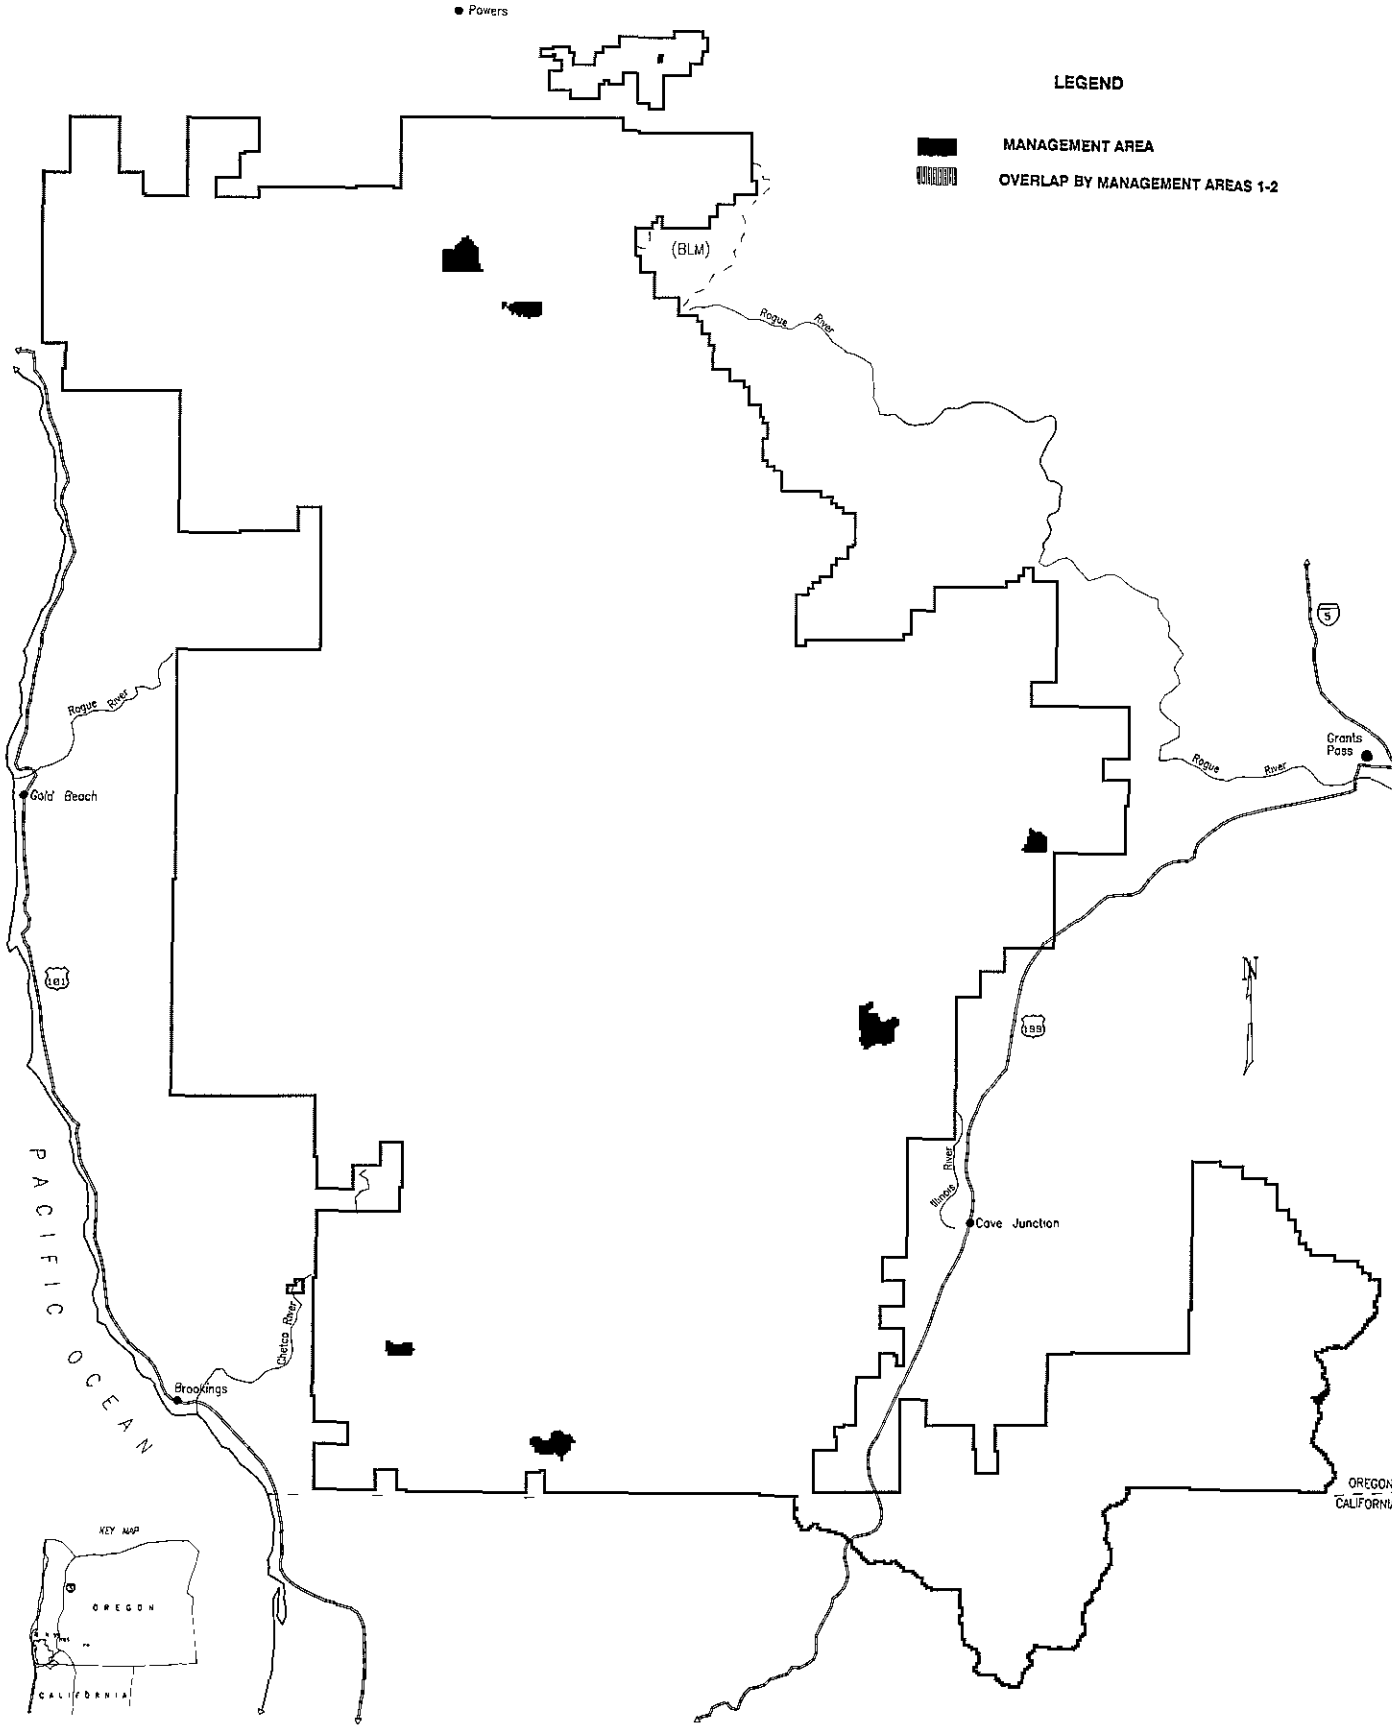

Figure IV-6. Research Natural Area Management Area Map

MANAGEMENT AREA 3 - RESEARCH NATURAL AREA

DESCRIPTION

This prescription is applicable to existing or recommended Research Natural Areas (RNA) (FSM 4063 Research Natural Areas)

Research Natural Areas are part of a national network of field ecological areas designated for research and/or to maintain biological diversity on National Forest System lands. Research Natural Areas are for non-manipulative research, observation, and study. They also may assist in carrying out provisions of special acts, such as the Endangered Species Act and the monitoring provisions of the National Forest Management Act

This Forest Plan provides overall direction and standards and guidelines for management of RNA's The Regional Forester and Pacific Northwest Station Director shall prepare an Establishment Record for each recommended area; this document will describe features, objective for establishment, and management direction. The Establishment Record will be submitted to the Chief of the Forest Service for signature (Designation Order). Once approved by the Chief, an RNA will not be re-evaluated in subsequent rounds of Forest Planning . Refer to Figure IV-6 for a map displaying allocated acres within the management area.

Table IV-16 Acres Allocated to Research Natural Areas

	Acres		
Name	Management Area 3	Overlap by Management Areas 1-2	Total Area
Cedar Log Flat	441	0	441
Coquille River Falls	501	0	501
Craggy Peak	100	0	100
Hoover Gulch	1,292	0	1,292
Lemmingsworth Gulch	818	0	818
Port Orford Cedar	1,120	0	1,120
Wheeler Creek	336	0	336
Total	4,608	0	4,608

MANAGEMENT GOAL

Preservation of naturally occurring physical and biological units where natural conditions are maintained insofar as possible for the purposes of: (1) comparison with those lands influenced by man; (2) provision of educational and research areas for ecological and environmental studies; and (3) preservation of gene pools for typical and rare and endangered plants and animals.

DESIRED FUTURE CONDITION

Areas in condition to provide for naturally occurring physical and biological processes without undue human intervention. Areas containing naturally functioning and evolving plant and animal populations that may serve as a source for gene pools and for education and research on plant and animal communities

STANDARDS AND GUIDELINES

Wild and Scenic Rivers

MA3-1 Wild and Scenic Rivers shall take precedence where they overlap with RNA's Land use regulations are generally more restrictive in Wild portions of Wild and Scenic Rivers than in RNA's, and less restrictive in Scenic portions. Management plans for Wild and Scenic Rivers shall address overlaps with RNA's.

Recreation

MA3-2 Recreation activities and uses within an RNA shall be discouraged if they threaten the values for which the RNA is established; this includes overnight camping, recreation use within 200 feet of lakes, ponds and streams, and pack and saddle stock use All recreation ORV use shall be prohibited If other recreation uses threaten research or education values, closures or permits should be instituted

Education use of an RNA should generally be directed toward the graduate level, but may be approved for any group or purpose On-site interpretive or demonstrative facilities should be prohibited Publicity that would attract the general public to the area shall be avoided.

Existing trails may be allowed to remain as long as the RNA objectives are not compromised See MA3-10 for direction on new trails.

Visuals

MA3-3 Visual management shall meet or exceed the inventoried VQO's of the specific areas

Wildlife and Fish

MA3-4 Introduction of exotic plant, animal, and fish species shall not be permitted. Reintroduction of former native species may be permitted as long as the objectives of the RNA are met. Control of excessive animal populations may be considered where such populations threaten the RNA objectives Hunting and trapping shall not be encouraged. Habitat improvement projects may be approved if they meet the objectives of the RNA

Range

MA3-5 No grazing of domestic livestock shall be permitted.

Timber

MA3-6 Cutting and removal of all vegetation, including firewood, shall be prohibited, except as part of approved scientific investigation.

No action shall be taken against insects or diseases unless the outbreak drastically alters the natural ecological processes within the RNA.

Soil and Water

MA3-7 In cooperation with the PNW Research Station, rehabilitation plans shall be developed and implemented in the event of soil disturbing activities such as fire suppression. Soil stabilization of naturally occurring soil loss or movement should not be permitted unless part of an authorized study.

Minerals

MA3-8 Valid claims existing prior to Research Natural Area designation may be developed. Valid claims existing prior to any withdrawal from mineral entry shall be required to have an operating plan providing the least amount of impact. Research Natural Areas may be recommended for withdrawal from mineral entry in situations where mitigation measures do not adequately protect management area values The mineral potential of the area shall be assessed before withdrawal is recommended.

Lands

MA3-9 An Establishment Record shall be written for each RNA recommended in the preferred alternative of the Forest Plan (joint responsibility of the PNW Station Director and Regional Forester - procedures described in Forest Service Manual 4063)

A management plan should be written for each established RNA The management plan should include analysis of surrounding lands as related to the integrity of the RNA.

All new special uses shall be denied except for permits for research approved by the PNW Experiment Station and directly related to the objective for the particular Research Natural Area (as determined in the Establishment Record) Noncompatible existing special uses shall be terminated

Rights-of-way easements existing before RNA establishment shall be honored Upgrading that would compromise the objectives of the RNA shall be discouraged. The Forest Service should recommend against FERC licenses or permits that compromise the objectives of the RNA

Facilities

MA3-10 New facilities shall not be built except on valid existing mining claims with approved operating plans or as required as part of an authorized study. New roads, fences, or signs shall not be permitted on RNA's unless they contribute to the objectives or to the protection of the area New trails may be allowed only if compatible with the objectives for the area and if approved by appropriate PNW Research officers and National Forest System line officers.

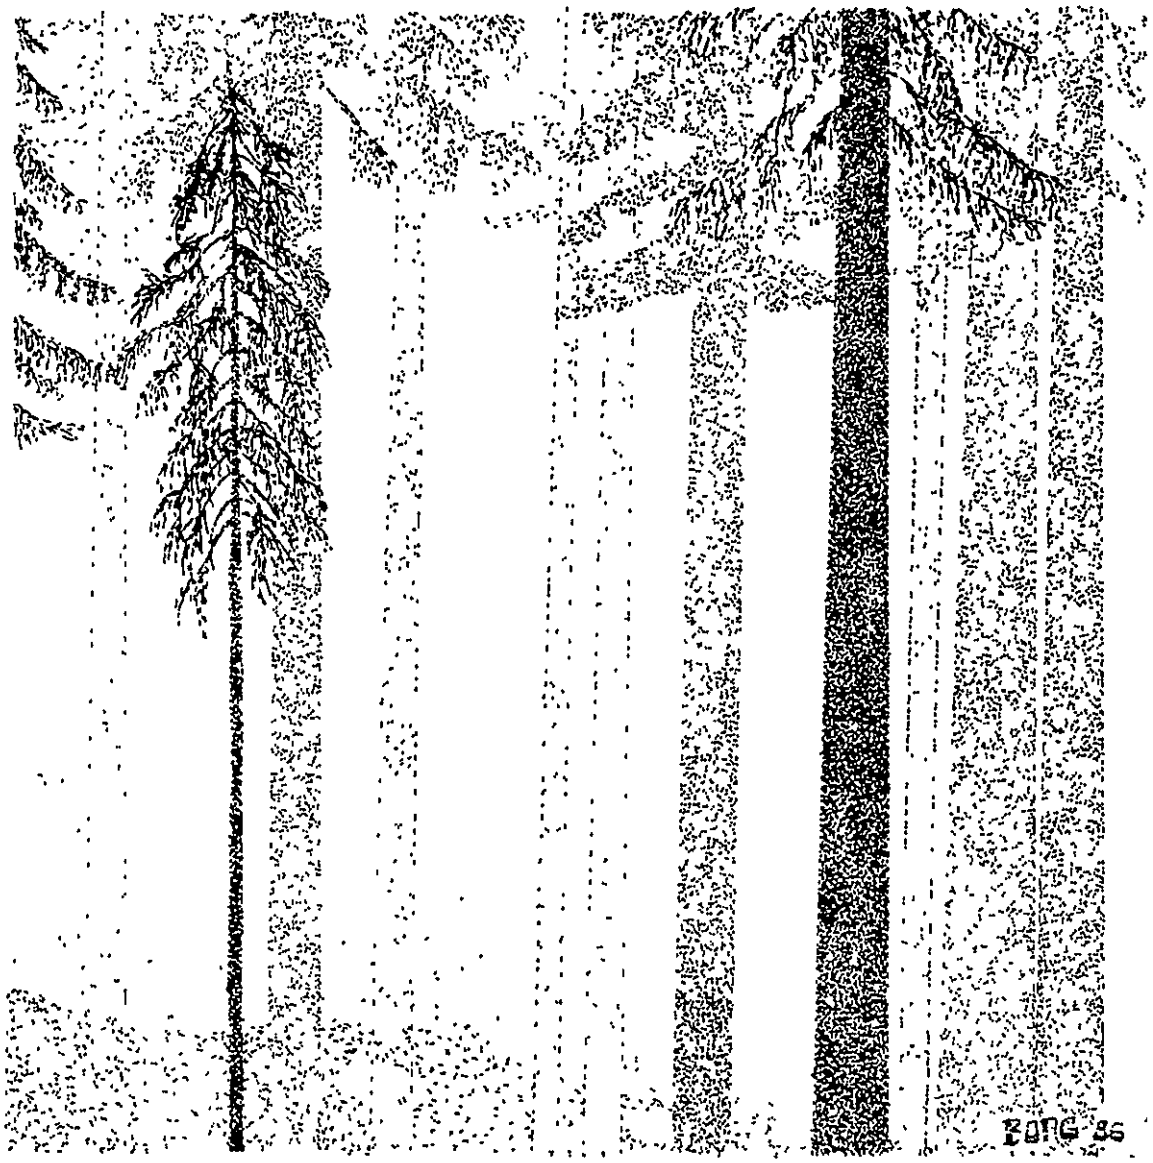
Future utility corridor siting should avoid this Management Area. This Management Area may only be entered following environmental analysis in which all other alternatives have been rejected by the Forest Service.

Hazard tree felling for safety reasons is permitted along trails or roads. Felled trees shall remain in place, unless lying across a trail or road. Trees shall not be removed.

Development of rock sources shall not be permitted; stockpiling of rock materials should not occur. Waste material from road construction, reconstruction, or maintenance shall not be left in RNA's.

Fire Management

MA3-11 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less, 90 percent of the time. A limited range of suppression technology and equipment emphasizing indirect attack should be used. In suppressing fires, chemical fire retardants and ground disturbing activity should be avoided Wildfires occurring at FIL 1 should be handled as outlined in the basic fire management direction for the Forest.



Management should provide for a low level of prevention activities. Prevention public contacts should be limited to those which are made incidental to normal fire management activities, with most of the effort concentrated on techniques that accomplish the fire prevention mission prior to the user entering the area.

If authorized by appropriate PNW Research officers and National Forest System officers, prescribed fire may be utilized as a tool to return fire to its natural role in the area and return plant communities to a condition similar to that which existed prior to active fire suppression. Managed or naturally occurring fire may be use to perpetuate the sere and thus the cell(s) that the RNA is meant to represent. If fire is used to perpetuate a sere, it should mimic a natural fire, but with prudent measures to avoid catastrophe.

Fuels normally should be allowed to accumulate at natural rates unless they threaten the objectives of the RNA

Research

MA3-12 All research proposals shall be approved by the PNW Station Director and any applicable permits obtained from the appropriate NFS line officer. Research should be limited to non-consumptive, non-destructive, and essentially observational activities. Some collecting of soil, plants, or animal specimens (State coordination needed) may be permitted on a case by case basis.

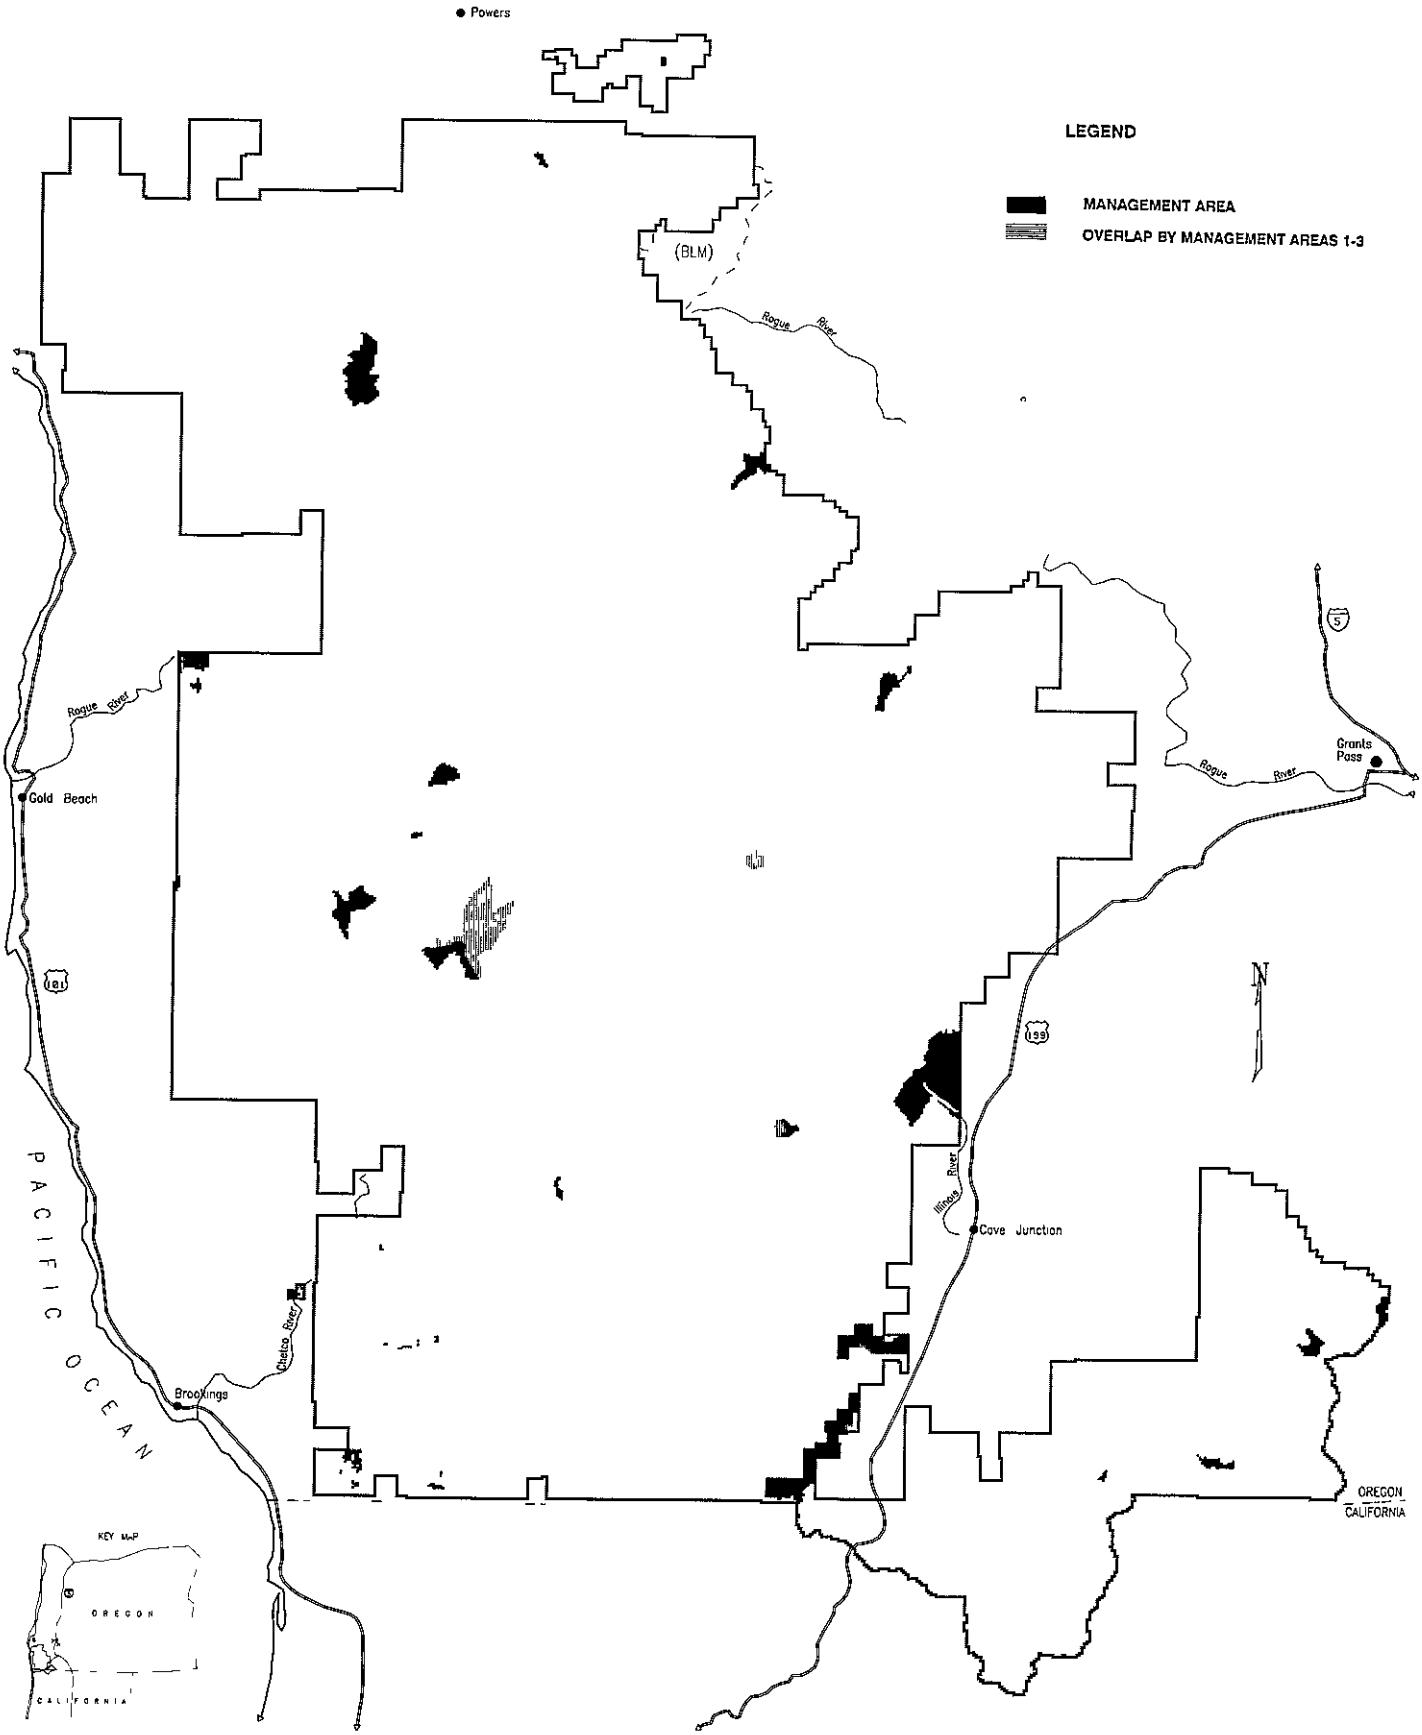


Figure IV-7. Botanical Management Area Map

MANAGEMENT AREA 4 - BOTANICAL

DESCRIPTION

Botanical areas are classified under 36 CFR 294.1 and managed to protect areas of the Forest with important botanical resources (FSM 2370 Special Recreation Designations, Areas Designated Administratively). Management Area 4 includes the best representations found on the Forest of unusual plants indigenous to southwestern Oregon, both sensitive plant and old-growth conifer sites Existing Botanical Areas (Babyfoot, Big Craggies, and York Creek) were established under authority of the Chief of the Forest Service and their status will not be reviewed. Refer to Figure IV-7 for a map displaying allocated acres within the Management Area. See Appendix F of the FEIS for detailed descriptions of areas listed below

Table IV-17 Acres Allocated to Botanical

	Acres		
Name	Management Area 4	Overlap by Management Areas 1-3	Total Area
Babyfoot	221	131	352
Bear Camp	630	0	630
Big Craggies	908	2,895	3,803
Bigelow Lakes	411	0	411
Big Tree	127	0	127
Bolan Lake	297	0	297
Chrome Ridge	589	0	589
Days Gulch	1,252	0	1,252
Eight Dollar Mountain	2,738	0	2,738
Grayback Mountain	197	0	197
Iron Mountain	1,866	0	1,866
Lobster Grove	534	0	534
Oregon Mountain	2,623	0	2,623
Page Mountain Grove	64	0	64
Red Flat	53	0	53
Redwood Groves	500	11	511
Rough and Ready Flat	1,499	0	1,499
Snaketooth Redwood	21	0	21
Snow Camp	1,041	0	1,041
Sourgame	571	0	571
Vulcan	133	0	133
York Creek	0	320	320
Total	16,275	3,357	19,632

MANAGEMENT GOAL

The goal is to protect, preserve, and enhance the exceptional botanical features of these areas

DESIRED FUTURE CONDITION

Natural physical and biological processes will prevail without human intervention. Plant and animal life inhabiting these unique ecosystems will continue to flourish.

STANDARDS AND GUIDELINES

General

MA4-1 Management plans may be developed for individual Botanical Areas; plans may supplement direction provided here, and ultimately should be appended to the Forest Plan (FSM 2372 3 and 2371 2).

Wilderness and Wild and Scenic Rivers

MA4-2 Wilderness shall take precedence where it overlaps with Botanical Areas Wild and Scenic Rivers shall take precedence where they overlap with Botanical Areas Land use regulations are generally more restrictive in Wild portions of Wild and Scenic Rivers than in Botanical Areas, and less restrictive in Scenic and Recreation portions Management plans for Wild and Scenic Rivers shall address overlaps with Botanical Areas.

Recreation

MA4-3 Management of recreational resources is important, but should be secondary to botanical aspects. Education and interpretation shall be the focus of recreational use Interpretive services should be provided to enhance visitor's understanding and appreciation of the area's special features Public use and enjoyment of each Botanical Area shall be encouraged up to the level that will insure protection of the special values for which the area was established.

Recreational use of Botanical Areas and the placement of protective improvements is consistent with the management goals. For instance, it may be appropriate to build trails or boardwalks to direct visitors to or away from specific sites Improvements such as picnic areas are appropriate in Old-growth Groves, however, protective measures may also be required, such as safeguarding Port-Orford-cedar from introduction of root rot.

Existing and potential trails should be permitted, consistent with the goals for the area In general, *use of pack and saddle stock should be discouraged. Vehicles shall not be used off roads and* trails.

Visual Resources

MA4-4 Visual management shall meet or exceed the inventoried VQO's of the specific areas.

Wildlife and Sensitive Plants

MA4-5 Habitat manipulation techniques may be used to maintain existing meadows, provided the objectives for the area are met (may include improvements such as bird boxes and water developments). No other special wildlife management practices should be permitted in these areas, except as needed to meet the objectives of 1) recovery plans for endangered or threatened species, or 2) management plans for sensitive species See Forest-wide Standards and Guidelines for direction on plant collecting.

Range

MA4-6 Livestock grazing shall be prohibited in Botanical Areas, except where such use is part of an existing allotment.

Bigelow Lakes is the only recommended Botanical Area with an existing grazing allotment (Big Grayback Allotment, administered by the Applegate Ranger District of the Rogue River National Forest) Cattle shall be prevented from reaching the Lakes area by a drift fence The effects of grazing in the Bigelow Lakes basin shall be monitored, and corrective action taken as necessary.

Timber

MA4-7 Timber harvesting shall not be programmed and should normally not occur. Timber harvest shall be permitted only under the conditions outlined below.

Timber harvest may be allowed: to eliminate hazards, remove timber incidental to construction or maintenance of improvements; or in case of natural catastrophe, when removal of such timber is necessary to achieving the goals of the management area

Timber harvest may be permitted, if it can be shown to be beneficial to specific endangered, threatened, or sensitive plant species and is shown by environmental analysis to best meet the goals of the management area.

MA4-8 If no other alternative exists, occasional trees situated just inside the boundary of the Botanical Area may be used as logging cable anchors to facilitate harvest of timber from nearby harvest units. Any tree used as an anchor shall be protected from girdling.

MA4-9 Firewood cutting shall not be allowed.

Minerals

MA4-10 Valid claims existing prior to botanical area designation may be developed. Every effort should be made to protect botanical resources, especially sensitive plant species Botanical areas may be recommended for withdrawal from mineral entry in situations where mitigation measures do not adequately protect management area values. The mineral potential of the area shall be assessed before withdrawal is recommended.

Facilities

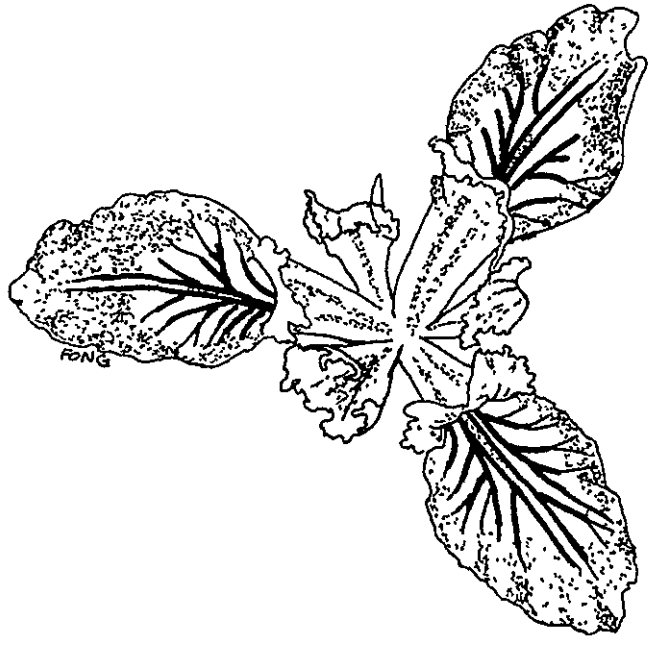
MA4-11 Roads, trails, sanitary facilities, picnic grounds, and parking spaces shall be located without disturbing the special features of Botanical Areas. Developments such as roads, trails, and other facilities shall be kept to the minimum necessary for public enjoyment of the area

Existing facilities should be allowed to remain New facilities (roads, buildings, towers, etc.) may be built if they do not detrimentally affect endangered, threatened, and sensitive plant species or their habitat. New trails, signing, and protective facilities (e.g. boardwalks, fencing) may be allowed.

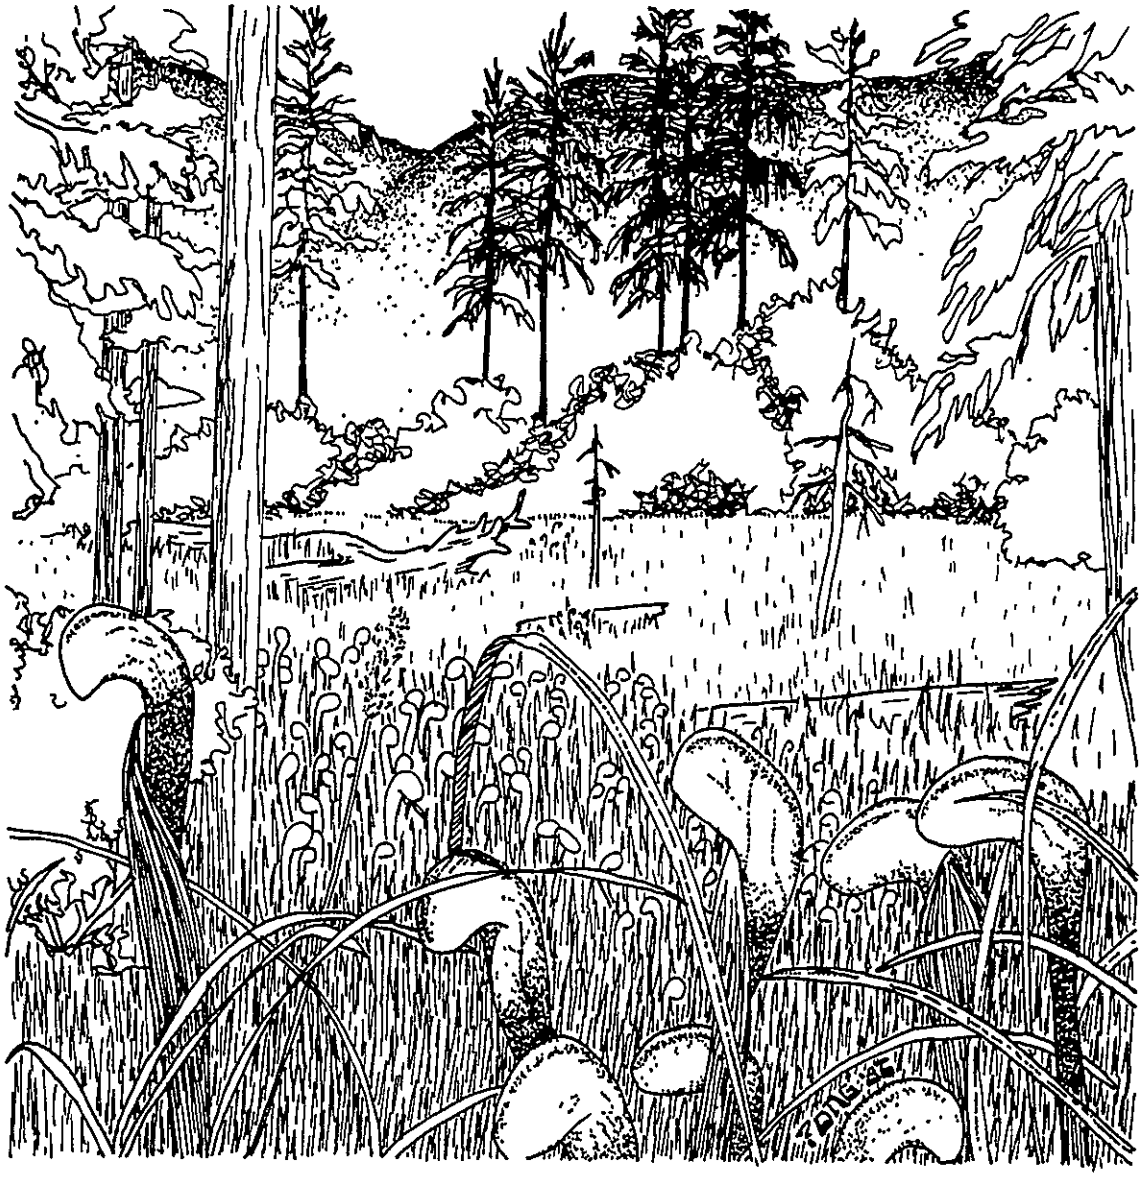
Hazard tree felling for safety reasons is permitted along trails or roads. Felled trees shall remain in place, unless lying across a trail or road. Trees shall not be removed

Development of rock sources shall not be permitted, stockpiling of rock materials should not occur. Waste material from road construction, reconstruction, or maintenance shall not be left in Botanical Areas.

The key resource values, identified in a thorough analysis of the potential effects, should be avoided in future utility corridor siting in this Management Area. Wherever possible, future utility corridor siting should avoid this management area.



Fire Management



MA4-12 All wildfires occurring at FIL 2 or above will be controlled at 30 acres or less 90 percent of the time. A modified range of suppression technology and equipment emphasizing indirect attack will be used. Wildfires occurring at FIL 1 will be handled as outlined in the basic fire management direction for the Forest.

Management should provide a low level of prevention activities Public contacts should be limited, with most of the prevention effort concentrated on techniques that will accomplish the fire prevention mission prior to the user entering the botanical area

MA4-13 *Insect and disease control activities should be used where necessary to protect the outstanding* botanical attractions of these areas

MA4-14 Prescribed fire may be utilized as a tool to return fire to its natural role in the areas and return plant communities to a condition similar to that which existed prior to active fire suppression

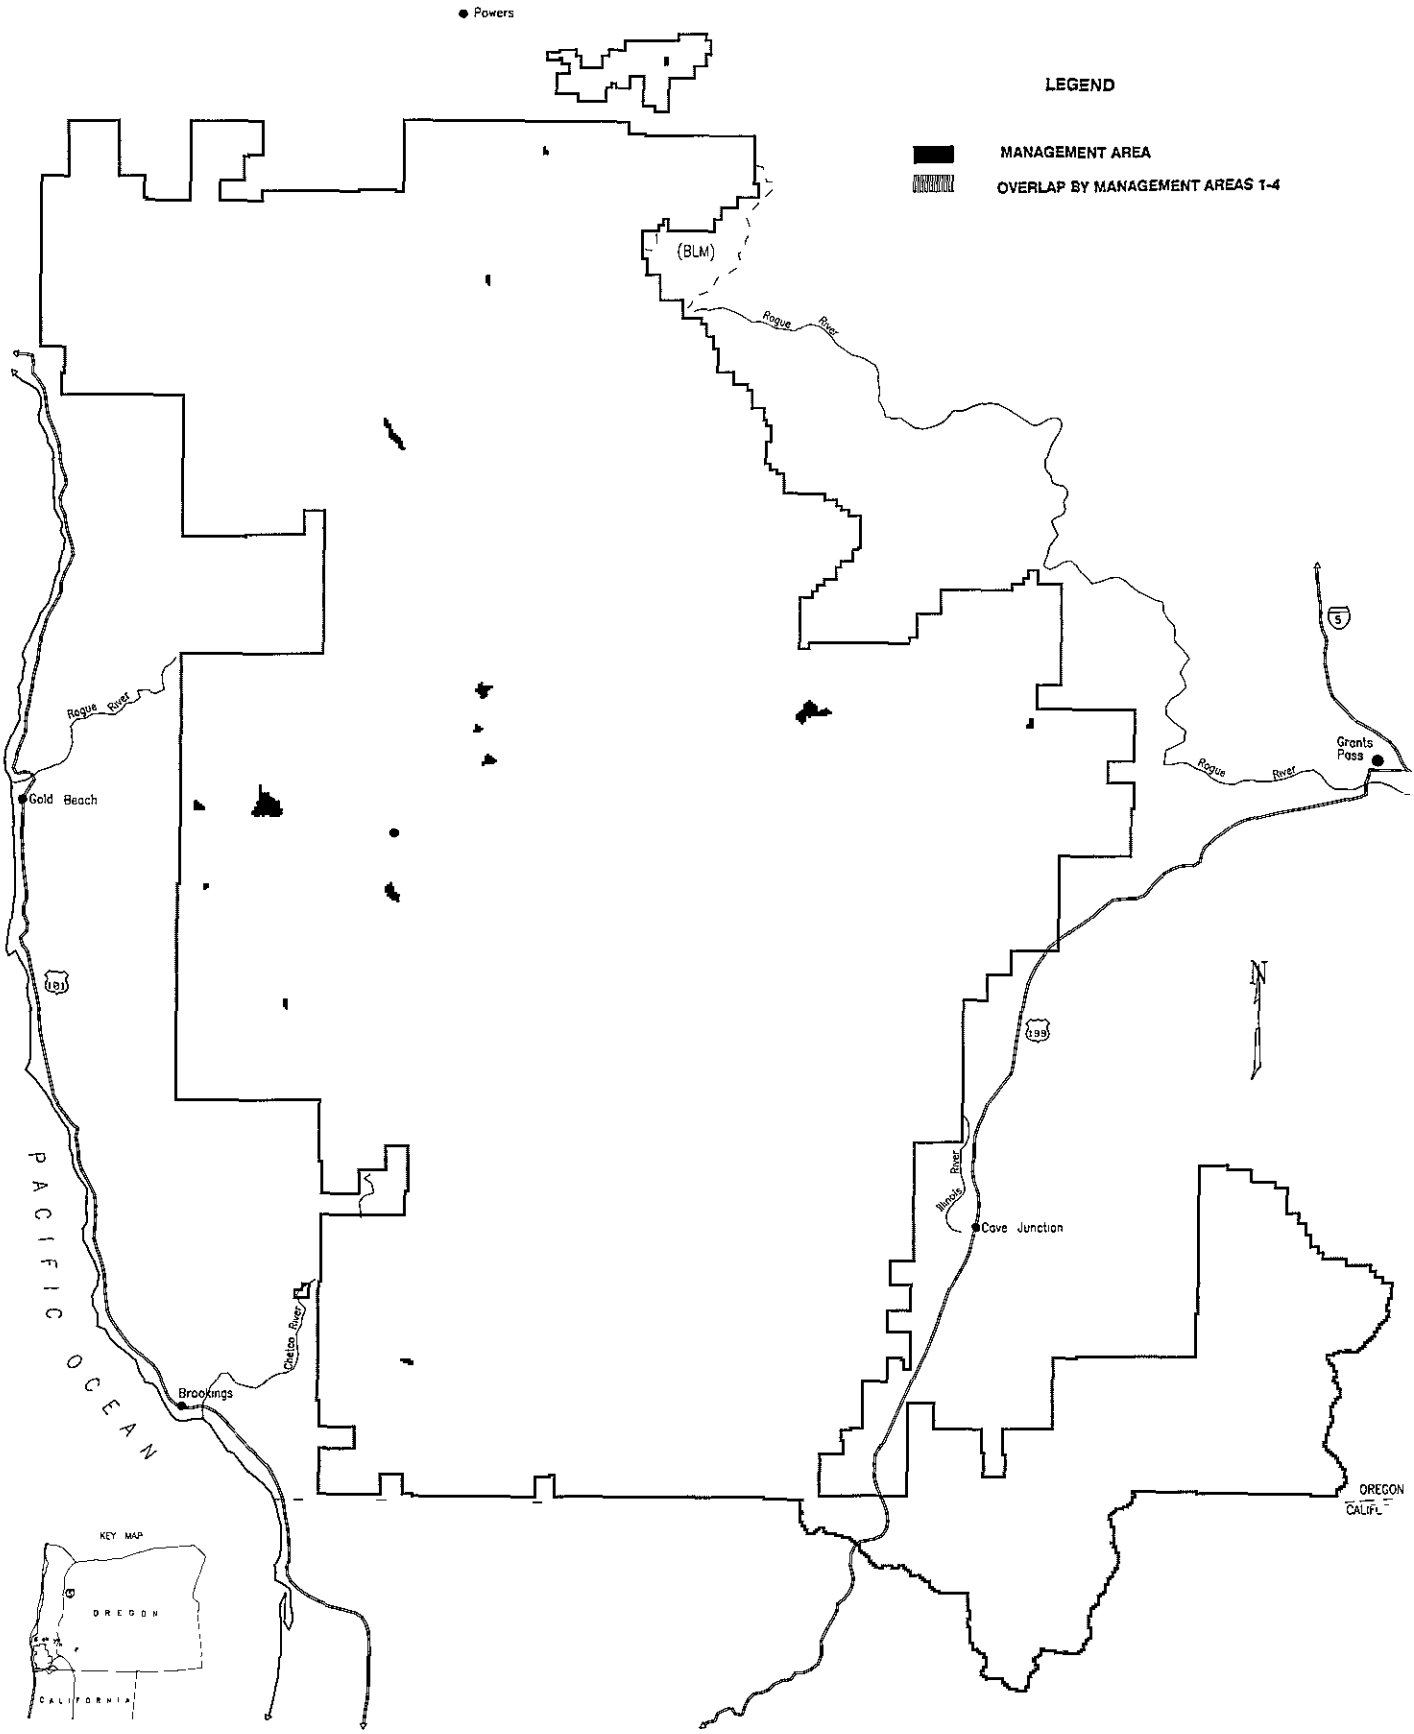


Figure IV-8. Unique Interest Management Area Map

MANAGEMENT AREA 5 - UNIQUE INTEREST

DESCRIPTION

Unique Interest areas are classified under 36 CFR 294.1 and managed to protect, and where appropriate, foster public use and enjoyment of significant cultural or exceptional geologic sites on the Forest (FSM 2360 Special Interest Areas). Cultural sites include prehistoric or historic sites, buildings, or objects of historical significance Geologic sites consist of prominent or unusual rock buttes or waterfalls Refer to Figure IV-8 for a map displaying allocated acres within the management area. This prescription includes the following areas·

Table IV-18 Acres Allocated to Unique Interest

	Acres		
Name	Management Area 5	Overlap by Management Areas 1-4	Total Area
Collier Butte	171	0	171
Devils Half Acre Ridge	203	0	203
Elk Creek Falls	32	0	32
Ferris Ford Cedar Log House	48	0	48
Gray Butte	48	0	48
Horse Sign Butte	101	0	101
Lawson Butte	155	0	155
Pyramid Rock	27	0	27
Quosatana Butte	543	0	543
Saddle Mountain	59	0	59
Signal Buttes	75	0	75
Silver Creek Falls	388	0	388
Stack Yards Rock	48	0	48
Taylor Creek Falls	64	0	64
Wheeler Creek Bomb Site	53	0	53
Total	2,015	0	2,015

MANAGEMENT GOALS

The goal is to protect the significant cultural sites or outstanding geological features on the Forest.

DESIRED FUTURE CONDITIONS

These sites and features will be preserved and managed for education, research, and to protect their unique character The primary benefiting uses of these areas will be for developed and dispersed recreation, research, and educational opportunities.

STANDARDS AND GUIDELINES

Recreation

MA5-1 Existing and potential trails should be permitted, but additional recreational developments should not be undertaken unless needed to protect cultural or geological values Recreational use of these areas and the placement of protective improvements is consistent with the management goals Management of recreational resources is important, but shall be secondary to cultural and geologic aspects.

Visual Resource

MA5-2 Visual management shall meet or exceed the inventoried VQO's of the specific areas

Range

MA5-3 Range use may be allowed if it does not detrimentally affect the management goals of the area.

Timber

MA5-4 Timber harvest shall not be programmed and shall be allowed only to eliminate hazards, remove timber which is incidental to construction or maintenance of improvements, or in case of natural catastrophe when removal of such timber is not detrimental to achieving the goals of the management area Firewood cutting shall not be allowed.

Minerals

MA5-5 Strong mitigation to protect Unique Interest Management Area values is essential Operators of valid claims shall be required to have an operating plan providing the least amount of impact. Unique Interest areas may be recommended for withdrawal from mineral entry in situations where mitigation measures do not adequately protect management area values. The mineral potential of the area shall be assessed before withdrawal is recommended. Rock quarries shall not be permitted.

Lands

MA5-6 Any special use permits issued shall meet the management objectives for these areas.

Facilities

MA5-7 Existing facilities shall be allowed to remain. Roads may be built if they do not detrimentally affect management goals for the area New trails, signing, and protective facilities may be allowed.

Future utility corridor siting should avoid this Management Area This Management Area shall be entered only after environmental analysis, in which all other alternatives have been rejected by the Forest Service

Fire Management

MA5-8 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Direct attack utilizing a modified range of suppression equipment and technology should be emphasized. Wildfires occurring at FIL 1 should be handled as outlined in the basic suppression direction for the Forest.

A high level of wildfire prevention activities with a low level of visibility should be maintained Only limited public field contacts should be made, with most of the contact effort handled through media efforts. Hazard reduction activities may be utilized near heavily-used sites

Both direct and indirect treatment methods should be emphasized in the treatment of activity fuels. Direct treatments should be used where visuals or management risks carry a high priority. Indirect treatment is appropriate outside of visually-sensitive or high-risk areas. Direct treatment of natural fuels is encouraged.

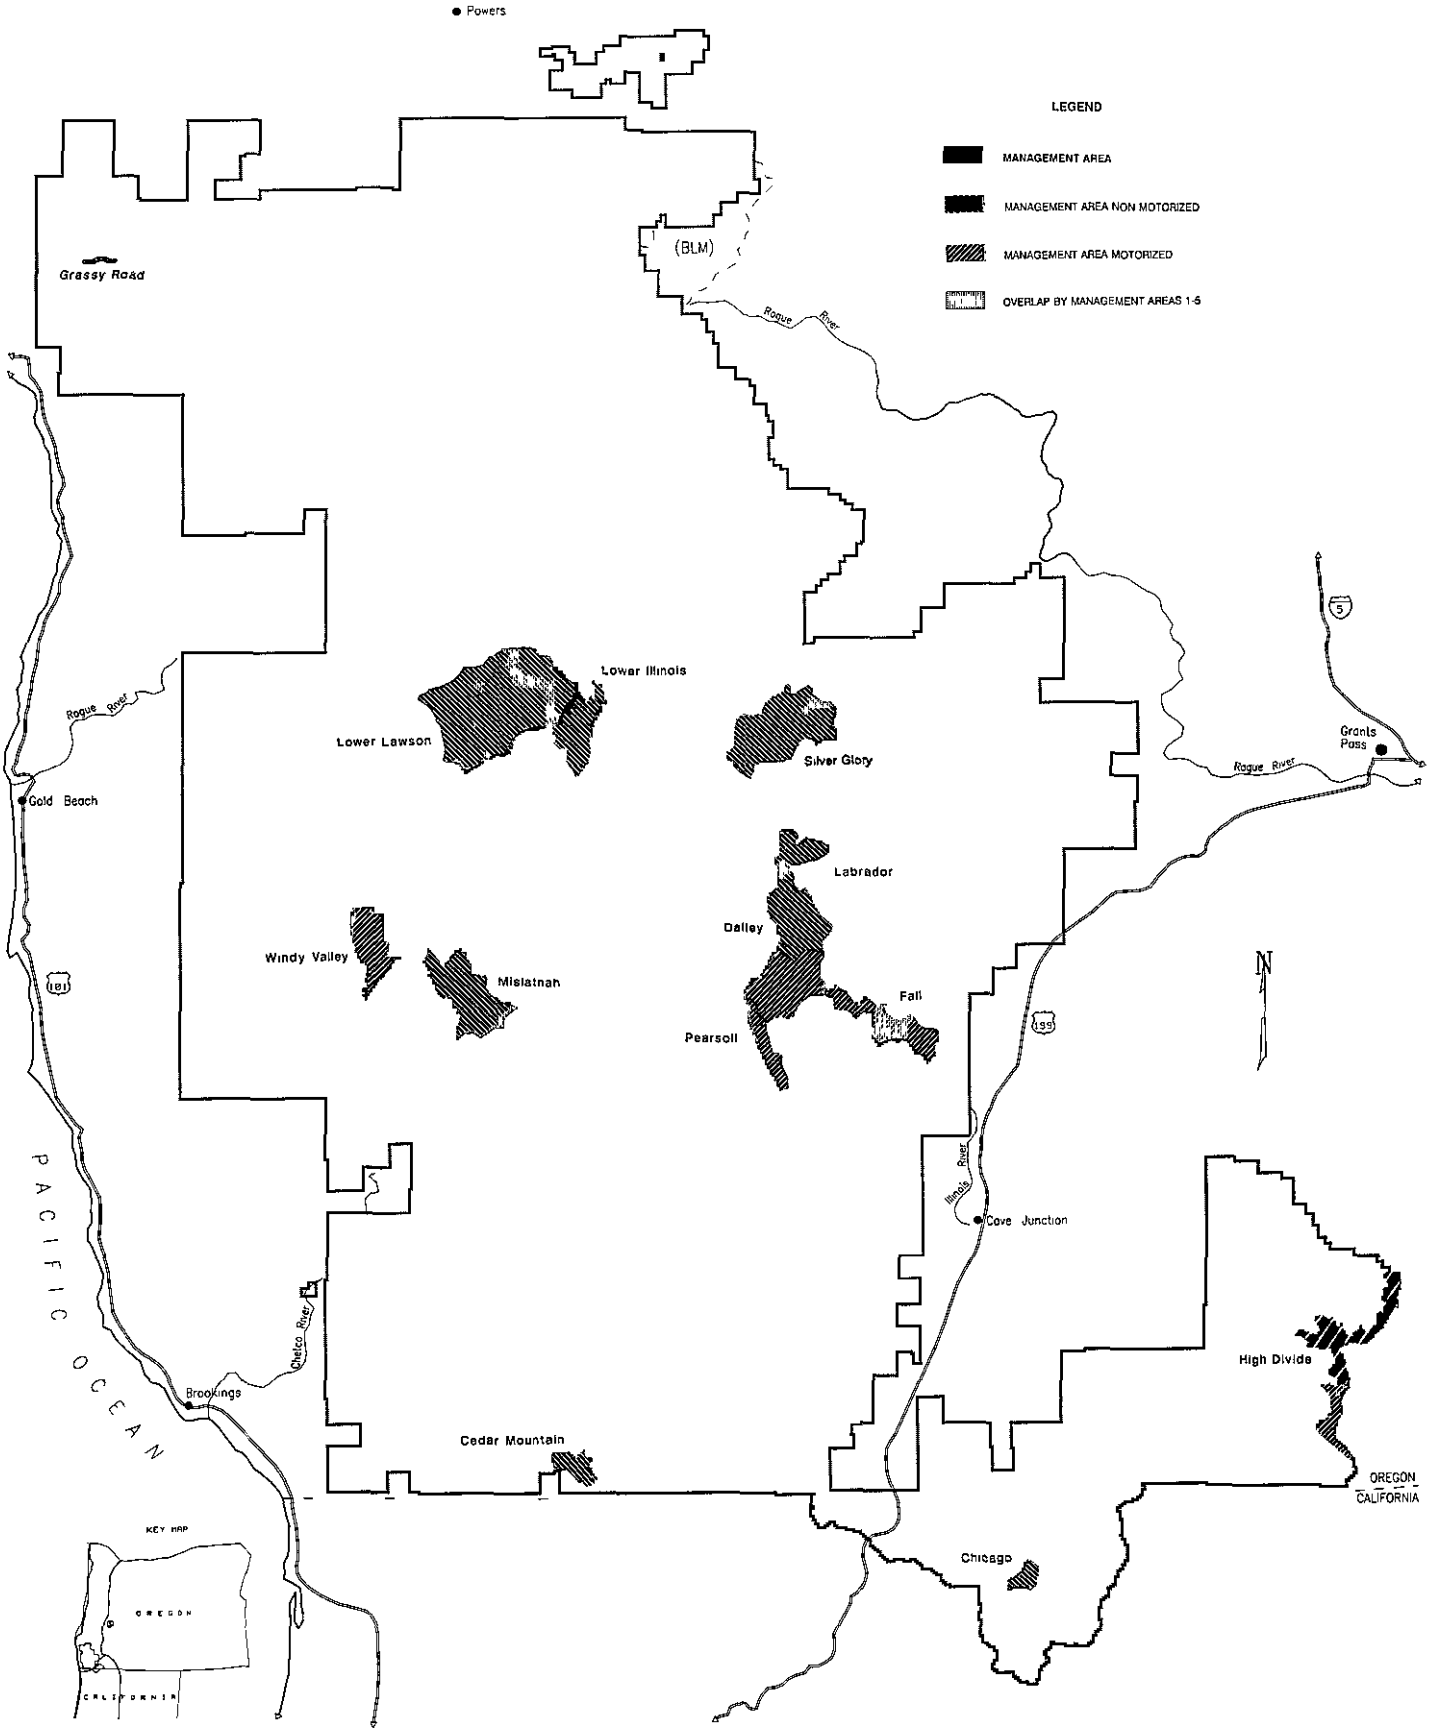

Figure IV-9 Backcountry Recreation Management Area Map

MANAGEMENT AREA 6 - BACKCOUNTRY RECREATION

DESCRIPTION

This prescription applies to areas on the Forest that are unroaded or have little road development. These areas are in a natural or near-natural state, with little or no evidence of human development. Refer to Figure IV-9 for a map displaying allocated acres within the management area. The specific areas covered by this prescription are:

Table IV-19 Acres Allocated to Backcountry Recreation

	Acres		
Name	Management Area 6	Overlap by Management Areas 1-5	Total Area
Motorized			
Dailey	3,598	0	3,598
Fall	1,611	1,247	2,858
High Divide	2,309	711	3,020
Pearsoll	1,333	0	1,333
Windy Valley	2,363	184	2,547
Non-motorized			
Grassy Road	74	0	74
Cedar Mountain	923	350	1,273
Chicago	629	1	630
Labrador	5,435	265	5,700
Lower Illinois	6,256	1,573	7,829
Lower Lawson	6,699	257	6,956
Mislatnah	3,829	417	4,246
Silver Glory	5,812	384	6,196
Total	40,871	5,389	46,260

MANAGEMENT GOALS

The primary goals for this management area are to·

1. Maintain or recreate an essentially undeveloped condition;
2. In areas designated "Non-motorized Backcountry", provide a recreation setting that is appropriate to facilitate Primitive and Semi-primitive, Non-motorized recreation use (Non-motorized use may include the use of human-powered mechanized devices, such as bicycles);
3. In areas designated "Motorized Backcountry", provide a recreation setting appropriate for Semi-Primitive, Motorized recreation use;
4. Provide a minimum of developed recreation facilities, where needed, and where appropriate for the desired recreational experience and environmental setting;
5. Conduct activities and provide improvements which are unobtrusive, or of short duration, and, which complement: (a) recreation management, (b) maintenance and enhancement of fish and wildlife habitat, and (c) administration or management of other resources; and
6. Sustain natural ecological processes, to the extent that other Management Area goals are not impaired.

DESIRED FUTURE CONDITION

In the interior of the areas, there will be moderate to high isolation from the sight and sounds of human facilities and activities Recreational use will be relatively light so that users meet infrequently. The only

facilities will be trails, Primitive camps (including some rudimentary facilities such as toilets, fire rings and cleared, level areas for tents), and relatively inconspicuous facilities needed for wildlife or fish habitat improvement (such as nest structures, created pools or stream passageways). Motorized Backcountry areas will also have primitive roads used as ORV and jeep trails, and may have roads used for mining, or to cross to management areas with timber harvest Human activities do not interfere with natural processes involving the development of vegetation communities and the interactions of wildlife and habitat In some instances, natural processes may be enhanced by management activity.

STANDARDS AND GUIDELINES

Recreation

MA6-1 The Management Area shall be divided into administrative subunits, based on location, presence of existing roads and past history of recreational use. A site-specific recreation management plan shall be developed for each subunit. Primitive facilities may be constructed and maintained, provided they are unobtrusive and do not alter the existing character of the area.

In areas designated "Non-motorized Backcountry," the use of motorized equipment is prohibited, except by:

1. Authorized Forest Service personnel, or their agents, in the performance of approved *administrative or management duties, and*
2. Mining operators, or their agents, within the provisions of approved operating plans.

Visual Resource

MA6-2 A visual quality objective of Preservation will be emphasized in the management of this area Visual quality will be managed at the inventoried VQO's on areas affected by mining activity under approved operating plans Visual quality management will emphasize the maintenance of undisturbed forest character in the viewshed seen from the Wild Illinois River between Silver Creek and Nancy Creek.

Wildlife and Fish

MA6-3 Backcountry Recreation Management Areas are important focal points for habitat diversity. In general, wildlife habitat should be maintained or improved. Fish and wildlife habitat improvement work may be done, provided that activities and structures do not conflict with the long-term recreational objectives for the area.

Habitat enhancement work for Sensitive plant and animal species may be done if recommended as part of a Biological Evaluation. Habitat enhancement work for Threatened and Endangered Species may be done in conjunction with an approved species Recovery Plan

Timber

MA6-4 Timber harvest is not programmed. Harvest shall be allowed only to eliminate hazards, or in capturing losses resulting from catastrophic events. Removal of timber should not occur where it is detrimental to achieving the goals of the Management Area. See Forest-wide Standard and *Guideline 1-12 for guidance on environmental analysis following catastrophic events. If analysis* is initiated, strong consideration should be given to the visual management guidance in MA6-2, above.

Minerals

MA6-5 Administration of mining activities shall be geared to produce the least impact to the Management Area values. On-site reviews by the Forest Mining Engineer shall be made before authorizing ground-disturbing activities in operating plans. Backcountry Recreation areas may be recommended for withdrawal from mineral entry where mitigation measures do not adequately protect resource values The mineral potential of the area shall be assessed before withdrawal is recommended

Facilities

MA6-6 Non-motorized Backcountry - Facilities may be constructed, maintained or managed as follows:

1. Trails and trail structures depending on recreational demand and the capability of the land to support such uses.
2. Facilities required for the administration of the Management Area in a Primitive or Semi-primitive condition.
3. Facilities required to protect the Forest from wildfire.
4. Facilities required to conduct mining operations under approved operating plans.
5. Existing roads not required for approved mining operations shall be closed to motorized use and may be obliterated

Motorized Backcountry - New facilities may be constructed, maintained or managed as follows:

1. Trails and trail structures depending on recreational demand and the capability of the land to support such uses.
2. Facilities required for the administration of the Management Area in a Semi-primitive condition.
3. Facilities required to protect the Forest from wildfire.
4. Facilities required to conduct mining operations under approved operating plans.
5 ORV or Jeep trails may be constructed depending on recreational demand and the capability of the land to support such uses.
6. Roads may be constructed across these areas if needed to manage lands with programmed timber harvest; Motorized Backcountry areas will not landlock other management areas. Environmental analysis of such road proposals will consider the values the Backcountry areas are established for in evaluating alternative routes.
7. Existing roads shall be maintained at Maintenance Level 2 for use as ORV or Jeep trails.
8. Closure may be considered on existing roads for the protection of other resource values.

Future utility corridor siting should avoid this Management Area. This Management Area shall be entered only after environmental analysis, in which all other alternatives have been rejected by the Forest Service.

Fire Management

MA6-7 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. A modified range of suppression technology and equipment emphasizing direct attack should be used. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire suppression direction for the Forest.

A high level of fire prevention activities should be maintained.

Direct treatment methods should be emphasized in the management of natural fuels and any activity fuels.

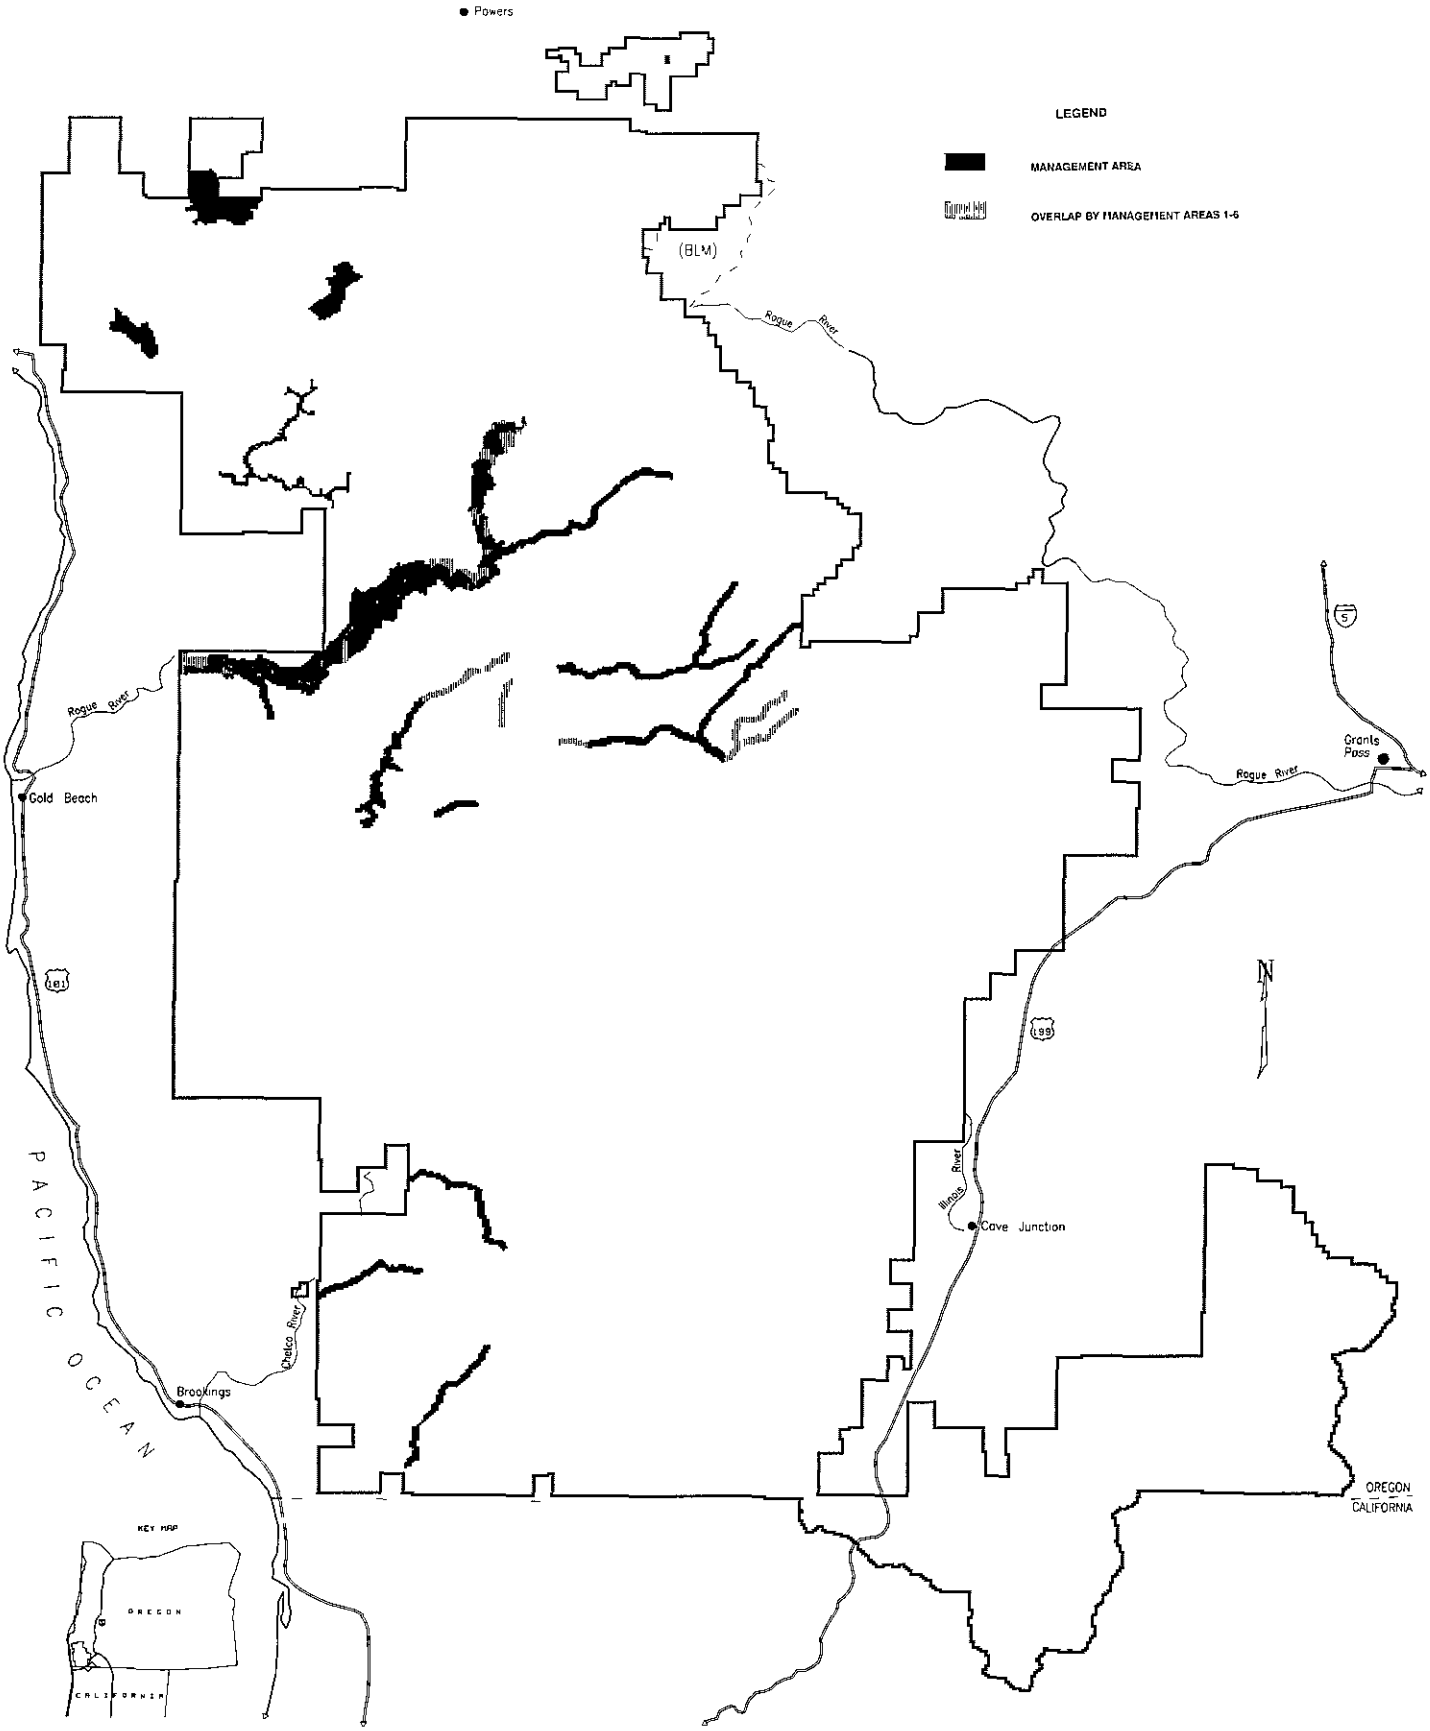

Figure IV-10. Supplemental Resource Management Area Map

MANAGEMENT AREA 7 - SUPPLEMENTAL RESOURCE

DESCRIPTION

This prescription is applicable to areas on the Forest which are considered highly productive or critical habitats for wildlife and fish; are critical for the maintenance of watershed condition; or have special recreation values. Most of these areas are inner gorge along major streams encompassing the land within 1/8 mile on either side of the stream. Refer to Figure IV-10 for a map displaying allocated acres within the management area. The specific areas covered by this prescription are:

Table IV-20 Acres Allocated to Supplemental Resource

	Acres		
Name	Management Area 7	Overlap by Management Areas 1-6	Total Area
Emily Creek	742	0	742
Father Mountain	373	0	373
Horse Sign Creek	0	389	389
Illahe East	469	81	550
Indigo Creek	2,267	0	2,267
Lawson Creek	1,493	691	2,184
Lobster Creek	1,416	0	1,416
North Fork Collier Creek	320	0	320
North Fork Elk River	1,333	606	1,939
Purple Mountain	708	0	708
Quosatana Creek	317	0	317
Rogue River Visual	9,238	705	9,943
Shasta Costa Creek	1,428	0	1,428
Silver Creek	2,357	1,520	3,877
South Fork Chetco	999	0	999
South Fork Sixes River	2,432	0	2,432
Winchuck River	1,029	17	1,046
Total	26,921	4,009	30,930

MANAGEMENT GOALS

The goals are to protect or enhance key fish and wildlife habitats; protect sensitive watershed areas, and protect recreation values.

DESIRED FUTURE CONDITION

These areas will remain in a near natural condition. Timber harvest shall not be programmed; however, some trees may be removed after a catastrophic event. These areas will be withdrawn from power, flood control and water entries.

STANDARDS AND GUIDELINES

Recreation

MA7-1 Trails and camping facilities should be consistent with primitive and Semi-primitive recreation experience Levels I, II, and III (FSM 2300). Existing and planned developed recreation sites may be permitted if compatible with the primary goals for these areas. These areas should generally be managed to remain in a near-natural condition.

The construction of minimum impact hiker trails and primitive camps should be permitted These areas should be maintained at the Semi-primitive, Non-motorized recreation level; except in some areas, motorized equipment may be permitted on designated trails.

Visual Resources

MA7-2 Visual management shall meet or exceed the inventoried VQO's of the specific areas.

Wildlife and Fish

MA7-3 Provide near maximum protection of fishery resources by maintaining, or where practicable, improving water quality and other habitat aspects affecting the production of fish.

Management activities should emphasize the protection or improvement of salmonid fish spawning, rearing, and migration habitat. The following activities may be used where appropriate to accomplish the fisheries objectives:

1. *Improve the rearing capacity for resident salmonids and juvenile anadromous salmonids* through creation of side channels, or pool areas three feet or more in depth Add woody debris where needed for fish cover or channel stability. Revegetate exposed stream banks where needed.
2. Create artificial spawning habitat for salmonid fish species through placement of log weirs or gabions in streams for catching part of the natural gravel progression downstream, or for backfilling with a suitable quality spawning gravel. Create cover for adult fish in connection with spawning habitat.
3. Improve or develop fish passage (migration habitat) at culverts, natural falls, velocity barriers, etc. where the desirability has been determined in cooperation with the Oregon Department of Fish and Wildlife. Examples of improvements are constructing concrete fish ladders, building baffles inside culverts, construction of log gabion or concrete structures to improve pool depth or correct water velocity problems, or modify existing barriers to allow fish passage.

MA7-4 Supplemental resource areas are important focal points for habitat diversity. In general, wildlife habitat should be maintained or improved.

Timber

MA7-5 Timber harvest shall not be programmed and should normally not occur. Timber harvest shall be permitted only under the conditions outlined below.

Timber harvest may be allowed to: eliminate hazards, remove timber which is incidental to construction or maintenance of improvements, or in case of natural catastrophe, when removal of such timber is not detrimental to achieving the goals of the management area.

Timber harvest may be permitted if it is shown to produce specific benefits for fisheries, wildlife, water, or visual resources, and is shown by environmental analysis to best meet the goals of the management area.

Salvage of dead trees should be limited to those trees which are considered to be in excess of wildlife habitat needs, in excess of large woody material needs, or trees in established recreation sites which pose a threat to human safety.

MA7-6 Occasional trees may be used as logging cable anchors to facilitate harvest of timber from nearby harvest units Where required to harvest adjacent areas, corridors for cable logging may be permitted.

MA7-7 Firewood cutting should not be allowed.

Water and Soil

MA7-8 Accelerated soil erosion resulting from management activities within the supplemental resource areas should be minimized or prevented. Minimum impact trails and special construction techniques should be used to minimize the risk of soil movement.

MA7-9 Water quality will be protected, and where practical, improved Efforts should be made to rehabilitate degraded sites or other areas yielding high levels of sediment or turbidity

Minerals

MA7-10 Mining activity is permitted in accordance with mining regulations and an approved operating plan.

Facilities

MA7-11 Stream crossings should be avoided. Where crossing a stream with a road is unavoidable, the stream should be crossed using methods that will minimize adverse impacts to water and fisheries resources. Construction of minimum impact trails and the development of flats into primitive campground sites may be permitted. All facilities shall be developed in keeping with the primary objectives of protecting fish, wildlife, recreation and aesthetic values.

The key resource values, identified in a thorough analysis of the potential effects, should be avoided in future utility corridor siting in this Management Area.

Fire Management

MA7-12 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less, 90 percent of the time. A limited range of suppression technology and equipment emphasizing direct attack should be used. Wildfires occurring at FIL 1 should be handled as outlined in the basic fire management direction for the Forest.

Management should provide for a low level of prevention activities, unless an industrial operation is started Public contacts should be limited, even during high-use periods, with cost of the prevention effort concentrated on techniques that accomplish the fire prevention mission to the forest user entering the area

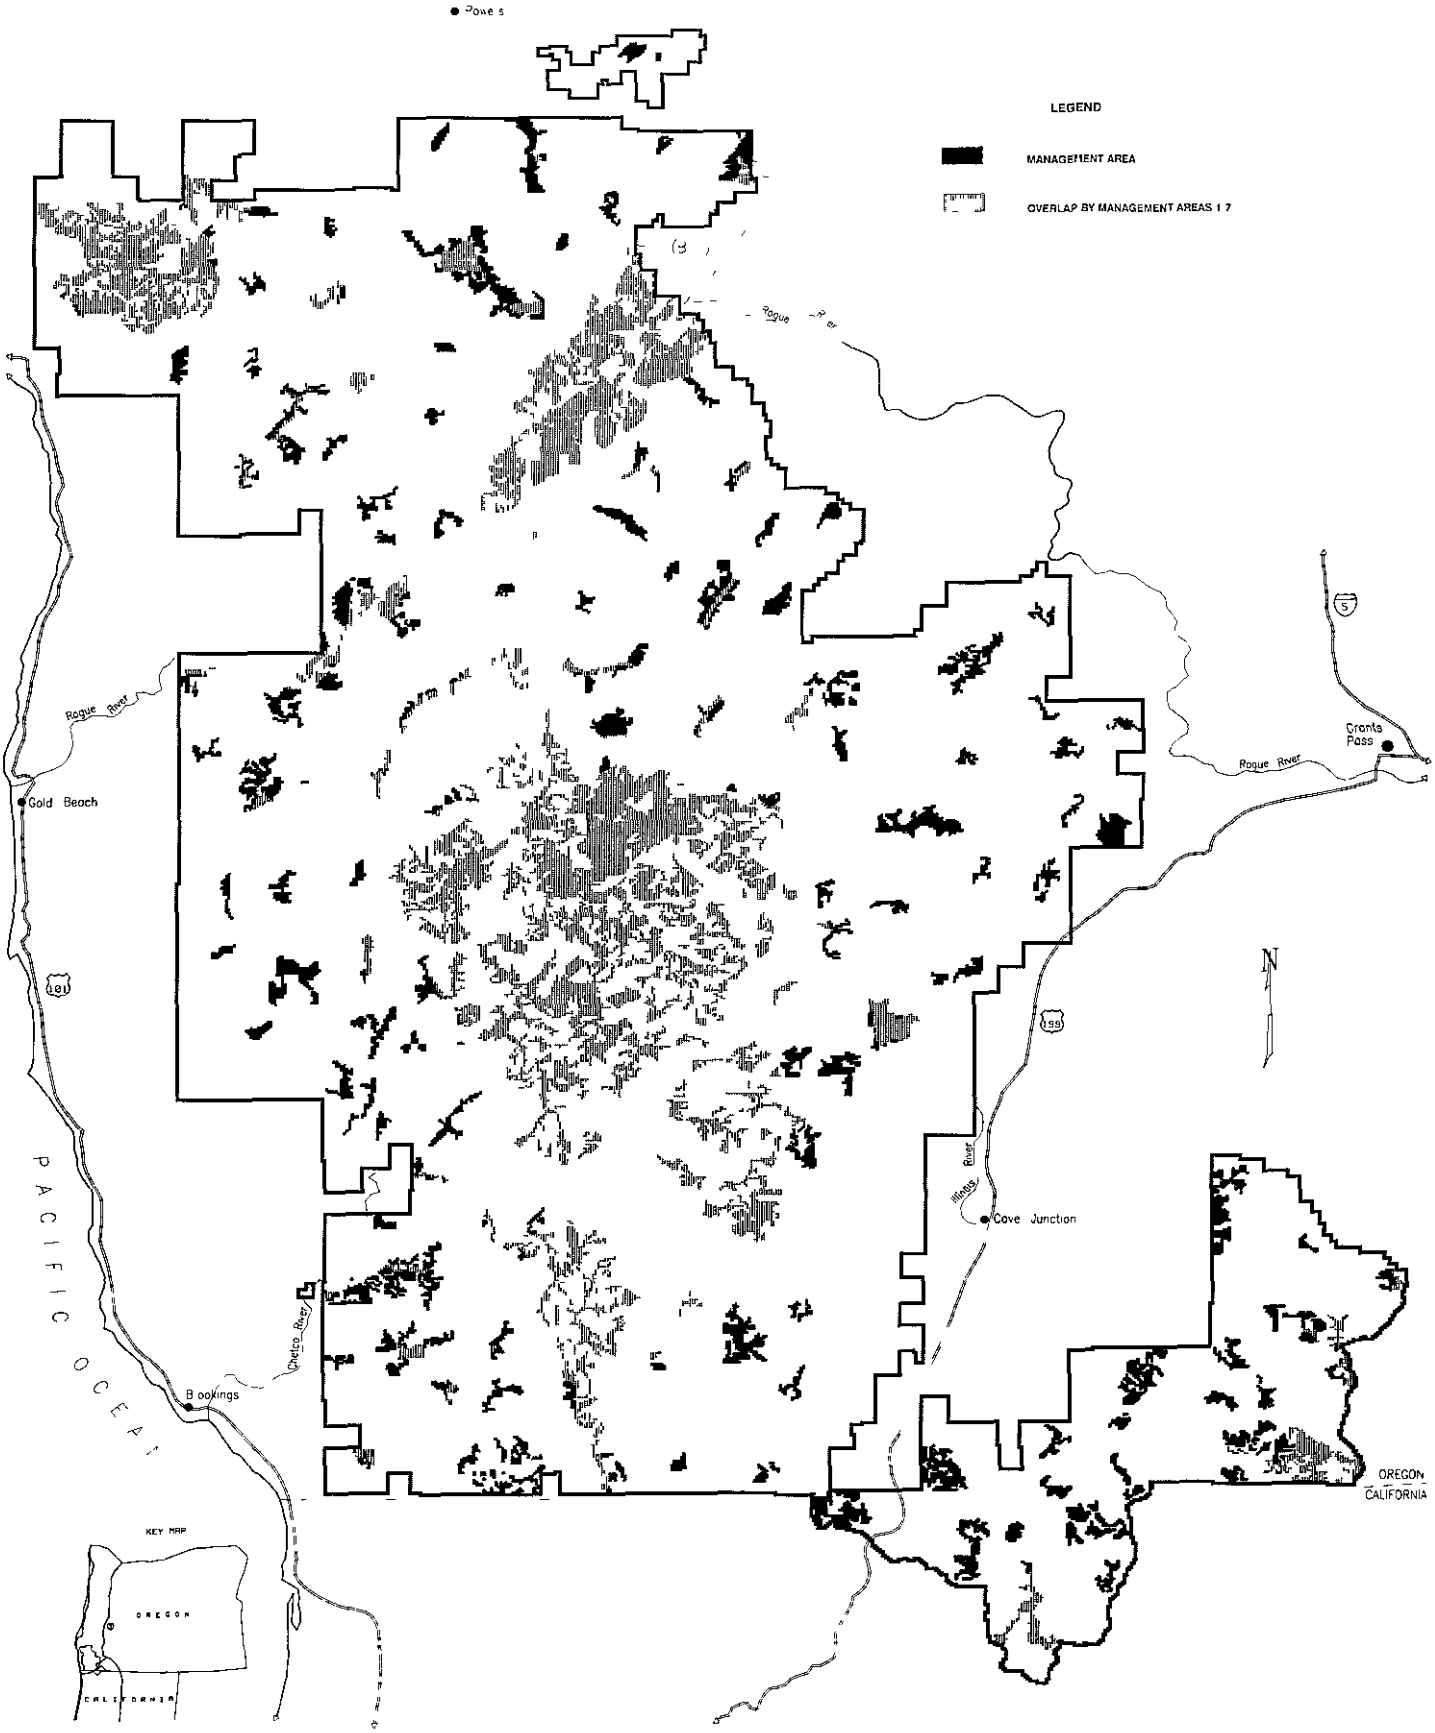

Figure IV-11 Designated Wildlife Habitat Management Area Map

MANAGEMENT AREA 8 - DESIGNATED WILDLIFE HABITAT

DESCRIPTION

This prescription protects habitat sites for spotted owls, pileated woodpeckers, and pine marten These three animals are indicator species for all wildlife inhabitants of mature or old-growth forests. A total of 132,727 acres of habitat are protected in Management Areas 1 through 7 plus 9. Another 5,444 acres of mature and old-growth forest in Management Areas 10-14 are not suitable for timber harvest because of soils or reforestation problems. Management Area 8 contains an additional 41,566 acres necessary to meet Management Requirements (MR's) for those wildlife species inhabiting mature and old-growth forest. Total mature and old-growth habitat protected over the long-term is 179,737 acres

Habitat areas are designated, rather than rotated; no substitute sites are identified as potential replacements. Refer to Figure IV-11 for a map displaying allocated acres within the management area.

Table IV-21. Acres Allocated to Designated Wildlife Habitat

	Acres		
Name	Management Area 8	Overlap by Management Areas 1-7	Total Area
Pileated Woodpecker	14,075	24,793	38,868
Pine Marten	11,851	6,248	18,099
Spotted Owl	24,363	78,619	102,982
Total	50,287	109,660	159,949

MANAGEMENT GOAL

The goal is to protect mature and old-growth habitat for all dependent flora and fauna by providing habitat for the three wildlife indicator species sufficient to maintain viable populations in a well distributed pattern *throughout the Forest (viable populations will be maintained in concert with management of spotted owl* habitat on adjacent public lands: Klamath, Six Rivers, and Rogue River National Forests; Medford, Coos Bay, and Roseburg Districts of the Bureau of Land Management; Oregon Caves National Monument).

DESIRED FUTURE CONDITION

The desired future condition is well dispersed mature and old-growth habitat areas with the optimum characteristics for survival and reproduction of dependent species Characteristics of individual areas will vary somewhat according to the specific indicator they are managed for (see following standards and guidelines for description of habitat areas for spotted owl, pileated woodpecker, pine marten). Although individual mature and old-growth stands may last for many decades, forest conditions are not static; individual areas will not remain as suitable habitat forever. Future plans will likely examine opportunities to enhance habitat in these areas, manage them in an uneven-aged condition, or substitute areas and gradually rotate the designated areas

STANDARDS AND GUIDELINES

Recreation

MA8-1 No new developed recreation sites should be permitted within mature and old-growth habitat areas Dispersed recreation activities are allowed within habitat areas, but should be directed 1,000 feet or more from spotted owl nest sites or roost areas.

These habitat areas shall be managed to provide inventoried levels of dispersed recreation opportunities Minimum developed facilities such as trails may be constructed provided that they do not conflict with management goals It may be desirable to use trails as interpretive facilities in explaining management area objectives to the public

Visual Resource

MA8-2 Visual management shall meet or exceed the inventoried VQO's of the specific areas.

Wildlife and Fish

MA8-3 Existing fish and wildlife habitat shall be maintained or improved, while meeting the primary management goals for the area.

MA8-4 Small inclusions of habitat other than mature or old growth may be included within a specific area, but these acres are not counted as part of the minimum acreage requirements per area, as described below.

MA8-5 Each habitat area (or habitat group, in the case of spotted owls) should be connected to three or more adjacent habitat areas the same size or larger.

MA8-6 Habitat area boundaries and locations may be adjusted to correct errors in mapping; but total acres shall be equal to existing programmed levels.

If an area becomes unsuitable as mature or old-growth forest through fire or other natural catastrophe, it shall be replaced with another nearby suitable area if available. If no suitable area exists, it may be replaced with a capable habitat area. In either case, Management Requirements shall be met as outlined below The exchange process, including disposition of the replaced area, shall be documented though environmental analysis procedures and could result in an amendment to this Forest Plan.

Specific habitat requirements for spotted owl (USDA 1988), and pileated woodpecker and pine marten (USDA 1986) are described below and summarized in Table IV-22

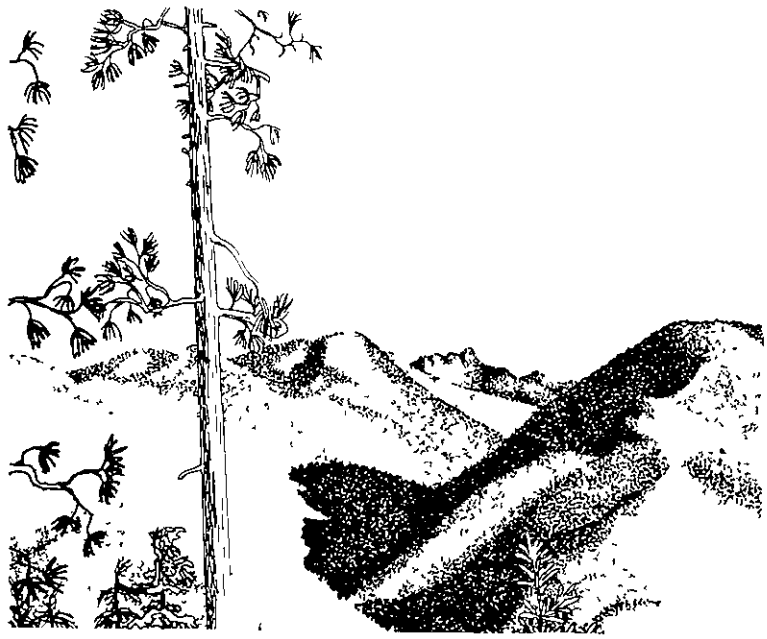

Table IV-22. Summary of Habitat Needs for Pine Marten, Pileated Woodpecker, and Northern Spotted Owl

Habitat Parameter	Pine Marten	Pileated Woodpecker	Northern Spotted Owl
Successional stages required	Mature or Old Growth	Mature or Old Growth	Old Growth or Mature
Acres/Habitat Area in mature/old-growth forest	160 acre/Habitat Area (represents territory of 1 female and part of territory of 1 male)	300 acres/Pair (within a 1,000 acre unit, which also includes 300 acres of feeding habitat)	1,000 acres/Pair (habitat must be within 1 1/2 miles of core center)
Canopy closure	50% or greater	---	Moderate to high
Minimum habitat block size (habitat within each area should be as *contiguous as possible*)	160 acres	50 acres (blocks maximum 1/4 *mile apart*)	300 acres in nesting core, 60 acres in *other habitat*
Maximum dispersal distance between habitat areas	One habitat area for every 4,000 to 5,000 acres (area of circle with diameter of 3 miles)	One habitat area for every 12,000 to 13,000 acres (area of circle with diameter of 5 miles)	6 miles between single pairs, 12 miles between groups of 3 or more pairs, edge to edge
Snag maintenance requirements in habitat areas	Maintain minimum average of 2 hard snags/acre > 12" DBH; 24 of the 320 snags should be > 20" DBH	Maintain minimum average of 2 hard snags/acre > 12" DBH, within the 300 M/OG area; 45 of the 600 snags should be > 25" DBH; within the 300 acres for feeding, maintain minimum average of 2 hard snags/ acre > 10" DBH	Must meet requirements for pileated woodpecker; should have dead standing trees and fallen decayed trees to support abundant populations of prey species, especially n. flying squirrel and woodrat
Down timber requirements	Minimum average of 6 down logs/acre > 12" DBH and 20' long.	Must meet requirements for marten	Must meet requirements for marten

Spotted Owl. The "Final Supplement to the EIS for an Amendment to the PNW Regional Guide (Spotted Owl)" (USDA 1988) provides a general description of suitable habitat; the Siskiyou habitat network for spotted owls conforms to standards and guidelines established in the preferred alternative (F).

Specifically, the Siskiyou's spotted owl habitat occurs predominately in California Mixed Evergreen and Mixed Conifer forest vegetation types; the Siskiyou also supplies relatively small amounts of habitat for spotted owls in the Redwood and Cedar/Hemlock/Douglas-fir forest vegetation types.

The general characteristics of the Forest's spotted owl habitat are (a) relatively large diameter of dominant trees (26 inch average DBH and greater than 20 MBF per acre), with Douglas-fir the dominant overstory species; (b) multi-layered canopy of trees with moderate to high canopy closure in overstory, midstory, and understory layers (greater than 60 percent canopy enclosure - dominant understory tree species are Douglas-fir, white fir, other conifers, and hardwoods), (c) large, tall trees with cavities, broken tops, mistletoe, or platforms of branches capable of holding accumulated organic matter suitable for nesting; (d) dead standing trees and fallen decayed trees to support abundant populations of prey species.

Specific old-growth stand characteristics vary from site to site. Objectives should be to maintain dense multi-layered stands on which overstory trees are at least 200 years old, and understory trees range in age from saplings to 200 years old; i e , uneven-aged understory

Each spotted owl habitat area shall contain at least 1,000 acres of coniferous old-growth habitat below 5,000 feet elevation. On each site managed for a pair of owls, maintain an old-growth core area of at least 300 acres around the nest and an additional 700 acres of old-growth foraging habitat within a 1 5 mile radius of the nest or core center. If 1,000 acres of old growth does not exist within a 1 5 mile radius of the nest, then the oldest stands available shall be designated and managed in the same manner as old growth. There shall be no overlap of breeding or feeding habitat between adjacent pairs. Each habitat area should be as contiguous as possible. For spotted owls, the habitat area should include at least one 300 acre block that includes the nest site; block size of other habitat should be at least 60 acres.

Whenever possible, spotted owl habitat areas should be in groups of three or more (three or more pair per group), with the core areas one to three miles apart. Habitat groups should be no more than 12 miles apart, edge to edge. Occasionally, single habitat areas must be designated where only remnant habitat exists, or to improve distribution or take advantage of areas with known nesting pairs. In these instances the nearest adjacent habitat area(s) must be spaced no more than six miles away (edge to edge). Whenever possible, habitat areas should be connected by 200-foot wide (minimum) corridors of forest land with trees at least 30 years old; gaps of not more than 500 feet are acceptable (Eric Forsman, personal communication).

Spotted owl habitat areas shall also serve as sites for pileated and marten habitat areas.

Habitat suitability index models can be used to rate sites designated for spotted owls. Laymon and others (1985) compare specific variables: average DBH of overstory trees (over 36 inches DBH is best), percent tree canopy cover (70 percent); tree canopy diversity (multi-storied)

Pileated Woodpecker Each pileated woodpecker habitat area shall contain at least 300 acres of mature or old-growth coniferous forest habitat for reproduction and 300 additional acres of feeding habitat (USDA 1986). The 300 acres of feeding habitat is not part of this management area. However, each 600-acre area shall be mapped and managed as one unit. The entire 600-acre area shall be surveyed during Forest Plan Monitoring activities

Each habitat area shall support one pair of pileated woodpeckers This 600 acres should be within a 1,000-acre unit Each habitat area should be as contiguous as possible. If contiguous habitat for pileated woodpeckers is not available, the minimum block size is 50 acres, with blocks no more than 1/4 mile apart.

Mature or old-growth forest will support pileated woodpeckers. Most habitat areas for pileated woodpeckers will be in old-growth forest. Old growth is described under spotted owls above Minimum stand age for mature forest habitat is approximately 100 years. Stand parameters for mature forest habitat are similar to those listed above for old growth in the spotted owl section, except that size of dominant trees is less (average 20 inches DBH, and volume per acre is in the 20 MBF range); trees are not as tall and cavities, broken tops, mistletoe, or platforms of branches are not as prevalent.

At least 2 hard snags per acre equal to or greater than 12 inches DBH shall be maintained in the 300-acre reproduction area. Forty-five of these 600 snags should be equal to or greater than 25 inches DBH. According to Brown (1985) reproduction habitat must contain at least six hard snags over 24 inches DBH and 40 feet tall per hundred acres. The 300 acres of feeding habitat may be of any age, but must contain a minimum average of 2 hard snags per acre equal to or greater than 10 inches DBH. Pileated habitat areas should be spaced at the rate of one site per every 12,000 to 13,000 acres (area of a circle with a diameter of five miles).

Pileated habitat areas will also serve as sites for marten habitat areas

Habitat suitability index models can be used to rate sites designated for pileated woodpeckers. Schroeder (1982) assumes overall habitat suitability for the pileated woodpecker is limited by either the density (over 75 percent canopy closure is best) and maturity (100 or more years) of the forest, or the abundance of snags. Other index models may be developed from studies done in southwest Oregon habitats (such as by Mellen [1987]).

Pine Marten. Each marten habitat area shall contain at least 160 acres of contiguous mature or old-growth coniferous forest At least 2 hard snags per acre equal to or greater than 12 inches DBH shall be maintained within each habitat area; 24 of the 320 snags shall be equal or greater than 20 inches DBH. Also, a minimum average of 6 down logs equal to or greater than 12 inches DBH and 20 feet long shall be maintained per acre (USDA Forest Service 1986).

Mature or old-growth forest will support pine marten. Most habitat areas for pine marten will be in old-growth forest. Old growth is described under spotted owls above; stand parameters for mature forest habitat are described under pileated woodpeckers. Each pine marten habitat area represents the territory of one female and part of the territory for a male. Habitat areas shall be spaced at the rate of one site per every 4,000 to 5,000 acres (area of a circle with a diameter of three miles)

Habitat suitability index models can be used to rate sites designated for pine marten Allen (1982) states that overall habitat suitability for marten is determined by four habitat variables: percent tree canopy closure (50 percent or better is optimum), percent of overstory canopy closure comprised of fir or spruce (more than 40 percent), successional stage of stand (mature or older), percent ground surface covered by downfall which is three inches or greater in diameter (best between 20 percent and 50 percent).

Timber

MA8-7 Timber harvesting shall not be programmed and should normally not occur. Down or dead material should not be salvaged Where necessary, uneven-aged management may be used to

insure that the goals for the management area are met Timber harvest shall be permitted only under the conditions outlined below.

1. Timber harvest may be allowed: to eliminate hazards; remove timber incidental to construction or maintenance of improvements; or in case of natural catastrophe, when removal of such timber is necessary to achieving the goals of the management area.
2. Timber harvest may be permitted, if it can be shown to be beneficial to specific endangered, threatened, or sensitive plant species and is shown by environmental analysis to best meet the goals of the management area.

MA8-8 Occasional trees situated just inside the boundary of a designated wildlife habitat area may be used as logging cable anchors to facilitate harvest of timber from nearby harvest units Any tree used as a anchor should be protected from girdling.

MA8-9 Firewood cutting shall not be allowed.

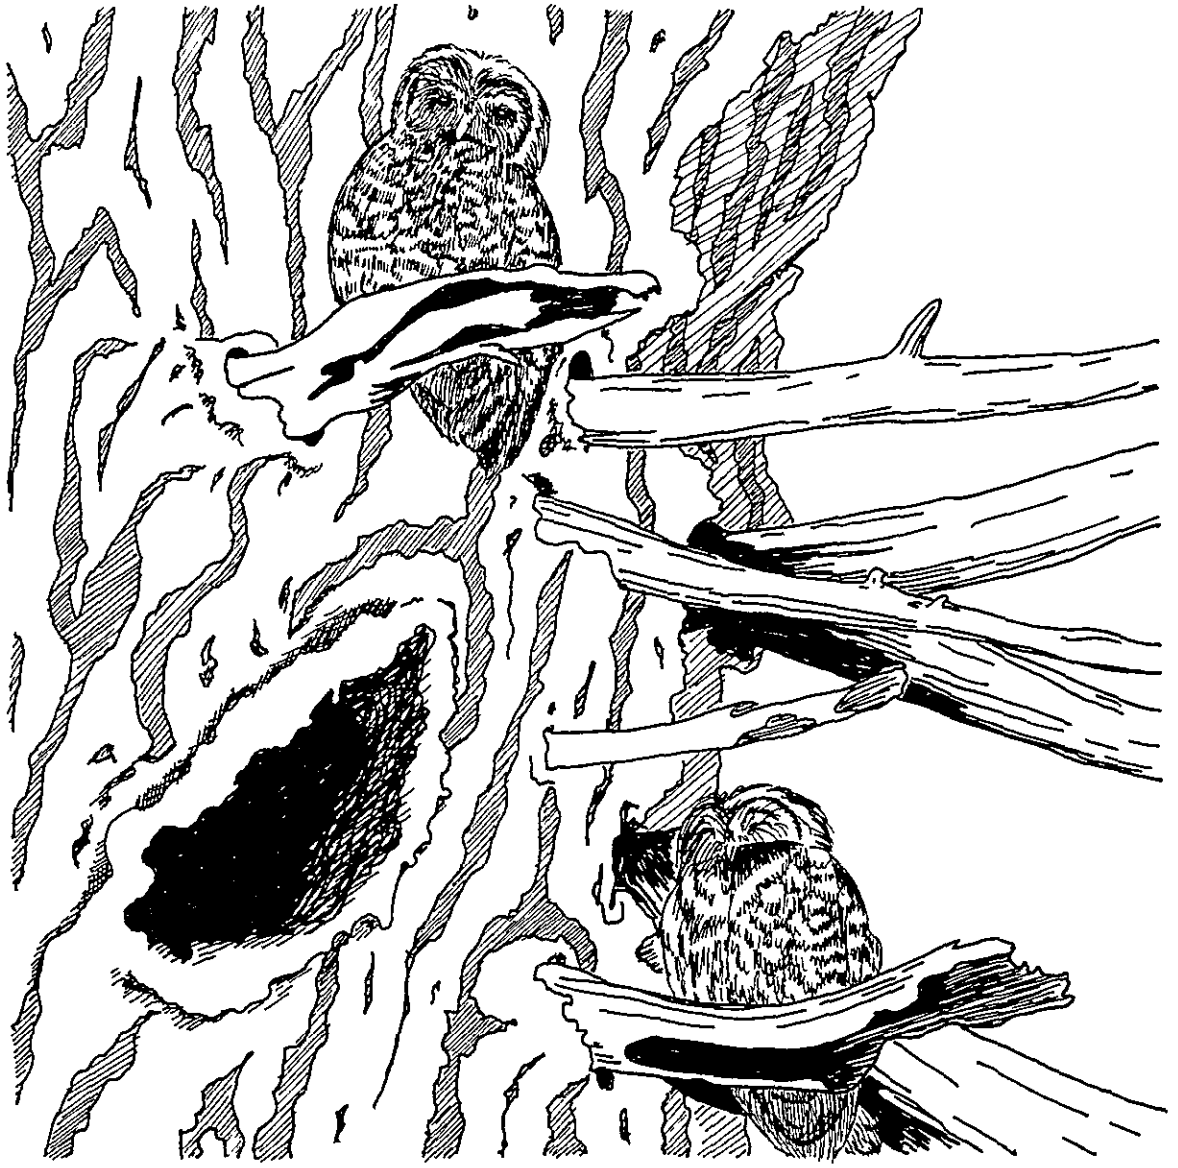
Range

MA8-10 Livestock may be grazed in openings within mature and old-growth habitat areas provided management objectives for the habitat areas are maintained.

Minerals

MA8-11 On valid claims, approve operating plans for mineral activities which minimize detrimental effects to designated habitat (mature and old growth).

Facilities



MA8-12 Trails, roads or buildings may be developed provided no significant impact occurs and they do not come within 1,000 feet of a spotted owl nest tree or regularly used roost area. Proposed road locations shall be intensively inventoried for pileated woodpecker and spotted owl nest and roost locations, and pine marten den sites. If new roads and trails usurp more than one percent of the mature and old-growth habitat in an area, then an equal amount of mature and old growth should be added to the habitat area along the periphery.

The key resource values, identified in a thorough analysis of the potential effects, should be avoided in future utility corridor siting in this Management Area.

Fire Management

MA8-13 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Direct attack should be emphasized utilizing a modified-to-full range of suppression technology and equipment. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction of the Forest.

A high level of prevention activities should be provided. Industrial and other operations should be carefully monitored. Industrial closures should be carried out as required by existing contracts and local fire weather conditions. Public contacts through field personnel and other media should be encouraged. Intensive prevention efforts should be made during high fire danger and high-use periods. Signing should be used as appropriate. Direct treatment methods should be emphasized in the management of natural fuels and any activity fuels.

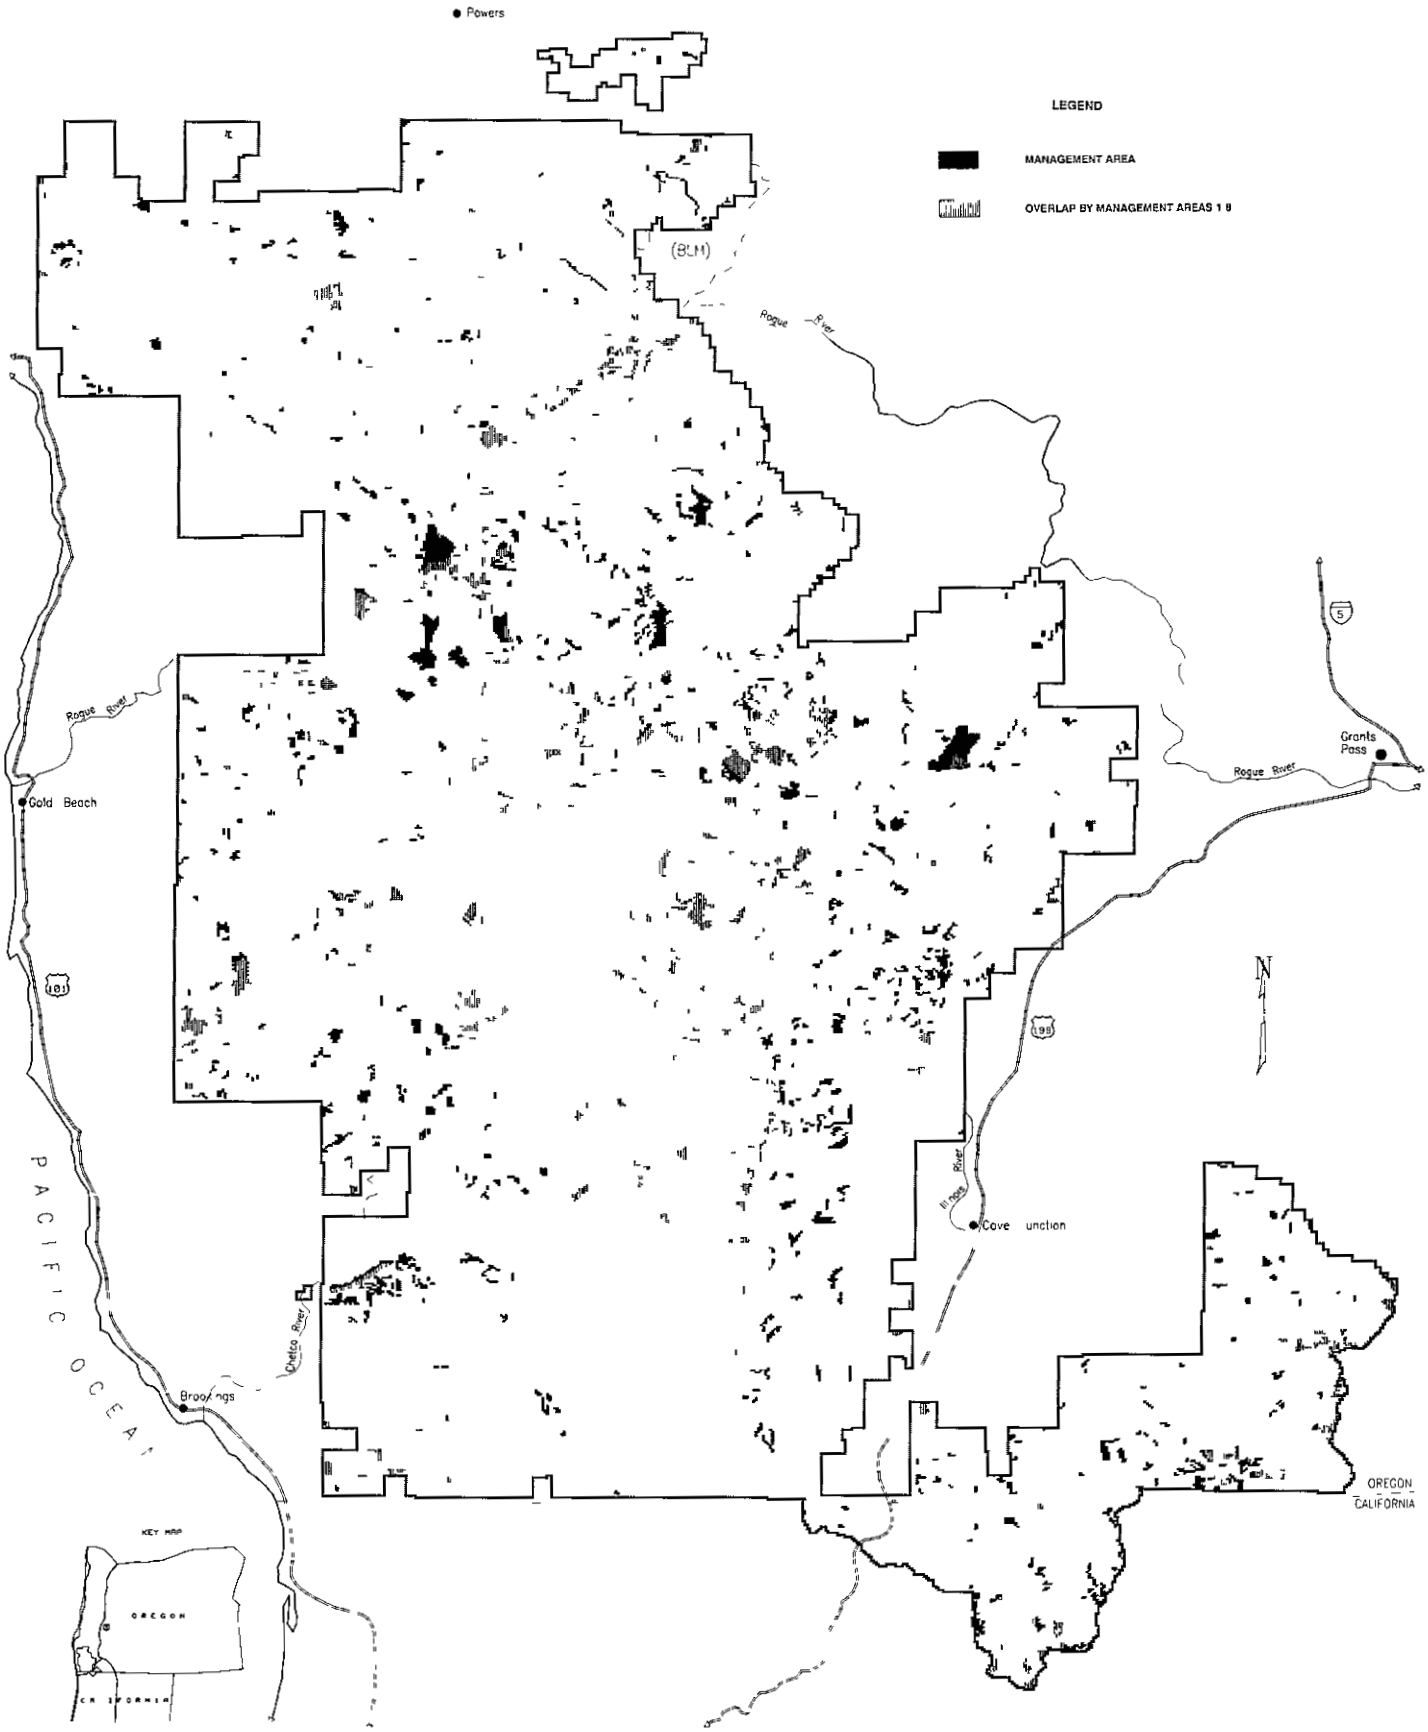


Figure IV-12 Special Wildlife Site Management Area Map

MANAGEMENT AREA 9 - SPECIAL WILDLIFE SITE

DESCRIPTION

This prescription is applicable to special wildlife habitat sites and botanical sites which are important components of overall wildlife habitat diversity and botanical values. Included are. meadows; meadow buffers; swamps, springs, and wet sites; lakes and ponds; tanoak sites; hardwood sites; Roosevelt elk sites, band-tailed pigeon sites; osprey nest sites (outside of Wild and Scenic River corridors); rock sites (cliffs, caves, talus); botanical sites; dispersed old-growth sites; and general wildlife sites. A total of 45,146 acres are identified as Special Sites. Refer to Figure IV-12 for a map displaying allocated acres within the management area The specific types of special sites are described below.

Table IV-23. Acres Allocated to Special Wildlife Site

	Acres		
Name	Management Area 9	Overlap by Management Areas 1-8	Total Area
Botanical Site	75	119	194
Dispersed Old-Growth	11,210	3,497	14,705
Elk Areas	283	26	309
Hardwoods	1,168	872	2,040
Lakes and Ponds	155	117	272
Meadow Buffers	2,859	1,487	4,346
Meadows	4,219	2,297	6,516
Osprey Nest Sites	5	0	5
Pigeon Areas	240	288	528
Rock Bluffs	4,512	6,597	11,109
Swamps, Springs and Wet Areas	15	0	15
Tanoak Areas	298	0	298
Wildlife Areas	3,723	1,086	4,809
Total	28,762	16,384	45,146

Meadows. This habitat type is an important integral component of overall habitat diversity on the Siskiyou. Meadows and meadow/forest edge areas provide hiding and thermal cover, nest and den trees, and food for wildlife species. The Siskiyou has identified 6,516 acres of meadow habitat; 200 feet (average radius) buffer zones surrounding the various meadows comprise 4,346 acres. The Siskiyou's meadow complex totals 10,862 acres. Inventoried meadows range in size from 1 to 250 acres. Meadows smaller than one acre are addressed in the Forest-wide Standards and Guidelines

Swamps/springs/wet sites and lakes/ponds. The Forest contains 287 acres of these water-dominated wildlife habitats; integral or surrounding riparian areas are included

Tanoak and Hardwood sites. Three tanoak sites totaling 298 acres have been identified as important forage areas for wildlife, especially deer, bear, and elk. These are "old-growth" tanoak sites with high mast production. An additional 2,040 acres of hardwoods devoted to wildlife use are interspersed within Designated Habitat (MA-8) (these sites come from the same "background" as those listed under Dispersed old growth).

Roosevelt elk sites 309 acres of these habitats have been identified. Sites include important travel corridors and calving areas.

Band-tailed pigeon sites 528 acres of these habitats have been identified Sites include key feeding areas and mineral spring areas.

Osprey nest sites. Includes active nest sites not in Wild and Scenic River corridors Two active nest sites (five acres) are currently in this category, one on the Galice Ranger District located three air miles from the Rogue River, and one in the Coquille drainage on the Powers District.

Rock sites (cliffs, caves, talus). These geologic features cover relatively few acres (11,706) of the Siskiyou, but contribute substantially to the diversity of wildlife found in the forest environment (the endangered peregrine falcon and sensitive big-eared bat depend on cliffs and caves, respectively). The total acreage includes some buffer areas.

Botanical sites. Seven sites totaling 194 acres have unique plant resources These include unique sites too small to be considered as Botanical Areas.

General wildlife sites Various sites (4,809 acres) with special values for wildlife have been identified over the years during environmental analyses and other field work. These are sites with multiple values for wildlife (e.g , a site may contain water, meadow, and hardwoods). Sites range from larger areas such as Horse Creek, Pebble Hill, Morris Rogers, and Fish Hook Peak, to smaller areas such as Cedar Swamp and Pony Keg.

Dispersed old growth. This term refers to small (less than 160 acres each) wildlife habitat areas which are mostly mature and old-growth forest and generally associated with Designated Wildlife Habitat (Management Area 8) (14,705 acres). This habitat type is sectioned into two categories:

1. The Forest contains many small parcels of mature or old-growth forest unsuitable for timber harvest. These small blocks provide habitat stepping stones between some Designated Wildlife Habitat areas (Management Area 8) (12,350 acres - unsuitable for timber harvest)
2. Small blocks of habitat other than mature or old-growth forest are frequently interspersed within individual Designated Wildlife Habitat areas These blocks may contain a variety of types including: shrubfields, immature conifer stands, and mixed hardwood/conifer stands. When separated from their associated Designated Habitat areas, these blocks would be very difficult to manage for timber products. These blocks add an extra level of habitat diversity to the Forest (2,355 acres - otherwise tentatively suitable for timber production).

MANAGEMENT GOAL

The goal is to protect or enhance these unique wildlife habitats and small botanical sites.

DESIRED FUTURE CONDITION

These areas will continue to provide the unique characteristics that resulted in their identification as special sites. Little change is expected to occur over the next several decades.

STANDARDS AND GUIDELINES

Inventory

MA9-1 During the life of this Forest Plan additional important wildlife and botanical sites will be discovered which are not included as part of this land allocation Each new area should be identified and evaluated as part of a site specific environmental analysis. Each Ranger District shall compile a list of potential candidates for future allocation to Special Wildlife Sites, at the next revision of the Forest Plan, these sites shall be considered for addition to Management Area 9.

Recreation

MA9-2 Use of existing developed recreation sites should not be changed New recreation sites may be developed if environmental analysis indicates that the wildlife habitat or botanical values in the Special Site are not detrimentally affected

MA9-3 Dispersed recreation (including trails) activities may be allowed in special sites; however, motorized activities should be prohibited except where such use is not detrimental to wildlife or botanical resources

Vehicle access should not be provided to meadows or meadow buffers, and no special use permits should be granted for long-term camping in meadows or meadow buffers.

Visual Resource

MA9-4 Management activities shall be planned to meet or exceed the inventoried VQO's of the specific areas.

Wildlife and Fish

MA9-5 Wildlife and fish habitat should be maintained or improved through enhancement projects. Individual wildlife sites may be managed to benefit specific wildlife species or species groups. Mark boundaries of Special Sites on the ground where necessary.

MA9-6 Each Ranger District should develop a comprehensive management plan for their wildlife and botanical sites. The plans, detailing the measures needed to maintain or enhance the sites, should be completed within four years after implementation of the Forest Plan.

MA9-7 *Meadows and meadow buffers* All meadows should be managed as natural openings All inventoried meadows and meadow edges should be maintained at existing size levels and, where opportunities exist, past encroachment by surrounding forest should be reversed Where needed, habitat improvement projects should be initiated in meadow areas. The following activities are important in maintaining optimum meadow habitat for wildlife.

1. Encroaching trees from surrounding forest and other undesirable vegetation should be removed from meadows.
2. Large, live trees within meadow areas may be left as is or girdled, depending on individual circumstances. Dead trees (standing or down) should not be removed.
3. Meadow areas lost to encroachment may be restored to their former size. The Forest's oldest aerial photographs (circa 1940) should be used as reference points in reestablishing the historical boundaries.

MA9-8 *Swamps/springs/wet sites and lakes/ponds.* These sites shall be managed to maintain or improve their value as wildlife habitat

MA9-9 *Tanoak and Hardwood sites* Mature tanoak stands produce outstanding acorn crops year after year; they shall be managed to maintain their inherent wildlife values. Hardwood stands shall be managed to maintain or improve their value to wildlife.

MA9-10 *Roosevelt elk sites.* Elk make greater use of certain forest habitats during the course of their daily and seasonal activities. Special sites such as riparian buffer zones, natural openings, calving areas, and specific old-growth stands meet important elk habitat needs These sites should be managed to maintain their outstanding value as elk habitat.

MA9-11 *Band-tailed pigeon sites.* Certain mineral springs, roosting sites, feeding sites, and fly-through areas on the Siskiyou receive concentrated use. They should be managed to maintain or improve their value to band-tailed pigeon.

MA9-12 *Osprey nest sites.* Occasionally this uncommon bird nests a considerable distance from water. Nest sites outside of the river corridors described under Forest-wide Standards and Guidelines shall be protected. See the Osprey section under Forest-wide standards and guidelines for Fish and Wildlife.

MA9-13 *Rock sites (cliffs, caves, talus).* Rock sites, including adjacent forested areas (edge) should be managed to protect their value to wildlife Rock sites are important habitat for sensitive species, including many plants, and wildlife such as Townsend's western big-eared bat and the Siskiyou Mountain Salamander. Brown (1985), Chapter 9 - Cliffs, Caves, Talus, shall be used as a guide in managing rock sites. Edge width (buffer) shall be designated on a site specific basis

MA9-14 *General wildlife sites.* These sites have multiple values for wildlife (such as a wet area/meadow/shrub complex) and add substantially to the mix of wildlife habitats on the Siskiyou. These areas should be managed to maintain or improve their value to wildlife Individual management plans may be developed for the more complex sites (such as Fish Hook Peak or Horse Creek).

MA9-15 *Botanical sites.* A few small sites with outstanding botanical values have been identified at various locations on the Forest (examples: Taylor fern site and Mud Springs sensitive plant site on the Galice District, and the Huntley Springs sensitive plant site on the Gold Beach District) These sites are too small to qualify as potential Botanical areas, but their plant resources need to be recognized and protected. These areas shall be managed to maintain or improve their outstanding plant values

MA9-16 *Dispersed Old Growth.* Wildlife values in these dispersed habitat areas should be maintained or improved.

Range

MA9-17 Special wildlife sites may be available for range livestock use where there is no conflict with the objectives set for this management area, but wildlife needs shall take precedence.

Maximum acceptable annual utilization levels for meadow sites are included below. These utilization levels shall be monitored under the Allotment Management Plans on meadows included within livestock allotments Studies shall be initiated as directed in FSH 2209.21.

Maintenance of meadow productivity and ecological condition depends on the level and season of use by wild ungulates or livestock. The following standards represent maximum forage utilization levels which may be used for development of proper use criteria for Allotment Management Plans (AMP's). Standards for use of shrubs are included since shrub complexes are often associated with meadows and will generally show browsing impacts by deer (and sometimes livestock) on overutilized habitats. Conflicts between livestock and wildlife use of meadows should be resolved through amendments to the AMP or the Annual Operating Plan, as appropriate. On meadows outside of allotments, these standards should be used to determine impacts to critical ranges for elk and deer; should unacceptable impacts be observed, recommendations may be made to Oregon Department of Fish and Wildlife regarding ungulate herd management.

These utilization levels represent the maximum allowed for all meadow types Some types may require lower use levels to maintain productivity. FSH 2209.21 lists acceptable use levels by ecosystem type.

Percent of Maximum Forage Utilization

Grazing System	% Ungrazed/Rest Rotation	% Season Long
Condition		
Satisfactory		
Grasses	60	50
Upland Shrubs	50	50
Riparian Shrubs	50	30
Unsatisfactory		
Grasses	55	35
Upland Shrubs	40	30
Riparian Shrubs	40	20

Timber

MA9-18 Timber harvesting shall not be programmed in any wildlife or botanical site and shall normally not occur. Down or dead material should not be salvaged. Timber harvest shall be permitted only under the conditions outlined below

1. Timber harvest may be allowed: to eliminate hazards, remove timber incidental to construction or maintenance of improvements, or in case of natural catastrophe, when removal of such timber is necessary to achieving the goals of the management area.
2 Timber harvest may be permitted, if it is shown to be beneficial to specific wildlife or plant species that the habitat is designated for, and is shown by environmental analysis to best meet the goals of the management area.

MA9-19 Occasional trees situated just inside the boundary of special wildlife or botanical sites may be used as logging cable anchors to facilitate harvest of timber from nearby harvest units. Any tree used as an anchor should be protected from girdling.

MA9-20 Firewood cutting shall not be allowed, unless necessary to meet management objectives for the area.

MA9-21 *Meadows and Meadow Buffers.* A forested 200-foot-wide (average) band should be maintained around each meadow one acre or larger (the meadow edge band should be at least equivalent to two "sight-distances"; one sight-distance is the distance at which 90 percent or more of an adult deer or elk is hidden from the view of a human). These buffers serve as hiding cover for many wildlife species that use the meadow or meadow-forest edge. Deer and elk populations are supported at or near maximum rates in meadow areas, assuming adequate hiding and thermal cover is adjacent to the meadows. The band is defined as follows:

1. The meadow edge vegetation (within 50 feet of the meadow edge) should generally not be disturbed (vertical habitat diversity is greatest here) Vegetation in the meadow edge may be manipulated, if beneficial to wildlife. For example, when manipulation of vegetation would help restore meadow areas already lost to encroachment; trees which must be killed should be girdled and left standing unless realization of meadow management objectives would be hampered. In reclaimed portions of meadows, a new buffer zone will be established

2. Ground cover, shrubs, and understory trees should be encouraged in a band from 50 to 200 feet away (average) from the meadow edges If trees need to be killed in this zone, they shall not be removed (harvested) unless necessary to meet meadow management objectives Habitat capability for cavity-using wildlife should never be less than the 100 percent level. As a general guideline, until comprehensive management plans are developed for each District's special wildlife and botanical sites, unprogrammed timber harvest activities should take place in no more than one-third of this buffer area in a 20-year period (one half if the meadow is less than 10 acres)

Standards for meadows of less than one acre are described in the Forest-wide Standards and Guidelines.

Minerals

MA9-22 On valid claims, approve operating plans for mineral activities which minimize detrimental effects to wildlife and botanical special sites

MA9-23 Rock quarries should be located at sites exhibiting the least desirable characteristics as wildlife habitat.

Lands

MA9-24 Special sites should not be available for land exchange, unless the exchange would result in increased habitat capability for endangered, threatened, or sensitive animals or plants However, lands located in areas of the Forest identified as retraction areas may be available for exchange; special wildlife sites in these areas shall be analyzed as part of a site specific environmental analysis

Facilities

MA9-25 New structures should not be permitted within special sites, except as provided in site-specific environmental analysis documents. Trail development is permissible. Roads shall be designed and managed to minimize vehicle access to meadows. New roads shall not be routed to or through meadows and other types of special wildlife or botanical sites unless no other alternative is available, and only after full analysis of values and impacts.

Future utility corridor siting should avoid this Management Area. This Management Area shall be entered only after environmental analysis, in which all other alternatives have been rejected by the Forest Service.

MA9-26 Consideration shall be given to minimizing the detrimental effects of existing or proposed facilities on special sites, including reducing impacts by gating or closing roads after use. Roadways and "wheel tracks" no longer needed should be revegetated and restored; this is especially important in meadow areas.

Waste material from road construction, reconstruction or maintenance should not be left in special wildlife sites

Fire Management

MA9-27 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Indirect attack should be emphasized utilizing a modified range of suppression equipment and technology. Suppression tactics in wildernesses should adhere to wilderness fire fighting principles. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire suppression direction for the Forest.

A low level of prevention activities should be provided. Public contacts should be limited, with most of the efforts concentrated on techniques that accomplish the fire prevention mission prior to the user entering the area. Passive activities keyed to heavily-used sites should be encouraged.

Direct treatment methods should be emphasized in the treatment of natural and activity fuels. The use of prescribed fire is appropriate for meadow restoration and enhancement.

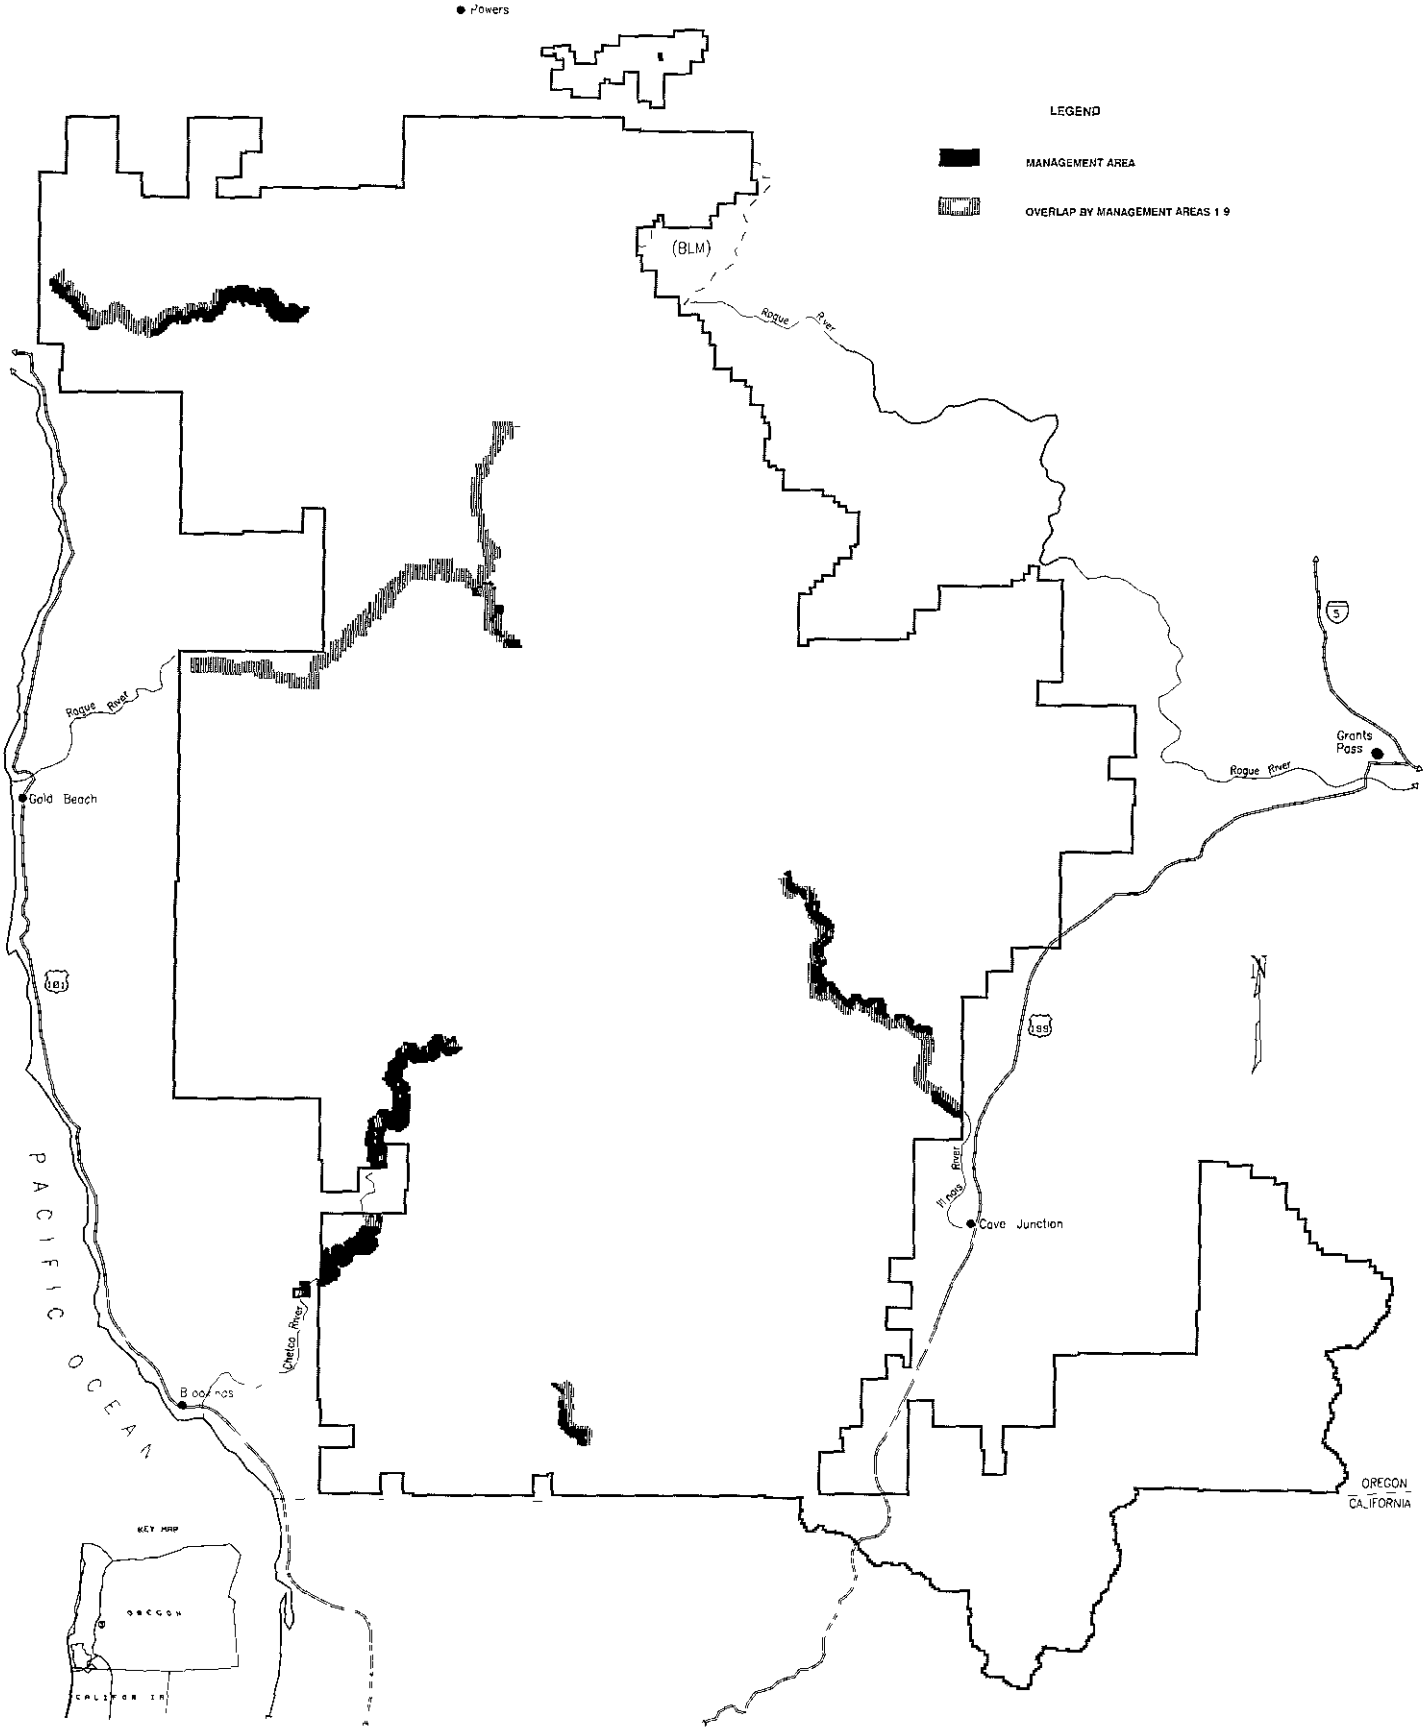

Figure IV-13. Scenic/Recreation River Management Area Map

MANAGEMENT AREA 10 - SCENIC/RECREATION RIVER

DESCRIPTION

This prescription applies to segments of the Rogue, Illinois, Chetco, North Fork Smith, and Elk Wild and Scenic Rivers, and adjacent corridors of land classified as "Scenic" and "Recreational" by the National Wild and Scenic Rivers Act By definition of this Act, a Scenic River must be of high scenic quality, free of impoundments, and have a largely undeveloped shoreline, but can be accessed in places by roads. The recreation classification applies to those river segments which are readily accessible by public roads and have undergone substantial modification to the scenery by man.

The Rogue is designated as Recreational from Watson Creek to Blue Jay Creek, Scenic from Blue Jay Creek to Slide Creek, and back to Recreational from Slide Creek to the bridge at Lobster Creek. The Illinois River is Scenic from the Forest boundary near Kerby to Briggs Creek and Recreational from Nancy Creek to the Rogue River. The Chetco River is designated as Scenic from Boulder Creek to Steel Bridge, and Recreational from Steel Bridge to the Forest boundary, one mile below Wilson Creek The North Fork Smith is designated Scenic from Horse Creek to Baldface Creek. The Elk River is designated Recreational from the confluence of the North and South Forks to Anvil Creek. Generally, the corridor width is 1/4 of a mile from each bank. Refer to Figure IV-13 for a map displaying allocated acres within the management area

Table IV-24. Acres Allocated to Scenic/Recreation River

	Acres		
Name	Management Area 10	Overlap by Management Areas 1-9	Total Area
Recreation-Chetco River	2,712	389	3,101
Scenic-Chetco River	1,973	301	2,274
Recreation-Elk River	2,741	2,057	4,798
Recreation-Illinois River	288	254	542
Scenic-Illinois River	2,123	3,313	5,436
Recreation-Rogue River	0	3,959	3,959
Scenic-Rogue River	0	2,541	2,541
Scenic-North Fork Smith River	480	800	1,280
Total	10,317	13,614	23,931

MANAGEMENT GOALS

For Scenic river segments, the goal is to maintain or enhance the high quality scenery and the largely undeveloped character of the shorelines. For Recreational river segments, the goal is to provide a wide range of recreation activities which are river oriented.

DESIRED FUTURE CONDITION

The Recreation and Scenic sections of the Rogue River will appear to be in a natural condition as seen from the river. An old-growth character will be prevalent along much of these sections of the river as a result of the foreground, with the inventoried visual objective of Retention, being managed with no programmed timber harvest. No new developed sites will have been constructed though use levels will have been monitored at existing sites in order to anticipate changes in future needs not identified in this plan. Recreation use will have increased and may have triggered some restrictions in use in all or portions of these river segments, though the type and extent are difficult to predict. Any changes will be accomplished through cooperation with the inter-agency management group with full public involvement.

The Recreation and Scenic sections of the Illinois River will have been maintained in a natural or near natural condition as seen from the river. Some timber harvest activities will have taken place, however these will not generally be noticed by Forest visitors since they will have been planned to achieve the Retention visual objective. Six new developed recreation sites are programmed for construction along these sections of the river and may be completed depending on the availability of funding. Recreation use will have been monitored and some restrictions may have been implemented in order to protect the Wild and Scenic values of these sections of the river.

The desired future conditions of the Chetco, North Fork Smith and Elk rivers will be natural or near natural conditions, as well Further details will be developed as part of the management plans for these recently designated Wild and Scenic Rivers, scheduled to begin in fiscal year 1989.

STANDARDS AND GUIDELINES

Many standards and guidelines for the river corridors are found in the management plans for the respective rivers and will not be repeated here.

Timber

MA10-1 Timber harvest should not occur in the inventoried foreground Retention areas of the "recreational" or "scenic" sections of the Rogue River, except in circumstances of catastrophic occurrences (fire, flood, wind, etc.) or to remove threats to human safety.

Other areas (not in this described foreground of the Rogue River) and otherwise suitable for timber management may be harvested subject to meeting the Retention VQO and other goals of the management area

Facilities

MA10-2 The Illinois River Road should be developed and maintained to accommodate recreational use and access to the Wilderness. Recreational access may be constructed and maintained to recreation sites along both rivers. Trail development is acceptable.

The key resource values, identified in a thorough analysis of the potential effects, should be avoided in future utility corridor siting in this Management Area.

Fire Management

MA10-3 *Scenic River.* All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. A modified range of suppression technology and equipment emphasizing indirect attack shall be used. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A high level of fire prevention activities shall be maintained. Extensive public contacts should be encouraged along the river, in addition to a signing program at key entrances and media contacts. Hazard reduction activities around heavily-used camping and picnic areas is appropriate.

Both direct and indirect methods should be emphasized in the treatment of activity fuels. Direct treatments should be used where visual or management risks carry a high priority. Indirect treatment is encouraged outside visually-sensitive or high-risk areas. Direct treatment of natural fuels is encouraged.

MA10-4 *Recreation River.* All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Direct attack using a modified range of suppression technology and equipment should be emphasized. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A moderate level of fire prevention activities should be provided Contacts with the public should be encouraged along the river areas, in addition to a signing program at key area entrances Hazard reduction activities around heavily-used camping and picnic areas should be conducted.

Both direct and indirect methods should be emphasized in the treatment of activity fuels Direct treatment should be used where visuals or management risks carry a high priority. Indirect treatment is encouraged outside visually-sensitive areas or high-risk areas. Direct treatment of natural fuels is encouraged.

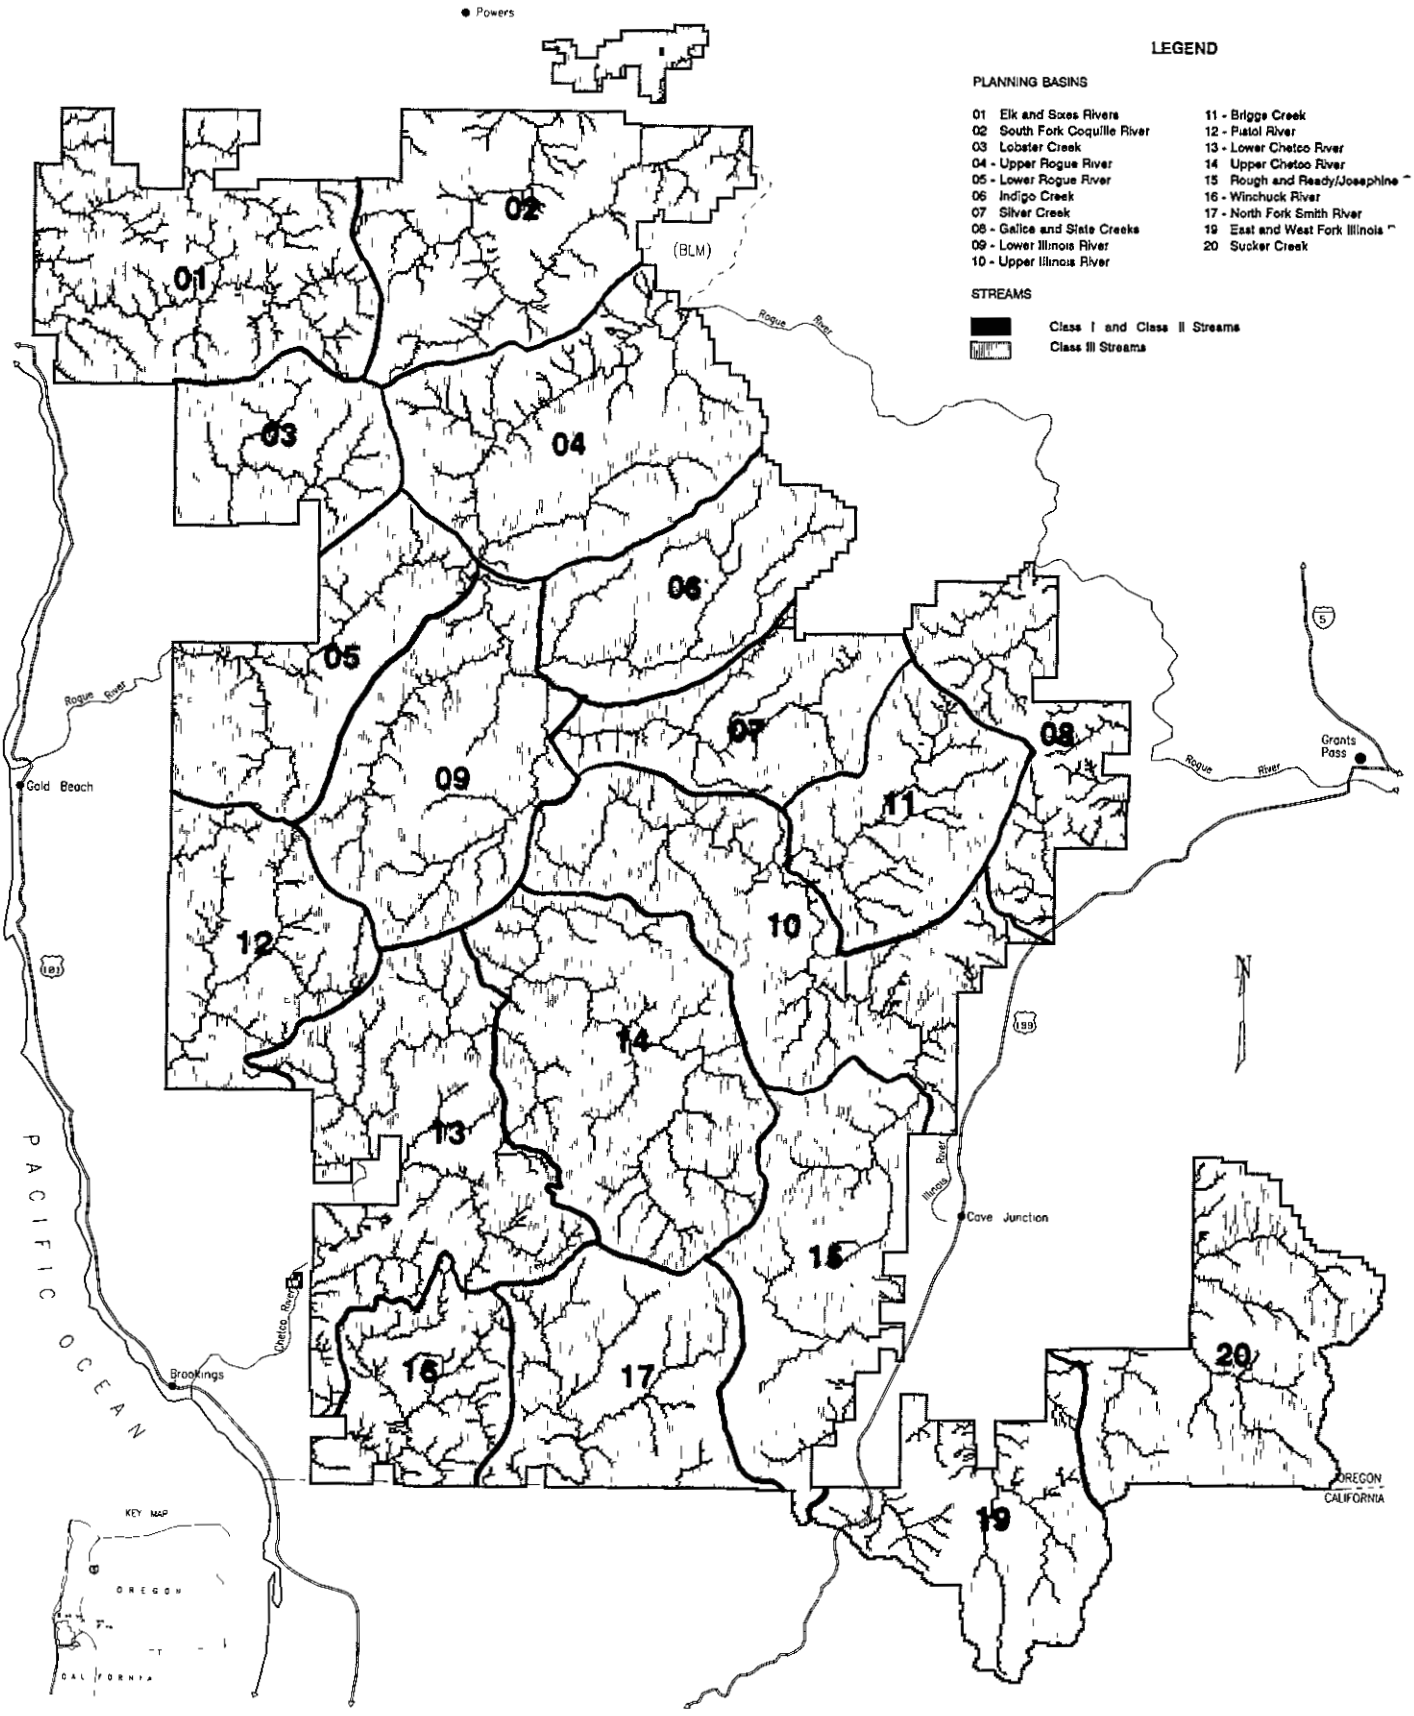

Figure IV-14. Riparian Management Area Map

MANAGEMENT AREA 11 - RIPARIAN

DESCRIPTION

This prescription applies to the riparian ecosystem along all perennial streams (Class I, II, and III) The minimum area of consideration is 100 feet measured horizontally from each side of the stream The actual width of the riparian zone is determined on the ground and varies based on site-specific conditions The expected average distance of consideration for Class I and II streams is 150 feet Within this Management Area there are three prescription themes that are assigned to individual Planning Basins. Two include multiple uses with the emphasis on watershed and fisheries values and limited timber production Prescription B is designed to manage vegetation to maintain water temperature Prescription C manages vegetation to reduce water temperature and improve watershed conditions over time The third prescription is Minimum Level (M) which programs no timber harvest that would remove stream shade producing vegetation Of an estimated 175,500 acres of riparian zones Forest-wide, approximately 70,000 acres are suitable for timber production and included in this Management Area While riparian areas are often overlapped by Management Areas 1 through 10, they are never assigned to Management Areas 12 through 14 since this would not meet the Management Requirements for watershed and fisheries protection Refer to Figure IV-14 for a map displaying allocated acres within the Management Area

Table IV-25 Acres Allocated to Riparian

Riparian Prescription 1/ Planning Basin No and Name	Acres		
	Management Area 11	Overlap by Management Areas 1-10	Total Area
Prescription B			
02-South Fork Coquille River	7,902	2,028	9,930
04-Upper Rogue River	5,836	6,058	11,894
08-Galice and Slate Creeks	6,076	974	7,050
09-Lower Illinois River	3,731	6,959	10,690
10-Upper Illinois River	3,587	10,419	14,046
11-Briggs Creek	5,232	997	6,229
15-Rough and Ready/Josephine Creeks	6,809	1,920	8,729
16-Winchuck River	4,971	1,375	6,346
17-North Fork Smith River	4,366	4,717	9,083
19-East and West Fork Illinois River	4,432	1,522	5,954
20-Sucker Creek	6,764	2,492	9,256
Prescription C			
01-Elk and Sixes Rivers	6,095	6,103	12,198
03-Lobster Creek	3,316	1,297	4,613
05-Lower Rogue River	4,044	2,965	7,009
06-Indigo Creek	6,041	1,810	7,851
07-Silver Creek	3,881	3,046	6,927
12-Pistol River	5,817	1,311	7,128
13-Lower Chetco River	7,723	7,020	14,743
Total	96,623	63,053	159,676

1/ Minimum Level (Prescription M) acres are intermingled within each Planning Basin The Upper Chetco Planning Basin (15,824 acres, all Prescription M) is not displayed because it is entirely within Wilderness (MA-1)

MANAGEMENT GOAL

The goal is to manage these areas under the principles of multiple use while maintaining the integrity of these riparian ecosystems which includes streambank stability, vegetation, terrestrial and aquatic habitats.

Class I and II stream temperature goals are to maintain or decrease summer temperatures in all Planning Basins For the Planning Basins managed under Riparian Prescription B, the objectives for canopy cover associated with these goals are to maintain 85 percent of pretreatment effective canopy cover along Class I and II streams, and 70 percent along Class III streams. For Planning Basins managed under Riparian Prescription C, the objective is to maintain a minimum of 90 percent of the pretreatment effective canopy cover along Class I and II streams and 80 percent along Class III streams.

DESIRED FUTURE CONDITIONS

The vegetation in some portions of the riparian area will be harvested to provide timber and wildlife forage. In other portions, vegetation will be preserved for protection of fish and watershed resources. The portions of the riparian area managed for timber will be in all stages of development from seedlings and saplings to mature timber greater than 100 years old. The vegetation in the riparian zone will be a mixture of hardwoods, with some conifers scattered throughout.

The protected portions of the riparian area will develop naturally. Streams will contain many fallen logs, which will add to fish habitat diversity. The vegetation will randomly vary from shrubs to older forest.

STANDARDS AND GUIDELINES

MA11-1 Activities shall be conducted in accordance with the Siskiyou Riparian Ecosystems Management Policy (FSM 2520.3 Siskiyou Supplement 1).

Visual Resource

MA11-2 Management activities shall be planned to meet or exceed the VQO's of individual areas as appropriate for allocations of adjacent areas. For example, a riparian area dissecting an area allocated to Retention should meet Retention, but if the adjacent area is allocated to General Forest the Visual Quality Objective would be Modification or Maximum Modification.

Fish

MA11-3 Management activities shall have, as a major emphasis, the protection and enhancement of salmonid fish spawning, rearing, and migration habitat.

1. *Spawning Habitat.* Maintain streambed intragravel fines (material less than 2 00 millimeters) at no greater than 20 percent above existing background Existing background will be determined through monitoring (Refer to the Monitoring Plan in Appendix D for fish. If this threshold is exceeded, basin specific analysis will be conducted to determine the appropriate management action.

2 *Rearing Habitat.* Stream temperature should be maintained or improved by management of canopy cover. Rearing capacity for resident salmonids and juvenile anadromous salmonids should be improved through land treatment and habitat work. Present and future sources of large woody debris should be provided to aquatic habitats, and existing instream debris should be maintained or enhanced.

3 *Migration Habitat.* Fish passage to upstream salmonid habitat beyond barriers may be improved or developed where desirability of passage has been determined in cooperation with the Oregon Department of Fish and Wildlife, and such improvements are consistent with other resource goals and objectives.

Wildlife

MA11-4 Habitat values for wildlife should be maintained or enhanced. These habitat values include species diversity; and foraging, watering, breeding, rearing, hiding, resting, and thermal cover. Dead and down woody materials, as described in the Forest-wide standards and guidelines, are particularly critical in riparian areas.

Timber

MA11-5 *Riparian Prescription B Planning Basins.* Timber management is programmed at a level that will provide for maintaining the stream temperatures without significant increase in critical summer temperatures Management activities may include the following: commercial harvest, site preparation, planting, release, and precommercial thinning.

To provide canopy cover for stream shading and large conifers for wildlife and stream habitats; the basal area of conifers should be maintained at or above 70 percent of natural conditions along Class I and II streams, and 30 percent along Class III streams. Harvest shall be done in such a way that damage to remaining streamside vegetation is minimized. Priority should be given to planting vegetation along shade-deficient stream channels. Directional falling and full suspension should be required within the streamside area.

The project level environmental analysis shall examine the cumulative effects of both past and future treatments. No more than 11 percent of the Riparian Area acreage within each planning basin shall be entered on a first entry basis per decade Harvest units shall be distributed within each basin, and subsequent reentries per site should not occur within 20 years.

MA11-6 *Riparian Prescription C Planning Basins.* Timber management is programmed at a level designed to result in up to a 2 degrees Fahrenheit decrease in summer stream temperatures, by the end of the third decade, improving fish habitat capability. Timber management shall include tree removal on a limited basis with the overall direction of retaining at least 80 percent of the basal area of commercial species along Class I and II streams and 60 percent along Class III streams. Harvest shall be done in such a way that damage to remaining streamside vegetation is minimized Priority should be given to planting vegetation along shade deficient stream channels. Directional falling and full suspension should be required within the streamside area.

No more than 11 percent of the Riparian Area acreage within the planning basin shall be entered per decade. Harvest units shall be distributed within the basin, and subsequent reentries per site should not occur within 20 years.

Minerals

MA11-7 Operating plans shall, where reasonable and operationally feasible, include measures to protect or regenerate riparian vegetation, protect water quality, and provide stream bank stability.

Lands

MA11-8 Special use permits should not be recommended if not compatible with riparian area objectives.

Facilities

MA11-9 Roads should avoid riparian zones when possible Necessary crossings should use methods that will minimize adverse impacts to water and fisheries resources (Refer to Appendix F and *General Water Quality Best Management Practices*, USDA 1988).

Fire Management

MA11-10 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less, 90 percent of the time. A modified range of suppression technology and equipment emphasizing direct attack should be used. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A level of prevention activities should be provided that is consistent with the land areas surrounding the riparian areas Industrial operations should have a high level of prevention activity.

Direct treatment methods should be emphasized in the management of natural and activity fuels

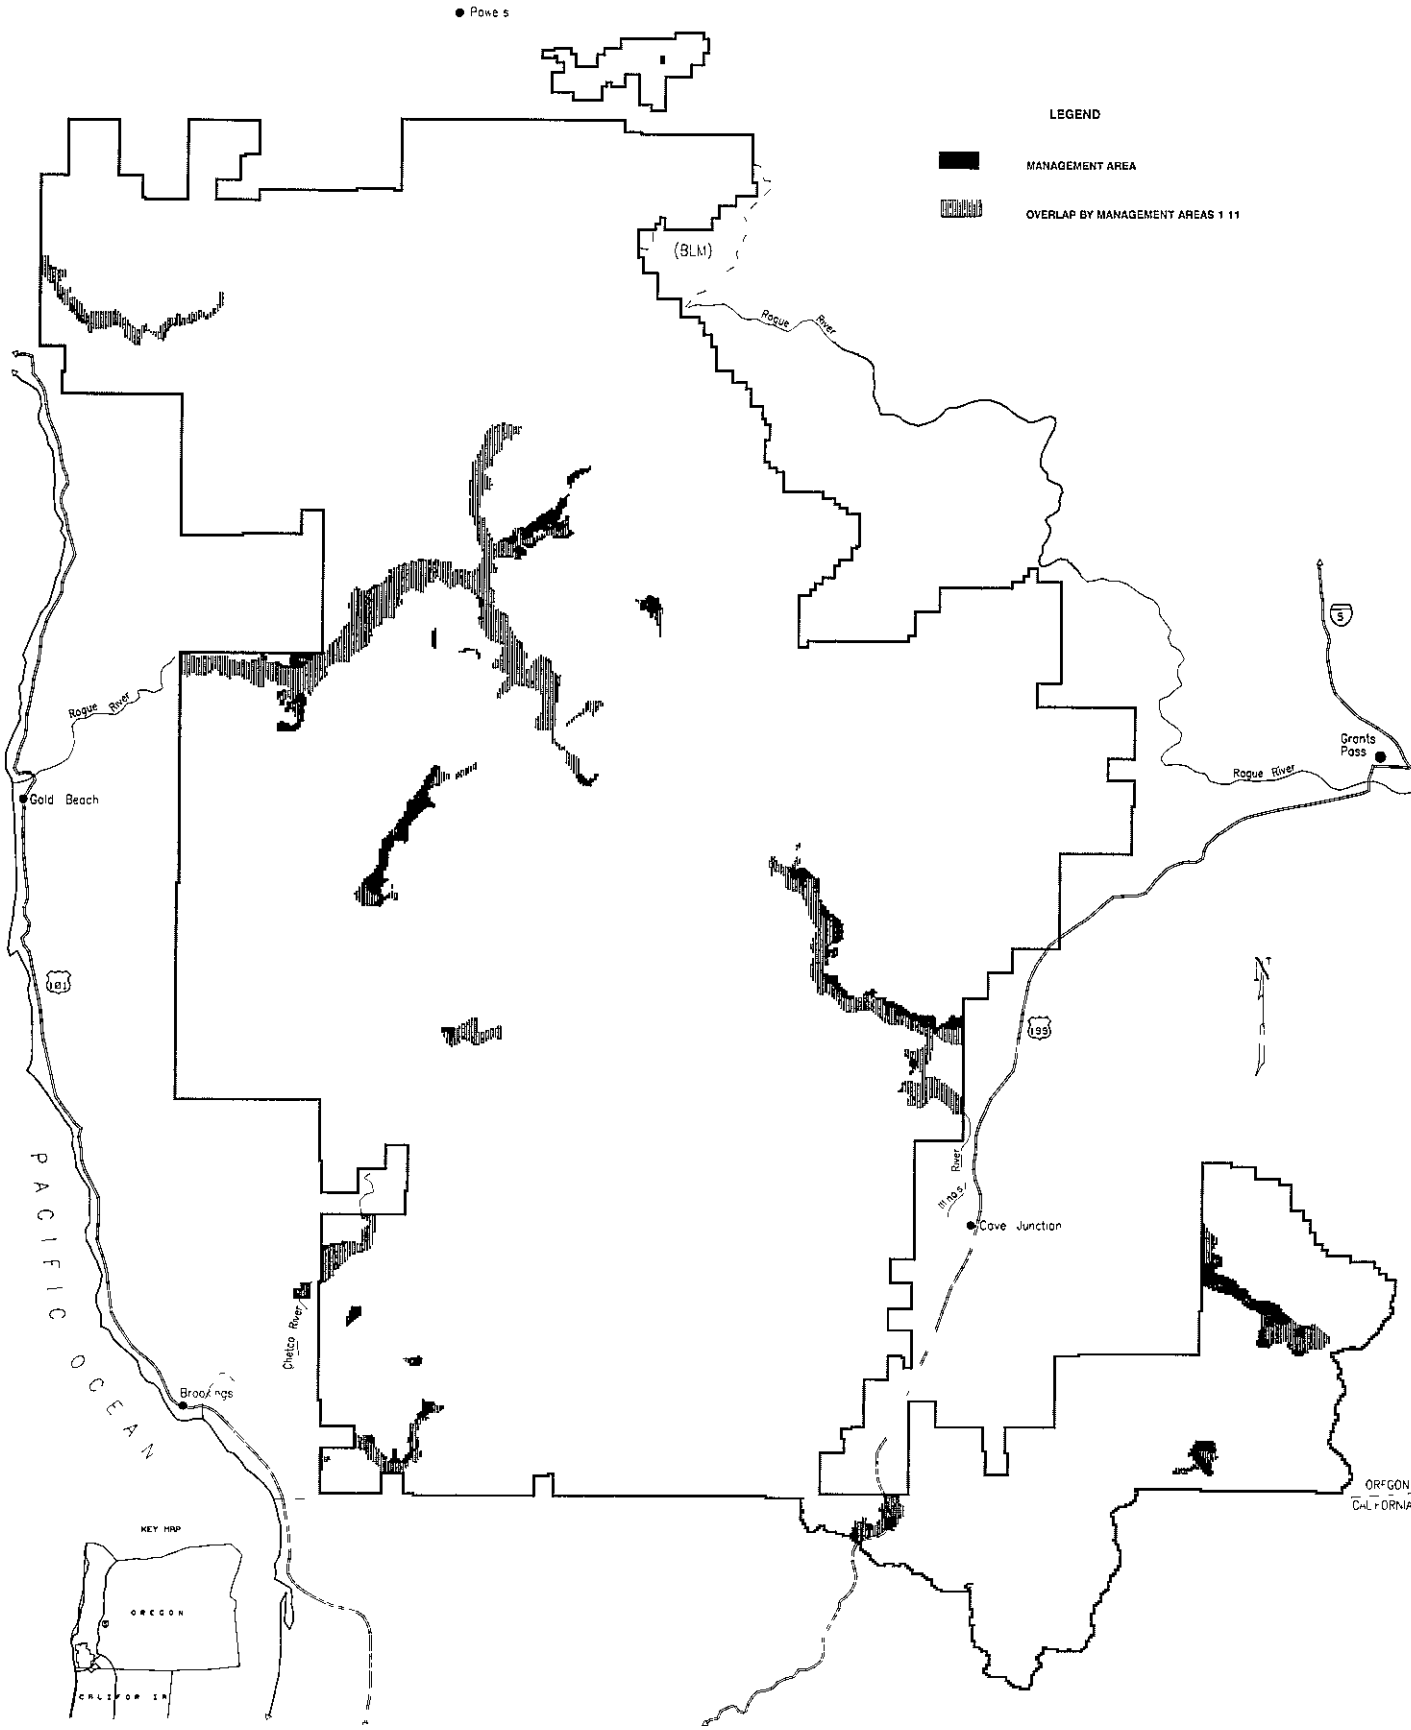

Figure IV-15 Retention Visual Management Area Map

MANAGEMENT AREA 12 - RETENTION VISUAL

DESCRIPTION

This prescription applies to land that is immediately adjacent and visible from major travel routes, rivers and other high use recreation areas. This is the land most seen by the public. The scenic quality of this land substantively affects the recreational experience of those viewing it.

There are 44 separate viewsheds on the Forest. This management area includes the National Forest land inventoried as Retention within those viewsheds allocated to achieve the full complement of VQO's.

Some of the land adjacent to or surrounded by this management area is in private ownership. Although the quality of the scenery from the viewing locations is sometimes determined by activities on private lands, the direction for this management area applies only to National Forest Lands. Refer to Figure IV-15 for a map displaying allocated acres within the management area.

Table IV-26. Acres Allocated to Retention Visual

	Acres		
Name	Management Area 12	Overlap by Management Areas 1-11	Total Area
Bolan Lake	575	363	938
Chetco	246	1,466	1,712
Elk River	222	1,736	1,958
Game Lake	1,922	1,001	2,923
Highway 199	275	109	384
Oregon Caves	1,645	2,024	3,669
Quail Mountain	67	973	1,040
Rogue-Illinois	2,683	15,687	18,370
Upper Illinois	1,667	6,567	8,234
Wheeler Creek	74	65	139
Winchuck River	485	555	1,040
Total	9,861	30,546	40,407

MANAGEMENT GOALS

The primary goal is to provide a level of attractive scenery by maintaining the area in a natural or near natural condition This area also has multiple use goals which include: production of wood products, maintenance of mature conifer, deciduous mix, mature riparian, and grass-forb wildlife habitats; and protection of watershed resources. Management activities will be conducted in such a way that they are completely subordinate to the character of the landscape and not evident to the casual Forest visitor (FSM 2380, *Landscape Management, Agriculture Handbook #462)*

DESIRED FUTURE CONDITION

Viewsheds with the VQO of Retention will have a natural appearance as seen from the viewing location. The results of a wide range of activities will be present, such as timber harvest units, roads, power lines, buildings, developed recreation sites, and fish and wildlife habitat improvements However, evidence of these activities will not be apparent to the average visitor. Most of the land will be in some stage of timber management, exhibiting an equal distribution of age classes Blocks of land may remain unharvested to camouflage the visual effects of management activities.

In a number of places, visual variety will have been purposefully introduced In this way, scenic features can be visually enhanced. Examples of these features include rock outcrops, river corridors, and particularly large trees or groups of trees.

STANDARDS AND GUIDELINES

Recreation

MA12-1 Developed recreation sites and recreation trails shall achieve Retention VQO's

Visual Resource

MA12-2 The viewsheds in which these areas are located should be studied to assess the Existing Visual Condition and to determine the degree of impact that may be permitted in the future, or the need for a rehabilitation plan, under the Retention management objectives.

Timber

MA12-3 All timber management activities shall be designed to meet the Retention VQO as defined in Agricultural Handbook 462, Visual Management System.

Examples of techniques that may be used to meet the Retention VQO are:

1. Limit the size of created openings to approximately five acres, provided they appear natural in the seen areas.
2. Manage foreground Retention areas to produce trees in the range of 36 inches DBH prior to final harvest
3. Program final harvest in Retention viewsheds at the rate of four percent of any Retention area per decade with not more than eight percent in visually perceived created openings at any one time. Schedule final harvest to facilitate meeting these guidelines on openings over the rotation period. This could result in rotation lengths of up to 250 years

Harvest units shall be considered visually perceived openings until the regenerated vegetation has reached a height of 20 feet.

MA12-4 Timber management practices may include all those described under Forest-wide Standards and Guidelines. Up to three commercial thinnings per rotations should be planned for most high and medium sites. Site-specific silvicultural prescriptions should plan to achieve regeneration at stocking levels sufficient to provide for these thinnings. Commercial thinnings should normally occur between stand ages 40 and 100 years, with the objective of contributing substantial volume during the next 8 to 10 decades, or until around the year 2080 Commercial thinning is not programmed for low sites.

Soil and Water

MA12-5 Improvement projects will be designed to restore degraded sites and complement Retention objectives.

Minerals

MA12-6 Reasonable and operationally feasible mitigation measures should be incorporated in approved operating plans to meet Retention objective.

Facilities

MA12-7 New facilities constructed for resource management shall be designed to meet the Retention objective.

Facilities should be constructed that utilize natural materials and muted, earthtone colors compatible with the surrounding landscape Color and line are key considerations in the architectural design.

The key resource values, identified in a thorough analysis of the potential effects, should be avoided in future utility corridor siting in this Management Area

Fire Management

MA12-8 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Direct attack using a modified range of suppression technology and equipment should be emphasized. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A high level of wildfire prevention activities should be maintained. Industrial and other operations should be carefully monitored. Industrial closures shall be carried out as required by the contract in accordance with local fire weather conditions. Public contact through field personnel and the media shall be used. The most intensive prevention efforts should be made during high or greater fire danger and during high-use periods. Signing and site-specific hazard reduction should be used as appropriate.

Both direct and indirect methods should be emphasized in the treatment of activity fuels. Direct treatment should be used where visual or management risks carry a high priority. Indirect treatment is encouraged outside visually-sensitive areas or high-risk areas. Direct treatment of natural fuels is encouraged.

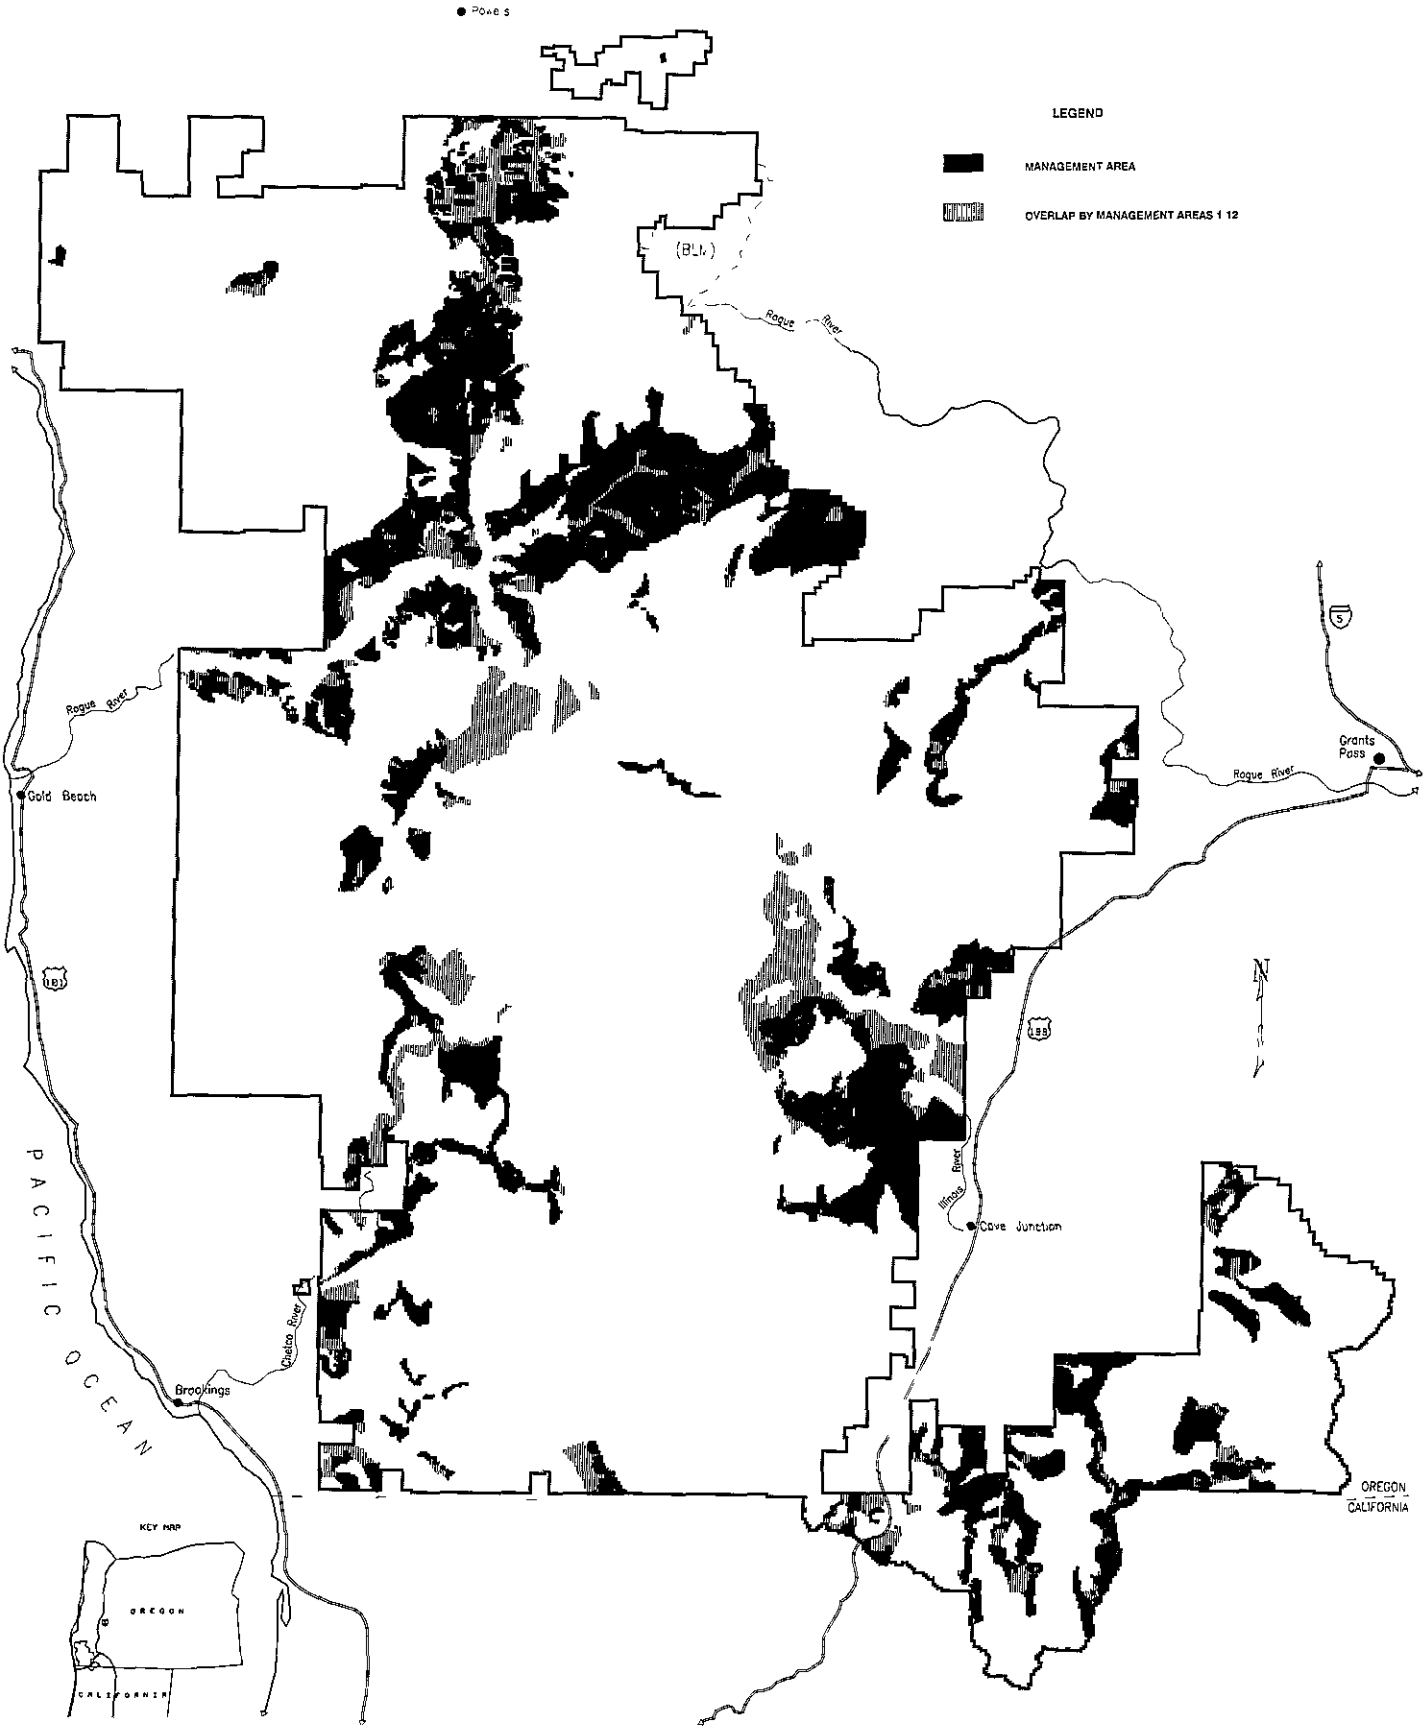

Figure IV-16 Partial Retention Visual Management Area Map

MANAGEMENT AREA 13 - PARTIAL RETENTION VISUAL

DESCRIPTION

This prescription applies to National Forest Land that is visible from major and secondary travel routes, rivers and other high use recreation areas (often in the middle to background).

There are 44 separate viewsheds on the Forest. This management area includes the National Forest land inventoried as Partial Retention within those viewsheds allocated to achieve the full complement of VQO's, and those areas inventoried as Retention or Partial Retention within those viewsheds allocated to achieve the VQO's up to and including Partial Retention.

Some of the land adjacent to or surrounded by this management area is in private ownership. Although the quality of the scenery from the viewing locations is sometimes determined by activities on private lands, the direction for this management area applies only to National Forest Lands Refer to Figure IV-16 for a map displaying allocated acres within the management area.

Table IV-27. Acres Allocated to Partial Retention Visual

	Acres		
		Overlap by	
Viewshed Name	Management Area 13	Management Areas 1-12	Total Area
Babyfoot Lake	12,181	3,275	15,456
Bear Camp	18,638	7,197	25,835
Bob's Garden	2,845	482	3,327

Upper Illinois	9,292	15,176	24,468
Winchuck River	1,775	645	2,420
Total	133,931	68,769	202,700

MANAGEMENT GOALS

The primary goal is to provide a level of attractive scenery by maintaining the area in a near natural condition. This area also has multiple use goals which include: production of wood products; maintenance of mature conifer, deciduous mix, mature riparian, and grass-forb wildlife habitats; and protection of watershed resources. Management activities will be conducted in such a way that they are subordinate to the character of the landscape. (FSM 2380 Landscape Management, Agriculture Handbook #462)

DESIRED FUTURE CONDITION

Viewsheds with the VQO of Partial Retention will have the same types of activities present as in areas for which the VQO is Retention (Management Area 12). As seen from the viewing location, however, evidence of management activities will be more apparent to the average visitor. Even so, the effects of these activities will be visually subordinate to the natural landscape, except in the first year or so of occurrence. There will also be less diversity and fewer scenic features than with a Retention objective.

STANDARDS AND GUIDELINES

Recreation

MA13-1 Developed recreation sites and recreation trails shall achieve Partial Retention VQO.

Visual Resource

MA13-2 Viewsheds allocated to Partial Retention Management Objectives should be studied to assess the Existing Visual Condition of the area, and to determine the degree of future impact that may be permitted, or the need for a rehabilitation plan, under the Partial Retention management objectives.

Timber

MA13-3 All timber management activities shall be designed to meet the Partial Retention VQO as defined in Agricultural Handbook 462, Visual Management System.

Examples of techniques that may be used to meet Retention VQO are:

1. Limit created openings along roads to no longer than 150 feet in length or, if openings are larger, leaving a screen buffer of vegetation of approximately 75 feet deep along the road. Variable width patterns, depending on topography and vegetation present, are preferred to a constant width
2. Limit created openings to approximately 8 acres in size in seen areas.
3 Develop a "feathered-edge" effect whenever possible (not an abrupt edge).
4. Manage foreground Partial Retention areas to produce trees in the range of 30 inches DBH prior to final harvest
5. Program final harvest in Partial Retention viewsheds at the rate of 8 percent of any seen area per decade with not more than 16 percent in visually perceived created openings at any one time. Schedule final harvest to facilitate meeting these guidelines on openings over the rotation period This could result in rotation lengths of up to 130 years.

Harvest units shall be considered visually perceived openings until the regenerated vegetation has reached a height of 20 feet.

MA13-4 Timber management practices may include all those described under Forest-wide Standards and Guidelines. Up to three commercial thinnings per rotations should be planned for most high and medium sites. Site specific silvicultural prescriptions should plan to achieve regeneration at stocking levels sufficient to provide for these thinnings. Commercial thinnings should normally occur between stand ages 40 and 100 years, with the objective of contributing substantial volume during the next 8 to 10 decades, or until around the year 2080. Commercial thinning is not programmed for low sites.

Minerals

MA13-5 Reasonable and operationally feasible mitigation measures should be incorporated in approved operating plans to meet Partial Retention objectives

Facilities

MA13-6 New facilities constructed for resource management should be designed to meet the Partial Retention objective.

Facilities should be located in unseen areas or in seen areas using topography or vegetation for screening during the season of recreation use. Subdued, earthtone colors compatible with the surrounding landscape should be utilized in all structural facilities. Natural building materials should be used for all architectural elements.

Fire Management

MA13-7 All wildfires occurring at FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. Direct attack using a modified range of suppression technology and equipment should be emphasized. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A high level of wildfire prevention activities should be maintained. Industrial and other operations should be carefully monitored. Industrial closures shall be carried out as required by the contract in accordance with local fire weather conditions. Public contact through field personnel and the media should be used. The most intensive prevention efforts should be made during high or greater fire danger and during high-use periods. Signing and site-specific hazard reduction should be used as appropriate.

Both direct and indirect methods should be emphasized in the treatment of activity fuels. Direct treatment should be used where visual or management risks carry a high priority. Indirect treatment is encouraged outside visually-sensitive or high-risk areas. Direct treatment of natural fuels is encouraged.

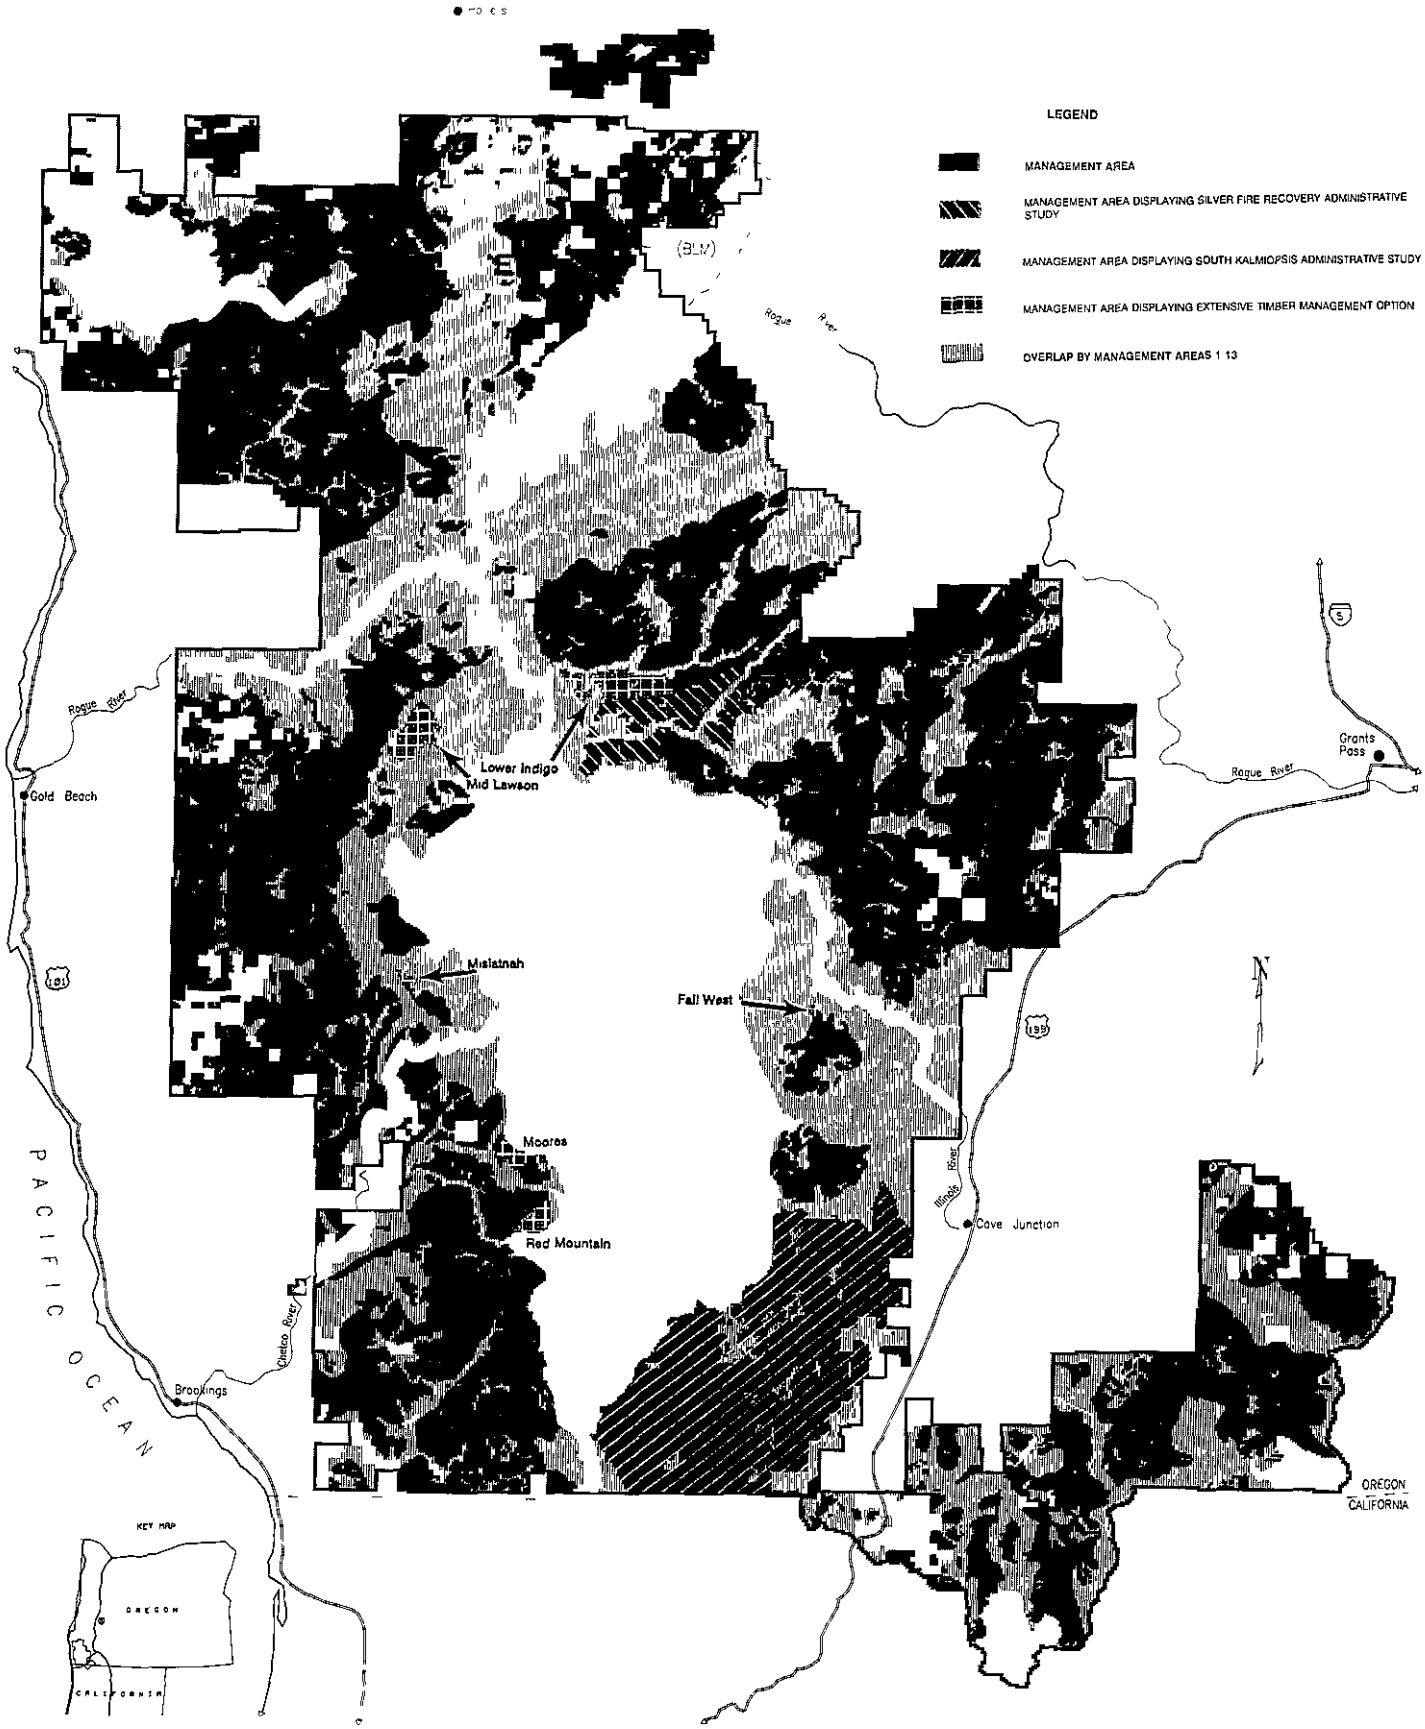

Figure IV-17 General Forest Management Area Map

MANAGEMENT AREA 14 - GENERAL FOREST

DESCRIPTION

This is forested land which is managed for multiple uses including timber production and maintenance of many wildlife habitats. It is the major timber producing portion of the Forest Timber harvest is programmed on lands selected as suitable for timber production throughout the area It is the most intensively managed and includes the most access roads. The vegetation is a mosaic of naturally occurring stands of conifers or hardwoods with interspersed plantations and recent harvest units. A number of other uses and land classifications are also included in the General Forest Management Area: developed campgrounds; roads; utility corridors; cultural sites; administrative sites; and unsuitable timber land. Silvicultural activities include timber harvest, precommercial and commercial thinning, and reforestation. Wildlife species that use early seral stages, such as deer and elk, benefit from the mosaic of harvest units that provide forage opportunities in proximity to hiding cover.

The General Forest Management Area also includes allocation "overlays", or sub-parts, designating some lands for extensive management, and some lands as administrative study areas. The extensive management areas are distinctive in that they lack the operability to gain reasonable road access for intensive timber management and will be managed under a less intensive schedule with no scheduled roading in this planning period. The administrative study areas are in two locations: one is the Silver Fire Recovery Area which was burned in 1987 and is still recovering from the effects of the fire, the other is known as the South Kalmiopsis which is a large area of very poor soils and generally sparse vegetation.

Refer to Figure IV-17 for a map displaying allocated acres within the management area, and overlays of Extensive and Administrative Study allocations.

Table IV-28. Acres Allocated to General Forest

Name (Acres)	Acres Management Area 14
Total	434,307
Extensive Timber Management (10,830)	(4,920)
Fall West (482)	
Lower Indigo (4,085)	
Mid Lawson (3,067)	
Mislatnah (1,120)	
Moores (978)	
Red Mountain (1,098)	
Administrative Study (65,544)	(47,782)
Silver Fire Recovery Project (10,975)	
South Kalmiopsis (54,569)	

MANAGEMENT GOALS

The primary goal is to obtain a full yield of timber within the capability of the land and the management requirements of all other resources. In addition, this area provides many recreation opportunities. It also provides habitat for many species of wildlife and is particularly important for those using openings and early seral stages The areas identified for extensive management have the same general goals with the recognition that management practices designed to produce timber will be less intensive

The goals of the administrative study areas are somewhat different

SILVER FIRE RECOVERY AREA. The goals for this area are to allow time for recovery from the effects of the Silver Fire; to monitor the recovery process; reassess and further refine the operability and suitability of this area for timber production. The area will also continue to provide Primitive and Semi-primitive Non-motorized recreation opportunities, and maintain habitat for many species of wildlife.

SOUTH KALMIOPSIS. The goals for this area are to provide opportunities for administrative studies of uneven-aged management, or other minimal entry timber management systems, on poor sites with scattered timber volume and poor soils; continue to provide mineral exploration and development opportunities, and provide for Semi-primitive Motorized recreation opportunities. The area will also continue to provide habitat for many species of wildlife and many other benefits

DESIRED FUTURE CONDITION

The landscape will be a patchwork of age classes and species of trees On lands suitable for timber production (except the administrative study areas), timber will be available for sale on a nondeclining evenflow basis There will be an orderly transition from the naturally occurring mature forest to a regulated forest with a balance of acres in each age group up to approximately 100 years old. This transition will take place over several decades as plantations progress through the various ages with new plantations created through the orderly harvesting of a portion of the mature stands in each decade There will also be interspersed stands of multiple ages as some stands are managed under uneven-aged prescriptions. Most of the existing plantations are from 1 to 30 years old; the progression to a regulated forest will proceed over the next 70 to 80 years, or more

The young stands will be managed to maintain vigor and growth. They will be predominately conifers of various species depending on the specific sites; although the natural variety of hardwoods, shrubs and forbs will continue to be components of the ecosystems with fluctuations occurring as stands progress through the seral stages. Managed stands will generally be well stocked with many appearing as dense stands of uniform size conifers through much of their lifetime.

The developed road system will provide the access necessary to harvest timber, transport the logs, and tend stands of growing trees. Some of this road system will be in a self-maintaining state with no vehicle traffic planned, to protect watershed conditions, provide for wildlife needs, and control costs. The Bald Mountain road as designed in the Preferred Alternative for the Silver Fire Recovery Project may be extended approximately 3 miles to provide access for timber salvage, reforestation needs, and long-term management for other resources No road construction is envisioned for the extensive areas or for the Silver Fire Recovery administrative area in this planning period.

STANDARDS AND GUIDELINES

Visual Resource

MA14-1 The VQO's are Modification and Maximum Modification Activities of vegetative and landform alteration must borrow from naturally established form, line, color, and texture so completely, and at such a scale that its visual characteristics are those of natural occurrences within the surrounding character type Impacts should be mitigated within five years after project completion.

Timber

MA14-2 To meet long-term Forest-wide timber production and harvest scheduling goals, the FORPLAN model selected a combination of timber management intensities for this management area. Approximately 40 percent of the high site acres were assigned to intensive management and 60 percent to moderate intensity (existing plantations generally went to intensive). The majority of medium site acres were assigned to intensive, only about 15 percent to moderate. Most low site were assigned to extensive management. Site-specific silvicultural prescriptions implemented during the life of this Plan (10 to 15 years) should be designed to achieve the stand conditions that will accommodate this framework for scheduling yields. The majority of high and medium site stands should have sufficient stocking to follow the intensive option. (The monitoring program will include an assessment of the acres meeting stocking objectives.) The analysis to determine which stands could go to moderate intensity should appropriately consider the economic efficiency and logging feasibility, as well as the stocking potential of the specific site.

Areas in the Extensive overlay allocation should normally be managed under the extensive option. More intensive timber management practices may be applied if such investments are justified though site-specific economic and environmental analysis.

SILVER FIRE RECOVERY AREA. This area has no programmed timber harvest and none should occur until recovery of the area has progressed sufficiently to mitigate the risks of adverse cumulative watershed effects. Dead trees and additional mortality that may result from the effects of the fire may be salvaged.

SOUTH KALMIOPSIS. This area has no programmed harvest; the majority of the area is classed as unsuitable for timber production due to reforestation difficulty. Timber harvest shall not be planned from this area except: as provided for in Forest-wide Standard and Guideline 6-2, which allows for research study to test the feasibility of silvicultural and harvesting practices; or, in the case of suitable lands, timber may be harvested where operationally feasible consistent with the direction for this management area.

MA14-3 *INTENSIVE TIMBER MANAGEMENT OPTION.* Timber management practices may include all those described under Forest-wide Standards and Guidelines. Based on silvicultural prescriptions, commercial thinnings should be planned for high and medium sites. Sufficient stocking levels should be prescribed to provide these opportunities. Thinnings should normally occur between stand ages 40 and 60 years, with the objective of harvesting the most thinning volume that can be removed without extending the rotation beyond that of the managed yield tables used in the planning analysis Commercial thinnings are not programmed for low sites; the intensive option does not apply.

The following ages, at which 95 percent of culmination of mean annual increment occurs in the managed yield tables, shall be used as the minimum stand age for final harvest unless site specific analysis is done as described in the Forest-wide Standards and Guidelines:

High Site : 95 years
Medium Site : 105 years

MA14-4 *MODERATE TIMBER MANAGEMENT OPTION.* All management practices may be used, except that no commercial thinning is planned.

The following ages, at which 95 percent of culmination of mean annual increment occurs in the managed yield tables, shall be used as the minimum stand age for final harvest unless site specific analysis is done as described in the Forest-wide Standards and Guidelines:

High Site : 75 years
Medium Site : 85 years
Low Site : 105 years

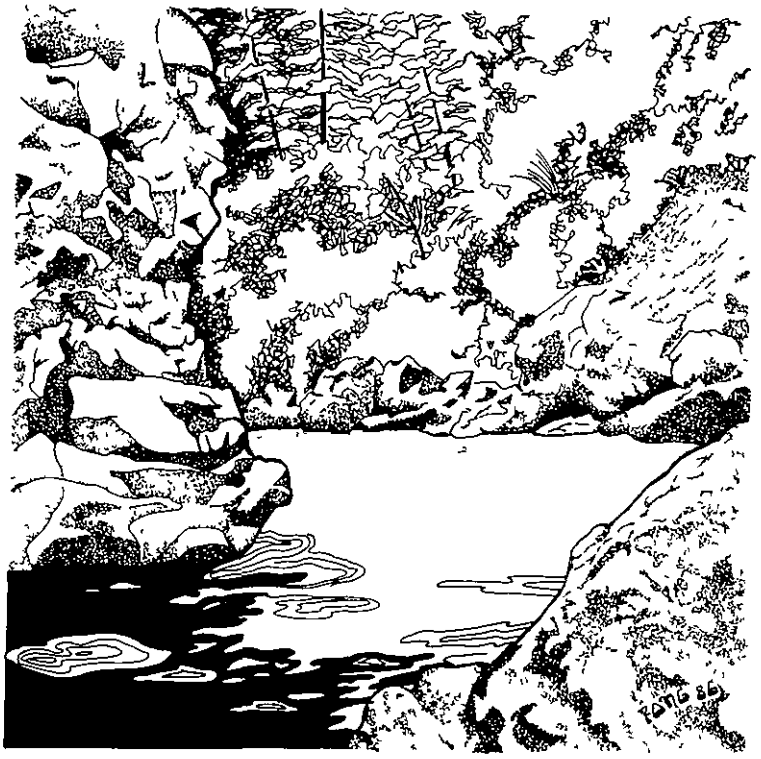
MA14-5 *EXTENSIVE TIMBER MANAGEMENT OPTION.* All management practices may be used, except that no precommercial or commercial thinning is planned. Additionally no scheduled roading is planned.

The following ages, at which 95 percent of culmination of mean annual increment occurs in the managed yield tables, shall be used as the minimum stand age for final harvest unless site specific analysis is done as described in the Forest-wide Standards and Guidelines:

High Site : 95 years
Medium Site : 95 years
Low Site : 135 years

Facilities

MA14-6 The Forest-wide Standards and Guidelines provide the direction for facilities appropriate for most of this management area. Specific direction for the administrative study areas is presented here.



1. *Silver Fire Recovery Area* - Facilities may be constructed, maintained or managed as follows.
   (a) Trails and trail structures depending on recreational demand and the capability of the land to support such uses.
   (b) Facilities required for the administration of the Management Area in a Primitive or Semi-primitive condition.
   (c) Facilities required to protect the Forest from wildfire.
   (d) Facilities required to conduct mining operations under approved operating plans.
2. *South Kalmiopsis* - Facilities may be constructed, maintained or managed as follows:
   (a) Trails and trail structures depending on recreational demand and the capability of the land to support such uses.
   (b) Facilities required for the administration of the area in a Semi-primitive condition
   (c) Facilities required to protect the Forest from wildfire
   (d) Facilities required to conduct mining operations under approved operating plans.
   (e) ORV or Jeep trails may be constructed depending on recreational demand and the capability of the land to support such uses
   (f) Roads may be constructed across this area if needed to manage lands with programmed timber harvest, to access areas harvested under administrative study plans, or for the harvest of suitable lands within this area
   (g) Existing roads should be maintained at Maintenance Level 2 for use as ORV or Jeep trails.

Fire Management

MA14-7 All wildfires occurring at Fire Intensity Level FIL 2 or above should be controlled at 30 acres or less 90 percent of the time. The full range of suppression technology and equipment is applicable. Direct attack should be emphasized. Wildfires occurring at FIL 1 shall be handled as outlined in the basic fire management direction for the Forest.

A high level of wildfire prevention activities should be maintained. Industrial and other operations should be carefully monitored. Industrial closures shall be carried out as required by the contract in accordance with local fire weather conditions. Public contact through field personnel and the media should be used. The most intensive prevention efforts should be made during high or greater fire danger and during high-use periods. Signing and site-specific hazard reduction should be used as appropriate.

Direct treatment methods should be emphasized in the management of natural and activity fuels.

CHAPTER V

IMPLEMENTATION OF THE FOREST PLAN

Chapter V

IMPLEMENTATION OF THE FOREST PLAN

INTRODUCTION

This chapter describes how the Forest Plan is to be put into practice. The first section is divided into three parts which explain how the management goals and objectives described in Chapter IV, Forest Management Direction, provide the driving force for project selection and scheduling. It sets target dates for achieving consistency with other plans on the Forest, as well as explaining the budgeting and environmental analysis processes. The second section describes the Evaluation and Monitoring Program which will be used in determining whether the Standards and Guidelines set forth in Chapter IV are met. Finally, the circumstances are described under which the Plan could be amended or revised.

IMPLEMENTATION DIRECTION

Implementation of the Forest Plan is achieved through identification, selection, and scheduling of projects and execution of management practices, to meet the management direction provided by the Plan. Implementation also involves responding to proposals by others for use or occupancy of National Forest System lands. In all cases, such use or occupancy will be in accordance with the goals and objectives of the Plan. Refer to Chapter IV, Standards and Guidelines, Special Uses, for further discussion regarding responses to requests for use or occupancy of National Forest System lands.

PROJECT PLANNING

The Forest Plan serves as the single land management plan for the Siskiyou National Forest; all other management plans are replaced by this direction. The Forest Plan incorporates the Rogue River Wild and Scenic River Management Plan (1972) and the Illinois Wild and Scenic River Management Plan (1985). A number of other plans have been (or will be) developed to give additional, more specific guidance to management activities. These are developed within the direction that is established in this Plan. They are needed for site-specific information or to carry out the direction in this Plan. Some examples of these include:

* Road Management Plan
* Area Transportation Analysis
* Fire Management Action Plans
* Wilderness Management Plans (Appendix A)
* Off-Road Vehicle (ORV) Plan (Appendix E)
* Corridor Viewshed Study
* Deer and Elk Management Plan
* Osprey, Bald Eagle and Peregrine Falcon Management Plans
* Wild and Scenic Rivers Management Plans
* Redwood Management Plan

The management direction provided by this Forest Plan comprises the framework within which project planning and activities take place. It defines management area goals and management standards that guide project activities toward achieving a desired future condition for the Management Area and, collectively, for the Forest. It specifies a schedule for project activities. It provides guidance concerning potential land and habitat limitations, including assumptions about the appropriate vegetation management practices for timber sale projects. Site-specific project level analysis verifies the appropriateness of those assumptions.

Within this guidance, projects are developed to most efficiently and effectively accomplish management goals and objectives. Project environmental analyses provide an essential source of information for Forest Plan monitoring. First, as project analyses are completed, new or emerging public issues or management concerns may be identified. Second, the management direction designed to facilitate achievement of the Management Area goals are validated by the project analyses. Third, the site-specific data collected for project environmental analyses serve as a check on the appropriateness of the land allocation. The information included in the project environmental analyses is used as part of the monitoring process to determine when changes should be made in the Forest Plan.

PROJECT SCHEDULING

The schedule of proposed and possible projects for the first decade is contained in the appendices of this document. Projects necessary to accomplish the goals and objectives of the Plan are scheduled through a process which takes Forest-wide outputs and activities and locates them to more site-specific areas on the Ranger Districts.

The Forest will maintain Forest-wide activity and project level data bases to support both plan implementation and program budget development. These data bases include the Ten-year Timber Sale Action Plan, Capital Investment Projects, and Projected Budgets (Appendix B).

The following direction from FSM 1922.52 governs the process of identifying capital investment and Timber Sale projects to be placed on an implementation schedule.

1. Projects will be analyzed to identify those that efficiently meet plan direction. (Appropriate analytical techniques are described in the Timber Sale Economic Analysis Guide [Kramer and Owen, n.d.])

2. An interdisciplinary approach will be used to document project identification and selection.

3. Costs for specific projects should generally be within the range of costs used in developing the Forest Plan with consideration given to on-the-ground conditions.

4. Environmental analysis and project decision making will be completed before a proposed project is placed on the implementation schedule.

5. The project must be consistent with the Forest Plan.

6. Normally, economic analysis of appropriate projects will be based on cost effectiveness (Least Cost analysis or Present Net Value). Partial cost-efficiency analysis (FSM 1970) may be used where costs or consequences are in question. Projects will be selected that reduce the overall cost while meeting the Plan's direction.

Projects are selected based on public issues, management concerns, resource opportunities, quality of the environment, major outputs, and management's costs. Resource specialists and managers will make priorities and select projects through an annual process.

Projects are scheduled in response to the planned output of goods and services and the annual budgeting process. All projects will comply with National Environmental Policy Act requirements and with the Standards and Guidelines of this Forest Plan.

Project scheduling will be available for review at the Ranger District offices and the Supervisor's Office. Schedules of possible projects will routinely change as projects are implemented or are removed from the listings for other reasons, and as new projects take their place. Adjustment to the schedule may be made based on budgets and other unforeseen events.

CONSISTENCY WITH OTHER INSTRUMENTS

The Forest Plan supersedes the following land and resource management plans prepared for the Siskiyou National Forest:

Land Management Plans	FEIS Filed
Land Use Plan for Rogue Planning Unit (Essentially the Wild Rogue Wilderness)	2/12/75
Land Use Plan for Mt. Butler-Dry Creek Planning Unit (Essentially the Grassy Knob Wilderness)	5/20/76
Rogue-Illinois Land Management Plan	10/12/79
Chetco-Grayback Land Management Plan	12/05/79
Multiple Use Plans	**Date Approved**
Powers Ranger District Multiple Use Plan	5/27/69
Illinois Valley Ranger District Multiple Use Plan (Revised)	6/08/70 6/08/82
Timber Resource Management Plan	**Date Approved**
Timber Management Plan, Siskiyou Working Circle	8/21/62

The Forest Plan incorporates the following land and resource management plans prepared for the Siskiyou National Forest:

River Management Plans	Date Approved
Illinois Wild and Scenic	10/85
Rogue National Wild and Scenic River (Combined BLM/FS Report)	7/7/72

Subject to existing rights, all other contracts (except as noted below for timber sale contracts) including cooperative agreements, memoranda of understanding, and instruments for occupancy and use of the lands will be brought into compliance with the plan generally within three years after the plan is enacted or as otherwise specified in Standards and Guidelines.

TIMBER

The schedule of timber sale offerings contained in Appendix C will be updated at least annually. All timber sales offered for sale will be in compliance with Forest Plan direction. Timber sales under contract prior to issuance of the Forest Plan will be administered under provisions of the existing contracts. Changes to existing timber sale contracts may be proposed on a case-by-case basis where over-riding resource considerations are present.

All reforestation, timber stand improvement and related silvicultural activities proposed will be in compliance with Forest Plan direction. Existing contracts for nontimber sale silvicultural work issued prior to Forest Plan approval will continue to be administered under provisions of the pre-existing contracts. Changes to pre-existing contracts may be made on a case-by-case basis when over-riding resource considerations exist. Ongoing silvicultural work being accomplished by Forest Service crews will immediately comply with direction upon approval of the Forest Plan.

Functional timber plans such as the Forest Tree Improvement Plan, Seed Orchard Management Plans and Tree Seed Inventory Plan will be brought into compliance with the Forest Plan within two (2) years of issuance. Updates to functional plans will be in compliance with provisions of the Forest Plan.

RECREATION

Issuance of new recreation special use permits or reissuing of existing annual recreation special use permits will be consistent with Forest Plan direction on the first issuance or reissuing date following Forest Plan implementation.

Reissuing of existing term recreation special use permits will be consistent with Forest Plan direction on the first reissuing date or the first proposed permit transfer date following Forest Plan implementation.

MINERALS

New minerals lease applications, permits, contracts and operating plans will be evaluated for consistency with the Forest Plan as they are received or proposed. All existing permits and operating plans will be reviewed for consistency with Forest Plan Standards and Guidelines within one year. Operators and permittees will be notified of any necessary, appropriate modifications. The circumstances under which an operating plan can be modified are detailed in 36 CFR 228.

Minerals materials sales now under contract will be administered under provisions of the existing contracts. Changes to these may be proposed on a case-by-case basis where over-riding resource protection considerations are present.

The Forest Service has no authority to modify stipulations attached to existing mineral leases.

LANDS

Issuance of new non-recreational special use permits or reissuing of existing special use permits will be consistent with Forest Plan direction on the first issuance or reissuing date following Forest Plan implementation. Term permits will be consistent with plan direction on the first reissuing date or the first proposed permit transfer date following Forest Plan implementation.

The Land Adjustment Program will be consistent with the Forest Plan when it is implemented. All future land ownership adjustment proposals will be evaluated for consistency with the Forest Plan as they are received or proposed.

All facilities and management plans thereof (e.g. roads, buildings, etc.) will be consistent with Forest Plan direction within one (1) year of issuance of the Forest Plan, subject to valid existing rights of outstanding permits, contracts and cooperative agreements.

RANGE

Issuance of new term grazing permits or reissue of existing term grazing permits will be consistent with Forest Plan direction on the first issuing or reissuing date following Forest Plan implementation.

At the time of new or reissue of existing term grazing permits, range allotment plans will be evaluated for, and brought into compliance with, the Forest Plan.

BUDGET

The Plan's scheduled projects are translated into multiyear program budget proposals. The schedule is used for requesting and allocating the funds needed to carry out the planned management direction. The

Forest's current year tentative annual program of work will be derived from this process. Upon approval of a final budget for the Forest, the annual work program will be updated and implemented. Accomplishment of the annual program is the incremental implementation of the management direction in the Forest Plan. Depending on final budgets, outputs and activities in individual years may be significantly different from those shown in Chapter IV. Cost and accomplishment data will be utilized to update and revise data bases and modify budget proposals.

The Forest program development and budget process consists of evaluating fixed and variable cost activities, and capital investment projects. Fixed cost activities include those necessary to ensure public safety and environmental protection, and to maintain existing capital assets at certain levels of service and availability. Additionally, long-term management planning and resource inventories, general administration costs, and other costs that cannot be assessed on a per-unit basis are included in fixed cost activities.

Variable cost activities generally include those whose outputs or uses can be controlled or changed. For instance, certain costs may vary relative to the number of acres harvested proposed in an alternative.

Capital investments entail monies spent to provide or improve a facility or product for continued or future use.

A summary of the budget proposal submitted by the Siskiyou National Forest in December, 1988, for fiscal year 1991, is displayed in Appendix B, Table B-1.

BUDGET PROPOSALS

The Plan's scheduled projects are translated into multiyear program budget proposals by extracting projects from the data bases described below and identifying needed expenditures. The schedule is used for requesting and allocating the funds needed to carry out the planned management direction. The Forest's current year tentative annual program of work will be derived from this process. Upon approval of a final budget for the Forest, the annual program of work will be updated and carried out. Accomplishment of the annual program is the incremental implementation of the management direction of the Forest Plan. Depending on final budgets, outputs and activities in individual years may be significantly different from those shown in Chapter IV. Cost and accomplishment data will be utilized to update the data bases and modify budget proposals.

The Forest program development and budget process consists of evaluating fixed cost activities, variable cost activities, and capital investment projects. National Activity Structure units of measure, activity and funding codes will be used in these data bases to provide a uniform, simple, and hierarchical way of displaying information. A summary of the budget proposal submitted by the Siskiyou National Forest in December, 1988 for fiscal year 1991 is in Table B-1 of Appendix B. Capital Investment Proposals for future years are displayed in the other tables in Appendix B.

(1) The fixed cost activities include non deferrable activities for ensuring public safety and environmental protection, costs to keep existing capital assets at agreed levels of service and availability, long-term management planning and resource inventories, cost of general administration, and cost that cannot be assessed on a per-unit basis.

(2) The variable cost activities includes costs incurred as a result of program activities of controllable outputs or controlled use, costs which vary between alternatives based on the acres of harvest.

(3) Capital investment projects are dollars spent to provide or improve a facility or product for future use.

ENVIRONMENTAL ANALYSIS

Projects and activities designed for implementation under the Forest Plan will be subject to environmental analysis to assure compliance with the National Environmental Policy Act (NEPA). The form of documentation for such analysis will be consistent with the Council of Environmental Quality Regulation (40 CFR 1500-1508). A NEPA document in the form of an Environmental Impact Statement or Environmental Assessment will be prepared; or if the analysis shows neither the activity nor the impacts to be significant and the activity conforms to the list of categories listed in Forest Service Manual 1950, the analysis would result in a Categorical Exclusion. The kind of project specific public input needed will be scoped as part of the analysis process. Regardless of the form of NEPA documentation, an analysis file will be maintained and available for public review.

MONITORING AND EVALUATION PROGRAM

The Monitoring and Evaluation Program is the management control system governing implementation of the Forest Plan. At established intervals (once per year), the Interdisciplinary Team shall evaluate implementation to verify compliance with the Standards and Guidelines established in Chapter IV of this Plan, and to determine the effectiveness of those Standards and Guidelines in meeting Land and Resource Management Plan objectives. Based upon this evaluation, the Interdisciplinary Team shall recommend to the Forest Supervisor such changes in management direction, revisions, or amendments to the Forest Plan as deemed necessary.

Monitoring involves a periodic comparison between the end results that are realized and those projected in the Forest Plan. Costs, outputs, and environmental effects, both experienced and projected, will be compared to gauge the overall progress in implementing the Forest Plan, as well as to determine whether the overall relationships on which the Forest Plan is based continue to be accurate. When differences occur, they will be evaluated as to their significance, and appropriate amendments or revisions will be considered and installed in compliance with NEPA and Forest Service processes.

The specific objectives of the Monitoring and Evaluation Program are to determine whether:

1. Planned goals and objectives are achieved.
2. Programs and activities address existing and emerging public issues and management concerns.
3. Management Standards and Guidelines are being followed.
4. Management Standards and Guidelines effectively maintain environmental quality.
5. Workforce, resource, and cost information used in projecting output and impacts are correct.
6. Activities on nearby lands managed by other agencies or landowners are affecting management of the Forest.
7. Research, beyond that identified in Chapter II of the Forest Plan, is needed.
8. The Forest Plan needs to be amended or revised.
9. Intensity of monitoring is commensurate with the risks, costs and values involved in meeting plan objectives.

Table V-1 displays the actions, effects, or resources to be measured in the Monitoring and Evaluation Program governing implementation of the Forest Plan. Appendix D contains additional explanatory

information on many of the items in Table V-1. Only actions necessary to comply with the Regulations set forth by the National Environmental Policy Act (P.L. 91-190) and National Forest Management Act (P L. 94-588) are included in this Monitoring and Evaluation Program. All monitoring necessary to comply with other laws and orders (functional monitoring) will continue to occur.

MONITORING

Components of the Monitoring and Evaluation Program are as follows:

RESOURCE ELEMENT - The decision variable code, which indicates the functional area of responsibility for completing listed activities.

ACTIVITY (UNIT OF MEASURE) - The item to be measured or evaluated, e.g., management direction, costs, outputs, or effects.

MONITORING PURPOSE - Each activity is designed to satisfy sections of the NFMA and NEPA regulations to demonstrate:

- Compliance with management direction (36 CFR 219.12 (k)).
- Achievement of output (goods and services) objectives (36 CFR 219.12 (k)(1)).
- Maintenance of environmental quality (effects) as projected (36 CFR 219.12 (k)(2)).
- Consistency with cost projections (36 CFR 219.12 (k)(3)).
- Resource mitigation measures are employed (40 CFR 1505.3).

THRESHOLD OF CONCERN - The degree by which actual performance may vary before further evaluation is initiated. It establishes the evaluation criterion for the first node in the Decision Flow Diagram (Figure V-1).

DATA SOURCE - A description of collection techniques or sources of information to be employed in Forest Plan monitoring.

A - *Administrative studies - requires a special project to gather information (not associated with* a timber sale).

A1 - Vegetative Inventory scheduled *1989* or *1990* (see description in "Resource Summaries - Timber" in Chapter IV).

B - Project plans, environmental analysis, or assessments - information required for or because of a project, such as a timber sale.

C - Data obtained from other agencies, ie. State of Oregon, Pacific Northwest Experiment Station, U.S. Geological Services, etc.

D - Management Reviews including general, activity, and program reviews

E - Resource Inventories.

F - Management Attainment Reports.

RESPONSIBLE POSITION - Position responsible for the implementation and specified reporting of the monitoring program.

MONITORING FREQUENCY - The number of times during the year when information will be collected, and the interval between measurements as appropriate

DATA STORAGE - A description of where the collected information will be maintained.

TRI (Subsystem Number) - Total Resource Information.

Layer Numbers

1. Master Cell File
2. Aquatic
3. Ecoclass
4. Genetic
5 Landline
6 Preattack
7. Range
8. Recreation
9 Soil
10 Timber
11. Travel
12. Visual
13. Wildlife
14. Mineral

GIS - Geographic Information System

DCC-FC - Departmental Computer Center at Ft. Collins

STORET - Environmental Protection Agency storage system for water quality data.

OTHER (Specify) - Computer files (Regional Office, Forest Level Information Processing System (FLIPS), Recreation Information Management System, etc)

PAPER FILES - Information stored other than on computers.

ANNUAL COST - The actual cost of completing the monitoring activity expressed in annual terms Project costs are NOT included; only the incremental cost associated with responding to the activity is indicated.

Table V-1. Monitoring and Evaluation Program

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
All Elements	Standards and Guidelines (S&G's)	----	(1) Any deviation identified and mitigation not prescribed. (2) Prescribed mitigation not implemented. (3) Applied management direction produces undesirable effect.	D	District Rangers, Forest Staff	Continuous	Computer, Other	$ 21,500
All Elements	Forest Programs and Budget	Outputs, Funding Levels	(1) +/- 20% projected outputs achieved. (2) +/- 20% funding of projected needs for fisheries, soil, and watershed for 3 years. (3) +/- 20% funding of projected needs for wildlife habitat for 3 years. (4) +/- 20% funding of projected needs for recreation for 3 years. (5) +/- 20% variable timber analysis costs for 3 years. (6) +/- 20% of analysis road costs for 3 years.	F	Forest Staff	Annual	Computer, DCC-FC	400
Recreation AN121(a)	Recreation (Undeveloped)	Acres	(1) >5% variance from objectives in Primitive and Semi-primitive. (2) Visible resource degradation in ORV areas.	A,B	District Rangers, Forest Landscape Architect, Recreation Staff	Annual	TRI/GIS	5,000
Recreation AN121(b)	Wild and Scenic Rivers	Acres by VQO	(1) Visible degradation within river corridors (2) Visual quality below Objectives	A	District Rangers, Forest Landscape Architect, Recreation Staff	Annual	Computer	10,000
Visuals AV121	Visual Resource Management	Acres by VQO	5% increase in retention, partial retention, or modification visual objectives.	B	District Rangers, Forest Landscape Architect, Recreation Staff	Continuous	TRI/GIS	5,000
Wilderness AW121	Wilderness Character	Acres by WRS	(1) 5% lower than Semi-primitive (2) Use >80% estimated capacity for WRS class	A,B	District Rangers, Forest Landscape Architect, Recreation Staff	Annual	TRI/GIS	10,000

Table V-1. Monitoring and Evaluation Program (continued)

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
Fish/Water CF121	Fish Habitat	Numerous	(1) 10% decline in pool vol. (2) 3 year decline or more in smolt production. (3) 10% decline in large woody material. (4) Stream temperatures exceed State Water Quality Standards. (5) Fine sediment >20% above background. (6) One scale-class reduction. (7) >25% failure rate of habitat improvement structures.	A,B,E	District Rangers, Forest Staff	Variable, rotation and annual	Computer, Paper File, STORET	86,000 to 113,000 1/
Wildlife CT121(a)	Endangered, Threatened, Sensitive, Unique Animals	Active Nests	(1) Nest site does not produce young for two consecutive years. (2) Surveys not completed. (3) Non-compliance with S&G's	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	9,200
Wildlife CT121(b)	Bald Eagle	Sightings	(1) Nest unoccupied >2 years. (2) <90% sites suitable for occupancy. (3) Non-compliance with S&G's	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	1,850 to 850 1/
Wildlife CT121(c)	Spotted Owl	Acres Occupied	(1) Thresholds exceed those set by Regional Monitoring Program. (2) Non-compliance with S&G's	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	97,500
Wildlife CT121(d)	Sensitive Plants	Acres	20% decline in population	A	District Rangers, Forest Staff	Annual	TRI/GIS	3,500
Wildlife CW121(a)	Pileated Woodpecker	Acres	(1) Habitat suitability less than minimum standards. (2) >15% decline in detected presence. (3) Habitat area numbers and distribution below minimum. (4) >20% decline in occupancy or reproduction success.	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	14,300 to 10,450 1/

Table V 1 Monitoring and Evaluation Program (continued)

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
Wildlife CW121(b)	Pine Marten	Acres	(1) Habitat suitability less than minimum standards. (2) >25% decline in detected presence. (3) Habitat area numbers and distribution less than minimum requirements.	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	10,600 to 3,520 1/
Wildlife CW121(c)	Osprey	Active Nests	(1) 25% decline in active nests over 3 years. (2) Surveys not completed for 2 consecutive years. (3) <90% of potential nest sites suitable for occupancy.	A	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	9,100 to 10,350 1/
Wildlife CT121(d)	Woodpeckers	Acres	(1) >10% of surveyed areas have <90% of prescribed trees and snags. (2) >10% decline in snags as shown in Forest-wide inventory. (3) Inadequate cavities created for secondary users	B	District Rangers, Forest Staff	Annual	Paper File, TRI/GIS	3,000 to 4,450 1/
Wildlife CW121(e)	Blacktail Deer and Roosevelt Elk	Acres	(1) Populations are <80% or >120% of plan objective for a 5 year period. (2) Habitat capability is <80% of objective.	A,C	District Rangers, Forest Staff	Annual - Summarize every 5 years	Computer, Paper File,	5,500 to 6,000 1/
Range DN121	Range Condition and Utilization	Acres	(1) >20% of an allotment shows downward trend. (2) Unauthorized range utilization or utilization <80% of authorized.	B	District Rangers, Lands and Recreation Staff	Annual	Paper File,	550

Table V-1. Monitoring and Evaluation Program (continued)

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
Timber ET121(c)	Land Suitability	Acres	(1) Change of more than 15,000 acres in productivity or vegetation class or more than 10,000 acres proposed for change of suitability classification.	B	District Rangers, Forest Planning Staff	Annual	TRI/GIS	2,000
Timber ET121(d)	Acres and Volume Harvested	Acres Volume	(1) Total acres harvested varies >10% from projected acres. (2) >10% variance in proportion of acres and volume harvested.	B	Timber Staff	Annual	TRI/GIS	2,000
Timber ET121(e)	Harvest Unit Size Limit	Acres	>10% of sold harvest units exceed 60 acre size limit.	B	Forest Silviculturist	Annual	(1) TRI/GIS	1,000
Timber ET121(f)	Reforestation and Intensified Forest Management Practices	Acres	(1) >10% reforestation acres lag time > than 5 years. (2) >10% certified acres stocked at less than recommended stocking level. (3) >10% of acres needing pre-commercial thinning at age 15, but not treated. (4) >10% acres prescribed for release but not treated within 3 years. (5) >10% acres prescribed for fertilization not treated.	B	District Silviculturists, Forest Silviculturist	Annual	Computer TRI/GIS	0
			(6) 10% change in predicted timber volume outputs.	A-I		Every 10 yrs	TRI/GIS	
Timber ET121(g)	Biological Diversity	Numerous	To be developed.	A,A-I,B	Forest Staff	Annual	Computer, TRI/GIS	40,000 1/
Timber ET121(h)	Social and Economic Setting	Numerous	(1) >15% unemployment in 4 counties. (2) <1 2 ratio bid price/ advertised rate. (3) >80% capacity in primitive or developed recreation areas. (4) +/- 15% change in local income levels. (5) Significant changes in community lifestyle,values, etc. (6) +/- 20% change in annual payments to counties	F,C	Planning Staff, Recreation Staff, Timber Staff	Annual	DCC-FC, Paper File,	700

Table V-1 Monitoring and Evaluation Program (continued)

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
Timber ET121(1)	Economics (Cash Flow)	Dollars	Negative annual cash flow for timber program.	F	Timber Staff	Annual	Computer, DCC-FC	50
Air Quality FA121	Suspended Particulate	Tons tot. Suspended Particles	>7,300 tons/year total suspended particulate.	B,C	Fire Staff	Annual	Computer	650
Soil/Water FW121(a)	Water Resources	Numerous	(1) BMP's not being implemented. (2) Water quality does not meet State of Oregon and California Water Quality Regs.	A,D	District Hydrologists, Forest Hydrologist (3) District Rangers,	Annual	Computer, STORET	43,250 to 21,500 1/
Soil/Water FW121(b)	Soil Productivity	Numerous	(1) Organic residues detrimentally altered (2) Mineral soil exposure >40% for low to moderate erosion soils, >30% for high erosion soils, and >15% for very high erosion soils. (3) >15% of activity area, including roads, have compaction, displacement, puddling or severely burned conditions. (4) Tree growth less than acceptable.	A,D	Variety of District Staff 1/ Variety of Forest Staff 1/	Continuous	Computer, Paper File, TRI/GIS	25,000 to 10,000 1/
Soil/Water FW121(c)	Water Resources	Numerous	(1) After 5 years, harvest acres >70% or <30% of projected basin harvest constraint. (2) Any quantifiable, management-related loss of favorable stream flow; cumulative effects are outside predicted range. (3) Loss of downstream, off-Forest favorable stream flow conditions as a result of NF activities. (4) Measurable increase in management-related landslides. (5) Decline in beneficial uses, on- or off-forest, related to management activities.	A,C,D	District Rangers, Dist. Specialists, Forest Hydrologist, Forest Geologist, Forest Fish Biol.	Continuous	Computer, Paper File, STORET	500 to 3,500 1/

Table V-1. Monitoring and Evaluation Program (continued)

Resource Element	Activity	Unit of Measure	Threshold of Concern	Data Source	Position Responsible	Reporting Frequency	Data Storage	Annual Cost ($)
Soil/Water FW121(d)	Water Resources	Landslide Frequency	(1) Observed landslide frequency exceeds frequency in project cumulative effects analysis. (2) Landslide frequencies correlate positively to cumulative area roaded and harvested, and there is potential for degrading beneficial uses of water or irretrievable loss in soil productivity. (3) Off-Forest landslides affect channel stability/beneficial uses; reduces management options for Forest lands.	A,C,D	Forest Geologist, Other Geologists, Soil Scientists	Annual	Computer, Paper File,	13,500 to 8,000 1/
Soil/Water FW121(e)	Acres burned by Wildfire	Acres	(1) Actual acres burned/decade exceed prediction. (2) Actual acres burned/year >50% predicted for decade.	B	Fire Staff	Annual	Computer	650
Minerals GM121	Mineral Resources	Numerous	(1) Field review reveals surface resources and environmental quality declines in excess of previously described thresholds of concern (2) Rehabilitation activities are not being performed or are below standards.	B,D	District Rangers, Lands and Recreation Staff	Annual	Paper File	2,760

1/ See LRMP, Appendix D for further information.

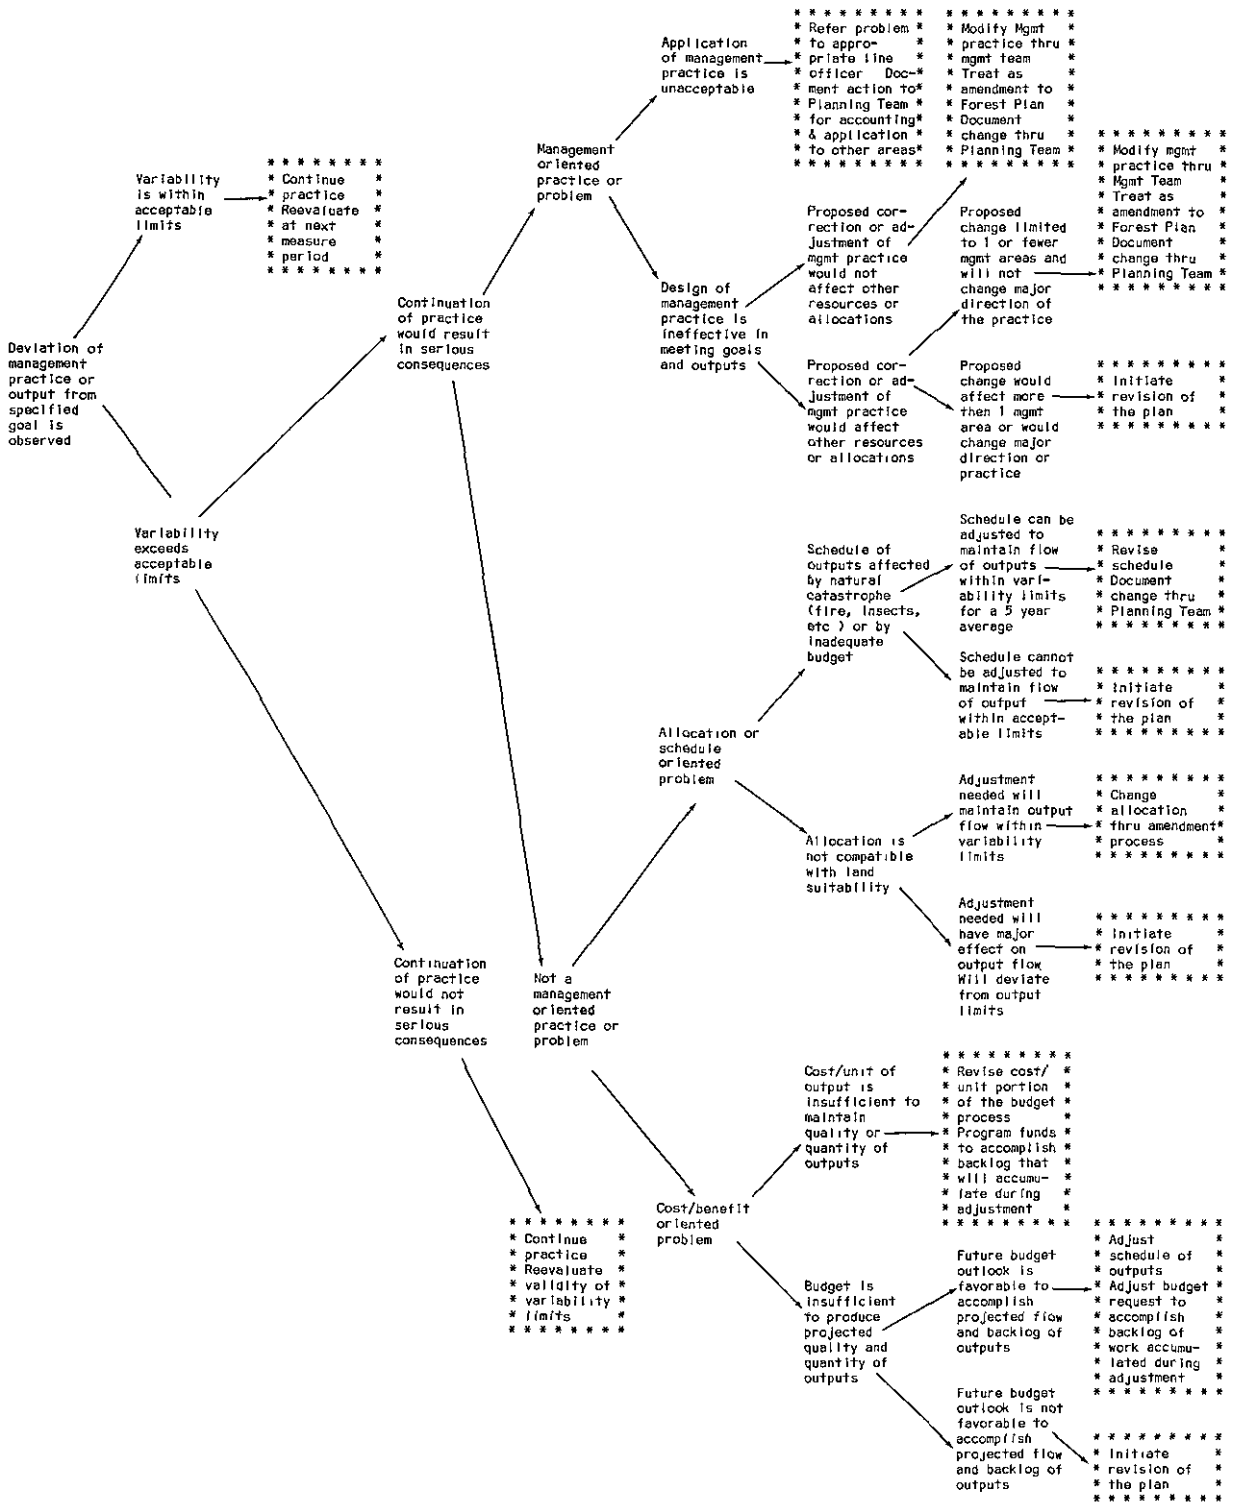
EVALUATION

The data collected during monitoring will be evaluated using the Decision Flow Diagram (Figure V-1) As indicated in the diagram, the results of the evaluation lead to recommendations of the following types:

1. Referring the problem to the appropriate line officer for action;
2. Modifying the management practice, or direction, as a Plan amendment;
3. Modifying the land allocation as a Plan amendment;
4. Revising the schedule of outputs;
5. Revising the cost/unit of output;
6. Initiating revision of the Plan.

The document resulting from the use of the Decision Flow diagram constitutes the evaluation report As applicable, the following will be included in each evaluation report:

1. A quantitative estimate of performance comparing outputs and services with those projected by the Forest Plan;
2. Documentation of measured effects, including any changes in productivity of the land;
3. Unit costs associated with carrying out the planned activities as compared with unit costs estimated during Forest Plan development;
4. Recommendations for changes;
5. A list of needs for evaluation of management systems and for alternative methods of management,
6 A list of additional research needed to support the management of the Forest;
7. Identification of additional monitoring needs to facilitate achievement of the monitoring goals



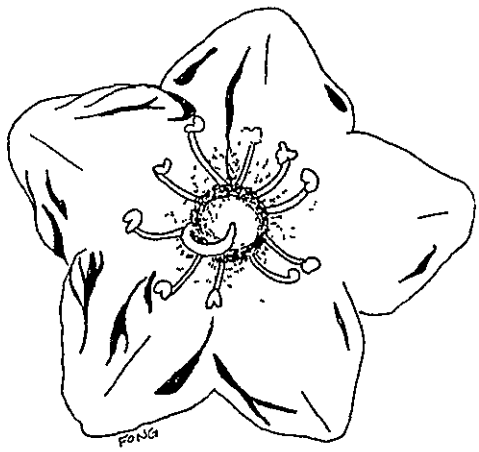


Figure V-1. Decision Flow Diagram

AMENDMENT AND REVISION

The Forest Plan incorporates legal mandates, professional judgement and the public's stated concerns into a future vision of the Forest. It charts a path for getting there by developing management goals and objectives and translating them into management direction in the form of standards and guidelines for management areas on the Forest. National Forest planning is a dynamic process, and the products -- Forest Plans -- are similarly dynamic. Forest Plans can and should be modified if conditions warrant As management goals are applied on the ground or goals and objectives, or activities the goals generate, may no longer be appropriate. In such instances, activities may be tailored to fit the resource, or planning objectives as stated in the Plan may be amended Plans do not apply direction in site-specific management activities. It would be unrealistic and wrong to try to identify, analyze and schedule the myriad projects or activities that occur on a National Forest Instead, this type of site-specific planning occurs at the project-level planning stage, such as allotment management planning.

The Forest Supervisor may amend the Forest Plan. Based on an analysis of the objectives, standards, and other contents of the Plan, the Forest Supervisor shall determine whether a proposed amendment would result in a significant change. If the change resulting from the proposed amendment is determined to be significant, the Forest Supervisor shall follow the same procedure as that required for development and approval of a Forest Plan. If the change resulting from the amendment is determined not to be significant for the purposes of the planning process, the Forest Supervisor may implement the amendment following appropriate public notification and satisfactory completion of NEPA procedures

The Forest Plan shall ordinarily be revised on a 10-year cycle or at least every 15 years It also may be revised whenever the Forest Supervisor determines that conditions or demands in the area covered by the Plan have changed significantly or when changes in Resource Planning Act policies, goals, or objectives would have a significant effect on Forest level programs. In the monitoring and evaluation process, the Interdisciplinary Team may recommend a revision of the Forest Plan at any time. Revisions are not effective until considered and approved in accordance with the requirements for the development and approval of the Forest Plan. The Forest Supervisor shall review the conditions on the land covered by the Plan at least every five years to determine whether conditions or demands of the public have changed significantly

GLOSSARY

A

Acre-foot
A unit of measurement equal to the volume which would cover one acre to a depth of one foot (i.e , 43,560 cubic feet)

Activity
The work processes or management practices that are conducted to produce, enhance, or maintain outputs or achieve administrative and environmental quality objectives An activity can generate multiple outputs.

Activity Fuels
Burnable material created by various management activities

Affected Environment
The natural, physical, and human-related environment that is sensitive to changes due to proposed actions

Age Class.
One of the intervals into which the age range of trees is divided for classification or use.

Airshed
A geographical area that, because of topography, meteorology, and climate, shares the same air

Allowable Cut Effect.
An increase in today's permissible timber harvest level that is made by intensive timber management practices applied now or in the future

Allowable Sale Quantity.
The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan. Both the time period and utilization standards are specified by the Plan. This is usually expressed on an annual basis as the "average annual allowable sale quantity "

Allocated Funds
Those funds transferred to the Forest from other agencies (including those from the Land and Water Conservation Fund, the Department of Labor, and the Soil Conservation Service) or provided from the K-V, Brush Disposal, Co-op Road Maintenance, or Purchaser Road Credits accounts.

Allocation
The assignment of management prescriptions to specific land areas to achieve the goals and objectives of an alternative

Alternative.
A mix of management prescriptions and land allocations applied to specific land areas to achieve a set of goals and objectives. The resulting alternative provides the management direction of the Forest

Amenity.
Resources or experiences enjoyed on the Forest that do not have established market values, e.g., scenic views, recreational activities, etc.

Anadromous Fish
Species of fish which mature in the ocean and migrate into streams to spawn; use herein refers to salmon and steelhead

Analysis Area
A delineated area of land subject to analysis of (1) responses to proposed management practices in the production, enhancement, or maintenance of Forest outputs and environmental quality objectives, and (2) economic and social impacts

Animal Community.
Any assemblage of animals which interact and occur in a common area.

Animal Unit Month (AUM)
The quantity of forage required by one mature cow and calf, or equivalent, for one month

Annual Sale Quantity
See Allowable Sale Quantity.

Appropriated Funds
Monies authorized by Congress which permit Federal agencies to incur obligations and to make payments for specific purposes

Appropriate Suppression Response
The kind, amount, and timing of suppression action on a wildfire which most efficiently meets fire management direction under current and expected burning conditions.

Area of Influence.
Local area where most of the goods and services produced from the Forest are processed or used, and where the employment, income, and other social impact of Forest policies are felt.

Arterial Road
A major transportation route that accesses and services a large land area; usually connects with public highways or other arterial routes.

Association.
(Plant Ecology) A kind of plant community with a definite species composition and structure, and relatively uniform environment.

Available Land.
Capable land which has not been administratively or legislatively withdrawn from timber production on a permanent basis by the Chief or higher authority.

B

Basal Area.
The cross-sectional area, in square feet, of a tree measured at breast height (4 5 feet).

Base Sale Schedule.
A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and that this planned sale and harvest for any decade is not greater than the long-term sustained-yield capacity. This definition expresses the principle of nondeclining flow.

Benchmark
An analysis reference point of the maximum physical/biological capability to produce a resource output from Forest lands while maintaining minimum legal requirements for production of other resources and maintenance of soil and water productivity. Benchmarks define the area (i.e., provide the bounds) within which alternatives can be formulated.

Benefit-Cost Ratio.
Measure of economic efficiency computed by dividing total discounted *primary benefits* by total discounted *economic costs*.

Best Management Practice (BMP)
The method, measure or practice selected by an agency to meet its nonpoint source pollution control needs. BMPs include, but are not limited to, structural controls, operations, and maintenance procedures. BMPs can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters.

Big Game
Those species of large mammals normally managed for sport hunting Herein, generally refers to Roosevelt elk, black-tail deer, or black bear

Biological Diversity.
The distribution and abundance of different plant and animal communities and species over time and space

Biological Growth Potential
The average net growth attainable in a fully stocked natural forest stand

Biotic Community.
Any interacting assemblage of animal and plant communities living in a prescribed area or physical habitat.

Board Foot (BF).
A unit of measurement equal to an unfinished board one foot square by one inch thick

Botanical Area
An area which has been designated by the Forest Service as containing specimens or groups of plants, and plant communities which are significant because of form, color, occurrences, habitat, location, life history, arrangement, ecology, environment, rarity and/or other features (FSM 2360).

C

Calibration
The process of adjusting modeled fire sizes by fire intensity levels for each Fire Management Analysis Zone against historical occurrence and burn acreage to accurately reflect the "real world " Adjustments are based on modeling the current organization (1978) against historical occurrence (1970-1979) using the same dispatch philosophy and suppression strategies.

Canopy.
The uppermost spreading, branchy layer of a forest

Canopy Closure
The progressive reduction in space between tree crowns as they spread laterally (Ford-Robertson 1971); a measure of the percent of potential open space occupied by the collective tree crowns in a stand.

Capability.
The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, and geology, as well as the application of management practices, such as silviculture or protection from fire, insects and disease.

Capability Area
A delineated area with a logical combination of biological potential and physical characteristics which are used to estimate responsiveness to various management practices, resource values, output coefficients, and multi-resource or joint production

Capital Investment
Money spent to provide a facility or product that will be used in the future.

Carrying Capacity.
The maximum number of organisms that a particular habitat can support without causing deterioration of the ecosystem.

Cavity Nester.
Wildlife species that excavate and/or occupy cavities in trees and snags.

Chargeable Volume.
All timber volume included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on regional utilization standards.

Clearcutting.
The harvesting of an entire stand of trees in one cutting operation, leading to the establishment of an even-aged stand

Climax.
The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition

Code of Federal Regulations (CFR).
The listing of various regulations pertaining to management and administration of the National Forests.

Collector Road.
A road which collects traffic from Forest local roads or other collector roads These roads serve smaller land areas than arterial roads and are usually connected to a National Forest arterial or public highway.

Commercial Forest Land (CFL)
See Tentatively Suitable Forest Land

Commercial Thinning
Timber sales which call for selective harvest in immature stands designed to improve the quality and growth of the remaining trees.

Commodity
A resource product with commercial value, all resource products which are articles of commerce (transportable)

Community Cohesion
The degree of unity and cooperation evident in a community as it defines problems and attempts to resolve them

Community Stability
A community's capacity to handle change without major hardships or disruptions to component groups or institutions.

Concern.
See Issues, Concerns, and Opportunities

Confine Wildfire Strategy
To restrict fire within determined boundaries.

Constraint.
A limit placed in the FORPLAN model designed to control the functioning of the model to meet specified goals, legal or feasibility requirements.

Consumptive Use
Those uses of a resource that reduce its supply.

Contain Wildfire Strategy.
To surround a fire with control line to check the fire's spread.

Control Wildfire Strategy
To complete and hold the control line around a fire

Conversion. (Management)
A change from one silvicultural system to another (e.g. from hardwood to conifer forest) or from one tree species to another

Cord
A wood stack equivalent to 128 cubic feet (4 x 4 x 8 feet).

Cost Effective
Achieving specified outputs or objectives under given conditions for the least cost

Cover.
Vegetation used by wildlife for protection from predators, or to ameliorate conditions of weather, or in which to reproduce

Cover/Forage Ratio.
The ratio, in percent, of the amount of area in forage conditions to that in cover conditions

Created Opening
An opening in the forest created as the result of even-aged silviculture through clearcutting, group selection, or shelterwood regeneration timber harvest systems

Critical Habitat
That habitat designated by the Secretary, USDI, as critical to the continued survival of threatened or endangered species

Critical Minerals
Minerals vital to the National defense; securing these minerals is less serious than those classified as strategic minerals

Cubic Feet Per Second (cfs)
A unit of measure applied to fluid flow A rate of discharge.

Cubic Foot.
A measure of volume equivalent to 1 foot by 1 foot by 1 foot

Culmination of Mean Annual Increment (CMAI)
The age at which the average annual growth is greatest for a stand of trees. Mean annual increment is expressed in cubic feet measure and is based on expected growth according to the management

intensities and utilization standards assumed in accordance with 36 CFR 219 16(a)(2)(i) and (ii). Culmination of mean annual increment (CMAI) includes regeneration harvest yields and any additional yields from planned intermediate harvests

Cultural Resources
Buildings, sites, areas, architecture, memorials, and objects having scientific, prehistoric, historic, or social values.

Cumulative Effect
The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Current Direction.
The combination of activities dictated by laws, regulations, the Forest Service Manual, and existing unit plans

D

Departure
A schedule which deviates from the principle of nondeclining flow by exhibiting a planned decrease in the sale schedule at any time during the planning horizon. A departure is characterized by a temporary increase, usually in the beginning decade(s) of the planning horizon, over the base sale schedule originally established. This increase does not impair the future attainment of the long-term sustained yield capacity.

Designated Habitat Area.
A mature of old-growth habitat area that has been located on a map or in the field, or both. For this document, specific areas identified for spotted owls, pine marten, and pileated woodpeckers.

Desired Residue Profile.
The desired level of both living and dead vegetative material that is desired by the land manager for a specific site or prescription. Residue includes slash materials, litter on the forest floor, living brush, tree and standing dead trees and snags.

Developed Recreation.
Outdoor recreation requiring significant capital investment in facilities to handle a concentration of visitors on a relatively small area Examples are ski areas, resorts and campgrounds

Diameter at Breast Height (DBH).
The diameter of a standing tree measured at a point four feet-six inches from ground level on the uphill side.

Direct Attack.
A method of fire suppression that treats the fire at its burning edge

Discounting
The process of estimating the present worth of an anticipated item of income or expenditure by determining the amount of money which, if presently invested and allowed to accumulate at compound interest, will exactly equal the expected item of income or expenditure at the time when it becomes due.

Dispersed Recreation.
Outdoor recreation in which visitors are diffused over relatively large areas Where facilities or developments are provided, they are more for access and protection of the environment than for the comfort or convenience of the people.

Diversity
The distribution and abundance of different plant and animal communities and species within an area

Downward Sloping Demand
A price-quantity demand schedule based on the assumption that the quantity offered inversely affects the price received.

E

Ecosystem
The complete system formed by the interaction of a group of organisms and their environment

Ecosystem Function.
The manner in which organisms interact with each other and their environments.

Edaphic.
Pertaining to the soil.

Edge
Where plant communities meet or where successional stages of vegetative conditions within plant communities come together, e.g., field and woodland, forest and meadow.

Edge Effect.
The increased richness of flora and fauna resulting from the mixing of two communities where they join, as at the edge of a meadow.

Effects (or Impacts).
Environmental consequences (the scientific and analytical basis for comparison of alternatives) as a result of a proposed action. Effects may be either *direct*, which are caused by the action and occur at the same time and place, *indirect*, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable, or *cumulative* (See definition above)

Empirical Yield Table.
A table showing, for one or more given species on a given site, the progressive development of a timber stand at periodic intervals covering the greater part of its useful life This table is prepared for existing stands on the basis of actual average stand conditions.

Endangered Species.
Any plant or animal species which is in danger of extinction throughout all or a significant portion of its range. (Endangered Species Act of 1973).

Endemic Species.
A species whose natural occurrence is confined to a certain region and whose distribution is relatively limited

Environment
The aggregate of physical, biological, economic, and social factors affecting organisms in an area

Environmental Analysis
An analysis of alternative actions and their predictable environmental effects, including physical, biological, economic, and social consequences and their interactions; short- and long-term effects; direct, indirect, and cumulative effects

Environmental Assessment (EA)
A concise public document which serves to (a) Briefly provide sufficient evidence and analysis for determining whether to prepare an EIS or a Finding of No Significant Impact, (b) Aid an agency's

compliance with NEPA when no EIS is necessary; (c) Facilitate preparation of an EIS when necessary.

Environmental Impact Statement (EIS)
A detailed statement prepared by the responsible official in which a major Federal action which significantly affects the quality of the human environment is described, alternatives to the proposed action provided, and effects analyzed.

Erosion.
Detachment or movement of soil or rock fragments by water, wind, ice, or gravity. Accelerated erosion is much more rapid than normal, natural, or geologic erosion, primarily as a result of the influence of activities of man, animals, or natural catastrophies

Escaped Fire Situation Analysis.
A study of the factors influencing the suppression of a fire not controlled during initial attack, conducted for the purpose of deciding which suppression strategy will be used.

Even-aged Management
The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together Managed even-aged forests are characterized by a distribution of stands of varying ages (and therefore tree sizes) throughout the forest area The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age Regeneration in a particular stand is obtained during a short period at or near the time that the stand has reached the desired age or size for regeneration and is harvested Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands

Expected Burned Acreage
The expected annual number of acres burned by fire size class and intensity level for a given program option or budget level, and which must equal or be less than the resource protection objective to be a valid option

F

Fire Intensity Level (FIL).
A relative measure of fire severity based on flame height, higher flames indicating a more intense fire

Fire Management Analysis Zone (FMAZ)
The geographically delineated areas into which the planning unit is divided for the purpose of analysis based upon common fire-behavior characteristics.

Fire Management Efficiency Index (FMEI).
An index based on the protection costs (less proposed fuels investment), expected annual fire-fighting costs, and expected annual net value change for the next planning period.

FIREPLAN
The title for a computer system consisting of eight programs which perform data retrieval and processing for the fire management analysis.

Fire Program Option
A given program mix funded at a given program level developed in response to specific fire management direction established for the Forest Plan

Fixed Program Management
The cost of managing Forest programs which is independent of output levels

Floodplain
The lowland and relatively flat areas adjoining inland and coastal waters, including, at a minimum, that area subject to a one percent or greater chance of flooding in any given year.

Forage.
Vegetation used for food by wildlife, particularly ungulate wildlife and domestic livestock

Forb.
Any herbaceous plant species other than those in the Gramineae (grasses), Cyperaceae (sedges), and Juncaceae (rushes) families; fleshy-leaved plants.

Forage Areas
Vegetated areas with less than 60 percent combined canopy closure of tree and tall shrub (greater than seven feet in height). This includes the grass-forb, shrub and open sapling-pole stand conditions and may include some older stands that have been thinned. In a managed forest the primary forage areas are those that have had all or most of the forest canopy removed, i e clearcut or shelterwood units

Forest Fragmentation.
The creation of habitat islands through land development or through natural causes, such as fire

Forest Land
Land at least 10 percent occupied by forest trees or formerly having had such tree cover and not currently developed for nonforest use Lands developed for nonforest use include areas for crops, improved pasture, residential, or administrative areas, improved roads of any width, and adjoining road clearing and powerline clearing of any width.

FORPLAN
A linear programming model used for development and analysis of Forest Plan alternatives, and to display long and short-term resource interactions in forest management.

Fry.
The life stage of salmonid fish species that refers to the juvenile fish which have either not emerged from the gravel or have recently emerged

Fuelbreak.
A natural or constructed barrier utilized to stop or control the spread of fire

Fuel Treatment.
The process of removing and/or modifying natural or human created fuels to reduce fire hazard and achieve other resource objectives.

Fuelwood.
Wood that is round, split, or sawn and/or otherwise generally refuse material cut into short lengths or chipped for burning.

Full Log Suspension.
The system of transporting logs from the cutting site to the landing without touching the ground.

G

Game Species
Any species of wildlife or fish for which hunting seasons and bag limits have been established, and which are normally harvested by hunters and fishermen.

Goal

A concise statement that describes a desired condition to be achieved sometime in the future. Normally expressed in broad, general terms, it is timeless in that it has no specific date by which it is to be completed. Goal statements form the basis from which objectives are developed.

Geographic Information System (GIS)

An information processing technology to input, store, manipulate, analyze, and display spatial resource data to support the decisionmaking processes of an organization. Generally, an electronic medium for processing map information, typically used with manual processes, to effect specific decisions about the land base and its resources

Gross National Product (GNP)

The sum of final products, such as consumption of goods and gross investment, produced in the Nation in a given year. It is reported in dollars, as a measure of the economic performance of the entire economy

Guideline.

An indication or outline of policy or conduct

H

Habitat

The natural environment of a plant or animal.

Habitat Capability Index.

An indirect measure of the quality and quantity of habitat for a specific species, or group of species. The index is usually a range that is based on the predicted number of animals that could theoretically occupy the habitat available given a certain set of management prescriptions.

Habitat Diversity.

Distribution and abundance of plant and wildlife habitats

Habitat Island.

The occurrence of a habitat, such as an old-growth forest, that is physically separated from the next closest habitat of the same type by vegetation that is markedly different in composition and structure.

Hard Snag.

A snag composed primarily of sound wood, particularly sound sapwood; generally merchantable.

Hardwood.

A conventional term for the wood of broadleaf trees Hardwood areas reference herein are usually the result of past forest fires, and once supported conifer trees in the past. See Tentatively Suitable Forest Land

Hardwood Conversion.

The replacement of broadleaf trees or brush with conifer trees.

Hazard Reduction.

Any treatment of forest fuels that reduces the threat, ignition, or spread of wildfire.

Hiding Cover

Vegetation capable of hiding 90 percent of a standing adult deer or elk at 200 feet or less. Includes some shrub stands and all forested stand conditions with adequate tree stem density or shrub layer to hide animals In some cases, topographic features also can provide hiding cover

I

Immature-Poles.
See Tentatively Suitable Forest Land.

Immature-Small Timber.
See Tentatively Suitable Forest Land

Impacts.
See Effects.

Indicator Species
Species of fish, wildlife, or plants which reflect ecological changes caused by land management activities See Management Indicator Species.

Indirect Attack.
A method of fire suppression in which the control line takes advantage of natural fire breaks, topography, and fuel between the line and the fire

Individual Tree Selection.
The selection of trees for harvest based on individual tree characteristics.

Instream Flow.
Streamflow required to support instream uses, the flow required varying widely by type of channel, water quality, and time of distribution.

Integrated Pest Management
A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed The information considered in selecting appropriate strategies includes the impact of the unregulated pest population on various resources values, alternative regulatory tactics and strategies, and benefit and cost estimates for these alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable.

Integrated Prescription.
A planning prescription in which the Forest ID team identifies and quantifies outputs, effects, benefits, and costs of all forest resources to the extent practical. The management emphasis may be single or multiple use.

Intensive Management
A high investment level of timber management that includes precommercial and commercial thinnings, planting with genetically improved stock, control of competing vegetation, and other practices which increase tree growth.

Irretrievable.
Applies to losses of production, harvest, or use of renewable natural resources. For example, where production is lost, the action is irretrievable, but not irreversible

Irreversible.
Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods; also includes loss of future options

Irreversible Soils.
See Unsuitable Forest Lands

Issue.
See Issues, Concerns, and Opportunities.

Issues, Concerns, and Opportunities (ICO)
A public issue is a subject or question of widespread public interest relating to management of the National Forest resources, as identified through public participation and addressed through the planning process A management concern is an issue, problem, or condition which constrains the range of management practices identified by the Forest Service in the planning process Opportunities are those resource uses and development possibilities suggested by both the public and the Forest Service.

K

K-V Funds
Funds collected from timber purchasers for reforestation under the Knutson-Vandenburg (K-V) Act of 1930 National Forest Management Act expanded collection authority to include other resource protection and improvement on the sale area.

Knutson-Vandenburg Act of 1930, as amended.
A law which provides for a special fund, derived from the sale of timber, which may be used to fund reforestation and the protection and improvement of the Forest renewable resources on the sale area

L

Land Allocation
The assignment of a management emphasis to particular land areas with the purpose of achieving the goals and objectives of the alternative

Land Class
The topographic relief of a unit of land. Land classes are separated by slope, which coincides with the timber inventory process

Land Exchange.
The conveyance of non-Federal land or interests to the United States in exchange for National Forest Land or interests.

Land Inventory Mapping (LIM)
A grid mapping system with overlay and computational capability to input, store, edit, manipulate, overlay, and display resource information layers in a geographical quadrangle format.

Landscape Ecology.
The science of describing and understanding how plant and animal species and communities interact across watershed- and regional-scale areas

Land Stratification
Inventory of land according to a set of specific land characteristics, such as the ability to grow timber or the ability to resist erosion

Leasable Minerals
Mineral deposits specifically excepted from the General Mining Law by Congress (principally through the Mineral Lands Leasing Act of 1920, the Mineral Leasing Act of Acquired Lands of 1947, the President's Reorganization Plan No 3 of 1946), and the Geothermal Act of 1970

Linear Programming
A mathematical process that provides numerical solutions to problems of meeting a certain objective, within given boundaries and constraints. Information is expressed in linear, mathematical format.

Local Road.
A road constructed to provide access to specific resource areas. As such, these roads connect terminal facilities with Forest collector or arterial roads or public highways.

Locatable Minerals
Mineral deposits open to exploration, location, development, and purchase under the General Mining Law of 1972, as amended and interpreted. Minerals in sufficient quality and quantity to be a "valuable deposit" (FSM 2810)

Long-term Productivity.
The redistribution of resources within the ecosystem into products used by humans.

Long-term Sustained Yield (LTSY).
The estimated timber harvest that can be maintained indefinitely over time, once all stands have been converted to a managed state under a specific management intensity consistent with multiple use objectives.

M

Management Area
An area composed of aggregate pieces of land (generally several to many analysis areas) to which a given management objective and prescriptions are applied.

Management Concern.
See Issues, Concerns, and Opportunities.

Management Direction
A statement of multiple use and other goals and objectives, along with the associated management prescriptions and standards and guidelines to direct resource management

Management Indicator Species
Management indicator species are animals or plants selected for special attention in the Forest Plan for one or more of three reasons They may be:

1. *Emphasis species* - species to be managed as key resources on the basis of identified issues, e.g., threatened, endangered, rare, sensitive, harvest, or special interest species;

2. *Indicate special habitat conditions* - species that require special habitat such as snags, riparian, old-growth forest stands, etc ; and/or

3. *Indicate cumulative forest ecosystem change* - generally species having large home ranges and requiring a diversity of habitats.

Management Intensity
A management practices or combination of management practices and associated costs designed to obtain different levels of goods and services

Management Practice
A specific action, measure, course of action, or treatment

Management Prescription
Management practices and intensity designed to attain multiple use benefits and other goals and objectives when applied to a specific land area at a particular point in time

Management Requirements (MR)
Requirements designed to assure compliance with the applicable laws and regulations, specifically 36 CFR 219.27 for resource protection

Mass Failure (also Wasting).
All geologic processes in which earth materials move downslope, either slowly or quickly, by gravitational forces.

Mature.
See Tentatively Suitable Forest Land.

Mean Annual Increment.
The average annual growth of a stand, calculated by dividing the total growth accrued over its life by its age in years at the time of measurement.

Mean Basin Variation (Coefficient of Variation).
The coefficient of variation is a statistical tool used to compare the amount of variation in populations having different means In this case, to compare the variation in accelerated sediment production in a Planning Basin over the first five decades. Lower values indicate a more even distribution of the sediment production, therefore less risk of watershed degradation that might result from concentrations of peak outputs

Minimum Management Requirements (MMR).
Specific requirements consistent with 36 CFR 219 27 that are designed to prevent damage to forest resources beyond a minimum threshold established by law or regulation An outdated phrase, see Management Requirements.

Mitigation
Actions to avoid, minimize, reduce, eliminate, compensate, or rectify the impact of a management practice.

Monitoring and Evaluation.
The evaluation, on a sample basis, of Forest Plan management practices to determine how well objectives are being met, as well as the effects of those management practices on the land and environment.

Multiple Use.
Management of all the various renewable surface resources of the National Forest so that they are utilized in the combination that will best meet the needs of the American people. The concept also includes making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions. Some of the land will be used for less than all of the resources There should be harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land. Consideration is given to the relative values of the various resources, and not necessarily to the combination of uses that will give the greatest dollar return or the greatest unit output.

N

Native species.
A plant or animal species that occurs indigenously in an area.

Natural Opening
A break in the forest canopy. A naturally-occurring area of bare soil, grasses, forbs, or shrubs located in a large area dominated by trees Also included are created openings no longer suitable for timber production

Naturalized Species.
A non-native species established as if it were a native species

NEPA Process
An interdisciplinary process, mandated by the NEPA, which concentrates decisionmaking around issues, concerns, alternatives and the effects of alternatives on the environment

Net Public Benefit (NPB).
The total benefits minus costs of all priced and non-priced resource outputs and effects. It is an expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not Maximization of NPB's to be derived from management of units of the National Forest system is consistent with the principles of multiple-use and sustained yield.

Nonchargeable Timber.
Timber volumes that are not included in calculations of a regulated sale schedule and therefore cannot be included when determining achievement of that timber sale schedule.

Nondeclining Flow and **Nondeclining Yield**
See base sale schedule.

Nonforest Land
Lands that never have had or that are incapable of having 10 percent or more of the area occupied by forest trees; or lands previously having such cover and currently developed for nonforest use.

Nonvegetative
Rock and rock outcrops.

O

O&C (Oregon and California) **Funds**
A fund administrated by the Bureau of Land Management accummulated from payments made by timber purchasers when timber is harvested on O&C lands. O&C lands are those which were repossessed by the U.S. Government from the Oregon and California Railroad Company in 1916. Payments are made to counties by BLM in lieu of taxes from these funds, and a portion of the fund is used for resource mitigation and enhancement projects on those lands.

Objective.
Specific statement of measurable planned results to be achieved within a stated time period. Reflects alternative mixes of all outputs or achievement which can be attained at a given budget level.

Objective Function
The item to be maximized or minimized; for example, timber or present net value in the solution of a linear programming model.

Off-Road Vehicle (ORV).
A vehicle capable of cross-country travel or travel on low-standard roads and trails, e g , motorbikes, ATV's, 4-wheel drive vehicles, snowmobiles

Old Growth.
Any stand of trees 10 acres or greater generally containing the following characteristics· (1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage, (2) stands will usually contain a multi-layered canopy with trees of several age classes; (3) standing dead trees and down material are present, and (4) evidence of human activities may be present, but do not significantly alter the other characteristics and are a subordinate factor in the stand description.

Opportunity.
See Issues, Concerns, and Opportunities.

Opportunity Cost.
The dollar-quantifiable net loss resulting from selecting a less efficient course of action.

Optimal Thermal Cover
A forest stand with. (1) four layers (overstory canopy, sub-canopy, shrub layer, and herbaceous layer); and (2) an overstory canopy which can intercept and hold a substantial amount of snow yet has dispersed, small (less than one-eighth acre) openings. These criteria are generally achieved when the dominant trees average 21 inches Diameter at Breast Height (DBH) or greater crown closure, and are in the large sawtimber or old-growth stand condition.

Outputs.
The goods, services, and products which are measurable and capable of being used to determine the effectiveness of programs and activities in meeting objectives Also goods, end products, or services that are purchased, consumed or utilized directly by people

Overstory.
The portion of trees in a forest which forms the uppermost layer of foliage

P

PARS
The burned acreage and fire occurrence guidelines which represent the annual average long-term loss; PARS are expressed by forest size classes and intensity levels

Peak Flow.
The highest value of stream stage or flow attained during a flood.

Perennial Streams.
Streams which normally flow throughout the year

Peridotite
Plutonic rocks containing olivine, amphibole, pyroxenes, and micas See Ultramafic.

Permittee
A holder of a permit to use public land or resources for a specific purpose

Persons At One Time (PAOT)
A recreation capacity measurement indicating the number of people who can use a facility or area at one time.

Pioneer Species
A plant capable of invading bare sites (newly exposed soil surface) and persisting there, i.e., "colonizing" them, until supplanted

Planning Basins
Geographical locator areas that approximate major drainages on the Forest. Designated for planning purposes.

Planning Horizon.
In the planning process, the overall time period that spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions that would influence the planning decisions; in this case, 150 years

Planning Period
The length of time that a Plan is intended to be in effect; in this case, 10 to 15 years.

Plant Community.
Any assemblage of plants which occur in the same area and that form a distinct ecological unit

Pool/Riffle Ratio.
The ratio of pools to riffles, expressed as a percentage, used to describe fish habitat rearing quality

Population.
All interbreeding individuals of a given species living in a particular area

Population Viability.
The degree to which a population can maintain itself over time, population viability analysis is the process by which this is estimated See also Viable Population.

Precommerical Thinning
The selective felling or removal of trees in a young stand, conducted to accelerate diameter growth on remaining trees, maintain a specific stocking density, and improve vigor and quality of remaining trees; conducted at an age before the trees are commercially merchantable

Prescribed Fire.
Intentional application of fire, of either planned or unplanned ignitions, to accomplish certain planned objectives

Prescription.
Management practices selected and scheduled for application on a specific area to attain goals and objectives

Present Net Value (PNV).
The difference between discounted benefits and discounted costs

Presuppression
Activities conducted in advance of fire occurrence to insure effective suppression.

Primitive Recreation Opportunities.
See Recreation Opportunity Spectrum

Programmed Harvest
Timber scheduled for harvest for a specific time period.

Public Issue.
See Issues, Concerns, and Opportunities

Purchaser Road Credit
Dollar credits earned by a timber purchaser for constructing or reconstructing roads needed for removal of timber included in a timber sale contract. Credits are applied toward the purchase price of the timber

R

Ranger District (R.D.)
Administrative subdivision of the Forest, supervised by a District Ranger who reports to the Forest Supervisor

Rare.
Plant or animal species which are uncommon in a specific area. All endangered, threatened, and sensitive species can be considered rare, but the converse is not true

Rearing Habitat.
The river or stream areas where juvenile salmonids must find food and shelter to survive for a period of time

Reconstruction
Activities performed on an existing road or other facility to restore it to a specified standard.

Recreation Capacity
The number of people that can take advantage of the supply of a recreation opportunity during an established use period without substantially diminishing the quality of the recreation experience or the resources.

Recreation Inventory Management (RIM)
The Forest Service system for recording the condition of recreation facilities and use

Recreation Opportunity Spectrum (ROS)
Land delineations that identify possible combinations of recreation activities, settings, and experience opportunities, from Primitive to Urban, arranged along a continuum. Classes used herein are.

Primitive - Area is characterized by essentially unmodified natural environment of a size or location that provides the opportunity for isolation from sights and sounds of people Motorized use within the area is normally not permitted

Semi-primitive Non-motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people. Motorized use is not normally permitted

Semi-primitive Motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people except for facilities essential for the use of motorized equipment Motorized use is permitted. Limited primitive road construction to enhance recreation opportunity is permissible.

Roaded Natural - Area is characterized by predominantly natural appearing environments with moderate evidences of the sights and sounds of people. Conventional motorized use is provided for in construction standards and design of facilities.

Rural - Area is characterized by substantially modified natural environment Facilities for intensified motorized use are available

Recreation Visitor Day (RVD)
A unit for measuring recreation activities One unit equals 12 visitor hours and may consist of one person for 12 hours, or 12 persons for one hour, or any equivalent combination

Recreation River
See Wild, Scenic and Recreation Rivers

Redd.
Nest in gravel of stream bottom where fish deposit eggs; herein, refers to salmon spawning redds

Reforestation.
The natural or artificial restocking of an area with forest trees; includes measures to obtain natural regeneration, as well as tree planting and seeding The work is done on National Forests to produce timber and other forest products, protect watershed functioning, prevent erosion, and improve other social and economic values of the forests, such as wildlife, recreation, and natural beauty.

Regeneration.
The renewal of a tree crop, whether by natural or artificial means Also the young tree crop (seedlings and saplings) itself

Release
All work done to free desirable trees from competition with other less desirable vegetation.

Research Natural Area (RNA)
An area representing the major natural timber types or other plant communities in unmodified condition (FSM 4060). A natural plant community established for research and study of ecosystem and their changes

Residue (Timber).
The portions of trees left in the forest during timber harvest, i e., tops, limbs, chunks and other material not usable for manufacturing into timber products.

Resource Allocation.
Designation of specific parcels of land for the production of certain resources; the resources derived may be commodities, amenities, or a combination of each See Land Allocation.

Riparian Areas.
Terrestrial areas where the vegetation and microclimate are influenced by perennial and/or intermittent water, associated high water tables and soils which exhibit some wetness characteristics, this habitat is transitional between true bottom land wetlands and upland terrestrial habitats and, while associated with water courses, may extend inland for considerable distance

Riparian Ecosystems.
See Riparian Areas

Riparian Habitat.
See Riparian Areas.

Riparian Prescription.
As used in this document, a method to provide flexibility for retaining shade, large organic material, and other inherent features in the riparian areas for long-term input to stream systems Three options are identified (B, C, and M Prescriptions) for management of the riparian vegetation in areas suitable for timber management; they differ in the amount of vegetation that must be retained after management activities

Risk
Different possible outcomes, where a probability can be assigned to each outcome with a degree of accuracy

River Corridor.
A strip of land, ridge top-to-ridge top, which is seen or potentially seen from a river

Road Corridor
A strip of land between two points used by a road, or some future road whose exact location remains to be determined; usually with an indefinite width

Roadless Area Review and Evaluation II (RARE II).
A comprehensive process (the second) instituted in 1977 to identify roadless and undeveloped land areas containing 5,000 acres or more in the National Forest System for the purpose of determining which of the inventoried areas should be recommended to Congress for inclusion in the National Wilderness Preservation System, which areas should be managed for nonwilderness uses, and which areas required further planning before a reasonable decision on them could be made. This assessment was documented through an FEIS.

Roaded Natural.
See Recreation Opportunity Spectrum

Rotation.
The planned number of years required to establish (including the regeneration period) and grow timber crops to a specified condition or maturity for regeneration harvest. Selected management prescriptions in the Forest Plan provide the basis for the rotation age.

S

Salable Minerals
Mineral deposits outside the scope of the General Mining Law because of widespread occurrence and "common" nature (disposal under the Materials Act of 1947, as amended).

Salmonid.
Member of the fish family *salmonidae*; includes salmon and trout.

Sale Schedule
The quantity of timber planned for sale by time period from the area of suitable land covered by a Forest Plan. The first period, usually a decade, of the selected sale schedule provides the allowable sale quantity. Future periods are shown to establish that long-term sustained yield will be achieved and maintained.

Salvage.
Removal of recently-dead or dying trees to minimize the loss of wood products.

Sawtimber
Trees that are nine inch Diameter at Breast Height (DBH) or larger and can be made into timber

Scenic Easement.
An interest in the land which allows the holder specified uses or rights without ownership of the land In this case, control of the use of land adjacent to public highways, parks, and rivers It may provide something attractive to look at within the easement area, an open area to look through to see something attractive beyond the easement itself, or a screen to block out an unsightly view beyond the easement area.

Scenic River
See Wild, Scenic and Recreation Rivers

Scoping.
The procedures by which the Forest Service determines the extent of analysis necessary for a proposed action, i e., the range of actions, alternatives, and impacts to be addressed, identification of significant issues related to a proposed action, and establishing the depth of environmental analysis, data, and task assignments needed.

Second Growth (Young Growth).
Timber stands established after natural or human-caused removal of the original stand or previous forest growth.

Seed Tree
A tree selected, and often reserved for seed collection.

Seed Tree Cutting
Similar to clearcutting, except that a few of the better trees of the desired species are left scattered over the area to provide seed for regeneration

Seedlings and Saplings
See Tentatively Suitable Forest Land.

Selection Cutting.
The annual or periodic removal of trees, individually or in small groups, from an uneven-aged forest in order to realize yield and establish a new stand of irregular constitution.

Semi-primitive Motorized
See Recreation Opportunity Spectrum.

Semi-primitive Non-motorized.
See Recreation Opportunity Spectrum

Sensitive Species.
Those plant and animal species identified by the Regional Forester for which population viability is a concern as evidenced by significant current or predicted downward trends in (a) population numbers or density, or (b) habitat capability that would reduce a species' existing distribution.

Separate Suitability Component (SSC).
See Tentatively Suitable Forest Land.

Seral Stage
A transitory or developmental stage of a biotic community in an ecological succession (does not include climax successional stage)

Serpentine.
A mineral or rock (serpentinite) consisting essentially of a hydrous magnesium silicate usually having a dull green color and often a mottled appearance. Term sometimes used with soil, to indicate environmental conditions found on soils derived from serpentinite or peridotite. See Ultramafic.

Shelterwood Cutting
A regeneration method under an even-aged silvicultural system A portion of the mature stand is retained as a source of seed and/or protection during the period of regeneration The mature stand is removed in two or more cuttings

Significant.
As used in NEPA, requires consideration of both context and intensity. Context means that the significance of an action must be analyzed in several contexts such as society as a whole, and the affected region, interests, and locality Intensity refers to the severity of impacts (40 CFR 1508.27)

Silviculture.
The art and science of growing and tending forest vegetation, i e , controlling the establishment, composition, and growth of forests, for specific management goals

Silvicultural System
A management process whereby forests are tended, harvested, and replaced, resulting in a forest of distinctive form. Systems are classified according to the method of carrying out the fellings that remove the mature crop and provide for regeneration, and according to the type of forest thereby produced

Sight Distance.
The distance at which 90 percent or more of an adult elk or deer is hidden from the view of a human.

Site Preparation.
Removal of unwanted vegetation, slash, roots, and stones from a site before reforestation.

Slash
Woody material left after logging, pruning, thinning, brush cutting, or other management activities and/or accumulating there as a result of storm, fire, or other damage.

Smolt
Juvenile salmon or steelhead which are ready to leave freshwater for the ocean They mature in the ocean before returning as adults to rivers and streams to spawn

Smolt Habitat Capability Index
An indicator of the quality of rearing habitat for young salmon or steelhead (smolt). It assumes that spawning gravels are adequate to provide sufficient spawning areas to fully seed the existing rearing habitat and that sufficient numbers of adults will escape past fishermen, dams, or natural mortality to return and fully seed the spawning gravels. It is expressed as the number of smolt which could be produced, estimating potential rather than actual production

Snag.
A standing dead tree

Spatial.
Referring to the distance, interval, or area between or within things.

Special Use Permit
A permit issued to an individual, organization, or company for use of National Forest Land for some specified purpose

Species.
Organisms that successfully reproduce among themselves and cannot reproduce successfully with other organisms

Species Diversity
The distribution and abundance of different plant and animal communities and species.

Spotted Owl Habitat Area (SOHA).
A habitat area designated to support one owl pair

Spotted Owl Management Area (SOMA).
A habitat area designated to support more than one owl pair. An outdated phrase, see Spotted Owl Habitat Area

Stand
A community of trees or other vegetation sufficiently uniform in composition, constitution, age, spatial arrangement, or condition to be distinguishable from adjacent communities and so form a silvicultural or management entity.

Standard.
A principle requiring a specific level of attainment, a rule to measure against

Steelhead.
A large-sized, silvery anadromous rainbow trout

Stocking.
The degree to which trees occupy the land, measured by basal area and/or number of trees by size and spacing, compared with a stocking standard, that is, the basal area and/or number of trees required to fully utilize the land's growth potential

Strategic Minerals.
Any mineral neither found or produced in the United States in sufficient quantities to sustain the Nation during a period in which the security and/or economy of the country is threatened by a foreign power.

Stream Class.
The classification of streams according to their beneficial uses Whole streams or parts of streams can be classified One stream may be divided into several classes

Class I. Perennial or intermittent streams have one or more of the following characteristics. (1) Is the direct source of water for domestic use (cities, recreation sites, etc.), (2) Are used by large numbers of fish for spawning, rearing, or migration, (3) Flow enough water to have a major influence on water quality of a Class I stream

Class II Perennial or intermittent streams have one or both of the following characteristics· (1) Are used by moderate though significant numbers of fish for spawning, rearing, or migration, (2) Flow enough water to have a moderate influence on downstream quality of a Class I or II stream.

Class III. All other perennial streams not meeting Class I or Class II definitions.

Class IV. All other intermittent streams not meeting Class I, II, or III definitions

Streamside Management Unit (SMU)
The stream and an adjacent area of varying width where practices that might affect water quality, fish, and other resources are modified, as necessary, to meet management goals for each class of stream.

Stumpage
Standing timber or its value.

Successional Stage
A stage or recognizable condition of a plant community which occurs during its development from bare ground to climax.

Suitable Forest Land.
Land to be managed for timber production on a regulated basis Also, see Tentatively Suitable Forest Land.

Suppression Strategy.
The broad application of plans and tactics to a specific fire situation, basic strategies include confine, contain, and control.

Sustained Yield.
The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System, without impairment of the productivity of the land.

T

Talus
The loose accumulation of fragmented rock material on slopes, especially at the base of a cliff

Temporal.
Referring to time

Tentatively Suitable Forest Land
Forest land that is producing or is capable of producing crops of industrial wood and. (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions, (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that it is possible to restock adequately within 5 years after final harvest; and (d) adequate information is available to project responses to timber management activities

Mature - In the context of timber -- trees or stands that have reached rotation age, generally around 100 years. In the context of wildlife -- Mature forest habitat with characteristics needed to provide habitat for species such as pine marten and pileated woodpecker (generally occurs around age 100) With regard to land type -- Lands with 100-year-old, or older, timber stands available for harvest cutting

Immature-Small Timber - With regard to land type -- Lands with well stocked timber stands less than rotation age that are suitable for commercial thinning in the next two decades

Immature-Poles - With regard to land type -- Lands with timber stands less than rotation age that do not have excess stocking available for commercial thinning

Seedlings and Saplings - With regard to land type -- Lands with non-commercial-size young stands, generally plantations.

Hardwoods - With regard to land type -- Lands occupied by hardwood stands with less than 10 MBF per acre stocking of conifer timber

Separate Suitability Component (SSC) - Lands with timber production potential less than 20 cubic feet per acre per year The vegetation on these lands was not inventoried in the 1979 timber inventory (they were arbitrarily considered noncommercial at that time)

Terrestrial.
Living on land· distinguished from aquatic (living in water)

Thermal Cover
Vegetation used by animals to modify the adverse effects of weather. A forest stand that is at least 40 feet in height with tree canopy cover of at least 70 percent These stand conditions are achieved in closed sapling-pole stands and by all older stands unless the canopy cover is reduced below 70 percent. Deciduous stands may serve as thermal cover in summer, but not in winter

Threatened Species
Any species of plant or animal which is likely to become endangered within the foreseeable future throughout all or a significant portion of its range

Timber Site Index
A measure of site productivity based on the maximum rate of tree height growth. It is normally expressed as the height in feet reached by a tree at a given or base age (the site index).

Timber Stand Improvement (TSI)
Measures such as thinning, pruning, release cutting, prescribed fire, girdling, weeding, etc , of unwanted trees with the objective of improving growing conditions of the remaining trees

Tolerance
The forestry term for expressing the relative capacity of a tree to compete under low light and high root competition·

Tolerant Trees - Trees which reproduce and form understories beneath canopies of less tolerant trees or even beneath shade of their own species

Intolerant Trees - Trees which reproduce successfully only in the open or where the canopy is greatly broken

Total Resource Information (TRI) System
A natural resource data base used on National Forests in the Pacific Northwest Region. This multimedia information system was established to provide storage and retrieval of large volumes of in-place resource data

Transportation Corridor
As used in this document, a strip of land of variable width designated to accommodate the clearing and access control of a State or Federal Highway

Tradeoff.
Foregoing certain options in the decision process to take advantage of others

Travel Corridor.
A road, trail, or waterway used by people; or a strip of land used by wildlife.

TRI Compartment
An area identified on an orthophoto map for indexing and storing data locations. Each compartment has a unique name and number.

Turbidity.
The optical property of water as affected by suspension of material such as sediment, i e , the muddy or cloudy state of water.

U

Ultramafic
Intrusive rocks composed chiefly of mafic minerals such as olivine, pyroxene, and serpentine Also called ultrabasic. See Peridotite and Serpentine

Unavailable Forest Land
Lands which have been legislatively or administratively withdrawn from timber production by law, the Secretary of Agriculture, or the Chief of the Forest Service.

Understory
Vegetation (trees or shrubs) growing under the canopy formed by taller trees

Uneven-age Management.
The application of a combination of actions needed to simultaneously maintain continuous high-forest cover, recurring regeneration of desirable species, and orderly growth and development of trees through a range of diameter or age classes to provide a sustained yield of forest products Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes Cutting methods that develop and maintain uneven-aged stands are single-tree and group selection

Unsuitable Land
Forest land withdrawn from timber utilization by statute or administrative regulation, or identified as not appropriate for timber production in the Forest planning process, i e., irreversible soil loss and nonreforestable within five years.

V

Viability.
Capable of living, growing, and developing

Viable Population.
A population of plants or animals large enough and distributed in such a way as to ensure their continued existence over a specified period of time, usually on the order of decades to centuries.

Viewshed.
A total landscape seen or potentially seen from specific points on a logical part of a travel route or water body.

Visual Corridor.
A series of viewsheds identified for special attention under visual quality management.

Visual Resource.
The composite of basic physiographic features and patterns, and land use effects that typify a land unit and influence the visual appeal the unit may have for visitors

Visual Quality Objective (VQO).
Measurable standards for visual resource management based on the acceptable degree of alteration of the characteristic landscape. The VQO's and their definitions are.

Preservation. Provides for ecological changes only.

Retention. Activities are not evident to the casual forest visitor

Partial Retention. Activities may be evident but must remain subordinate to the characteristic landscape.

Modification. Activities may dominate, but must utilize naturally-established form, color, and texture. These areas should appear natural when viewed in foreground or middleground situations

Maximum Modification. Activities may dominate, but should appear as a natural occurrence in background situations

W

Watershed.
The land area drained by a river system

Wetlands.
Areas that are inundated by surface or ground water with a frequency sufficient to support, and that, under normal circumstances, do or would support, a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction Wetlands generally include swamps, marshes, bogs, wet meadows, river overflows, mud flats and natural ponds

Wild, Scenic, and Recreation Rivers
Rivers or river segments which have been designated as part of the National Wild and Scenic Rivers System (Public Law 90-542, 1968) Criteria for classification are as follows:

Wild Rivers - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America

Scenic Rivers - Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

Recreation Rivers - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Wilderness.
All lands included in the National Wilderness Preservation System by public law; generally defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation

Wilderness Recreation Spectrum (WRS).
A further refinement of the *primitive* portion of the Recreation Opportunity Spectrum. The following terms deal only with officially designated wilderness:

Pristine - The most remote; generally the core area which is least accessible. The area is characterized by no trails. A *most outstanding* opportunity exists for isolation and solitude free from evidence of past human activity.

Primitive - The sights, sounds, and smells relating to human activities outside the wilderness are essentially nonexistent. The area is generally accessible by trail. An *extremely high opportunity* exists for exploring and experiencing considerable isolation, tranquility and self-reliance.

Semi-primitive - The least remote; generally areas nearest trailheads and major access points or the wilderness periphery. Opportunities for a wilderness-related experience are only *moderate*.

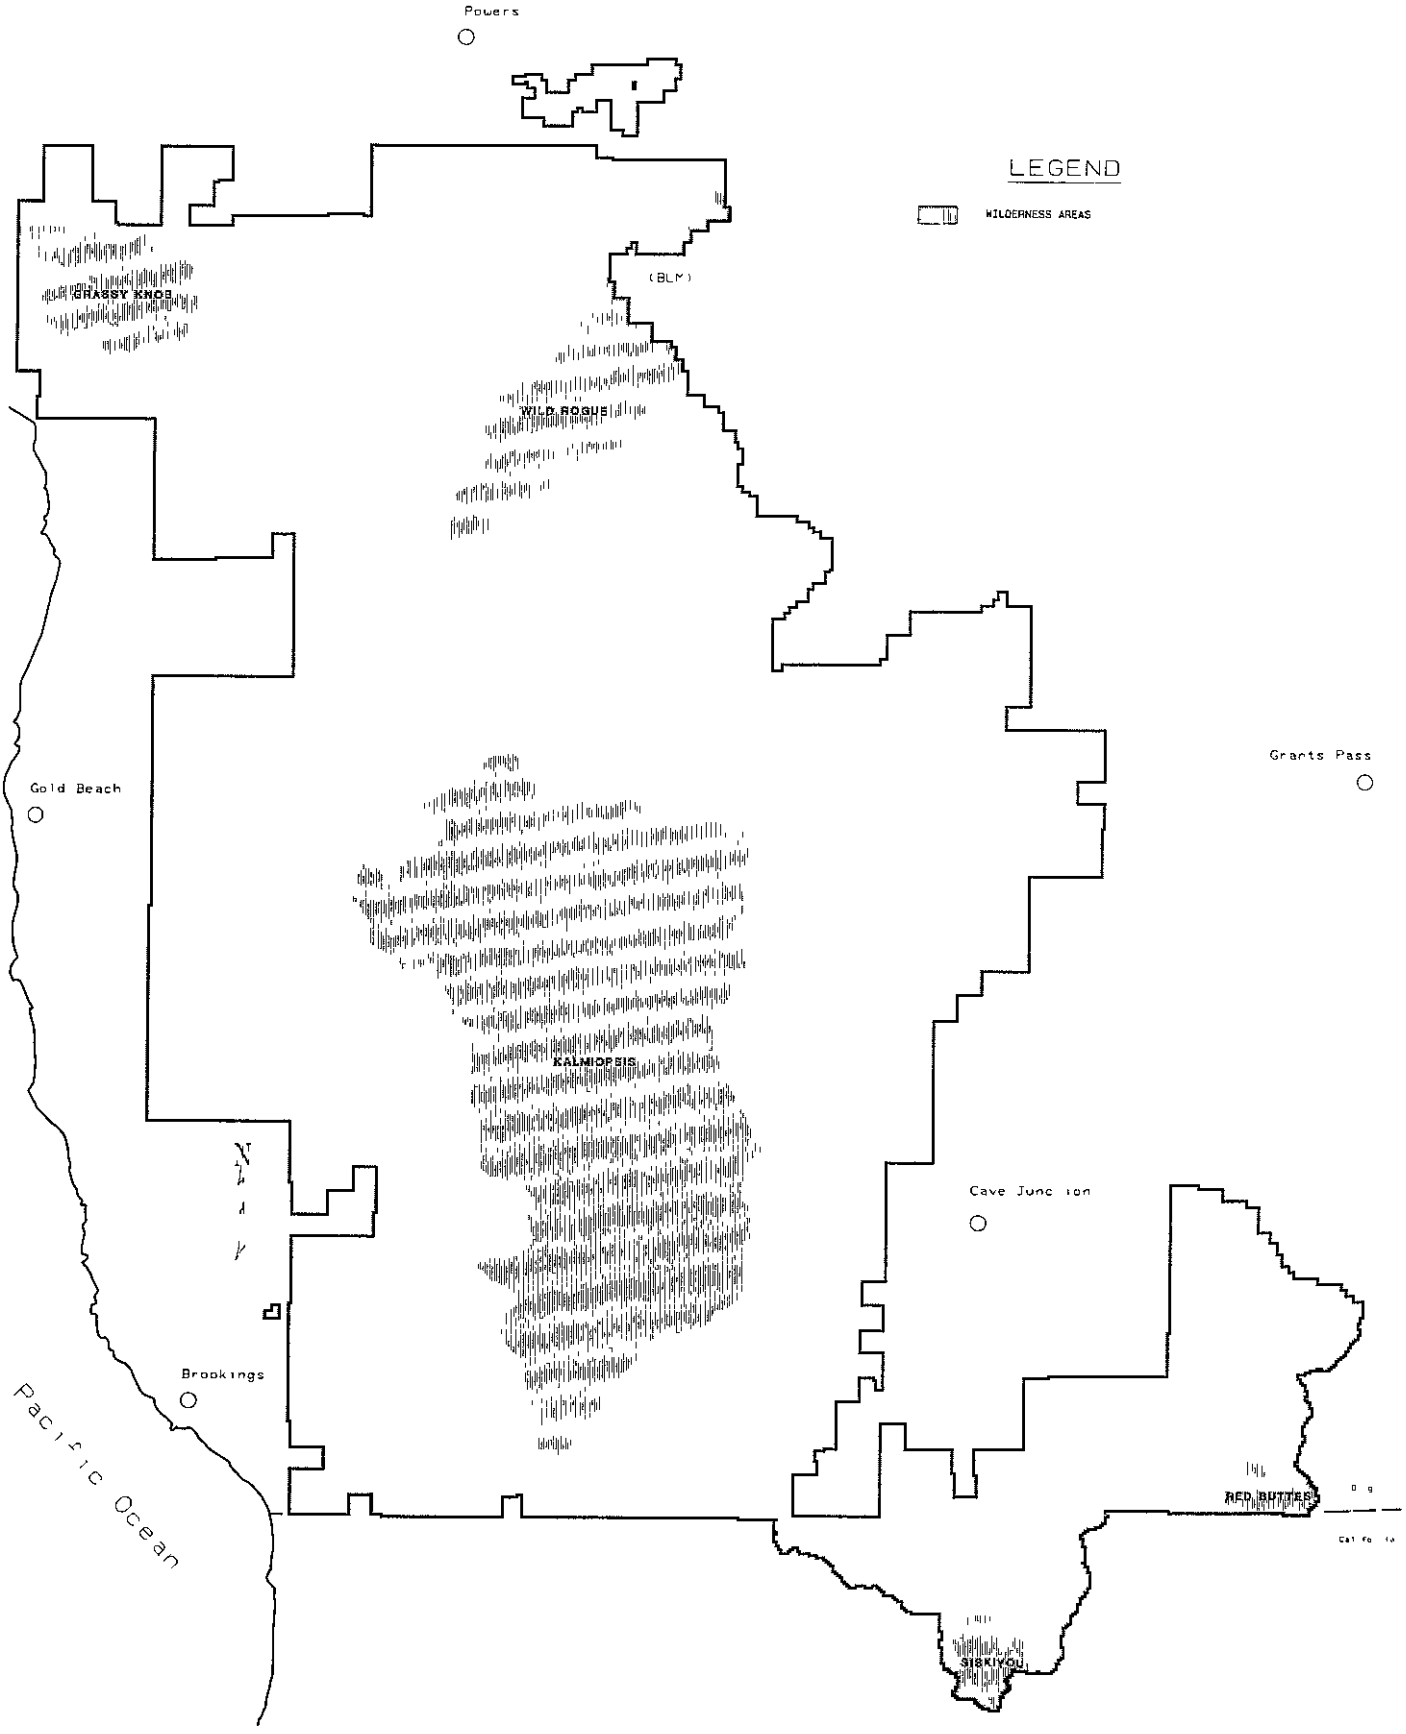
Wildlife Tree.
A snag or a live tree designated for wildlife habitat

Wild River
See Wild, Scenic, and Recreation Rivers.

Winter Range.
An area used by deer and elk during the winter months, usually at lower elevation and/or south and west exposures

Withdrawn
Land areas where certain uses are excluded.

Y



Yield Table.
A table of timber volumes expected to be produced under a specified set of conditions

WILDERNESS MANAGEMENT PLANS

Wilderness Map

GRASSY KNOB

OVERVIEW

The Grassy Knob Wilderness consists of 17,200 acres of very steep, rugged terrain Over most of the area there is little or no evidence of past human activity. Travel in the Wilderness is difficult due to dense vegetation and the lack of maintained trails. Congressional records of the Oregon Wilderness Bill of 1984, which designated Grassy Knob as a wilderness, stated that protection of anadromous fisheries habitat is of prime importance in the Grassy Knob area. Dry Creek provides prime spawning habitat for 65 percent of the salmon and 25 percent of the steelhead in the Sixes River system In addition, Grassy Knob provides spawning habitat and cool water during critical summer months to the Elk River and the Elk River State Fish Hatchery Grassy Knob also provides an opportunity to study the Port-Orford-cedar root disease *Phytophthora lateralis*, in an undisturbed setting. The Powers Ranger District is the administrative unit responsible for management of the Wilderness.

OCCUPANCY

SITUATION

The greatest evidence of human activity within the Grassy Knob Wilderness is the timber harvest and road construction that took place in the early 1960's. At that time, Section 36 was privately owned, and the entire area was clearcut Road access was from the north in the area of China Peak. The Forest Service acquired the land in 1972. In addition, evidence of cedar harvest from as long as one hundred years ago is still evident on the lower stretches of Dry Creek No known structures or cabins are in the wilderness.

OBJECTIVE

Maintain the Grassy Knob Wilderness in a condition as free from human structures and impacts as possible.

MANAGEMENT DIRECTION

Section 36 and the road into the area are healing over naturally, though still quite evident. These areas will be left to return to a natural state Any structures found will be inventoried and evaluated for cultural resource values and a determination will be made at that time whether to remove the structures or leave them to break down with time.

RECREATION CAPACITY

SITUATION

At the present time, recreational use in the Grassy Knob Wilderness is very low, estimated to be less than 100 Recreation Visitor Days (RVD's) per year. Most of this use consists of day trips to the old Grassy Knob Lookout site for the panoramic views of the ocean that it affords The estimated capacity of the Wilderness is 4000 RVD's days per year. At the present time, the Wilderness provides a very challenging trailless experience. Suitable campsites are very limited due to steep slopes and V-shaped canyon bottoms. Along the lower 1-1/2 miles of Dry Creek, approximately 10 small bars exist that would be suitable as campsites, if trail access is provided. Summer access up Dry Creek is very good via the creek bed

OBJECTIVE

Determine actual use and insure that this level of use will not prevent the preservation of the wilderness resource and its natural condition Maintain the Wilderness for a semi-primitive, limited trail or trailless recreation experience

MANAGEMENT DIRECTION

Monitor overall use and recreational impacts on the Wilderness Potential campsites will be monitored by the Wilderness Ranger and impacts evaluated using the Limits of Acceptable Change system to determine if restrictions on use are needed At the present time, no restrictions are needed. An information board will be set up at the trailhead to Grassy Knob, and users will be encouraged to register upon entry into the wilderness so better information on use can be collected

TRANSPORTATION

SITUATION

Prior to the designation of Grassy Knob as a Wilderness, a road was constructed from the Forest Boundary in Section 19 to Section 33 Under the Wilderness Bill, this road was excluded from the wilderness. The wilderness boundary is located 33 feet on either side of the road prism. At the present time, this road is blocked by a guard rail and dirt mound in Section 32 Beyond the guard rail, the roadbed is being used as a trail to the Grassy Knob lookout site. The old road into Section 36 is blocked off at the Wilderness boundary This road is not being maintained as a trail at this time There are no proposed trail construction projects at this time, although potential projects have been identified

OBJECTIVE

Maintain the Wilderness in a condition to provide a Semi-primitive wilderness recreation experience.

MANAGEMENT DIRECTION

The road blockage of the Grassy Knob road in Section 32 will be maintained to reduce the amount of road noise in the Wilderness and to reduce road maintenance costs. The road "finger" from Grassy Knob east is a Backcountry Recreation Management Area The application of Standards and Guidelines for this area are found in Chapter IV of the Forest Plan An administrative closure under a Code of Federal Regulations (CFR) will be issued to enforce the closure The roadbed beyond the closure will be maintained as a Level II trail to the lookout site The road into Section 36 will not be maintained as a trail. No other trails are planned for construction or maintenance, though potential trail locations have been identified if the decision is made at a later date to develop a trail system in the Wilderness

COMMERCIAL OPERATIONS

SITUATION

There are sixteen mining claims on the boundary of the Wilderness along the Elk River and three on the boundary of Butler Creek. In addition, nine claims are in the Wilderness on the slopes above the Elk River None of these claims are active, and only one has proposed an operations schedule. The Forest Service is disputing the validity of this claim No special use permits have been issued, and there are no outfitter or guide operations in the wilderness.

In the Wilderness Bill, provisions were made to allow tailholds in the Wilderness for the China Peak Timber Sale, which had been sold and the roads constructed prior to the enactment of the Bill

OBJECTIVE

Minimize or eliminate any adverse impacts on the wilderness resource resulting from commercial operations.

MANAGEMENT DIRECTION

Insure that any operating plans submitted for mining operations in the Wilderness are compatible with the Wilderness objectives and contain the appropriate rehabilitation measures to insure that the wilderness resource is protected and returned to a natural condition to the greatest extent possible Prior to approval of any operating plan, a mineral examination will be conducted to determine the validity of the mining claim. Collect K-V funds to clean up and remove any evidence of logging where tailholds were used in the wilderness

FIRE

SITUATION

The present fire frequency is very low with only one recorded fire in the Wilderness in the last 60 years, the last major fire occurring in 1929 Historical records and vegetative types in the wilderness show that fire has played an important role in vegetative development. Fires were high intensity due to steep slopes and the fuel types present, resulting in stand replacement on the north slopes, and conversion to, or maintenance of, brush fields on the south slopes Major man-caused fires in the late 1800's swept through most of Grassy Knob The large conifers date to this period.

OBJECTIVE

The principle objective for fire management is to minimize the total acres and intensity of burns over time The protection of water quality and associated fish habitat, and maintenance of the natural functioning of this tanoak/Douglas fir ecosystem are the primary goals of protection.

MANAGEMENT DIRECTION

Fire suppression strategies and tactics developed in the Escaped Fire Situation Analysis (FSM 5132.1) should provide for the least acres burned Both the short-term and long-term effects of the selected fire suppression strategy and tactics on water quality, and fish habitat need to be clearly displayed.

Fire suppression efforts will emphasize direct attack whenever possible. The use of mechanized equipment and aerial retardant in the Wilderness requires prior approval by the Forest Supervisor A more thorough description of fire suppression techniques allowed in the Wilderness are found in the Fire Management Action Plan for the Siskiyou National Forest

Prevention efforts will be concentrated on reaching the users prior to entering the wilderness Areas of emphasis in the prevention effort should be on protection of anadromous fisheries habitat from the adverse effects of wildfire, and personal safety of the user. Because of the dense vegetation and steep slopes, travel is slow, and escape from a wildfire would be difficult for wilderness users.

KALMIOPSIS OVERVIEW

The harsh, rugged terrain, coupled with the unique botanical values and mining history, give the Kalmiopsis Wilderness a character much different than most Pacific Northwest Wilderness areas The management emphasis for the Kalmiopsis is aimed at preserving the natural ecosystem and sensitive plants, as well as providing a place a visitor can experience solitude in a natural environment. The Chetco, Galice, and Illinois Valley Ranger Districts are the administrative units responsible for management of the Wilderness

OCCUPANCY

SITUATION

As a result of past and current mining activities, there are numerous facilities and disturbances that are non-conforming with the Wilderness concept They are:

CABINS

1. Emily
2 Petersen
3 Benjamine
4. Hilltop
5 Copper Creek
6 McTimmonds
7. Numerous ruins of other old cabins

LOOKOUTS

1. Pearsoll Peak

MINING EQUIPMENT AND DISTURBANCE

1 Along Little Chetco River
2 Bowers Mine
3 Carter Creek
4. Slide Creek
5. Taggarts Bar
6. Sluice Creek/Mouth Box Canyon Creek
7. Gold Basin
8. McTimmonds
9 Hilltop

Makeshift cabins and shelters have also occasionally been constructed

OBJECTIVE

Remove existing improvements, structures, equipment and facilities not essential to the protection of the Wilderness resource or to support valid mining operations. Restore the site to pre-existing condition as much as possible and let nature do the rest.

MANAGEMENT DIRECTION

A cultural resource evaluation will be carried out for non-conforming facilities, and appropriate National Historic Preservation Act (1980 amendments) compliance procedures will be followed, including consideration of a range of options to avoid or minimize adverse effects A mining claim validity determination will be made for any facilities recommended for removal. Do not maintain or permit others to maintain these facilities.

RECREATION CAPACITY

SITUATION

Although lightly used overall, there are two areas that are easily accessible and are receiving heavy use.

Present use is approximately 20,100 RVD's.

The capacity is approximately 29,300 RVD's. Although the present use is well below capacity, the Babyfoot Lake area is experiencing overuse

Limits of Acceptable Change concept will be applied to the heavy use areas by 1989 Some of those areas are:

HEAVY USE AREAS

1. Babyfoot Lake
2 Vulcan Lake
3. Mouth of Slide Creek

OBJECTIVE

Determine and manage a standard and capacity of visitor use that preserves the Wilderness resource and opportunities for Wilderness recreation.

MANAGEMENT DIRECTION

Specific direction for each zone (Primitive Trailless, Primitive Trailed, Semi-primitive) is contained in Wilderness Management Area Prescription, Chapter IV, of the Forest Plan.

CORRECTIVE ACTION

The following are specific areas where corrective actions should be implemented during the planning decade. Some of these actions may currently be in effect or planned.

Continue to eliminate nonvalid mining activity in the Babyfoot Lake Area.

Establish and monitor Limits of Acceptable Change.

TRANSPORTATION

SITUATION

There are numerous old mining roads and trails that provide the main transportation network. Some of the roads are occasionally traveled by miners in motorized vehicles as permitted in their Operating plans

Because of rugged terrain and dense brush, cross-country travel is extremely difficult and seldom attempted.

TRAILHEADS

There are thirteen trailhead or entry points into the Wilderness. Improvements are minimal and may consist of only a sign on a post and a registration box. The trailheads are:

1 Babyfoot Parking Area
2 Onion Camp
3 Chetco Pass
4 Briggs Creek
5. Rough and Ready Lakes
6 Sourdough Camp
7. Vulcan Lake
8. Chetco Divide
9 Upper Chetco Trail
10 Pupps Camp Trail
11. Red Mountain
12 Game Lake
13. Oak Flat

TRAILS

Many of the trails are in a relatively primitive condition Although most are passable by pack animals, they are narrow, steep and often treacherous. The serpentine-peridotite geologic formation is very hard on dogs' feet and usually results in a very sore-footed dog within a day or two.

1. There are 153 miles of existing trails
2 There are 28 miles of proposed trails that would open up new areas to Wilderness users
3. There are 120 miles of potential trails that could be added, to more evenly distribute use throughout the area.

ROADS

There are approximately 27 miles of old mining roads within the Wilderness that are sometimes used by miners with motorized vehicles to access their claims.

HELISPOTS

Some helispots have been constructed prior to creation of the Wilderness, but are no longer maintained.

RIVER USE

The Illinois River and, to a very minor degree, the Chetco River are used for white water raft and kayak trips Use of the Illinois is addressed in the Illinois Wild and Scenic River Management Plan (1985).

OBJECTIVE

Provide and maintain a trail system to a standard that will meet legal direction, and management needs for protecting resources and distributing visitor use, eliminating duplication of routes, and minimizing maintenance costs Roads will be converted to hiking trails when they are no longer needed for mining Temporary helispots may be constructed on a limited basis for the management of suppression and prescribed fire activities

MANAGEMENT DIRECTION

Modify trail maintenance and construction standards in order to achieve Wilderness objectives Modified standards can address clearing widths, "step-over" logs, alignment, maximum grade, bridges, and drainage

Develop and implement a trail relocation and reconstruction plan that emphasizes correction of poor alignment, reconstruction of old roadbeds, and design to distribute use away from overused areas

COMMERCIAL OPERATION

SITUATION

There are numerous mining claims within the Wilderness that are in various stages of activity and development. Access to the claims and activities on the claims frequently involve motorized equipment.

Excluding the Illinois River raft trips, outfitter guide use is light There has and will continue to be a demand for some commercial outfitter guide permits.

A mining access road built under a Special Use Permit still exists and is occasionally traveled by motorized vehicles for mining purposes.

OBJECTIVE

Reduce or eliminate the adverse effects on the Wilderness environment caused, or contributed to, by non-conforming uses or activities

MANAGEMENT DIRECTION

After a mining claim validity determination and a cultural resource evaluation, facilities and activities that are not authorized will be eliminated.

FIRE MANAGEMENT

SITUATION

The Wilderness is located in difficult terrain with heavy fuels accumulations in many places. Fuels consist mostly of dense brush but vary from dense forest growth to very open scattered Jeffrey pine and scattered grass The area has a history of large fires, the most recent being the 53,340 acre Silver lightning fire in 1987, preceded by the 34,627-acre Cedar Camp lightning fire in 1938 Many of the historic fires have been high intensity fires, resulting in stand replacement on the north slopes and conversion to, or maintenance of, brush fields on the south slopes. Portions of the Wilderness lend themselves well to the use of "confine" or "contain" strategies. The Illinois National Wild and Scenic River is located in the northeast portion of the Wilderness.

OBJECTIVE

The primary objectives for fire management activities are:

1. Maintain the natural ecosystems of the area and allow fire to play its role in those ecosystems.
2 Reduce the risks and consequences of wildfire in the Wilderness and adjacent areas.

MANAGEMENT DIRECTION

A fire management plan, emphasizing prescribed fire from both planned and unplanned ignitions, should be developed and implemented to ensure the maintenance of the natural ecosystems in the Wilderness and reduce the risk presented to Wilderness resources and adjacent resources caused by the unnatural accumulation of fuels.

A thorough description of fire suppression techniques allowed in the Wilderness should be presented in a fire management action plan. The use of mechanized equipment and aerial retardant in the Wilderness requires prior approval by the Forest Supervisor.

The use of "confine" and "contain" suppression strategies may be appropriate under all burning conditions

WILD ROGUE

OVERVIEW

The Wild Rogue Wilderness was established by the Endangered American Wilderness Act of 1978 (Public Law 95-237). Two provisions of that Act have directed some unusual management considerations for this Wilderness.

The first situation involves the Rogue National Wild and Scenic River, which bisects the Wild Rogue Wilderness. The river was designated a component of the National Wild and Scenic Rivers System by the original Wild and Scenic Rivers Act (1968). The 1978 Wilderness legislation states in part, "...certain lands ...shall be known as the Wild Rogue Wilderness: Provided, That the portion of the segment of the Rogue River designated as a component of the National Wild and Scenic Rivers System which lies within the Wild Rogue Wilderness shall be managed as a wild river *notwithstanding section 10(b) of that Act* (meaning the river act) *or any provision of the Wilderness Act to the contrary* .." (emphasis and parenthetical comment added). This provision was included in recognition of certain established uses (including motorboats) along the river corridor which are not in conformance with the Wilderness concept, but which Congress did not wish to eliminate. The effect of this provision is that, within the Wilderness boundary, the areas north and south of the river are managed in accordance with the Wilderness Act (1964), but the river corridor is managed as a separate entity

The second unusual situation involves public domain land located within the boundaries of the Wild Rogue Wilderness. This land would normally be administered by the Bureau of Land Management, an agency of the Department of the Interior. The 1978 wilderness legislation, in a paragraph titled "Administration of Wilderness Areas," states in part "...each Wilderness area designated by this Act shall be administered by the Secretary ". Elsewhere, the Act states that the "Secretary" is the Secretary of Agriculture. The Bureau of Land Management and the Forest Service reviewed the Act and agreed that the entire Wilderness, including that portion outside the Siskiyou National Forest boundary, should be administered by the Forest Service for purposes of efficiency. If some form of trespass or other legal problem should occur in this portion of the Wilderness, Bureau of Land Management enforcement authority will have to be utilized

The Wild Rogue Wilderness is characterized by rugged, heavily timbered canyons and is located mostly on the Gold Beach Ranger District, with minor portions located on the Galice and Powers Districts plus the aforementioned public domain lands The Gold Beach District is the administrative unit responsible for management of the Wilderness.

OCCUPANCY

SITUATION

There are some existing facilities within the Wilderness that are not in conformance with wilderness concepts or objectives These include:

NONCONFORMING FACILITIES

1. Various abandoned mining cabins and other mining related structures.
2. A seldom used mine and mill site, at which mechanized equipment is used to process ore.
3. Some short water lines and one small concrete dam serving private property located in the river corridor
4 One road used infrequently to access a mining claim, and several abandoned roads.

There are also some structures on private land within the Wilderness, but because they are not on public land, they are not within the scope of management direction.

OBJECTIVE

Remove those non-conforming improvements or facilities that are not essential to protection of the Wilderness or which do not have historical significance.

MANAGEMENT DIRECTION

The older mining structures will be evaluated for significance as cultural resources Those that do have historical value will be retained, but will not receive any maintenance or other preservation effort Other non-conforming structures will be removed. The water lines serving private property may remain because they existed prior to the Wilderness designation, but should any of these become unused they will be removed The mining road will remain if its use is valid under the mining laws; otherwise it is to be blocked to vehicles and revegetated.

RECREATION CAPACITY

SITUATION

No area of the Wilderness is being used in excess of capacity.

Carrying capacity is calculated to be 6,000 RVD's

Because recreational use of the Wilderness is low, there are no unacceptable impacts occurring as a result of this type of activity.

OBJECTIVE

Determine a capacity and manage a standard of visitor use that recognizes the Wild and Scenic River values and preserves the Wilderness values.

MANAGEMENT DIRECTION

Expand the carrying capacity by construction of approximately 10 miles of new trail. Monitor levels of use to insure that recreation use does not prevent the maintenance of the Wilderness character of the area

TRANSPORTATION

SITUATION

Although there were a number of trails and several roads constructed in this area in the past, very little of this system is currently maintained. A description of the transportation system is outlined below:

TRAILHEADS

The only active trailheads are those for the Mule Creek Trail, Panther Ridge Trail and the Mt Bolivar Trail.

TRAILS

Existing

Trails currently being maintained are the above-mentioned, Mule Creek (lower end only), Panther Ridge and Mt Bolivar Trails.

Proposed

There are several abandoned trails that can be reconstructed and would be appropriate for Wilderness uses These include the following.

1. Remainder (upper portion) of the Mule Creek Trail
2. Several unnamed trails in the historic Marial mining district
3. Clay Hill Trail
4. The Bob's Garden Cut-Off (East Creek) and Fall Creek
5. Trails on the south side of the river.

Potential

New trails that could be added to the system include a second connection between the Rogue River and Panther Ridge Trails, and a trail to the Pinnacle Peak area

ROADS

There is a four-wheel-drive road accessing the Old Red Mine in the Mule Creek area, and some abandoned logging roads at Watson Creek The logging roads date from the time that a section of land was in private ownership and have become vegetated since the land was acquired by the Forest Service

HELISPOTS

No permanent helispots are maintained in the wilderness.

OBJECTIVE

Provide and maintain a trail system that meets Wilderness management needs. Close the mining road and facilitate growth of native vegetation to help return it to a natural state

MANAGEMENT DIRECTION

Conduct a mineral exam at the Old Red Mine to determine if the claim and use of the road are valid. Close the road if the use is not valid or if the claim is abandoned. Temporary helispots may be constructed on a limited basis for the management of suppression and prescribed fire activities. Trail construction and maintenance will be to a reduced standard for most of the trails, in keeping with wilderness values.

COMMERCIAL OPERATIONS

SITUATION

Commercial operations in the Wilderness are sporadic, and in recent times have been limited to mining This mining activity has been located in the Mule Creek area only. There are no outfitter-guide special use permits in effect at the present time.

OBJECTIVE

Prevent, minimize and/or mitigate (rehabilitate) those mining activities that have adverse impacts on the Wilderness values Allow limited outfitter-guide services that meet a legitimate public need for use of the wilderness.

MANAGEMENT DIRECTION

Mining claims for which operations are proposed are to be reviewed to determine if such claims are valid Operating plans for valid claims are to include reasonable conditions to protect wilderness values, but which do not interfere with the statutory rights of claimants

Proposals for outfitter-guide special use permits may be approved if the operations meet a public need associated with legitimate use of the Wilderness Self-outfitted use of the Wilderness will be favored, however, and commercial use may be restricted or reduced as necessary to allow for other public use

FIRE

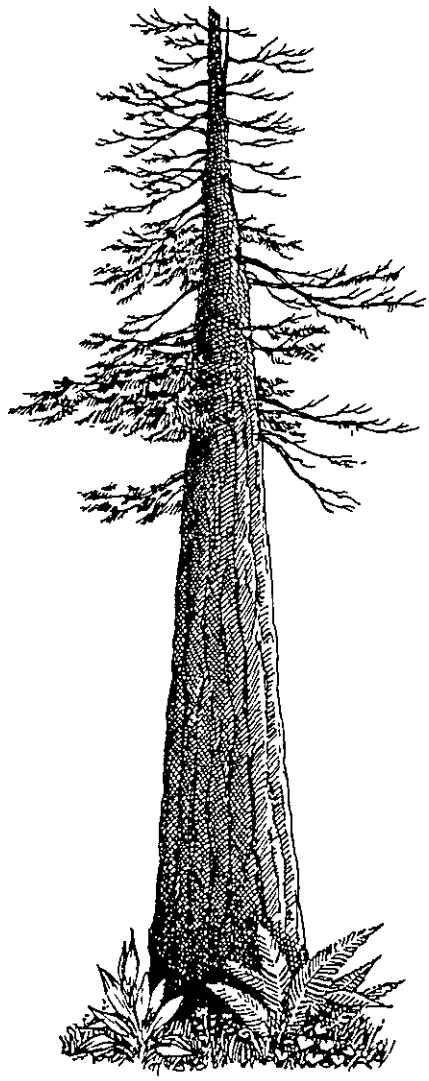
SITUATION

The Wilderness is located in steep canyon country with difficult terrain and heavy fuel accumulations in many places. Fine "flashy" fuels, such as grass, are commonly found adjacent to high use areas and extend to the brush and timber on the middle and upper slopes The Wilderness itself has not had a history of major fires in recent years, but there have been fires in adjacent areas and other portions of the canyon However, the hazard is high, and the risk is great Fire has played a significant role in the development of the vegetation present in the canyon today. The Rogue National Wild and Scenic River is a heavily used white water and fishing river. Located within this river corridor are privately owned lodges and summer homes. Because of the relatively small size and the narrow shape of this Wilderness and the presence of the Wild and Scenic River, the area does not lend itself to "confine" or "contain" suppression strategies

OBJECTIVE

There are four primary management objectives for fire suppression and other fire and fuels related activities that may take place in the Wilderness. These are

1. Protecting life and property in the river corridor.
2. Reducing the risks and consequences of a wildfire in the Wilderness
3. Maintaining the natural ecosystems of the Wilderness.
4. Providing for the least possible impact to visitors to the Wild and Scenic River



MANAGEMENT DIRECTION

Fire suppression strategies and tactics developed in the Escaped Fire Situation Analysis (FSM 5132.1) should provide for a high degree of public safety and the least amount of operational impairment. Closure of the Rogue River corridor to use by the public should be avoided in all but the extreme cases due to the following reasons:

1. Such a closure would be of limited effectiveness, because it could take up to three days for rafters already on the river to float out of the canyon.
2. Denial of the chance to float the river would be a greater hardship than normal for affected recreationists, because of the permit reservation system which limits access to the Rogue
3. Loss of income that would be suffered by the tour boat services, outfitter-guides, and commercial lodges in the corridor.

Suppression tactics which most protect the Wilderness values and adhere to accepted wilderness fire fighting principles will be used. The use of mechanized equipment and aerial retardant in the Wilderness requires prior approval by the Forest Supervisor A more thorough description of fire suppression techniques allowed in the Wilderness are found in the Fire Management Action Plan for the Siskiyou

National Forest Snags within a fire will be left standing when they do not constitute an unacceptable hazard. Following suppression activities, sites will be restored as appropriate

APPENDIX B

PROJECTED BUDGET

INTRODUCTION

The following tables, B-1 through B-9, depict the activities and projects (capital investments) necessary to provide the level of outputs and services identified in the Forest Plan.

Table B-1 displays information included in the budget proposal submitted for the Fiscal Year 1991. Final approval of the budget proposal is pending; some changes are likely to occur due to the requested level differing from approved funding. The costs associated with activities listed in Table B-1 may not include all costs identified with projects and activities scheduled for Fiscal Year 1991 in Tables B-2 through B-9 since the latter tables were developed subsequent to the date required for revising the 1991 budget

Definitions for the column headings used in the tables are provided below:

Activity Name	Action taken to manage natural resources
Activity Code or Acty	An alpha-numeric label for an activity or grouping of activities
Fund Code or Fund	An alpha label used for budgeting purposes.
Measure or Meas	A quantity descriptor of an activity, used when applicable
Unit	A quantification of measure, used when applicable
M $	Estimated costs in thousands of 1989 dollars
Project Name	Used in tables B-2 through B-9 to indicate a specific capital investment project or work activity.
FY	Fiscal Year.
Preconst	Preconstruction.
Const	Construction.
Struc	Structure.
RD	Ranger District: Chetco=01; Galice=02, Gold Beach=03, Illinois Valley=04; Powers=05; Multi-District=09, Forest-wide=11
Pri	Priority for project funding.
Plan	Used in tables B-4 and B-5 to indicate an expected output, generally in report form, resulting from project completion.
Road No.	Forest Development Road Number.

APPENDIX C

TEN-YEAR ACTION PLAN

Planning Basins Map

INTRODUCTION

The following planned timber sale activity schedule was compiled from site-specific proposals in various stages of project planning. Sales proposed in the earlier years of the decade generally have more intensive field reconnaissance completed, while those in the out-years are based on less refined estimates from aerial photos and extensive field reconnaissance. For instance, the timber volumes (Net MMBF and MMCF), road miles, harvest methods, and yarding systems in Table C-1, are **estimates** and **probable** methods. As the schedule progresses, more intensive field investigation will result in refinement of sale information. Periodic revision of the ten-year plan and estimated sale information will be necessary as more site-specific information becomes available. Individual proposals may be revised, deleted, or added as necessary to accomplish the goals of the Forest Plan. Firm timber sale programs will be announced in the Forests' General Notice of Planned Sales at six month intervals. Additional information and maps are available at the Ranger District offices. The following chart is the key to Table C-1:

Column Heading	Description
Fiscal Year	Fiscal Year 1989 through 1998 with Sale Number identified as last three numbers after Fiscal Year which is first two numbers
Sale Name	Sale Name (TBV=Turn Back Volume)
Planning Basin No	Planning Basin Number
Legal Description	Sec =Section (ie S29) Twn =Township (ie T38S) Rng =Range (ie R12W) Mer =Meridian (WM = Willamette Meridian)
Acres	Number of Acres
Net MMBF	Million Board Feet
MMCF	Million Cubic Feet
Road Miles	C =Construction R =Reconstruction
Harvest Method	HCC =Harvest Clearcut HCR =Harvest Clearcut, with Reserve Seed Trees HFR =Harvest Final Removal Cut HSC =Harvest Selection Cut HSH =Harvest Shelterwood Cut HSM =Harveat Streamside Management Cut HSV =Harvest Salvage Cut HTH =Harvest Thinning Cut
Yarding System	S =Skyline MS =Mobile Skyline C =Cable, or Hilead HEC =Helicopter T =Tractor

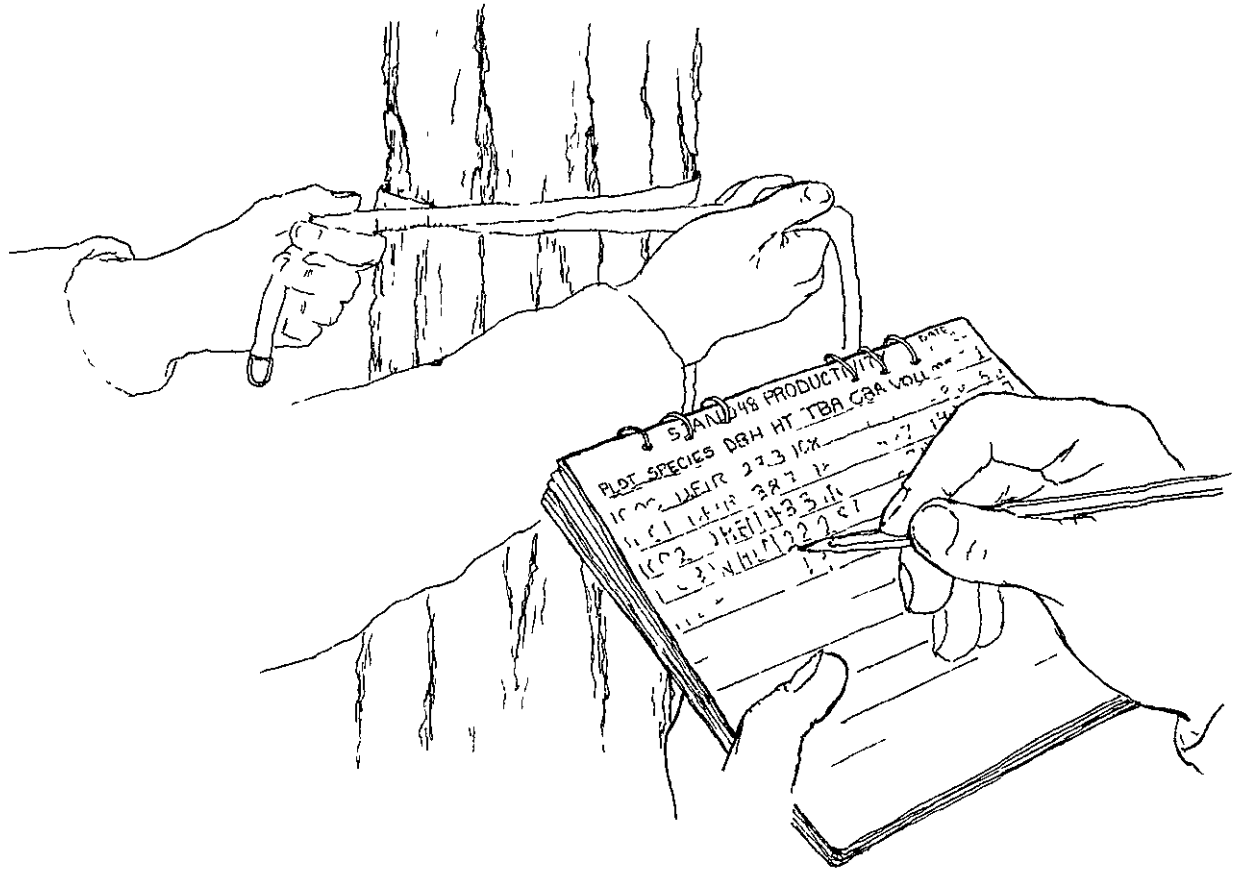
APPENDIX D



MONITORING AND EVALUATION

PROGRAM BACKGROUND

INTRODUCTION

The Monitoring Plan is the control system for implementation of the Land and Resource Management Plan (LRMP). The Monitoring Plan, which is composed of a series of Resource Elements, will determine if the LRMP is being implemented as specified in the Standards and Guidelines (S&G's). The Monitoring Plan also serves as a check to see if the effects of implementation are as predicted

A description of each Resource Element follows. The alphanumeric code preceeding the Resource Element name represents the appropriate activity code used in the Forest budget process For example, *annual monitoring costs identified for Resource Element - AN121(a) Recreation (Undeveloped) are $5,000* This amount is included in Table B-1 of Appendix B under Recreation Resource Administration having the activity code AN12. For a summary of all Elements in the Monitoring Plan, refer to Table V-1.

Resource Element - All Elements

ISSUE

Implementation of management direction as described in the LRMP, Chapter IV.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Insure that management direction is identified and applied in project planning and implementation

MANAGEMENT AREA

Management Areas 1 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

1	X	1	=	1
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Ensure that applicable S&G's are incorporated into project-level planning and implementation.
2. Ensure that unavoidable deviations from S&G's, along with appropriate mitigative measures, are identified in project-level NEPA planning, and that mitigative measures are carried through to implementation.

MONITORING PURPOSE

Compliance with management direction.

THRESHOLD OF CONCERN/VARIABILITY

1. Any deviation from S&G's which, through the project-level National Environmental Policy Act (NEPA) process, is not identified and for which mitigation is not prescribed.
2. Any instance where mitigative activities prescribed in the project planning were not implemented on the ground.
3. Instances where management direction was apparently applied in an appropriate manner, but did not produce the desired effect on-the-ground.

SAMPLING AND RESPONSIBILITY

Suggested Sampling Method	Responsibility
In all project-level NEPA processes identify: (1) applicable S&G's, (IDT) and Deciding Officer, (2) expected deviations from the S&G's, and (3) appropriate mitigative measures. Prepare a summary report of the items above and forward to Forest Planning Staff.	Project Interdisciplinary Team

Conduct post-implementation reviews on selected projects to confirm that the S&G's and mitigative measures were properly identified and applied on-the-ground. Prepare a summary report of the items above and forward to the Forest Planning Staff.	Deciding Officer, IDT, and Staff
Compile periodic, Forest-wide reports on compliance with the S&G's at both planning and implementation stages.	Forest Planning Staff Officer
With the the Forest Management Team, conduct periodic reviews of compliance with the S&G's. Identify areas of success and areas needing improvement.	Forest Supervisor

EXPECTED PRECISION AND RELIABILITY

Precision is moderate and the reliability is high

RESPONSIBILITY

District Rangers and Forest Supervisor's Office (SO) Staff.

ANNUAL MONITORING COST

Elements	**$/Year**
Preparation of project-level reports	5,000
Compiling Forest-wide reports	1,500
On-the-ground management reviews	12,000
Forest Management Team reviews	3,000
TOTAL ANNUAL COST	21,500

MANAGEMENT REVIEWS

Compliance with the Forest-wide Standards and Guidelines (S&G's) for the following resource areas:

* Developed recreation
* Dispersed recreation
* Visual resource
* Cultural resource
* Threatened, endangered, and sensitive species
* Deer/elk habitat
* Salmonid habitat
* Dead and down tree habitat
* Timber management practices
* Soil productivity
* Best Management Practices
* Cumulative effects
* Air quality
* Land acquisition
* Special uses
* Land lines
* Minerals
* Transportation planning
* Fire management
* Silvicultural practices

Compliance with the Management Area Prescriptions. The following is a list of the 14 Management Areas on the Forest:

* Wilderness
* Wild River
* Research Natural Areas
* Botanical
* Unique Interest
* Backcountry Recreation
* Supplemental Resource
* Designated Wildlife Habitat
* Special Wildlife Site
* Scenic/Recreational River
* Riparian
* Retention Visual
* Partial Retention Visual
* General Forest

In addition, those S&G's that are particularly important to resolving Planning Problems, as stated in Chapter III (e.g., mineral development, management of sensitive plants, preservation of old growth, etc.), need to be monitored.

Resource Element - All Elements (Forest Programs and Budgets)

ISSUE

Are funding levels received by the Forest adequate to support planned outputs?

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The management of the Forest has the budget necessary to achieve the projected outputs while progressing to the desired future condition as stated in the Forest Plan

MANAGEMENT AREA

Management Areas ? through 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Is the management of the Forest achieving planned outputs?
2. Are funding levels for capital investments adequate to achieve projected improvements?
3. Are the major variable costs used in the analysis consistent with actual implementation costs?

MONITORING PURPOSE

1. *Compliance with management direction.*
2. Achievement of output objectives.
3. Consistency with cost projections.

THRESHOLD OF CONCERN/VARIABILITY

1. Individual outputs achieved are + or - 20% projected in this Forest Plan (as displayed in Table IV-1).
2. Funding for fisheries, soil, and watershed capital investments + or - 20% of projected needs to 3 consecutive years.
3. Funding for wildlife habitat capital investments + or - 20% of projected needs for 3 consecutive years.
4. Funding for recreation capital investments + or - 20% of projected needs for three consecutive years.
5. *Variable costs incurred for the timber management program + or - 20% of analysis costs for 3* consecutive years.
6. Road costs incurred are + or - 20% of analysis costs for 3 consecutive years.

SUGGESTED SAMPLING METHODS

Use existing accomplishment reporting systems, e.g., MARS and PAMARS. Compare annual budgets with projected capital investments. Compare TSPIRS data with variable costs used in the analysis.

EXPECTED PRECISION AND RELIABILITY

Both precision and reliability are rated as high

RESPONSIBILITY

1. All Staff Officers
2. Fish and Wildlife, and Watershed Staff Officers
3. Fish and Wildlife Staff Officer
4. Recreation Staff Officer
5. Timber Staff Officer
6. Forest Engineer

ANNUAL MONITORING COST

$400.

Resource Element - AN121(a) Recreation (Undeveloped)

ISSUE

Affect of management direction on recreation opportunities in Backcountry Recreation.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to provide an array of recreation opportunities within the Primitive, Semi-primitive Motorized, and Semi-primitive Non-motorized Recreation Opportunity Spectrum (ROS) categories

MANAGEMENT AREA

Management Areas 6 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

$$\frac{1}{\text{(Cost of Error)}} \times \frac{1}{\text{(Likelihood of Error)}} = \frac{1}{\text{(Risk Index)}}$$

MONITORING QUESTIONS

1. Are the setting indicators of access, non-recreation management impacts, social encounters, facilities, and visitor management maintained at levels sufficient to provide Primitive and Semi-primitive (Motorized and Non-motorized) recreation opportunities?
2. Is resource degradation occurring as the result of sanctioned Off-road vehicle (ORV) use?

MONITORING PURPOSE

The objective of monitoring the ROS inventory categories is to track the effects of management activities, to determine if the management objectives and recreation setting required for the Primitive and Semi-primitive ROS categories are being met during the planning and implementation stage of resource management projects.

1. Compliance with management direction.
2. Achievement of output (goods and services) objectives.

THRESHOLD OF CONCERN/VARIABILITY

1. Five percent variance from LRMP objectives for Primitive and Semi-primitive Non-motorized recreation opportunities in Backcountry Recreation.
2. Visible degradation to soil, water, or vegetation resources on trails or in other areas open for ORV use.

SUGGESTED SAMPLING METHODS

1. Annual field observations and analysis of the effects of management activities within or adjacent to the management areas during project planning.
2 Inventory update every five years.
3. Projects planned in the various management areas currently categorized as primitive, semi-primitive non-motorized or motorized would be monitored in order to assess the effects of planned projects on the recreation setting in the area and the appropriate ROS category after project implementation.
4. Planned harvest units and attendant road systems will be recorded on the appropriate TRI/GIS (Total Resource Inventory/Geographic Information System, a computer/microfilm/map base

system) after the project analysis and documentation is completed and the decisions are made (District responsibility). This information will be overlayed with ROS and shifts from one opportunity spectrum to another will be determined at least every other year (Forest Landscape Architect responsibility).

5. Annual field observations of 33 percent of designated ORV areas and 100 percent of all ORV mitigation measures for review of effectiveness

EXPECTED PRECISION AND RELIABILITY

Data for ROS categorizing, as well as impacts to areas or trails open to use by ORV's, is collected with a large degree of accuracy. The data will have a high level of reliability.

RESPONSIBILITY

Recreation Staff, District Rangers, and Forest Landscape Architect.

ANNUAL MONITORING COST

$1,000/District X 5 Districts = $5,000.

Additional monitoring is included in project costs

Resource Element - AN121(b) Wild .and Scenic Rivers

ISSUE

Protection of wild and scenic river resources

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

In the wild sections of the rivers, the goal is to provide a Primitive or Semi-primitive recreation experience in an essentially undisturbed forest setting as prescribed in the S&G's, or in the objectives of the applicable Wild and Scenic River Management Plan (River Management Plan) River Management Plans, for rivers subsequently designated, will be written following the designation?

In the recreation and scenic sections of the rivers, the goal is to provide a high quality river recreation experience in a natural or near natural forest setting as prescribed in the S&G's, or in the objectives of the applicable River Management Plan.

MANAGEMENT AREA

Management Areas 2 and 10.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	1	=	3
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Is the protection and management of the Forest's Wild and Scenic Rivers consistent with the Wild and Scenic Rivers Act and the management objectives identified in the applicable River Management Plan?
2. Are the facilities and improvements scheduled in the LRMP being accomplished?
3. Do management activities within the Rogue River corridor meet inventoried or allocated Visual Quality Objectives?
4. Does Partial Retention in middleground distance zones satisfy the user demand for scenic quality within the Rogue River corridor?

MONITORING PURPOSE

1. Compliance with management direction.
2 Achievement of output (goods and services) objectives.
3. Satisfaction of user demand for scenic quality.

THRESHOLD OF CONCERN VARIABILITY

1. Visible degradation of the setting within or adjacent to the Wild River corridors
2. Any visible evidence of human intrusion causing a reduction in the existing character of the landscape within or adjacent to the Wild River corridor of the Illinois.
3 Any activity in a viewshed adjacent to the Recreation/Scenic River corridors, which would result in visual quality below the objectives either inventoried or allocated to the area

SUGGESTED SAMPLING METHODS

Annually observe the length of each Wild River corridor to inventory the effects of recreation use on the following

1. Campsites - Vegetative disturbance due to compacted soils, tent pads, or other activities Individual sites should be photographed and effects of use measured and recorded for annual comparison Limits should be established and use restricted as limits are reached. Other effects of use include human waste and garbage, the presence of permanent structures including fire rings, tent poles, drying poles, hitching posts, rails for stock, etc Any structural improvements to campsites within a Wild River corridor should be removed or broken up (See S&G's).
2. Social factors - Solitude for travelling and campsites. Conflicts between visitors with different travelling methods (hikers and rafters typically). Conflicts regarding party size, noise, or others that may be identified.
3. Evidence of humans - Discarded debris such as old tires, cans, plastic, raft accessories, paper, human waste, etc. (remove where possible).
4. Assessment of past and planned management activities against recommended levels of harvest for the various visual objectives through the Rogue River Visual Management Plan. Assessment will include:
   (a) Roads
   (b) Harvest units that have not achieved a 20' tree height in regenerated stands Units in approved EA's that are planned for harvest within 5 years.
   Impacts are assessed against recommended rates of harvest for each VQO These are
   Retention - 4 percent harvest within viewshed/decade Eight percent disturbance at any time
   Partial Retention - 8 percent harvest within viewshed/decade Sixteen percent disturbance at any time.
   Modification - 13 percent harvest within viewshed/decade Twenty-seven percent disturbance at any time.
5. Monitoring user feedback to District managers

Formal review of compliance with the LRMP and the applicable River Management Plan every 2 years

EXPECTED PRECISION AND RELIABILITY

Data for impacts to the lands within or adjacent to the Wild and Scenic River corridors is collected with a large degree of accuracy. The data will have a high level of reliability

RESPONSIBILITY

Recreation Staff, District Rangers, Forest Landscape Architect.

ANNUAL MONITORING COST

$10,000 (for all five designated rivers).

Additional monitoring is included in project administration costs

Resource Element - AV121 Visual

ISSUE

Protection of forest scenic values through Visual Resource Management.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The goal of the Forest is the maintenance of a natural or near natural forest setting in areas allocated to Retention and Partial Retention Visual Quality Objectives (VQO's) In areas allocated to General Forest, the VQO's will be to maintain a modified forest setting

MANAGEMENT AREA

Management Areas 12, 13, and 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Are planned or programmed management activities implemented within the constraints identified for the Retention and Partial Retention VQO's?
2. Are the allocated VQO's being achieved?

MONITORING PURPOSE

Compliance with management direction.

THRESHOLD OF CONCERN/VARIABILITY

Five percent increase over recommended levels of impact/decade in Retention, Partial Retention, and Modification VQO's.

SUGGESTED SAMPLING METHODS

1. As part of day-to-day project work in sensitive viewsheds, project plans and environmental documents are continuously monitored to verify that scenic values are adequately protected. For all projects planned in sensitive viewsheds, a field review will be conducted to verify that mitigation measures have been carried through project planning to on-the-ground implementation. In addition, all projects planned in areas allocated to General Forest will be field reviewed to verify that modification objectives have been met.
2. Post sale project reviews will include a comparison of anticipated and actual effects after project implementation.
3. Impacts to visual resources in sensitive viewsheds will be assessed on a project-by-project basis *and recorded by size (acres) and estimated time of release (year) in the TRI/GIS When the results* and recommendations of the management review team have been evaluated and made available to the appropriate resource managers, they will be stored in TRI/GIS Management reviews and reports will be made at least annually.

EXPECTED PRECISION AND RELIABILITY

Data for impacts to visual resources within viewsheds is collected with a large degree of accuracy. The data will have a high level of reliability. Projects are assessed using computer plots and can only be verified after implementation. Results in the past have been acceptable

RESPONSIBILITY

Recreation Staff, District Rangers, Forest Landscape Architect.

ANNUAL MONITORING COST

$1,000/District X 5 Districts = $5,000.

Additional monitoring in included in project administration costs.

Resource Element - AW121 Wilderness

ISSUE

Maintenance of wilderness character.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The goal of the Forest is to maintain the existing character of each designated Wilderness Frequent monitoring will assess the effects of all human related impacts on a wilderness environment, and to *determine if a wilderness character is being adequately maintained.*

MANAGEMENT AREA

Management Area 1.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

Are the physical/biological, social, and managerial settings of each Wilderness Recreation Spectrum (WRS) class maintained within the levels outlined in the S&G's and R-6 Supplement No. 81 to Forest Service Manual (FSM) 2320, as included in the LRMP?

MONITORING PURPOSE

1. Achievement of output (goods and services) objectives.
2. Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

Five percent of Wilderness acres in a condition assessed as lower than Semi-primitive. Eighty percent of estimated capacities for WRS classes occurs.

SUGGESTED SAMPLING METHODS

1. Implement the Limits of Acceptable Change (LAC) concept in order to insure that management objectives are met and that wilderness character and related values are identified and adequately protected. Field observations should be made annually in areas of heavy use. Levels of use, party *size, numbers of encounters, and degradation due to recreation use will be reported by wilderness* guards and other field-going personnel in order to prevent resource degradation and maintain the characters of the Wilderness.
2. Data from administrative studies, other wilderness plans, and past management practices will be used by the review team as input for their review. Once results and recommendations of the *management review team have been evaluated and made available to appropriate resource* managers, they will be stored in TRI/GIS.
3. Management reviews and reports will be made at least annually Field reports will be done continuously throughout the year.

EXPECTED PRECISION AND RELIABILITY

Data for human related impacts is collected with a large degree of accuracy The data will have a high level of reliability.

RESPONSIBILITY

Recreation Staff, District Rangers, Forest Landscape Architect

ANNUAL MONITORING COST

$2,000/District X 5 Districts = $10,000

Resource Element - CF121 Fish Habitat

ISSUE

Provide and maintain salmonid habitat.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Provide and maintain fish habitat with diversity and quality, capable of maintaining or enhancing populations of resident and anadromous salmonid game fish species.

Salmonid rearing, spawning, and migration habitat capability will be improved across the Forest Riparian prescriptions will maintain or lower summer water temperatures, with additional protection of the fisheries habitat occurring in designated Supplemental Resource and Special Wildlife Sites. Habitat improvement projects will increase habitat diversity and maintain stream channel stability.

MANAGEMENT AREA

Management Areas 1 through 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. What are the cumulative effects on fish habitat capability?
2. Is fish habitat and smolt production being maintained or improved as predicted by the LRMP Final *Environmental Impact Statement* (FEIS)?
3. Is the quantity and quality of rearing pools being maintained?
4. Is the fish population changing in terms of numbers, species composition, or age structure?
5. Is large woody material being retained in the stream channel for fish habitat?
6. Is stream temperature being maintained or decreased as predicted by the LRMP FEIS?
7. Is sediment affecting stream habitat?
8. What are the effects of fish habitat improvement structures on stream channel configuration, large woody material, and fish populations?
9. What is the lifespan of stream habitat improvement structures?

MONITORING PURPOSE

1. Achievement of output (goods and services) objectives.
2. Maintenance of environmental quality (effects) as projected.
3. Resource mitigation measures are employed.

THRESHOLD OF CONCERN/VARIABILITY

1. Monitoring Questions 1, 2, 3, and 8: A ten percent decline in overall pool volume, area, or average maximum depth by Class I or II stream.
2. Monitoring Questions 1, 2, 4, and 8: Declining trend (three years or more) in juvenile salmonid populations with overall population reduction of greater than 25 percent for age 1+ steelhead or 50 percent for age 0 chinook (as monitored at established critical reach stations).

3. Monitoring Questions 5 and 8: A ten percent management related decline in the amount of large woody material located in stream channels.
4. Monitoring Question 6: Increasing trend in stream temperatures on monitored Class I and II streams by basin (Exceeding State Water Quality Standards).
5. Monitoring Question 7: Fine sediment component that increased by twenty percent above background levels as monitored at established critical reaches by basin.
6. Monitoring Questions 6 and 7. A one scale-class reduction in the community tolerance quotient for macroinvertebrates as measured at established critical reach stations by basin
7. Monitoring Question 9: Functional or structural failure rate of habitat improvement structures that exceeds 25 percent. Minor maintenance of structures is expected and would not be considered failure.

SUGGESTED SAMPLING METHODS

1. Monitoring Questions 1, 2, 3, 4, 5, 8, and 9: Develop baseline data to determine changes in fish habitat capability based on standard Region 6 method developed by Hankin and Reeves Initially survey all Forest streams during a three year period. Approximately five percent of the stream miles will be resurveyed annually. These stream miles will be well distributed and should focus on the sensitive low gradient habitat. The remainder of the stream miles will be resurveyed at the rate of 20 percent per year.

2 Monitoring Questions 1, 2, 4, and 8: In addition to the summer surveys outlined in the Hankin and Reeves Hankin methodology, if Chinook are present, the stream miles that are surveyed annually should also have spawning ground counts and spring surveys for juvenile Chinook abundance There is an opportunity to mesh these areas with the Oregon Department of Fish and Wildlife (ODFW) index streams.

3 Monitoring Questions 6 and 7: Develop baseline stations for aquatic invertebrate sampling. Approximately 50 stations will be established. These stations should be tied to the streams that will be surveyed annually. Aquatic invertebrate sites will be monitored annually.

4 Monitoring Question 6: See monitoring item FW121(a) Water Resources for pre- and post-harvest effective stream shade canopy monitoring.

5. Monitoring Question 6: Monitor temperatures in fish bearing streams during the summer with thermographs. Approximately 15 streams will be monitored. Sites should be near aquatic invertebrate sampling stations (in cooperation with the Watershed Element). See monitorin item FW121(a) Water Resources for additional water temperature monitoring.

6 Monitoring Question 7: Establish baseline sediment data on selected streams using freeze core samples. These sites should be spawning areas and tied to the invertebrate, temperature and stream survey areas. Approximately 50 sites will be established. These sites will be monitored at the rate of 20 percent per year. If aquatic invertebrate sampling indicates damage is occurring then the sampling frequency will be increased.

7 Monitoring Question 9: Monitor all habitat improvement projects in the first year following project completion to evaluate structural and functional success. Monitor at least 20 percent of the structures annually.

EXPECTED PRECISION AND RELIABILITY

The monitoring will provide information that will be moderately to highly precise and reliable. It will provide excellent information on fish habitat quality, quantity, and trends.

RESPONSIBILITY

District Rangers and Forest Staff.

ANNUAL MONITORING COST

Stream surveys and fish populations. Years 1-3 - $88,000/year; years 4-10 - $61,000/year.

Aquatic invertebrate sampling: Years 1-10 - $10,000/year.

Stream temperature monitoring Thermographs: Year 1 - $16,000; years 2-10 - $7,500.

Stream gravel Sediment Monitoring: Year 1 - $24,000; years 2-10 - $5,000

Habitat structure monitoring: Years 1-10 - $2,500.

TOTAL ANNUAL COST - $86,000 to 113,000

A one-time baseline inventory cost of $160,000 will be incorporated into the normal Forest program.

Resource Element - CT121(a) Endangered [E], Threatened [T], Sensitive [S], Unique [U] Animals

ENDANGERED OR THREATENED SPECIES

American Peregrine Falcon [E-ORegon and CAlifornia], Bald Eagle [T-OR, E-CA]

SENSITIVE SPECIES

Sensitive species include the Siskiyou Mountain Salamander [S-OR], Western Spotted Frog [S-OR], Western Pond Turtle [S-OR], Northern Spotted Owl [S-OR/CA] Northern Goshawk [S-CA], Willow Flycatcher [S-CA], Townsend's Western Big-eared Bat [S-OR], White-footed Vole [S-OR], California Wolverine [S-OR/CA], Fisher [S-CA], Pine Marten [S-CA]. Unique species include the Marbled Murrelet [U-OR], and the Gold Beach and Pistol River Pocket Gophers [U-OR]

Management of Endangered or Threatened species is governed by the federal Endangered Species Act, and is coordinated with the UDSI Fish and Wildlife Service. Sensitive species require special consideration; Regional Foresters are concerned about the population viability of sensitive species, the Forest is obligated to determine the distribution, status, and trend of sensitive species, and their habitat (FSM 2670 45)

The bald eagle, spotted owl, and pine marten are treated under their own elements (CT121[b], CT121[c], and CW121[b] respectively). Sensitive and Unique animals other than spotted owl and pine marten are treated in this element as species needing inventory rather than monitoring

A few Unique species of special interest are also included in this element. The marbled murrelet is not presently listed as sensitive, but the state of Oregon was petitioned in January 1988 to list the species as Threatened; the United States Department of Interior (USDI) Fish and Wildlife Service has also been petitioned (1988) to list the species under the provisions of the Endangered Species Act. Populations are judged to be relatively low in Oregon (Marshall 1988). The Gold Beach and Pistol River pocket gophers are listed as Category 2 species by the USDI Fish and Wildlife Service (status insufficiently known at present, but species could be proposed as threatened or endangered at some future date)

The costs for species inventories (Sensitive and Unique) have been ascribed to the Capital Investment schedule in Appendix B, rather than to the Monitoring Plan (Monitoring is part of the operations budgets in CT1 and CW1 [Table B-1, Appendix B]).

ISSUE

Maintaining habitat for these species.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Meet or exceed the recovery levels established in Pacific Coast Recovery Plan for the American Peregrine Falcon (Pacific Population) (USDI Fish and Wildlife Service 1982). For inventory species, maintain viable populations.

MANAGEMENT AREA

Potentially all management areas.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is high because species are thought to be in low numbers on the Forest. Likelihood of error is moderate for all species: (a) except for the murrelet and vole, the best habitat is located within land allocations without programmed timber harvest, (b) populations of the murrelet and vole are thought to be large enough to be reasonably resistant to short-term habitat change. Loss of habitat to natural catastrophe is low to moderate, depending on the species

MONITORING QUESTIONS

PEREGRINE FALCON

1. Are existing nest sites producing young as anticipated?
2. Are surveys being completed to locate new or previously unknown nest and roost sites?
3. Are potential sites being protected?

OTHER SPECIES

Are habitat inventories and surveys being completed as scheduled?

MONITORING PURPOSE

1. Compliance with management direction
2. Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

PEREGRINE FALCONS

1. Active nest sites do not produce young two years in succession.
2. Surveys not completed on schedule.
3. Non-compliance with S&G's.

OTHER SPECIES

Surveys not completed on schedule.

SUGGESTED SAMPLING METHODS

PEREGRINE FALCON

1. Annual monitoring of active nest sites. For each site set up a minimum yearly schedule during the breeding season to determine nesting chronology and success.
   a. Make one or two visits as needed during April to determine occupancy and nesting chronology (consider nest site unoccupied if birds are not present by April 30).
   b. After nesting chronology is determined, return every two weeks to check on progress
   c. Sometime during late May to mid-June (depending on chronology) band young and collect eggshell fragments and prey remains.
   d. After step (c) is completed, check progress of nesting attempt one or two times, then make one last visit check for post-fledging survival (between June 15 and July 15)

2 Field survey of potential sites. Field review sites at 2 year intervals. Investigate specific reports of peregrine falcons.
3 Road building or timber activities in the vicinity of identified potential nest sites will be addressed in site specific environmental analyses. Manage activities in accordance with S&G's. Review project plans for any management activities which may affect active or potential nest sites. Monitor management activities during and after implementation to insure adherence to S&G's.

OTHER SPECIES

Use appropriate survey methods. Fisher habitat will be surveyed as part of the Pine Marten Element Goshawk and willow flycatcher habitat will be surveyed in California only See Cooperrider and others (1986) for a summary of inventory and monitoring methods.

EXPECTED PRECISION AND RELIABILITY

PEREGRINE FALCON

Precision is moderate because known nest sites will be monitored, but we may not be aware of other active nest sites. Reliability is high because direct counts will be made

OTHER SPECIES

No estimates (information garnered from surveys and inventories may be used to set up monitoring schemes)

RESPONSIBILITY

All items - District Rangers Forest Staff coordinates sampling methods, compilation of data, and Forest report.

ANNUAL MONITORING COST

PEREGRINE FALCON

Item 1: 16 days per year per active site (3 existing), plus expenses for analyses of eggshell fragments and prey remains ([16 x $100] + 200 = $1,800 per site or $4,800 for 3 sites). Item 2: The Forest contains approximately 40 sites which should be inventoried every other year (2 days per site) (20 x 2 x $100 = $4,000) Annual SO administration costs for items 1 and 2 = $400. Item 3 costs will be borne by other functions (ET113 support to timber, etc).

Annual cost for peregrine falcon monitoring = 4,800 + 4,000 + 400 = $9,200.

OTHER SPECIES

Costs associated with Monitoring Elements C1 through C8 and peregrine falcon (part 1 of C9) are included as budget items under support to the Wildlife (CW) or Endangered/Threatened/Sensitive (CT) programs However, costs listed for the species below are for survey and inventory, rather than monitoring For budgeting purposes, these costs have been included in the Forest Capital Investment Program (see schedule Appendix B) and are not costs of the Forest Monitoring Plan.

The following costs are listed for information purposes only.

Species	Fiscal Year (M $) 1	2	3	4	5
Siskiyou Mountain Salamander [S]				2 0	
Spotted Frog [S]				1 0	
Western Pond Turtle [S]			3 0	3 0	
Marbled Murrelet [U]	13 0				13 0
Spotted Owl [S]	7.5	7 5	7.5	7 5	7 5
Northern Goshawk [S]		1 0		1 0	
Willow Flycatcher [S]		1 0		1 0	
Townsend's Western Big-eared Bat [S]			3 0		
White-footed Vole [S]		10 0	10 0		
Gold Beach/Pistol R Pocket Gophers [U]	2.0		2 0		
California Wolverine [S]		3 0		3 0	
Fisher [S]		See Pine Marten Element			
Pine Marten [S]		See Pine Marten Element			

REMARKS

Revise S&G's for OTHER SPECIES as data becomes available. Work with State and Federal Fish and Wildlife agencies, universities (research), and conservation groups to develop census methods and determine effectiveness of existing S&G's.

A January 14, 1988 letter from USDI Office of Environmental Project Review contains suggestions for monitoring of peregrine falcons. This letter is FEIS comment number 1789.

Resource Element - CT121(b) Bald Eagle

ISSUE

Maintaining Habitat for Bald Eagles.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Meet or exceed recovery levels established in Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986).

MANAGEMENT AREA

Management Areas 1 to 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is high because the species is in low numbers on the Forest (Threatened status in Oregon). Likelihood of error is moderate because the best habitat is located within land allocations without programmed timber harvest; existing sites are easily identified and monitored. We may not be aware of other active nest sites or eagle activity. There is also a moderate likelihood of catastrophic loss of nest trees to wildfire or wind. Thus risk index is moderate.

MONITORING QUESTIONS

1. Are existing nest sites producing young as anticipated?
2. Are potential sites being protected (are areas identified as prime in the FEIS actually being protected)?
3. Are surveys being completed to locate new or previously unknown nest and roost sites?

MONITORING PURPOSE

1. Compliance with management direction.
2. Resource mitigation measures are employed

THRESHOLD OF CONCERN/VARIABILITY

1. Active nest site unoccupied for two years in succession.
2. Not less than 90 percent of the potential sites are suitable for occupancy at any given time
3 Non-compliance with S&G's.

SUGGESTED SAMPLING METHODS

1. Annual Interagency survey of nest sites ODFW annually conducts a mid-summer productivity survey on known active nest sites.
2 Field survey of potential sites. Sites reviewed at 5-year intervals
3. Survey for new bald eagle nest sites during osprey surveys (see CW121(c) Osprey Element) Participate in midwinter (country-wide) bald eagle count in cooperation with ODFW and the National Wildlife Federation. District personnel will keep accurate, up-to-date, complete records of bald eagle sightings. Specific reports of bald eagle nesting activity will be investigated Sighting information should be gathered from commercial jet-boat or raft float pilots.

EXPECTED PRECISION AND RELIABILITY

Precision is moderate because known nest sites and concentration areas will be monitored, but we may not be aware of other active nest sites or eagle activity. Reliability is high because direct counts will be made

RESPONSIBILITY

Item 1 - Forest Staff; Items 2, 3 - District Rangers. Forest Staff coordinates sampling methods, compilation of data and Forest report.

ANNUAL MONITORING COST

Item 1 - no cost. Item 2 - 5 days every 5 years ($100 x 10 days {2 people} = $1,000) Item 3 - three person days per year (one 2-person field day for mid winter survey, 2 office days for coordinating sighting information, etc. -- 100 x 4 = $400).

Depending on year, total annual cost is 1,000 + 400 + 300 + 150 = $1,850, or 400 + 300 + 150 = $850

REMARKS

Nest site surveys currently are coordinated with the state agencies. Coordinate winter monitoring efforts with other monitoring efforts of the ODFW, Pacific Bald Eagle Working Team, and National Wildlife Federation.

A January 14, 1988 letter from USDI Office of Environmental Project Review contains suggestions for monitoring of bald eagles. This letter is Forest plan comment number 1789.

Resource Element - CT121(c) Spotted Owl

ISSUE

Maintaining Habitat for Spotted Owls

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain a viable population of spotted owls as per S&G's established in the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide - Spotted Owl Guidelines, 1988 (FSEIS). Maintain network of Spotted Owl Habitat Areas (including connections to habitat in wilderness and other reserved areas). Spotted owls, pileated woodpeckers, and pine marten are ecological indicators for other species that use or depend upon mature and older aged timber stands.

MANAGEMENT AREA

Management Area 8, plus portions of other land allocations where they serve as part of the established habitat network for spotted owls, or where inventories need to be conducted.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is high because ineffective S&G's could result in a decline of the species population to the point of being listed as threatened or endangered by the USDI Fish and Wildlife Service. Likelihood of error is moderate because acres of old growth required per pair on the Forest is unknown; on balance, the option to designate more habitat per Spotted Owl Habitat Area (SOHA) is available at most sites for at least the next 5 years. Thus risk index is moderate. There is some risk to habitat areas from wildfire.

MONITORING QUESTIONS

Determine pair occupancy and reproductive status of spotted owls within SOHA's or Random Sample Areas.

1. Are SOHA's occupied by a pair of reproductively successful spotted owls in any given year?
2. What are the trends in pair occupancy, breeding status, and reproductive success of SOHA's through time?
3 How correct are the assumptions and expected outcomes of implementing the S&G's detailed in the FSEIS for spotted owls?
4. What are the general population trends of the spotted owl (random sample areas)?
5. Are SOHA's being managed as required by S&G's?
6. Is potential habitat being surveyed for spotted owls?

MONITORING PURPOSE

1. Compliance with management direction
2. Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

1 through 4. Thresholds set as part of the Regional monitoring program.
5 and 6. Non-compliance with Forest S&G's

SUGGESTED SAMPLING METHODS

1 through 4. Use methods detailed in the Region 5/Region 6 Spotted Owl Inventory and Monitoring Handbook.

5. Review plans for all projects occurring within or adjacent to SOHA's to determine if areas are being maintained and that S&G's are being followed (very few projects, other than an occasional road, should affect the Designated Wildlife Habitat area). Projects will be reviewed as they occur.

6. Inventory habitat outside of SOHA's affected by proposed projects; as a guide, use techniques outlined in the Handbook.

Monitor SOHA's throughout the life of the LRMP. Approximately 75 percent of the SOHA's (19) will be monitored annually. Up to 31 Random Sample Areas will be monitored annually. Inventory areas will be surveyed as necessary.

EXPECTED PRECISION AND RELIABILITY

Precision is high because all Designated Wildlife Habitat areas will be monitored, and reserved areas will be sampled. Although each SOHA will be monitored at regular intervals, reliability is moderate.

RESPONSIBILITY

District Rangers are responsible for District monitoring; Forest Staff coordinates sampling methods, compilation of data and Forest report.

ANNUAL MONITORING COST

Costs for items 1-4 are listed below (and include all associated costs, such as Forest coordination); costs for item 5 and 6 will be borne by other functions (ET113 support to timber, CT1 Operations, etc).

Monitor 19 SOHA's at a cost of $1,950 each	= $37,050
Monitor 31 RSA's at a cost of $1,950 each	= $60,450
ANNUAL COST	= $97,500

REMARKS

See description of Management Area 8 for details on habitat requirements (Chapter IV)

Cooperate with ODFW. Apply research findings as they become available, amend or supplement Forest Plan as necessary.

The Forest will assist the Regional Office in meeting the terms of the 1988 Interagency agreement on spotted owls. The four agencies (USDA Forest Service, and USDI Fish and Wildlife Service, Bureau of Land Management, and National Park Service) have agreed to cooperate in an effort to maintain population viability for spotted owls.

Resource Element - CT121(d) Sensitive Plants

ISSUE

Maintenance of Sensitive Plant Populations.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Provide and maintain diverse high quality habitats capable of maintaining viable populations of all sensitive plant species. Selected locations will be monitored to determine population trends of sensitive plant species. Concentration areas of sensitive plants will be sampled and management activities will be reviewed as a gauge on the effectiveness of S&G's.

MANAGEMENT AREA

Management Areas 1 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is moderate because small areas would be affected at one time, rather than large areas. Likelihood of error is moderate because much information on occurrence and habitat requirements still needs to be gathered. Risk Index is thus moderate.

MONITORING QUESTIONS

Are sensitive plant populations being maintained?

MONITORING PURPOSE

1 Compliance with management direction.
2 Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

Twenty percent decline in the size of a population at a monitoring site.

SUGGESTED SAMPLING METHODS

Fifty plots will be monitored long-term. The 20 percent threshold will trigger a review of management activities which may be responsible for these changes. If management reviews show that sensitive plants are being detrimentally affected by ground-disturbing activities, this will trigger a review of S&G's See REMARKS section for details on example monitoring procedures.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are both considered moderate. A very small portion of the sensitive plant resource will be monitored, but the resource is reasonably well insulated from wholesale detrimental change

RESPONSIBILITY

District Rangers are responsible for District monitoring, Forest Staff coordinates sampling methods, selects monitor sites, compiles data, and produces Forest report.

ANNUAL MONITORING COST

Monitor 50 permanent plots - ten per year.

During the **First** visit to a site (first five years of LRMP) permanent plots will need to be set up, which will require 1 day of field work and 1/2 day office work per site, or 1.5 days x 10 sites x 2 people (GS-7) x $100 per day = **$3,000.** During **Subsequent** visits to a site (after first five years of Plan), 1 site can be monitored per day including office work, or 1 day x 10 sites x 2 people x $100 per day = **$2,000.** After the second-visit regime begins in the sixth year, we expect one site per year to drop below the 20 percent threshold; the subsequent management review will cost **$1,000.** Each year the Forest Botanist (GS-11) will need to spend three days analyzing data and preparing a report

First five years:	$3,000	+	$0	+	$450	=	$3,500
	(Field Surveys)	+	(Review)	+	(Compilation/report)	=	(Annual Cost)
Thereafter	$2,000	+	$1,000	+	$450	=	$3,500
	(Field Surveys)	+	(Review)	+	(Compilation/report)	=	(Annual Cost)

Two Forest Service employees cost $100 per day per person (GS-7) plus expenses for vehicle and per diem). There are no extra costs associated with review of S&G's in conjunction with management reviews of ground-disturbing activities. A database will be established during the first two years

REMARKS

Coordinate work on federal candidate species with the USDI Fish and Wildlife Service Coordinate work on sensitive species with the Oregon Department of Agriculture and Oregon Natural Heritage Data Base. Coordinate research needs with Oregon State University, University of Oregon, and Southern Oregon State College

Detailed Suggested Monitoring Plan

For monitoring, one-fifth of the selected plots will be evaluated annually. Plant indicator species will be grouped by habitat (e.g., will be "plant indicator groups" or more precisely "indicator habitats", rather than indicator species). At least ten sites each in plant groups 1 through 4 will be monitored (2 or 3 species at one location counts as 1 site). Where possible, sites selected will be those with the most potential for resource conflicts (timber harvesting, road building, mining, recreation, or areas where unauthorized digging of sensitive plants may occur). If possible, those plants prefixed by a 1/ in the table below should be represented in the sample plots. Most of the plants listed below are considered sensitive; a few are monitor or watch list species.

Permanent photo plots or transects should be set up at all sites. Each site will be monitored every fifth year. Small populations will be individually counted, plant numbers in large populations will be estimated systematically (Regional Ecologist's techniques for photo plots should be used; consult Forest Ecologist)

Indicator Species Groups - Plants (# known sites)

Bog and wet/moist places, serpentine subgroup

Cypripedium californicum (30)
Darlingtonia californica (114) 1/
Gentiana bisetaea (19) 1/
Hastingsia bracteosum (2) 1/
Viola lanceolata ssp. occidentalis (3)

Bog and wet/moist places, non-serpentine subgroup

Bensoniella oregana (47) 1/
Gentiana setigera (1)
Erigeron cervinus (18)
Lilium vollmeri (19) 2/
Lilium wigginsii (2) 1/
Salix tracyi (2)
Smilax californica (1)

Rocky Places (serpentine/non-serpentine)

Dry

Arabis koehleri var. stipitata (12)
Arabis mcdonaldiana (2) 1/
Arctostaphylos hispidula (4)
Calochortus howellii (7)
Dicentra formosa ssp. oregana (18) 1/
Eriogonum pendulum (7)
Fritillaria glauca (6)
Lewisia leana (3)
Lomatium engelmannii (2)
Microseris howellii (13)
Monardella purpurea (8)
Pedicularis howellii (8+) 1/
Poa piperi (6)
Sedum laxum ssp. heckneri (10)
Streptanthus howellii (3) 1/
Thlaspi montanum var siskiyouense (13) 1/

Moist

Lewisia cotyledon var cotyledon (6)
Lewisia cotyledon var. howellii (?) 1/
Lewisia cotyledon var purdyi (?) 1/
Lewisia oppositifolia (7) 1/

Open slopes, fields, meadows, and woods (serpentine/non-serpentine)

Allium bolanderi (6)
Balsamorhiza sericia (B. platylepis) (5)
Brodiaea ida-maia (5)
Epilobium rigidum (11)
Erythroniun howellii (8)
Frasera umquaensis (2) 1/
Lathyrus delnorticus (14)
Kalmiopsis leachiana (3 outside of wilderness)
Mimulus douglasii (2)
Ribes marshallii (6)
Senecio hesperius (3)
Sophora leachiana (10) 1/
Sidalcea setosa ssp. querceta (1) 1/
Vancouveria chrysantha (8)

1/ Plants should be represented by at least two sites (unless only one is known).
2/ A large population of *Lilium vollmeri* on the Gold Beach Ranger District should be monitored, it is the largest known population of this species (see TRI/GIS Sensitive Subsystem for details).

Resource Element - CW121(a) Pileated Woodpecker

ISSUE

Maintain Pileated Woodpecker Habitat.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain habitat effectiveness of the 63 (45 outside of wildernesses) pileated woodpecker habitat areas designated to meet management direction. These sites (including SOHA's) provide mature and old-growth forest habitat to insure the Forest will maintain a well distributed viable population of pileated woodpeckers Pileated woodpeckers are ecological indicators of other species that use or depend upon mature and older aged timber stands.

MANAGEMENT AREA

Management Area 8.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is moderate because this species is widespread on the Forest and much habitat is available outside of Designated Wildlife Habitat areas Likelihood of error is moderate because site specific territorial requirements are not known for the Forest; pileated woodpeckers may require more than 300 acres of mature/old-growth forest per pair (Mellen 1987). Thus the risk index is moderate There is some risk to habitat areas from wildfire.

MONITORING QUESTIONS

1. Are the areas suitable habitat for pileated woodpeckers?
2. Is there evidence of pileated woodpeckers (diggings, cavities, birds)?
3. Are the number of areas identified in the plan being maintained?
4. Are the areas occupied and productive?

MONITORING PURPOSE

1. Compliance with management direction.
2. Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

1. Habitat suitability less than minimum standards.
2. Decline of more than 15 percent in detected presence.
3. Habitat area numbers and distribution less than minimum requirements.
4. Decline of more than 20 percent in occupancy or reproduction success (nest failure)

SUGGESTED SAMPLING METHODS

1. Examine 50 or 25 percent of the habitat areas annually (depending on year) to sample for maintenance of habitat effectiveness for pileated woodpeckers (include both the 300 acres of Designated Wildlife Habitat and 300 acres of foraging habitat). Establish permanent plots for sampling habitat capability; use Habitat Suitability Index Model (Schroeder 1982) or another

credible suitability index A potential sampling scheme may consist of randomly selecting four permanent transects (or equivalent plots) per habitat area. At 500 foot intervals along each transect characterize habitat for pileated woodpeckers (use standard resource inventory plot size) Along transect route, observer will also note feeding cavities, nest/roost cavities, and actual sightings Monitoring of spotted owl areas will include incidental gathering of pileated data, as SOHA's also qualify as pileated woodpecker habitat areas (pileated areas will also be sampled for pine marten habitat data - see pine marten element). Record sightings and sign of other wildlife species noticed along the transects.

2. Sampling method 1 will also serve to answer monitoring question 2
3. Examine those sites where natural occurrences such as windthrow or fire may have affected the sites. Examine affected habitat areas within a year after the event.
4. Examine 10 percent of habitat areas annually to sample for occupancy and productivity of pileated woodpeckers. Use tape recorded territorial calls and drummings to elicit responses from pileated woodpeckers Search areas for nests to determine productivity (see Mellen 1987 for methods)

EXPECTED PRECISION AND RELIABILITY

Precision is considered moderate, because credible models will be used to assess habitat capability (see citation above). Reliability is considered moderate, because all designated habitat areas will be monitored; conversely, actual territorial requirements on the Forest are not well understood Over the short term this habitat resource is reasonably well insulated from significant detrimental change

RESPONSIBILITY

District Rangers are responsible for District monitoring; Forest Staff coordinates sampling methods, compilation of data and Forest report.

ANNUAL MONITORING COST

Monitor 63 pileated woodpecker areas throughout the life of the LRMP. Half of the sites will be monitored in each of the first two years, 25 percent in each year thereafter. A database will be established during the first two years. Costs for sampling methods 1, 2, and 5 are listed below. Costs for sampling methods 3 and 4 will be borne by other functions (ET113 support to timber, etc).

A. First 2 years (items 1 and 2):

63 areas x .5(%) = 32 areas monitored per year. On the average it will take two people 1 day to monitor one area.

32 areas x $100 per day x 2 persons	=	$6,400	
32 areas x 4 track plates x $10	=	1,300	(see pine marten element)
1 day each SO & RD Admin. x $150	=	300	
ANNUAL COST	=	$8,000	

B Every year thereafter (items 1 and 2):

63 areas x 25 (%) = 16 areas monitored per year. On the average it will take two people 1 day to monitor one area

16 areas x $100 per day x 2 persons	=	$3,200	
16 areas x 4 track plates x $10	=	650	(see pine marten element)
1 day each SO & RD Admin x $150	=	300	
ANNUAL COST	=	$4,150	

C. Every year (occupancy and productivity monitoring -- item 5):

63 areas x .10 (%) = 6 areas monitored per year. On the average it will take two people 5 days to monitor one area.

6 areas x $100 per day x 2 person x 5 days	=	$6,000
1 day each SO $ RD Admin. x $150	=	300
ANNUAL COST	=	$6,300

Total Cost of Monitoring

First 2 years = A + C = 8,000 + 6,300	=	$14,300
Year 3 and beyond = B + C = 4,150 + 6,300	=	$10,450

REMARKS

See description of Management Area 8 for details on habitat requirements (Chapter IV)

Data on pine marten (and fisher) will be collected in pileated woodpecker habitat areas.

Research is needed to establish habitat requirements for pileated woodpeckers on the Forest (how many acres of mature/old-growth Forest is required). Habitat requirements may be significantly different in three separate areas of the Forest: eastside, south coast, north coast. Revise S&G's for pileated woodpecker habitat areas as data becomes available. Work with State and Federal Fish and Wildlife agencies, universities (research), and conservation groups to develop census methods and determine effectiveness of S&G's.

Various methodologies for sampling the snag component in habitats of the Blue Mountains or Oregon are currently being evaluated by Evelyn Bull, Pacific Northwest Research Station, LaGrande, Oregon Information from her investigation should be available in the next few years, and may be useful in developing sampling schemes for pileated woodpecker habitat areas.

Resource Element - CW121(b) Pine Marten

ISSUE

Maintain Pine Marten Habitat.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain habitat effectiveness of the 85 (66 outside of Wildernesses) pine marten habitat areas designated to meet management direction. These sites (including spotted owl and pileated woodpecker areas) provide mature and old-growth forest habitat to insure the Forest will maintain a well distributed viable population of pine marten.

MANAGEMENT AREA

Management Area 8

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	3	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is moderate because marten habitat is widespread on the Forest, with much habitat available outside of Designated Wildlife Habitat areas. Likelihood of error is moderate because of incomplete habitat relationship information and lack of site specific habitat information for the Forest. Thus the risk index is moderate. Marten are ecological indicators of other species that use or depend upon mature and older aged timber stands There is some risk to habitat areas from wildfires.

MONITORING PURPOSE

1. Compliance with management direction
2 Maintenance of environmental quality (effects) as projected.

MONITORING QUESTIONS

1. Are the areas suitable habitat for pine martens?
2. Is there evidence of pine marten (scat, tracks, animals)?
3. Are the number of areas identified in the plan being maintained?

THRESHOLD OF CONCERN/VARIABILITY

1. Habitat suitability less than minimum standards.
2. Decline of more than 25 percent in detected presence (after all areas visited and analyzed--after database developed for all sites--set at 25 percent because of expected difficulty in gathering information).
3. Habitat area numbers and distribution less than minimum requirements

SUGGESTED SAMPLING METHODS

Monitor 85 pine marten areas throughout the life of the LRMP. Half of the sites will be monitored in each of the first 2 years, 12.5 percent in each year thereafter.

1. a. Depending on year, examine 50 or 12 5 percent of habitat areas annually to sample for maintenance of habitat effectiveness for pine marten Establish permanent plots for sampling

habitat capability, use Habitat Suitability Index Model (Allen 1982) or other acceptable suitability index. A potential sampling scheme may consist of randomly selecting four permanent transects (or equivalent plots) per habitat area. At 500 foot intervals along each transect characterize habitat for pine marten (use standard resource inventory plot size). Along transect route, observer will also note any marten sign or sightings. One track plate (baited aluminum platforms coated with carbon black) or hair trap will be placed per transect to monitor for the presence of marten Winter track counts may be another option to consider

b. In pine marten areas look along the transect route for signs of pileated woodpeckers (diggings, cavities, birds) Technically, marten areas do not serve as pileated areas, however, very little extra effort will be needed to collect this additional information on habitat use by pileated woodpeckers, and it may prove useful when this LRMP is revised in 10-15 years. Record sightings and sign of other wildlife species noticed along the transects. Monitoring of SOHA's and pileated areas will include incidental gathering of marten data, as both spotted owl and pileated woodpecker habitat areas also qualify as pine marten habitat areas

2 Sampling method 1 will also serve to answer monitoring question 2.

3. Examine those sites where natural occurrences such as windthrow or fire may have affected the sites. Examine affected habitat areas within a year after the event.

EXPECTED PRECISION AND RELIABILITY

Precision is considered moderate, because acceptable models will be used to assess habitat capability (see citation above). Reliability is considered moderate, because all designated habitat areas will be monitored; conversely, actual territorial requirements on the Forest are not well understood Over the short term this habitat resource is reasonably well insulated from detrimental change.

RESPONSIBILITY

District Rangers are responsible for District monitoring, Forest Staff coordinates sampling methods, compilation of data, and Forest report.

ANNUAL MONITORING COST

Costs for sampling methods 1 and 2 are listed below. Costs for sampling method 3 will be borne by other functions (ET113 support to timber, etc.). A database will be established during the first two years.

A First 2 Years·

85 areas x .5 (%) = 43 areas monitored per year. On the average it will take two people 1 day to monitor one area.

43 areas x $100 per day x 2 persons	=	$ 8,600
43 areas x 4 track plates x $10	=	1,720
1 day each SO & RD Admin. x $150	=	300
ANNUAL COST	=	$10,600

B. Every year thereafter:

85 areas x .125 (%) = 13 areas monitored per year. On the average it will take two people 1 day to monitor one area

13 areas x $100 per day x 2 persons	=	$2,600
13 areas x 4 track plates x $10	=	520
1 day each SO & RD Admin. x $150	=	300
ANNUAL COST	=	$3,520

REMARKS

Data on fisher will be collected in pine marten areas.

See description of Management Area 8 for details on habitat requirements (Chapter IV).

Revise S&G's for pine marten habitat areas as data becomes available. Work with State and Federal Fish and Wildlife agencies, universities (research), and conservation groups to develop census methods and determine effectiveness of standards.

Resource Element - CW121(c) Osprey

ISSUE

Maintain Habitat for Osprey

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain viable population of osprey as per S&G's Osprey are ecological indicators for other species that use or depend upon habitat along major rivers

MANAGEMENT AREA

Management Areas 1 to 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is moderate; the osprey is not numerous on the Forest, but most nest sites are located in areas which have no programmed timber harvest. Likelihood of error is moderate because nest sites are relatively easy to locate and monitor. We may not be aware of all active nest sites or osprey activity Thus risk index is moderate. There is also a moderate likelihood of catastrophic loss of nest trees to wildfire or wind.

MONITORING QUESTIONS

1. Are existing nest sites occupied and productive?
2. Are surveys being completed to locate new or previously unknown nest and roost sites?
3 Are potential habitat sites being maintained, as specifically described in the S&G's?

MONITORING PURPOSE

1. Compliance with management direction.
2 Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

1. A 25 percent decline in active (reproductively successful) osprey nest sites over a three year period.
2 Surveys not completed in two successive years.
3 More than 10 percent of the identified potential nest sites are unsuitable for occupancy at any given time

SUGGESTED SAMPLING METHODS

1 Survey of nest activity and productivity: There are three options available for monitoring osprey populations. At a minimum, option A should be implemented. If the data gathered under options A or B shows a 25 percent decline in the current (1988) number of active osprey nests for two successive years, then option C should be implemented for the third year to verify the perceived decline *If the three year decline is the result of management activities on the Forest, S&G's for* osprey will be revised as necessary to prevent the current number of active nests from declining further (if a remedy for the decline is within the purview of the Forest Service, it will be implemented)
a Survey of nesting activity - boat and vehicle. Conduct a nesting activity survey once each year on the Rogue River by Forest Service boat during May/June (it may be possible to do the osprey

survey as part of regularly scheduled river patrols). Surveys along the Coquille, Illinois, and Chetco Rivers will be conducted by vehicle (or on foot as necessary).
b. Survey of nesting activity - aircraft and vehicle. Conduct a nesting activity survey once each year on the Rogue River by helicopter or fixed wing aircraft during May/June (this activity will be occasionally conducted by the ODFW) Care will be taken not to disturb the osprey. Surveys along the Coquille, Illinois, and Chetco Rivers will be conducted by vehicle (or on foot as necessary).
c Survey of nesting productivity - helicopter (primarily). Conduct helicopter survey of osprey nests throughout the breeding season to determine population trends and fledging success Nests need to be visited 4 times· early April, mid to late April, and twice during the last week of July through the first 3 weeks of August (see page 117, Jackman and Scott 1975).

2. Done at the same time as sampling method 1.
3. Field survey of potential sites. Each site reviewed at five-year intervals.

EXPECTED PRECISION AND RELIABILITY

Precision is moderate because known nest sites (active/inactive) will be monitored, but undiscovered nest sites probably exist. Reliability is high because direct counts will be made.

RESPONSIBILITY

District Rangers are responsible for District monitoring; Forest Staff coordinates sampling methods, compilation of data, and Forest report.

ANNUAL MONITORING COST

Sampling methods 1 and 2: annual costs (a survey of the Rogue by two observers takes a full day, the other three rivers can be checked in one day [combined total] by single [separate] observers) .

A. 4 person days per year - field time	4 x $125	=	525	(including vehicle)
1 person day per year - office	1 x $100	=	100	
Forest Service Jet Boat		=	100	
1 day SO Administration	1 x $150	=	150	
TOTAL		=	$ 875	per year
B. 4 person days per year - field time	4 x $125	=	525	(including vehicle)
1 person day per year - office	1 x $100	=	100	
Forest Service contract helicopter		=	1,000	(2 5 hours/ $400)
1 day SO Administration	1 x $150	=	150	
TOTAL		=	$1,775	per year

C. 16 person days per year - field time	16 x $125	=	$2,000	(including vehicle)
3 person day per year - office	3 x $100	=	300	
Forest Service contract helicopter		=	4,000	(2 5 hours x $400 x 4)
1 day SO Administration	1 x $150	=	150	
TOTAL		=	$6,450	per year

Sampling method 3: it will take a wildlife biologist approximately 10 days every fifth year to survey the potential nest sites described in the S&G's and write Forest report 10 days x $125 = **$1,250 every fifth year.**

REMARKS

Nest site surveys currently are coordinated with the state agencies. Work with State and Federal Fish and Wildlife agencies, universities (research), and conservation groups to develop census methods and determine effectiveness of standards.

The 25 percent threshold of concern for osprey (item 1) may seem high, but year to year fluctuations in population level are common. This is due in part to variations in counting techniques (different observers, intensity or thoroughness of survey, weather, new nest sites not discovered), the 25 percent threshold will trigger a review of management activities which may be responsible for these changes A 25 percent reduction is significant and a reasonable trigger point for reviewing S&G's for osprey.

Resource Element - CW121(d) Woodpeckers

ISSUE

Maintain Woodpecker Habitat (Primary Cavity Excavators)

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain number, size, and distribution of green trees and snags to meet habitat capability objectives as shown by snag management area in the Siskiyou Wildlife Tree (Snag) Guidelines

MANAGEMENT AREA

Management Areas 10 to 14.

All forested areas will have habitat capability objectives levels prescribed but only those where timber harvest or fuelwood gathering is permitted will be significantly affected

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)		(Likelihood of Error)	=	(Risk Index)

Cost of error is high because once the dead tree component is gone from an area it may be many years before adequate replacement trees are available. Loss of this habitat component would have serious adverse affects on timber productivity due to the relationship of birds to insects that damage trees The likelihood of error is moderate because detrimental change would occur at a relatively slow pace across the landscape. Thus the risk index is moderate. Risk index could be high if the Forest has problems reserving dead trees due to pressure from wood cutting or for safety reasons; this is not expected.

MONITORING QUESTIONS

1. Are snags and replacement trees being left in the right numbers, sizes, and distribution on lands available for timber removal?
2. Are snags and replacement trees being maintained as planned on all other lands?
3. Are management indicator species (primary excavator guild) occupying the habitat?

MONITORING PURPOSE

1 Compliance with management direction.
2. Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

1. More than 10 percent of the surveyed areas have less than 90 percent of the prescribed trees and snags.
2. More than 10 percent decrease in snag numbers shown in consecutive forest-wide Timber Inventories (done every 10 years).
3. Cavities are not being created to support a viable population of secondary cavity users

SUGGESTED SAMPLING METHODS

1. Timber sale activities will be monitored to determine trends in habitat capability for woodpecker species (as a group - see: Brown 1985)
   a. Examine habitat on 20 percent of timber sales within 1 year of sale closure per district Analyze snags numbers, dispersion, and use by primary excavators (woodpeckers) Annually.
   b. Establish and measure transects to measure longevity in areas where fuelwood is gathered Once every 2 years.
2. Evaluate resource inventory plot data each 10-year period. 10-year interval
3. See methods under item 1.

RESPONSIBILITY

District Rangers are responsible for District monitoring; Forest Staff responsible for 10-year inventory (item 2), coordination of sampling methods, compilation of data, and Forest report

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are considered moderate because accepted methods will be used to access habitat capability (see citation above). Although only 20 percent of each district's timber sales will be monitored annually, this level of analysis should provide a clear picture of the effectiveness of S&G's for wildlife tree habitat.

ANNUAL MONITORING COST

Variable but less than $5M per year

Some data entry and collection will be accomplished as part of routine scheduled work, the analysis below includes costs associated strictly with monitoring.

A. Annually. Items 1(a) and 3 (20 percent of sales analyzed). Each District will need 5 person days (4 at GS-5/7 {@$100} and 1 day at GS-9/11 {@$125}) Compiling and analyzing the data for the Forest will require 2 days (GS-11) (@$150).

(20 x $100) + (5 x $125) + (2 x $150) = $3,000 (Approximated per year)

B. Every other year. Items 1(B) and 3 (fuelwood areas) Each District will need 2 person days (@$100). Compiling and analyzing the data for the Forest will require 1 day (@$150).

(10 x $100) + $150 = $1,150

C. Once per Decade. Item 2. Compiling and analyzing the data for the Forest will require 2 days (@$150), or $300

Years 1, 5, 7, 9 = $3,000.
Years 2, 4, 6, 8, 10 = $3,000 + $1,150 = $4,150.
Year 3 = $3,000 + $1,150 + $300 = $4,450 (1991)

REMARKS

Research is needed to establish habitat relationships and population levels by physiographic province May use local conservation groups to establish and read transects to determine use by cavity nesters Work with State and Federal Fish and Wildlife agencies, universities (research), and conservation groups to develop census methods and determine effectiveness of standards.

Additional detail for suggested methods (items 1 and 3). Record wildlife tree data for each sale, store data on TRI/GIS. Map general locations of wildlife trees/snags on the TRI/GIS project area map (R6-2200-32, ground vegetation activity record) Count wildlife trees (individuals and clumps) when they are first designated and after management activities cease (following sale closure). Trees serving as streamside cover can serve as snags only if they are surplus to those needed to shade the watercourse Develop methods to display wildlife tree data for the reviews and document recording of snag data

Resource Element - CW121(e) Blacktail Deer and Roosevelt Elk

ISSUE

Maintain Deer and Elk Habitat.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Maintain or increase habitat capability to support populations identified in this Plan

MANAGEMENT AREA

All Management Areas.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

Cost of error is high because of the considerable demand for big game. Likelihood of error is moderate because of some uncertainty of the quantity of thermal cover needed by big game, especially in southwest Oregon. There is virtually no chance of deer and elk populations being suppressed by timber management activities to levels approaching minimum viable.

MONITORING QUESTIONS

1. Are the populations being maintained as predicted in the FEIS?
2. Are the S&G's being followed as required to meet established habitat capability goals?

MONITORING PURPOSE

Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

1. Populations are more than 20 percent below or above the FEIS objective for a five year period.
2. Habitat capability is more than 20 percent below the objective in any given management unit; measure at five year intervals ("given management unit" may equate to Oregon Department of Fish and Wildlife (ODFW)/California Department of Fish and Game (CDFG) game management units, or the Forest may be treated as a single management unit, or new management units may be established as part of a Forest-wide deer and elk management plan to be developed within three years after implementation of this LRMP).

SUGGESTED SAMPLING METHODS

1. a Use ODFW and CDFG census records. Summarize every five years. Data from state trend routes will be used to monitor deer/elk herd populations.
   b. Elk range expansion will be monitored through collection of sighting/sign data by Forest personnel and other observers. Complete and accurate elk sightings will be kept by district personnel. This will help identify elk concentration and calving areas, as well as minimum population sizes. Summarize each five years.
2. a. Model cover types to determine rate of compliance with set of habitat criteria furnished by the ODFW (ODFW 1985). As they occur, assess timber sales and other projects which affect habitat capability ratings Summarize every 5 years.

b. Monitoring habitat criteria (ODFW 1985). The TRI or GIS systems will be used to gauge the effectiveness of criteria provided by the ODFW for management of deer and elk habitat. Timber stands will be categorized by age, which will in turn be converted to feeding, hiding, and thermal cover zones. The ODFW has established year-round cover/forage requirements for elk and deer: a total of 50 percent in well distributed thermal cover stands (of which at least 25 percent is optimal thermal cover) and about 20 percent in forage areas (ODFW 1985). For further guidance on cover requirements, see Brown (1985). Road densities per unit area (open roads) will be included in the analysis.

c. Monitoring S&G's. Timber sale reviews will be used to gauge the effectiveness of S&G's established for deer and elk. Evaluation procedures will be developed. If necessary, S&G's will be revised to meet stated objectives.

RESPONSIBILITY

District Rangers are responsible (all or in part) for all items except 1a. Forest Staff are responsible for coordination of sampling methods, compilation of data, and Forest report (includes Item 1a.).

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are considered low, because the data collected will provide relatively crude indices for interpreting habitat changes Conversely, the viability of the Forest deer and elk herds is not expected to be in question under any reasonable timber management scheme.

ANNUAL MONITORING COST

Ranger Districts. For item 2a., $200 per project (5-10 projects per year per District), or 5 projects x 5 RD x $200 = $5,000 annual cost.

SO Staff. First year start-up cost for item 1a = $500.

Ranger District and SO combined cost of summary at 5-year intervals = $1,000.

REMARKS

Will rely on ODFW and CDFG for census data. Need additional research on habitat relationships. Wisdom and others (1986) may serve as a source document for evaluation of elk habitat.

Monitoring for deer and elk is based on fluctuations in habitat capability, not populations. A given area of habitat can support a theoretical maximum number of individuals of a specific species. This ability of habitat to support a maximum number of individual animals is termed "Habitat Capability". The habitat capability rating calculated for a specific area at a specific moment in time does not necessarily equate to the number of individual animals actually present

Resource Element - DN121 Range

ISSUE

Range Condition and Utilization.

FOREST GOAL, DESIRED FUTURE CONDITION, OUTPUTS

Utilize transitory range economically on an environmentally sound, sustained yield basis Provide Range for 3000 AUM's annually.

MANAGEMENT AREA

Management Areas 4 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

1	X	1	=	1
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Is vegetation condition and trend being maintained or improved? Have areas in unsatisfactory condition improved?
2. Is available range being fully utilized?

MONITORING PURPOSE

1 Achievement of output (goods and services) objectives
2 Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

1. Greater than 20 percent of any allotment shows a downward trend of forage quality or site integrity Areas of unsatisfactory condition exhibit further deterioration.
2. Any additional range utilization without authorization. Utilization more than 20 percent below authorized use levels

SUGGESTED SAMPLING METHODS

1. Establish permanent, intensive transects on all ranges and monitor 33 percent annually In addition, extensive transects will be established and monitored annually.
2. Actual head counts will be made on 20 percent of range allotments annually.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are both considered high. This sampling intensity reports an accurate representation of range condition and utilization

RESPONSIBILITY

District Ranger, Lands and Recreation Staff.

ANNUAL MONITORING COST

$50/allotment X approximately 11 allotments = $550.

Resource Element - ET121(a) Port-Orford-cedar

ISSUE

Is Port-Orford-cedar threatened in regard to its economic and non-economic uses? Is it threatened as a functioning part of the Forest ecosystem in its native range?

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to maintain Port-Orford-cedar as a viable, functioning member of the Forest ecosystem by reducing the rate of spread of Port-Orford-cedar root rot disease, *Phytophthora lateralis*. Desired future condition will be to maintain healthy (disease-free) stands of Port-Orford-cedar.

MANAGEMENT AREA

Management Areas 1 through 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	3	=	9
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Which stands of Port-Orford-cedar are disease-free and which are infected?
2. Is the rate of spread of the disease increasing or decreasing?
3. Are management strategies effective in controlling the rate of spread?

MONITORING PURPOSE

1. Compliance with management direction.
2 Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

The threshold of concern relates to whether the spread of the disease is increasing or decreasing. If spread accelerates, concern will be heightened. If spread decreases, it could be an indication that control strategies are effective.

SUGGESTED SAMPLING METHODS

Aerial photography will identify healthy and diseased stands which will be mapped. Intensive sampling of infected road systems occur at least every three years These observations will indicate the extent of Port-Orford-cedar root rot disease along transportation routes and will be compared to determine the rate of spread of the disease over time.

Regularly scheduled reforestation surveys after the first, third, and fifth growing seasons will indicate performance in plantations. Aerial photography will continue to occur on an as-needed basis.

Aerial detection surveys, valuable indicators of spread along streams and roads and within forest stands, will occur at least every two years.

Research will be implemented to measure genetic diversity, develop trees that are resistant to the disease, and evaluate methods of control. Summaries of disease status will be made for all control activities as they

are completed and a Forest summary will be completed annually to coincide with the interregional summary and report.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability will be moderate, though sufficient to show effectiveness of management strategies in decreasing the rate of spread of the disease.

RESPONSIBILITY

Forest and District Silviculturists are responsible for developing, monitoring, and reporting control strategies.

ANNUAL MONITORING COST

Aerial detection surveys, research, and seed collection for genetics study will cost about $150,000 for the first year. Continued research for the next three years will be about $65,000 annually and $35,000 annually thereafter.

Resource Element - ET121(b) Destructive Insect and Disease Organisms

ISSUE

Are effects from insects and disease resulting in unacceptable damage and/or growth loss?

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to have a healthy ecosystem with timber stands performing at optimum levels without significant damage from insects or disease.

MANAGEMENT AREA

Management Areas 1 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

Are insects and disease creating significant damage and growth reductions on the Forest?

MONITORING PURPOSE

1. Compliance with management direction.
2. Maintenance of environmental quality (effects) as projected.
3. Resource mitigation measures are employed.

THRESHOLD OF CONCERN/VARIABILITY

Insect and disease populations are analyzed in regard to their potential effects. If damage or growth loss is anticipated, both management practices and predicted outputs will be evaluated.

SUGGESTED SAMPLING METHODS

Insects and diseases are monitored as part of stand examinations and reforestation surveys. Aerial detection surveys are conducted annually or bi-annually depending upon need.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability will be moderate, though sufficient to show effectiveness of management strategies in decreasing the effects of insects and disease.

RESPONSIBILITY

Forest and District Silviculturists will work together to summarize and evaluate the potential for damage.

ANNUAL MONITORING COST

Part of the ongoing program. No additional costs anticipated.

Resource Element - ET121(c) Land Suitability

ISSUE

Only lands suitable for timber production should be harvested to accomplish timber output goals; timber harvest levels should be computed based on only the suitable land base. Also harvest levels should be computed on the land capability and inventory condition.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Particularly relates to Forest Goals 1, 2, and 3. Directly connected to the level of timber outputs.

MANAGEMENT AREA

Management Areas 10 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

Monitor changes in the land base, or proposed changes as a result of new information, that could have implications for adjusting levels of activities or outputs. This includes potential changes in the lands suitable for timber production (36 CFR 219.12 (k)(5)(ii).

MONITORING PURPOSE

Compliance with management direction.

THRESHOLD OF CONCERN/VARIABILITY

Change of more than 15,000 acres in productivity class or vegetation class beyond that expected to result from planned activities; more than 10,000 acres proposed for change of suitability classification; or in the case of land suitability, at intervals not to exceed 10 years. These thresholds would have implications for an approximate five percent difference in timber outputs.

SUGGESTED SAMPLING METHODS

1. Summarize changes in productivity class, vegetation class, and proposed changes in land suitability resulting from project inventories. Also compare the results of the resource inventory scheduled for 1989 and 1990.
2. Frequency: Summarize annually.

EXPECTED PRECISION AND RELIABILITY

As information is updated from field inventory work done in conjunction with project planning, land suitability changes should be mapped to units as small as one acre and changes in productivity or vegetation condition classes should be mapped to 10 acres. The data would be verified as the project inventory work is completed; reliability would be high due to the intensive field surveys, however, only a fraction of the Forest would be examined in any one year.

The resource inventory will cover the entire Forest, but the field data collection will be less intensive resulting in less reliability for individual areas. Continued monitoring as project implementation inventories are completed will still be needed.

RESPONSIBILITY

Districts periodically update TRI/GIS. Forest Planning Staff extracts TRI/GIS data to summarize changes.

ANNUAL MONITORING COSTS

$2,000.

Resource Element - ET121(d) Acres and Timber Volume Harvested

ISSUE

Are timber outputs consistent with those projected by this Forest Plan? (36 CFR 219.12(k)(1)

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Projected timber volume outputs are achieved as planned and long term harvest levels are feasible.

MANAGEMENT AREA

Management Areas 10 to 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	1	=	2
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

Are actual timber outputs comparable to those projected in this FEIS?

MONITORING PURPOSE

1. Compliance with management direction.
2. Achievement of outputs (goods and services) as projected.

THRESHOLD OF CONCERN/VARIABILITY

Total acres harvested Forest-wide varies more than ten percent from projected harvest acres. The timber inventory was designed to have a ten percent confidence interval. If more than a ten percent variance in the proportion of acres or volume is observed, an evaluation will be made to determine the source of the deviation.

SUGGESTED SAMPLING METHODS

Districts report for each timber sale the acres scheduled for harvest by planning basin by management area. Also estimate the volume by planning basin by management area (This data could also be used as part of the watershed cumulative effects monitoring). Sale volumes will be compiled to make certain that Forest-wide goals are achieved.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability will be moderate, though quite adequate for measuring how well actual outputs compare to predictions.

RESPONSIBILITY

Timber Staff (Ranger District Timber Management Assistants will submit data).

ANNUAL MONITORING COST

$2,000.

Resource Element - ET121(e) Harvest Unit Size Limit

ISSUE

Monitor harvest unit size to determine if maximum size limits should be continued (36 CFR 219.12(k)(5)(iii).

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to vary harvest unit size to fit site-specific conditions and requirements, but to avoid exceeding the 60 acre size limit in most cases. Future unit size will relate to overall diversity on the Forest as well as other resource needs.

MANAGEMENT AREA

All areas managed for timber outputs.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

$$\frac{1}{\text{(Cost of Error)}} \times \frac{1}{\text{(Likelihood of Error)}} = \frac{1}{\text{(Risk Index)}}$$

MONITORING QUESTIONS

Is the Forest exceeding the 60-acre size limit?

MONITORING PURPOSE

1. Compliance with management direction.
2. Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

If ten percent or more of the harvest units sold exceed 60 acres in size, the need to continue the size limitation should be evaluated.

SUGGESTED SAMPLING METHODS

A summary of the harvest units exceeding 60 acres will be compiled annually from TRI/GIS. Report will include Environmental Assessments for all units exceeding the 60-acre size limitation.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability will be high.

RESPONSIBILITY

Forest Silviculturist.

ANNUAL MONITORING COST

$1,000.

Resource Element - ET121(f) Reforestation and Intensified Forest Management Practices

ISSUE

Are regeneration harvested acres reforested within five years after cutting? Is plantation tree stocking, growth, and yield at a level that will support projected outputs?

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to reforest harvested units within five years after cutting at a stocking level, with growth and yield, that will achieve projected outputs (successful reforestation).

MANAGEMENT AREA

All areas managed for timber outputs.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

$$\frac{2}{\text{(Cost of Error)}} \times \frac{1}{\text{(Likelihood of Error)}} = \frac{2}{\text{(Risk Index)}}$$

MONITORING QUESTIONS

1. What is the elapsed time between harvest of acres and successful reforestation?
2. What proportion of the acres certified stocked with no additional work planned, are above minimal stocking, but below the recommended stocking level that would produce full yield?
3. How many acres are carried with excess stocking that may result in reduced growth and yield?
4. How many acres impacted by vegetation competition where yield may be reduced or delayed?
5. How many acres received fertilizer treatment?
6. Are stands growing at a rate that will produce the predicted yields?

MONITORING PURPOSE

Achievement of output (goods and services) objectives.

THRESHOLD OF CONCERN/VARIABILITY

1. Ten percent or more of the acres having reforestation lag time greater than five years
2. Ten percent or more of the acres being certified stocked with less than the recommended stocking level
3. Ten percent or more of the acres with excess stocking at age 15 need precommercial thinning, but are not being treated.
4. Ten percent or more of acres prescribed for release not receiving treatment within three years of the prescribed need.
5. Ten percent or more of the acres prescribed for fertilization do not receive treatment
6. Timber volume outputs are ten percent more or less than predicted

SUGGESTED SAMPLING METHODS

First-, third-, and fifth-year surveys will be utilized to assess accomplishment for elements 1 through 4 Accomplishment reporting will serve as a basis for validating element 5 A summary will be prepared

annually for all elements. Managed stand inventory (as part of the revegetation inventory) will provide actual growth data to be measured initially in 1989 (or 1990) and then, once every 10 years

EXPECTED PRECISION AND RELIABILITY

Precision and reliability will be high Determination of whether the standards are met will be straight-forward and obvious.

RESPONSIBILITY

District Silviculturists gather and submit data Forest Silviculturist summarizes and analyzes data

ANNUAL MONITORING COST

No additional costs anticipated.

Resource Element - ET121(g) Biological Diversity

ISSUE

Biological Diversity touches many planning issues. Issues related to forest structure and distribution over time potentially relate to Biological Diversity, such as the amount and distribution of old-growth forest, the conversion of hardwood-dominated stands to conifer-dominated stands, the amount and rate of timber harvested, the amount, quality, and distribution of animal habitat, and the structure of our streams Other issues are more commonly related to species composition concerns. Sensitive plant and animal species, management indicator species, and species diversity are examples. On the other hand, issues such as long-term forest productivity, management of logging residues, species viability, and forest fragmentation relate to the functions of the forest as an ecosystem. Most of these issues are covered by specific monitoring elements.

Management indicator species are monitored in various ways. Most are monitored by tracking their habitat For example, deer and elk habitat, particularly critical habitat, will be tracked and efforts are being made to learn more about population dynamics Occasionally direct observation is used, as is the case with spotted owls Sensitive plant species habitat is being monitored and inventories are continually being initiated (species not yet surveyed) and updated (species with a completed survey) Resource inventories are being used to track traditional variables such as existing vegetation, volume growth, standing volume, and condition classes. They will be used to measure less traditional variables such as successional stages, stand structure, and edge contrast Ecosystem functions are more difficult to track However, soil productivity monitoring and site organic material management cover the issue of long-term site productivity quite well. Analysis of this data will help to refine thresholds and feedback into future S&G's Most of the variables needed to evaluate species and habitat diversity are being measured by a variety of inventories (timber inventory, stand exams, vegetation management exams, reforestation exams, staked tree evaluations, ecology plots, and specific monitoring).

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest goal is to maintain native and desirable introduced or historic plant and animal species and communities. Provide all seral stages of terrestrial, aquatic, and edaphic plant associations in a distribution and abundance to assure species diversity and viability. Species/habitat relationships (habitat requirements) have not been established. The spotted owl is an example of one of the most studied species, yet we are only beginning to determine firm habitat needs. A desired future condition is to establish the local needs of management indicator species, rare species, and the proportion of seral stages that allows for natural diversity Continued long-term monitoring will be necessary to establish critical relationships and thresholds for the abundance of the various seral stages, their distribution, and specific species requirements for sensitive species

MANAGEMENT AREA

Monitoring will be Forest-wide Future monitoring may be more local. Ultrabasic areas that support many rare species, for example, may have to be monitored and analyzed separately Although they are not managed for consumptive use and stand little chance of disturbance, they may need to be evaluated as a unit since few established inventories cover the areas.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

1. Critical Habitat: The loss of critical habitat is of concern The worst case could result in extinction if the amount or quality of habitat falls below viable levels A loss of species would be a high cost, but the likelihood of extinction is low

3	X	1	=	3
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

2. Diversity: A loss of diversity is also of concern. A reduction in the abundance or evenness could occur for species or plant associations Overall impact of losses in abundance of species or plant associations is low as long as they are maintained above viable levels However, it is certain some seral stages of specific plant associations will be reduced

3	X	1	=	3
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. What is the present distribution and proportion of seral stages by plant association (FEIS, Chapter III, Table III-37)?
   a. How do they compare to past distributions?
   b. What distribution and proportion is expected in the future?
   c What are the trends?
   d. Does the distribution, proportion, and absolute amount provide viable habitat for management indicator species, rare species, and biological diversity?
2. Has habitat capability changed?
3. What is the present status of sensitive species?
   a. What are the population numbers?
   b. What is the distribution of known sites?
   c. Is there a trend in population density?
4 What are the trends in overall species diversity on the Forest?
   a. Are there trends in species richness?
   b. Are there relationships to management practices and direction?
   c. Are there relationships with natural processes or events?
5. Can species/habitat relationships be established from present data?

MONITORING PURPOSE

Maintenance of environmental quality (effects) as projected

THRESHOLD OF CONCERN/VARIABILITY

There are no established thresholds for biological diversity on the Forest. Thresholds and requirements of individual species (such as fish, woodpecker, and spotted owl) have been established and will be monitored. Management direction has been set in some cases such as for fish habitat improvement, meadow maintenance and enhancement, and maintenance of early seral stages for wildlife forage and cover Present proportions of the seven benchmark seral stages can be used to compare changes in the amounts of seral stages on the Forest (FEIS, Chapter III, Table III-17). However, Forest-wide averages are only an indication of general trends. The percent of mature stage varies from 27 in the Kalmiopsis, to an average of 70 in the other wildernesses combined. The seedling/sapling stage varies from about one

percent in wilderness to about 17 percent in non-wilderness As we accumulate information, planning basins may be used to evaluate the trends in biological diversity.

SUGGESTED SAMPLING METHODS

1. Use the resource inventory (Chapter IV, Resource Inventories) to determine plant association and seral stage and assess the presence/absence of selected common wildlife species
2. Continue to use RESURV, stake tree plots, stand exams, silvicultural visits, unit exams, and ecoplots to map plant associations and existing seral stages. These exams are ongoing and used to update databases. With the installation of the TRI/GIS the process will be streamlined and can be efficiently used to display distribution of seral stages The Forest wildlife biologist, ecologist, silviculturist, and botanist will be responsible parties.
3. The Forest botanist will use rare plant surveys to evaluate population abundance and trends in density
4. Information combined from the above sources on species abundance and distribution will be used by the Forest wildlife biologist and ecologist to evaluate the trends in species richness and evenness.
5. Records will be kept in TRI/GIS to compare trends at least every 5 years

EXPECTED PRECISION AND RELIABILITY

At least two cycles of monitoring will be necessary to evaluate the process. The first cycle will determine whether particular measures are adequate measures of habitat, and species diversity. The second cycle will help to establish appropriate comparative processes for evaluating trends

RESPONSIBILITY

Coordinated by the Forest Staff.

ANNUAL MONITORING COST

$40,000.

Resource Element - ET121(h) Social and Economic Setting

ISSUE

Has the social and economic setting changed significantly and can the management of the Forest enhance or mitigate?

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The management of the Forest is responsive to the needs of local and national social and economic conditions.

MANAGEMENT AREA

Management Areas 1 through 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)
2	X	1	=	2

MONITORING QUESTIONS

1. What is the average yearly unemployment rate for Josephine, Jackson, Coos, and Curry Counties?
2. What is the demand for timber?
3. What is the demand for recreation?
4. What are the social and economic trends in local communities? (Trends in fisheries demand is not a question because the demand greatly exceeds supply Fisheries outputs are not sensitive to changes in demand.)

MONITORING PURPOSE

1. Compliance with management direction.
2. Achievement of output (goods and services) objectives

THRESHOLD OF CONCERN/VARIABILITY

1. >15 percent average yearly unemployment for the four county area.
2. <1:2 ratio of bid price divided by the advertised rate. The bid premium applied to ineffective purchaser credit will be excluded from the bid price and added to the advertised rate.
3. >80 percent of carrying capacity in primitive or developed recreation areas
4. +/- 15% change in local average income levels, corrected for inflation.
5. Significant changes in local community lifestyle, attitudes, beliefs, or values (This does not include subtle or temporary shifts in trends)
6. +/- 20% change in annual payments to counties.

SUGGESTED SAMPLING METHODS

1. State of Oregon Labor Statistics.
2. Annual Bid Monitoring Report.
3. RIM data.
4. U.S. census, State publications, County and local agency reports, etc.
5. Interview with and observation of key public and community opinion leaders
6. Payment to counties report.

EXPECTED PRECISION AND RELIABILITY

High.

RESPONSIBILITY

Planning Staff, Timber Staff, and Recreation Staff.

ANNUAL MONITORING COST

$700.

Resource Element - ET121(i) Economics (Cash Flow)

ISSUE

The management of the Forest realizes positive cash flows in the timber program as predicted by the Forest Plan.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The management of the Forest results in conditions as predicted by the FEIS

MANAGEMENT AREA

Management Areas 11 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	1	=	2
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTION

Are the predicted net values for the timber program accurate or do the actual values for the Forest require a change?

MONITORING PURPOSE

1. Compliance with management direction.
2. Achievement of output (goods and services) objectives.

THRESHOLD OF CONCERN/VARIABILITY

A negative annual cash flow for the timber program.

SUGGESTED SAMPLING METHODS

Annual TSPIRS report.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are both rated as high.

RESPONSIBILITY

Timber Staff.

ANNUAL MONITORING COST

$50.

Resource Element - FA121 Suspended Particulate

ISSUE

Total suspended particulate (TSP) production from prescribed burning

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

TSP production from planned ignitions should not exceed 7,300 tons on an annual Forest-wide basis

MANAGEMENT AREA

Management Areas 1 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)
1	X	1	=	1

MONITORING QUESTIONS

Does TSP produced from planned ignitions exceed 7,300 tons Forest-wide annually?

THRESHOLD OF CONCERN/VARIABILITY

TSP in excess of the 7,300 ton baseline on an annual Forest-wide basis.

SUGGESTED SAMPLING METHODS

Emissions from 100 percent of planned ignitions will be tracked utilizing data developed for the Oregon State Smoke Management Plan and emissions models being developed by the Pacific Northwest Forest and Range Experiment Station

EXPECTED PRECISION AND RELIABILITY

Anticipate high precision and reliability.

RESPONSIBILITY

Fire Staff Officer.

ANNUAL MONITORING COST

$650.

Resource Element - FW121(a) Water Resources

ISSUE

Best Management Practices (BMP's) and S&G's implementation and effectiveness.

Maintenance of the beneficial uses (fisheries, domestic water supplies, white-water rafting, etc) of water.

Compliance with State requirements in accordance with the Clean Water Act (CWA) for protection of the waters of the State of Oregon and California, including the State of Oregon's anti-degradation policy for high quality waters and Wild and Scenic Rivers

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

1. Maintain or enhance water quality in all forest streams to maintain the beneficial uses of water
2. Maintain stream channel stability and favorable conditions of stream flow.
3. Comply with State requirements in accordance with the CWA for protection of the waters of the Rogue and South Coastal Basins in the State of Oregon, and the North Coast Basin in the State of California.
4. The desired future condition/outputs are water quality and channel condition sufficient to support at least the current levels of beneficial uses

MANAGEMENT AREA

Management Areas 2, 7, 10, 11, 12, 13, and 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Are water resource-related BMP's being implemented?
2. Are water resource-related S&G's and BMP's effective for:
   a. Maintaining or enhancing water quality and the beneficial uses of water?
   b. Allowing compliance with State water quality requirements, such as Oregon's Anti-degradation policy for high quality waters and National Wild and Scenic Rivers.

MONITORING PURPOSE

1 Maintenance of environmental quality (effects) as projected.
2 Resource mitigation measures are employed.

THRESHOLD OF CONCERN/VARIABILITY

1. Monitoring question 1: BMP's are not being implemented.
2. Monitoring question 2a. Water quality and channel condition is insufficient to maintain existing beneficial uses of water.
3. Monitoring question 2b: S&G's and BMP's are not maintaining water of sufficient quality to comply with the requirements set forth in the State of Oregon and California water quality regulations

SUGGESTED SAMPLING METHODS

Monitoring question 1 (BMP Implementation): The field implementation of site-specific BMP's will be monitored to some extent for each project, by either watershed specialists, fish biologists, timber sale administrators, road construction engineering representatives, foresters, or others This information will be documented in a check list and/or narrative format and stored in the project records.

Management and activity reviews will be used to assess the implementation of BMP's on a forest-wide basis. A yearly summary for the Forest will be compiled by SO watershed personnel The summary will be made available to the public/agencies for information and review.

Monitoring question 2 (BMP Effectiveness):

The effectiveness of BMP's will be monitored by using: visual observations/measurements, water quality monitoring, and beneficial uses monitoring.

1. Visual Observations and Measurements.
   a. Surveillance Monitoring - Visual: Periodic visual observations of constructed roads, harvest units, etc. will be used as the initial method of measuring the effectiveness of site-specific BMP's Visual observations during storm periods will be used to decide where to take grab turbidity samples
   b. Stream Shading: Before and after-harvest stream shading measurements will be made in from 10 to 20 percent of the Class I, II, and III streams in from 2 to 4 timber sales per District. The information will be used to verify whether the stream shading goal in the site-specific riparian BMP's was met.
      (1) Channel Condition. See monitoring items CF121 Fish Habitat Monitoring and FW 121(c) Cumulative Watershed Effects.
      (2) Soil Surface Cover: See monitoring item FW121(b) Soil Productivity.
2. Water Quality Sampling.
   a. Surveillance Monitoring - Turbidity· Discrete grab samples will be taken at selected project sites on each District. From 3 to 8 sites will be sampled for each district in any one year Potential sites will be identified during Surveillance Monitoring - Visual, as described above. Sampling will generally be taken "above" and "below" the selected activity. However, grab turbidity samples may, in some cases, be taken by "pulse," when samples are taken at two or more pre-determined sites at the same time. Sampling will be designed to measure and document:
      (1) The turbidity of water from harvest units, newly constructed roads, existing roads, and other areas of soil disturbance.
      (2) The turbidity of water leaving selected watersheds with active timber sales.
      (3) Time/turbidity recovery trends for timber harvest, road construction, and other management activities.
   b. Automated Turbidity Sampling:
      (1) Wild and Scenic Rivers and Tributaries. Automated turbidity samplers will be installed in up to two locations, or up to six total locations, on the Illinois River, Elk River, and Chetco River or at the mouths of selected, managed tributaries flowing into the Wild and Scenic Rivers
      (2) Other Forest Streams and Rivers: Automated turbidity samplers will be installed at up to three additional locations per district, or up to 23 additional locations on the Forest (includes 8 samplers for the duration of Silver Fire Recovery, Galice/Gold Beach). The samplers will be used to measure base-line turbidity, stream turbidity below timber harvest and road construction, and turbidity "above" and "below" timber harvest and road construction A primary factor in selecting sites for automated turbidity sampling will be the safety and feasibility of collecting samples and servicing the equipment.
   c *Water Temperature:*
      (1) Extensive - Maximum/minimum thermometers will be placed at from 4 to 10 selected stream locations per district, where automated temperature data-loggers are not installed

(2) Intensive - Automated temperature data-loggers would be installed at from 3 to 5 sites per district, or from 15 to 35 sites for the Forest (includes 10 sites for the Silver Fire Recovery Project, Galice/Gold Beach). The streams will be chosen based on their value as fish habitat. Some sites will be located on Wild and Scenic Rivers

3. Beneficial Uses Monitoring Fish habitat and population monitoring is discussed under CF121 Fish Habitat Monitoring

EXPECTED PRECISION AND RELIABILITY

By using a combination of (a) visual observations and measurements, (b) instream water sampling, and (c) instream beneficial uses sampling, we expect the precision and reliability to be good. We expect that the monitoring information to be adequate to document and verify implementation and effectiveness of the BMP's, as well as providing a basis for modifying practices if necessary

RESPONSIBILITY

Forest/District Hydrologists and District Rangers

Resource Element - FW121(b) Soil Productivity

ISSUE

Maintenance of productivity at levels capable of supporting the Forest resources. This issue centers on the ability to maintain chemical, biological, and physical soil properties at levels capable of supporting a wide variety of forest resources.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Forest productivity in the future decades equivalent to present (1988) conditions.

MANAGEMENT AREA

Acreage selected as suitable for timber production in Riparian, Partial Retention Visual, and General Forest Management areas.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	2	=	4
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Are soil and site organic matter and nutrient levels being maintained following timber harvest and site preparation?
2. Are soil physical properties being maintained following timber harvest and site preparation?
3. Is growth of trees being maintained at satisfactory rates?

MONITORING PURPOSE

1. Achievement of output (goods and services) objectives.
2. Maintenance of environmental quality (effects) as projected.
3. Resource mitigation measures are employed.

THRESHOLD OF CONCERN/VARIABILITY

1. When organic residues and biological and chemical properties are detrimentally altered by timber harvest and site preparation, resulting in reduced soil productivity.
2. When mineral soil exposure is greater than 40 percent for low to moderate erosion soils, 30 percent for high erosion hazard soils, and 15 percent for very high erosion hazard soils.
   a. When compaction, displacement, puddling, or severely burned conditions exceed 15 percent of the activity area, including roads.
3. When tree growth is less than acceptable levels:
   a. Short-term productivity monitoring will be correlated with standards developed through analysis of tree growth measured by reforestation surveys.
   B. Long-term productivity monitoring will be compared to appropriate growth curves for that site at fifth and tenth year, and at 10-year intervals through at least one rotation.

SUGGESTED SAMPLING METHODS

Current productivity research on the Forest by scientists of the Pacific Northwest Forest and Range Experiment Station and Oregon State University will be continued. Methods for monitoring the effects of organic residues on soil biological and chemical properties will be developed by the same scientists along

with Forest personnel. Seedling and tree growth will be measured at one, three, five, and ten year intervals with formal surveys monitoring plots for crop and non-crop species.

EXPECTED PRECISION AND RELIABILITY

Monitoring the physical and chemical properties has good precision and accuracy and would be quite reliable. Determining the implications of changed soil/site properties on seedling and tree growth has less precision and accuracy and as a result would be reliable in the long-term, but less reliable in the short-term

RESPONSIBILITY

Soil scientists, silviculturists, ecologists, and geologists at the District and Forest level are responsible for developing monitoring strategy and plans, making collecting field data, and writing reports. The Forest Watershed and Timber Staff are responsible for review and recommendations.

ANNUAL MONITORING COST

1. $25,000 annually for first two years to establish monitoring sites and make initial measurements
2. $10,000 annually thereafter to collect, analyze, and report results.

Resource Element - FW121(c) Water Resources

ISSUE

Cumulative Watershed Effects

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

1. Provide favorable conditions of stream flow in Forest streams and rivers, by maintaining channel stability, channel capacity, and watershed condition.
2. Maintain or enhance current levels of the beneficial uses of water.
3 Minimize the potential for off-Forest downstream cumulative effects by implementing/monitoring BMP's on a Forest-wide basis
4. The desired Future Condition/Outputs of streams, rivers, watersheds, and levels of beneficial uses are at or above the condition described in the Soil, Water, and Fish sections of Chapter III of the FEIS.

MANAGEMENT AREA

Management Areas 2, 7, 10, 11, 12, 13, and 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Are the timber harvest basin constraints for scheduling timber harvest in the Planning Basins and Watershed Analysis Areas (WAA's):
   a. Being applied according to the S&G's? (WAA's only)
   b. Adequate for minimizing the potential for adverse cumulative effects* (on/off Forest) on: (1) Stream channels and (2) water quality and the beneficial uses of the water? (Some examples of adverse cumulative effects are: channel aggradation, loss of riparian vegetation and stream bank stability, and reduction in fish habitat)
2. Are the effects within the range predicted in the FEIS?

THRESHOLD OF CONCERN/VARIABILITY

Monitoring question 1:

1 After the first five years of implementation, actual harvest acres in any basin are greater than 70 percent or less than 30 percent of the projected basin harvest acreage constraint per decade (see below).

Basin Number and Name	Basin Harvest Constraint/Decade (Percent)
01 Elk and Sixes	12
02 South Fork Coquille River	12
03 Lobster Creek	12
04 Upper Rogue River	16
05 Lower Rogue River	15
06 Indigo Creek	11 1/
07 Silver Creek	7 1/
08 Galice and Slate Creeks	14
09 Lower Illinois River	14
10 Upper Illinois River	17
11 Briggs Creek	16
12 Pistol River	12
13 Lower Chetco River	9
14 Upper Chetco River	-
15 Rough and Ready and Josephine Creeks	17
16 Winchuck River	15
17 North Fork Smith River	17
19 East and West Fork Illinois Rivers	12
20 Sucker Creek	17

1/ Reflects first decade reduction for Silver Fire

2. Any quantifiable (management-related) loss of favorable conditions of stream flow (see above examples of cumulative effects) on Forest streams and rivers; cumulative effects outside the range predicted in the FEIS.
3. Loss of downstream, off-Forest favorable conditions of stream flow that can be attributed to Forest resource management activities, cumulative effects outside the range predicted in the FEIS
4. Measurable increase in the frequency of management-related landslides (see monitoring element FW121(d)).
5. Decline in on/off forest levels of beneficial uses when the loss can be attributed to Forest resource management activities.

SUGGESTED SAMPLING METHODS

Monitoring question 1:

1 Harvest Scheduling

Planning Basins. Harvest records will be used to verify that timber harvest within planning basins is within the levels specified in the Forest-wide S&G's

Watershed Analysis Areas (WAA's) When more than 20 percent of a WAA is proposed to be harvested in a decade, a more detailed cumulative effects analysis is required. From 20 to 50 percent of these reports will be reviewed to ensure that the intent of the S&G's are met

2. Harvest Scheduling Effectiveness:

   On-Forest: Photo-points - Develop a network of photo-points (up to 20 per basin) for critical streams in selected Planning Basins. The photo-points will be re-photographed every other year, or in the summer following a flood event with at least a 10-year return period The long-term, photo-point record will complement information on pool habitat, bank stability, and macroinvertebrate studies from fish habitat stream surveys (CF121 Fish Habitat).

   Pool Volume Change - Pool volume trends will be monitorined as part of the Hankin and Reeves fish habitat capability surveys (CF121 Fish Habitat)

   On-Forest/Off-Forest· Aerial photo analysis stream condition - An aerial photo survey will be used to evaluate the downstream effects of Forest practices on stream channels, this will supplement other field monitoring. Selected stream reaches will be re-evaluated every 4 years when new aerial photos are available

   Landslide inventory: See monitoring item FW121(d) Soil Inventory, slope stability and cumulative effects.

   Beneficial Uses/Water Quality: See monitoring items:
   CF121 Fish Habitat Monitoring
   FW121 Watershed Resource Monitoring

Monitoring question 2:

Cumulative Effects Within the Range Predicted in FEIS

Review/Analysis of monitoring data: Forest and district resource specialists (fish, water, soil, and geology) will annually evaluate and summarize cumulative effects monitoring data and determine whether effects are within the range predicted Activities will be modified if necessary to meet S&G's.

EXPECTED PRECISION AND RELIABILITY

The precision and reliability of the monitoring data is expected to be good and useful for determining whether the harvest basin dispersion constraints are adequate for preventing cumulative effects

RESPONSIBILITY

Forest Hydrologist/Geologist/Fish Biologist, District Specialists, and District Rangers.

ANNUAL MONITORING COST

Monitoring Area	Project-Related Percent	Project-Related Dollars	Plan-Related Percent	Plan-Related Dollars
Harvest Scheduling	-	-	100	1,500
Harvest Scheduling Effectiveness	-	-	-	-
Photo-points	-	-	100	500 1/
Pool Volume Trends (See CF121 Fish Habitat)				
Aerial Photo Analysis	-	-	100	2,000
Stream Condition				
Landslide Inventory (See FW121(d) Soil Inventory - Slope Stability)				
Beneficial Uses and Water Quality (See CF121 Fish Habitat Monitoring and FW121 Watershed Resource Monitoring)				
Review/Analysis of Monitoring Data	-	-	100	1,000
TOTAL	-	-	100	3,500 2/
	-	-	100	500 to 3,500 3/

1/ Most of the work and cost will be covered by FW121 Fish Habitat Monitoring
2/ First year initial cost
3/ Recurring cost

Resource Element - FW121(d) Water Resources

ISSUE

Slope Stability and Cumulative Watershed Effects.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The Forest Goal is to obtain a current inventory of landslide frequency under natural, roaded, and harvested conditions to be used for:

1. Landslide hazard and risk zonation.
2 Selecting coefficients for sediment-yield predictive models
3. Selecting coefficients for models predicting loss of soil productivity due to landslides
4 The desired future condition is no significant difference in the rate of landsliding under both managed and unmanaged (natural) conditions.

MANAGEMENT AREA

Management Areas 11 to 14

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

2	X	3	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. What are the sizes and frequencies of landslides that have occurred on different soil and rock types under natural versus managed conditions from 1976 to 1986?
2 What volume of sediment has been delivered to streams from 1976 to 1986?
3. How many acres and what percentage of land has experienced a loss of soil productivity due to landslides resulting from roading or timber harvest over the last ten years (1976 to 1986)?
4. What will be the future size and frequency of landslides occurring on managed lands in comparison to that under natural conditions?
5 What is the rate of management versus natural landsliding on other ownerships (Federal, State, County, and Private) within planning basins with substantial managed Forest acreage?

MONITORING PURPOSE

Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

1. When the observed landslide frequency exceeds the frequency predicted in project cumulative watershed effects analyses
2 When landslide frequencies begin to correlate positively with the cumulative area roaded and harvested and.
   a. Create the potential for degrading the beneficial uses of water.
   b. Threaten to result in an irretrievable loss in soil productivity.
3. When the rate of management-related landsliding on non-Forest Service managed lands threatens channel stability/beneficial uses, and reduces management options for Forest lands.

SUGGESTED SAMPLING METHODS

Monitoring questions 1-5: Landslide Inventory - Aerial Photo: Landslide inventories will be completed for planning basins once every four years by inventorying about one-quarter of the basins each year The initial landslide inventory will include an interpretation of the 1973 Infra-red, 1979, and 1986 aerial photography Special aerial photo coverage will be flown for selected basins following storms with a return frequency of at least 25 years. The inventory data will be stored in TRI/GIS Future updates will use the most recent aerial photography.

Where aerial photo coverage of non-National Forest lands exists, extensive aerial photo survey of natural versus activity-related landslides will be made every four years. The aerial photo interpretation will only be done if critical downstream beneficial use exist. Inventory data will be used in cumulative effects analyses.

Monitoring questions 1-4: Landslide Inventory - Field Verification: A minimum of ten percent of the landslides identified on the aerial photographs will be field checked to verify size and cause information obtained from aerial photo interpretation.

Landslides discovered during field surveys of timber sales will be added to the database

EXPECTED PRECISION AND RELIABILITY

Moderate precision due to inability to detect small landslides on aerial photos. High reliability due to training of aerial photo interpreters on Forest.

RESPONSIBILITY

Forest Resource Geologist in conjunction with other Geologists and Soil Scientists

ANNUAL MONITORING COST

Aerial Photo Inventory

$ 9,500	Initial Inventory: First four years of initial inventory and database entry. 2 weeks per photo date per planning basin = 16 weeks = 4 months
4,000	Subsequent years: Subsequent years of update inventory. 2 weeks per planning basin = 8 weeks = 2 months.
4,000	Ground Checking
$17,500	TOTAL

REMARKS

Initial inventory is completed and entered into TRI/GIS for Elk-Sixes. Inventory partially complete for Silver Planning Basin (need slide area and volume measurements and database) Other initial inventories will be completed during normal project planning (e.g., Upper Rogue covered by Illahe and Shasta Costa projects).

Additional efficiency could be gained by using the analytical stereoplotter to locate and measure landslides and store database attributes. Need for Forest Planning Basins to have bridging for control files work completed in order to take advantage of this potential efficiency

Resource Element - FW121(e) Acres Burned

ISSUE

Acres burned by wildfire.

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

The expected acres burned by fire size class per decade should not exceed the fire frequency and size distribution for the Forest as presented in the Fire Management Action Plan

MANAGEMENT AREA

Management Areas 1 through 14.

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

$$\frac{1}{\text{(Cost of Error)}} \times \frac{1}{\text{(Likelihood of Error)}} = \frac{1}{\text{(Risk Index)}}$$

MONITORING QUESTIONS

Do acres burned by fire size class per decade exceed the frequency and size distribution as presented in the Fire Management Action Plan?

THRESHOLD OF CONCERN/VARIABILITY

1. When the actual acres burned per decade exceeds the expected acres burned per decade
2. When the actual acres burned in any single year is more than 50 percent of the expected acres burned per decade.

SUGGESTED SAMPLING METHODS

The data necessary to complete the analysis will be extracted from the Individual Fire Report (FS-5100-29), which is completed for each wildfire occurrence. These reports will be compiled into a Forest-wide summary.

EXPECTED PRECISION AND RELIABILITY

Anticipate high precision and reliability

RESPONSIBILITY

Forest Fire Staff Officer.

ANNUAL MONITORING COST

$650.

Resource Element - GM121 Minerals

ISSUE

Mineral resources will be developed in coordination with other resource management concerns

FOREST GOAL, DESIRED FUTURE CONDITION, AND OUTPUTS

Facilitate mineral exploration and development while protecting surface resources and environmental quality Maintain at least 89 percent of Forest lands, excluding legislative withdrawals, for location and leasing

MANAGEMENT AREA

Management Areas 1 through 14, except locations specifically withdrawn from mineral entry

RISK ASSESSMENT (Low = 1, Medium = 2, High = 3)

3	X	2	=	6
(Cost of Error)	X	(Likelihood of Error)	=	(Risk Index)

MONITORING QUESTIONS

1. Are the S&G's for mineral operations reasonable and effective?
2. Are the rehabilitation S&G's reasonable and effective?

MONITORING PURPOSE

1. Achievement of outputs (goods and services) objectives.
2. Maintenance of environmental quality (effects) as projected.

THRESHOLD OF CONCERN/VARIABILITY

Field review reveals surface resources and environmental quality declines in excess of the thresholds of concern described for (FW121(a) and CF121) Fish Habitat and Water Quality, AW121 Wilderness, CW121(a) through (f) Wildlife, and CT121(a) and (b)/(FW121(b) and (c) Soil/Water. Rehabilitation activities are not being performed, or are below the standards described in approved operating plans.

SUGGESTED SAMPLING METHODS

Field review and evaluation of 100 percent of current operating mineral projects annually.

EXPECTED PRECISION AND RELIABILITY

Precision and reliability are both considered high.

RESPONSIBILITY

District Ranger, Lands and Recreation Staff

ANNUAL MONITORING COST

$10 00/operating plan X approximately 276 operating plans = $2,700.

APPENDIX E

OFF-ROAD VEHICLE MANAGEMENT PLAN

SUMMARY

The majority of the Siskiyou National Forest is available for off-road vehicle (ORV) use. The total area open to ORV use is approximately 828,800 acres, which includes some areas that are subject to temporary or seasonal closures. However, the actual area used is by ORV's is far less. The nature of the terrain, vegetative cover, and resource management requirements place restraints on the amount of area that is actually suitable.

Area	Acres	
Permanent Yearlong Area Closures Affecting Off-Road Vehicle Use		
Kalmiopsis Wilderness	179,850	
Wild Rogue Wilderness	26,708	1/
Grassy Knob Wilderness	17,200	
Red Buttes Wilderness	3,414	2/
Siskiyou Wilderness	5,323	2/
Other Areas	30,985	
TOTAL	263,480	

1/ BLM addition - 9,392 acres
2/ Siskiyou portion

The other permanent yearlong closure areas include Research Natural Areas, Botanical Areas, and sensitive sites such as meadows

There are approximately 450 miles of trail on the Forest Approximately 44 percent of the total trail system will be affected by some type of restriction All Wilderness trail systems are closed to motorized use and bicycles. All or a portion of seven trails which traverse about 31 miles outside Wilderness are permanently closed to motorized use based on concerns for public safety, resource protection needs, and law.

Estimated Trail Miles Closed or Restricted to ORV use follows·

Trail	Miles	
Kalmiopsis Wilderness	153	
Grassy Knob Wilderness	0	
Wild Rogue Wilderness	6	
Red Buttes Wilderness	8	
Siskiyou Wilderness	8	
Illinois River	26	1/
Rogue River	15	1/ 2/
Mt Elijah	1	
TOTAL	217	

1/ Some of this mileage is within the Wilderness
2/ Closed to horses and ORV use

INTRODUCTION

The purpose of an ORV plan is to provide Forest Service managers with the framework to coordinate ORV use with other resource management objectives. A second purpose is to insure, over time, the continued availability of ORV recreation opportunities on the Forest. A third purpose is to provide public users of the Siskiyou National Forest with trip planning information.

Executive Order 11644, as amended May 25, 1977, requires Federal land management agencies to adopt regulations to ensure that ORV use is controlled and directed to protect resources, promote safety of all users, and minimize conflicts among the various users of public land Land and resource management planning direction requires that each National Forest establish locations where ORV use will be allowed, restricted to some degree, or prohibited. The Code of Federal Regulations (CFR) provides the authority and process to restrict motorized use on Federal land In addition, the Kalmiopsis, Wild Rogue, Grassy Knob, Siskiyou, and Red Buttes Wildernesses have been closed to motorized use by National legislation

The review and analysis has been completed for the Siskiyou National Forest This document is the result of the combined input from interested members of the public and Forest Service administrators This Plan satisfies the requirements of 36 CFR 295 1. This Plan will be dynamic to meet changes in ORV use patterns and resource management situations

Prior to Executive Order 11644, problems and conflicts relating to ORV use were resolved as they occurred During the public involvement initiated as a result of the Executive Order, few new conflicts were identified and little dissatisfaction was expressed about the ORV regulations in effect on the Forest

Concerns identified during the public involvement process involved safety to hikers and horsemen, the noise level of motorized use, and providing opportunities for two, three, and four-wheel recreation vehicles Resource concerns identified on the Forest include water quality, soil stability, vegetative cover, deer and elk winter range, elk calving areas, and fragile environments.

Additional use opportunities will be provided by the estimated 45 miles of trail to be constructed in the next 10 years which may be suitable for ORV use. Construction activities related to resource management may make available trailhead and parking areas for ORV use Snow related ORV uses could be developed in suitable high mountain areas of the Illinois Valley Ranger District.

For much of the Forest, the heavily dissected ridge systems, which feature terrain steepness and dense vegetative cover, nearly precludes use by ORV's except on roads and trails. Use during the winter season by over-the-snow vehicles is also minor due to warm intense winter storms which result in poor snow conditions. However, the large blocks of serpentine-peridotite located on the south end of the Forest are far more conducive to ORV use This landtype is relatively gentle, with slopes being less steep and more rounded, the vegetation more "open," and the land surface more resistant to traffic impacts Much of the present ORV use occurs in these areas.

ORV OPPORTUNITIES

ORV use is a part of the overall travel management planning for the Forest In some places this use coexists with other road and trail uses The present trail system available for ORV use totals 171 miles This represents 74 percent of the current trail system on the Forest outside of Wilderness areas Within the next 10 years, there may be about 216 miles available for some form of ORV use. In addition, considerable area of the Forest has been allocated to Backcountry Recreation management (see Standards and Guidelines for Management Area 6 - Backcountry Recreation, in Chapter IV of the Land and Resource Management Plan). Some of these areas are specifically designed to accommodate motorized recreational uses Trail

systems planned in these motorized areas will be designed to include ORV's, including jeep type vehicles Interagency management plans, like the Rogue River Wild and Scenic River Plan, may affect the restrictions on certain areas. The Forest may accommodate over-the-snow vehicle use at certain times of the year in suitable locations

In addressing the problems relating to ORV use, this plan was prepared with the following criteria

1. There would be as few restrictions as possible based on present use and problems As new problems are identified, they will be resolved by revising this plan
2. Closures and restrictions should be clearly defined for the benefit of users and administrators
3. The needs of the Forest user will be met whenever possible.

CLOSURES AND RESTRICTIONS

In order to formulate management direction within the established criteria and mitigate the problem, ORV limitations can be identified in two ways: (1) on an area basis, and (2) by a specific road or trail These limitations also relate to season of use. In area closures, the roads and trails are open to ORV's unless they are posted and specifically closed.

There are permanent yearlong ORV closures for Wilderness, Research Natural Areas, Botanical Areas, and similar land allocations that carry a specific theme. Closures occur on trails within Wilderness and some trails serving as access to sensitive areas, and for roads on which long-term use is not desirable for some reason Long-term seasonal ORV restrictions apply primarily to trails and roads, and in some cases to campgrounds. There are instances where short-term temporary (up to several years duration) closures or restrictions will be applied to areas, trails, and roads found on the Forest Although they may be applied for a variety of resource protection and public safety reasons, they will have an effect on ORV use. Restrictions on ORV use may be applied in areas to resolve or eliminate conflicts with other user groups and resource management activities. Organized activities such as hill climbs, moto-cross, or timed speed events will not be permitted; these are not considered as part of the ORV recreation role of National Forest lands.

AREA CLOSURES

Closures involve a variety of considerations, including wildlife winter range, elk calving areas, fragile soils and meadows. Each of these considerations include elements of incompatibility with various kinds of ORV use. Ground cover, soil type, water table, wildlife habitat requirements, human needs and established patterns of use have all been considered in defining the boundaries for the area closures.

MOTORIZED TRAIL CLOSURE

Closures may be initiated based on management objectives on those trails where motorized use has caused a public safety hazard, contributed to serious soil erosion problems, is not compatible with designed standards, or has introduced use into a trail system closed by National legislation. A trail leading to an area (such as Oregon Caves National Monument) where ORV's are prohibited may be closed A trail designed by objective to accommodate horses may be closed to ORV use if such use present substantial hazards to horse travelers

Trails may be closed seasonally due to conflicts in patterns of use. For example, the Illinois River Trail where motorcycle and hiker conflicts occur during summer months, little conflict arises during the fall and winter period. Motorcycles have used this trail system during the "off-season" period for fishing and hunting access, with little hiker conflicts The trail may be closed to motorized use in the summer season only

ROADS

Roads may be closed in support of area closures, as well as to protect the road and adjacent areas from erosion damage. Some roads which appear to be closed may be available for use by ORV's less than 40 inches in width, if posted for such use.

FIRE AND PUBLIC SAFETY

Short-term closures may be applied to ORV use during high fire danger which limits vehicle use to only Forest development roads. Under extreme situations, all roads may be closed to all uses. Other short-term closures for public safety purposes may effect use of ORV's.

MANAGEMENT REQUIREMENTS

ENFORCEMENT

Closure orders will be issued by the Forest Supervisor Orders issued by the Forest Supervisor affecting ORV usage will become part of this plan Orders rescinded by the Forest Supervisor will be removed from this plan Currently there are numerous closure orders specific to certain roads Many of these closure orders may be replaced by a Forest-wide closure order in the future. Closures and restrictions will be enforced by the District Rangers on the Siskiyou National Forest

SAFETY

The Forest Service assumes the public to be responsible for prudent use and safe operation of ORV's on all National Forest System roads or trails open for motorized uses. Information specific to any trail or road system is available upon request

PUBLIC INVOLVEMENT

Plan updates may be scheduled periodically to incorporate ongoing public comment regarding the need to meet changing conditions Where conflicts arise involving ORV use and other resources, the public will be encouraged to participate in the resolution of differences.

PUBLIC NOTICE

All closures and restrictions will be posted on signs in a manner that will reasonably inform the public of the intended action. In addition, each Ranger District Office and the Supervisor's Office will post a copy of the regulations and a map showing the designated areas on the Forest

IMPLEMENTATION AND EVALUATION

Each Forest Service office on the Siskiyou National Forest will display a map identifying area, trail and road closures, and restrictions. The Forest Off-Road Vehicle Use Map is in the process of production and will be made available to the public Maps are available for review at the Forest Supervisor's and District Office

ORV use will be monitored. The ORV Plan will be reviewed annually and revised as new problems are identified.

SPECIFIC CLOSURES AND RESTRICTIONS

The following codes summarize ORV related Forest Closure Orders which are shown on Tables E-1 through E-4. Also included are some of the exceptions allowed.

CODES AND DESCRIPTIONS

Code	Description
1a	Permanent Yearlong Closure, any motor driven vehicle prohibited
1b	Permanent Yearlong Closure, any motor driven vehicle prohibited **on** meadow areas
1c	Permanent Yearlong Closure, any motor driven vehicle prohibited, **except** over-the-snow machines.
1d	Permanent Yearlong Closure, any motor driven vehicle prohibited **off** Forest Development Road(s) and or trail(s)
1e	Permanent Yearlong Closure, any motor driven vehicle prohibited **on** Forest Development Road(s) and or trail(s)
2a	Temporary Yearlong Closure, any motor driven vehicle prohibited.
2b	Temporary Yearlong Closure, any motor driven vehicle prohibited **on** meadow areas
2c	Temporary Yearlong Closure, any motor driven vehicle prohibited, **except** over-the-snow machines.
2d	Temporary Yearlong Closure, any motor driven vehicle prohibited **off** Forest Development Road(s) and or trail(s)
2e	Temporary Yearlong Closure, any motor driven vehicle prohibited **on** Forest Development Road(s) and or trail(s).
3a	Temporary Yearlong Closure, being **upon** area prohibited.
3b	Temporary Yearlong Closure, being **on** trail prohibited
3c	Temporary Yearlong Closure, being **on** road prohibited.
4	Seasonal Closure to motorized use from May 15 through September 15
5a	Seasonal Closure (restriction) when signed for closure.
5b	Seasonal Closure (restriction) when gate closed/locked.
6a	Trail also closed to bicycle use.
6b	Trail also closed to bicycle, and saddle, pack, and draft animal use.
7a	Lake closed to motor boat use.
7b	River bar speed restriction for any motor driven vehicle (5 mph or less)
8	Trailer prohibited **off** Forest Development Road(s)

Table E-1. Area Closures Managed under 36 CFR 261.16 - Legislative

Wilderness	Area Affected	Closure Acreage	Code
Grassy Knob	Entire	17,200	1a, 7a
Kalmiopsis	Entire	179,850	1a, 7a
Red Buttes (Siskiyou NF portion)	Entire	3,414	1a, 7a

APPENDIX F

BEST MANAGEMENT PRACTICES

INTRODUCTION

DEFINITIONS

Nonpoint Sources refer to diffuse or unconfined sources of pollution where wastes can either enter into, or be conveyed by the movement of water to, public waters (Oregon Water Quality Standards, OAR 340-41-007(17)). Silvicultural sources, such as erosion from a harvest unit or surface erosion from a road are considered nonpoint sources.

Best Management Practices are defined as "methods, measures or practices selected by an agency to meet its nonpoint source control needs BMP's include, but are not limited to, structural and nonstructural controls, operations, and maintenance procedures. BMP's can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters (EPA Water Quality Standards Regulation, 40 CFR 130 2)."

Usually BMP's are applied as a system of practices rather than a single practice BMP's are selected on the basis of site-specific conditions that reflect natural background conditions and political, social, economic, and technical feasibility (EPA 1985)

BMP's are basically a preventative rather than an enforcement system BMP's are a whole management and planning system in relation to sound water quality goals, including both broad policy and site-specific prescriptions.

SUMMARY

Best Management Practices are the primary mechanism to enable the achievement of water quality standards (EPA 1987) BMP's will be selected and tailored for site-specific conditions to arrive at the project level BMP's for the protection of water quality The process for determining appropriate BMP's and for ensuring their implementation at both the Forest Plan and project level is described

Following is a description of the methods and procedures that will be used to control or prevent nonpoint sources of pollution from resource management activities, and to ensure compliance with the.

Clean Water Act of 1972, as Amended (1977 and 1987). Section 319 of the Clean Water Act Amendments of 1987 requires that the States determine those waters that will not meet the goals of the Act, to determine those nonpoint source activities that are contributing pollution, and to develop a process of determining BMP's to reduce such pollution to the "maximum extent practicable." This Appendix is designed to fulfill the intent of the requirements of Section 319

Oregon Administrative Rules (OAR 340-41-001-975). Department of Environmental Quality (DEQ) Oregon's Administrative Rules contain water requirements for the protection of identified beneficial uses of water.

Memorandum of Understanding. The Oregon Department of Environmental Quality and USDA, Forest Service (February 12, 1979, and December 7, 1982), and "Attachments A and B" referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest 12/78 and Best Management Practices for Range and Grazing Activities on Federal lands, respectively).

California Porter-Cologne Water Quality Control Act (California Water Code, Division 7) The Water Quality Control Plan for the North Coast Region was approved by the North Coast Regional

Water Quality Control Board on April 28, 1988 It is pending approval by the State Water Resources Control Board and the U S. Environmental Protection Agency

The Draft North Coast Regional Water Quality Control Plan contains water quality objectives that are considered necessary to protect those present and probable future beneficial uses of water

Memorandum of Understanding The State Water Resources Control Board, State of California, and USDA, Forest Service, Pacific Southwest Region, 1981

The EPA has certified the Oregon Forest Practices Act as BMP's The State of Oregon compared Forest Service practices with these State practices and concluded that Forest Service practices meet or exceed State requirements As State practices change, comparisons are made to ascertain that Forest Service practices meet or exceed these changes Monitoring and evaluation will determine the need for changes in BMP's and/or State standards.

Forest Service management practices will meet, as a minimum, the substantive State BMP requirements, and other considerations required by the National Forest Management Act (NFMA), and other authorities, for the protection of the soil and water resource.

The general BMP's described herein are action initiating mechanisms which call for the development of detailed, site-specific BMP prescriptions to protect beneficial uses and meet water quality objectives They are developed as part of the NEPA process, with interdisciplinary involvement by a team of individuals that represent several areas of professional knowledge, learning, and/or skill appropriate for the issues and concerns identified. BMP's also include such requirements as Forest Service Manual direction, contract provisions, environmental documents, and Forest Plan Standards and Guidelines. Inherent in prescribing project-level management requirements is recognition of specific water quality objectives which BMP's are designed to achieve.

BMP IMPLEMENTATION PROCESS

In cooperation with the State, the primary strategy for the prevention and control of nonpoint sources is based on the implementation of BMP's determined necessary for the protection of the identified beneficial uses

The objective is to identify the most practical means of attaining water quality objectives Water quality objectives include water quality measures that adequately reflect the needs of identified beneficial uses

The Forest Service Nonpoint Source Management System consists of:

1. Selection and design BMP's based on site-specific conditions, technical, economic and institutional feasibility, and the water quality standards of those waters potentially impacted

2. Implementation and enforcement of BMP's

3. Monitoring to ensure that practices are correctly applied as designed.

4 Monitoring to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards.

5. Evaluation of monitoring results and mitigation where necessary to minimize impacts from activities where BMP's do not perform as expected.

6 Adjustment of BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level Evaluation of the appropriateness of water quality criteria to reasonably assure protection of beneficial uses Consideration of adjustment of water quality standards

BMP SELECTION AND DESIGN - STEP 1

SCOPING

Potential concerns and major issues are identified, e g , water quality, as part of the NEPA process for environmental analysis. Public notices are dispersed inviting comment and participation in the process Alternatives are developed to address the major issues and potential problems, and to accomplish project objectives.

ENVIRONMENTAL ANALYSIS

Each alternative is evaluated for its potential effect on different resources, including water. From this analysis, a preferred alternative is identified, along with the measures (BMP's) needed to reduce risk and increase the potential for success

DOCUMENTATION

When an Environmental Assessment (EA) or Environmental Impact Statement (EIS) is prepared to document the analysis; these documents include the management requirements and mitigation measures, including the site-specific BMP's. A Finding of No Significance (FONSI) and Decision Notice or, in the case of an EIS, a Record of Decision is issued which identifies the selected alternative, the rationale for the decision, and accompanying measures (BMP's).

On many projects, water quality is an important environmental component. The analysis and comparison of possible alternatives are disclosed in the required documents (EA or EIS); the description of the affected

environment and evaluation of potential activity effects on water quality are included. BMP's are incorporated into the design of the alternatives to avoid or minimize potential adverse water quality problems The selected alternative, as described in the decision, occasionally is accompanied by additional water quality mitigations (BMP's) to meet management goals and improve overall protection of the resources. Water quality standards are used as objectives towards which practices are designed to protect beneficial uses.

More specifically, appropriate BMP's are selected for each project by an interdisciplinary team BMP selection and design are dictated by water quality objectives, soils, topography, geology and landform, channel morphology, vegetation, climate, economics, institutional constraints, etc. Environmental effects and water quality protection options are evaluated and a range of practices considered A final set of practices are selected that not only protect beneficial uses, but meet other resource needs These final selected practices constitute the BMP's.

The selected BMP's, an estimate of their effectiveness, and a plan for monitoring them is included in the project EA or EIS. The site-specific BMP prescriptions are normally included in project implementation plans (analysis files), but may also be included in the body or appendix of a project environmental document.

BMP IMPLEMENTATION AND ENFORCEMENT - STEPS 2 AND 3

The site-specific BMP prescriptions are taken from plan-to-ground by a combination of project layout and resource specialists (hydrologists, fisheries biologists, soil scientists, foresters, geologists, etc) Final adjustments to fit the BMP prescriptions to the site conditions and needs are made before implementing the resource activity.

When the resource activity (e.g., timber harvest or road construction) begins, timber sale administrators, engineering representatives, resource specialists, and others ensure that the BMP's are implemented according to plan. A similar implementation process is used for other resource activities (range treatments, mining exploration and development, etc) on National Forest lands

BMP implementation monitoring is done before, during, and after resource activity implementation This monitoring answers the question: Did we do what we said we were going to do? Some examples of implementation monitoring for a streamside management unit BMP prescription may be·

BEFORE PROJECT

Checking Streamside Management Units (SMU's) to see if timber sale layout meets the objectives of the BMP prescription, or if the road crossing of a stream is properly located and designed relative to the estimate of potential environmental effects made during the environmental analysis Items reviewed in the sale layout often include which trees are selected in the "individual tree marking" of the SMU, and location of the SMU's upper unit boundary.

DURING PROJECT

During timber felling, the timber sale administrator checks to see if the timber fallers understand the marking prescription for timber to be felled in the SMU The timber sale administrator also observes on-going harvest operations to see if the activity meets the objectives defined in the environmental document and accompanying project plan.

AFTER PROJECT

Measuring stream shade canopy to determine if the amount specified in the BMP prescription was retained, or monitoring a beneficial use of the water to determine a change or trend in use

Enforcement is carried out primarily through internal project reviews and during contract administration, i e , assuring that timber sale contract, grazing or special use permit, etc , are adhered to and accomplished per agreement

Contract enforcement is a more formal method used to achieve desired results Normally, each project is assigned to a contracting officer For timber sales, that person is called a "timber sale administrator " The project is routinely monitored to ensure that practices are being carried out in the manner and method prescribed in the contract, permit, etc. When a contractor or permittee is not in compliance, they can be held in breech with penalties (e.g., bond forfeiture) until remedies are implemented.

Often during the course of an activity, adjustments are made if it is determined that unsatisfactory results are occurring or may occur from continued operation This often requires that the contract be modified to resolve or minimize the problem (as in the case of a timber sale). Under some conditions where resolution of a problem is not possible, contract termination could result. While this is used very sparingly, the provisions to do so are within the contract.

BMP MONITORING - STEP 4

Once BMP's have been implemented, further monitoring is done to evaluate their effectiveness BMP "effectiveness monitoring" answers the question: Are BMP's effectively meeting management objectives for protection of water quality?

Water quality standards are the "yardstick" against which the effectiveness is tested If through objective monitoring BMP's do not meet the prescribed objectives, then information is available to modify either the BMP's for future management application, or the objectives, or both

The natural variability of water quality under undisturbed conditions is an important factor that will be considered during the monitoring and evaluation. Additionally, effectiveness monitoring will include measurement against land management objectives as well as water quality objectives

Some examples of the types of BMP effectiveness monitoring to be conducted are.

1. Measuring stream temperatures to see if the riparian prescriptions in a watershed are maintaining water temperature

2. Surveillance monitoring of a road system during storms to see if road rocking is effectively preventing road surface erosion.

The monitoring and evaluation section of the Forest Plan (Chapter V and Appendix D) provides that monitoring will be done on a appropriate sample basis. Once a specific project is designed, a site-specific monitoring plan may be developed.

Results of monitoring should be shared with State and local agencies, as well as made available to the public. Monitoring design, sampling, and laboratory analyses will be coordinated

BMP EVALUATION AND ADJUSTMENT - STEPS 5 AND 6

The technical evaluation/monitoring described above will determine how effectively BMP's protect and/or improve water quality. If the evaluation indicates that water quality objectives are not being met and/or beneficial uses do not appear to be receiving adequate protection, corrective action will consider the following three components.

1. **The BMP:** Is it technically sound? Is it really best, or is there a better practice which is technically sound and feasible to implement?

2 **The implementation program or processes:** Was the BMP applied entirely as designed? Was it only partially implemented? Were personnel, equipment, funds, or training lacking which resulted in inadequate or incomplete implementation?

3. **The water quality standards:** The water quality standards are established to protect the beneficial uses of water. They include numeric and narrative criteria that, when exceeded, are assumed to indicate detrimental impacts on beneficial uses. They are intended to provide a benchmark for evaluating harm to beneficial uses

Assessing the applicability of the standards is a responsibility of the State. The Forest Service will provide information to the State to address the following types of questions·

1. Do the standards describe the conditions necessary for protecting beneficial uses?

2 Are standards higher or lower than that necessary for protecting beneficial uses?

3. Do the standards reflect the natural variability occurring within the natural and human-affected ecosystem?

4 Do the parameters and criteria that constitute water quality standards adequately reflect (are they sensitive enough) human-induced changes to water quality and beneficial uses?

To made this assessment, "validation" monitoring may be needed. The purpose of validation monitoring is to answer the question whether standards, coefficients, requirements, and guidelines are appropriate to meet objectives, e.g , to protect the established beneficial uses

Examples: (1) Did the change in water temperature impact the fish population?
(2) Did the soil compaction affect tree growth?

Validation monitoring will need to be closely coordinated with or, in some cases, conducted by research. It may require the establishment of permanent plots or administrative studies This kind of monitoring will be generally quite limited and will require good coordination to properly select projects that will have broad application and prevent duplication of efforts. Only those coefficients and standards that are not reasonably validated by existing research or documentation should be candidates for this monitoring.

Corrective action may be initiated once the reason for failing to achieve the management objectives is determined The management practice may have to be changed; the water quality objectives modified, or both

TRAINING

National Forest personnel involved with project planning and location, design, layout, administration, and maintenance activities will receive BMP training. The training will consist of BMP awareness, accompanied by the more technical aspects such as planning, implementation, monitoring and evaluation.

GENERAL BEST MANAGEMENT PRACTICES AND EXAMPLES

Individual general Best Management Practices are described in:

California

Water Quality Management For National Forest Systems Lands in California - Best Management Practices, Chapter 10, Draft Soil and Water Conservation Handbook, Pacific Southwest Region, San Francisco, March 1988

Oregon

General Water Quality Best Management Practices, Pacific Northwest Region, November 1988

Siskiyou National Forest Best Management Practices, Siskiyou National Forest Planning Records, October 1988

Included in the General Water Quality Best Management Practices document is a description of the process and limitations and use of these BMP's. This document, while providing guidance, is not considered direction.

A Forest-wide evaluation of effectiveness and ability to implement each general BMP is contained in the Siskiyou National Forest Best Management Practices document More specific evaluations at the project level are made following site-specific prescriptions The sensitivity of the project determines whether the site-specific BMP prescriptions are included in the environmental documents (EA or EIS) or in the sale project plan (or analysis files)

Evaluations of the ability to implement and estimated effectiveness are most appropriately made at the project level At the project level, the greatest level of precision in the expected effectiveness of a BMP can be made as site-specific conditions are essentially "knowns" (i e , the chance of significant variance in the estimate is greatly reduced).

For the more general BMP, the effectiveness and ability to implement can be estimated with some degree of precision. However, as the BMP is applied to larger areas or outside the physiographic areas for which it was developed, the rating of effectiveness and ability to implement is more a professional estimate that encompasses the many variables under which it would be applied. For Forest Plans, this estimate is fairly reliable as resource conditions are well defined; any substantial variation in conditions would likely be accompanied by either an additional BMP, or accounted for in the BMP prescription when applied at the project level. Criteria for rating the "ability to implement" and "effectiveness" of general BMP's is included at the end of this appendix.

Not all of the general BMP's listed will normally apply to a given project, and there may be specific BMP's which are not represented by a general BMP in this document. During the monitoring activity, reference should be made to the Forest Plan monitoring resource element (Appendix D) - "Water Resource Monitoring."

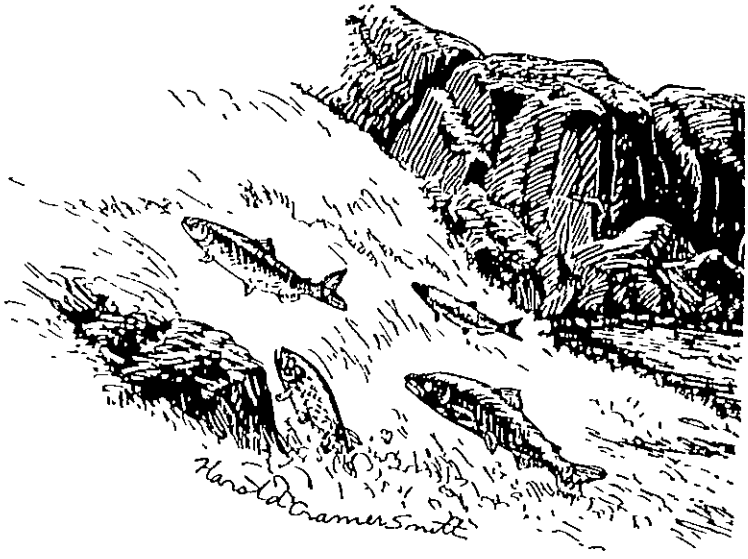
FORMAT OF BMP'S AT FOREST PLAN AND PROJECT LEVELS

Each general and site-specific Best Management Practice (BMP) consists of the Title, Objectives, Explanation, Implementation and responsibility, Ability to implement, Effectiveness, and Monitoring Each section with a brief description follows·

Title: Includes the sequential number of the practice and a brief title

Objective Describes the objectives of the Best Management Practice (BMP) and the desired results for protecting water quality

Explanation: Further defines the brief title, and describes under what conditions and how the practice is applied. Criteria or standards are described when applicable This section contains a description of the range of site-specific water quality protection measures to be implemented.



Implementation and Responsibility: Describes how the practices are expected to be applied and identifies the person(s) responsible for implementing the BMP.

Ability to Implement: Provides a qualitative estimate of the ability of the Forest Service to implement the BMP. The estimate is made at either the project level or Forest Plan level (see Siskiyou National Forest Best Management Practices for general BMP rating). Criteria for rating the "ability to implement" general BMP's is included at the end of this appendix

Effectiveness Provides a qualitative assessment of the expected effectiveness that the applied measure will have on preventing or reducing impacts on water quality and beneficial uses. The effectiveness of each BMP will be evaluated with an index that rates the effectiveness of each BMP at either the project level or Forest Plan level (see Siskiyou National Forest Best Management Practices for general BMP rating) Criteria for rating "effectiveness" of general BMP's is included at the end of this appendix.

Monitoring. Either describes how the site-specific practices for this BMP will be monitored, or lists the appropriate section of the Forest Plan Monitoring Plan (see Appendix) that would verify implementation and/or effectiveness

Following is an example of a general BMP, as described in the Siskiyou National Forest Best Management Practices, along with an example of a site-specific BMP which is developed at the project level.

GENERAL BMP EXAMPLE

T-5. Title· Limiting the Operating Period of Timber Sale Activities

Objective To ensure that the Purchaser conducts their operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC)

Explanation. The TSC specifies a Normal Operating Season, during which, operations may generally proceed without resource damage Operations are permitted outside the Normal Operating Season only when they can be conducted without damage to soil, water, and other resources. Where determined to be necessary through the environmental analysis, the TSC will limit operations to specific periods or weather conditions. Operations are not permitted to continue if damage will occur

Implementation and Responsibility: Limited operating periods are identified and recommended during the timber sale planning process by the interdisciplinary team and followed through the life of the timber sale primarily by the Sale Administrator

Ability to Implement: High

Effectiveness: High

Monitoring: During implementation of timber sale activities by the Sale Administrator, Forest Service Representative (FSR), engineers, and watershed specialists

SPECIFIC BMP EXAMPLE

T-5. Title: Limiting the Operating Period of Timber Sale Activities

Objective· To ensure that the Purchaser conducts their operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC)

Explanation: The Ship Mountain Timber Sale contains sensitive soils that are subject to soil compaction during tractor skidding, and a non-surfaced road that is not suitable for wet weather haul The normal operating season for the Forest will be enforced for the Ship Mountain Timber Sale All operations off Road FR 10 (non-surfaced) will be halted at the onset of wet weather to prevent erosion and damage to the road. Tractor skidding on Units 1-5 will be restricted if soil moisture is above the level established by the soil scientist Other operations can continue outside the normal operating season if they can be conducted without damage to soil, water, and other resources.

Implementation and Responsibility: For the Ship Mountain Timber Sale the normal operating season for the Forest will be enforced. All operations off of Road FR 10 (non-surfaced) will be halted at the onset of wet weather to prevent erosion and damage to the road. Other operations can continue outside of the normal operating season if they can be conducted without damage to soil, water, and other resources The Forest watershed specialists will work with the timber sale administrators to evaluate the potential for resource damage if operating outside of the normal operating season.

Ability to Implement: High

Effectiveness: High

Monitoring: During implementation of timber sale activities by the Sales Administrator, Forest Service Representative (FSR), engineers, and watershed specialist

CRITERIA FOR RATING "ABILITY TO IMPLEMENT" AND BMP "EFFECTIVENESS"

Forest-wide ratings of both the "ability to implement" and "effectiveness" for each general BMP are located in the Siskiyou National Forest Forest Plan planning records. These estimates are general, given the range of conditions throughout the Forest More specific estimates are made at the project level when the specific BMP's are developed.

Ability to implement: Provides a qualitative estimate of the ability of the Forest Service to implement the BMP The following index is used to rate the ability to implement as either **High, Moderate,** or **Low**:

High: Almost certain the BMP can be implemented as planned
Moderate: Greater than 75% certainty the BMP can be implemented as planned.
Low: Less than 75% certainty the BMP can be implemented as planned.

Effectiveness: Provides a qualitative assessment of the expected effectiveness that the applied measure will have on preventing or reducing impacts on water quality and beneficial uses. The effectiveness of each BMP will be evaluated with an index that rates the effectiveness of each BMP as either **High, Moderate,** or **Low** The index is:

Effectiveness of the BMP as indicated by literature & research, administrative studies, and professional experience

High: Practice is highly effective (> 90%) and one or more of the following types of documentation are available.

a Literature/Research - must be applicable to area
b Administrative studies - local or within similar ecosystem
c Experience - judgment of an expert by education and/or experience
d. Fact - obvious by reasoned (logical) response

Implementation and effectiveness of this practice will be monitored and the practice will be modified if necessary to achieve the objective of the BMP

Moderate: Documentation shows that the practice is effective less than 90% of the time, but at least 75% of the time.

or

Logic indicates that this practice is highly effective, but there is little or no documentation to back it up

Implementation and effectiveness of this practice will be monitored and the practice will be modified if necessary to achieve the objective of the BMP

Low: Effectiveness unknown or unverified, and there is little or no documentation

or

Applied logic is uncertain in this case, or the practice is estimated to be less than 75% effective.

This practice is speculative and needs both effectiveness and validation monitoring

Chapter I - INTRODUCTION

This Record of Decision documents my decision and rationale for selecting an alternative for the Land and Resource Management Plan (Forest Plan) for the Siskiyou National Forest After careful consideration of all available information, my decision is to implement Alternative S, as modified (hereafter called the Selected Alternative), as the Forest Plan to guide management of the Forest for the next 10 to 15 years Alternative S is described in the Final Environmental Impact Statement (FEIS) Modifications made to Alternative S in developing the Selected Alternative are described in this Record of Decision (For a detailed description of changes from Alternative S to the Selected Alternative, refer to "The Selected Alternative in Chapter IV of this Record of Decision.)

This first chapter, "Introduction," is offered as background information. Reviewers desiring immediate review of the Decision are directed to Chapter II.

PURPOSE AND NEED

The purpose of the Forest Plan is to provide direction for all natural resource management activities on the Forest. Preparation of the Forest Plan is part of the long-range resource planning process established by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), and its associated National Forest System Land and Resource Planning Regulations (36 CFR 219).

The Forest Plan puts in place a dynamic management system for future decision making It establishes goals and objectives for forest management, and Standards and Guidelines for management activities. It is not a plan for the various administrative activities needed to carry on the Forest Service's day-to-day internal operations. For example, the Plan does not address personnel matters, law enforcement, fleet equipment, or internal organization changes. It is a plan for managing this National Forest in an environmentally sound manner to produce goods and services in a way that maximizes long-term public benefits.

The preparation of an Environmental Impact Statement (EIS) that discloses the environmental consequences of this proposed action and its alternatives is required by the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality's (CEQ) regulations for implementing NEPA (40 CFR 1500 et seq), and the implementing regulations of NFMA (36 CFR 219). For purposes of disclosure under NEPA, the FEIS and the accompanying Forest Plan are treated as combined documents, along with the associated Planning Records.

The EIS is required because the implementation of the Forest Plan is a major Federal action significantly affecting the quality of the human environment. It provides decisionmakers with an environmental disclosure sufficiently detailed to aid in the selection of management direction for the Forest. Equally important, it makes information on the environmental impacts of alternatives available to the public, and encourages public participation in the development and refinement of that information

The Forest Plan is part of the 50-year framework for long-range resource planning established by the RPA. The Forest Plan period covers the next 10 to 15 years. The alternatives presented in the FEIS contain management direction for the Plan period Within that period, conditions on the Forest will be reanalyzed at least every five years and, under certain circumstances, the Forest Plan may be amended or revised. (For further discussion of amendments or revisions to the Forest Plan, see Chapter VI of this document.)

The Forest Plan analysis considers a 150-year planning horizon to ensure that management plans can be implemented over the long term, and to aid in the disclosure and evaluation of long-term environmental consequences. The projection of effects and attributes of the alternatives beyond the Plan period are provided only to broadly indicate the anticipated consequences of each Plan alternative if that alternative

were selected to continue into the future The Forest Service is required to revise the Plan within 15 years of its adoption; this revision may establish different long-term goals with different projected effects and outputs.

The emphasis of the Plan is not on site-specific decisions or specific resource outputs. Rather, the emphasis is on applying various general management practices at various intensities to areas of land to achieve multiple-use goals and objectives in the most cost efficient manner To respond to changing needs and opportunities, Congressional land designations, catastrophic events, new information and inventories, or major new management or production technologies, the Plan may have to be amended or revised If there is a significant change to the Plan, it must be altered by a procedure identical to that used in the development and approval of the original Plan If the change does not significantly affect the Plan, the Forest Supervisor may amend it through a less extensive procedure, however public notification will be required.

All proposals in the Plan can be accomplished from a physical, biological, economic, social, and legal perspective; however it is not certain that these proposals will be accomplished. The outputs proposed by the Plan are estimates, targets, or projections based on available inventory data and assumptions; and are subject to the annual budget. The Plan is implemented through various site-specific projects, such as the building of a road, development of a campground, or the sale of timber. If the budget changes for any given year covered by the Plan, the projects scheduled for that year may be rescheduled However, the goals and land activity assignments described in the Plan would not change unless the Plan itself were changed. If budgets change significantly over a period of several years, the Plan may have to be amended and, consequently, would reflect different target outputs and environmental conditions.

TIERING

As required by NEPA, RPA, NFMA, and the related implementing regulations cited above, the Forest Service uses a multi-level, integrated planning process. At the National level, the RPA Program establishes long-range resource objectives that are based on the present and anticipated supply of, and demand for, various resources Portions of each of the National resource objectives included in the RPA Program are distributed to each of the nine Forest Service Regions

At the Regional level, a Regional Guide is developed. This guide distributes the Region's portion of RPA National objectives to each National Forest within the Region. The Regional Guide also establishes Regional management Standards and Guidelines. The Pacific Northwest Regional Guide (USDA-Forest Service, 1984) provides this direction for the Siskiyou National Forest. Standards and Guidelines for management of spotted owl habitat are established in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA 1988). The EIS for Managing Competing and Unwanted Vegetation (USDA 1988) provides direction for vegetation management for the Pacific Northwest Region.

At the Forest level, a Forest Plan is prepared. Ranges of different resource objectives form the basis for alternatives considered in the EIS for the Plan. One of these alternatives incorporates the RPA Program resource objectives displayed in the Regional Guide. The Forest Plan includes direction provided by RPA, NFMA (including the implementing regulations), and the Regional Guide.

A schedule of proposed and possible projects is contained in the Forest Plan appendices Project development will be accomplished in accordance with NEPA requirements, including site-specific analysis and documentation. The Forest Plan can be changed as monitoring and evaluation of the results of the future project level decisions indicate such a need; changes are to be expected. The Forest Plan, itself, however, does not include the project level decisions.

As a long-range strategy for the Forest, the Plan and accompanying EIS are programmatic. During implementation, when the various projects are designed, more site-specific analyses will be performed

These analyses may result in environmental assessments, environmental impact statements, or categorical exclusions and, possibly, an amendment or revision of the Plan The Forest Plan and FEIS will be used for "tiering" pursuant to 40 CFR 1508 28 Tiering means that environmental analyses conducted for site-specific projects being implemented under the direction of the Forest Plan will refer to the FEIS, Forest Plan, and associated documents. Information from them will be used to help narrow discussions and concentrate on issues pertinent to the project. Scoping, public and other agency involvement, and the ensuing environmental analyses will then be able to focus on issues specific to those projects and site conditions

EXISTING PLANS

The Forest is currently managed through direction provided within the Chetco-Grayback, Rogue-Illinois, Rogue, and Mt. Butler-Dry Creek Land Management Plans, the Powers and Illinois Valley District Multiple Use Plans, the Timber Management Plan, and other sources, including the Forest Service Manual, Regional Guide, and numerous environmental documents, laws, regulations, and Executive Orders These documents call for a blend of land and resource uses. Fish and wildlife, developed and dispersed recreation, and wilderness resources are emphasized along with timber and minerals resources. Other values associated with visual quality, old growth, soil, water, and sensitive plants and animals also receive considerable attention.

The plans previously in effect do not provide the direction to appropriately meet the intent of NFMA. They also do not adequately respond to or have the ability to resolve many of the newer issues and concerns. Therefore, the EIS and Forest Plan have been prepared with direct involvement of other agencies and the public to provide totally integrated and detailed management direction with land allocations which are complementary to the intent of multiple-use.

The regulations guiding the development of Forest Plans state, "...if in a particular case, special area authorities require the preparation of a separate special area plan, the direction in any such plan may be incorporated into the Forest Plan without modification " For this reason the Rogue National Wild and Scenic River Management Plan (Federal Register, July 7, 1972), and the Illinois Wild and Scenic River Management Plan (1985), were incorporated, unchanged, into all Forest Plan alternatives. The Forest Plan replaces all previous resource management plans prepared for the Forest, subject to existing rights, contracts, and specific direction for special areas such as Wild and Scenic Rivers, Wilderness, and Research Natural Areas

OVERVIEW

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released August 28, 1987. The Proposed Forest Plan was developed around the DEIS Preferred Alternative, Alternative K The DEIS analyzed and disclosed the environmental consequences of implementing each of 13 alternatives

After a 150-day public review period lasting until January 25, 1988, comments were evaluated and the FEIS and accompanying Forest Plan were prepared. The FEIS analyzes and discloses the environmental consequences of implementing each of 12 alternatives. Two alternatives that were fully developed in the DEIS were not included in the FEIS. Alternative S, the FEIS Preferred Alternative, was developed after reviewing public and other agency comments on the DEIS. (For more information on the alternatives, see Chapter IV of this document and FEIS, Chapter II.) The Selected Alternative is a modification of Alternative S. Differences between Alternative S and the Selected Alternative are discussed in this document The Forest Plan contains direction for implementing the Selected Alternative.

1987 FIRES

On August 30, 1987, at the beginning of the public review period for the DEIS, lightning ignited numerous fires in southwestern Oregon. Several of the fires burned together, forming the Silver, Galice, and Longwood Fire Complexes. These fires burned more than 110,000 acres on the Siskiyou National Forest. (For more information on these fires, see FEIS, Chapter III, "1987 Fires.")

As part of the Silver Fire Recovery Project's environmental analysis, a major on-the-ground effort was made to verify existing resource inventories and to determine what changes had occurred because of the fire. Similar efforts were made in the environmental analyses for the Longwood and Galice Fires. This updated inventory has been used in completing the Forest Plan.

Minor inventory adjustments as a result of the 1987 fires have been included in the Forest Plan. It was not necessary to modify each of the alternatives in the FEIS. The implications of the inventory changes are addressed in Chapters II and IV of the FEIS.

I have considered the effects of the Silver Fire and of the Silver Fire Recovery Project, as well as those of the other 1987 fires and associated salvage harvests, in selecting a management direction for the Forest, and especially for the inventoried North Kalmiopsis Roadless Area. The Silver Fire Recovery Project FEIS and Record of Decision are incorporated by reference into the Forest Plan FEIS. The Record of Decision for the Silver Fire Recovery Project included rehabilitation of burned area outside the wilderness through recovery of approximately 157 million board feet of burned timber from approximately 9,500 acres. Also included are decisions for road construction, reforestation, monitoring other resources, and deferral of future green timber harvest in the fire area until it has recovered Copies of the Silver Fire Recovery Project EIS and the Record of Decision are available from the Siskiyou National Forest, P.O. Box 440, Grants Pass, Oregon 97526.

WILD AND SCENIC RIVERS

The Omnibus Oregon Wild and Scenic River Act of 1988 was enacted in October 1988, shortly before completion of the FEIS and Forest Plan. The Chetco, North Fork Smith, and Elk Rivers were designated as Wild and Scenic Rivers by this Act. The Congressionally designated rivers are accurately represented in the Selected Alternative; they are treated differently in each of the alternatives due to the timing of the legislation.

Management plans for the three newly designated rivers will be prepared. Any management activity in the interim will be planned to meet the objectives for maintenance of the Wild and Scenic River characteristics and values for which they were established. (For more information on Wild and Scenic Rivers, see sections headed "Wild and Scenic Rivers," FEIS, Chapters II, III, and IV.)

PUBLIC PARTICIPATION

Identification of the major issues, concerns, and opportunities (ICO's) to be used in developing the Forest Plan began in 1979. A potential list of ICO's was developed from previous public comments on Forest management problems and several Forest Service employee and public meetings. In 1980, the ICO's were published as a Forest Plan Report and sent to a wide variety of interested citizens and groups, and county, state, and Federal agencies in Oregon and California. The ICO's have changed with time. As new events occurred and local, regional, and National goals and policies changed, the ICO's were modified accordingly.

On August 28, 1987, the DEIS and Proposed Forest Plan were formally released to the public. In addition, a 40-page "Reviewer's Digest" was distributed to hundreds of individuals. A slightly condensed version

titled "An Invitation to Comment" was printed and 62,000 copies were circulated through the local newspapers

The comment period was originally scheduled to end on November 27, 1987. Two days after the DEIS and Proposed Forest Plan were released, lightning ignited fires which lasted for several months. Forest personnel and local communities were unable to carry out a timely review of the DEIS and Proposed Forest Plan as resources were committed to the fire-fighting effort. The comment period was extended to December 24.

During the review period, the Proposed Forest Plan was the featured topic at 37 open meetings attended by more than 600 people. Briefings were held in Washington, D.C., for Congressional aides, professional societies, and special interest groups. The Planning Team worked with many individuals and groups to answer requests for information, share knowledge, discuss issues, and resolve questions.

In response to several requests that more time was needed to fully analyze the draft documents and formulate comments, the formal review period was extended an additional 30 days. After 150 days of review, the public input period ended on January 25, 1988.

Public participation in the Forest planning process also included three working groups on issues of public concern: the Eight Dollar Mountain Consensus Group, the Port-Orford-Cedar Coordinating Group, and the Wet Weather Timber Haul Working Group. I have considered the results of these work groups as described in the following paragraphs, and management direction contained in the Forest Plan is consistent with their findings and recommendations.

Eight Dollar Mountain is one of the most significant botanical sites in Oregon. It provides diversified habitat for 11 plant species which are under review by the USDI Fish and Wildlife Service for listing as threatened or endangered. The Eight Dollar Mountain Consensus Group was formed in 1984. The group consisted of private citizens, The Nature Conservancy, the Forest Service, the Bureau of Land Management, Josephine County, the Division of State Lands, and the Eight Dollar Mountain Landowners Association The consensus group developed five alternative approaches for management of the area. These approaches have all been considered during the Forest planning process. (For more information on Eight Dollar Mountain and the Consensus Group, see FEIS, Appendix F.)

The Forest Service in Oregon and California established the Port-Orford-Cedar Coordinating Group out of a concern from within the Forest Service, and as expressed by interest groups, that there be a coordinated effort to control Port-Orford-cedar root disease (*Phytophthora lateralis*). The group made recommendations on inventory and monitoring, research, public involvement and education, and management policy. ("The Port-Orford-Cedar Root Disease Action Plan" is available at the Siskiyou National Forest Supervisor's Office.)

Members of both timber industry and environmental groups were concerned that road management was inadequate, either unduly restricting logging operations or allowing them to degrade resource values The Forest used a workshop made up of members of the public, timber sale contract holders, and Forest Service employees to develop solutions. (The report, "Resolution of Wet Weather Timber Haul on the Powers Ranger District," is available at the Siskiyou National Forest Supervisor's Office.)

PUBLIC RESPONSE TO THE DEIS

During the review period for the DEIS and Proposed Forest Plan, the Forest received a total of 16,983 responses with 17,277 signatures. Approximately 100,000 comments were identified. Types of responses included resolutions, petitions, form letters and coupons, and written letters and postcards.

Public response analysis described what the public had said, as completely and directly as possible. It did not assign any weights or policy recommendations. The analysis process was designed to provide decisionmakers with an awareness of the range of values and opinions expressed, and to indicate what the public considers to be major areas of concern. Public response to the DEIS was not a voting process, the number of comments alone does not prescribe agency decisions

DEMOGRAPHICS

Responses came from 49 states, the District of Columbia, and five foreign countries The majority of the responses came from Oregon (10,469), followed by Illinois (1,601), Texas (1,592), Wisconsin (877), and California (649).

The bulk of the responses were from individuals acting for themselves (99 percent). The next largest groups of responses were from environmental or conservation groups (36 responses), the timber industry (27 responses), and city and municipal officials (13 responses).

Form letters made up more than 90 percent of the responses. One group of form letters (9,155) expressed support for a proposal to create a National Park A campaign by the Southern Oregon Timber Industry Association (SOTIA) generated 5,479 form letters in support of their proposed Evergreen Alternative, which emphasized a higher allowable sale quantity (ASQ) than the Proposed Forest Plan.

AREAS OF CONCERN

The majority of those responding were concerned with several aspects of the Forest Plan The following is a summary of the areas of concern.

Fisheries

Broad agreement existed among nearly all the commenters that anadromous fisheries are vital to the Siskiyou National Forest and must be carefully managed

Some comments supported the capital expenditures for fish habitat improvements, some recommended even higher levels. Others questioned the effectiveness of improvement projects and implied they are used in the analysis to mitigate impacts of other management activities.

Some commenters maintained that the Siskiyou's streamside lands, fish habitat, and water resources need much greater protection. There were charges that the Forest Plan does not contain the necessary measures to insure that logging activities will meet the requirements of the Clean Water Act There was also concern, however, that the Forest Plan is too restrictive, specifically regarding buffers on some perennial streams Comments suggested that a monitoring and evaluation program for determining compliance with water quality objectives be established

Recreation

Many of those responding expressed general interest in developing the area's potential for recreation and tourism to diversify and bolster the local economies Many also wanted more emphasis on visual management than was proposed in the DEIS Preferred Alternative

Timber

Viewpoints on this issue were polarized, supporting either increased or decreased timber harvest

Numerous ways to increase harvest levels were offered, from relaxing policy constraints to technical changes in the analysis Some of those responding felt that the ways or means of meeting Management

Requirements (MR's) for the protection of fish, watershed, and wildlife resources were formulated without public involvement and are unduly restrictive on the timber resource.

Other comments stated that the Forest is harvesting at a rate that cannot be sustained, causing environmental damage, as well as a future timber shortage.

Roadless Areas

Some commenters felt that the designation of Custodial (Roadless) Management Areas violated the release/sufficiency language of the Oregon Wilderness Act of 1984. On the other side, many commenters suggested that the Forest Service protect all of the roadless area resources from logging and road building.

Wild and Scenic Rivers

Support was expressed for the designation of the Chetco and North Fork Smith as Wild and Scenic Rivers. Additionally, other rivers, including the Elk, Pistol, Winchuck, South Fork Coquille, and Sixes were suggested for study and possible inclusion in the National Wild and Scenic River System.

National Park Proposals

Various National Park proposals were raised during the planning process. Viewpoints on these proposals were polarized. (For more information on National Park proposals, see Chapter IV of this document and FEIS, Chapter II, "Alternatives Considered, But Eliminated From Detailed Study.")

Those in favor of a National Park emphasized protection of roadless or Wilderness areas. Support of a park was often tied to support for Alternative M, which would provide high levels of protection for old growth and roadless areas

Comments opposing a National Park asserted that the process for considering formation of a National Park is separate from the Forest planning effort These commenters felt that including a National Park alternative in the FEIS would be illegal

Wildlife

Some responses stated that management direction for game species was deficient. Comments recommended inclusion of information on peregrine falcons and marbled murrelets in the EIS.

Threatened, Endangered, and Sensitive Plants

Many of those responding described the Proposed Forest Plan as exceptional in its recognition of the importance of the Siskiyou National Forest in terms of rare plant protection and habitat. Comments supported the proposed establishment of additional Research Natural Areas and Botanical Areas in the Preferred Alternative. They also called for establishment of even more Botanical Areas, and suggested that more botanical inventory be done to provide the information needed for management of rare species. Some also suggested development of interpretive sites.

Biological Diversity

Comments called for a separate, comprehensive discussion of biological diversity. Some suggested changes in land allocations to achieve a better distribution of protected areas.

Minerals

Some of those commenting expressed concern that Forest Service direction on mineral exploration and development is placing minerals in a role subordinate to all other resources. Prescriptions were viewed as being overly restrictive to access and development of the mineral resource.

Monitoring

Some who commented felt that the monitoring and evaluation program on the Siskiyou would be inadequate and may have little likelihood of actually being implemented without assured funding

Information Adequacy

A large number of comments stated that information in the DEIS was inadequate Many also felt that the information was inaccurate, not clearly defined, contradictory, and difficult for the public to understand.

Regional Direction

Some comments expressed concern that there was no apparent relationship between the Forest Plan, the EIS for Managing Competing Unwanted Vegetation, and the Final Supplement for an Amendment to the Pacific Northwest Regional Guide for Spotted Owl Habitat Management.

The majority of the responses, even those expressing dissatisfaction with parts of the EIS or Forest Plan, included a commendation for the Siskiyou staff and Planning Team. Many of those responding felt that the Forest staff sincerely encouraged and facilitated public participation, showed an awareness and sensitivity for the management of the Siskiyou National Forest, and did a professionally competent analysis

PLANNING PROBLEMS

A list of major issues and concerns was developed from public comments on Forest management, and from several meetings of Forest Service employees and the public. Many of the issues and concerns are interrelated; having more of one thing often requires having more or less of something else, whether desired or not Nine "Planning Problems" were developed from the issues and concerns. These Planning Problems were addressed through the development and evaluation of the alternatives. (For a more complete discussion of the Planning Problems, see Chapter III of this document and Appendix A and Chapter I of the FEIS. The Planning Problems are listed below:

1. How Much Timber Should the Forest Produce?

2. How Much Old-Growth Forest Should be Preserved?

3. How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved?

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

5. How Should Sensitive Plant Resources be Managed?

6. How, and to What Extent, Should Forest Scenic Values be Protected through Visual Resource Management?

7. How Should Wildlife Habitats on the Forest be Managed?

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Chapter II - DECISION

My decision is to implement Alternative S of the FEIS with some modifications to· reduce the allocations to the Backcountry Recreation Management Area by approximately 67,000 acres, place the bulk of these areas in an administrative study classification, adjust the boundary of the Fall Backcountry Recreation area, change the Butler and Copper areas from the Backcountry Recreation Management Area to the Supplemental Resource Management Area, and include the inventory changes that resulted from the timber killed in the 1987 fires and the field information collected in conjunction with the environmental analysis for the Silver Fire Recovery Project. These changes and the rationale for them are described further in the following sections and have been incorporated into the Forest Plan and accompanying map The changes in environmental consequences expected during the Plan period from these modifications are very minor, but a slightly different management emphasis is provided. Alternative S thus modified is termed the Selected Alternative in this document, and will become the basis for the Forest Plan to guide the management of the Forest over the next 10 to 15 year period

The Selected Alternative addresses the desires of a wide range of user groups and interests, continues to supply goods and services vital to the maintenance of local and National economic development, while maintaining a healthy diverse ecosystem. This requires that the Forest capitalize on the multi-product nature of land allocations that minimize tradeoffs between goods and services

In implementing the Forest Plan, I am making the decisions regarding the following (which are discussed in further detail below):

1. Forest multiple-use goals and objectives, including an identification of the quantities of goods and services that are expected to be produced.

2 Multiple use prescriptions and associated Standards and Guidelines for each Management Area on the Forest, including proposed and probable management practices.

3 Identification of land that is suitable for timber production.

4. Determination of the allowable sale quantity for timber and the associated sale schedule.

5. Allocation of certain roadless areas to multiple-use management prescriptions with scheduled timber harvest and road construction that will result in these areas being roaded during the Plan period.

6. Monitoring and evaluation requirements

Taken together, these items establish general and specific goals for the Siskiyou National Forest and a set of standards and guidelines to follow in pursuit of these goals. In addition, they establish a monitoring process to help determine how well the standards and guidelines are working and whether the goals remain appropriate during the period when the Forest Plan is implemented.

GOALS

The Forest Plan will be designed to achieve the following Forest-wide goals:

1. Provide a balance of resource management that will maintain a healthy Forest ecosystem, and help to supply local, regional and National social and economic needs.

2. Provide a sustained yield of resource outputs at a level that will promote the stability of local communities.

3. Maintain a healthy, diversified, and visually pleasing forest setting that enhances local tourism and provides an attractive visual backdrop to surrounding communities.

4. Fully implement the National Recreation Strategy through the development of partnerships with other local and federal agencies (e g , counties and states), and other groups and individuals. Support local economic development strategies that focus on increased recreation and tourism.

5. Recognize special areas and resources for their unique values and manage them to protect and perpetuate those values.

6. Provide diverse, high quality water and fish habitat capable of maintaining or enhancing populations of game fish species with emphasis on anadromous fish habitat.

7. Maintain viable populations of existing native animal and plant species. Maintain or improve all existing seral stages of terrestrial and aquatic plant associations in a distribution and abundance to accomplish this goal.

8. Provide habitat to contribute to the recovery of threatened and endangered plant and animal species in accordance with approved recovery plans.

9. Recognize and promote the intrinsic ecological, social, and economic value of wildlife and wildlife habitat Provide sufficient quantity and quality of wildlife habitat to ensure diversified recreational use and public satisfaction.

10. Offer a wide range of dispersed recreation opportunities by providing recreational settings, access, facilities, and education necessary to meet public demand.

11. Protect and enhance identified, outstandingly remarkable values and free flowing condition of Wild and Scenic Rivers

12. Protect the values and character of designated Wildernesses.

13. Provide firewood for personal use in a fair and equitable manner.

14. Inventory and interpret significant prehistoric and historic cultural resources.

15. Plan, design, operate, and maintain a safe and economic transportation system to provide efficient access for the movement of people and materials involved in the use and protection of National Forest Lands

16. Protect and enhance resource values through cost-effective fire and fuels management programs, emphasizing fuel treatment through the utilization of prescribed fire.

17. Protect resource values through the practice of integrated pest management.

18. Facilitate mineral exploration and development while protecting surface resources and environmental quality.

19. Meet or exceed state and Federal requirements which provide protection to the air, water, and cultural resources of the Forest.

20 Provide water of sufficient quality and quantity for local and downstream beneficial uses.

21. Maintain health and function of riparian ecosystems (including stream channel stability) for the protection or enhancement of riparian-dependent resources.

22. Provide administrative sites and facilities that effectively and safely serve the public and accommodate the workforce

23 Provide for biological diversity and long-term productivity by maintaining ecosystem function, maintaining large woody material, and minimizing adverse impacts to the soil resource.

24. Perpetuate Port-Orford-cedar as a functioning part of the Forest vegetation throughout its natural range and maintain it for economic and noneconomic uses.

LAND ALLOCATION

A critical part in design of the Forest Plan is the land allocation. All lands are assigned to one of 14 "Management Areas " A Management Area is a category of land with the capability to respond to certain issues or to meet specific management objectives Management Areas may include some multiple uses, but often emphasize one or a few resources, resulting in a dominant use or management of selected resources for some areas. (For specific information on Management Areas, see LRMP, Chapter IV, "Management Prescriptions," and FEIS, Chapter II, Management Area Maps and Tables II-2 and II-3.)

Inventoried areas are used as the building blocks to create the land allocations by Management Area. Each inventoried area is a discrete unit that can be identified on the ground. Collections of these then become the Management Area which may be scattered over the Forest, but will be managed under the same direction.

With all of the potential land allocations, overlaps between inventoried areas are numerous Where Plan design results in overlap, the acres are assigned to the Management Area with the most restrictive management prescription. The lower numbered Management Areas are those with the greatest constraints.

For example, a Botanical area (Management Area 4) may exist within Wilderness (Management Area 1). The acres in the Botanical area are included as inventoried acres for both Management Area 1 and Management Area 4 However, the acres are assigned to Management Area 1 and will be managed under its more restrictive management prescription Because of this process, the acres listed for the assigned inventoried areas will seldom add up to the Management Area acres.

Land allocations showing inventoried and assigned acreages to each Management Area on the Forest.

Management Area			Inventoried Area
No	Acres	Name	Acres
1	232,495	Wilderness	232,495
2	5,029	Wild River	27,128
3	4,608	Research Natural Area	4,608
4	16,275	Botanical	19,632
5	2,015	Unique Interest	2,015
6	40,871	Backcountry Recreation	46,260
7	26,921	Supplemental Resource	30,930
8	50,287	Designated Wildlife Habitat	159,949
9	28,762	Special Wildlife Site	45,146
10	10,317	Scenic/Recreation River	23,931
11	96,623	Riparian	175,500
12	9,861	Retention Visual	40,407
13	133,931	Partial Retention Visual	202,700
14	434,307	General Forest	-

MANAGEMENT AREA 1 - WILDERNESS

The objective of the Wilderness allocation is to maintain the area's character in a natural condition and perpetuate the wilderness resource, while providing opportunities for solitude and recreation. These areas are managed to comply with the requirements of the Wilderness Act of 1964.

Management Area acres in Wilderness total 232,495 acres. Inventoried acres total the same amount There are five existing Wildernesses, as listed below:

Grassy Knob
Kalmiopsis
Red Buttes
Siskiyou
Wild Rogue

When Congress passed the California and Oregon Wilderness Act in 1984, it included language which stated that "the Department of Agriculture shall not be required to review the wilderness option prior to the revision of the [Forest] plans. .." There has been no designation on the Forest since 1984. Additional Wilderness can be designated only through Congressional action.

MANAGEMENT AREA 2 - WILD RIVER

The objective of the Wild River allocation is to maintain the natural, free-flowing, and primitive character of the immediate environment in Wild segments of Wild and Scenic Rivers.

The Illinois and Rogue Rivers are existing Wild Rivers. The Omnibus Oregon Wild and Scenic Rivers Act of 1988 designated segments of the Chetco, North Fork Smith, and Elk Rivers as Wild Rivers The Winchuck, Pistol, South Fork Coquille, South Fork Chetco, and South Fork Sixes Rivers were evaluated by Forest staff for Wild River status. None were found to be eligible for potential inclusion into the National Wild and Scenic River System.

Two additional sections have been inventoried as Wild but were not included in the Oregon Omnibus Act of 1988· (1) the two-mile section of the North Fork Smith River from Baldface Creek to the California Border and (2) the two-mile section of the Chetco River from Boulder Creek to Mislatnah Creek I intend to carry these two sections of rivers as Wild until a determination is made in future River Management Plans

Management Area acreage in Wild River is 5,029 acres (27,128 total, but many acres are overlapped by Wilderness). Those rivers with Wild River segments are listed below:

Chetco
Elk
Illinois
Rogue
North Fork Smith

MANAGEMENT AREA 3 - RESEARCH NATURAL AREA

The objective of this allocation is to provide opportunities for research, observation, and study of ecosystems influenced only by natural processes.

There are three existing Research Natural Areas on the Forest. My decision is to recommend the addition of four new areas. Their establishment is subject to approval by the Chief of the Forest Service. Recommended for inclusion as Research Natural Areas are 2,651 acres (See FEIS, Appendix F) In the interim, these four additional areas will be managed as Research Natural Areas. The total Management Area will be 4,608 acres. The areas are listed below.

Cedar Log Flat
Craggy Peak
Lemmingsworth Gulch
Wheeler Creek (Existing)
Coquille River Falls (Existing)
Hoover Gulch
Port Orford Cedar (Existing)

MANAGEMENT AREA 4 - BOTANICAL

The objective of this allocation is to provide exhibits of plants, plant groups, and communities with exceptional botanical and ecological value

There are three existing Botanical areas on the Forest I am allocating an additional 19 Botanical areas comprising 15,157 inventoried acres (See FEIS, Appendix F). This will bring the acres of Botanical Areas to 19,632 with 16,275 acres in the Management Area (other acres are overlapped by higher order Management Areas). The Botanical areas are listed below:

Babyfoot (Existing)
Bear Camp
Big Craggies (Existing)
Big Tree
Bigelow Lakes
Bolan Lake
Chrome Ridge
Days Gulch
Eight Dollar Mountain
Grayback Mountain
Iron Mountain
Lobster Grove
Redwood Groves
Oregon Mountain
Page Mountain
Red Flat
Rough and Ready Flat
Snaketooth Redwood
Snow Camp
Sourgame
Vulcan
York Creek (Existing)

MANAGEMENT AREA 5 - UNIQUE INTEREST

The objective of this allocation is to provide opportunities for understanding the earth's unique geologic, historical, and archaeological features.

I am allocating 2,015 acres to this Management Area. I have decided to create the Unique Interest areas listed below:

Collier Butte
Devils Half Acre Ridge
Elk Creek Falls
Ferris Ford Cedar Log House
Gray Butte
Horse Sign Butte
Lawson Butte
Pyramid Rock
Quosatana Butte
Saddle Mountain
Signal Buttes
Silver Creek Falls
Stack Yards Rock
Taylor Creek Falls
Wheeler Creek Bomb Site

MANAGEMENT AREA 6 - BACKCOUNTRY RECREATION

The objective of this allocation is to provide opportunities for non-motorized and motorized recreation in an undeveloped setting, with the minimum management necessary for resource protection. Motorized access is permitted in areas with high potential for mineral development to reduce access restrictions and promote more efficient mineral exploration and development opportunities.

Alternative S, as described in the FEIS, included 16 Backcountry Recreation areas I have decided to allocate 40,871 acres in 12 areas to the Backcountry Recreation Management Area (46,260 total acres, but many are overlapped by higher order management areas) in the Selected Alternative. Below is discussion related to changes from Alternative S and the Selected Alternative. (For more information on these changes, see LRMP, Forest Plan Map)

Part of the Silver Backcountry Recreation area delineated in Alternative S will be allocated to General Forest (Management Area 14) to be managed as the Silver Fire Recovery Project Administrative Study Area in the Selected Alternative. Some uncertainty remains as to land suitability for timber production and feasibility of logging operations and road building in this part of the Silver Fire. Further evaluation will be completed to resolve these resource questions. No timber harvest is programmed for this area in the Plan period. Some helicopter salvage of areas contained in the Silver Fire Recovery Project FEIS (and included in subsequent timber sale contracts as "optional" salvage units) may be accomplished.

The major part of the South Kalmiopsis Roadless Area that would have been Backcountry Recreation as described in Alternative S will be allocated to General Forest to be managed as an administrative study area in the Selected Alternative. No timber harvest is programmed for this area although some timber may be removed to provide further information about uneven-aged management and harvesting on poor sites.

The southern boundary of the Fall Backcountry Recreation Area in Alternative S will be moved up to ridgelines to exclude areas not visible from the Illinois River or the Illinois River Road in the Selected Alternative.

The Butler and Copper Backcountry Recreation areas in Alternative S will be allocated to Supplemental Resource (Management Area 7) and called South Fork Sixes River and North Fork Elk River respectively in the Selected Alternative. Fisheries and watershed values are more evident than recreation attributes for these areas.

Of the 40,871 acres allocated to Backcountry Recreation areas 99 percent fall within inventoried roadless areas. (For more information about specific areas, see FEIS, Appendix C). The inventoried areas and associated roadless areas are listed below.

Backcountry Recreation areas associated with inventoried roadless areas.

	Backcountry Recreation Area			
Inventoried Roadless Area	Non-motorized	Acres	Motorized	Acres
North Kalmiopsis	Silver Glory Lower Lawson Lower Illinois Labrador Mislatnah	5,808 6,699 6,256 5,435 3,829	Dailey	3,600
Windy Valley			Windy Valley	2,363
Siskiyou	Chicago	629		
Kangaroo			High Divide	2,309
Packsaddle	Cedar Mountain	923		
South Kalmiopsis			Pearsoll Fall	1,333 1,611

MANAGEMENT AREA 7 - SUPPLEMENTAL RESOURCE

The objective of this allocation is to provide quality fisheries, water, wildlife habitat, and recreation opportunities in a largely undeveloped setting.

I have decided to modify Alternative S, as described in the FEIS, by changing the Butler and North Copper areas from the Backcountry Recreation to the Supplemental Resource Management Area and name them South Fork Sixes River and North Fork Elk River respectively. I am allocating 26,921 acres to the Supplemental Resource Management Area (30,930 total acres, but some are overlapped by higher order management areas). I have decided to create the Supplemental Resource areas listed below. These areas are all within inner gorge areas of major streams and rivers or their tributaries.

Emily Creek
Father Mountain
Horse Sign Creek
Illahe East
Indigo Creek
Lawson Creek
Lobster Creek
North Fork Collier Creek
North Fork Elk River
Purple Mountain
Quosatana Creek
Rogue River Visual
Shasta Costa Creek
Silver Creek
South Fork Chetco River
South Fork Sixes River
Winchuck River

MANAGEMENT AREA 8 - DESIGNATED WILDLIFE HABITAT

The objective of this allocation is to provide mature and old-growth habitat for dependent wildlife species

I have decided to designate wildlife habitat meeting management requirements (MR's) for spotted owl, pine marten, and pileated woodpecker. These MR's are consistent with direction contained in the Final Supplement for an Amendment to the Pacific Northwest Regional Guide (USDA 1988). There are over 100 of these areas I am allocating 50,287 acres to this Management Area (159,949 total acres, but many are overlapped by higher order management areas).

MANAGEMENT AREA 9 - SPECIAL WILDLIFE SITE

The objective of this allocation is to provide an array of unique plant and animal conditions that contribute to overall wildlife habitat diversity.

I am allocating 28,762 acres to this Management Area (45,146 total acres, but many are overlapped). There are several hundred of these areas I have decided to allocate to this Management Area the types of inventoried areas listed below

Botanical Sites
Dispersed Old-Growth
Elk Areas
Hardwoods
Lakes and Ponds
Meadow Buffers
Meadows
Osprey Nest Sites
Pigeon Areas
Rock Bluffs
Swamps, Springs, and Wet Areas
Tanoak Areas
Wildlife Areas

MANAGEMENT AREA 10 - SCENIC/RECREATION RIVER

The objective of this allocation is to provide river-oriented recreation in an area of high quality scenery and largely undeveloped shoreline in Scenic and Recreation segments of Wild and Scenic Rivers.

The Rogue and Illinois Rivers contain Scenic and Recreation segments. The Omnibus Oregon Wild and Scenic Rivers Act of 1988 designated segments of the Chetco and North Fork Smith Rivers as Scenic Rivers. The Act also designated segments of the Chetco and Elk Rivers as Recreation Rivers. The Winchuck, Pistol, South Fork Chetco, South Fork Coquille, and South Fork Sixes Rivers were evaluated by Forest Staff for Scenic and Recreation River status. None were found to be eligible for potential inclusion in the National Wild and Scenic River System. Management Area acres in Scenic/Recreation River total 10,317 acres (23,931 total acres, but many are overlapped by higher order management areas). Those rivers with Recreation River or Scenic River segments are listed below:

Recreation	**Scenic**
Chetco	Chetco
Elk	Illinois
Illinois	North Fork Smith
Rogue	Rogue

MANAGEMENT AREA 11 - RIPARIAN

The objective of this allocation is to protect the intrinsic values of ecosystems bordering bodies of water, streams, and wetlands, while providing limited multiple-use development opportunities, including programmed timber harvest.

The Riparian Management Area is defined by site specific conditions. It includes the riparian area along all Class I, II, and III streams and other bodies of water within lands suitable for timber production (traversing Management Areas 12-14). This area is identified as the land containing riparian vegetation, not to be less than a 100 feet wide strip along all Class I, II, and III streams. Using the average expected width of the riparian areas, there are 96,623 acres (70,086 suitable) in the Riparian Management Area. Riparian Management Areas will be managed under one of the following prescriptions assigned by planning basin:

Prescription B

This prescription allows a moderate level of vegetation removal from riparian areas. It is designed to maintain existing water temperatures within planning basins, and meets the MR's for riparian area management and maintenance of water quality. I have decided to manage the riparian areas in the following planning basins (43,308 suitable acres) under Riparian Management Prescription B:

South Fork Coquille River
Galice and Slate Creeks
Upper Illinois River
Rough and Ready/Josephine Creeks
North Fork Smith River
Sucker Creek
Upper Rogue River
Lower Illinois River
Briggs Creek
Winchuck River
East and West Fork Illinois River

Prescription C

This prescription allows minimal removal of vegetative cover for stream shading, and is estimated to have a net effect of two degrees Fahrenheit reduction in summer water temperature over time. I have decided to manage the riparian areas in the following planning basins (26,778 suitable acres) under Riparian Management Prescription C.

Elk and Sixes Rivers
Lower Rogue River
Lower Chetco River
Indigo Creek
Lobster Creek
Pistol River
Silver Creek

Because of effects of the Silver Fire, I have decided to manage the Silver and Indigo Planning Basins under Prescription C for the first decade to allow for stream shade recovery. At the end of the first decade, they will be reevaluated and assigned the most appropriate prescription. (Upper Chetco River Planning Basin is entirely within the Kalmiopsis Wilderness so it is not included here.)

MANAGEMENT AREA 12 - RETENTION VISUAL

The objective of this allocation is to protect the scenic values of the Forest. It provides opportunities for multiple-use development, including a constrained level of programmed timber harvest, that are not visually evident to the casual Forest visitor.

I am allocating 9,861 acres to this Management Area (40,407 total acres, but many are overlapped by higher order management areas). The following viewsheds contain Retention acres:

Bolan Lake
Chetco
Elk River
Game Lake
Highway 199
Oregon Caves
Quail Mountain
Rogue-Illinois
Upper Illinois
Wheeler Creek
Winchuck River

MANAGEMENT AREA 13 - PARTIAL RETENTION VISUAL

The objective of this allocation is to protect the scenic values of the Forest. It provides multiple-use development opportunities, including a slightly reduced level of programmed timber harvest, that are visually subordinate to the characteristic landscape

I am allocating 133,931 acres to this Management Area (202,700 total acres, but many are overlapped by higher order management areas) The following viewsheds contain Partial Retention acres.

Babyfoot Lake
Bear Camp
Bob's Garden
Bolan Lake
Briggs Valley/Shan Creek
Chetco
Coquille River
Crazy Peak
Eden Valley
Elk River
Game Lake
Highway 199
Lawson Creek
Mt. Butler
Oregon Caves
Quail Mountain
Rogue-Illinois
Silver Trails
Sourdough
Upper Chetco
Upper Illinois
Winchuck River

MANAGEMENT AREA 14 - GENERAL FOREST

The overall objective of this allocation is to provide a full range of multiple-use development opportunities and produce a high yield of timber, subject to multiple-use constraints. I am allocating a total of 434,307 acres to this Management Area.

I am also designating "overlays", or sub-parts of the General Forest Management Area to lands for *Extensive Management* and some lands for *Administrative Study* areas Acreage for these areas is identified in the table below. The Extensive Management areas are distinctive in that they lack the operability to gain reasonable road access for intensive timber management and will be managed under a less intensive timber harvest schedule with no roading scheduled for this planning period.

The Administrative Study areas are in two locations. one is the Silver Fire Recovery Area which was burned in 1987 and is still recovering from the effects of the fire, the other is known as the South Kalmiopsis which is a large area of very poor soils and generally sparse vegetation. No timber harvest is programmed for

either of the Administrative Study areas areas. The goals for the Silver Fire Recovery administrative area are to allow time for recovery from the effects of the Silver Fire; to monitor the recovery process; reassess and further refine the operability and suitability of this area for timber production; provide for Primitive and Semi-primitive recreation opportunities; and provide habitat for many species of wildlife. The goals for the South Kalmiopsis area are to provide administrative studies of uneven-aged management, or other minimal entry timber management on low sites and poor soils; continue to provide mineral exploration and development opportunities; and provide opportunities for Semi-primitive Motorized recreation; and provide habitat for many species of wildlife.

Acres Allocated to General Forest Management Area.

Name (Acres)	Acres Management Area 14
Total	434,307
Extensive Timber Management (10,830)	(4,920)
Fall West (482)	
Lower Indigo (4,085)	
Mid Lawson (3,067)	
Mislatnah (1,120)	
Moores (978)	
Red Mountain (1,098)	
Administrative Study (65,544)	(47,782)
Silver Fire Recovery Project (10,975)	
South Kalmiopsis (54,569)	

STANDARDS AND GUIDELINES

As part of this decision, I adopt the system of Standards and Guidelines described in the Forest Plan (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Management of the Forest is subject to all applicable laws and regulations; particular reference is made to the NFMA regulations which guide Forest Planning (36 CFR 219.27). The Standards and Guidelines are intended to help managers achieve Forest goals and objectives, while staying within constraints prescribed by law and constraints designed to provide environmental safeguards. The Standards and Guidelines address the following topics:

1. Recreation
2. Visual Resources
3. Cultural Resources
4. Fish, Wildlife, and Sensitive Plants
5. Range
6. Timber Management
7. Soil and Water
8. Air Quality
9. Lands
10. Minerals
11. Transportation Facilities
12. Fire and Pest Management
13. Biological Diversity

CAPITAL INVESTMENTS

Capital investments are dollars spent to provide or improve a facility or product for future use. The Selected Alternative emphasizes fisheries and recreation. I have decided to include in the Forest Plan the following amounts (shown in millions of dollars) through Fiscal Year 1993 for the resources listed below. (For more information on capital investment projects, see LRMP, Appendix B.) Actual investments may vary depending on the amounts budgeted by Congress and allocations through the National Forest System.

Recreation	2,531.2	
Fish	1,760.0	
Soil and Water	1,155.0	
Threatened, Endangered, and Sensitive Wildlife and Plants	510.0	
Wildlife	1,820.5	
Trails	898.3	
Road and Bridge	7,628.0	
Buildings, Water, and Sewer	1,365 0	(through FY 95)

OTHER DECISION ELEMENTS

ALLOWABLE SALE QUANTITY

The Allowable Sale Quantity (ASQ) will be 28.7 million cubic feet (MMCF) of timber (including salvageable dead volume) under this plan This is an average annual quantity not to be exceeded for the decade. Volume sold in any one year may vary depending on funding, environmental conditions, economic conditions, and other factors. The ASQ is based on projection of a non-declining flow harvest schedule for future decades, with stands not scheduled for final harvest until generally reaching culmination of mean annual increment (CMAI).

The ASQ will be tracked and controlled on a cubic foot measure. The board foot volume associated with the cubic volume (i.e , board foot/cubic foot conversion ratio) varies from stand to stand depending on the size and form of the trees. The mosaic of stand conditions on the Siskiyou, and the need to make site specific decisions on harvest unit design, combine to make the identification of a precise board foot volume to be associated with the cubic foot ASQ impossible. While the harvest will primarily come from mature stands, actual harvest units often have small inclusions of other stand conditions. The need to disperse the harvest will also result in programming some otherwise low priority stands to avoid creating a scheduling problem for future decades. The stands expected to be harvested in the Plan period will yield approximately 160 million board feet (MMBF) associated with the 28.7 MMCF. This will be used as a goal in the early part of the Plan period; the transition from use of board foot measure to use of cubic foot measure should be made during this Plan period.

It was not possible to resolve all of the concerns surrounding the issues of inventory and yield tables before the release of the Forest Plan. Studies to answer the remaining questions will continue and will be completed within 12 months following the release of the Forest Plan. Forest personnel are also presently engaged in planning and implementing a new total Forest resources inventory. As these analyses and inventory are completed, the Forest ASQ will be examined in light of the new data. If warranted, the Forest Plan will be revised or amended as appropriate (see section "Amendment and Revision" in Chapter IV of this document).

The ASQ is also dependent on the application of intensive timber management practices including thinning and fertilization which are subject to budgets. The condition of young timber stands will be monitored to verify that stands are receiving cultural treatments when needed. If it is determined that these treatments

are not being carried out sufficiently to support the ASQ, this would also be cause for the Forest Plan to be revised or amended

SELECTED SUITABLE LANDS

Through the land allocations described above for the Selected Alternative, I have designated 510,000 acres of land as suitable for timber production. As a result of Forest Plan implementation, final harvest is expected to occur on an approximately 4,700 acres per year, on the average, during the first decade.

TRANSPORTATION SYSTEM

New roads will be constructed as needed during the planning period to achieve the objectives specified in the Forest Plan. This is highly variable from year to year; the locations and extent of roading will be determined through site specific analyses at the project level.

ROADLESS AREAS

A total of 284,245 acres (143,406 tentatively suitable for timber) are currently inventoried as roadless (For more information on inventoried roadless areas, refer to FEIS, Appendix C.) Acres allocated to Management Areas 1 through 9 total 91,555, or about 32 percent These acres have no programmed timber harvest and will remain undeveloped. The remaining 192,690 acres are allocated to Management Areas 10 through 14; suitable acres in these management areas (106,240) have programmed timber harvest, with the exception of the administrative study areas.

Approximately 70 MMCF, or about 25 percent of the timber harvest scheduled for the first decade is in areas that are now inventoried as roadless. Of course this is approximate and may vary depending on site-specific analysis for timber sales, however it should be clear that my intent is for significant development to occur during the next decade in those portions of the roadless areas with programmed timber harvest.

Inventoried roadless areas showing acreage associated with Management Areas 1-9 and 10-14.

		Roadless Area Disposition (Acres)		
		MA's 1-9	MA's 10-14	
Roadless Area	Total Acres	Total	Total	Suitable
Grassy Knob	5,428	3,067	2,361	2,261
Copper Mountain	9,354	2,736	6,618	5,872
Mule Creek	352	169	183	128
Rogue	3,839	784	3,055	2,982
Potato Mountain	5,963	2,664	3,299	3,146
Shasta Costa	14,261	3,040	11,221	10,272
North Kalmiopsis	88,582	43,883	44,699	33,760
Quosatana	5,097	1,267	3,830	3,418
Briggs	5,544	1,131	4,413	3,115
Squaw Mountain	7,704	1,371	6,333	3,445
Windy Valley	10,214	3,615	6,599	5,595
Kalmiopsis Addition	1,166	32	1,134	1,024
Mount Emily	5,945	3,349	2,596	2,357
Siskiyou	3,284	1,354	1,930	960
Kangaroo	6,651	3,456	3,195	2,848
North Fork Smith	952	117	835	400
Packsaddle	5,289	3,120	2,169	1,222
South Kalmiopsis	104,620	16,400	88,220	23,435

SILVICULTURAL SYSTEMS

Timber harvest systems will be decided on a site-specific level for each project. The Standards and Guidelines indicate the systems generally appropriate for given combinations of site and stand conditions and Management Area goals and objectives. The systems indicated as most appropriate for the broad categories presented should be those most often used; however, it is not intended that other systems should not be used when site-specific conditions warrant.

Clearcut, shelterwood, seed tree, single-tree selection, and group selection harvest methods are all available tools. Each of these systems will be used to some extent. Due to the particular combinations of environmental conditions and management objectives, even-aged systems will be the most commonly used, with clearcutting the most common method of regeneration in this group. Key factors in the determination of appropriate systems on this Forest are the intensity of vegetative competition commonly encountered, the difficulty of protecting residual trees through harvest operations on steep slopes, the desirability of perpetuating high proportions of shade intolerant species, and other resource objectives and environmental effects

Uneven-aged systems will be used more frequently on sites where the soil, climate, and other factors result in a natural tendency for uneven-age stands to develop; or where uneven-aged systems will best meet resource objectives. (For more information on silvicultural systems, see FEIS, Appendix G, "Description of Silvicultural Systems.")

BIOLOGICAL DIVERSITY AND SITE PRODUCTIVITY

Based on the most current scientific information, the Selected Alternative is designed to maintain a diverse and healthy ecosystem. The Selected Alternative maintains essential components of the ecosystem scattered throughout the Forest in allocations to: large Wilderness areas, Designated Wildlife Areas, hundreds of Special Wildlife Sites, Botanical areas, Research Natural Areas, large areas which are unsuitable for timber production, and Riparian areas with varying prescriptions. These areas comprise over half of the total acreage of the Forest.

I also recognize that biological diversity cannot be maintained through "set-aside" areas alone, but must be integrated into management activities. Standards and Guidelines have been updated to include consideration for biological diversity in a number of areas For example, basic to diversity is maintenance of the long-term productivity of the ecosystem. Management activities will be planned to maintain enough large woody material (dead and down) to maintain a healthy forest ecosystem. Forest-wide Standards and Guidelines provide direction for size and amount of woody material to be left on each site. Site-specific needs will be considered in environmental analyses. Another example in the Standards and Guidelines is consideration to be "given to regenerating and maintaining minor species, where appropriate for the site, as viable components of future stands, and for the enhancement of vegetative diversity."

LOGGING SYSTEMS

Logging systems will be matched to the site-specific conditions for each project. The system which meets the resource objectives at the least cost will be selected. Skyline systems will likely continue as the predominant means of harvest, due to environmental and feasibility concerns. All systems, including helicopter, are available and will be used where appropriate.

POTENTIAL DEFERMENT OF ACTIVITIES DUE TO CUMULATIVE EFFECTS

Based on site-specific analysis, activities, including timber harvest and road building, may be adjusted in areas where practices on private or other lands have recently or are currently adversely affecting water quality or other forest resources, and where activities on the National Forest may contribute to adverse cumulative effects.

ELK RIVER STATE SCENIC WATERWAY

The State of Oregon has included portions of the Elk River in the State Scenic Waterway system and will be completing a management plan in cooperation with the Forest Service. Recommended management of the river corridor will be identified in that plan. In the interim, the Forest Service will manage the corridor to protect visual and water quality values.

WILDERNESS FIRE MANAGEMENT PLANS

The extent of prescribed fire programs in Wilderness areas will be determined by future Wilderness Fire Management Plans. My intent is to use planned and unplanned ignitions to: (1) reduce the risks and consequences of wildfire within the Wilderness, or escaping from the Wilderness and (2) allow fire to play its natural ecological role in Wilderness areas.

FERTILIZATION

I have decided to use a fertilization program on the Forest The results of fertilization have been considered in calculating the ASQ, and are expected to increase ASQ by .8 MMCF per year. The area of application *and specific constraints will be identified through the project design in site-specific project level analysis.* Accomplishment of the fertilization program is subject to budget, if adequate funding is not available to accomplish fertilization, amendment or revision of the Plan may be necessary as determined through monitoring.

HARDWOOD CONVERSION

I have decided that conversion of mixed hardwood stands to managed commercial stands will be limited to no more than 7,500 acres per decade, subject to market conditions and site specific analysis (including consideration for maintaining species diversity).

MITIGATION AND MONITORING

As part of this decision, I adopt the mitigation measures, including the Best Management Practices (BMP's), and Monitoring Plan discussed in the Forest Plan, Appendices D and F, and in Chapters VII and VIII of this document.

Chapter III - RATIONALE

SUMMARY

The National Forests in the Pacific Northwest Region are composed of similar resources; however, each has its own unique mix of resources and values that sets it apart from its neighboring Forest. The Siskiyou National Forest offers southwest Oregon and the Nation a distinctive set of economic benefits and social values.

I have reviewed summaries of the condition of the natural resources on the Siskiyou National Forest, the current land management situation, and a synopsis of public response to the DEIS. I have also driven roads, hiked trails, and floated the Rogue River on this Forest It is clear to me that the key attributes of the Siskiyou are.

*** The productive capacity of the Forest to provide wood resources**

*** Extremely valuable spawning and rearing habitat for salmon and steelhead**

• Botanical, biological, and geological diversity far beyond the ordinary

*** The many rivers on this Forest and their associated recreation values**

The challenge is to develop a management plan that recognizes and utilizes these values, while protecting and perpetuating them and other associated resources. Developing that special combination appropriate for this National Forest is a key objective

The Forest Supervisor, his Management Team, and Land Management Planning Interdisciplinary Team closely analyzed the public response to the DEIS. I have reviewed the results, along with their suggested changes to the proposed Forest Plan accompanying the DEIS.

A new National Forest Plan will have an effect on the economic structure and social fabric of surrounding communities. I am fully aware of this effect. I have made a strong effort to have developed and selected an alternative that maximizes net public benefits, and provides a basis for local communities to predict and manage any change set in motion by the decisions in this Plan.

This information and perspective led me to select Alternative S, with some modifications. This "Selected Alternative" recognizes the solid productivity of the Forest and its importance in supplying Southern Oregon with a sustained supply of wood for a variety of products and uses. The Selected Alternative also recognizes the equal importance of water quality, fisheries, and outdoor recreation values, as well as the unique geologic and biologic features. It is my judgement that the Selected Alternative is well balanced, sensitive to both economic and environmental values, and will provide optimum net public benefits. It is appropriate direction for the Siskiyou National Forest for the next decade.

RESPONSE TO ISSUES, CONCERNS, AND OPPORTUNITIES

The great diversity of Forest resources and multiple uses produces an extremely complex management situation. The variety of uses leads to competition for the limited resources. Land allocations, which emphasize various uses, also generate tradeoffs between conflicting interests. The range of possible solutions to these management challenges is reflected in the responses to the Planning Problems which characterize each alternative.

The Selected Alternative responds positively and thoroughly to public issues raised during the planning process, and to management concerns. It is not possible to totally resolve all, as many are in direct conflict.

I have examined each issue both independently and in context of any conflicting issues. Following is my evaluation of how the Selected Alternative responds to each issue or concern (Planning Problems).

1. **How Much Timber Should the Forest Produce?**

The lands of the Siskiyou National Forest have demonstrated their capacity to produce timber. Timber supply is critical to the communities of southwest Oregon The amount of timber supplied by the Forest has been and will continue to be an important part of the economic picture. Timber production also contributes to the National economy, generates receipts to Oregon counties, and contributes to the overall economic health of the Nation The Selected Alternative, with an ASQ of 28.7 MMCF (including salvage), achieves an appropriate and realistic balance between protection of the land and resources and the economic needs of the communities and the Nation.

Timber management is intertwined with almost every other issue. While some uses are compatible with timber production, others such as primitive recreation are not. In many places it is necessary to constrain timber harvests to protect other values such as fish habitat or scenic vistas. It is a difficult judgement that I must make, but I have examined the alternatives and determined that Alternative S, as modified, achieves the best balance between preservation and environmental protection at one end of the scale, and development at the other.

The Selected Alternative takes all appropriate measures to mitigate the effects of other resource allocations and prescription constraints on the timber resource. Land allocations that preclude timber management are carefully evaluated to minimize the effects on ASQ For Example, Designated Wildlife Habitat areas in mature and old-growth forest stands are located first in areas not available for timber management such as Wilderness and Wild Rivers; then additional acres needed are located in areas not suitable for timber management; areas that would otherwise have reduced yields are taken next; finally, only areas that can not be satisfied by one of these low tradeoff categories are taken out of the General Forest area. Allocations to Backcountry Recreation are also carefully designed with consideration given to the suitability of the lands for timber management, and the economic and operational implications associated with timber management of each specific area. Backcountry Recreation allocations are made primarily in areas where Semi-primitive recreation opportunities exist, and where a low proportion of land would be suitable for timber management. Frequently, high economic and environmental costs of harvesting in the these areas make them less desirable for timber management than other parts of the Forest.

The Selected Alternative also mitigates the effects on the timber resource by using management prescriptions designed to protect critical resource values while still providing for timber harvests, though at reduced levels. Prescriptions for Retention visual quality corridors and riparian area management are examples where this is done The riparian areas of the Siskiyou are some of the most productive sites on the Forest Riparian management prescriptions are designed to allow multiple uses, including timber management, to occur to the extent practical in light of the over-riding need to protect the soil, water, and fisheries resources

The ASQ of the Selected Alternative is based on the use of intensive timber management practices to culture stands for wood products in those areas with programmed timber harvest. Practices to be applied where applicable include: reforestation through planting and natural processes, release as consistent with the FEIS for Managing Competing and Unwanted Vegetation, precommercial thinning, commercial thinning, and fertilization. The management prescriptions provide for producing a high yield of harvestable wood consistent with the multiple-use goals and objectives associated with each Management Area. The use of intensive management practices allows society to receive the most from the productive capacity of the Forest in the form of both wood products and other resource uses and benefits.

The ASQ calculations include the use of fertilization in managed stands to increase the yield of wood products This program accounts for 0.8 MMCF (approximately 4 MMBF) of the ASQ. The increases

projected are supported by field trials on the Siskiyou using comparisons of treated and untreated stands. The rationale for the adoption of intensive timber management practices above also applies to fertilization. The availability of fertilizer has been of some concern; however, there is no shortage at the current time and if at some future time the program can not be accomplished, the monitoring plan will trigger a re-evaluation and recomputation of ASQ.

The Selected Alternative provides for the sale of timber on a non-declining flow schedule. I have decided not to depart from non-declining yield in part because of recent timber supply studies which indicate that the availability of timber will not improve for the next few decades. Accelerating the harvest now could contribute to an even greater shortfall in the future, in addition to making it more difficult to produce the other resource benefits desired from the Forest.

2. **How Much Old-Growth Forest Should be Preserved?**

It is important to have old growth as part of a diverse and healthy forest if the myriad of benefits the National Forest is capable of producing is to be realized. Old growth provides habitat critical for certain species of wildlife, contributes to recreational experiences through the aesthetic quality of large old trees and forests, and constitutes an important element in the natural ecology of the Forest. The protection of and management for old growth directly competes with the need to produce timber. The decisions to manage areas for old growth are carefully weighed against the impacts on the timber resource. In my judgement, the proper balance is achieved in the Selected Alternative.

The design of the Selected Alternative results in 174,293 acres having mature and old-growth characteristics being reserved in Management Areas 1-9 with no programmed timber harvest. Another 5,444 acres with mature and old-growth characteristics are retained on lands unsuitable for timber production scattered within Management Areas which provide timber opportunities. In addition, Class I and II rivers and larger streams are considered "managed" old-growth stands and will retain old-growth characteristics over time. Approximately 320,000 acres will exhibit old-growth characteristics by the end first decade; an estimated 235,000 acres will remain by the end of the fifth decade.

Many of the old-growth acres reserved are in areas that would not be programmed for harvest because of some other resource values. Some areas are allocated to management specifically to protect or foster the perpetuation of the old-growth stage. Designated habitat for mature and old-growth associated wildlife is the most significant of these with 50,287 acres reserved in this category. Special groves of old-growth, particularly redwood, have also been set aside to preserve some unique and magnificent examples for recreational and aesthetic enjoyment. These old-growth groves total 1,321 acres.

The inventory information available for the Forest was not developed to specifically identify old growth. Available data on the vegetation condition has been used to assess the location and extent of old growth on the Forest. This data does not have the resolution to stratify stands with old growth characteristics from other mature stands. This results in some acres classed as old growth that do not exhibit old-growth characteristics. I am fully aware of this aspect of the analysis. I also recognize that there are inclusions within the mature and old-growth wildlife habitat that do not exhibit old-growth characteristics. These limitations in the data do not cloud the decisions made here. The areas identified for mature and old-growth wildlife habitat are predominately old growth; small inclusions of other classes do not render them unsuitable as old-growth wildlife habitat. The areas identified for management to preserve unique stands for recreational and aesthetic values are not identified from inventory data. During implementation of the Forest Plan, site-specific project inventory and field reconnaissance has and will continue to identify unique stands of trees with old-growth characteristics. Relative to the wide-scale ecology and biological diversity considerations, significant acreage in older age classes will be in reserved areas distributed around the Forest.

It is important to perpetuate stands in the old-growth stage distributed around the Forest to create and maintain biological diversity. The Selected Alternative has the balance of allocations reserving old growth which is most appropriate for the Siskiyou. The variation in size and spatial distribution is appropriate with large blocks reserved in the Wildernesses and Backcountry Recreation allocations and smaller, yet substantial, blocks distributed across the Forest in Designated Wildlife Habitat, RNA's, Botanical Areas, and Wild Rivers. Supplemental Resource areas along the major streams and Class I and Class II rivers and streams also significantly contribute by maintaining corridors of old growth through the General Forest.

As noted, several small areas of very special groves of old growth that are readily accessible for the enjoyment by recreationists have been assigned to Botanical Areas. These comprise 1,321 acres, and represent little impact on the Forest's potential to produce timber. The most significant of these areas are the 720 acres of redwood groves. The Siskiyou National Forest contains the northern-most natural redwood stands and few acres of old-growth remain It is important to retain the significant remaining old-growth stands at the fringe of the species range to avoid losing the diversity they contribute. (Less significant stands and younger age classes of Redwood, particularly those intermixed with other species, will continue to be managed as part of the Forest's General Forest land base.)

3. **How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?**

The Siskiyou National Forest contains extremely valuable salmon and steelhead habitat. The commercial fishing industry is very important to the coastal communities The social and economic value provided by sport fishing is also very important. It is critical to maintain the fisheries resource and manage the other resources in a manner that does not degrade the habitat. In some cases this means foregoing or curtailing opportunities for timber production.

Fish habitat will be improved through land allocations that minimize soil disturbance and reduce summer water temperatures Watershed conditions will be maintained in pristine areas and improved in areas presently degraded. Of the total riparian habitat, approximately 102,803 acres will be afforded complete protection by prohibiting site-disturbing activity Much of this area is included in allocations such as Wilderness or Wild River, however some areas not overlapped by such allocations deserve special management to assure that fish and watershed values are not degraded. The Selected Alternative allocates 26,921 acres of these critical inner-gorge areas along streams and rivers with high fish values to the Supplemental Resource Management Area. These inner gorge environments are generally steep and often contain large areas of unstable slopes where potential for risk of impacts associated with activities would be high. The values along these major streams for recreation, wildlife habitat and protection of fish habitat and riparian ecosystems are not quantifiable. In my judgement, the inherent values of these resources exceed the potential value that could be derived if these riparian corridors were allocated to management that includes timber harvest.

Riparian areas intermingled with Management Areas which provide timber harvest opportunities will be managed under either Riparian Prescription B or C These prescriptions and their associated effects are viewed on a basin-wide scale and provide standards to guide the management of activities within the riparian areas of each specific Planning Basin. Site-specific prescriptions will be developed in project level planning. The direction communicated through Riparian Prescriptions B and C establishes the upper limits for allowable change within the riparian environment; neither prescription requires that activities, such as timber harvest, take place if fish habitat and water quality cannot be maintained.

Riparian Prescriptions B and C vary in the degree of modification of the riparian environment allowed Prescription B continues current direction and is designed to maintain watershed and fisheries values. Prescription C allows less modification of the riparian environment and, over time, will result in net increases in fish habitat capability as regrowth of riparian vegetation exceeds the rate of vegetation removal. The *selection of a riparian prescription for each Planning Basin is influenced by several factors specific to each*

basin. These factors include the fisheries values, risk to fish habitat as influenced by soil landtypes and management activities, the condition of the entire drainage relative to past, present, and relatively foreseeable practices and events, and public and agency input

The seven Planning Basins assigned to Riparian Prescription C are generally the coastal streams with high fish values and steep stream banks where greater restriction of activities will have the greatest payoff in terms of improved fish production. Another reason for tighter restrictions in some basins is the treatment of riparian areas on other ownerships within the watersheds. This activity of others has substantially increased the potential for adverse cumulative impacts. This is a major factor in both Lobster and Pistol Planning Basins. Silver and Indigo Creeks do not fit the same rationale as the other Prescription C basins The Silver and Indigo Planning Basins are allocated to the more restrictive prescription for this planning period to facilitate recovery of the riparian and terrestrial ecosystems impacted by the Silver Fire of 1987.

The Winchuck River is a coastal stream with high fisheries value not allocated to Prescription C. There are two reasons why it is different. First, the Winchuck Planning Basin is predominantly National Forest land and lacks the same potential for cumulative impacts associated with practices on other ownerships Second, the geology poses less risk and thus better opportunities to utilize the timber resources of the riparian areas without adversely affecting the other riparian and watershed values

A high level of capital investment ($581,000 per year) for fish habitat and watershed improvement is scheduled in the Selected Alternative. An annual investment of $350,000 will be used for fish habitat improvement structures. No substantial tradeoffs in terms of other resources are associated with this program. The costs are justified by the improvements in habitat that can be attained and the subsequent economic values associated with increased fish production I am aware that not all instream structures will be effective, however success of the program does not depend on all of the structures functioning as envisioned. We will continue to improve the design and provide corrective maintenance of instream structures to achieve a high rate of success. I would also like to dispel the misconception that the Forest Plan will allow for degradation of fish habitat through adverse impacts of activities, and then plan to compensate for this degradation by assuming large increases in habitat capability through capital investments. This is simply not the case. Standards and Guidelines are provided to protect fish habitat through controls placed on location, design, and implementation of management activities (e.g , timber harvest, road construction). Additional road-related capital investments will provide for both the proper functioning of road crossings of streams in respect to fish passage with improvement in habitat capability over the current level. Some restoration of habitat degraded from past activity will occur, but this work will be evaluated and implemented at the project level. Many of the structural improvements will be funded in association with timber sales

To avoid the risks of cumulative impacts that might occur as a result of road construction and timber harvest, it is essential that these activities be distributed over time and space. The analysis of the Interdisciplinary Team has resulted in a process for modeling which limits by decade the acres of timber harvest within each specific Planning Basin (i.e., the timber harvest dispersion constraints). The factors used in modeling Alternative S are highly specific to each Planning Basin and are based on the sensitivity of the watersheds, impacts of past practices and scheduled activities, impacts of past and expected practices on adjacent ownerships, and the impacts of the 1987 fires. These constraints are carefully designed to assure that dispersion of activities can be achieved with minimal impact on timber outputs. Implementation of the Forest Plan will be monitored to assure that levels of activity remain within these levels. If project scheduling results in the prescribed level being exceeded in any Planning Basin, a cumulative effects analysis will be completed specific to that basin prior to implementation of the activities. These precautions are necessary to assure that watersheds will not be adversely affected by cumulative impacts.

4 **How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?**

When the scoping was done for the Forest Plan EIS, the Rogue and Illinois Rivers were in the National Wild and Scenic River System, the Chetco and North Fork Smith Rivers were inventoried for possible inclusion, and the other rivers on the Forest not evaluated for eligibility. The alternatives in the DEIS were designed to evaluate the options for allocations or recommendations of the two inventoried rivers, and the options for management of lands adjacent to the both the inventoried and designated Wild and Scenic River river corridors In response to the DEIS, commentors suggested that other rivers on the Siskiyou should also be reevaluated for possible inclusion into the Wild and Scenic River System as the original determination of eligibility was based on criteria that had since been revised. In July of 1988, the Elk, South Fork Coquille, South Fork Sixes, Pistol, South Fork Chetco, and Winchuck Rivers were evaluated for potential eligibility. Of these, only the Elk River was determined to contain "outstandingly remarkable values" related to its quality anadromous fishery, the Elk was added to the list for possible inclusion.

Shortly before the FEIS was to go to print, Congress passed the Omnibus Oregon Wild and Scenic River Act of 1988 The Elk, Chetco, and North Fork Smith were designated National Wild and Scenic Rivers, precluding the need for a decision or recommendation for these rivers. Alternative S (and this Selected Alternative) include the corridors (1/4 mile either side) of both these new rivers and the existing corridors along the Rogue and Illinois Rivers in the appropriate Management Areas for the classified Wild, Scenic, and Recreation segments.

In response to public comments, several sections of rivers were reassessed for Wild characteristics. Two sections were determined appropriate for classification as Wild River, but were not included in the Oregon Omnibus Act of 1988 They are: (1) the two-mile section of the North Fork Smith River from Baldface Creek to the California Border and (2) the two-mile section of the Chetco River from Boulder Creek to Mislatnah Creek. These inventoried sections will be managed as Wild until a determination is made in future River Management Plans.

Several other land allocations coincident to Wild and Scenic River assignments complement management of the Wild and Scenic River values. Most compatible are the Supplemental Resource and Backcountry Recreation Management Areas. In key areas, these allocations provide additional protection of water quality, fish habitat, and recreational settings under which the five rivers were Nationally designated.

Allocation of Visual Quality Objectives (VQO's) for the viewsheds in the canyons surrounding the Wild and Scenic River corridors also contributes to the quality of the recreational setting. In examining the tradeoffs associated with such allocations and evaluating the options, the fact that a river is in the National Wild and Scenic River System does not weigh heavy in the decisions for surrounding lands. The decisions are driven by the demand for, and character of, the recreation opportunities of the specific area. The Rogue and Illinois Rivers offer exceptional recreation opportunities. The viewsheds of these rivers are allocated to the inventoried or higher VQO's to protect the scenic quality and recreational experience.

The scenic quality of the Rogue River is very important to the many recreational users and for the local tourist industry. The allocation of the foreground seen area to the Supplemental Resource Management Area with no programmed timber harvest is done to assure the protection of the scenic quality for these recreation opportunities and the established tourist industry in this area. It has been suggested that the middleground seen area also be allocated to the more restrictive Retention category instead of the inventoried VQO of Partial Retention. In my judgement, the Partial Retention allocation will adequately provide for protection of the scenic quality in this area. The added assurance that the more restrictive allocation provides does not justify the opportunity cost in lost timber production. Specific monitoring in this area will provide information to determine if Partial Retention management adequately satisfies the need for scenic quality associated with the recreation use and, if warranted, provide the basis for adjustment.

5. **How Should Sensitive Plant Resources be Managed?**

The Siskiyou National Forest is one of the most floristically diverse areas in the Nation. The wide range of geology and climate, coupled with the unique pattern of development throughout time, have resulted in large numbers of species inhabiting a relatively small area, many of which are endemic to the Forest and surrounding area Habitat for many of these species is protected in allocations such as Wilderness. Numerous habitat areas are distributed across many other parts of Forest. The Interdisciplinary Team has carefully evaluated each area in light of the timber, mineral, and plant resources, as well as consideration of public comments. A number of areas with unique plant habitat or outstanding examples of plant communities exist where their intrinsic values exceed that which could be derived by developing these areas for commodity goods. The Selected Alternative allocates these special places as Botanical Areas. Nineteen new Botanical Areas are allocated which add 15,157 acres to the inventory of 4,475 acres in the three existing Botanical Areas.

The Selected Alternative also recommends that four new Research Natural Areas (RNA's) totalling 2,651 acres be added to the three existing RNA's. These areas are needed to fill cells in a National network oriented to research and educational purposes. It is important to preserve physical and biological units where natural processes are maintained to provide a base for comparison with lands under different types of management. The benefits for education and research, and the preservation of gene pools for typical as well as rare plants and animals, has greater value than that which might be derived from development of these areas.

The distribution of RNA's and Botanical Areas across the Forest also significantly contributes to maintenance of biological diversity. Coupled with the Standards and Guidelines designed to protect the unique plant communities and habitats, these allocations serve to perpetuate the species and types across the range of natural variability, particularly those near the ends of the range which may be most sensitive to change. This is particularly important in its contribution to the resiliency of the forest, or the capacity of the forest to withstand and adapt to changing conditions.

There are many areas of sensitive plant habitat not included on the special allocations that preclude development activities. The sensitive plant resources in these areas will be managed under the Standards and Guidelines which require that an evaluation be done for any project where sensitive species are found, and that habitat be managed to maintain viable populations throughout their existing range. In most cases, projects can be designed or successfully mitigated to be compatible with perpetuating sensitive species and their habitat.

In my view, the Selected Alternative contains the best balance of allocations to preserve special habitats and emphasize protection of sensitive plants and their habitat throughout the Forest during project planning. The best examples and most unique habitats are allocated to Botanical Areas and RNA's. In other areas where plant resource values are lower and the opportunity costs in terms of timber would be higher, the sensitive plant resources will fully considered and managed according to the Standards and Guidelines in project planning, implementation, and monitoring.

6. **How, and to What Extent, Should Forest Scenic Values be Protected through Visual Resource Management?**

The Forest contains some fine scenery, particularly along the rivers and in the higher country. It also contains many acres of productive timber land which lack quality scenery. These areas receive only light recreation and hunting use In my judgement, it is most appropriate to manage the higher use recreation areas and special places on the Forest to meet the Visual Quality Objectives (VQO's) of Retention and Partial Retention However, there are many areas of the Forest where these allocations are not warranted in view of their opportunity costs and limited recreation use. The Selected Alternative contains a good balance of visual allocations with Retention and Partial Retention on the highly used travel routes such as the Oregon Caves and Redwood Highways, and the Rogue and Illinois Rivers. Partial Retention is assigned to the less heavily used, but popular recreation routes. The remainder of the Forest in General Forest is managed with less emphasis on visual quality.

Some specific areas have been the subject of considerable debate and are worthy of mention here. The Bear Camp Road is used by numerous recreationists travelling back from raft trips down the Rogue River; it is developing into a major cross-Forest travel route The west portion of this road leaving the river area affords the traveler some vistas of natural appearing landscapes; as the east end of the road is approached, there are many more roads and activities evident; then the route leaves the National Forest and disturbance to the landscape is predominate. In my judgement, the allocation of Retention along the western portion of this route with a transition to Partial Retention along the eastern portion approaching the Forest boundary is the most appropriate management scheme.

The rivers are the focus of many of the recreation opportunities on this Forest Visual management in the canyons surrounding the Rogue and Illinois Rivers was included with the discussion of Wild and Scenic Rivers above. Other rivers do not receive nearly the degree of river traffic, but roads along these river corridors are frequently major routes for recreationists. The road along the South Fork Coquille River and up through Agness Pass over to the Rogue River at Illahe has been suggested for Retention visual management This road traverses mixed ownership along the South Fork Coquille River which greatly limits our ability to control the visual quality along the route. Considering the opportunity cost of the Retention allocation, the relatively light recreational use, and our limited ability to control the visual quality along this route, the assignment of Partial Retention is most appropriate in my judgement.

The route along the Chetco River which continues on to access the western edge of the Kalmiopsis Wilderness will have Retention in the foreground seen area along the route. Partial Retention in selected locations complements the Retention foreground allocation for much of the viewshed based on heavier river recreation use in the lower reaches of the Chetco, and user sensitivity relative to the Wilderness access and other key scenic features along these routes.

Many small areas with special values for recreation and scenic views are allocated to combinations of Retention and Partial Retention depending on the quality of the view and the use the area receives. These areas include such locations as Bolan Lake, Game Lake, and Wheeler Creek where, in my judgement, the values for recreation and scenic quality outweigh the opportunity costs of the visual allocations. Areas not allocated to Retention or Partial Retention management will still be required to meet minimum levels of visual quality as specified by the Standards and Guidelines and management area prescriptions.

7. **How Should Wildlife Habitats on the Forest be Managed?**

Various species of wildlife have differing habitat requirements. The requirements of different species often conflict; what is good for one may be detrimental to another. Some species need old-growth forest, others require openings. Some need snags or down logs, some need seclusion. Several species, such as deer and elk, find optimum conditions where there are both openings for forage and forest stands for protection and hiding cover. Two basic objectives drive my approach to the wildlife question. One is to provide habitat

to maintain viable populations of all species across their current range on the Forest, the other is to maintain an appropriate balance and diversity of habitat across the Forest for all species considering the opportunity costs of special allocations While the Forest Service manages the habitat on the National Forest, it should be noted that the states of Oregon and California are responsible for management of the wildlife populations (e g., setting of hunting seasons, bag limits, etc.).

Most species do not need extraordinary attention to maintain viable populations across the Forest. Special emphasis must be given to species requiring mature or old-growth conifer habitat and those that require snags for nesting or foraging. Habitat will be maintained for the spotted owl, pine marten, and pileated woodpecker through Designated Wildlife Habitat areas. The management requirements for spotted owl are consistent with direction contained in the Final Supplement for an Amendment to the Pacific Northwest Regional Guide (USDA 1988). The habitat network designed for the mature and old-growth indicator species will provide the necessary habitat Forest-wide. Coincident allocations such as Supplemental Resource, Backcountry Recreation, and existing Wilderness and Wild Rivers also provide habitat for these and associated species in addition to the network designed to meet Management Requirements With this spatial distribution of mature and old-growth habitat areas of various sizes, it is my judgement that additional allocations are not warranted given the associated opportunity costs.

The effects of management activities on species dependent on snags or down woody material for breeding or foraging will be mitigated by the application of Standards and Guidelines designed to provide these materials across the Forest. Areas that remain undeveloped will continue to contain their natural levels of snags and down trees. Areas managed for commodity production will have snags and down trees capable of sustaining populations of woodpeckers and other dependant species, even though at somewhat less than the maximum population densities for any given land area. In my judgement, this is the appropriate management strategy, increasing the requirement for woodpecker habitat to near the maximum density is not warranted, and decreasing much below the 60 percent level of the Selected Alternative would unnecessarily increase the risk that some species might not be well distributed across areas capable of supporting habitat.

Habitat for deer and elk is largely a function of timber harvest and disturbances such as fire. These disturbances create openings in the forest canopy and stimulate the growth of forage plants, but also reduce the available cover. The best balance through time will be achieved by distributing harvest activities across the Forest. The Selected Alternative provides the framework for this through dispersion of activities to minimize the potential for cumulative watershed effects. The primary variable in the alternatives with potential to increase or decrease the habitat capability for deer and elk is the amount of the land base under timber management. Increasing the areas allocated to timber production beyond that of the Selected Alternative for the purpose of producing big game forage is not warranted.

The Selected Alternative also allocates numerous small areas to be managed as Special Wildlife Sites. Many of these areas have special value as unique habitat niches or high producers of mast or other forage, but the greatest value in allocation of these sites is their contribution to biological diversity. These areas, in general, have minor opportunity costs since many are either unsuitable for timber production, contain low volume, or are in locations difficult to access. The land allocations of the Selected Alternative, which include large blocks of undeveloped areas in Wilderness and various size areas in Wild Rivers, RNA's, Botanical Areas, Designated Wildlife Habitat, Backcountry Recreation, Supplemental Resource, and the Special Wildlife Sites, combine to create tremendous diversity across the forest and, in my judgement, provide the best balance of wildlife habitat considering the other resource values involved.

8. **How Will Management Direction Affect Recreation Opportunities In the Wilderness and Unroaded Areas?**

Opinions on management of roadless areas remain strongly polarized. Many people commenting on the DEIS support management of the roadless areas in an undeveloped state. Such allocations, however, have

significant opportunity costs in terms of timber production that many others feel are unacceptable This controversy has been hotly contested for decades, and unfortunately is no less controversial today. The management of these areas over the next decade is a critical decision and one that I have weighed carefully for some time.

Factors of this decision include the values associated with managing any particular area to maintain the roadless character such as: Primitive and Semi-primitive recreation opportunities offered, uniqueness of the area, and contribution to complementary allocations. The demand for Primitive recreation is expected to exceed the capacity of the Forest within the next few decades This is of particular interest relative to the cross-Forest trails in the North Kalmiopsis area which provide recreation experiences where substitute opportunities rarely exist. Some of the unroaded areas also have the potential to provide Semi-primitive Motorized recreation opportunities on existing trails and primitive roads that were constructed for mining access in the past There are some unroaded areas adjacent to Wild segments of the river corridors where the recreation experiences are high. Others in the Siskiyou high country offer their own special qualities. Unroaded areas also have the potential to contribute to other resource values such as increased old-growth protection, and reduced risks to watershed and fisheries.

The consideration of opportunity costs to timber production are no less important. These areas contain significant acreage of high volume timber stands. However, many of the areas that remain roadless tend to be more difficult to access and manage than the roaded portions of the Forest. Some have very high percentages of their acreage classed as unsuitable for timber production. The opportunity costs to timber necessarily includes consideration of the suitability and operability of the area in question. This is not to say that decisions will be based on management difficulty, but rather that the tradeoffs are taken in a somewhat different light where the expenses associated with management and operation are high. This is further compounded where the potential for environmental risks are also high due to steep slopes and unstable soils.

North Kalmiopsis. The inventoried North Kalmiopsis Roadless Area has been the focus of controversy. This was heightened when a large part of the area was impacted by the large wildfire in 1987. The fire-killed mature and old-growth trees equated to substantial volumes of timber being subjected to either rapid salvage or decay. Under the Silver Fire Recovery Project, the resource situation was evaluated and conditions within the fire area reinventoried. Much of the fire area was within this unroaded area. The intensive field investigation of this heretofore difficult-to-access unroaded area revealed significantly more area of both highly sensitive soils and lands unsuitable for timber management. In addition, the project analysis indicated that the locations of the Illinois River Trail (along Bald Mountain Ridge) and the Hobson Horn-Silver Peak Trail to be the only feasible locations for roads to access fire killed timber. These irreplaceable trail systems are valuable east-west, cross Forest trails offering various recreational opportunities for hiking and other user experiences.

These findings, plus the marginal economics of timber salvage associated with extensive road construction, led to the Forest Supervisor's selection of Alternative I-Modified in the Silver Fire Recovery Project Record of Decision and accompanying FEIS (1988). Much of the suitable area is now accessed through the Silver Fire salvage timber sales and is currently being salvage logged, much of it by helicopter. This portion will remain in General Forest and be managed for timber production as well as other uses Those areas not selected for access in the Silver Fire Recovery Project have generally higher values for recreation and high percentages of unsuitable land making them more logical candidates for other allocations.

Some of these are clearer choices than others. The area in the Silver Creek canyon around Silver Falls contains little land suitable for timber production and has recreation opportunities associated with Silver Falls and trails in that locale. The areas near the Illinois River in the lower Silver Creek drainage and across the river in Horse Sign and Lawson Creeks contribute to the quality of an unblemished recreational setting of the Wild segment of the Illinois River. Again, much of this land has a high percentage of unsuitable land.

In my judgement, the values associated with the recreation and other noncommodity uses in these areas exceed the potential benefits for timber production, particularly in view of the environmental risks that would accompany development. Therefore, these specific areas are allocated to the Backcountry Recreation Management Area.

Management for the area on the north face of Bald Mountain is not quite as clear. There is still considerable controversy as to the suitability and operability of these areas For this reason, I have modified Alternative S of the FEIS to change this area from the Backcountry Recreation Management Area to an "Administrative Study" overlay in General Forest. The purpose of the administrative study is to allow time for recovery from the effects of the Silver Fire, and to refine and verify the suitability and operability of the area. In this interim period, this area will continue to provide Primitive and Semi-primitive recreation opportunities, with the environmental consequences being the same as those projected for Alternative S of the FEIS. No timber harvest is programmed for this area during the planning period. These modifications of Alternative S, including the areas allocated to Backcountry Recreation and Silver Fire Administrative Study, are shown on the map titled "Land and Resource Management Plan."

North Kalmiopsis and South Kalmiopsis along Illinois River. The area along the Illinois River east of the Kalmiopsis Wilderness is noteworthy. This is beautiful river country with ample opportunities for unique recreation experiences. It is one of the prime areas identified to provide recreation opportunities in conjunction with the economic comeback strategy of the southwestern Oregon counties which emphasizes tourism. Parts of the North Kalmiopsis and South Kalmiopsis Roadless Areas are in this river canyon and border the Kalmiopsis Wilderness. Much of this area contains serpentine soils that are very low in productivity; much is unsuitable for timber production. In my judgement, the areas identified in Alternative S that are adjacent to the river corridor and are visible from both the river and the road from Selma have far greater value for recreation and watershed protection than the opportunity costs to timber production. They are appropriately allocated to the Backcountry Recreation Management Area In the Selected Alternative, I have adjusted the boundary in what is described as the Fall Backcountry Recreation area. In the vicinity of MaCaleb Ranch, an area within the lower reach of Fall Creek has been placed into General Forest This area is screened from view from the river and road by topographic features.

North Kalmiopsis along the Chetco River. There is some unroaded area on the west side of the Kalmiopsis Wilderness along the Chetco River that has high value for recreation and for contributing to maintenance of the outstanding qualities of the classified and allocated Wild River segment of the Chetco Wild and Scenic River. Road access and logging feasibility has been examined in depth for this area within the last decade. Opportunities for efficient and environmentally acceptable projects within this Mislatnah area are quite limited and strongly cost deficit. The area has several access trail routes into both the Wilderness and established Big Craggies Botanical Area. Designated Wildlife Habitat and Special Wildlife Sites cover the landscape above the Wild and Scenic River corridor. It is my judgement that the composite of these values outweigh the opportunity costs and associated potential adverse impacts if the area was to be further developed. The complementary assignment of the balance of this area to Backcountry Recreation is appropriate.

South Kalmiopsis. This is a large area with only primitive roads that were constructed for old mining operations. Much of the area exhibits soil conditions where chemical imbalances inhibit plant growth. A large portion of this serpentine area is classed as unsuitable for timber production. Vegetation tends to be sparse with widely scattered conifers, although there are some isolated stands of trees suitable for timber management. Parts of the area have special values represented in the unique and rare plant resources; these sites have been allocated accordingly. Due to the more open nature and gentler topography, both motorized and non-motorized recreation use exists. Access, both on existing trails and cross country travel, is far less restricted by vegetation than most areas on the Forest. Scenic quality is unusual and outstanding in its own right; it is far different than what may normally be expected in the National Forest System

Alternative S would have allocated a large portion of the area to the Backcountry Recreation Management Area to be managed for Semi-primitive Motorized recreation. I have changed this to General Forest with an Administrative Study overlay. For this planning period, this will allow Forest personnel and others to evaluate the feasibility of timber management, including uneven-aged management, in this area. This does not preclude use of the area for Semi-primitive Motorized recreation, but proposes that the administrative studies will help determine if some low level of timber management is compatible with maintaining the the recreation opportunities

Packsaddle The area consists of the lower Cedar Creek watershed immediately abutting the Wild River segment of the Smith Wild and Scenic River corridor. The area has virtually no land suitable for timber production, but does have the potential for minerals associated with the serpentinite-peridotite geology. Additionally, unique and rare plants are frequent; the southern boundary of the recommended Lemmingsworth RNA forms the common boundary for this area. My decision, based on the intrinsic values within the area and lack of conflicting uses, is to allocate this land to Backcountry Recreation. Coupled with the Wild River corridor and Lemmingsworth RNA, the area and its environs should enhance the river recreation and botanical values present

Siskiyou and Kangaroo. These areas contain spectacular high country associated with the Siskiyou Mountains Rock bluffs and glades, and open vistas across high ridges dotted with numerous small mountain peaks contributed to one of the finer recreational settings in southern Oregon and northern California. This high divide country is partly subalpine, and provides a perfect opportunity for continued recreation emphasis Local people utilize the area for a day's adventure and relief from the hot valley; visitors to the adjacent Oregon Caves National Monument frequently hike the trail systems, including the National Recreation Trail. Several Botanical areas and a recommended RNA occupy this cooler environment These selected portions of the unroaded areas contain only small areas of land suitable for timber production; reforestation success at these high elevations in the Siskiyou Mountains have proved difficult. The area has only minor tradeoffs associated with other commodity resources such as grazing and minerals

In my judgement, these areas have significant scenic and recreation values and are appropriately allocated to the Backcountry Recreation Management Area The Forest Supervisor and District Ranger have carefully located the boundary of the Backcountry Recreation area in both the inventoried Kangaroo and Siskiyou Roadless Areas to assure that lands with a good reforestation and timber production potential remain in the timber base while lands with less opportunity cost and higher recreation and scenic value are included in the Backcountry Recreation area and other complementary allocations

Windy Valley. This unroaded valley is an anomaly for the Siskiyou in that the terrain is moderately gentle and a large meadow exists within the bowl of the small headwater area. While much of the land is suitable for timber production, the Snow Camp Botanical Area caps the northern border, Designated Wildlife Habitat covers a good share of the basin, and Special Wildlife Sites (such as the meadow) inhabit non-forested parts. The recreation attributes are largely unknown and not frequented by visitors from afar However, it is well used by local people for hunting and day hikes. Windy Valley was prescribed to special management in the past for the above values, and is well supported by residents of the adjacent communities. Therefore I see it appropriate to assign this area to Backcountry Recreation.

Grassy Knob and Copper Mountain Alternative S would have allocated parts of these areas to the Backcountry Recreation Management Area. Due to their relatively small size, isolation from other unroaded and unique areas, character of the terrain, and limited recreation opportunities, they do not match other Backcountry Recreation assignments. However, they do contribute significantly to the protection of the watershed values and extremely fine salmon and steelhead fish habitat of the Sixes and Elk Rivers. For these reasons, I have changed the allocation of the two areas proposed for Backcountry Recreation to Supplemental Resource Management Area in the Selected Alternative.

Other Roadless Areas. I have carefully considered the allocation and management of each of the inventoried roadless areas on the Siskiyou National Forest Appendix C of the FEIS provides me with an indepth description and analysis of the specific area attributes associated with management under a roaded or unroaded scenario. The areas not specifically discussed above have been allocated predominately to management areas which include programmed timber harvest as part of the multiple-use prescription, although many areas with special value for purposes such as wildlife habitat, sensitive plant habitat, or watershed and fisheries protection have been allocated to those uses. Areas with significant timber values have been kept in the timber base unless protection and enhancement of other values to be gained from other allocations outweigh the opportunity cost to timber.

Some areas that have poor accessibility and poor operability have been kept in the General Forest Management Area under the Extensive Management prescription with a slightly reduced yield. This provides for utilization of the timber opportunities without requiring roading for intensive management and investments that would not be practical.

The range of allocations in the Selected Alternative is tremendously varied and provides a strong array of multiple-resource opportunities. The inventoried roadless areas have been analyzed in-depth, received considerable public involvement and review, and the specific areas accordingly evaluated and allocated to a mix of Backcountry Recreation, General Forest-Administrative Study, General Forest-Extensive Management, other special areas or unique sites, or management with programmed timber outputs In my judgement, these Management Area allocations and accompanying prescriptions and Standards and Guidelines provides the best balance of resource uses for the inventoried roadless areas

9. **How Should Mineral Resources of the Forest be Developed in Coordination With the Management of Other Resources?**

The Siskiyou National Forest contains deposits of a number of minerals of commercial value, including significant amounts of the strategic minerals such as nickel, cobalt, and chrome. It is essential that the mineralized areas be keep open to exploration and development for the values they may contribute to the communities and Nation in the future. At the same time, it is important to have assurances that other resources are managed to protect associated values. Some areas have competing resource values that cannot reasonably be protected through mineral development and are withdrawn from mineral entry. Current withdrawn areas total approximately one-fourth (267,000 acres) of the Forest.

Implementation of the Selected Alternative will facilitate mineral exploration and development by retaining nearly three-fourths of the Forest in an accessible category. Approximately six percent will have high restrictions to protect other values; these restrictions may effectively preclude some mining opportunities. However, these higher level restrictions are only applied to a very limited portion of the Forest, and on even less area with a high potential for mineral development.

I fully recognize the relative importance of the mineralized areas of the Siskiyou to the State and Nation. I also realize and appreciate the role of those in the mineral exploration and development industry. In my judgement, the Selected Alternative provides the appropriate balance associated with; keeping the largest part of the Forest open for mineral activities, and yet providing protection for other resources commensurate with the values involved.

RESPONSE TO PUBLIC COMMENTS

The Forest received extensive comments from the public, other agencies, and the Governor of Oregon. Numerous suggestions for improvement were incorporated throughout the analysis, various documents, design of the FEIS Preferred Alternative S, and Selected Alternative. The Forest continued to work with individuals, groups (timber industry, environmental and other interest groups), and the State of Oregon representatives to further refine elements. We have a better product as a result of the excellent public

participation. My decision of the Selected Alternative is based on this valuable input as well as technical, resource, and legal factors The following discussion highlights some of the changes made in the design of Alternative S and the Selected Alternative as a result of the public response (See Appendix K of the FEIS for discussion of comments made to the Draft documents and the Forest Service response to those comments.)

Numerous comments were received pointing out the high values of the Forest's fishery resource which is supported by the water resource and stream habitat, and the social and economic importance of this resource to local communities. Alternative S increases the allocation of high fish value Planning Basins from one to seven (of the 19 total basins) to be managed under the Riparian Prescription C, affording additional protection to the stream shade and a net improvement in fish habitat capability. Allocations to Supplemental Resource areas were also increased along major streams in Alternative S and again through the Selected Alternative to give additional stream protection.

Dispersion of harvest units is modeled through the use of basin constraints. Harvest within each Planning Basin on the Forest will be limited to a percentage of the area of each basin. These timber harvest dispersion constraints were criticized as imposing an unwarranted opportunity cost to timber. Many respondents to the DEIS felt that the computer modeling used in calculating basin constraints could be improved. In response to these comments, the model was refined to correct an inconsistency in the analysis and adjust the individual basin constraints to be more specific to individual basins in Alternative S than in Alternative K.

Fertilization was not considered in the alternatives developed in the DEIS. Many respondents felt that this ignored a feasible and desirable opportunity. In response to these comments, the fertilization was included as one of the management practices available to the FORPLAN model in the design of Alternative S. Fertilization accounts for 0 8 MMCF of the ASQ for the Selected Alternative.

There is tremendous support for maintaining more of the Forest in an undeveloped condition to provide Primitive and Semi-primitive recreation opportunities, as well as reserves of old-growth conifer forest and other values associated with large undeveloped areas Additionally, people are concerned that this not be a "preservation" category so the emphasis has been changed from "Custodial (Roadless)" to Backcountry Recreation A large increase in Backcountry Recreation areas was made in the design of Alternative S. This total amount was reduced in the Selected Alternative (as described in Chapters II and III of this Record of Decision). But there are still considerably more Backcountry Recreation areas in the Selected Alternative than was previously proposed in the Draft. To accommodate historic use described in public comments, specific Backcountry Recreation areas will be managed for Semi-primitive Motorized recreation to allow four-wheel drive and motorbike travel on primitive roads and trails existing in these areas.

Forest scenic values will be managed to complement high recreation use travel corridors and viewsheds. In response to public concern, several areas of Retention and Partial Retention that were not included in the Preferred Alternative in the DEIS have been added to Alternative S. These include the Bear Camp Road viewshed, a major Forest road that receives heavy recreational use

Comments received from the public and other agencies reflect a great deal of interest in tourism and recreation. The counties in southwestern Oregon have identified "tourism" as the focus for their strategy as part of the Oregon Comeback. In response, Alternative S programs higher levels of capital investments to complement the emphasis of State and local governments and private industry. In addition, some land allocations have been increased, such as the visual and Backcountry Recreation allocations mentioned above, that are complementary to this emphasis.

A number of people expressed concern about the appropriateness of intensive timber management and road development in some areas with very steep slopes and rocky soils Such areas were reassessed and are designated in Alternative S for "extensive" management. These areas are in within General Forest

Management Area, keeping them in the timber management base, but a less intensive management schedule and logging by helicopter or skyline without road development is planned. Others were interested in further refinement of suitability, the possibilities for uneven-age management, and fire-recovery. "Administrative study" areas are designed into the Selected Alternative for these purposes

There are many people interested in maintaining the biological diversity of the Forest and do more to protect diversity including the rich botanical resources. Biological diversity was highlighted in the documents, Forest-wide Standards and Guidelines were updated, and more consideration given diversity in the design of Alternative S. More Botanical Areas were allocated in Alternative S to give added protection to sensitive and rare plant habitat.

The Draft proposal studied, but did not recommend, designation of the Chetco or North Fork Smith Rivers for inclusion in the Wild and Scenic River system. Public comments on the DEIS greatly favored recommendation of these two rivers for designation. Additionally, many respondents felt that several other rivers should be included for study. The Oregon Omnibus Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers which is reflected in Alternative S.

Many people pointed out that the level of mineral restrictions proposed in the DEIS went beyond the intent of mining legislation. This issue was re-evaluated; the level of access restrictions was reduced, and no additional mineral withdrawn is proposed in Alternative S.

A number of technical suggestions were made to improve the the analysis. And many were incorporated, e.g., harvest dispersion constraints and the board foot to cubic foot ratio (see Appendix B in the FEIS for detailed discussion). These technical discussions have proven valuable for better analysis and will continue in the future. I recognize we will be in a continuing process of updating as better information and analysis is made.

Chapter IV - ALTERNATIVES

ALTERNATIVES ANALYZED IN THE FEIS

The FEIS displays 12 alternatives that provide a broad range of options. These options serve as a basis for identifying the alternative that best maximizes net public benefit (NPB) through responding to public issues. Each alternative emphasizes the resolution of one or more Planning Problems through a combination of land allocations and capital expenditures. The distribution of National Forest land to one of 14 Management Areas establishes management practices and activity schedules. These provide unique combinations of resource outputs, land uses, and environmental effects (For more information on the alternatives, see FEIS, Chapter II)

Following the evaluation of alternatives, I have identified a Selected Alternative for the Forest Plan Alternative S, as modified in this Record of Decision, is selected as the alternative that best maximizes NPB's while responding to the Planning Problems.

ALTERNATIVE NC - NO CHANGE

The "No Change" alternative has been developed as a no-action alternative representing current management plans. The purpose of Alternative No Change is to continue the levels of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1962 Timber Management Plan. This alternative does not comply with all provisions of NFMA, and could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law.

ALTERNATIVE A - CURRENT DIRECTION

This is the "no action" alternative required by the National Environmental Policy Act. It would continue the present course of action established in plans and policies formulated and approved prior to passage of the NFMA that are consistent with present laws and regulations Relatively high levels of timber production, combined with maintenance of inventoried Visual Quality Objectives and moderate levels of fish and wildlife, are emphasized in this alternative.

ALTERNATIVE A-Departure

Using the same land allocations and management direction as Alternative A, timber production is further emphasized through a harvest scheduling plan that departs from the policy of nondeclining yield. This maintains the current timber program for the next two decades. Average annual timber harvest levels in subsequent decades would decline.

ALTERNATIVE B-RPA

This alternative is designed to meet the RPA production targets displayed in the Regional Guide. Very high levels of timber production are emphasized through departures from nondeclining yield during the first two decades. Large capital expenditures in fisheries improvements are necessary to realize program objectives Big-game wildlife objectives are achieved using the forage that results from timber harvest activity.

ALTERNATIVE C

Timber management opportunities are emphasized in this alternative. It produces current levels of timber volume on a nondeclining yield basis. Under implementation of NFMA regulations, Alternative C has the highest amount of land selected as suitable for timber production, and the highest long-term sustained

yield (LTSY) Hunting and roaded recreation opportunities are enhanced as a result of the timber program Land allocations for other resource objectives are among the lowest of the alternatives considered.

ALTERNATIVE D

Goods and services with established market prices are emphasized in this alternative. Intensive timber production would utilize 98 percent of the land tentatively suitable for the production of timber A moderate increase in anadromous fish is achieved by applying prescriptions that provide additional stream protection.

ALTERNATIVE D1

This alternative is identical to Alternative D, except timber harvest rotation lengths would be shortened. The culmination of mean annual increment (CMAI) requirement would be relaxed to allow harvest of trees that are as much as twenty years younger than the normal rotation age of 100 years. Average annual timber harvest volumes would increase approximately 10 percent, relative to Alternative D.

ALTERNATIVE E

Aesthetic values of the Forest are emphasized in this alternative It promotes goods and services which do not necessarily have established market values. Land allocations reflect the subordinate role of timber production in this alternative. Land allocations that benefit old growth, anadromous fish, Wild and Scenic Rivers, sensitive plants, visual quality, and roadless recreation are among the highest of any alternative considered. Former RARE II areas, for example, would remain unroaded.

ALTERNATIVE G

This alternative is designed to promote the health and productivity of the Forest's water-related resources, particularly rivers and streams associated with the Illinois drainage. Alternative G preserves many existing unroaded areas It favors management governed by high Visual Quality Objectives to maintain the area's natural beauty and to accommodate recreation-oriented industries. Low to moderate levels of timber production are provided by land allocations that emphasize wildlife diversity and travel corridors, preservation of old growth, enhancement of water quality for fisheries, and protection of sensitive plants.

ALTERNATIVE K

This alternative is designed to minimize the tradeoffs between competing goods and services by capitalizing on the multi-product nature of various land allocation possibilities. The preservation of aesthetic values, for example, is limited to areas of high recreational value, but is achieved by utilizing land allocations that provide some development opportunities. High levels of anadromous fish and protection of sensitive plants are provided, along with moderate levels of timber, old growth, and wildlife habitat.

ALTERNATIVE M

This alternative would preserve the Forest as it is today by limiting all development activities to those portions of the Forest currently under active management. Timber management would utilize rotation lengths of 250 years, and harvest activity would occur only on lands accessible from existing roads. Land allocations for this alternative yield the fewest development opportunities, and the greatest level of protection for old growth, Wild and Scenic Rivers, visual quality, and unroaded areas.

ALTERNATIVE S

This alternative is the Preferred Alternative in the FEIS. It is designed to minimize the tradeoffs between goods and services by capitalizing on the multi-product nature of land allocation possibilities. Alternative S was developed by modifying Alternative K, the Preferred Alternative in the DEIS, in response to public

comments. Recreation is emphasized through significant allocations to Backcountry Recreation. Intensive timber management, including fertilization, is practiced in areas with programmed timber harvest.

THE SELECTED ALTERNATIVE

The Selected Alternative is a modification of Alternative S, the Preferred Alternative in the FEIS. It is structured to feature the four key attributes listed under "Rationale" (see Chapter III of this Record of Decision). The Selected Alternative is designed to minimize the tradeoffs between goods and services by capitalizing on the multi-product nature of land allocation possibilities. The preservation of aesthetic values, for example, is limited to areas of high recreational value, but is achieved by using land allocations that provide some development opportunities High levels of anadromous fish and protection of sensitive plants are provided along with moderate levels of timber, old growth, and wildlife habitat. Recreation is emphasized through allocations to Backcountry Recreation in key areas. Intensive timber management, including fertilization, is practiced in areas with programmed timber harvest.

The Selected Alternative is very similar to Alternative S as described in the FEIS, but differs in the following ways:

1. Approximately 54,000 acres of Backcountry Recreation Management Area in Alternative S in the South Kalmiopsis area is an Administrative Study area within General Forest Management Area in the Selected Alternative. (Administrative Study areas have no programmed timber harvest.)

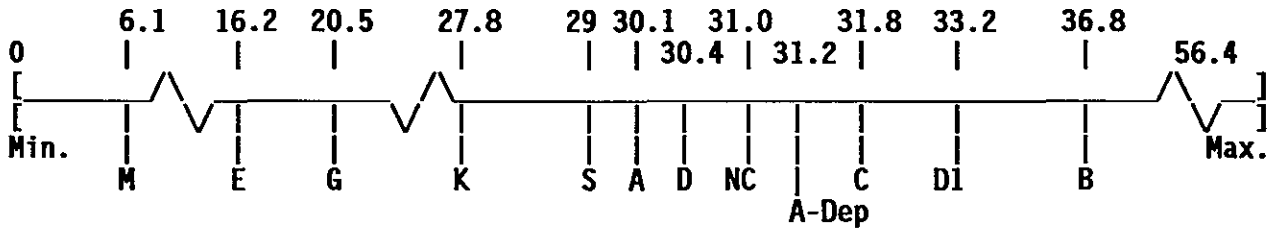
2 Approximately 11,000 acres of Backcountry Recreation area in Alternative S in the North Kalmiopsis area is in the Silver Fire Recovery Project Administrative Study Area in the Selected Alternative.

3 The southern boundary of the Fall Backcountry Recreation area in Alternative S was adjusted up to the ridgeline in the Selected Alternative The area not seen from the Illinois River is in General Forest in the Selected Alternative rather than in the Fall Backcountry Recreation area.

4. Alternative S Backcountry Recreation areas Butler and Copper did not have high recreation potential compared to their high value for fisheries and watershed. As a result these two areas are changed to Supplemental Resource Areas in the Selected Alternative

5. The reduction of acres allocated to the Backcountry Recreation Management Area, and the adjustment of the inventory information in the Silver Fire area have resulted in a slightly different number of suitable acres in the Selected Alternative. The net effect in the Selected Alternative has approximately 11,000 acres more suitable lands than did Alternative S. However, this acreage is for the most part in the administrative study areas with no programmed timber harvest.

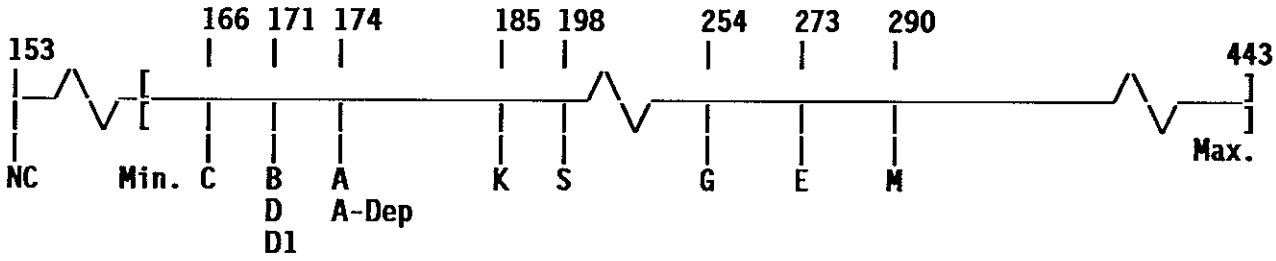
6. The ASQ in Alternative S is 29.0 MMCF or 29.3 MMCF including salvageable dead. ASQ in the Selected Alternative is 28.7 MMCF (including salvageable dead) The reduction in ASQ for the Selected Alternative is due to the change in timber inventory adjustments reflecting the timber killed in the 1987 fires and the revised suitability information in the fire area (see Chapter III of the FEIS).



The environmental consequences of the Selected Alternative over the Plan period are essentially the same as described in the FEIS for Alternative S Any minor variations generally fall within the range between Alternative K and Alternative S.

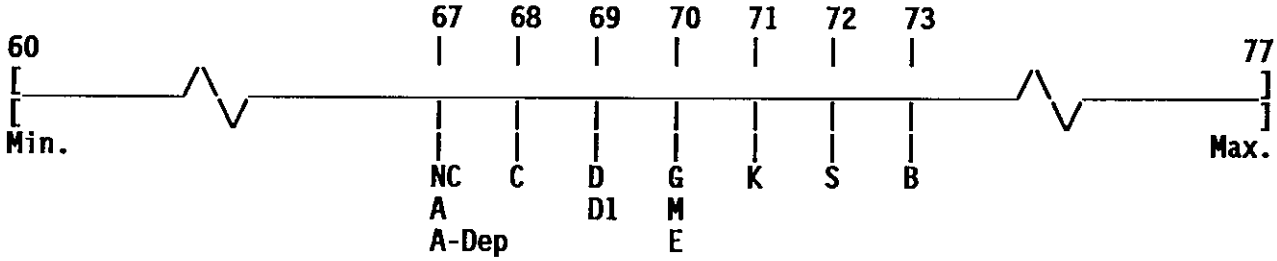
RESPONSIVENESS TO PLANNING PROBLEMS

The following line graphs display several key indicators of the major planning problems that are part of the respective alternative design, land allocations, outputs, or effects. The graphs illustrate the range of alternatives considered in the FEIS and distribution through the decision space. Maximums and minimums for each key indicator reflect the concept of the decision space. Numbers along the line represent the values for the alternatives from the FEIS; the letters below the line identify each alternative. The relationship of the Selected Alternative to the alternatives in the FEIS is discussed for each indicator.



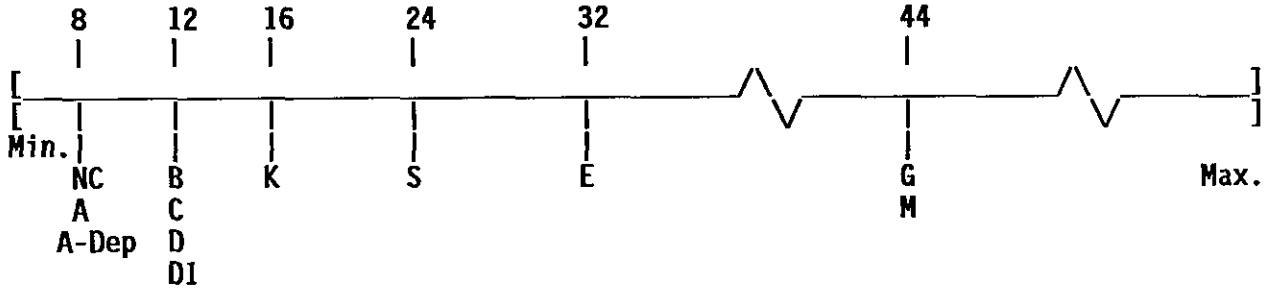
Average annual timber production for the first decade, measured in millions of cubic feet, is displayed below. Alternatives B and A-Departure are departures from non-declining even flow, and Alternative D1 has shortened rotations Alternative M has extended rotations of 250 years. Data provided in the timber production line graph does not include an estimated one percent of chargeable salvage harvest volume for each alternative. The Selected Alternative is equivalent to Alternative S, updated for the minor inventory changes resulting from the 1987 Fires. These changes result in the Selected Alternative having a value of 28.4 MMCF, or an ASQ of 28.7 MMCF including the one percent salvage.

Timber Production
(First Decade Volume, MMCF/Year)



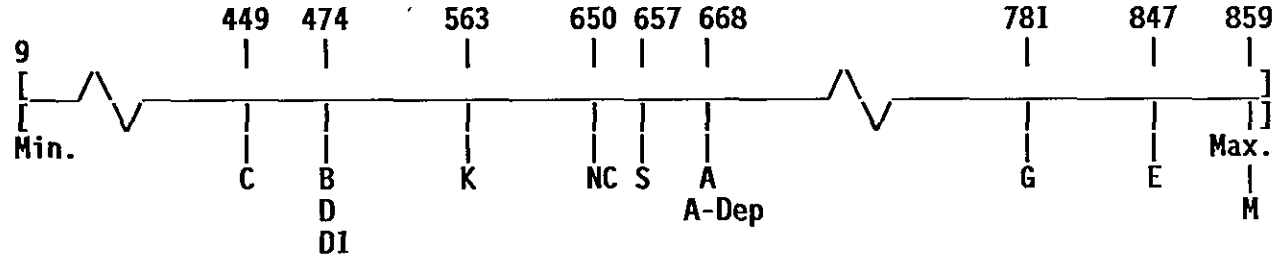
The number of acres, measured in thousands, of mature and old growth timber reserved from timber harvest is presented below. Reserved areas include Management Areas 1 through 9 and mature and old-growth stands unsuitable for timber production in Management Areas 10 through 14. The Selected Alternative has very similar allocations to Alternative S. The 1987 Fires reduced the oldgrowth in Management Areas 1 through 9 for all alternatives (approximately 16,000 acres for Alternative S). With the inventory update and the modifications made to Alternative S, the Selected Alternative has 180,000 acres of mature and old-growth timber in reserved areas Alternative NC has fewer acres than the minimum required since certain Management Requirements were not applied to the alternative.

Old Growth and Mature Reserved
(with Timber Characteristics, M Acres)



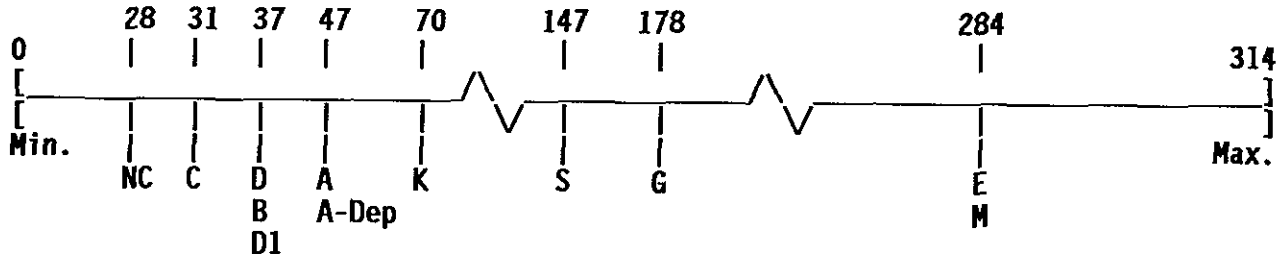
The projected number of average annual anadromous sport-fish user days, in thousands, for the first decade is displayed below. The data are primarily reflective of the functions of land allocations, riparian prescriptions, and capital investments. The Selected Alternative is identical to Alternative S.

Fisheries
(First Decade Use, M WFUD's)



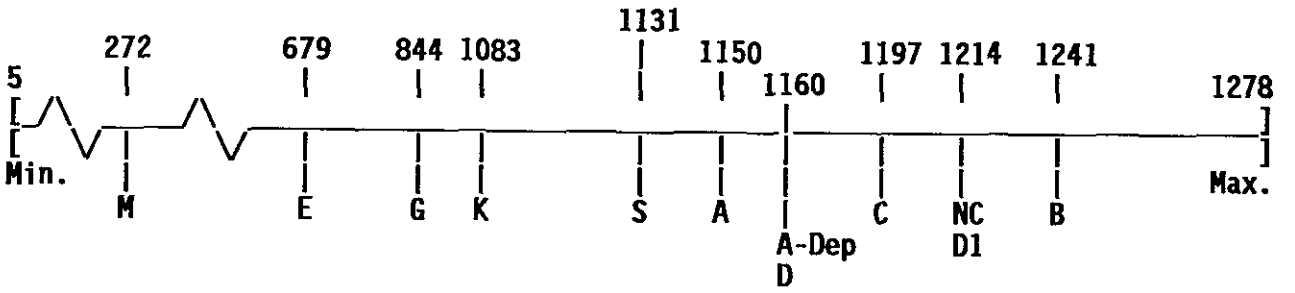
The number of acres, in thousands, of allocated Research Natural Areas and Botanical Areas is provided below as an indicator of sensitive plant habitat protection from site-disturbing activities. The Selected Alternative is identical to Alternative S.

Botanical and Research Natural Areas
(M Acres)



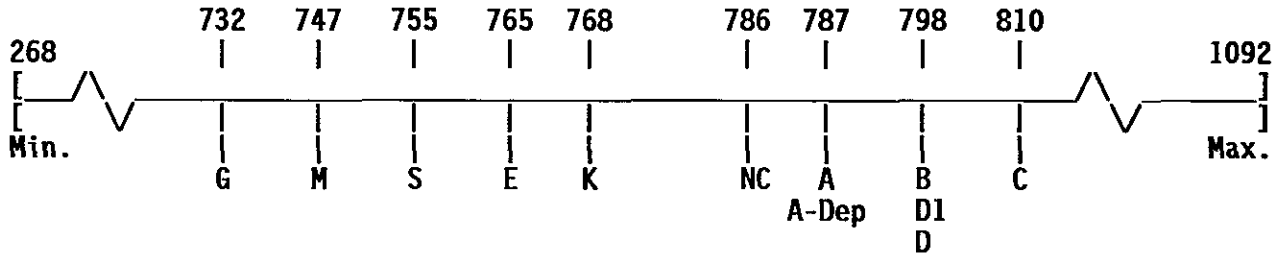
Visual resource management of Forest scenic values is reflected in the number of acres, in thousands, displayed below for areas assigned the Preservation, Retention, and Partial Retention Visual Quality Objectives. The Selected Alternative is very similar to Alternative S. Technically, the administrative study areas in General Forest are not counted in the higher Visual Quality Objective categories so the value for this display would be 605 thousand acres. However, the administrative study areas will have little development and the environmental consequences will be very similar to Alternative S

Visual Resources
(Preservation, Retention and Partial Retention VQO's, M Acres)



Unroaded recreational opportunities are reflected in the number of acres, in thousands, assigned to unroaded management prescriptions in Management Areas 1 through 9 as illustrated below The Selected Alternative is essentially the same as Alternative S, although the administrative study areas within Management Areas 10 through 14 of the Selected Alternative are not counted as unroaded. Acres in Management Areas 1 through 9 are 92 thousand, however the administrative study areas will remain largely unchanged from their existing condition in the next decade resulting in effects closer to Alternaitve S.

Inventoried Unroaded Areas Assigned to Unroaded Management Prescriptions (M Acres)



Present net value is an indicator of economic efficiency displaying the difference between discounted costs and discounted benefits, expressed in millions of dollars (MM $), over a 150-year planning horizon. A four percent annual discount rate was used. The Selected Alternative has similar economic consequences to Alternative S updated for the change in ASQ resulting from the 1987 Fires; present net value is 1,101 million dollars.

Present Net Value
(150 Year Planning Horizon, MM $)

Opportunities for mining activities are reflected in the acres of low and moderate accessibility restrictions and are displayed below with data expressed in thousands of acres. Mineral accessibility is primarily a function of the land area allocated to management categories where mineral restrictions apply. The only difference between Alternative S and the Selected Alternative in this measure results from the shift of Backcountry Recreation areas to the Supplemental Resource Management Area which is anticipated to be more restrictive This results in the Selected Alternative having 748 thousand acres in the low and moderate restriction categories.

Mineral Accessibility
(Accessible Areas with Low and Moderate Restriction, M Acres)

ALTERNATIVES CONSIDERED, BUT ELIMINATED FROM DETAILED STUDY

In addition to the alternatives discussed above, the Interdisciplinary Team evaluated other approaches to managing the Forest, but did not study all of them in detail. (For more information on these alternatives, see FEIS, Chapter II, "Alternatives Considered, But Eliminated From Detailed Study ")

DESIGNATED AREAS

Several areas of the Forest have received special designation by Congress or the Chief of the Forest Service. These include Wild and Scenic Rivers, Wildernesses, RNA's, and Botanical areas. An alternative could have been developed that proposed changing the management direction for some or all of these existing areas. Although there has been considerable public debate about some of the areas, there seems to be widespread support for the present designations

PARK ALTERNATIVES

Several alternatives have been proposed by individuals or groups for areas surrounding the Rogue, Illinois, and Smith Rivers for possible designation as National Parks. At one time, the National Park Service suggested study of a potential "Wild Rivers National Park," but later withdrew its proposal. These alternatives were considered, but eliminated from detailed study for a number of reasons

Although the CEQ regulations do provide for agencies to "include all reasonable alternatives not within the jurisdiction of the lead agency" (40 CFR 1502.14), alternatives which place lands currently administered by the Forest Service into the hands of other jurisdictions were not reasonable considering the scope of this Forest Plan proposal. The purpose of the Forest Plan is to "provide for multiple use and sustained yield of goods and services ." (36 CFR 219 1(a)). National Parks are, by law, not managed under the principles of multiple use and sustained yield.

Consideration of possible inclusion in the National Park System has been specifically assigned by Congress to the Secretary of the Interior; designation of a National Park requires Congressional action

In response to public comments, several aspects of what National Parks offer the public were seriously considered by the Forest Suggestions for increased emphasis in tourism and recreation have resulted in cooperative efforts with local government, State, and other Federal agencies Alternatives E and G include land allocations to Backcountry Recreation and other Management Areas that allow uses and activities similar to those encompassed in National Park proposals. Considerable unroaded area is allocated to Backcountry Recreation in the Selected Alternative. Increased emphasis is given to visual allocations along more heavily used recreation travel routes.

DEPARTURES

A departure from nondeclining yield would allow harvesting more timber in the near future with a reduction in timber harvest in decades three through five. Two alternatives which include a departure from nondeclining yield were evaluated. A third departure alternative, Alternative K-Departure, was developed in the DEIS, but was dropped from detailed consideration in the FEIS. Departure alternatives could have been developed for all of the alternatives, but none were identified that would have added to the resolution of the Planning Problems. Additionally, there was little public support expressed for creation of additional departure alternatives

SHORT ROTATIONS

Use of rotations shorter than culmination of mean annual increment (CMAI) of growth for intensively managed timber stands has been suggested by individuals and organizations. Timber would be harvested at a higher rate in the near future. However, instead of a reduction in future harvest levels, this option would schedule stands to be harvested at ages prior to CMAI to fill in the gap and maintain nondeclining flow

The NFMA requires the Forest Service to harvest, generally, only stands of trees that have reached CMAI. However, alternatives that incorporate exceptions to these standards can be analyzed "if it is reasonable to expect that the overall multiple use objectives would be better attained" (36 CFR 219.16).

Alternative D1 develops this option for detailed study and comparison purposes. Additional alternatives or variations were considered but eliminated from detailed study. Analysis of the use of short rotations has not clearly shown that overall multiple use objectives would be better attained. Developing alternatives in detail with variations of this option would not provide significant new information.

BENCHMARKS

A benchmark is an analysis reference point used to define the bounds within which an alternative can be formulated They were not developed with the intent that they be implementable. Several benchmarks were modified and are included as full alternatives. Others were dropped from further consideration The following benchmarks were used in the alternative development process:

Minimum Level. This benchmark proposed only maintenance of the basic resources of the Forest. This would be a "no activity" alternative, but was not considered to be the NEPA-required "No Action" alternative It was dropped from further consideration because Alternative M has a similar focus on nondevelopment, yet better satisfies the Planning Problems.

Maximum Present Net Value. This benchmark emphasized timber harvest activity. The results were similar to the timber benchmark.

Current Direction This benchmark was modified slightly to become Alternative A Alternative A is the NEPA-required "No Action" alternative.

Maximum Timber This benchmark was modified slightly to become Alternative C.

Recreation. This benchmark was modified to become Alternative E.

Wildlife. A preliminary alternative was developed based on this benchmark. It was dropped from further consideration because it was similar to Alternative G.

Fish. The elements of this benchmark which contribute to high quality fish habitat were incorporated into several alternatives.

PRELIMINARY ALTERNATIVES

The following alternatives were developed and evaluated, but subsequently dropped from detailed consideration

Habitat Diversity Alternative F: This alternative was developed from the wildlife benchmark. It was dropped from detailed study because it was similar to Alternative G.

Maximum Fish. Alternative H: This alternative was developed to produce high levels of fish outputs. It was dropped from detailed study because many of its elements were duplicated in other alternatives.

Selected Amenity. Alternative I: This alternative was developed to respond to a wide range of user groups and interests by concentrating undeveloped allocations in areas unsuitable for timber. This did not result in a logical delineation to respond to Planning Problem Eight, dealing with roadless areas, and offered little else not included in other alternatives.

Economic Efficiency. Alternative J: This alternative was developed to maximize present net value. It was similar to the Maximum Present Net Value and Maximum Timber Benchmarks and Alternative C.

Variations of Alternative K. Several minor variations of land allocations along the north boundary of the Kalmiopsis Wilderness were considered for Alternative K. They were dropped for the same reasons as the Selected Amenity Alternative

DEIS ALTERNATIVES

Two alternatives developed in detail in the DEIS were eliminated from evaluation in the FEIS

Alternative K-Departure Land allocations and management direction for this alternative are identical to Alternative K, except for the timber program. Timber harvest schedules depart from the policy of nondeclining flow. This alternative does not offer any better way to meet multiple-use objectives and did not receive broad public support.

Alternative L. This alternative received little public support, other than for its retention of unroaded areas. This element of Alternative L is represented with some modification in Alternative S.

ADDITIONAL WILDERNESS DESIGNATION

Another possible area for alternative development would have involved the proposal of additional Wilderness and higher levels of trail development within Wilderness. No alternatives proposing additional

Wilderness on the Forest were considered in detail. Alternatives such as E, G, K, and M provide the option for future Wilderness designation through the maintenance of existing roadless areas.

When Congress passed the Oregon Wilderness Act in 1984, it included language which stated that "the Department of Agriculture shall not be required to review the wilderness option prior to the revision of the [Forest] plans...." There has been no designation on the Forest since 1984.

Alternative levels of trail development are considered for the Wildernesses. Higher levels could have been considered, but there has been no expressed public interest in this type of wilderness development

ALTERNATIVES WITH MORE DETAILED IMPLEMENTATION

The planning process could have developed additional implementation direction, down to the project level, for the alternatives. The choice is to make this a programmatic FEIS. If project-level planning had been included, an already complex process would have become unwieldy.

Evergreen Alternative

This alternative was proposed by the Southern Oregon Timber Industries Association (SOTIA), and was supported by a large number of people who responded to the DEIS. All of the elements suggested as part of the Evergreen Alternative were considered in the development of Alternative S. Some of these elements are included in Alternative S and in the Selected Alternative. A number of elements are included in other alternatives.

Gregory Alternative

This alternative was developed by Gregory Forest Products, Inc., of Glendale, Oregon It is based on Alternative A of the DEIS. The elements of this alternative are found within the range of the alternatives; several are incorporated in Alternative S and the Selected Alternative.

State of Oregon Alternative

This alternative was developed by the State of Oregon with a public review process separate from the review conducted by the Forest Service. It includes suggested changes in land allocations. It also recommends a number of technical corrections and refinements to improve the analysis and reliability of resource output projections, and emphasizes intensification of timber management for areas where the management objectives include timber production.

Alternative S and the Selected Alternative have many similarities to the State of Oregon Alternative. Many of the recommendations are incorporated in the Selected Alternative and vary only by degree. A number of the technical corrections and refinements have been incorporated in the analysis. Other elements of this alternative are included in various forms throughout the range of alternatives.

Chapter V - REQUIRED COMPARISONS OF ALTERNATIVES

HIGHER PRESENT NET VALUE ALTERNATIVES

Net Public Benefit (NPB) is the overall long-term value of all benefits less all associated costs. Many priced benefits and all financial costs of management can be measured in dollars. However, other nonpriced public concerns, benefits, and negative effects cannot be fully valued in economic terms.

The future value to society of this Forest will depend upon the mix of economic and other values that are produced and the costs of managing the Forest to produce these values. In determining the most economically efficient alternative, the Forest uses an estimate of present net value (PNV). PNV is the sum of priced benefits minus the sum of costs for the 150-year planning horizon, discounted to the present.

Emphasizing responses to issues that focus on nonpriced outputs reduces net economic values, principally because of reductions in the timber production land base. Timber is the main component of PNV. Land allocations to the Backcountry Recreation, Supplemental Resource, Research Natural Area, Botanical, Unique Interest, and Designated Wildlife Habitat Management Areas reduce the area for programmed timber harvest.

The Selected Alternative has a PNV of 1,101 million dollars (MM$). The following Alternatives have higher PNV's than the Selected Alternative:

Alternative	PNV(MM$)
B	1,241
D1	1,214
NC	1,214
C	1,197
D	1,160
A-Departure	1,160
A	1,150
S	1,131

Although the Selected Alternative has a lower PNV than alternatives listed above, it provides greater overall Net Public Benefits. While recognizing the importance of the Siskiyou National Forest to local and National economies, it provides higher overall benefits recognizing the importance of non-priced values such as water quality, fish and wildlife habitat, scenic values, and biological diversity. The Selected Alternative is sensitive to both economic and environmental issues, striking an appropriate and realistic balance among commodity and amenity values.

The Selected Alternative is more responsive to public concerns expressed during the comment period than any of those alternatives having higher PNV's. It includes more acreage in the Backcountry Recreation Management Area, reducing its timber base, and consequently its PNV. Allocations to Backcountry Recreation were increased partly in response to numerous public comments on the DEIS.

Another issue that generated numerous public comments is riparian area management. The Selected Alternative addresses this concern through assignment of additional Planning Basins to a more restrictive Riparian Management Prescription. This reduces PNV through limiting timber harvest in those areas.

Alternative B has the highest PNV of all of the alternatives. It would result in higher levels of accelerated forest sedimentation than the Selected Alternative. It would also result in fewer acres of reserved old growth, and substantially fewer acres allocated to Backcountry Recreation, Botanical Areas, Unique Interest Areas, Supplemental Resource Areas, and Special Wildlife Sites than in the Selected Alternative.

Similar comparisons can be made between the Selected Alternative and each of the other alternatives with higher PNV's. The Selected Alternative strikes a balance between economic benefits and environmental concerns, as illustrated by these comparisons. (For more detailed comparisons of the alternatives, see FEIS, Chapter II, "Comparisons of the Alternatives Considered in Detail.")

The average timber sale sold on the Forest has revenues exceeding costs by approximately 1,000,000 dollars. (For more information, see the Planning Records.) However, there are some conditions where below cost sales may occur. These areas are characterized by a combination of factors such as low-valued species, low volumes of commercial species per acre, high logging costs, high site preparation and regeneration costs, and expensive road building for the initial entry. Cost reduction reviews, scheduling of sales, economic analysis, and organization of harvest units within sales are presently used to minimize the timber sale program costs

ENVIRONMENTALLY PREFERABLE ALTERNATIVES

Alternatives E and G are the environmentally preferable alternatives. "Environmentally preferable alternative" is defined by CEQ regulations as the alternative causing the least adverse impact to the biological and physical environment.

Alternative E emphasizes the aesthetic values of the Forest by promoting goods and services which do not necessarily have established market values. Alternative G emphasizes the health and productivity of the Forest's water-related resources.

I did not select either Alternative E or G because they fail to provide the balance between economic benefits and environmental concerns provided by the Selected Alternative. Implementation of Alternative E would result in a first decade ASQ of 16.2 MMCF; Alternative G in an ASQ of 20.5 MMCF. PNV's of Alternatives E and G are 679 million dollars and 844 million dollars, respectively.

Two of the goals of the Forest Plan are to "help to satisfy local, regional, and National social and economic needs" and to "provide a sustained yield of resource outputs at a level that will promote the stability of local communities...." The Selected Alternative does this with an ASQ of 28.7 MMCF and a PNV of 1,101 million dollars. Alternatives E and G fail to meet the economic needs of or promote the stability of local communities because of their emphasis on nonpriced outputs.

Chapter VI - IMPLEMENTATION SCHEDULE

SCHEDULE AND IMPLEMENTATION

The Forest Plan will be implemented through identification, analysis, selection, and scheduling of projects to meet the management goals and objectives provided by the Plan.

The schedule of proposed and possible projects for the first decade is contained in the appendices of the Forest Plan. Project schedules will be available for review at the Ranger District Offices and the Supervisor's Office Schedules of possible projects will routinely change as projects are implemented or are removed from the listings for other reasons, and as new projects take their place Adjustment to the schedule may be made based on results of monitoring, budgets, and unforeseen events

The Forest Plan provides direction in the form of goals and objectives, Standards and Guidelines, monitoring requirements, and probable scheduling of management practices. It does not cover projects on specific sites except in a broad manner. Each proposed project will be subject to site-specific analysis and documentation in compliance with NEPA. Considerations revealed through this process may result in a decision not to proceed with the proposed project, even though the project may be permissible under the Forest Plan.

The Plan's scheduled projects are translated into multiyear program budget proposals The schedule is used for requesting and allocating the funds needed to carry out the planned management direction. The Forest's current year tentative annual program of work will be derived from this process Upon approval of a final budget for the Forest, the annual work program will be updated and carried out.

The Forest work program will implement the management direction of the Forest Plan Outputs and activities in individual years may be significantly different from those shown in Chapter IV of the Forest Plan, depending on final budgets, new information derived from updated inventories and monitoring, and any future amendments or revisions of the Forest Plan.

The Forest Plan supersedes or incorporates all previous land and resource management plans prepared for the Siskiyou National Forest. Upon implementation of the Forest Plan, Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest System Lands and resource uses must be in conformance with the Forest Plan. Such documents will be revised where needed as soon as practicable, subject to valid existing rights. This updating will generally be done within three years.

All timber sales offered for sale after issuance of the Forest Plan will be in compliance with direction contained in the Plan. Timber sales now under contract will be administered under provisions of the existing contracts. Changes to existing timber sale contracts may be proposed on a case-by-case basis where overriding resource considerations are present.

The Forest Plan will be implemented 30 days after the Notice of Availability of the Forest Plan, EIS, and Record of Decision appears in the Federal Register.

AMENDMENT AND REVISION

This Forest Plan may be changed either by an amendment or a revision An amendment may become necessary as a result of many different situations. These could include:

1. Recommendations of the Interdisciplinary Team based on their review of monitoring results

2. The determination that an existing or proposed permit, contract, cooperative agreement, or other instrument authorizing occupancy and use are not consistent with the Forest Plan but should be approved.

3 Changes in proposed implementation schedules needed to reflect differences between funding levels assumed in the plan and funds actually appropriated.

4. Changes necessitated by resolution of administrative appeals.

5. Changes to correct planning errors.

6. Changes made necessary by altered physical, biological, social, or economic conditions

Based on an analysis of the objectives, guidelines, and other aspects of the Forest Plan, the Forest Supervisor shall determine whether a proposed amendment would result in a significant change to the plan. If the change is determined to be significant, the Forest Supervisor shall follow the same procedure as that required for development and approval of a plan. If the change is determined not to be significant, the Forest Supervisor may implement the amendment after appropriate public notice and compliance with the NEPA.

I will approve any significant amendments while the Forest Supervisor will approve non-significant amendments The determination of significance will be documented in a decision notice and would be appealable under 36 CFR 217.

With respect to revision, the NFMA requires revision of the Forest Plan at least every 15 years. However, it may be revised sooner if physical conditions or demands on the land and resources have changed sufficiently to affect overall goals or uses for the entire forest. If a revision becomes necessary, the procedures described in 36 CFR 219.12 will be followed The Chief, however, must approve the scheduling of such revision.

Because the timber issues on the Siskiyou National Forest remain polarized and emotionally charged, I will monitor personally the ongoing analyses and discussions in that area. One of the primary reasons I selected Alternative S, as modified, is the fact that it strikes the best balance between community stability and protection of the environment. The allowable sale quantity of 28.7 MMCF reflects that balance. However, outstanding technical questions continue to be raised.

We have already told the primary commenters that resolution of all technical questions is not possible prior to publishing the final plan, but that analysis of technical issues would continue thereafter. We have also indicated that the results of the new inventory may be used to change the final plan. Should the targeted allowable sale quantity change by five to ten percent, I would have to reconsider certain aspects of my decisions here.

Chapter VII - MONITORING AND MITIGATION

The Monitoring and Evaluation Program is the management control system for the Forest Plan. It will provide information on the progress and results of implementation. The results of the Program will be used to assess the need for amending or revising the Forest Plan. (For more information on the Monitoring and Evaluation Program, see LRMP, Chapter V, Table V-1 and Appendix D.)

The Interdisciplinary Team will use information from this program to check that the Standards and Guidelines established in the Plan are met. They will also evaluate the effectiveness of the Standards and Guidelines in meeting Forest Plan objectives, and in maintaining environmental quality.

Additionally, the information will be used to meet the following objectives:

Determine whether programs and activities are responsive to public issues and management concerns.

Determine whether work force, resource, and cost information in projecting output and impacts are correct.

Determine whether and how activities on nearby lands managed by other agencies or landowners are affecting management of the Forest.

Determine whether research, beyond that identified in Chapter II of the Forest Plan, is needed.

Mitigation measures are intended to cause an action to become less harsh or severe. These measures are an integral part of the Standards and Guidelines for each Management Area and, therefore, an essential part of the Forest Plan. Mitigation is extremely important in the design and implementation of all projects.

Implementation of the Forest Plan is guided by the Forest-wide Standards and Guidelines and the Management Area Prescriptions called for in Chapter IV of the Forest Plan. These management standards were developed through an interdisciplinary effort and contain measures necessary to mitigate or eliminate any long-term adverse environmental effects.

Also included in the Forest Plan as mitigation measures are the Best Management Practices (BMP's) (For more information on BMP's, see LRMP, Appendix F)

To the best of my knowledge, all practical mitigation measures have been adopted and are included in the Forest Plan.

Chapter VIII - APPEAL RIGHTS AND APPROVAL

This decision may be appealed in accordance with the provisions of 36 CFR 217 by filing a written notice of appeal within 90 days of the date of this decision. The appeal must be filed with the reviewing officer.

F. Dale Robertson, Chief
USDA Forest Service
P.O Box 2417
Washington, D.C. 20013

A copy must simultaneously be sent to the deciding officer:

James F. Torrence, Regional Forester
